Background: *IDH1/2* mutations occur in ~25% of cholangiocarcinomas (CCAs). Preclinical studies suggest synergy between PARP inhibition and PD-L1 blockade. We previously conducted a phase II trial of olaparib plus durvalumab in advanced *IDH*-mutant CCA. We report matched baseline tissue and serial cell-free DNA (cfDNA)-based correlative analysis of pts samples. The primary objective was to develop a cfDNA methylome signature as a non-invasive biomarker. **Methods:** This single-arm, open-label phase II study (NCT03991832) enrolled patients with unresectable/metastatic *IDH*-mutant CCA and $\leq$2 prior lines of systemic therapy. Patients received olaparib 300 mg orally twice daily and durvalumab 1500 mg IV every 4 weeks. Blood samples were collected at baseline and monthly while on treatment for planned correlatives to examine R2HG, S2HG, and artemin levels using HPLC (High-Performance Liquid Chromatography). Cell-free methylated DNA immunoprecipitation and high-throughput sequencing (cfMeDIP-seq) was performed on pts cfDNA samples and case-matched *IDH*-wildtype pts. Formalin-fixed, paraffin-embedded blocks of baseline tumor biopsies were used for multispectral fluorescent IHC (FL-IHC) using a 6-marker panel composed of pan-cytokeratin, CD4, CD8, CD163, PD-L1, and CD68. **Results:** Ten patients were enrolled (median age 63.5 y; 50% female; 90% received prior platinum). Median treatment duration was 1.95 mo (range 1.8–13.5). No complete or partial responses were observed. DCR was 30% (3 patients with stable disease); one patient remained on therapy for 13.5 mo before progression. Median PFS was 1.97 mo (95% CI 1.73–3.93). HPLC from baseline plasma showed lower baseline artemin levels correlated with stable disease (p=0.038), while R2HG/S2HG ratios showed no association with outcome. FL-IHC showed enriched immune cell populations, specifically $CD4^+$ T cells (p=0.0032) and a trend for $CD68^+$ macrophages (p=0.062), in the tumor stroma compared with tumor core. 54 plasma samples (from 8 patients) were profiled with cfMeDIP-seq along with 8 *IDH*-wildtype controls. Using top 100 differentially methylated regions, the circulating tumour DNA methylome exhibited a highly specific signature, accurately discriminating *IDH*-mutant and *IDH*-wildtype CCA regardless of treatment status. The specific differentially methylated gene pathways between groups were comprehensively examined in both on-treatment and baseline plasma samples. **Conclusions:** Advanced *IDH*-mutant CCA harbors an immune-excluded phenotype, which may underlie primary resistance to immunotherapy. Plasma cfDNA methylome signature can accurately discriminate CCA with *IDH* mutations. Clinical trial information: NCT03991832. Research Sponsor: None.

The molecular landscape and clinical nomogram of cholangiocarcinoma harboring ESCAT I alterations. First Author: George Laliotis, Johns Hopkins University, Baltimore, MD

Background: Cholangiocarcinoma (CCA) is the second most common primary liver cancer, with rising global incidence and mortality. Despite molecular advances, most patients present with advanced disease unsuitable for curative resection, resulting in poor prognosis. ESCAT I alterations, including FGFR2 fusions, IDH1/IDH2 mutations, BRAF V600E, HER2 amplification, MSI-high, and NTRK fusions, represent validated therapeutic targets with FDA/EMA-approved treatments, occurring in 25% of CCAs. Here, we analyze genomic and transcriptomic data to characterize the molecular landscape and develop an OS nomogram for CCA patients with ESCAT I alterations. **Methods:** In this retrospective study, we analyzed publicly available data from 1928 CCA patients, enrolled in participating institutions between 2012 and 2022, sourced from the cBioPortal for Cancer Genomics. We investigated frequencies of ESCAT I alterations, copy number alterations, mRNA expression, clinicopathological factors, and OS. Transcriptomic profiling and pathway enrichment analysis identified survival-associated genes. A nomogram integrating clinical, pathological, and molecular features was constructed and validated for OS prediction. **Results:** Genomic analysis of 1,845 CCA samples revealed revealed *IDH1* mutations (12%), *FGFR2* fusions (8%), HER2 amplification (6%), *BRAF*V600E (4%), MSI-high (4%), *NTRK1/2/3* fusions (3.4%) and *IDH2* mutations (2%). Notably, ESCAT I alterations were associated with inferior OS (log-rank P = 0.009; mOS altered vs wild-type 33.84 vs 24.31 months). Transcriptomic and GSEA profiling linked these alterations to dysregulation of oncogenic pathways, including DNA damage repair, cell cycle regulation, epithelial-mesenchymal transition, and immune pathways. The prognostic nomogram incorporated age, stage, differentiation, ESCAT I subtype, and top 5 most significantly identified transcriptomic signatures. **Conclusions:** This study provides comprehensive molecular characterization of ESCAT I-altered CCA, revealing distinct genomic and transcriptomic profiles associated with specific alterations and oncogenic pathway dysregulation. The validated nomogram offers a practical tool for personalized OS prediction, potentially guiding treatment selection, surveillance intensity, and clinical trial stratification. These findings emphasize the importance of routine molecular profiling in CCA and support precision medicine integration to improve outcomes and target therapy resistance mechanisms in this population. First-line GemCis ± immunotherapy vs FGFR inhibition in ctDNA-detected *FGFR2* fusion–positive advanced cholangiocarcinoma: A real-world analysis. First Author: Richard D. Kim, Moffitt Cancer Center Magnolia Campus, Tampa, FL

Background: Advanced cholangiocarcinoma (aCCA) carries a poor prognosis. Approximately 40% of aCCA harbor targetable biomarkers; however, standard first-line (1L) therapy is gemcitabine-cisplatin (GemCis) ± immune checkpoint inhibitors (ICI), regardless of genomic status. Emerging data suggest that oncogene-driven molecular subsets of aCCA may exhibit reduced sensitivity to ICI, raising questions about the benefit of adding ICI to chemotherapy in genomically defined populations. Therefore, we compared outcomes for aCCA pts with ctDNA-detected *FGFR2* fusions (*FGFR2*+) treated with targeted therapy vs. GemCis ± ICI. **Methods:** Real-world data was sourced from InfinityAI Data Library, a database combining de-identified genomic information from Guardant360 (Guardant Health, Palo Alto, CA) and clinical data from administrative claims. aCCA pts with an *FGFR2* fusion detected prior to 1L therapy between Sept. 2018 and June 2025 were analyzed. Outcomes were assessed via real-world time to treatment discontinuation (rwTTD), real-world time to next treatment (rwTTNT) and real-world overall survival (rwOS) in months with 95% confidence intervals. Log-rank tests were used to compare Kaplan-Meier survival curves. **Results:** 149 *FGFR2*+ aCCA pts with treatment and outcomes data were identified. 18.1% (27) were treated with GemCis, 45.6% with GemCis + ICI (68), and 19.5% (29) with FGFRi. *FGFR2*+ pts treated with 1L FGFRi had improved rwTTD, rwTTNT, and rwOS compared to GemCis and GemCis + ICI, with significantly improved rwTTD in those treated with FGFRi vs GemCis + ICI (Table 1). Based on these data, the addition of ICI to GemCis was not associated with improved outcomes in *FGFR2*+ pts. **Conclusions:** Real-world outcomes in ctDNA-detected *FGFR2*+ aCCA did not improve with addition of ICI to 1L GemCis. In contrast, 1L FGFRi was associated with longer treatment duration and delayed need for subsequent therapy. These findings suggest standard chemo-immunotherapy may not be optimal for all biomarker-defined aCCA subgroups and support the use of ctDNA testing to inform biomarker-drive 1L treatment selection abd sequncing strategies, warranting prospective validation. Research Sponsor: None.

Outcomes in FGFR2+ pts by 1L therapy.

	rrwTTD	rrwTTNT	rrwOS
FGFRi vs GemCis	9.1 (4.9-11.5) vs 4.2 (2.3-6.2) HR=0.68, p=0.22	20.8 (8.3-20.8) vs 13.8 (5.6-30.3) HR=0.64, p=0.33	NR (16.9-NR) vs 17.5 (10.3-28.4) HR=0.48, p=0.16
FGFRi vs GemCis + ICI	9.1 (4.9-11.5) vs 5.2 (3.9-7.8) HR=0.62, p=0.03	20.8 (8.3-20.8) vs 8.9 (7.9-NR) HR=0.51, p=0.06	NR (16.2-NR) vs 20.9 (10.7-NR) HR=0.43, p=0.11

Durvalumab or pembrolizumab plus gemcitabine and cisplatin versus gemcitabine and cisplatin alone as first-line therapy for advanced cholangiocarcinoma: A meta-analysis. First Author: Abdullah Esmail, Houston Methodist Neal Cancer Center, Houston, TX

Background: Cholangiocarcinoma (CCA) is a rare, aggressive malignancy of the bile duct epithelium with rising incidence and mortality. Curative surgery is feasible in few cases; for unresectable or metastatic disease, systemic therapy is standard. Gemcitabine plus cisplatin (GemCis) has been the first-line backbone, but phase 3 trials (TOPAZ-1 and KEYNOTE-966) demonstrated overall survival (OS) benefit with added immune checkpoint inhibitors (durvalumab or pembrolizumab). This systematic review and meta-analysis evaluates the efficacy and safety of immunotherapy (IO) plus GemCis versus GemCis alone in advanced CCA. **Methods:** We systematically searched PubMed, Embase, Scopus, and Google Scholar for English-language studies (2009–2025) including randomized controlled trials (RCTs) and cohort studies of first-line GemCis alone or with durvalumab or pembrolizumab in unresectable/metastatic CCA. Primary endpoint: OS. Secondary: progression-free survival (PFS) and grade 3-4 adverse events (AEs) per CTCAE. Kaplan-Meier curves were digitized, and individual patient data reconstructed using IPD tools for pooled estimates. Random-effects models generated hazard ratios (HRs) and pooled medians; heterogeneity assessed via I^2. **Results:** We included 3,703 patients from TOPAZ-1, KEYNOTE-966, ABC-01/02, and six cohort studies: 1,737 on GemCis alone, 1,433 on GemCis + durvalumab, and 533 on GemCis + pembrolizumab. In the full meta-analysis, GemCis + durvalumab showed the best outcomes (median OS 14.1 months, PFS 7.38 months) versus GemCis + pembrolizumab (OS 12.8 months, PFS 6.62 months) and GemCis alone (OS 9.27 months, PFS 5.81 months). Restricting to RCTs only, IO + GemCis improved OS versus GemCis alone (median 12.82 vs. 11.1 months; HR 0.78, 95% CI 0.71–0.86, $p<0.001$), with no significant PFS difference (p=0.20). Grade 3-4 AEs were infrequent across arms; thrombocytopenia was higher with pembrolizumab (p=0.0002), but other severe toxicities were comparable. **Conclusions:** Adding immunotherapy to GemCis significantly enhances survival in unresectable/metastatic CCA, with durvalumab + GemCis providing the most pronounced benefit in this pooled analysis incorporating RCTs and real-world cohorts. Regimens were well-tolerated with manageable toxicity. These findings reinforce chemoimmunotherapy as first-line standard and highlight potential differential efficacy between PD-L1 and PD-1 inhibitors warranting further study. Research Sponsor: None.

4161 **Poster Session**

Real-world analysis of epigenomic molecular tumor-type prediction for biliary tract cancer in CUP. First Author: Daniel Hintz, Guardant Health, Palo Alto, CA

Background: Biliary cancers (BTC) are often diagnosed at advanced stages and can present as metastatic liver tumors, making determination of the primary site difficult, leading to frequent cancer of unknown primary (CUP) designations. Conventional histopathology or imaging may misclassify tumor origin, yet accurate distinction is essential because therapies differ for BTC and CUP. A novel liquid biopsy (LB) molecular tumor type (MTT) classifier using epigenomic signatures predicts tumor origin across 14 solid tumors with graded confidence. This study evaluated concordance, genomic features, and real-world outcomes of high-confidence MTT-BTC predictions in patients (pts) with BTC or CUP using the Infinity AI, a clinical-genomics and epigenomics database. **Methods:** Guardant360 LB results showing high-confidence (>80%) MTT predictions for BTC in pts with BTC or CUP listed on the test requisition form (TRF) were identified. Infinity AI links de-identified clinical, genomic, epigenomic, and administrative claims The LB assay interrogated >700 genes and thousands of methylation regions. First-line (1L) therapies were categorized as chemotherapy (chemo), immunotherapy (IO), or chemo-IO. Real-world time to treatment discontinuation (rwTTD) and time to next treatment (rwTTNT) were compared between TRF-BTC and TRF-CUP cohorts using log-rank tests. **Results:** Among pts with high-confidence MTT-BTC predictions (TRF-BTC n=410; TRF-CUP n=56), MTT accuracy for TRF-BTC was 51.7%. Female proportion was 58% (TRF-BTC) and 64% (TRF-CUP), respectively. Median ages for TRF-BTC and TRF-CUP pts were 68 years, respectively. The most frequent oncogenic mutations in TRF-BTC were *TP53* (34), *ARID1A* (8), *KRAS* (7), and *IDH1* (6); none had *FGFR2* . In TRF-CUP, common mutations included *TP53* (3), *ARID1A* (2), and *IDH2* (2). For TRF-BTC pts, rwTTD was longer with 1L IO+chemo vs IO or chemo alone (7.9 vs 4.3 vs 3.4 mo; $p<0.0001$). TRF-CUP pts showed similar, but non-significant trends. rwTTNT was longer for TRF-BTC pts receiving IO (p=0.00026) and trended higher for TRF-CUP (p=0.069). **Conclusions:** Guardant360 LB epigenomic–based MTT classifier consistently predicted biliary origin in pts labeled as BTC and in a subset labeled as CUP, with broadly concordant genomic features and real-world treatment patterns. CUP pts with high-confidence MTT-BTC predictions demonstrated outcomes that approximated those of TRF-BTC, supporting biologic similarity and suggesting that some CUP cases may represent occult BTC. These findings support consideration of MTT as a tool to refine uncertain diagnoses, guide BTC-aligned therapy selection (including targetable alterations), and improve clinical trial matching. Larger cohorts with longer follow-up and prospective validation are needed to define the impact of MTT-guided management on patient outcomes. Research Sponsor: None.

An immune-related pathologic response score as a predictor of survival after immune checkpoint inhibitor–based conversion therapy in hepatocellular carcinoma. First Author: Yi-Jun Lu, Department of Hepatobiliary Surgery and Liver Transplantation, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Immune checkpoint inhibitor (ICI) based conversion therapy is increasingly utilized in the management of initially unresectable hepatocellular carcinoma (HCC). However, the clinical significance of immune-related pathologic response (irPR) features remain poorly understood in HCC. **Methods:** We enrolled 217 HCC patients undergoing ICI-based conversion therapy followed by curative-intent resection and assigned them to discovery and validation cohorts (2:1). Thirteen immune-related pathological response (irPR) features—tumor-infiltrating lymphocytes, tertiary lymphoid structures, lymphoid aggregates, plasma cell infiltration, granulomas, neutrophils, foamy macrophages, cholesterol clefts, hemosiderin-laden macrophages, giant cells, neovascularization, necrosis, and mature fibrosis—were assessed on H&E-stained tumor bed sections. To explore differences in the tumor microenvironment, bulk mRNA sequencing was performed on FFPE samples from patients in the discovery cohort. **Results:** In the discovery cohort, four irPR features (tumor-infiltrating lymphocytes, lymphoid aggregates, neutrophils, and foamy macrophages) were integrated to construct the immunotherapeutic response score (ITRS), classifying patients as ITRSlow (0–1) or ITRShigh (2–4). $ITRS^{low}$ patients showed significantly improved OS (HR = 4.17; 95% CI 1.64–10.60; P = 0.003) and RFS (HR = 2.07; 95% CI 1.32–3.23; P = 0.001), with longer median RFS (32.3 vs 8.5 months). ITRS remained independently associated with OS (HR = 2.81; 95% CI 1.06–7.43; P = 0.038) and RFS (HR = 2.10; 95% CI 1.32–3.33; P = 0.002) and was validated in an independent cohort. FFPE transcriptomic profiling (n = 41) showed that $ITRS^{low}$ tumors were immune-inflamed, with enrichment of immune-related GO/KEGG pathways and globally higher immune/stromal infiltration (higher ESTIMATE immune/stromal scores, lower tumor purity; all $P < 0.001$). Unsupervised clustering identified hot/cold states, with hot tumors enriched in $ITRS^{low}$ (65.4% vs 13.3%, P = 0.003); $CD8^+$ T-cell infiltration was higher across MCPcounter/CIBERSORT/TIMER and was accompanied by stronger antigen presentation (MHC-II gene sets) and increased $CD8^+$ T-cell activation/cytotoxicity as well as exhaustion signatures (all $P < 0.05$), supporting an immune-active microenvironment linked to favorable outcomes. **Conclusions:** An irPR feature–based ITRS robustly predicts both OS and RFS in HCC patients following ICT. The ITRS is readily applicable in routine diagnostic pathology practice and provides novel insights into the biological mechanisms underlying immunotherapy resistance. Comparative outcomes of first-line atezolizumab plus bevacizumab (A+B) and durvalumab plus tremelimumab (D+T) in hepatocellular carcinoma (HCC). First Author: Sarina Ailawadi, Department of Medicine, University Hospitals, Case Western Reserve University, Cleveland, OH

Background: Standard first-line systemic therapy for hepatocellular carcinoma involves immune checkpoint inhibitors, including A+B and the STRIDE regimen consisting of D+T. However, there is limited data comparing outcomes of patients receiving these two regimens. We aimed to compare the survival and safety profiles of patients receiving A+B versus D+T as first-line systemic therapy for advanced HCC in a propensity score matched analysis. **Methods:** We performed a retrospective cohort study using data from TriNetX, a healthcare database of over 150 million patients in the United States. We identified adult patients with a history of HCC and included those who received A+B or D+T as first line treatment. Propensity score matching (PSM) was conducted, matching for patient demographics (age, sex, race), clinical history (alcohol use, ascites, esophageal varices, viral hepatitis), and laboratory parameters [platelets, albumin, bilirubin, INR, alpha-1-fetoprotein (AFP)]. Median overall survival (mOS) and relevant patient safety events were compared between those who received A+B or D+T. **Results:** We identified 2,762 patients who had HCC who were treated with A+B or D+T, of which 2,030 patients received A+B and 723 patients received D+T. Compared to patients in the A+B cohort, those who received D+T were more often older (68.5 vs 66.9 years, standardized mean difference (SMD) = 0.17), had lower platelet counts (186.4 vs 198.6, SMD = 0.11), had higher prevalence of ascites (33.1% vs 20.3%, SMD = 0.29), and alcohol use (23.8% vs 18.8%, SMD = 0.12). After PSM, 723 patients were included in survival analyses, with all variables adequately balanced except for albumin, which was higher in the A+B group (3.6 vs 3.5, SMD = 0.19). At 90 days after starting therapy, D+T was associated with higher incidence of immune-mediated colitis [5.3% vs 2.6%, odds ratio (OR) 2.1; 95% confidence interval (CI), 1.2-3.7], and a higher risk of hospitalization [35.4% vs 27.9%, OR 1.4; 95% CI, 1.1-1.8]. At 6 months, the risk of hypertension and proteinuria was higher in the A+B cohort [21.9% vs 13.7%, OR 0.57; 95% CI, 0.34-0.95], which persisted at 1 year [28.1% vs 16.5%, OR 0.51; 95% CI, 0.32-0.81]. There was no significant difference in mOS between those receiving A+B or D+T [18.3 months vs 22.8 months, hazard ratio (HR) 0.94; 95% CI, 0.79-1.1]. **Conclusions:** In patients with advanced HCC who received A+B or D+T as first-line systemic therapy, we found that A+B was associated with higher risk of hypertension and proteinuria, while D+T was associated with a higher risk of immune-mediated colitis and hospitalization. No significant difference in mOS was observed between the cohorts. These findings suggest that safety profiles, rather than survival differences, may be used to guide optimal first-line treatment regimens. Prospective studies are warranted to further assess differences in patient outcomes. Research Sponsor: None.

DEB-TACE combined with apatinib and camrelizumab as second-line therapy for unresectable intrahepatic cholangiocarcinoma: A prospective, single-arm, phase II study. First Author: Xuegang Yang, Sichuan Cancer Hospital & Institute, Chengdu, Sichuan, China

Background: This study aimed to evaluate the efficacy and safety of drug-eluting bead transarterial chemoembolization (DEB-TACE) combined with Apatinib and Camrelizumab as second-line therapy for unresectable intrahepatic cholangiocarcinoma (ICC). **Methods:** This is a prospective, single-arm, phase II study. Eligible patients were those with unresectable ICC who had progressed after first-line gemcitabine-containing chemotherapy. These patients received DEB-TACE combined with Apatinib and Camrelizumab therapy. The primary endpoints were to assess the objective response rate (ORR) and disease control rate (DCR) in accordance with both Response Evaluation Criteria in Solid Tumors (RECIST) V1.1 and modified RECIST (mRECIST) criteria. Secondary objectives included measuring progression-free survival (PFS), overall survival (OS), and safety profiles. Adverse events (AEs) were graded according to Common Terminology Criteria for Adverse Events (CTCAE) v5.0. **Results:** Twenty patients participated in this study. The ORR was 65% (95% confidence interval [CI]: 40.8%–84.6%) per mRECIST and 25% (95% CI: 8.7%–49.1%) per RECIST V1.1. The DCR was 95% (95% CI: 74%–99%) per mRECIST and 85% (95% CI: 62.1%–96.8%) per RECIST V1.1. The median PFS was 7.7 (95% CI: 5.5–9.8) months. The median OS was 13.2 (95% CI: 3.1–23.3) months. Treatment-related adverse events (TRAEs) occurred in all 20 (100%) patients. The most common TRAEs included decreased lymphocyte count, hypertension, and abdominal pain, with grade $\geq$3 TRAEs manageable via appropriate interventions. **Conclusions:** DEB-TACE combined with Apatinib and Camrelizumab as second-line therapy for unresectable ICC demonstrated promising efficacy and an acceptable safety profile, providing a viable treatment option for patients with unresectable ICC progressing after first-line gemcitabine-containing chemotherapy. Clinical trial information: NCT04834674. Research Sponsor: None.

Outcomes of combined HCC-cholangiocarcinoma with adjuvant chemotherapy: An NCDB cohort. First Author: Maria Diab, Henry Ford Health/Michigan State University, Detroit, MI

Background: Combined (or mixed) hepatocellular carcinoma-cholangiocarcinomas (cHCC-CCA) are rare liver tumors that are associated with poor prognosis. Patients (pts) presenting with limited disease are candidates for curative intent surgery. However, the role of adjuvant chemotherapy is not established. **Methods:** This retrospective review was based on the National Cancer Data Base (NCDB) participant user file (PUF) from 2014 to 2022. Patients were identified using International Classification of Diseases for Oncology, 3rd Edition (ICD-O-3) topography (C22.0–22.1) and histology code 8180 for cHCC-CCA. Adjuvant chemotherapy was defined as chemotherapy administered on or after 6 weeks from surgery. Patients who had neoadjuvant chemo were excluded. Analytical stage variable captures data from pathological stage, and if pathological stage is missing, then clinical stage is captured. Pathological stage data were available only for 13% of pts. Hence, analytical stage was used with about 31% data available. Frequency and proportions were reported for categorical variables. Median overall survival (mOS) and corresponding 95% confidence intervals were reported using Kaplan-Meier (KM) estimates. Cox's proportional hazard model was used to report the adjusted and unadjusted analysis of OS. Hazard ratio (HR) and 95% confidence intervals were reported. All statistical analysis were performed using SAS version 9.4 software. Analysis of the NCDB PUF is exempt from IRB review. **Results:** 2815 pts with cHCC-CCA were identified, of which 2174 pts data were used for final analysis. 394 (18.1%) pts received adjuvant chemotherapy and 1780 (81.9%) did not receive any chemotherapy. 90% were above age 50 years; 76.2% were Caucasians and 67.7% were Male. Of those who received adjuvant chemotherapy, 162 (41.1%) received chemotherapy as single agent and 203 (51.5%) received chemotherapy as multiple agents. Among 668 data on analytic stage, 28.3% were stage 1, 36.8% were stage 2, 20.9% were stage 3 and 14.1% were stage 4. LVI data was also available for 549 patients. Of these, 38.1% had LVI present. Adjuvant chemotherapy was associated with improved OS compared to no chemotherapy (HR = 0.87 (95% CI: 0.77 – 0.99) p = 0.0296) in the entire population. Adjusted OS analysis for adjuvant chemotherapy with analytical stage showed significant survival benefit with adjuvant chemotherapy (HR = 0.73 (9%% CI: 0.56 – 0.96), p = 0.0261). Further adjustment for LVI was not performed due to large missing data. **Conclusions:** Adjuvant chemotherapy is not currently a standard for pts with cHCC-CCA after curative intent surgery. However, it appears to be associated with improved survival. Prospective studies evaluating the role of adjuvant therapy in this pt population are needed. Research Sponsor: None.

Performance of a multi-cancer early detection test (MCED) for detecting small hepatocellular carcinoma (HCC) in a screening population. First Author: Gangchao Xu, Department of General Surgery, Huidong People's Hospital, Huizhou, China

Background: Early diagnosis of small HCC (defined as single nodule $\leq$ 3 cm) is crucial, as it represents the optimal window for curative treatments. Abdominal ultrasound with alpha-fetoprotein (AFP) is recommended for HCC surveillance in high-risk population. However, traditional modality detects only ~63% of small HCC, resulting in most HCC being diagnosed at advanced stages. Genie-Seq, a cfDNA-based MCED assay, covers 5 high-mortality cancers including HCC. Here, we report preliminary results evaluating the performance of Genie-Seq for small HCC in an asymptomatic screening population. **Methods:** Participants aged 40-74 years with no clinical suspicion of cancer were enrolled in a prospective, interventional study. All participants underwent Genie-Seq testing and standard-of-care (SOC) screenings according to the China Guidelines for Cancer Screening, including abdominal ultrasound and AFP. Genie-Seq detects cancer signals and localizes tissue-of-origin (TOO) simultaneously. Further HCC-focused diagnostic workup was performed per physician's discretion if: 1) suspicious findings on HCC screening, or 2) positive MCED results with liver as the top-predicted TOO. Diagnostic outcomes were reviewed for cancer status, TOO prediction accuracy, and stage. **Results:** As of December 2025, 1210 participants completed MCED testing and HCC screening. Nine participants were suspected of HCC and underwent further evaluation, with definitive diagnosis achieved in 7. Of these, 4 were confirmed as HCC (3 small HCCs, 1 stage II), 1 had synchronous gastric and colorectal cancers, and 2 had benign hepatic lesions. Genie-Seq identified all HCC cases with 100% TOO prediction accuracy, including 2 that were missed or initially misdiagnosed by traditional imaging. Patient 885 was exclusively identified by MCED, as no nodule was detected by ultrasound. Patient 888 had atypical features on contrast-enhanced CT/Gd-EOB-DTPA MRI (initial suspicion of inflammatory pseudotumor), and Genie-Seq positivity prompted contrast-enhanced ultrasound, leading to definitive diagnosis of small HCC. **Conclusions:** Genie-Seq exhibits excellent performance for small HCC detection in screening population, supporting it as a complementary tool to conventional preventive care and potentially improving curable HCC detection. Research Sponsor: Shanghai Xiaohe Medical Laboratory Co. Ltd.

Diagnostic outcomes of participants achieved diagnostic resolution.

Participants	Suspicious Lesions Detected by Ultrasound	AFP (ng/ml)[1]	MCED Results	Diagnosis	Tumor Stage (AJCC)
0108	Yes	2.96	Negative	Hepatic cysts	
0572	Yes	4.25	Negative	Hepatic cavernous hemangioma	
0640	No	2.6	Positive	Multiple primary cancers	Gastric cancer: IIB Colorectal cancer: I
0723	Yes	58.55	Positive	HCC	II
0885	No	8.16	Positive	HCC	IA
0888	Yes	42.53	Positive	HCC	IB
0971	Yes	9.11	Positive	HCC	IA

[1]AFP levels of $<$ 7 ng/mL were defined as normal.

Phase I/II, first-in-human study of yttrium-90 carbon microspheres in patients with unresectable hepatocellular carcinoma: Safety and early efficacy profiles. First Author: Lei Zhang, Department of Radiology, Center of Interventional Radiology and Vascular Surgery, Zhongda Hospital, Medical School, Southeast University, Nanjing, China

Background: Yttrium-90 microsphere selective internal radiation therapy (Y-90 SIRT) plays a significant role in the treatment of unresectable hepatocellular carcinoma. The phase I clinical study evaluated the safety and efficacy of Y-90 Carbon Microspheres Injection in patients with unresectable hepatocellular carcinoma. **Methods:** This multicenter, single-arm, prospective study was conducted across eight centers in China. It enrolled all eligible patients with uHCC who underwent radioembolization between 2023 and 2024. Eligibility criteria included unresectable hepatocellular carcinoma, Child-Pugh A cirrhosis, and an Eastern Cooperative Oncology Group performance status of 0-1. The primary endpoints included the incidence of adverse events and serious adverse events post-infusion, and the objective response rate in the treated area at first assessment according to mRECIST criteria. Among the 40 enrolled patients, 40.0% had an ECOG status of 0. According to China Liver Cancer Staging (CNLC), there were 12 cases (30.0%) in stage Ia, 9 cases (22.5%) in stage Ib, 6 cases (15.0%) in stage IIa, 4 cases (10.0%) in stage IIb, and 9 cases (22.5%) in stage IIIa of liver cancer. The median tumor size was 55.36 mm (range: 11.2–141.2). **Results:** All subjects received radioembolization as primary treatment, with a median tumor target absorbed dose of 450 Gy (range: 196.5 Gy-2000 Gy). According to the SPECT/CT results after treatment with NRT6003 injection, the median tumor absorbed dose was 429.93 Gy (range: 197.1 Gy-2827.7 Gy). As of February 21, 2025, the median follow-up of 9.5 months, a total of 221 treatment-related adverse events were reported, including 16 events of grade ≥3 and 2 serious adverse events (Upper abdominal pain, gastrointestinal bleeding). The best overall objective response rates were 92.5% (37/40) for whole-body and 97.5% (39/40) for local responses. The confirmed objective response rates were 82.5% (33/40) for whole-body and 85% (34/40) for local assessments. Six patients were re evaluated for surgical treatment due to tumor shrinkage. **Conclusions:** In this multicenter Y-90 SIRT study, treatment with Y-90 Carbon Microspheres demonstrated a favorable safety and efficacy were observed in the treatment of unresectable HCC, providing a highly promising treatment option. Clinical trial information: NCT06310590. Research Sponsor: None.

Lanreotide for advanced gastroenteropancreatic neuroendocrine tumors (GEP-NETs) in a Korean population: A multicenter prospective observational study (AIM-NETs). First Author: Changhoon Yoo, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) are a heterogeneous group of malignancies. Somatostatin analogues (SSAs) are the standard of care for patients with unresectable or metastatic well-differentiated G1/G2 GEP-NETs. However, most pivotal data including the CLARINET trial were derived from Western cohorts. We prospectively evaluated the efficacy and safety of lanreotide in a real-world Korean cohort to bridge this geographic data gap. **Methods:** AIM-NETs is a prospective, observational, multicenter study of patients with unresectable or metastatic GEP-NETs treated with lanreotide. Patients received lanreotide 120 mg deep SC every 4 weeks (dose reduction to 90 mg permitted). Tumor response evaluation was done every 8 to 12 weeks according to the RECIST v1.1. The primary endpoint was the 2-year progression-free survival (PFS) rate. Secondary endpoints included median PFS and overall survival (OS), and safety. **Results:** Between Feb 2021 and Feb 2023, 71 patients were enrolled in five tertiary referral cancer centers in Korea. Median age was 59 years (range 25-82); 53.5% (n = 38) were male. Primary sites included pancreas (n = 40, 56.3%), rectum (8, 11.3%), colon (3, 4.2%) and stomach (3, 4.2%). Only two patients (2.8%) had functioning tumors. Tumor grades were G1 (n = 20, 28.2%), G2 (50, 70.4%) and G3 (1, 1.4%). The 2-year PFS rate was 50.6% (95% CI, 38.2%-63.0%) and median PFS was 26.0 months (95% CI, 15.2-32.7). The 2-year OS rate was 89.9% (82.9%-97.0%); median OS was not reached. The objective response rate was 23.5% (95% CI, 14.1%-35.4%). Higher tumor grade was significantly associated with worse PFS ($p < 0.0001$) and OS ($p < 0.0001$). High somatostatin receptor expression (Krenning score of 3 or higher on baseline Ga-68 DOTATOC scan) did not significantly correlate with PFS (p = 0.358) or OS (p = 0.199). No new safety signal of lanreotide were identified. **Conclusions:** Lanreotide provides robust disease control and a manageable safety profile in Asian patients with advanced GEP-NETs. The observed efficacy, including a favorable ORR, supports lanreotide as a standard of care in this population, aligning with previous clinical trial outcomes. Clinical trial information: NCT04696042. Research Sponsor: Ipsen.

4171 **Poster Session**

Quality of life in patients with gastroenteropancreatic neuroendocrine tumors receiving ^{177}Lu-edotreotide or everolimus: Results from the COMPETE study. First Author: Jaume Capdevila, Hepatobiliary Pancreatic Cancer and Endocrine Tumors Group, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: The Phase 3 COMPETE trial demonstrated a significant treatment effect in favor of ^{177}Lu-edotreotide over everolimus in patients with Grade 1/2, well-differentiated, gastroenteropancreatic neuroendocrine tumors; ^{177}Lu-edotreotide significantly improved progression-free survival (primary endpoint) and objective response rate (secondary endpoint) compared to everolimus. Nowadays, treatment choice also considers the impact of therapy on patients' quality of life (QoL); here, we present QoL results from the COMPETE trial. **Methods:** The European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ)-C30 and EORTC QLQ-gastrointestinal neuroendocrine tumors (GI.NET) were completed by patients at baseline, each month during the first year, and every 3 months thereafter until disease progression or end of study. Mean change from baseline, duration of maximum health-related quality of life (HRQoL) improvement (until deterioration), and time to deterioration were calculated. Between-group comparisons were conducted using repeated measure analysis with factors for treatment, randomization stratification factors, visit, baseline value, and treatment-by-visit interaction; all HRQoL analyses were prespecified and exploratory. **Results:** Based on repeated measure analysis, mean change from baseline was in favor of ^{177}Lu-edotreotide: overall mean change (95% confidence interval [CI]) in global health score was 0.9 (-2.7, 4.4) in the ^{177}Lu-edotreotide arm vs -9.9 (-13.9, -6.0) in the everolimus arm (nominal $p<0.0001$) (positive change corresponds to improvement). Time to deterioration in global health status/QoL was longer in the ^{177}Lu-edotreotide arm vs the everolimus arm (Table 1). Similar trends were observed in the EORTC QLQ-C30 and EORTC QLQ-GI.NET subdomains. In the ^{177}Lu-edotreotide arm, 90/207 (43.5%) participants had a clinically meaningful improvement (≥10 points) in global HRQoL score, vs 31/102 (30.4%) participants in the everolimus arm. Among these participants, the median duration of improvement was 22.0 (95%CI: 10.1, not evaluable [NE]) vs 10.2 (95%CI: 3.3, NE) months in the ^{177}Lu-edotreotide and everolimus arm, respectively. **Conclusions:** Consistent with the overall COMPETE outcomes, this analysis demonstrated clinically meaningful and durable HRQoL benefits for ^{177}Lu-edotreotide compared with everolimus. Clinical trial information: NCT03049189. Research Sponsor: None.

Time to deterioration in global health status/QoL (≥10 points).

Parameter / Statistics	^{177}Lu-edotreotide (N=207)	Everolimus (N=102)
Patients with ≥10 points deterioration, n (%)	114 (55.1)	78 (76.5)
Median, months (95% CI)[a]	10.251 (7.359, 15.901)	2.267 (2.004, 3.253)
Nominal stratified p-value[b]	<0.0001	
Stratified hazard ratio (95% CI)	0.392 (0.292, 0.527)	

[a]Estimated via Kaplan-Meier method.

Organotropic and genomic characterization of pancreatic neuroendocrine carcinoma. First Author: Sara Wallam, Columbia University Irving Medical Center, New York, NY

Background: Pancreatic neuroendocrine carcinoma (PNEC) is a rare, aggressive malignancy. Neuroendocrine carcinomas (NEC) of other primary sites, such as small cell lung cancer (SCLC), have a propensity to metastasize to the brain. Incidence of brain metastases in PNEC is poorly characterized, and most staging recommendations for extrapulmonary NEC do not include routine brain imaging. We evaluated the incidence of brain metastases in PNEC, identified factors associated with brain metastases, and characterized the genomic profile of PNEC. **Methods:** We reviewed the genomic profile of patients with PNEC, pancreatic ductal adenocarcinoma (PDAC), SCLC, and pulmonary large cell neuroendocrine carcinoma (LCNEC), who underwent next generation sequencing (NGS) at Memorial Sloan Kettering Cancer Center (MSKCC). We queried the Surveillance, Epidemiology, and End Results (SEER) database to identify all cases of metastatic PDAC and small cell or large cell PNEC diagnosed 2010-2022. We performed multivariable logistic regression to identify demographic and clinical factors associated with brain metastases. We used chi-squared testing to compare metastatic site frequency between tumor types. **Results:** The SEER query identified 412 cases of metastatic PNEC and 60,668 cases of metastatic PDAC with documented site of metastasis at diagnosis. Compared to PDAC, PNEC had higher rates of metastasis to the brain (8% vs 0.8%, $p<0.001$), bone (16% vs 9%, $p<0.001$), and distant lymph nodes (15% vs 8%, $p<0.001$) but lower rates to the lung (19% vs 25%, p=0.03). The incidence of liver metastases was similar in both tumor types (88% vs 87%). Within the PNEC cohort, lung metastasis was positively associated with brain metastasis (odds ratio [OR] 5.4, 95% confidence interval [CI] 2.4-12.5, $p<0.001$), but liver metastasis was negatively associated with brain metastasis (OR 0.2, 95% CI 0.1-0.5, $p<0.001$). The presence of brain metastases did not impact overall survival. Twenty eight patients with PNEC underwent NGS at MSKCC, including 12 with mixed ductal-neuroendocrine carcinoma or mixed acinar-neuroendocrine carcinoma. TP53 alterations were common (>50%) in all tumor types. RB1 alterations were seen frequently in SCLC (78%), PNEC (54%), and LCNEC (24%), but not in PDAC (2%). KRAS alterations were highly prevalent in PDAC (84%), uncommon in SCLC (3%), and with intermediate frequency in PNEC (36%). **Conclusions:** We found a high incidence of brain metastasis in PNEC, especially in patients with lung metastases, supporting neuroimaging in many patients with this disease. The strong association between lung and brain metastases is also noted in breast cancer, possibly explained by sequential seeding or shared features driving organotropism to these organs. PNEC demonstrated genomic features of both PDAC and SCLC. More research is needed to determine how these genomic features can inform management practices in individual patients. Research Sponsor: None.

Cohort-level safety and efficacy results for [^{212}Pb]VMT-α-NET in advanced somatostatin receptor subtype 2 (SSTR2+)–expressing neuroendocrine tumors (NETs): Cohorts 1–3. First Author: Thorvardur Ragnar Halfdanarson, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: [^{212}Pb]VMT-α-NET is an alpha-particle radiation-delivering agent targeted to somatostatin receptor type 2 (SSTR2)-expressing tumors. Here, we present safety and efficacy results from the dose-finding phase 1/2a clinical trial (NCT05636618). **Methods:** This phase 1/2a dose-escalation study uses a Bayesian algorithm to identify an optimal dose of [^{212}Pb]VMT-α-NET for participants with advanced, well-differentiated NETs expressing SSTR2. Eligible participants must have unresectable or metastatic disease, documented radiologic progression following at least one prior systemic treatment, and evidence of SSTR2 expression (Krenning Score ³2) in ≥1 lesion confirmed on an FDA-approved somatostatin receptor PET scan. Patients previously treated with systemic peptide receptor radionuclide therapy (PRRT) are excluded from enrollment. During the dose-finding phase, participants may receive up to four administrations of [^{212}Pb]VMT-α-NET at their assigned dose level, and they are monitored for dose-limiting toxicities (DLTs) for 42 days and safety throughout the study. Efficacy is evaluated by investigators according to RECIST criteria v1.1. Dosimetry is included as a supportive analysis. **Results:** As of the 10-Dec-2025 data cut-off (DCO), 56 participants had been enrolled across Cohorts 1, 2, and 3 and received at least one dose of [^{212}Pb]VMT-α-NET: 2 participants in Cohort 1 (2.5 mCi), 46 in Cohort 2 (5 mCi), and 8 in Cohort 3 (6 mCi). No dose-limiting toxicities, grade 5 adverse events, treatment-related discontinuations, serious renal events, dysphagia, or clinically meaningful treatment-related myelosuppression were observed. The median follow-up for all treated participants was 40 weeks (range 6–97). Efficacy has been summarized in this abstract for 25 participants (2 in Cohort 1 and 23 in Cohort 2). Nineteen of these 25 participants remained progression-free at the time of the DCO, with a median efficacy follow-up of 49 weeks (range 6–97). In Cohort 2, investigators observed RECIST v1.1 objective responses in 9 of 23 participants (39%), including 8 confirmed responses. Both participants in Cohort 1 continued to exhibit stable disease after two years of follow-up. Updated safety for all participants and updated efficacy for participants with sufficient maturity beyond the 25 summarized here will be presented at the congress. **Conclusions:** Treatment with [^{212}Pb]VMT-α-NET continues to demonstrate a favorable safety profile across all treated participants (n = 56) and shows signs of sustained efficacy at the 2.5 mCi and 5 mCi dose levels. The therapy has been well-tolerated with no observed dose-limiting toxicities or serious treatment-related adverse outcomes. Based on these encouraging safety and efficacy findings, the study is ongoing, and enrollment into Cohort 3 (6 mCi) remains active. Clinical trial information: NCT05636618. Research Sponsor: None.

DISCO update: Diagnostic performance of ^{64}Cu-SARTATE compared to ^{68}Ga-DOTATATE in patients with known or suspected neuroendocrine tumors. First Author: Eva Lengyelova, Clarity, Sydney, NSW, Australia

Background: Diagnostic imaging is critical in the management of neuroendocrine tumors (NETs). ^{64}Cu-SARTATE may provide advantages over existing imaging agents due to its longer half-life and sarcophagine chelator, with a potential to accurately detect additional disease in NETs. **Methods:** This multi-center Phase II study assessed the safety and efficacy of ^{64}Cu-SARTATE (200 MBq) in participants with known or suspected gastroenteropancreatic (GEP)-NETs (NCT04438304). (SARTATE; at 4 ± 1 h and 20 ± 4 h post-injection) were assessed by two independent blinded central readers, and . Discordant lesions (only present on either DOTATATE or SARTATE PET/CT) were subsequently evaluated by an independent assessor against a standard of truth (SOT; biopsy and/or follow-up conventional imaging). The per-lesion sensitivity (SE) for discordant lesions was calculated for both SARTATE and DOTATATE (SE=proportion of true positive foci / [true positive foci + false negative foci]). Lesion detection rate (DR) was calculated for a composite (best-case scenario) lesion detection across both SARTATE time points and for DOTATATE (DR= total number of lesions detected on scan / total number of lesions on scan pair). Values express the averages across readers and both PET/CT time points (for SARTATE). **Results:** 45 participants were enrolled and received SARTATE (41 known and 4 suspected NETs). Most had stage 3 or 4 disease. The mean number of foci detected by SARTATE was 441 vs. 227 by DOTATATE. A total of 238 discordant foci were identified in 34 participants; 223 of these were detected by SARTATE alone and 15 by DOTATATE alone. For the 122 discordant foci with evaluable SOT, the difference in SE for SARTATE vs. DOTATATE was statistically significant 94.7% [95% CI 65.1, 99.5] for SARTATE vs. 5.4% [95% CI 0.5, 34.9] for DOTATATE; $p<0.001$). The lesion DR was 97.2% [95% CI 75.9, 99.5] for SARTATE and 44.4% [95% CI 32.3, 57.5] for DOTATATE. The liver had the highest number of foci detected by both tracers (352 foci on SARTATE vs. 180 on DOTATATE) among all regions. Seven (15.6%) participants experienced 9 SARTATE-related AEs; 8 were Grade 1 and one was Grade 2, with most resolving within 2 days. **Conclusions:** ^{64}Cu-SARTATE was found to be safe and well-tolerated in patients with GEP-NETs. SARTATE lesion detection was higher than that of DOTATATE, with the liver having the highest number of lesions identified. SARTATE was able to detect additional true positive lesions compared to DOTATATE. The enhanced diagnostic performance offered by SARTATE, especially in key organs affected by GEP-NETs, may have important clinical implications to inform treatment decisions. A phase III study of ^{64}Cu-SARTATE in NETs is being planned. Clinical trial information: NCT04438304. Research Sponsor: None.

Genomic and biomarker landscape of MTAP deficiency in gastrointestinal cancers. First Author: Rohit Thummalapalli, Memorial Sloan Kettering Cancer Center, New York City, NY

Background: Genomic loss of *MTAP* and *CDKN2A* is frequently observed across cancers, with ongoing development of MTA-selective PRMT5 inhibitors aiming to achieve synthetic lethality in the setting of MTAP loss. However, the biomarker landscape of patients with gastrointestinal (GI) cancers and MTAP deficiency remains poorly defined, and whether subsets of GI cancers harbor non-genomic mechanisms of MTAP deficiency remains unknown. **Methods:** All GI cancer samples sequenced with MSK-IMPACT v7, a DNA-based next generation sequencing (NGS) panel with coverage for *MTAP*/*CDKN2A* were queried. *MTAP* and *CDKN2A* deletions (del) were defined by low read counts in coverage-based copy number analyses. Genomic and pathologic analyses were completed in tumors with high *MTAP* del prevalence: esophagogastric cancers (EGC), pancreatic adenocarcinoma (PDAC), pancreatic neuroendocrine tumors (PanNETs), and biliary tract cancers (BTCs). MTAP immunohistochemistry (IHC) was completed on PDAC, PanNET, small bowel NET, and BTC samples to investigate prevalence of MTAP protein loss. **Results:** Among 8346 GI cancer samples, *MTAP* del was identified in 456 (5.5%), co-occurring with *CDKN2A* del in 98.8% of cases, with 79.8% confirmed homozygous del by FACETS, and was associated with higher tumor purity compared to *MTAP*-intact samples ($p < 0.001$). *MTAP* del prevalence was 14.4% in esophageal squamous cell carcinoma (SCC), 5.9% in esophagogastric adenocarcinoma (EGA), 12.4% in PDAC, 7.4% in PanNET (grade 1 [G1]: 3.4%, G2: 4.3%, G3: 19.4%), 0% in small bowel NET, 10.2% in BTCs (including 11.5% in intrahepatic cholangiocarcinoma [iCCA]), and 0.7% in colorectal cancer. *MTAP* del was associated with wild-type (WT) *KRAS* amplifications (amp) in EGC, *KRAS G12V* and WT *KRAS* amp in PDAC, and *KRAS* mutations and *FGFR2* fusions in iCCA. Among EGA, PDAC, and BTCs, *MTAP* del tumors were associated with higher fractions of genome altered ($p < 0.001$ for each) and rates of whole genome duplication ($p < 0.001$ for each). Among 463 samples profiled by MTAP IHC, MTAP deficiency was found in 29/93 (31%) PDAC, 3/33 (11%) BTC, 15/60 (25%) PanNETs, and 196/277 (71%) small bowel NETs. Analysis of MTAP deficiency and activity of standard systemic therapies, as well as metabolomic and epigenomic profiling of MTAP-deficient GI cancers are ongoing and will be presented. **Conclusions:** *MTAP* genomic del are recurrently identified across GI cancers, most notably in esophageal SCC, PDAC, G3 pancreatic NETs, and iCCA. *MTAP* del are associated with distinct genomic drivers across GI cancers and markers of chromosomal instability more broadly. We found evidence of discrepancy between MTAP loss by NGS and IHC across multiple GI cancers, most notably small bowel NETs, which demonstrate frequent MTAP IHC deficiency in complete absence of genomic loss, suggesting non-genomic mechanisms of MTAP silencing. These observations may help define the role for therapies targeting MTAP deficiency in GI cancers. Research Sponsor: U.S. National Institutes of Health.

A multicenter single-arm study of induction EC/EP plus camrelizumab followed by maintenance camrelizumab plus apatinib in treatment-naive advanced or metastatic extrapulmonary neuroendocrine carcinoma. First Author: Yuhong Dai, Department of Oncology, Tongji Hospital, Huazhong University of Science and Technology, Wuhan, China

Background: Extrapulmonary neuroendocrine carcinoma (EP-NEC) is a poorly differentiated and highly aggressive malignancy with poor prognosis. Platinum (cisplatin or carboplatin) plus etoposide (EC/EP) remains the standard first-line regimen. However, clinical outcomes are suboptimal, highlighting the need for more effective strategies. Camrelizumab is a programmed cell death-1 (PD-1) inhibitor, and apatinib is a vascular endothelial growth factor receptor-2 (VEGFR2) inhibitor. Both have demonstrated antitumor activity in multiple solid tumors. Therefore, we investigated a sequential regimen consisting of induction EC/EP plus camrelizumab followed by maintenance camrelizumab plus apatinib in treatment-naive patients with advanced or metastatic EP-NEC. **Methods:** This multicenter, single-arm trial enrolled patients with previously untreated advanced or metastatic EP-NEC. Patients received 4–6 cycles of induction therapy with cisplatin (25 mg/m² iv, d1-3, q3w) or carboplatin (AUC = 5 iv, d1, q3w) plus etoposide (100 mg/m² iv, d1-3, q3w) in combination with camrelizumab (200 mg iv, d1, q3w). Patients without disease progression received maintenance camrelizumab (200 mg iv, q3w) plus apatinib (250 mg, qd) until progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. Tumor response was assessed every 6 weeks per RECIST v1.1. The trial is registered on ClinicalTrials.gov, NCT05142865. **Results:** As of January 2026, 30 patients were enrolled (median age of 59.5 years, range 30–73), and all 30 patients were evaluable for efficacy. The ORR was 66.7% and the DCR was 83.3%. Median PFS was 9.87 months (95% CI, 6.23–NA). Median OS was not reached, and the 1-year OS rate was 74.6%. All patients experienced adverse events (AEs), with grade ≥3 AEs observed in 43.3% (13/30). Grade ≥3 AEs were mainly hematologic toxicities, including anemia (13.3%), neutropenia (13.3%) and thrombocytopenia (13.3%). Common non-hematologic AEs included elevated transaminases (43.3%), mainly grade 1–2, with grade ≥3 events in 10.0%. **Conclusions:** Induction EC/EP plus camrelizumab followed by maintenance camrelizumab plus apatinib showed encouraging activity and manageable safety in treatment-naive advanced or metastatic EP-NEC. Further studies are warranted to confirm these findings. Clinical trial information: NCT05142865. Research Sponsor: Natural Science Foundation of Hubei Province of China; No. 2023AFB1059.

Postoperative pancreatic fistula after resection of pancreatic neuroendocrine tumors: Incidence, predictors, and clinical impact. First Author: Oliver Overheu, Department of Hematology and Oncology with Palliative Care, St. Josef Hospital, Ruhr University, Bochum, Germany

Background: Postoperative pancreatic fistula (POPF) remain a major source of morbidity after pancreatic surgery. Data specific to pancreatic neuroendocrine tumors (pNETs) are limited, although these neoplasms differ biologically and surgically from pancreatic adenocarcinoma, potentially influencing POPF risk and outcomes. This study evaluated the incidence, predictors, and clinical impact of POPF in a well-characterized cohort of patients undergoing resection for pNETs. **Methods:** All patients who underwent resection for histologically confirmed pNETs between 2010-2019 at a tertiary center were retrospectively analyzed. Clinicopathological parameters and surgical procedures were assessed for association with POPF occurrence and severity according to the International Study Group on Pancreatic Fistula (ISGPF) criteria. Statistical analyses included χ^2, Fisher's exact, Spearman correlation tests, and multivariable regression analysis; significance was defined as $\alpha = 0.05$. **Results:** Among 106 patients (44% female, mean age 61 ($\pm$ 13.5) years), 85% received a formal pancreatic resection, 15% an atypical resection. More than half (53%) of pNETs were located in the pancreatic tail. The majority (64%) of tumors were G1, only 4% G3, with 72% of diseases in early stages UICC I or II. 12% of pNETs were functional and exclusively insulinomas. 53 patients (50%) developed a POPF, predominantly Grade B (60%), followed by Grade A (34%) and Grade C (6%). No surgery- or POPF-related mortality was observed. POPFs were most frequent after distal pancreatectomy for tail lesions (60% vs. 23% body vs. 17% head; p = 0.065), and in functional pNETs (77% vs. 46% in non-functional pNETs; p = 0.072). Distant metastases were inversely associated with POPF (M0 54% vs. M1 28%; p = 0.043). A nonsignificant trend toward higher POPF rates was observed after atypical resections (73% vs. 48%; p = 0.095). Higher POPF grade was associated with female sex (p = 0.016), and tumor proliferation index (p = 0.046); female sex remained independently associated with POPF grade in multivariable regression analysis (beta = 0.334, p = 0.044). Patients with POPF exhibited lower long-term mortality during follow-up (8% vs. 29%; p = 0.009) and lower mean preoperative chromogranin A levels (82.8 ng/mL vs. 167.8 ng/mL; p = 0.038). **Conclusions:** POPF occurred in half of all pNET resections, most commonly of Grade B severity. Tumor location, functionality, and absence of metastases were associated with higher POPF risk, and female sex with higher grade POPF. The association of POPF with lower long-term mortality likely mirrors the favorable tumor biology and localized disease profile of patients selected for curative surgery. This underscores the long-term oncological benefit of surgical resection in pNETs and provides relevant insights for postoperative risk stratification and perioperative management. Research Sponsor: None.

Efficacy and safety of cabozantinib (CABO) in advanced neuroendocrine tumors (NET) according to hormone functional status: Subgroup analysis of phase 3 CABINET trial (Alliance A021602). First Author: Nikolaos Trikalinos, Siteman Cancer Center, Washington University School of Medicine, Saint Louis, MO

Background: In the CABINET trial, CABO significantly prolonged progression-free survival (PFS) compared to placebo (PB) in patients (pts) with advanced, previously treated extrapancreatic NET (epNET) or pancreatic NET (pNET) (Chan et al., NEJM, 2025). Here we report outcomes according to functional status based on NET hormone secretion. **Methods:** Pts with locally advanced or metastatic epNET or pNET were randomized 2:1 in separate cohorts to receive CABO 60 mg daily vs PB. Eligibility included progression by RECIST within 12 months (mo) before registration, $\geq$ 1 prior systemic therapy not including somatostatin analogs (SSA). Pts with functional NET due to hormone secretion and non-functional NET were included. In this post hoc subgroup analysis, we analyzed PFS by blinded independent central review and adverse events for pts receiving CABO vs PB based on functional status. Cox regression models were used with stratification on primary tumor site (epNET vs pNET). Subset analyses to evaluate treatment arm differences were conducted in pts with functional and non-functional tumors. Due to small numbers, separate results for those with unknown functional status are not included. **Results:** Of the total 298 pts enrolled in both cohorts, 74 had a functional NET (CABO, n = 47; PB, n = 27); 179 had a non-functional NET (CABO, n = 123; PB, n = 56); 45 had unknown functional status (CABO, n = 28; PB, n = 17). For functional NET, primary tumor sites were GI tract (n = 50; 68%), pancreas (n = 15; 20%), unknown (n = 4; 5%), lung (n = 3; 4%), and thymus (n = 2; 3%). Secreted hormones that were reported included serotonin (55%), somatostatin (18%), gastrin (16%), glucagon (4%), insulin (4%), ACTH (1%), and vasoactive intestinal peptide (1%). For non-functional NET, primary tumor sites were pancreas (n = 75; 42%), GI tract (n = 42; 23%), lung (n = 30; 17%), unknown (n = 17; 9%), thymus (n = 8; 4%), and other (n = 7; 4%). Concurrent SSA was received by 91% and 53% of pts with functional and non-functional NET, respectively. In both subgroups, CABO was associated with improved PFS compared to PB (for functional NET: stratified hazard ratio [sHR], 0.40; 95% confidence interval [CI]: 0.20-0.82, P = 0.012; for non-functional NET: sHR, 0.26; 95% CI: 0.17-0.41, P $<$ 0.001). The most frequent grade 3/4 adverse events (AEs) attributed to CABO vs PB in pts with functional NET included hypertension (21% vs 11%), diarrhea (9% vs 11%), and fatigue (2% vs 15%); in pts with non-functional NET, grade 3/4 AEs included hypertension (21% vs 4%) and fatigue (18% vs 4%). **Conclusions:** Subset analyses of the CABINET trial suggest that CABO is an effective treatment option for pts with functional and non-functional epNET or pNET. Efficacy and safety results for pts with functional or non-functional NET treated with CABO are consistent with results for the entire trial. Clinical trial information: NCT03375320. Immune microenvironment signatures as prognostic biomarkers in gastroenteropancreatic neuroendocrine carcinoma (GEP-NEC). First Author: Ruoyu Miao, Emory University School of Medicine, Atlanta, GA

Background: GEP-NEC is an aggressive malignancy with rising incidence and limited therapeutic options. While immune checkpoint inhibitors (ICIs) have become standard of care in small cell lung cancer (SCLC), their role in GEP-NEC remains undefined. Characterizing immune cell signatures in the tumor microenvironment (TME) across different NEC histologies may help identify prognostic biomarkers and guide immunotherapy strategies. **Methods:** We included 4863 NEC tumors that underwent DNA (592-gene panel, whole exome) and RNA (whole transcriptome) sequencing at Caris Life Sciences. Composition of the TME was estimated from bulk RNA sequencing using QuanTIseq method. Overall survival (OS) and IO-associated OS (IO-OS) were derived from insurance claims and calculated from date of tumor biopsy (OS) or IO initiation (IO-OS) to last contact using Kaplan-Meier estimates and Cox proportional hazards models. Statistical significance was determined by Fishers Exact, Chi-square and Mann-Whitney U test with adjustments for multiple comparisons ($P<$ 0.05). **Results:** The cohort was comprised of small cell (SCNEC, n = 2320), large cell (LCNEC, 618), high-grade NEC (HGNEC, 414) and NEC not otherwise specified (NOS, 1511). Primary sites included lung (2642), pancreas (459), non-pancreatic GI (931) and other sites (831). SCNEC had lower Treg, M1 or M2 macrophage and neutrophils, and higher CD4+ T-, NK-, B- and dendritic-cell infiltration than other histologies, suggesting more lymphocyte-driven immune milieu with reduced myeloid-driven suppression. Compared with lung NEC, GEP-NEC demonstrated a more immunosuppressive TME, characterized by lower NK-, B- and dendritic-cell infiltration and higher Treg, M1/M2 macrophage and neutrophils—most pronounced in non-pancreatic GI primaries. Pancreatic NEC had reduced dendritic cells in LCNEC, HGNEC and NOS subtypes and higher neutrophils in HGNEC and NOS. Elevated B-cell infiltration was associated with improved OS in SCNEC of non-pancreatic GI (HR 0.56, 95%CI 0.37-0.85, *P*= 0.032) and lung (HR 0.81, 0.72-0.90, *P*= 0.001) origin. High M2 macrophage and NK-cell scores were associated with prolonged OS in NOS of non-pancreatic GI (M2: HR 0.35, 0.28-0.45, $P<$ 0.001; NK: HR 0.32, 0.26-0.41, $P<$ 0.001) and pancreas (M2: HR 0.46, 0.33-0.62, $P<$ 0.001; NK: HR 0.64, 0.48-0.84, *P*= 0.010) origin. Among patients receiving ICIs (n = 1811, 910 with SCLC), only higher B-cell infiltration was associated with improved IO-OS in SCLC (HR 0.79, 0.68-0.92, *P*= 0.029); data was insufficient to analyze IO-OS for other histologic and anatomic subgroups. **Conclusions:** GEP-NEC exhibits a distinct and relatively immunosuppressive TME compared with lung NEC. B-cell, NK-cell, and macrophage signatures are prognostic across GEP-NEC subtypes. These findings support further evaluation of immune-based stratification and biomarker-driven therapeutic development in GEP-NEC. Research Sponsor: None.

Therapy-related myeloid neoplasms after radioligand therapy in neuroendocrine tumors: A multicenter real-world analysis. First Author: Deevyashali Parekh, SUNY Upstate Medical University, Syracuse, NY

Background: Therapy-related myeloid neoplasms (t-MNs), including myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML), represent a rare but serious long-term hematological toxicity associated with radioligand therapy (RLT). Real-world data on the incidence of t-MNs and associated risk factors following RLT in are limited. We sought to investigate the incidence and risk factors of t-MN in patients with NETs treated with 177Lu-Dotatate. **Methods:** We conducted a multicenter retrospective cohort study using the TriNetX research network. Adult patients with NETs who received 177Lu-Dotatate were identified, with first administration defined as the index date. The primary outcome was development of t-MNs (incident MDS or AML) with a 12-month latency period after target treatment. Incidence was calculated and Cox proportional hazards models were used to evaluate associations between baseline covariates and t-MN risk. Covariates included age, sex, race, primary tumor site (small bowel, colon, pancreas, lung), liver and bone metastases, prior alkylating chemotherapy (temozolomide exposure), chronic kidney disease (CKD), and nicotine or alcohol dependence. Treatment pathways were assessed for 177Lu-Dotatate re-treatment and temozolomide. **Results:** A total of 1,811 patients met inclusion criteria. Mean age at index was 65.4 $\pm$ 10.9 years; 977 (54.0%) were male, and 1,503 (83.0%) were White. Median follow-up duration was 20.5 months. Following 177Lu-Dotatate, 37 of 1,807 patients (2.05%) developed MDS, and 15 of 1,804 patients (0.83%) developed AML, with an overall incidence of t-MNs 2.88% (52/1,804). At baseline, mean age (67.1 $\pm$ 9.3 vs 65.4 $\pm$ 11.0 years, p=0.27) and sex (males 42.0% vs 54.2%, p=0.14) were comparable between patients who did and did not develop t-MNs. On multivariable Cox proportional analysis, higher age at index (HR 1.03; 95% CI 1.01–1.07; p=0.048) and baseline CKD (HR 2.69; 95% CI 1.32–5.49; p=0.006) were independently associated with increased risk of t-MNs. Sex, race, primary tumor site, presence of liver or bone metastases, alkylating chemotherapy exposure, and nicotine or alcohol dependence were not significantly associated with t-MN risk. Evaluation of treatment pathways demonstrated similar 177Lu-Dotatate re-treatment rates (2.33% vs 2.77%, p=1.0), and comparable receipt of temozolomide for $\geq$12 months (18.6% vs 16.4%, p=0.66) between groups that did and did not develop t-MNs, respectively. **Conclusions:** In this large real-world cohort of NET patients treated with 177Lu-Dotatate, t-MNs were uncommon but clinically significant. Older age and CKD were associated with increased risk, whereas repeat 177Lu-Dotatate and alkylating chemotherapy exposure were not associated with increased t-MN incidence. These findings may inform risk stratification, patient counseling, and long-term hematologic surveillance following 177Lu-Dotatate. Research Sponsor: None.

Germline pathogenic/likely pathogenic (P/LP) variants in epithelial neuroendocrine neoplasms: The case for universal germline genetic testing. First Author: Udhayvir Singh Grewal, Department of Hematology and Oncology, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Current National Comprehensive Cancer Network (NCCN) guidelines for germline testing in neuroendocrine neoplasms (NENs) rely on organ-specific, syndrome-driven algorithms that may not adequately capture hereditary risk. We sought to analyze prevalence of P/LP germline variants in epithelial NENs and investigate relevant associations. **Methods:** Germline genetic testing results were analyzed from 3,611 probands. Cohort 1 included 3,409 patients identified by ICD-10 code C7A (2015–2025), and Cohort 2 included 201 consecutively curated patients with pathology information (2019–2021). Patients with paraganglioma, pheochromocytoma, or medullary thyroid carcinoma were excluded. Except 59 single-gene tests, multigene panels included a mean of 67 and 62 genes in Cohorts 1 and 2, respectively. Data were classified as P/LP, variant of uncertain significance (VUS), or negative. Comparisons of variant classification frequencies between cohorts were performed using chi-square or Fisher's exact tests. Multivariable logistic regression evaluated clinical and demographic predictors of P/LP variant detection, with results reported as likelihood ratios (LR) and two-sided p-values ($<$ 0.05 considered significant). **Results:** Among all 3,611 probands, mean age was 56 years in Cohort 1 and 53 years in Cohort 2, with females comprising 63% and 71%, respectively. VUS and negative results differed between cohorts (VUS 21.9% vs 32.9%, p = 0.002; negative 67.4% vs 55.0%, p $<$ 0.001), while P/LP rates were similar (10.6% vs 12.1%, p = 1.0), permitting pooled analysis. Overall, 387 patients (10.7%) harbored P/LP variants, with 399 P/LP variants identified across 49 genes. Sixty percent of P/LP variants were accounted for by *CHEK2, MEN1, BRCA2, ATM, FH, HOXB13, PALB2,* and *BRCA1*. Clinically actionable variants per NCCN guidelines were identified in 348 patients (9.6%). Among 479 probands with curated family history, meeting NCCN criteria for multigene testing or having a family history of NEN was not predictive of P/LP detection. Logistic regression demonstrated that male sex was a significant predictor of P/LP variants (LR = 4.538, p = 0.03), while age at NEN diagnosis and primary NEN site were not predictive, nor were the interaction terms significant. **Conclusions:** In this 10-year, multicohort study of patients at a commercial laboratory, more than one in ten patients with epithelial NENs harbored a germline P/LP variant, frequently outside classic hereditary NEN syndromes and inadequately predicted by NCCN criteria, family history, age, or tumor site. These findings suggest that current germline testing frameworks may miss clinically relevant hereditary cancer risk. Broader approaches to germline testing in these patients may be needed to improve identification of hereditary cancer risk and enable personalized prevention and surveillance strategies. Cabozantinib in high-grade neuroendocrine neoplasms. First Author: Nikolaos Trikalinos, Washington University School of Medicine, Division of Medical Oncology, St. Louis, MO

Background: High grade neuroendocrine neoplasms (HG-NENs) are treated with platinum doublets mirroring guidelines for small cell lung cancer (SCLC) but recurrences are common and salvage options are limited in efficacy. Cabozantinib (CABO), an inhibitor of VEGFR, MET, and TAM kinases (TYRO3, AXL, and MER) was approved by the FDA for treatment of well differentiated (WD) NENs of both pancreatic and extrapancreatic origins based on the CABINET study (Chan, NEJM 2025). However, its efficacy in the whole spectrum of HG-NEN patients including poorly differentiated disease (PDD) has not been prospectively explored. **Methods:** This was a single institution, Phase II study of CABO in patients with HG-NENs who had progressed on at least one prior treatment. Key inclusion/exclusion criteria were NENs of any origin except SCLC, high grade by Ki-67 of $>$ 20% or histology consensus, ECOG of $<$ = 1, appropriate hematological parameters and no history of bleeding or active cardiac disease. CABO was given orally starting at 60 mg po daily in 3-week cycles. The primary endpoint of this study was overall response rate (ORR). Secondary endpoints included progression free survival (PFS) and overall survival (OS). A Simon optimal 2-stage design tested the null hypothesis that the true ORR is $<$ = 1% at the type I error rate of 5%, resulting in projected enrollment of up to 32 total patients. Toxicities were graded according to CTCAE v5.0 and response was evaluated according to RECIST v1. **Results:** All patients have been accrued, with 4/32 patients still on treatment. Median age at diagnosis was 62 years and male to female ratio was 1.46. Origin of tumor was GI in 68.8% of the cases, the rest being thoracic (6.3%), prostate (6.3%) cervical (6.3%) head/neck (3.1%) and unknown (9.4%). Median Ki-67 was 55%, 11 patients had Ki-67 $>$ 70%. Histology was WD-HG in 40% of patients and PDD in 60%. Two patients had mixed PDD/other components (MiNEN). Median PFS in evaluable patients was 4.01 months [95% CI 1.61 to 9.30] and mOS was 9.89 mo [95% CI 6.73 to 18.96]. Three patients so far (9.3%) have had partial response as best response (PDD-colon, WD-pancreas and PDD-cervical) while 19/32 (59.4%) patients have had stable disease as best response so far (disease control rate 68.8%). Five (15.6%) patients have received more than 10 treatment cycles. The three longest treated patients had WD-pancreas (23 and 17 cycles) and PDD-unknown (12 cycles). One patient had eventual resection of a metastatic site and is currently without evidence of disease. Three patients withdrew from the trial because of toxicities (shortness of breath, GI bleeding, thromboembolism). Twenty-six patients have expired. **Conclusions:** CABO monotherapy showed efficacy in some HG-NEN patients with not just WD but also the very aggressive PDD histology. No new side effects to the ones previously described for this agent were noted. Supported by Exelixis and a Siteman investment program grant. Clinical trial information: NCT04412629. Research Sponsor: Exelixis; The Foundation for Barnes-Jewish Hospital (BJHF); GR0033156.

Insurance, hospital, and racial disparities in surgical treatment and mortality among patients with neuroendocrine tumors: A national analysis. First Author: Swamynathan Umamaheswaran, Personio, New York, NY

Background: Neuroendocrine tumors (NETs) are the second most common gastrointestinal malignancy with increasing incidence. Surgical resection remains curative, yet population-level disparities data are lacking. We examined insurance, hospital, and racial disparities in NET surgical treatment and outcomes. **Methods:** Using the National Inpatient Sample (2019-2022), we identified NET hospitalizations (ICD-10: C7A, C7B, C25.4, C4A). Outcomes were surgical resection and in-hospital mortality. Multivariable logistic regression estimated adjusted odds ratios (aOR) by insurance, hospital type, and race, controlling for demographics, tumor site, and metastatic status. **Results:** Among 198,955 NET hospitalizations (mean age 64.9 years; 52.7% metastatic), surgical resection was 35.3% and mortality 5.2%. Medicaid (aOR 0.58, 0.56-0.60) and Medicare (aOR 0.64, 0.63-0.66) patients had significantly lower surgery odds versus private insurance (p$<$0.001). In localized disease, surgery rates were 58.9% (Private) vs 36.9% (Medicare). Rural patients had 50% lower surgery odds (aOR 0.50, 0.48-0.53) and 47% higher mortality (aOR 1.47, 1.34-1.61) versus urban teaching hospitals. Black patients had 19% lower surgery odds (aOR 0.81, 0.78-0.83) and 18% higher mortality (aOR 1.18, 1.11-1.25) versus White patients. **Conclusions:** This largest national NET analysis reveals profound multilevel disparities: Medicaid/Medicare patients are 36-42% less likely to receive surgery, rural patients face 50% lower surgical access with 47% higher mortality, and Black patients experience significant treatment and survival inequities. Findings support targeted interventions including insurance coverage expansion, rural referral networks, and equity-focused initiatives. Research Sponsor: None.

Multilevel disparities in surgical resection and mortality among patients with neuroendocrine tumors.

Disparity Type	Comparison	N	Surgery Rate	Mortality	aOR (Surgery)	aOR (Mortality)	95% CI	P-value	Key Finding
Overall Cohort	—	198,955	35.3%	5.2%	—	—	—	—	Mean age 64.9y; 52.7% metastatic
INSURANCE DISPARITIES									
Insurance	Medicare vs Private	—	29.9% vs 45.3%	—	0.64	0.90	0.63-0.66 / 0.84-0.95	$<$0.001	36% lower surgery odds
Insurance	Medicaid vs Private	—	—	—	0.58	1.26	0.56-0.60 / 1.16-1.37	$<$0.001	42% lower surgery; 26% higher mortality
HOSPITAL DISPARITIES									
Hospital	Rural vs Urban Teaching	—	—	7.0% vs 4.9%	0.50	1.47	0.48-0.53 / 1.34-1.61	$<$0.001	50% lower surgery; 47% higher mortality
RACIAL DISPARITIES									
Race	Black vs White	—	—	—	0.81	1.18	0.78-0.83 / 1.11-1.25	$<$0.001	19% lower surgery; 18% higher mortality
Localized NETs	Private vs Medicare	87,100	58.9% vs 36.9%	1.7% vs 3.6%	—	—	—	—	22-point surgery gap

Circulating tumor deoxyribonucleic acid (DNA) and treatment outcomes of gastroesophageal cancer: A systematic review and meta-analysis. First Author: Thuraya Al-Sayegh, University of California San Francisco, Fresno, CA

Background: Gastroesophageal tumors are some of the most highly prevalent cancers worldwide. Despite the high prevalence and advancement in treatments, they represent a major cause of cancer-related deaths. Thus, advancement in gastroesophageal cancer treatment and post-treatment monitoring are imperative in improving disease prognosis. In this study, we aimed to investigate the association between pre- or post-treatment plasma circulating tumor deoxyribonucleic acid (ctDNA) and post-treatment outcomes. **Methods:** We searched PubMed, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and Scopus on October 30, 2025 using ctDNA and gastroesophageal cancer as the keywords along with their related MeSH terms. Studies were included if they investigated the association between the detection of pre- or post-treatment plasma ctDNA and disease outcomes among patients with esophageal or gastric cancer. Our exposure of interest was the detection of pre- or post-treatment ctDNA in plasma while the outcomes of interest were tumor recurrence and tumor progression. The odds ratio (OR) and its 95% confidence interval (95%CI) were the effect measures of choice in the analysis. **Results:** We included a total of 1,897 patients with gastric or esophageal cancer from 21 prospective or retrospective cohorts. Our analysis revealed that pre-treatment detection of ctDNA in the plasma was associated with higher odds of tumor recurrence (OR=4.37; 95%CI: 1.20-15.92) and progression (OR=4.80; 95%CI: 2.51-9.18). These results were consistent in the subgroup analysis among patients with esophageal cancer while they lost their significance among patients with gastric cancer and among good quality studies (Newcastle Ottawa Scale$>$5). Moreover, the detection of post-treatment ctDNA was associated with higher odds of tumor recurrence (OR=6.14; 95%CI: 3.79-9.94) and progression (OR=8.28; 95%CI: 5.03-13.64). These results were consistent in the subgroup analysis of patients with esophageal cancer, gastric cancer and among good quality studies. **Conclusions:** Our results highlight that detection of pre-treatment but more so post-treatment ctDNA is associated with post-treatment cancer outcomes. Our results emphasize the potential use of ctDNA as a valuable tool for detection of early gastroesophageal cancer recurrence and post-treatment progression. Research Sponsor: None.

Evaluation of clinical success and adverse events with endoscopic ultrasound-guided biliary drainage (EUS-BD) compared to percutaneous transhepatic biliary drainage (PTBD) after failed ERCP in malignant biliary obstruction: A systematic review and meta-analysis. First Author: Era Gupta, Bangalore Medical College and Research Institute, Bangalore, India

Background: ERCP fails to achieve biliary decompression in ~3–10% of malignant biliary obstruction cases. Rescue drainage is typically performed using percutaneous transhepatic biliary drainage (PTBD) or endoscopic ultrasound–guided biliary drainage (EUS-BD). Although PTBD is widely available, it carries substantial morbidity, requires external catheters, and is associated with recurrent infections and reduced quality of life. EUS-BD offers internal drainage with favorable outcomes across established techniques, but comparative evidence versus PTBD remains limited. We performed a systematic review and meta-analysis comparing EUS-BD and PTBD after failed ERCP in malignant biliary obstruction. **Methods:** This review followed PRISMA guidelines. PubMed, Google Scholar, and ScienceDirect were searched using a comprehensive strategy. Comparative studies evaluating EUS-BD versus PTBD and reporting technical success (TS: bile duct puncture with stent/catheter placed in the intended position), clinical success (CS: $>$ 50% bilirubin reduction at 2 weeks), adverse events (AD: graded as per the ASGE endoscopic AE severity lexicon), and reintervention (RN) were included. The data was analysed using the Meta, Metadata and the Metafor packages of R Studio. The Mantel-Haenszel method and the Inverse variance method were utilized to analyse the odds ratio for TS, CS, AD, and RN. The I^2 test was used to assess the heterogeneity of the studies. **Results:** Twenty-six studies were included. EUS-BD was associated with higher clinical success (OR 2.46, 95% CI 1.47–4.11) and lower odds of adverse events (OR 0.38, 95% CI 0.26–0.57) and reintervention (OR 0.19, 95% CI 0.09–0.42). Technical success did not differ significantly between groups (OR 0.49, 95% CI 0.21–1.13). **Conclusions:** Compared with PTBD, EUS-BD is associated with improved clinical success and fewer adverse events and reinterventions after failed ERCP in malignant biliary obstruction. Where expertise is available, EUS-BD may be favored over PTBD. Prospective randomized trials are needed to confirm these findings and support broader adoption. Research Sponsor: None.

Pooled outcomes for EUS-BD vs PTBD.

Outcome/Metric	Comparison	Effect measure	Estimate (OR)	95% CI (lower)	95% CI (upper)	p-value	Direction/ Interpretation
Clinical success	EUS-BD vs PTBD	OR	2.46	1.47	4.11	0.1328	Favors EUS-BD (higher odds of success)
Adverse events	EUS-BD vs PTBD	OR	0.38	0.26	0.57	0.1923	Favors EUS-BD (lower odds of adverse events)
Reintervention	EUS-BD vs PTBD	OR	0.19	0.09	0.42	0.0003	Favors EUS-BD (lower odds of reintervention)
Technical success	EUS-BD vs PTBD	OR	0.49	0.21	1.13	0.3321	Not statistically significant

4188 **Poster Session**

Prevalence and prognostic value of Claudin 18.2 expression in pancreatic ductal adenocarcinoma. First Author: Kevin Zi Ming Lim, Department of Oncology, Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark

Background: Although Claudin18.2 expression (CLDN18.2) has been investigated in pancreatic ductal adenocarcinoma (PDAC), prevalence and prognostic significance remain inconsistent. This study evaluated both the prevalence and prognostic value of CLDN18.2 expression in PDAC. **Methods:** CLDN18.2 expression was assessed by IHC on FFPE tumor samples from 201 patients with PDAC enrolled in the BIOPAC study (NCT03311776) between Jan 2013-Feb 2024. Staining was performed using the Ventana CLDN18 (43) CE IVD Assay (Roche Diagnostic Solutions). All slides were independently scored by two pathologists, with discrepancies resolved by consensus. Positive expression was defined as moderate (+2) or strong (+3) staining in $\geq$75% of tumor cells. Patients with non-metastatic disease were excluded from the survival analysis to reduce prognostic confounding. OS and PFS were evaluated using Kaplan-Meier estimates, log-rank tests, and multivariable Cox models adjusted for stage, age, sex, chemotherapy type, diabetes, ECOG performance status, Body Mass Index, and Charlson Age-Adjusted Comorbidity Index. Associations with clinicopathological variables were evaluated using Mann-Whitney U, χ^2, or Fisher's exact tests with Bonferroni correction ($p < 0.05$ considered significant). **Results:** Of 201 patients, 56 had non-metastatic disease and 145 had metastatic disease. Positive CLDN18.2 expression was detected in 54 tumors (27% overall): 14 (25%) non-metastatic and 40 (28%) in metastatic cases. In patients with metastatic disease, the median OS was 9.9 months (95% CI, 6.7-12.8) in the CLDN18.2 positive group and 6.3 months (95% CI, 4.9-8.5) in the negative group, with a significant difference as demonstrated by log-rank test (p = 0.009). CLDN18.2 positivity was associated with improved OS in univariate analysis (HR = 0.60; 95% CI 0.41-0.89; p = 0.010) but was not statistically significant after adjustment for covariates (HR = 0.69; 95% CI 0.47-1.02; p = 0.064). A similar pattern was observed for PFS, with median PFS of 6.0 months (95% CI, 3.6-7.6) in the CLDN18.2 positive group and 4.1 months (95% CI, 3.4-5.3) in the negative group (log-rank p = 0.036). The unadjusted association between CLDN18.2 positivity and longer PFS (HR = 0.67; 95% CI 0.46-0.98; p = 0.037), was not maintained after multivariable adjustment (HR = 0.67; 95% CI 0.43-1.03; p = 0.066). No significant associations were identified between CLDN 18.2 expression and clinicopathological variables after correction for multiple testing. **Conclusions:** CLDN18.2 was expressed in 27% of PDAC tumors. While its association with OS and PFS was not statistically significant after adjustment for clinical covariates, its prevalence in metastatic cases highlights its potential relevance as a therapeutic target in PDAC. Ongoing validation in an expanded cohort may further clarify the prognostic and predictive significance of CLDN18.2 expression. Research Sponsor: Astellas Pharma Europe Ltd.

Multicenter phase 2 study of hydroxychloroquine (HCQ) and chlorphenesin carbamate (CPC) in combination with mFOLFIRINOX in patients with advanced pancreatic adenocarcinoma (PDAC). First Author: Hyehyun Jeong, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: PDAC is one of the most lethal malignancies, with most patients (pts) presenting with advanced disease. Although combination chemotherapy, including modified FOLFIRINOX (mFOLFIRINOX) has improved survival, overall prognosis remains poor. Our preclinical studies suggest that HCQ and CPC synergistically enhance the antitumor activity of mFOLFIRINOX by inhibiting autophagy-dependent and AKT-mediated epithelial-mesenchymal transition pathways. **Methods:** This multicenter, single-arm phase 2 study included pts with locally advanced unresectable or metastatic PDAC in the first-line setting from three academic institutions in Korea. HCQ (200 mg) and CPC (250 mg) were administered orally twice daily in combination with mFOLFIRINOX for up to 24 cycles or until disease progression or unacceptable toxicity occurred. The primary endpoint was safety profile. Secondary endpoints included objective response rate (ORR), progression-free survival (PFS), overall survival (OS), cumulative incidence of new distant metastases, and health-related quality of life (HRQOL). **Results:** Between December 2021 and February 2023, 45 pts were screened and a total of 40 patients received study treatment. The median age was 61 years, and 23 (57.5%) were male; 73% (n = 29) and 27% (n = 11) had metastatic and locally advanced disease, respectively. The median number of cycles patients received was 13 (range, 1-24). Dose reductions for HCQ and CPC occurred in four (10%) pts each, with median $>$ 90% of treatment compliance for both agents. Safety profiles are mostly consistent with known adverse events (AEs) with mFOLFIRINOX; grade 3-4 neutropenia (40%), nausea (13%), anemia (10%) were most common severe AEs. In the efficacy analysis set (n = 39), the ORR was 39% (CR or PR; n = 15), and the disease control rate was 92.3% (CR, PR or SD; n = 36). Curative-intent conversion surgery was performed in five pts (13%). With a median follow-up of 33.3 months, the median PFS was 7.4 months (95% CI, 6.2–13.3); in pts with objective response, median PFS was 13.6 months (95% CI, 7.4–33.8). The median OS was 14.8 months (95% CI, 9.6–27.9); median 20.5 months (95% CI, 14.8–NE) for locally advanced disease and median 13.9 months (95% CI, 9.2-NE) for metastatic disease. The cumulative incidence of new distant metastases was 38.8% at 12 months. HRQOL indicators did not deteriorate during the first 6 months of study treatment. **Conclusions:** HCQ and CPC in combination of mFOLFIRINOX were well tolerated and showed clinically promising efficacy outcomes in pts with advanced PDAC. Biomarker analysis using proteomics is ongoing. Clinical trial information: NCT05083780. Research Sponsor: Oncocross.

HRS-4642 combined with adebrelimab in previously treated patients with metastatic pancreatic ductal adenocarcinoma. First Author: Xianjun Yu, Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Nearly 90% pancreatic ductal adenocarcinoma (PDAC) tumors were driven by RAS mutations, including KRAS G12D (~40%). The high prevalence of KRAS G12D mutations is thought to play a vital role in the universally immunosuppressive tumor microenvironment of PDAC. HRS-4642 is a highly selective KRAS G12D inhibitor. Here, we report preliminary results of HRS-4642 combined with adebrelimab (an anti-PD-L1 antibody) in patients (pts) with KRAS G12D-mutant PDAC. **Methods:** The study comprised two parts. Phase 1 (Dose escalation): A "3+3" design was used to determine the recommended phase 2 dose (RP2D) of HRS-4642 (4 dose levels: 300, 400, 500mg, qw; and 500mg D1/1200mg D8, q3w) combined with fixed-dose adebrelimab (1200mg iv, Day 1, q3w). Phase 2 (Dose expansion): Simon's two-stage optimal design was applied, requiring at least five objective responses. The primary endpoints were safety and RP2D (phase 1), and objective response rate (ORR; phase 2). The key secondary endpoints included progression-free survival (PFS), overall survival (OS), and disease control rate (DCR). **Results:** As of Dec 31, 2025, 48 pts were enrolled, with 87.5% having received $\geq$2 prior lines of therapy. No dose-limiting toxicity (DLT) occurred during phase 1, and the RP2D was determined as HRS-4642 (500mg D1/1200mg D8, q3w) with adebrelimab. Treatment-related adverse events (TRAEs) occurred in 47 pts (97.9%). The most common grade 3/4 TRAEs included lipase increased (16.7%), gamma-glutamyl transpeptidase increased (12.5%), and blood cholesterol increased (8.3%). No treatment related deaths occurred. Among 43 pts with post-baseline tumor assessment, the confirmed ORR was 41.9% and DCR was 83.7%, with a median mPFS of 5.6 months; the median mOS was not reached. Notably, the RP2D group (n=33) achieved a confirmed ORR of 48.5% and a DCR of 90.9%, successfully meeting the primary endpoint. **Conclusions:** HRS-4642 combined with adebrelimab showed a manageable safety profile and promising anti-tumor activity in metastatic PDAC harboring KRAS G12D mutation. Clinical trial information: NCT06427239. Research Sponsor: None.

SHR-A2102, a Nectin-4 targeted antibody-drug conjugate, combined with HRS-4642 in previously treated pancreatic ductal adenocarcinoma harboring KRAS G12D mutation. First Author: Jin Xu, Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Patients (pts) with previously treated advanced pancreatic ductal adenocarcinoma (PDAC) have limited options. The high prevalence of Nectin-4 expression (~71%) and KRAS G12D mutations in PDAC provides a rationale for dual targeting. Here we report results from a molecularly defined cohort in a phase 2 platform trial evaluating the combination of SHR-A2102 and HRS-4642, a KRAS G12D inhibitor. **Methods:** Eligible pts with Nectin-4 expression and KRAS G12D mutation who had failed standard therapy were enrolled. During the safety run-in, 2 dose levels of SHR-A2102 were evaluated in combination with HRS-4642 (500mg Day 1/1200mg Day 8, iv, q3w) to determine the recommended expansion dose (RED). The Bayesian Optimal Phase II (BOP2) design was applied for efficacy expansion, with a planned enrollment of 10 to 30 pts. The primary endpoints were safety and RED (safety run-in), and objective response rate (ORR; efficacy expansion). The key secondary endpoints included progression-free survival (PFS), overall survival (OS), duration of response (DoR), and disease control rate (DCR). **Results:** As of Dec. 31, 2025, 36 pts were enrolled and treated (median age, 61 years; ECOG PS 1, 86.1%; $\geq$2 lines of prior therapy, 88.9%; median Nectin-4 H-score, 10). No dose-limiting toxicity (DLT) occurred, and the RED was established as SHR-A2102 (8mg/kg iv, q3w) plus HRS-4642. Treatment-related adverse events (TRAEs) occurred in all pts (100%), with no grade 5 TRAEs. 13 pts (36.1%) experienced grade 3/4 TRAEs, the most common including neutrophil count decreased and gamma-glutamyl transpeptidase increased (each 11.1%), and anemia (8.3%). In the RED group (n=30), the confirmed ORR was 36.7% (11PR) and the DCR was 86.7%, meeting the primary endpoint. ORR showed no apparent correlation with Nectin-4 H-score. The median DoR was 6.3 months (range: 4.4-NR); the median PFS was 4.1 months (range: 2.7-5.7), and the median OS was not reached. **Conclusions:** SHR-A2102 combined with HRS-4642 showed a tolerable safety profile and promising preliminary anti-tumor activity in advanced PDAC harboring KRAS G12D mutation, irrespective of Nectin-4 expression. Clinical trial information: NCT06547736. Research Sponsor: None.

Spevatamig (PT886), a claudin 18.2 (CLDN18.2)/CD47 bispecific antibody, in combination with gemcitabine plus nab-paclitaxel (GnP) in frontline (1L) treatment of metastatic pancreatic ductal adenocarcinoma (mPDAC). First Author: Anwaar Saeed, University of Pittsburgh Medical Center (UPMC) and UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Spevatamig is an IgG1-based bispecific antibody targeting CLDN18.2 and CD47 with an optimized anti-CD47 arm designed to bind to CD47 more highly on cancer cells than on human red blood cells. We have previously described its monotherapy safety data and preliminary combination efficacy data in 1L mPDAC (Saeed et al., J Clin Oncol. 2026). Herein, we provide updated data from patients in the 1L mPDAC cohort, including additional efficacy data from the 2 mg/kg QW spevatamig + GnP dose level and new safety data from the 3 mg/kg QW spevatamig + GnP dose level. **Methods:** TWINPEAK is a multi-cohort Phase 1/2 dose escalation and expansion study (US: NCT05482893; China: CTR20252758) of spevatamig as monotherapy or combination therapy (with chemotherapy and/or an immune-checkpoint inhibitor) in patients with select gastrointestinal (GI) cancers. Here we report data from the Phase 2 cohort of spevatamig + GnP in 1L mPDAC at 2 dose levels: 2 mg/kg QW (N=22) and 3 mg/kg QW (N=22). Key endpoints include safety and tolerability, objective response rate (ORR), disease control rate (DCR), median progression-free survival (mPFS) and median overall survival (mOS). **Results:** As of January 15, 2026, 151 patients have been treated with spevatamig collectively in monotherapy and combination settings. In the 2 mg/kg QW spevatamig + GnP dose level (N=22), spevatamig continues to demonstrate tolerability when combined with chemotherapy, with cytopenia rates not exceeding those anticipated with GnP and no grade $\geq$ 3 nausea or vomiting events. The ORR is 48%, DCR is 90%, mPFS is 7.3 months (95% confidence interval: 5.6 months - not yet reached) and mOS is $>$ 13 months (still maturing), with a median follow-up duration of 8.9 months. Antitumor activity was demonstrated irrespective of tumor CLDN18.2 expression levels and RAS mutational status. In the 3 mg/kg QW spevatamig + GnP dose level (N=22), no significant additive toxicity was noted when compared to the adverse event profile anticipated with GnP alone among patients with available safety data. No grade $\geq$ 3 nausea or vomiting events occurred. Updated safety data will be provided at the meeting for patients in this dose level. **Conclusions:** Overall, spevatamig 2 mg/kg QW or 3 mg/kg QW + GnP is well tolerated, with no significant additive toxicity compared to the adverse event profile anticipated with GnP alone. The additional efficacy data from patients treated at the 2 mg/kg QW spevatamig + GnP dose level continues to demonstrate promise when compared to pivotal trials of GnP in 1L mPDAC; enrollment into the 3 mg/kg QW spevatamig + GnP dose level is ongoing with maturing efficacy data. These two dose levels exhibit good combinability with chemotherapy and can be assessed in future combination studies with novel targeted therapies such as KRAS inhibitors. Clinical trial information: NCT05482893. Research Sponsor: None.

4193 **Poster Session**

Safety and efficacy of nesuparib (JPI-547) with gemcitabine-nab-paclitaxel (GemAbraxane) or modified FOLFIRINOX (mFOLFIRINOX) in patients with locally advanced or metastatic PDAC: Results from an ongoing phase Ib/II study. First Author: Hye Jin Choi, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies with poor outcomes in advanced disease. Nesuparib is a dual tankyrase (TNKS) and poly(ADP-ribose) polymerase (PARP) inhibitor that induces a "BRCAness" phenotype via WNT and Hippo signaling. This Phase Ib study evaluated the safety, tolerability, and preliminary antitumor activity of nesuparib combined with standard first-line chemotherapy in patients with locally advanced or metastatic PDAC. **Methods:** This multicenter, open-label, Phase Ib dose-finding study evaluated oral nesuparib plus GemAbraxane or mFOLFIRINOX in advanced PDAC. Nesuparib was administered orally using a 3+3 dose-escalation design with intermittent schedules, including DL1 (25 mg, 5 days on/2 days off), DL-1 (12.5 mg, 5 days on/2 days off), and DL-2 (12.5 mg, 3 days on/4 days off). Primary objectives were to assess safety and determine the maximum tolerated dose and recommended Phase II dose. Secondary objectives included preliminary efficacy. **Results:** As of December 31, 2025, 27 patients were enrolled and treated (GemAbraxane, n = 14; mFOLFIRINOX, n = 13). Most patients had metastatic disease. In the GemAbraxane arm, acceptable tolerability was confirmed at DL-1 and DL-2, whereas tolerability was not established in the mFOLFIRINOX arm. Across both treatment arms, grade 3/4 AEs were mainly hematologic toxicities. Rates of anemia, thrombocytopenia, and neutropenia were 57.1%, 64.3%, and 92.9% in the GemAbraxane arm, compared with 84.6%, 92.3%, and 84.6% in the mFOLFIRINOX arm, respectively. No treatment-related deaths occurred, and most AEs were manageable with standard supportive measures. Non-hematologic AEs were mostly low-grade and manageable. In the GemAbraxane arm, the objective response rate (ORR) and disease control rate (DCR) were 53.8% and 92.3%, respectively, including one patient with a complete response (CR) of the target lesion and overall survival exceeding 3 years. Median progression-free survival (mPFS) was not reached, and median overall survival (mOS) was 14.2 months (data immature and follow-up is ongoing). In the mFOLFIRINOX arm, the ORR was 38.5% with a DCR of 92.3%, while mPFS and mOS were 7.33 and 18.5 months, respectively. **Conclusions:** Nesuparib combined with GemAbraxane demonstrated acceptable tolerability and encouraging antitumor activity in advanced PDAC. These findings support further evaluation of nesuparib using a 12.5 mg intermittent dosing schedule in the first-line treatment setting; a Phase II trial is currently ongoing. Clinical trial information: NCT05257993. Research Sponsor: None.

Outcome	Nesuparib + GemAbraxane (n=13)	Nesuparib + FOLFIRINOX (n=13)
PR	7 (53.8%)	5 (38.5%)
SD	5 (38.5%)	7 (53.8%)
PD	1 (7.7%)	1 (7.7%)
ORR	53.8%	38.5%
DCR	92.3%	92.3%
mOS	14.20 mo (data immature)	18.50 mo
mPFS	Not reached	7.33 mo

MUC5AC-driven transcriptional reprogramming for stratification of pancreatic ductal adenocarcinoma by immune suppression and stromal remodeling. First Author: Yonghua Laura Bao, The Ohio State University, Columbus, OH

Background: Mucin 5AC (MUC5AC) is aberrantly expressed in pancreatic ductal adenocarcinoma (PDAC) and associated with tumor progression; however, its role in altering the tumor immune microenvironment (TIME) and immunotherapy-relevant pathways is poorly understood. Thus, we evaluated whether MUC5AC expression delineates PDAC into distinct transcriptional and immunologic subtypes based on TIME. **Methods:** Bulk RNA-seq data from 730 PDAC tumors (Oncology Research Information Exchange Network, ORIEN) and 360 normal pancreatic tissues (GTEx) were analyzed. Differential gene expression and pathway enrichment were assessed using Gene Ontology and KEGG analyses. Immune infiltration and stromal states were inferred using multiple complementary deconvolution algorithms (CIBERSORT and xCell). Tumors in the lowest quartile of MUC5AC expression ($\leq$25th percentile; MUC5AC-low, MUC5AC-L) were compared with the remaining samples (MUC5AC-high, MUC5AC-H). Associations between MUC5AC expression and immune cell populations and immunomodulatory genes were evaluated by using correlations and group-based analyses with false discovery rate (FDR) corrections. **Results:** Principal component analysis demonstrated clear separation between PDAC tumors and normal pancreas and revealed distinct transcriptional programs between MUC5AC-H (N = 544) and MUC5AC-L (N = 186) tumors. MUC5AC-H tumors exhibited a profoundly immunosuppressive and stromal-remodeled TIME, including enrichment of M2 macrophages, regulatory T cells, activated natural killer ells, fibroblast-associated signatures, and significantly higher immune and stromal scores (multiple FDR $\leq 10^{-6}$ to $\leq 10^{-28}$). In contrast, MUC5AC-L tumors showed relatively enrichment of immune-activating populations, including naïve B cells, dendritic cell subsets, resting $CD4^+$ memory T cells, and $CD8^+$ T cells (multiple FDR $< 10^{-15}$). MUC5AC expression strongly correlated with immune checkpoint genes *CD274* (PD-L1) and *TIGIT*, and with multiple suppressive immune populations ($p < 0.01$ to $< 10^{-10}$). **Conclusions:** MUC5AC defines a transcriptionally distinct, immunosuppressive PDAC subtype characterized by stromal activation, macrophage/Treg enrichment, and immune checkpoint engagement. MUC5AC may serve as a biomarker for immune stratification and supports rational combination strategies integrating stromal targeting with immune checkpoint modulation in PDAC. Research Sponsor: ORIEN Foundation.

First-line NALIRIFOX in patients with metastatic pancreatic ductal adenocarcinoma and pre-existing diabetes: NAPOLI 3 post hoc analysis. First Author: Sreenivasa R. Chandana, START Midwest, Grand Rapids, MI

Background: Approximately 29% of patients with metastatic pancreatic ductal adenocarcinoma (mPDAC) present with pre-existing diabetes. Diabetes increases the risk of peripheral neuropathy (PN), raising concerns that oxaliplatin-containing regimens may exacerbate PN risk. NALIRIFOX (liposomal irinotecan, oxaliplatin, leucovorin and 5-fluorouracil) is approved for first-line (1L) treatment of mPDAC based on significantly improved overall survival versus nab-paclitaxel plus gemcitabine (Gem+NabP) in the phase 3 NAPOLI 3 trial (hazard ratio 0.83; 95% confidence interval [CI] 0.70–0.99). The overall response rate (ORR) for NALIRIFOX was 41.8% (95% CI: 36.8–46.9%) and no unexpected safety concerns were identified. This *post hoc* exploratory analysis of NAPOLI 3 evaluates outcomes including PN development among patients with pre-existing diabetes. **Methods:** Patients randomized to 1L NALIRIFOX in NAPOLI 3 who had pre-existing diabetes were assessed, with subgroups according to whether or not they developed PN. The primary endpoint was ORR; patient characteristics and adverse event rates were also described. No hypotheses were tested owing to small sample sizes; results are descriptive. **Results:** Of 383 patients randomized to receive NALIRIFOX in NAPOLI 3, 96 (25%) had pre-existing diabetes, of whom 94 were included in the safety population. PN developed in 13/94 (14%) patients (Grade ≥3: 2/13 [15%]) with pre-existing diabetes, none of whom had evidence of PN at baseline. Among patients without diabetes, PN developed in 53/276 (19%; Grade ≥3: 10/53 [19%]). Patients with pre-existing diabetes who developed PN had a lower median age, lower proportion of males, higher metastatic burden, and higher frequency of tumors in the body of the pancreas than patients who did not develop PN (Table). Among patients with pre-existing diabetes, ORR for NALIRIFOX was 43.8% (42/96 [95% CI: 33.6–54.3%]); all responses were partial. ORR was 69.2% (9/13 [95% CI: 38.6–90.9%]) among patients with pre-existing diabetes who developed treatment-emergent PN and 40.7% (33/81[95% CI: 29.9–52.2%]) among those who did not (Table). **Conclusions:** In this exploratory analysis, PN incidence and clinical outcomes in patients with pre-existing diabetes were consistent with those without diabetes and with the overall NALIRIFOX population. In this small population, pre-existing diabetes did not appear to put patients at risk of developing treatment-emergent PN or to impact treatment outcomes. Clinical trial information: NCT04083235. Research Sponsor: Ipsen.

Precision Promise (PrP): Success rates of paired biopsies and biomarker testing results for metastatic pancreatic cancer (mPDAC) in a multi-center trial. First Author: Eric Andrew Collisson, Fred Hutch Cancer Center, Seattle, WA

Background: PrP, a phase 2/3 Bayesian adaptive platform trial sponsored by the Pancreatic Cancer Action Network, was developed to test multiple experimental arms efficiently against common controls and explore biomarkers of response/resistance in mPDAC (Picozzi, ASCO TPS 4188, 2022). **Methods:** At screening, core tissue biopsies and matched blood collection were performed for first- and second-line patients (pts) with mPDAC. Week 8 (W8) core tissue biopsies and blood collection were performed for pts receiving study drug. Formalin-fixed paraffin embedded (FFPE) tissue slides were prepared at the central lab; tissue and matched blood samples were analyzed for genomic and transcriptomic analyses using Tempus xT (DNA) and xR (RNA) testing, respectively. The workflow prioritized DNA followed by RNA isolation. **Results:** Tissue biopsies were obtained at screening from 491 of 700 (70%) pts across 24 US sites; W8 tissue biopsies were obtained from 228 of 443 (51%) pts receiving study drug. Reasons for biopsies not being collected included: contraindicated; attempted, but no tissue obtained; pt screened out; pt stopped study drug before W8 (W8 only). 21% (103/491) screening and 32% (74/228) W8 biopsies submitted for biomarker testing contained insufficient tumor tissue for testing; 4% (20 pts) of screening and 4% (10 pts) of W8 biopsies were not processed into FFPE or testing was cancelled. Of the 368 pts with screening tissue sequenced, genomic data were generated for 83% (304 pts); 17% (64 pts) had Quantity Not Sufficient (QNS) for DNA. Transcriptomic data were generated for 49% (179 pts); in 42% (155 pts) insufficient tumor tissue remained for RNA testing and 9% (34 pts) had QNS for RNA. Of the 144 pts with W8 tissue sequenced, genomic data were generated for 71% (102 pts); 29% (42 pts) had QNS for DNA. Transcriptomic data were generated for 31% (44 pts); in 58% (84 pts) insufficient tumor tissue remained for RNA testing and 11% (16 pts) had QNS for RNA. Locations of tissue biopsies across both timepoints (719) were: 68% liver, 16% pancreas, 16% other metastatic sites. Success rates for biomarker testing across all tissue obtained was higher for liver metastases (65% DNA results; 37% RNA results) than for primary tumors in the pancreas (42% DNA results; 19% RNA results). Distribution of actionable biomarkers detected will be presented. **Conclusions:** These data demonstrate success rates of paired biopsy acquisition and subsequent genomic and transcriptomic analysis in a large phase 2/3 multi-center platform trial for mPDAC. Attrition was noted for biopsy collection and downstream biomarker testing at screening and more so at W8 on study drug. Biomarker testing success rates varied by tissue location. These findings along with planned data interrogation and future sample analyses will provide insights to guide future trial design and clinical decision making. Clinical trial information: NCT04229004. Research Sponsor: Pancreatic Cancer Action Network.

LAP-NET1: Results of a phase 1b evaluating NP137, an inhibitor of the epithelial-to-mesenchymal transition, in combination with mFOLFIRINOX for the first-line treatment of locally advanced pancreatic ductal adenocarcinoma. First Author: Gael Roth, Department of Hepatogastroenterology, University Hospital of Grenoble, Grenoble, France

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal malignancy characterized by aggressive tumor dissemination and resistance to therapy; processes significantly driven by the epithelial-to-mesenchymal transition (EMT). Netrin-1 is a key regulator for EMT. NP137, an anti-netrin-1 antibody, has shown to inhibit EMT in preclinical models and in a phase 1 monotherapy trial. **Methods:** LAPNET-01 (NCT06203821) is a single arm phase Ib clinical study to assess the combination of NP137 with mFOLFIRINOX in naive locally advanced unresectable PDAC. A safety lead-in (3–12 pts, 3+3 design, NP137 14 vs 9 mg/kg) was followed by a 40-patient expansion. Treatment consisted of NP137 + mFOLFIRINOX every 2 weeks, up to 12 cycles. The primary endpoint was safety at 6 months (all-grade and grade 3/4 adverse events [AEs], CTCAE v5.0). Secondary endpoints included objective response rate (ORR), progression-free survival (PFS) and overall survival (OS), surgical conversion rate and exploratory transcriptomic analyses. Laser capture microdissection was performed on 22 pre-treatment and 6 surgery samples to allow microbulk RNA sequencing. Immunohistochemistry was also performed on pre-treatment samples. **Results:** A total of 43 patients were enrolled in this trial. NP137 was well tolerated. AE occurred in 100% of patients (58% grade ≥ 3). ORR and disease control rate were 29% and 95%. Median PFS was 10.9 months (95% CI, 10.0 – 15.6) and median OS was 16.4 months (95% CI, 12.8 – NR) with 21 patients still alive at time of the data cut-off. Surgery was made possible in 23% of patients. Microbulk RNA sequencing revealed that the main pathway downregulated with the combination mFOLFIRINOX+NP137 is EMT, bringing a clinical validation of the main mechanism of action of NP137. Moreover, patients with tumors expressing high levels of the netrin-1 receptor neogenin (high-NEO1) at baseline (both at the RNA and proteic level (IHC)) demonstrated an improved outcomes compared to the low-NEO1 subgroup including longer median PFS (15.7 vs 10.2 months, p = 0.01) and longer median OS (not reached vs 16.5, p = 0.024). These results are consistent with experimental data demonstrating the implication of NEO1 in PDAC EMT and its progression. **Conclusions:** NP137 in combination with mFOLFIRINOX demonstrates a favorable safety profile, promising clinical activity and a mechanistically distinct mode of action supported by translational analyses. These results warrant further investigation of netrin-1 blockade in randomized trials and provide a rationale for biomarker-driven development of NP137 in PDAC. Further work is ongoing to better characterize the distribution of NEO1 in first-line unresectable PDAC. Clinical trial information: NCT06203821. Research Sponsor: NETRIS Pharma; CHU Grenoble Alpes.

Surufatinib plus KN046 and chemotherapy as first-line treatment for advanced pancreatic ductal adenocarcinoma: Updated results and biomarker analysis from a phase 1b/2 trial. First Author: Wen-Quan Wang, Department of Pancreatic Surgery, Zhongshan Hospital, Fudan University, Shanghai, China

Background: In China, gemcitabine (G) and nab-paclitaxel (nP) remain the standard first-line (1L) therapy for patients (pts) with advanced pancreatic ductal adenocarcinoma (PDAC). Our previous report (Wang W, et al; 2025 ASCO) showed that the add-on of surufatinib (S, multi-kinase inhibitor) and KN046 (K, bi-specific PD-L1/CTLA-4 antibody) to GnP chemotherapy provided enhanced anti-tumor activity in advanced PDAC. Here we present the updated results and findings from a biomarker analysis. **Methods:** In this single-arm, phase 1b/2 trial (NCT05832892), eligible pts with treatment-naïve advanced PDAC received oral S (200~250 mg, once daily), intravenous K (5 mg/kg, on day 1) and GnP (G 1000 mg/m^2, nP 125 mg/m^2, on days 1 & 8) at 21-day cycles till disease progression or intolerable toxicity. The primary efficacy endpoint was ORR per RECIST 1.1; secondary endpoints included DCR, PFS, OS and safety; efficacy-predictive biomarkers were exploratory endpoints. **Results:** Overall, 31 pts were enrolled with a median age of 56 years (range 40–74) and a predominant male gender (74.2%). Distant metastasis was present in 28 (90.3%) pts and 24 (77.4%) had liver metastasis (LM) at baseline. Best overall responses included 4 CR, 18 PR, and 6 SD. The ORR was 71.0% (95% CI 52.0–85.8) and DCR was 90.3% (95% CI 74.2–98.0). As of Dec 25, 2025, with a median follow-up of 15.9 months, median PFS was 8.2 months (95% CI 6.1–not estimable [NE]). Median OS was 18.0 months (95% CI 13.8–NE) with a 12-month OS rate of 68.2% (95% CI 50.8–91.6). Baseline LM was correlated to significantly worse PFS (8.0 vs NE months, log-rank *P*= 0.02), though no significant impact on ORR (73.9% vs 62.5%, *P*= 0.66), DCR (91.3% vs 87.5%, *P*= 1.00) or OS (13.8 vs NE, log-rank *P*= 0.12) was observed. Among the 27 pts who received ≥4 cycles of treatment, 22 (81.5%) and 19 (70.4%) experienced a decline in CA199 and CA125 from baseline, respectively, while fewer (37.0%) had CEA declined. A ≥50% decline in CA199 was correlated to significantly improved PFS (10.3 vs 8.1 months, log-rank *P*= 0.01) and a trend towards improved OS (NE vs 11.1 months, log-rank *P*= 0.11), as compared to a milder decrease or increase in CA199; Such correlation was not observed for CA125 or CEA. Treatment-related adverse events (TRAEs) occurred in 29 (93.5%) pts, of whom 14 (45.2%) experienced Grade ≥3 events, with hypertension (12.9%), neutropenia (12.9%), and thrombocytopenia (9.7%) being the most frequently observed. No treatment-related serious adverse events or deaths occurred. **Conclusions:** S plus K and GnP demonstrated consistently encouraging efficacy and manageable safety in 1L treatment of advanced PDAC. Early and sharp decline in CA199 may predict more favorable survival benefit. Analyses in genetic profile and its impact on clinical outcome will be carried out in future, and investigations in larger population are warranted. Clinical trial information: NCT05832892. Research Sponsor: HUTCHMED, ALPHAMAB.

Precemtabart tocentecan (Precem-TcT, M9140), an anti-CEACAM5 antibody-drug conjugate (ADC), in patients with metastatic pancreatic ductal carcinoma (mPDAC): Results from the phase 1b/2 PROCEADE-PanTumor PDAC substudy. First Author: Zev A. Wainberg, Department of Medicine, University of California, Los Angeles, Medical Center, Los Angeles, CA

Background: CEACAM5 is overexpressed in many cancers, including PDAC, with limited expression in normal tissues. Precem-TcT, an anti-CEACAM5 ADC with an exatecan payload (topoisomerase 1 inhibitor [TOP1i]), showed a predictable, manageable safety profile and promising clinical activity (ORR: 31.0%; mPFS: 6.9 months) in the Phase 1 PROCEADE-CRC-01 study (NCT05464030) in patients with heavily pretreated metastatic colorectal cancer (mCRC). **Methods:** PROCEADE-PanTumor (NCT06710132) is an ongoing, Phase 1b/2, open-label study investigating the efficacy and safety of Precem-TcT monotherapy in advanced PDAC, gastric cancer, and non-small cell lung cancer. Here, we report interim results from the PDAC substudy, which enrolled patients with pretreated mPDAC (ECOG PS $\leq$1; and CEACAM5^{high} expression [$\geq$50% tumor cells with immunohistochemistry $\geq$2+ staining]) in the US, Australia, France, Japan, and Korea, who were treated with Precem-TcT 2.8 mg/kg Q3W. **Results:** Between May and September 2025, 46 patients have been enrolled into the study (median age: 62.0 years; female: 65.2%; ECOG PS 0/1: 47.8%/52.2%). Most patients received one or two prior lines of therapy, and were irinotecan pretreated. As of November 2025, median duration of Precem-TcT treatment was 12.6 weeks. Treatment emergent adverse events (TEAEs) occurred in 95.7% of patients; grade $\geq$3: 78.3%. Most common grade $\geq$3 TEAEs were neutropenia (43.5%) and anemia (32.6%). Gastrointestinal TEAEs were mostly grade 1-2, and there were no cases of interstitial lung disease or ocular toxicities. TEAEs led to dose reductions in 15.2% and to permanent discontinuation in 4.3% of patients. There were no treatment-related deaths. As of January 2026, 10 patients had a PR (21.7%), 20 SD (43.5%), and 11 PD (23.9%); 14 patients remain on study. Updated data, including mPFS and CEACAM5 expression, will be presented at the congress. Preliminary pharmacokinetics of the conjugated antibody and unconjugated exatecan appeared generally consistent with previous data from patients with mCRC. **Conclusions:** Precem-TcT, the first anti-CEACAM5 ADC with a TOP1i-payload reporting clinical data in patients with mPDAC, showed a predictable safety profile in this population, consistent with data from patients with mCRC. Efficacy data in this highly refractory, mostly irinotecan-pretreated 2L/3L population benchmark favorably with the current SoC for 2L mPDAC. Clinical trial information: NCT06710132. Research Sponsor: The healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Phase Ib/II clinical study of adebrelimab combined with decitabine, nab-paclitaxel, and gemcitabine as first-line (IL) treatment for metastatic pancreatic cancer (mPC). First Author: Rui Liu, Department of Gastrointestinal Medical Oncology, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Background: Epigenetic enzyme inhibitors may synergize with immunotherapy by modulating antigen presentation and enhancing tumor-related gene expression. Preclinical studies suggest that low-dose decitabine can restore chemosensitivity in chemotherapy-resistant tumors. We conducted the Ib/II study to explore the efficacy and safety of decitabine combined with adebrelimab, nab-paclitaxel, and gemcitabine as 1L treatment for mPC. **Methods:** Eligible patients (pts) were prior untreated mPC or pts who had experienced disease progression more than six months after the end of postoperative adjuvant therapy. In the phase Ib, enrolled pts received dose escalation of decitabine (10 mg/m²/15 mg/m²,iv,d1-d3,q4w), adebrelimab (1200mg,iv,d1,q3w) , nab-paclitaxel (125 mg/m^2, iv,d1,d8,d15,q4w), and gemcitabine (1000 mg/m^2,iv,d1,d8,d15,q4w) to determine the recommended phase 2 dose (RP2D) in a standard 3+3 design. In the phase II, pts received decitabine at the RP2D, adebrelimab, nab-paclitaxel and gemcitabine combination therapy. Primary endpoints were dose-limiting toxicities, RP2D, and objective response rate (ORR). Secondary endpoints included overall survival, progression free survival, disease control rate (DCR), duration of response, and safety. **Results:** From April 2024 to February 2025, 28 pts were enrolled and the median age was 62 yrs; 69.2% male, and 80.8% ECOG PS 1. The Ib phase established the RP2D of decitabine as 10 mg/m². Total of 22 pts were included in the efficacy analysis. The median follow-up was 11.9 mo. The ORR was 46% (10PR, 9SD, 3PD) and DCR was 86.4%. Median duration of response (mDoR) was 10.94 months, while the median progression-free survival (mPFS) was 6.47 months. 24 pts were analyzed for safety. The most common TRAEs of any grade were anemia (95.8%), lymphocyte count decreased (79.2%), hypoalbuminemia (75.0%), hyponatremia (75.0%), vomiting (66.7%). Grade $\geq$3 TRAEs were were anemia (25.0%), white blood cell decreased (20.8%), platelet count decreased (20.8%), lymphocyte count decreased (12.5%), neutrophil count decreased (12.5%). No new safety signals were observed. **Conclusions:** This study preliminarily demonstrates that the decitabine combination regimen has favorable efficacy and safety in 1L treatment of mPC. Future clinical studies with larger sample sizes are needed to be validated. Clinical trial information: NCT06454448. Research Sponsor: Tianjin Science and Technology Commission key project; 25JCLZJC00360.

BXCL701 plus pembrolizumab in second-line advanced pancreatic ductal adenocarcinoma: Final outcomes of the EXPEL PANC trial. First Author: Benjamin Adam Weinberg, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Background: Pancreatic ductal adenocarcinoma (PDAC) is resistant to immune checkpoint inhibitors, in part due to a cold tumor immune microenvironment (TME). BXCL701 ('701) is a small molecule inhibitor of dipeptidyl peptidases 4, 8, 9 and fibroblast activation protein. We have shown that combinations of '701 and anti-PD1 antibodies lead to tumor regression in murine PDAC models due to 1) activation of the inflammasome and expression of CXCL9 to attract and activate CXCR3+ lymphocytes, 2) tumor invasion of CD8+ T cells and other effector cells, 3) induction of adaptive immunity, and 4) reduced fibrosis in the PDAC TME. We sought to evaluate the efficacy of this combination in patients (pts) with previously-treated advanced PDAC. **Methods:** In this phase II clinical trial (NCT05558982), pts with second-line advanced PDAC received '701 at a 0.2 mg PO BID dose on days 1-7 and then 0.3 mg BID on days 8-14 during cycle 1 (21 days) followed by 0.3 mg BID on days 1-14 every 21 days in all subsequent cycles, administered with pembrolizumab 200 mg IV every 21 days (all cycles). The primary objective was to determine the 18-week progression-free survival rate ($PFS_{18weeks}$) in pts with advanced PDAC treated in the second-line setting. We estimated that the historical second-line $PFS_{18weeks}$ is 30% or less; using a Simon's two-stage (minimax) design, a type I error rate of 0.05 and a power of 80%, if the true rate is 50%, we would need 19 pts in stage 1 and 20 pts in stage 2 (a total of 39 evaluable). Seven of 19 evaluable pts would need to be progression-free at 18 weeks to trigger stage 2. **Results:** Twenty-one pts were enrolled. Four out of 18 evaluable pts (22%) were alive and progression-free at 18 weeks. Three had partial responses (PR, 17%), and 4 had stable disease (SD, 22%), for a disease control rate of 39%. One responder had MSI-H PDAC, while the other 2 had MSS disease. Median follow-up was 4.5 months. Median PFS was 2.3 months (95% CI 1.6 – 5.3), and median overall survival was not reached (NR, 95% CI 4.5 – NR). Three pts (14%) had PFS exceeding 6 months (2 PR, 1 SD). No new safety signals have been identified. Baseline and on-treatment tumor biopsies will be analyzed to understand the mechanisms underlying therapeutic benefit and to examine the characteristics of responders vs. non-responders. **Conclusions:** '701 plus pembrolizumab in second-line advanced PDAC did not reach the preliminary efficacy endpoint to trigger the second stage. However, there were encouraging signs as this combination induced objective responses in 2 MSS pts, and PFS exceeded 6 months in 3 pts. Ongoing correlative studies should elucidate predictive markers of efficacy and resistance to this novel immunotherapy combination. Clinical trial information: NCT05558982. Research Sponsor: BioXcel Therapeutics; Merck; Ruesch Center for the Cure of Gastrointestinal Cancers.

4202 **Poster Session**

Proglumide, gemcitabine (GEM), and nab-paclitaxel (NAB-P) in patients (pts) with pancreatic ductal adenocarcinoma (PDAC): Results of the phase 1 PROGEM trial. First Author: Jill P. Smith, Georgetown University, Department of Medicine, Washington, DC

Background: PDAC has a poor prognosis and resistance to therapy due to its desmoplastic and immunosuppressive tumor microenvironment (TME). In animal models of PDAC, the cholecystokinin-B receptor (CCK-BR) antagonist, proglumide, was shown to decrease tumoral fibrosis, alter the tumor immune cell signature, and increase chemotherapy uptake and T-cell infiltration into tumors, resulting in decreased metastases and improved survival. We sought to evaluate the safety of proglumide with GEM/NAB-P chemotherapy in pts with metastatic PDAC (mPDAC). Using tumor biopsies and a blood biomarker assay, we also studied the combined effects of proglumide with GEM/NAB-P on the TME. **Methods:** The PROGEM study was a phase 1 trial of proglumide 1200 mg PO daily, GEM 1000 mg/m2 IV, and NAB-P 125 mg/m2 IV days 1, 8, and 15 every 28 days in GEM-naive pts with mPDAC (NCT05827055). The primary endpoints were safety and determination of the recommended phase 2 dose (RP2D). Safety was assessed with adverse events (AEs) according to CTCAE v. 5 criteria. Tumor biopsies were obtained pre-treatment and at 8 weeks on-treatment and analyzed by histology and multiplex immunohistochemistry for changes in the TME. A liquid biopsy serum sample was collected at baseline, week 8, and end-of-treatment (EOT) for analysis of a microRNA biomarker panel reflecting changes in the TME. McGill pain surveys were done at baseline, week 8, and at EOT. **Results:** Six pts were enrolled. Three pts were treatment-naïve, and 3 had had prior mFOLFIRINOX. No AEs related to proglumide were reported. Five pts had stable disease, and 1 pt had disease progression as the best response, for a disease control rate of 83%. Median progression-free survival was 4 months, and median overall survival was 8.5 months. Compared to baseline, on-treatment biopsies showed an 81% decrease in Ki67+ cells; a 75% decrease in M2-polarized tumor-associated macrophages; a 42% decrease in tumor collagen content, and a 13-fold increase in CD8 T-cells. Pre- and on-treatment blood biomarkers showed changes correlated with histology and clinical course. Anti-fibrosis markers (miR185, miR346, and miR378) and inhibitors of epithelial to mesenchymal transition (miR200 and miR205) increased with therapy. MiR122, which regulates cell cycle and growth, decreased initially but increased at the time of progression. Pain scores showed improved pain at week 24 or EOT. **Conclusions:** Proglumide is safe in pts with mPDAC, and the RP2D is 1200 mg PO daily with standard dose GEM/NAB-P. Proglumide remodels the TME by decreasing fibrosis and immunosuppression while increasing T-cell infiltration. Changes in circulating microRNAs offer a promising non-invasive biomarker panel for monitoring treatment response. These results support further investigation of proglumide with GEM/NAB-P in a phase 2 clinical trial and future immunotherapy combinations. Clinical trial information: NCT05827055. Research Sponsor: Ruesch Center for the Cure of Gastrointestinal Cancers; Pancreatic Cancer Action Network.

QL1706 combined with nab-paclitaxel and gemcitabine as first-line treatment for locally advanced or metastatic pancreatic adenocarcinoma: A prospective, multicenter, single-arm phase II study. First Author: Biyang Cao, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing, China

Background: First-line chemotherapy with nab-paclitaxel and gemcitabine (AG) provides limited efficacy in advanced pancreatic ductal adenocarcinoma (PDAC). QL1706, a bifunctional antibody targeting PD-1 and CTLA-4, has demonstrated favorable efficacy and safety. This phase II study evaluated the efficacy and safety of QL1706 plus AG as first-line treatment in patients with locally advanced or metastatic PDAC. **Methods:** Adult patients with histologically confirmed, unresectable locally advanced or metastatic PDAC, ECOG performance status 0–1, no prior systemic therapy, and at least one measurable lesion were enrolled. Patients received QL1706 (5 mg/kg, IV, day 1) in combination with nab-paclitaxel (125 mg/m², IV, days 1 and 8) and gemcitabine (1,000 mg/m², IV, days 1 and 8) every 3 weeks. Tumor assessments were performed every two cycles. Up to eight cycles were administered, followed by QL1706 maintenance in patients without disease progression. Primary endpoints were objective response rate (ORR) and safety. **Results:** A total of 30 patients were enrolled. The median age was 59 years (range, 44–74), and 20 patients were male. Primary tumors were located in pancreatic head in 14 (46.7%) and in body or tail in 16 (53.3%). Eight (26.7%) and 22 (73.3%) patients had locally advanced (stage III) and metastatic (stage IV) disease, respectively. Among 26 patients assessed for KRAS mutations, the G12D variant was most prevalent (46.2%), followed by G12R (30.8%) and G12V (23.0%). At data cutoff, after a median follow-up of 5.2 months (range, 4.1–6.8), 18 patients remained on treatment. Of these, 2 underwent curative surgery and 4 transitioned to maintenance therapy. Twelve patients discontinued treatment due to disease progression, including 5 who subsequently died. The median number of treatment cycles administered was 4.5 (range, 2–8) for chemotherapy and 4 (range, 1–8) for QL1706. All patients had at least one post-baseline tumor assessment. Best overall response were complete response in 1(3.3%), partial response in 8 (26.7%), stable disease in 16 (53.3%), and progressive disease in 5 (16.7%).The ORR was 30.0% (95% CI, 14.7–49.4%) and disease control rate was 83.3% (95% CI, 65.3-94.4%). The survival data were not mature by analysis. All patients experienced at least one treatment-related adverse event (TRAE). Grade ≥3 TRAEs occurred in 16 patients (53.3%). The most frequent grade 3–4 TRAEs were neutropenia (23.3%) and leukopenia (20.0%), followed by hypersensitivity reactions (13.3%), thrombocytopenia (6.7%), thromboembolism (6.7%), and pancreatitis (6.7%). No grade 5 TRAEs or treatment-related deaths occurred. **Conclusions:** QL1706 combined with AG demonstrated promising antitumor activity with a manageable safety profile as first-line treatment for advanced PDAC. Clinical trial information: NCT06750861. Research Sponsor: None.

4204 **Poster Session**

Multicentre trial of telemonitored circadian rhythms and electronic patient-reported outcomes (ePROs) for improving tolerability of initial mFOLFIRINOX cycles in patients (pts) with advanced pancreatic ductal adenocarcinoma (PDAC): MultiDom (NCT04263948). First Author: Francis Albert Lévi, UPR Chronotherapie, Cancers et Transplantation, Université Paris Saclay, Hôpital Paul Brousse ID Isco 13918, Villejuif, France

Background: Severe Adverse Events (SAEs) requiring emergency admissions (EAs) alter quality of life and treatment efficacy, and increase health costs. Toxicities, EAs, and reduced survival have been linked to the disruption of circadian rhythms, whose relevance is tested here in a multicentre, prospective, longitudinal, single-arm interventional trial. **Methods:** Continuous telemonitoring and automatic analyses of circadian rhythms and daily body weight and ePROs over 50 days (d) aim to reduce EAs in PDAC pts receiving the first 3 cycles of mFOLFIRINOX. The hypothesis (H_0) is that EAs involve <15% of the pts, rather than a historical rate of 15-30%. Pts data were collected through telecommunicating chest sensor, balance and tablet connected to a multidimensional digital platform. The main circadian parameter was (I<O), the % of accelerations per min In-Bed that are below the median accelerations per min Out-of-Bed. Control(I<O) is 97-100%. An (I<O) ≤96% defined circadian disruption. Electronic alerts were sent out if (I<O) ≤96%, body weight loss ≥5%, or self-rated symptoms ≥7 using the MD Anderson Symptoms Inventory (MDASI). **Results:** 28 males and 24 females had a median age of 65 years (33-82), and WHO performance status of 0-1 in 92% of them. PDAC was metastatic in 69% of cases, including liver in 50%. An EA occurred in 2 pts (3.8% [95% CL, 1.1-13%]), thus validating H_0. SAEs in both EA pts were grade (Gr) 3 febrile neutropenia and diarrhea; and Gr 3 leuco-neutropenia and hypokaliemia respectively. Symptom-free circadian disruption preceded EA by 8 d in both pts. Circadian disruption occurred at least once in 65-75% of the pts on treatment, and lasted > 20 d in 27 pts (52%). Severe fatigue and anorexia were self-reported by 62% and 58% of the treated pts respectively. Main Grade 3-4 toxicity was neutropenia in 17% of the pts [95% CL, 9-30]. Disease control rate at 2 months was 75% [53-100]. Multidom revealed (i) a high level of pt engagement supported both by data compliance rates of 84-92% for circadian rhythms, 93-100% for body weight, and 86-100% for ePROs; and by median duration of platform use of 46 d (IQR, 38-50]; (ii) 1881 medical type e-alerts for circadian disruption (43%), MDASI symptoms (25%), and body weight loss (12%); (iii) 883 categorized responses to medical e-alerts, and (iv) highest global score of self-rated pt experience of participation (median, 5/5 (4 to 5). **Conclusions:** Combining telemonitoring of circadian rhythms, body weight and symptoms in remote PDAC pts on mFOLFIRINOX revealed potential benefit on pts real life through informed proactive telecare, and likely improved treatment safety. Actual benefits from such telemonitoring-telecare platform with circadian metrics need further confirmation in trials involving pts at risk of SAEs. Clinical trial information: NCT04263948. Research Sponsor: Research and Education Group of Ramsay-Santé, France.

4205 **Poster Session**

Final results and preliminary correlative analysis of a phase I study of anetumab ravtansine in combination with checkpoint inhibitors and gemcitabine in mesothelin-positive advanced pancreatic adenocarcinoma (NCI10208). First Author: Carlos Diego Holanda Lopes, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Anetumab-ravtansine (AR) is an ADC composed of IgG1 targeting the protein mesothelin (MSLN) linked to DM4, a tubulin inhibitor (*Spiliopoulou, ASCO 2022*). Here, we present the final analysis of a phase I study evaluating AR in combination with nivolumab, ipilimumab, or gemcitabine in patients (pts) with metastatic pancreatic adenocarcinoma (PDAC). **Methods:** Eligible pts had histologically confirmed MSLN-positive PDAC (≥5% expression by IHC), ECOG 0–1, and progression after ≥1 prior line of systemic therapy. The dose-escalation phase included: AR + nivolumab (ARM1), AR + nivolumab + ipilimumab (ARM2), and AR + gemcitabine + nivolumab (ARM3). The latter was chosen for dose-expansion. Two dose levels of AR: DL1 5.5 mg/kg and DL2 6.5 mg/kg (RP2D) were evaluated. Blood and tissue-based correlative analysis included paired tumor biopsies on C1D7 and C2D7 for comparison of immune cell shifts by multiplex immunofluorescence. **Results:** As of the final data cutoff on 15/11/2023, 46 pts were treated: ARM1 (n = 11), ARM2 (n = 13), ARM3 (n = 10), and dose expansion (n = 12). Median age was 66 years (40–83), the majority were males (52.2%) and had received prior gemcitabine (63%). The median number of prior treatment lines was 2 (1–5). Among 44 evaluable pts, 95.7% experienced some treatment emergent adverse events, with G1/2 and G≥3 occurring each at 47.8%. Dose limiting toxicities occurred in 6 pts (13%): 2 in ARM2DL2 (upper gastrointestinal hemorrhage and G3 thrombocytopenia), 2 in ARM3DL2 (G3 AST and G3 ALT elevation), and 1 in each of the dose expansion DL2 (G3 AST and G3 ALT elevation). Blurred vision occurred in 13%, peripheral neuropathy in 6.5%, pneumonitis in 4.3%, and keratitis in 2.2%, most of them being G1/2. No treatment-related deaths occurred. Among 41 evaluable pts, 1 (2.2%; ARM3DL2) had a complete response, 20 (43.5%) had stable, and 20 (43.5%) had disease progression. The median duration of treatment was 7.9 (1.9-32.9) weeks which was statistically longer in pts with stable disease than those with progressive disease as best response (16.4 vs 6.3 weeks, respectively; $p < 0.05$). Twenty-seven pts were included in the multiplex immunofluorescence, and no statistically immune-cell shifts were detected between C1D7 and C2D7. **Conclusions:** AR had an acceptable safety profile in PDAC and the 6.5 mg/kg was identified as the R2PD. Evidence of clinical benefit was observed with some pts with prolonged disease stabilization and one complete response in a setting of limited therapeutical options. Correlative analysis to identify predictive biomarkers for treatment benefit is ongoing. Clinical trial information: NCT03816358. Research Sponsor: Experimental Therapeutics Clinical Trials Network (NCI-ETCTN); North American STAR Consortium.

Ultra-refractory PD–PD pancreatic cancer: Clinical and molecular insights across first- and second-line therapy. First Author: Natalia Soledad Tissera, Hepatobiliary Pancreatic Cancer and Endocrine Tumors Group, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: A subset of pancreatic cancer (PC) patients exhibits progressive disease (PD) as the best response to both first- and second-line chemotherapy (PD-PD), representing an ultra-refractory population with dismal outcomes. This group remains poorly characterized, highlighting a critical unmet need for novel therapeutic strategies. **Methods:** We retrospectively analyzed PC patients treated at Vall d'Hebron University Hospital (2012–2025) who received both first- and second-line chemotherapy with 5-FU- or gemcitabine-based regimens. Clinical, histopathological and molecular data were collected. Characteristics of PD-PD patients were compared with those achieving clinical benefit, defined as complete or partial response (CR/PR) in at least one treatment line. Progression-free survival (PFS2) was calculated from the start of first-line therapy to documented PD after second-line treatment. Overall survival (OS) was calculated from the start of first-line therapy to death or last follow-up. Survival curves were estimated using the Kaplan–Meier method. RNA-seq was performed on diagnostic tumor samples to explore transcriptomic features. **Results:** Median follow-up for the entire cohort was 58 months. Among 400 patients, 46 (12%) were classified as PD-PD. Median PFS2 was 5.4 months in PD-PD vs 14.5 months in CR/PR, and median OS was 8.1 vs 20.8 months, respectively ($p < 0.001$ for both). Treatment sequences in PD-PD patients included 5-FU followed by gemcitabine (18, 39%) and gemcitabine followed by 5-FU (28, 61%). Patients receiving 5-FU first were younger (median age 57 vs 72 years, p = 0.035). Histopathological features were similar in both groups. Inflammatory markers were largely comparable; however, median CRP/albumin ratio was higher in PD-PD, 0.86 vs 0.24 in CR/PR ($p < 0.001$). Molecular profiling was available for 34 (74%) of patients. Among these, *KRAS* mutations were present in 84% of patients, with G12V slightly more frequent in PD-PD than CR/PR (45% vs 31%, p = 0.5). *TP53* mutations occurred in 81% vs 65% (p = 0.083), and *SMAD4* alterations were more common in CR/PR (19% vs 6.3%, p = 0.082). DDR pathway alterations were rare in PD-PD patients. Exploratory RNA-seq of six PD-PD compared with CR/PR (n = 2) tumors revealed upregulation of coagulation and lipid metabolism genes (*FGB, APOA1*) and downregulation of pancreatic function genes (*PNLIP, CPA1*), suggesting potential alterations in inflammatory and metabolic pathways. **Conclusions:** PD-PD patients represent an ultra-refractory subset (~12%) of PC with very poor outcomes despite standard therapy. Differences in inflammatory markers and transcriptomic trends may reflect underlying biological features of this highly resistant phenotype. These findings underscore the need for further studies to clarify mechanisms of primary resistance and guide the development of novel therapeutic strategies in this high-risk population. Research Sponsor: None.

4208 **Poster Session**

Phase 1/2 study of YL201, an anti-B7H3 antibody–drug conjugate (ADC), in patients with previously treated advanced pancreatic ductal adenocarcinoma (PDAC). First Author: Liwei Wang, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

Background: The prognosis for patients with advanced PDAC after failure of first-line therapy remains dismal with limited effective treatment options. There is a critical unmet need for novel therapeutic agents in the second-line and beyond (2L+) setting. YL201 is a B7H3-targeting ADC with promising clinical activity in multiple advanced solid tumors. Here, we report the safety and preliminary efficacy of YL201 monotherapy in patients with 2L+ PDAC from a phase 1/2 dose expansion study. **Methods:** Patients with metastatic PDAC who had progressed on at least one prior line of systemic therapies without irinotecan were enrolled and treated with YL201 intravenously Q3W at 2.0 mg/kg or 2.4 mg/kg until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** A total of 60 patients were enrolled, including 30 treated at 2.0 mg/kg and 30 at 2.4 mg/kg. The median age was 61.0 years, 63.3% were male, and 91.7% had an ECOG PS of 1. 48.3% of patients had ≥3 metastatic sites at baseline. Patients had received a median of 1 prior line of therapy (range: 1–3). 90.0% had received prior gemcitabine-based regimen and 46.7% had received prior fluoropyrimidine. As of 12 December 2025, the median follow-up was 9.2 months (95% CI: 8.2–9.8). Among the 60 patients enrolled, the confirmed ORR was 28.3% (95% CI: 17.5–41.4) with a median DoR of 7.6 months (95% CI: 4.9–NR), and the DCR was 85.0% (95% CI: 73.4–92.9). The median PFS was 7.7 months (95% CI: 5.5–9.7), and the median OS was 14.6 months (95% CI: 8.2–NR). Membrane B7H3 expression was detected by immunohistochemistry in most tumor samples with a median H-score of 65 (range: 0–275). However, no association was observed between tumor response and B7H3 expression level in PDAC patients. Treatment-related adverse events (TRAEs) of any grade and grade ≥3 occurred in 100.0% and 43.3% of patients, respectively. The most common grade ≥3 TRAEs included leukopenia (16.7%), neutropenia (15.0%), anemia (15.0%), and hypokalemia (6.7%). The rate of treatment discontinuation due to TRAEs was 5.0%, and no treatment-related deaths were reported. **Conclusions:** YL201 monotherapy showed promising antitumor activity and a manageable safety profile in pretreated patients with advanced PDAC. These compelling results warrant further investigation of YL201 in a randomized controlled trial for patients with advanced PDAC in the 2L+ setting. Clinical trial information: NCT06057922. Research Sponsor: MediLink Therapeutics.

Efficacy of multimodal thermal therapy combined with immune checkpoint inhibitors and chemotherapy in unresectable pancreatic cancer with liver metastases. First Author: Chuntao Wu, Department of Pancreatic Surgery, Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Treatment of pancreatic cancer with liver metastasis (PCLM) remains extremely challenging. Multimodal thermal therapy (MTT) is a novel treatment method consisting of alternated liquid nitrogen cooling and radiofrequency heating, which was proven to effectively remodel the immune environment and trigger systemic antitumor immunity. This study aims to explore the primary application of MTT combined with subsequent ICIs-based systemic therapy in PCLM. **Methods:** Patients aged 18-70 years with primary diagnosed unresectable PCLM were enrolled in this single-center, prospective clinical trial. Participants received MTT at least one of the liver metastases combined with subsequent ICIs and chemotherapy (camrelizumab 200 mg IV on Day 1, gemcitabine 1000 mg/m2 IV, and nab-paclitaxel 125 mg/m2 IV on Days 1 and 8, every 3 weeks for 6 cycles), which was started on day 7 post MTT. The primary endpoints were safety and efficacy. Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), and disease control rate (DCR). Exploratory endpoints included immune marker changes induced by MTT. **Results:** Five patients were enrolled in the trial group and four patients in the control group. All patients in the trial group were well tolerated with MTT, and the MTT-treated liver tumors were completely ablated. One patient withdrew due to autoimmune hepatitis after the first ICIs treatment. One patient achieved success conversion and underwent curative resection 6 months after MTT. Median OS per RECIST was 16.0 months (95% CI 15.3–16.7) in the trial group surpassing 6.2 months (95% CI 1.8–9.2) in the control group (HR 0.26 [95% CI 0.04–1.99]). Histological analysis indicated that combination therapy reversed the immunosuppressive tumor microenvironment, accompanied by enhanced immune-cell infiltration and tertiary lymphoid structures formation within both primary and metastatic lesions. Single-cell RNA-seq of peripheral blood immune cells on day 7 after MTT but prior to ICIs and chemotherapy revealed that MTT promoted the maturation of APCs, increased expression of homing-associated chemokine receptors on circulating B cells and monocytes, and induced the expansion of tumor-trafficking monocytes and $CD8^+$ T cells subsets, which were correlated with favorable prognosis. The effector functions of T cells were also enhanced post MTT, accompanied by increased PD-1 level, which provided the basis for subsequent anti-PD-1 therapy. **Conclusions:** MTT reshaped both primary and metastatic tumor immune environments, sensitized tumors to subsequent immunotherapy and chemotherapy, well correlating to prolonged OS of PCLM patients. Clinical trial information: NCT06307080. Research Sponsor: None.

AI-driven RNA-based homologous recombination deficiency algorithm to predict first-line platinum response in metastatic pancreatic cancer. First Author: Hannah J. Glover, Tempus AI, Inc., Chicago, IL

Background: Developing predictive diagnostics for metastatic pancreatic cancer remains an unmet clinical need. Here, we present the Tempus HRD-RNA algorithm: an AI-driven, 1,660-gene logistic regression model trained on RNA-seq (Tempus xR) from pan-cancer solid tumor tissue samples. This dynamic RNA-based signature can identify clinically relevant patient populations likely to benefit from platinum-based regimens and PARP inhibitors, including patients without BRCA1/2 or PALB2 mutations. **Methods:** This is a prospectively designed retrospective RWD analysis in an independent validation cohort of 1,083 patients (pts) with treatment-naive metastatic pancreatic cancer diagnosed between 2017 and 2025. Treatment arms included first-line platinum-containing regimens (Arm A; n = 779; 97.0% FOLFIRINOX, 1.4% NALFIRINOX, 1.5% Gemcitabine/Cisplatin) or a non-platinum regimen (Arm B; n = 304; 86.6% Gemcitabine/Nab-paclitaxel, 13.4% Gemcitabine/Paclitaxel). BRCA1/2 and PALB2 mutations were determined via paired Tempus xT DNA sequencing. Key prognostic criteria included age, sex, ECOG score (0 or 1), surgery status and biopsy site. Unknown ECOG was imputed using the Laboratory Imputation Framework for EHRs (LIFE; PMID: 40595435). Overall survival (OS) differences between treatment arms were evaluated as independent Cox models for HRD+ vs. HRD- pts, including covariate adjustment. **Results:** Overall, 9.5% of pts were classified as HRD+: 78 pts (10.0%) in the platinum arm (Arm A) and 15 pts (8.2%) in the non-platinum arm (Arm B). OS was significantly higher in platinum-treated HRD+ pts than non-platinum. Median OS (mOS) was 12.8 months (95% CI: 8.5–16.6) in HRD+ platinum pts (Arm A) vs. 8.5 months (95% CI: 5.4–12.9) in HRD+ non-platinum-treated pts (Arm B; HR: 0.57; 90% CI: 0.33–0.99; p = 0.048). In contrast, in the HRD- group, there was no statistically significant difference in OS between platinum (Arm A; mOS 8.1 months; 95% CI: 7.1–9.1) and non-platinum (mOS 7.6 months; 95% CI: 6.6–8.8) arms (Arm B; HR: 0.91; 90% CI: 0.76–1.09; p = 0.190). Additional analyses were performed within the platinum-treated arm (Arm A) to assess if the survival benefit held independent of BRCA1/2 or PALB2 mutations. HRD+ and BRCA/PALB2mut pts (4.8%; n = 37) had a mOS of 13.3 months compared to 11.5 months in HRD+ and BRCA/PALB2wt (5.3%; n = 41) pts (HR: 0.7; 90% CI: 0.4–1.1). Comparatively, HRD- and BRCA/PALB2mut pts (2.1%; n = 16) had a mOS of 10.5 months compared to 8.3 months in HRD- and BRCA/PALB2wt (80.9%; n = 623) pts (HR: 0.7; 90% CI: 0.4–1.3). **Conclusions:** Tempus HRD-RNA is a novel predictive clinical biomarker that identifies a higher percentage of pts who may benefit from targeted treatment than current guidelines. The HRD-RNA algorithm offers a remarkable precision oncology tool to improve outcomes in pancreatic cancer, and has important clinical value in the era of novel HRD drug development. Research Sponsor: None.

The SPIN Score, a simple clinical score to predict pain response following celiac plexus radiosurgery for retroperitoneal cancer pain. First Author: Yaacov Lawrence, Jusidman Cancer Center, Sheba Medical Center, Ramat Gan, Israel

Background: Celiac plexus radiosurgery is a novel non-invasive palliative treatment for pancreatic cancer pain that was recently added to NCCN guidelines. In the pivotal phase 2 trial (NCT03323489; Lancet Oncol 2024;25:1070-79), pain response was 53% (95% CI 42-64%). Prespecified exploratory analysis identified age and BMI as predictors; however, no clinically actionable patient selection tool was developed. We sought to identify additional predictors and create a practical risk stratification score. **Methods:** Post-hoc analysis of 90 evaluable patients from the phase 2 trial. Pain response was defined per protocol (≥2-point reduction in average pain from baseline to three weeks, on Brief Pain Inventory–Short Form). Candidate baseline predictors were examined by univariate and multivariate logistic regression. Only variables remaining significant in multivariate analysis were included in the final score to ensure independence and avoid overfitting. Internal validation used bootstrap resampling (500 iterations with replacement) to calculate optimism-corrected AUC. Analysis performed using Stata IC/16.1. **Results:** Univariate analysis identified 4 significant predictors: neurotoxic chemotherapy exposure (OR 5.33, 95% CI 2.13-13.4, $p<0.001$), baseline pain intensity (OR 1.73, p=0.003), age (OR 1.06, p=0.014), and therapy line (OR 0.65, p=0.04). On multivariate analysis, only neurotoxic exposure (OR 5.1, p=0.009) and baseline pain (OR 1.8, p=0.003) remained independently significant predictors. Age and therapy line lost significance due to collinearity. Dose-response analysis confirmed pain threshold optimization: >5 (61.5% response), >6 (65.8%), >7 (83.3%), >8 (85.7%), with >6 providing optimal discrimination. We created the SPIN (Severe Pain + Intact Nerves) score (0-2 points): baseline Pain >6 (+1), No prior Neurotoxic chemotherapy (+1). Response rates by score: 0 points: 32% (n=31); 1 point: 53% (n=40); 2 points: 89% (n=19). The 2-variable model achieved an apparent AUC=0.716. Following bootstrapping, the optimism-corrected AUC was=0.714. **Conclusions:** The simple score allows identification of distinct patient subgroups with markedly different probabilities of pain response following celiac plexus radiosurgery. This suggests the intervention should be considered earlier in the disease course, before exposure to neurotoxic agents. External validation is needed prior to clinical implementation. Financial support: Gateway for Cancer Research, The Israel Cancer Association. Clinical trial information: NCT03323489. Research Sponsor: None.

4212 **Poster Session**

A phase II study of FOLFIRINOX (FFX) combined with the glycogen synthase kinase-3beta (GSK-3β) inhibitor elraglusib (ELRA) and the transforming growth factor beta (TGFβ) inhibitor losartan (LOS) in patients with untreated metastatic pancreatic ductal adenocarcinoma (mPDAC). First Author: Priyadarshini Satyajit Pathak, Department of Medicine, Division of Hematology & Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Concurrent inhibition of GSK-3β and TGF-β signaling pathways aims to target epithelial-mesenchymal transition (EMT) plasticity, metabolic reprogramming, desmoplasia and immune escape mechanisms that underlie therapeutic resistance in mPDAC **Methods:** In this multi-institutional, open-label, four-arm (non-comparator) phase II trial conducted across three academic centers in the United States, 49 patients with newly diagnosed, treatment naive mPDAC were randomized to Arm 1: FFX alone (biomarker control, n=4) or Arm 2: FFX plus LOS (50 mg daily); Arm 3: FFX plus ELRA (9.3 mg/kg IV twice weekly); Arm 4: FFX plus LOS plus ELRA (n=15/arm). After 12 cycles of FFX without progression, patients transitioned to maintenance 5-FU (plus ELRA/LOS, based on the arm) and resumed full therapy at progression; treatment withdrawal required progression on full therapy or treatment-limiting toxicity. The primary endpoint was progression-free survival (PFS). **Results:** Between September 19, 2022, and January 2, 2025, 49 patients were enrolled (median age 65 years; 51% female; 74% White). At the data cutoff (July 6, 2025), 14 (28.6%) patients remained alive with a median follow-up of 9 months. Median PFS was 5.1 months (95% CI 1.1–NR) in Arm 1, 5.9 months (95% CI 1.6–9.9) in Arm 2, 6.0 months (95% CI 1.8–9.8) in Arm 3, and 6.5 months (95% CI 3.8–8.5) in Arm 4. 9-month PFS could not be calculated in arm 1, 29.3% (95% CI 9.2-53.3) in Arm 2, 37.3% (95% CI 13.6 – 61.5%) in Arm 3, and 21.7% (95% CI 5.3 –45.1) in Arm 4. Median overall survival (OS) was 7.7 months (95% CI 1.1–NR), 8.2 months (95% CI 3.3–14.5), 9.8 months (95% CI 4.3–NR), and 9.8 months (95% CI 5.6–15.6), respectively in each arm. Objective response rate 24.5% (12/49);stable disease 44.9% (22/49). 14/49 (28.5%) patients received maintenance therapy, with a median duration of 2.4 months. Treatment was generally well tolerated, grade ≥3 treatment-related adverse events occurred in 34.7% of patients; one treatment-related death due to sepsis occurred in Arm 3. Notably, a subset of patients in Arms 3 and 4 demonstrated deep and sustained clinical responses; Correlative biomarker analyses are ongoing to identify molecular and immune features associated with these long term responders. **Conclusions:** Although clinical outcomes with the novel combinations did not exceed historical standards of care, this non-comparator phase II study demonstrates the feasibility and tolerability of combinatorial pathway inhibition in mPDAC. This study enables ongoing correlative analyses of EMT plasticity, stromal remodeling, and immune escape in mPDAC and establishes a robust platform to define determinants of resistance and durable response. Clinical trial information: NCT05077800. Research Sponsor: Lustgarten Foundation; Actuate Therapeutics Inc.

Post-hoc efficacy and biomarker analysis of elraglusib plus gemcitabine/nab-paclitaxel versus chemotherapy alone in metastatic pancreatic ductal adenocarcinoma. First Author: Devalingam Mahalingam, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL

Background: Elraglusib (9-ING-41), a glycogen synthase kinase-3β (GSK-3β) inhibitor, has multimodal antitumor activity. In the international, open-label, randomized phase 2 1801 Part 3B study, elraglusib plus gemcitabine/nab-paclitaxel (GnP) was evaluated in previously untreated metastatic pancreatic ductal adenocarcinoma (mPDAC), with patients randomized 2:1 to weekly elraglusib/GnP or GnP alone. Primary endpoints were median overall survival (mOS) and 1-year survival. The GnP control arm demonstrated shorter mOS than contemporary randomized trials (7.2 months vs 9.2 months in NAPOLI-3 and 9.7 months in PASS-01), driven by higher early mortality (0–2 months: 23.1% vs 10.1% in NAPOLI-3). Given balanced randomization, similar early mortality was inferred in the elraglusib/GnP arm, prompting post-hoc analyses to contextualize efficacy and identify factors associated with early death. **Methods:** Efficacy and safety were summarized descriptively. Time-to-event endpoints were analyzed using Kaplan–Meier estimates, log-rank testing, and Cox proportional hazards models. Response rates were compared using the Cochran–Mantel–Haenszel test. Post-hoc subgroup, sensitivity, and machine-learning–based multivariate analyses explored clinical, demographic, and biomarker correlates of survival and early mortality. **Results:** In the full randomized population (elraglusib/GnP n=155; GnP n=78), elraglusib/GnP improved mOS by 2.9 months versus GnP (10.1 vs 7.2 months; HR 0.62; 95% CI 0.46–0.84; p=0.01), with 1-year survival rates of 44.1% versus 22.3%. Among patients receiving ≥1 full treatment cycle, mOS was 12.5 months with elraglusib/GnP and 8.5 months with GnP, comparable to contemporary registrational trials. Across multiple post-hoc sensitivity analyses—including evaluable patients, those matched to NAPOLI-3 baseline tumor burden, patients treated in the EU (early mortality 4%), and those achieving ≥20% CA19-9 decline within the first 1–2 cycles—elraglusib/GnP consistently demonstrated a ≥4-month OS advantage. Early death was associated with low baseline albumin (<3 g/dL), high CA19-9 (>800 U/mL), high tumor burden, and KRAS, TP53, and CDKN2A co-mutations. **Conclusions:** The elevated early mortality in the GnP control arm reflects enrollment of a heterogeneous, real-world mPDAC population with less restrictive eligibility than recent registrational trials. Post-hoc analyses identify key clinical and molecular drivers of early death and confirm a consistent survival benefit with elraglusib/GnP. These hypothesis-generating findings directly inform eligibility criteria, stratification, and endpoint assumptions for the planned phase 3 trial. Clinical trial information: NCT03678883. Research Sponsor: Actuate Therapeutics.

Time toxicity in patients with advanced pancreatic cancer in Mexico. First Author: Cecilia Ximenez Camilli, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, DF, Mexico

Background: Advanced pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies despite advances in systemic therapy. Beyond survival, the burden of time spent receiving health care (also known as time toxicity) has emerged as a relevant patient-centered outcome, particularly in diseases where treatment benefits may be modest. This study aimed to quantify time toxicity in patients with advanced PDAC and to analyze differences in time toxicity by demographic and clinical characteristics. **Methods:** We conducted a subanalysis of a single-center prospective cohort of patients with advanced solid tumors enrolled in a patient navigation program in Mexico. Patients ≥18 years diagnosed with advanced PDAC between June 2017 and August 2023 were included; patients with a second invasive malignancy or treated outside the institution were excluded. Demographic and clinical variables, baseline quality of life (FACT-G), and days with in-person healthcare encounters (clinic visits, treatments, tests, emergency visits, and hospitalizations, regardless of whether oncology-related) were collected from the diagnosis of advanced disease. Overall survival (OS) was defined as the time from diagnosis of advanced PDAC to death or loss to follow-up. Time toxicity was defined as the proportion of days involving in-person healthcare contact relative to OS. Comparisons used nonparametric tests and beta regression models were fitted to evaluate factors associated with time toxicity. **Results:** A total of 103 patients were included. Median age was 64 years, 65% were women, 83.5% presented with de novo advanced PDAC, and 75.7% received palliative chemotherapy. The mean baseline FACT-G score was 63.7±15.4. Median follow-up was 13.0 months, and median OS for the entire cohort was 11.5 months (95% CI, 6.2-16.7). The median time toxicity of the sample was 21.8% (IQR, 14.9-31.7). Patients with recurrent advanced PDAC experienced lower time toxicity than those with de novo disease (14.9% vs 22.8%, p = 0.003). In multivariable beta regression, disease presentation remained the only independent factor associated with increased time toxicity (β-0.51, p = 0.011). Age, sex, receipt of chemotherapy, and baseline FACT-G score were not independently associated with time toxicity. In an exploratory subgroup analysis among patients receiving palliative chemotherapy, patients ≥65 years had higher time toxicity compared to younger patients (23.4% vs. 17.9%; p = 0.041). **Conclusions:** In this cohort of Mexican patients with advanced PDAC, approximately one-fifth of OS time was spent in direct contact with health care system. Time toxicity was associated with disease trajectory rather than treatment or patient characteristics. Among patients receiving palliative chemotherapy, older patients experienced higher time toxicity. These findings highlight the importance of incorporating time toxicity into shared decision-making. Combined safety and efficacy results from three clinical studies evaluating alpha radiotherapy for advanced pancreatic cancer. First Author: Corey Miller, Jewish General Hospital, McGill University, Montreal, QC, Canada

Background: Pancreatic cancer (PDAC) remains associated with poor prognosis and limited treatment options, particularly in patients with advanced disease. Diffusing Alpha-Emitter Radiation Therapy (Alpha DaRT), a novel alpha-emitting radiation source, has shown initial clinical benefit in superficial epithelial solid tumors. The pooled studies presented here evaluated the safety and efficacy outcomes for endoscopic ultrasound (EUS)-guided alpha radiotherapy using Alpha DaRT in patients with PDAC. **Methods:** This analysis pooled data from three prospective clinical studies at 3 medical centers in Canada and Israel evaluating Alpha DaRT in patients with locally advanced or metastatic PDAC, regardless of previous lines of therapy. Primary outcome was safety, as assessed by CTCAE V5. Secondary outcomes were best overall response (BOR) of the primary tumor assessed per RECIST V1.1 and overall survival (OS), defined from Alpha DaRT treatment. **Results:** A total of 58 subjects (31 male, 27 female), median age 72 (range 41-91), were recruited between 2023 and 2025 across the three trials. Treatment-associated AEs of any grade occurred in 21 patients (36%). Grade ≥3 AEs occurred in 5 patients (9%) (biliary obstruction, abdominal pain, fever, liver enzyme imbalance and bacteremia). There were no treatment-related deaths and all grade ≥3 AEs resolved. Across all patients evaluable for response, the BOR showed a disease control rate of 87% and an objective response rate of 27%, with 3 complete and 9 partial responses. Median OS for the cohort was 7.9 months (95% CI: [6.1–11.6]): 10.4mo (95% CI: [7.3–13.4]) when given in 2nd line (N = 24) and 7.5 months (95% CI: [4.2–11.8]) when given in 3rd line (N = 21). **Conclusions:** In this pooled analysis of three clinical studies, EUS-guided Alpha DaRT demonstrated a reassuring safety profile and promising early efficacy signals in patients with advanced PDAC. The observed survival outcomes and radiographic responses support further clinical investigation, which is underway. Clinical trial information: NCT04002479; NCT05781555; NCT05657743. Research Sponsor: None.

Single-cell circulating tumor cell genomics of KRAS-independent oncogenic sub-populations and longitudinal clonal evolution in metastatic pancreatic adenocarcinoma. First Author: Mandana Kamgar, Medical College of Wisconsin, Milwaukee, WI

Background: KRAS mutations are a dominant oncogenic driver in metastatic pancreatic ductal adenocarcinoma (mPDAC) and are routinely detected using ctDNA. However, ctDNA reflects pooled signals from dominant high-shedding clones and may incompletely capture intra-patient heterogeneity or tumor evolution. Circulating tumor cells (CTCs) enable single-cell genomic interrogation and longitudinal tracking of evolving subpopulations. We compared genomic alterations, tumor heterogeneity, and pathway dynamics using ctDNA and single-cell CTC DNA in mPDAC. **Methods:** Under an MCW IRB approved protocol (PREDICT-MCW; NCT05802069), 16 patients with mPDAC receiving standard of care were enrolled. Peripheral blood was collected at baseline and longitudinally at 90-day intervals. Live single CTCs were isolated using the OncoIncytes platform with anti-EpCAM–based glass bead capture and gentle release. Genomic DNA from individual CTCs underwent linear amplification and targeted sequencing using a 1080-gene panel on the Illumina NextSeq 2000. Matched ctDNA was analyzed using the same panel. Variant calling used the iCore pipeline. Alterations were compared at gene and patient levels. Tumor heterogeneity was assessed using mutant-allele tumor heterogeneity (MATH). **Results:** CTC counts were highest at baseline (mean 6.5 CTCs per patient; range 2–11) and varied longitudinally with marked inter-patient heterogeneity. At first on-treatment assessment, 50% of evaluable patients showed reduced CTC counts, while others exhibited stable or increased levels. Across all timepoints, 49 altered genes were identified. Single-cell CTC profiling revealed broader genomic representation, with 32 genes (65%) detected exclusively in CTC-DNA, 14 (29%) shared with ctDNA, and 3 (6%) detected exclusively by ctDNA. At the patient level, CTC-DNA identified genomic alterations in all patients (16/16), whereas ctDNA detected alterations in 75% (12/16). At baseline, 61% of CTCs achieved $\geq 11\times$ coverage across KRAS exon 2 and codon 12. KRAS alterations were detected in only 6% (1/16) of patients by CTC-DNA compared with 44% (7/16) by ctDNA, persisting longitudinally (13–19% vs 59–76%, CTC-DNA vs ctDNA). KRAS-negative CTCs harbored recurrent alterations in MAPK, DNA damage response, receptor tyrosine kinase, and tumor suppressor pathways. CTCs demonstrated higher intra-patient heterogeneity than ctDNA (MATH 50.5 vs 25, $p < 0.05$). **Conclusions:** Single-cell CTC profiling reveals KRAS-independent tumor sub-populations present from baseline and dynamic clonal evolution not captured by ctDNA alone, revealing tumor heterogeneity and KRAS-independent disease biology. Paired CTC and ctDNA analysis provides complementary resolution of persistent atypical oncogenic and tumor suppressor sub-clones not evident from bulk liquid biopsy. Research Sponsor: None.

Knowledge distillation for pancreatic cancer diagnosis: EfficientNet-based deep learning for stage stratification with real-world deployment optimization. First Author: Lalith Akaash Ramasamy, Saveetha Medical College and Hospital, Chennai, India

Background: Pancreatic cancer is among the most lethal malignancies, with a 5-year survival below 12%. Prognosis is strongly stage dependent, yet early disease is frequently misclassified as chronic pancreatitis or benign cystic lesions, resulting in diagnostic delay and loss of surgical opportunity. Although deep learning models demonstrate high accuracy on cross-sectional imaging, their computational demands limit deployment in resource-constrained settings. Knowledge distillation enables transfer of diagnostic capability from high-capacity teacher models to lightweight student networks while preserving performance. We evaluated whether a distilled EfficientNetB0 model could retain EfficientNetB7-level accuracy for pancreatic cancer stage stratification while enabling real-world deployment. **Methods:** We analyzed 2,840 contrast-enhanced abdominal CT studies, including pancreatic ductal adenocarcinoma (n = 1,400; 700 early-stage resectable or borderline-resectable, 700 locally advanced or metastatic), chronic pancreatitis (n = 900), and benign pancreatic lesions (n = 540) from multiple international centers. Ground truth was established by multidisciplinary consensus incorporating histopathology, surgical findings, and longitudinal follow-up. A high-capacity EfficientNetB7 teacher model (≈66M parameters; 37 GFLOPs) trained on multiphasic CT served as reference. A lightweight EfficientNetB0 student model (≈5.3M parameters; 0.39 GFLOPs; $>$ 90% parameter reduction) was trained using temperature-scaled knowledge distillation with regularized cross-entropy loss. Performance metrics included accuracy, sensitivity, specificity, F1-score, and AUROC. Deployment feasibility was independently evaluated by abdominal radiologists and oncologists across six continents. **Results:** The distilled EfficientNetB0 achieved 96.6% accuracy for stage stratification (early vs advanced disease), with sensitivity of 97.4%, specificity of 95.8%, and AUROC of 0.989. Differential diagnosis accuracy was 94.8% for pancreatic cancer versus chronic pancreatitis and 95.6% versus benign lesions. External validation accuracy ranged from 93% to 97%. Mean inference time was 38 ms per image compared with 330 ms for EfficientNetB7. Knowledge distillation preserved 99.1% of teacher performance while reducing computational cost by $>$ 95%. **Conclusions:** Knowledge distillation enables a lightweight EfficientNetB0 to achieve near–EfficientNetB7 accuracy for pancreatic cancer stage stratification while markedly reducing computational complexity. This scalable approach supports real-time imaging decision support and addresses key barriers to global deployment of AI-assisted pancreatic cancer diagnosis. Research Sponsor: None.

Phase IIb randomized trial of FOLFIRINOX plus ibrilatazar (ABTL0812) versus placebo as first-line treatment in metastatic pancreatic cancer: An analysis from the PanC-ASAP study. First Author: Davendra Sohal, Division of Hematology/Oncology, University of Cincinnati Cancer Center, Cincinnati, OH

Background: Metastatic pancreatic ductal adenocarcinoma (mPDAC) has poor prognosis and limited first-line treatment options. Ibrilatazar (ABTL0812) is a first-in-class oral agent that induces cytotoxic autophagy selectively in cancer cells. Favorable safety and tolerability of the combination with FOLFIRINOX were established in a Phase I study. D.S. and T.M. are equal contributors. **Methods:** PanC-ASAP is a Phase IIb double-blind, randomized, placebo-controlled (1:1) study evaluating the efficacy and safety of ibrilatazar (1300 mg TID) plus FOLFIRINOX versus placebo plus FOLFIRINOX as first-line therapy in mPDAC, conducted across 23 sites in the US, Spain, France, and Israel. Eligible patients had histologically confirmed mPDAC, ECOG PS 0–1, and no prior systemic treatment for metastatic disease. Treatment continued until disease progression or intolerable toxicity. Primary endpoint was progression-free survival (PFS), defined as time from randomization to radiographic disease progression or death, assessed by blinded independent central review in the intention-to-treat (ITT) population. Overall survival (OS) was a key secondary endpoint. Safety was assessed in all treated patients. Pre-specified stratification analysis revealed an imbalance in ECOG between arms (ECOG 0/1: 40%/60% ibrilatazar vs 54%/46% placebo), prompting an exploratory efficacy analysis by ECOG PS subgroup. Time-to-event endpoints were analyzed using Kaplan–Meier methods and log-rank tests. **Results:** In the ITT population (n = 140), median PFS for ibrilatazar vs placebo was 9.4 vs 7.9 mths (HR 0.95; 90% CI, 0.69-1.33; p = 0.814). An exploratory analysis by ECOG showed that, among patients with ECOG 0 (n = 66; ibrilatazar, n = 28; placebo, n = 38), median PFS of 11.1 vs 6.5 mths (HR 0.60; 95% CI, 0.34–1.08; p = 0.089), and median OS of 19.3 vs 12.0 mths (HR 0.57; 95% CI, 0.31–1.05; p = 0.072). Consistent trends favoring ibrilatazar were observed across efficacy endpoints, including objective response rate and duration of treatment. Safety profile of ibrilatazar plus FOLFIRINOX was consistent with the known FOLFIRINOX toxicities. The most common grade ≥3 treatment-emergent adverse events in the ibrilatazar vs placebo were neutropenia (21% vs 22%), diarrhea (21% vs 16%), and neurotoxicity (0% vs 14%). **Conclusions:** Although primary PFS endpoint was not met in the ITT population, exploratory analysis showed clinically meaningful and consistent efficacy improvements among ECOG 0 patients treated with ibrilatazar plus FOLFIRINOX, with 60% and 70% increases in median OS and median PFS respectively. These findings support further investigation in selected mPDAC populations and suggest ECOG may modify treatment benefit. Clinical trial information: NCT04431258. Research Sponsor: RFA-FD-20-001 (Clinical Studies of Orphan Products Addressing Unmet Needs of Rare Diseases (R01)); FD-R-006817-01; Funding Source Name: H2020 - EIC - SMEInst - 2018 - 2020; 954825.

A phase II trial of binimetinib in combination with encorafenib in patients with pancreatic malignancies and a somatic *BRAF*^{V600E} mutation. First Author: Tara Tamar Arouchian, Samuel Oschin Comprehensive Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a notoriously difficult-to-treat malignancy, with limited therapy options for patients with advanced disease. While KRAS mutations are the dominant oncogenic driver in PDAC, next-generation sequencing has enabled the identification of rare, targetable alterations such as the BRAF V600E mutation, which occurs in approximately 2-3% of cases. BRAF mutant cell lines are responsive to MEK and RAF inhibitors. This study evaluates the efficacy of the combination of encorafenib and binimetinib as ≥ 2nd line therapy in this specific molecular subgroup of pancreatic cancer patients. **Methods:** This study used a planned two-stage design. Seven patients were pre-registered; one did not meet eligibility criteria and was excluded. Six patients were enrolled in Stage 1, which required an objective response (OR) in 40% of patients to proceed to Stage 2. Stage 2 was planned to enroll an additional 16 patients, contingent on meeting this efficacy threshold. Enrolled patients received treatment in 28-day cycles until disease progression or for a maximum of 36 cycles. Patients self-administered encorafenib (450 mg orally once daily) and binimetinib (45 mg orally twice daily) starting on Day 1 of each cycle. Objective responses were assessed using RECIST version 1.1 over 24 weeks. **Results:** The median number of cycles was 8. The objective response rate at 24 weeks was 33.33%. The overall objective response rate was 50%. The median time to response for progression-free survival, overall survival, duration of response, and time to response was 7.1, 15.0, 9.9, and 3.9 months respectively, with 95% CI in all categories. 50% of patients experienced at least one Grade ≥3 adverse event, including anemia, thromboembolic events, and acute kidney injury. **Conclusions:** The six BRAF-V600E-mutated PDAC patients in our cohort demonstrated meaningful antitumor activity with a manageable safety profile after treatment with encorafenib and binimetinib. Although the study was prematurely terminated due to limited accrual, observed objective responses and survival outcomes suggest that dual RAF/MEK inhibition may represent a feasible therapeutic strategy in this rare molecular subgroup. Larger studies are warranted to further define the efficacy and safety of this treatment combination in BRAF-V600E-mutated pancreatic cancer. Clinical trial information: NCI-2020-02972. Research Sponsor: None.

TME-informed bioprinted 3D tissue model as used to characterize architecture-associated drug uptake and response in PDAC. First Author: Amr Mahmoud, CerFlux, Birmingham, AL

Background: Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest solid tumors despite extensive drug development efforts. Beyond tumor cell-intrinsic factors, therapeutic failure in PDAC is strongly influenced by the tumor microenvironment (TME), which is dominated by a collagen-rich desmoplastic extracellular matrix (ECM). This architecture alters tissue mechanics, restricts diffusion, and limits effective drug delivery to tumor cells. However, most preclinical platforms rely on 2D models that fail to capture human-relevant TME architecture, potentially leading to overestimation of drug uptake and potency. Amid growing regulatory and scientific momentum toward New Approach Methods (NAMs), there is an urgent need for human-relevant, architecture-aware models that improve translational predictivity in PDAC. **Methods:** Primary human PDAC specimens were analyzed using quantitative, spatially resolved TME mapping to characterize extracellular matrix (ECM) composition, collagen density, and intratumoral versus peripheral distribution. From our prior PDAC analysis, human tumors exhibited collagen-dominant ECM with diffuse intratumoral organization rather than peripheral confinement. These architectural features were used to configure a 3D bioprinted *ex vivo* slice tissue (BEST) PDAC model using PANC02 cells. Drug uptake kinetics and therapeutic response were evaluated in TME-informed 3D BEST models and directly compared with conventional 2D monolayer cultures using matched compounds and exposure paradigms. **Results:** Spatial TME mapping confirmed that human PDAC tumors harbor dense, heterogeneously distributed collagen spanning the tumor parenchyma, a feature not captured by simplified culture systems. Incorporation of these intratumoral collagen features into the 3D BEST model resulted in delayed drug uptake and attenuated response dynamics consistent with diffusion-limited transport. In contrast, 2D models demonstrated accelerated growth kinetics, more rapid drug uptake, and higher apparent drug potency over shorter exposure durations. These findings indicate that architecture-associated transport barriers intrinsic to PDAC substantially modulate therapeutic response and that conventional 2D systems may overestimate drug efficacy by failing to account for collagen-mediated resistance mechanisms. **Conclusions:** By directly linking quantitative TME mapping to 3D model configuration, this NAMs-aligned bioprinted PDAC platform captures architecture-associated constraints on drug uptake that are absent from conventional models. This approach provides a human-relevant framework for evaluating therapeutic response in desmoplastic tumors and supports improved translational fidelity and therapeutic prioritization in PDAC. Next-generation cancer organoids 2.0 in precision cancer medicine: Patient-derived pancreatic ductal adenocarcinoma organoids model to describe drug sensitivity and complexity of tumor biology. First Author: Joo Kyung Sophie Park, Samsung Medical Center, Seoul, South Korea

Background: Organotypic models of patient-specific tumors are revolutionizing our understanding of cancer heterogeneity and its implications for personalized medicine. The study's aims were as follows: 1) to establish a PDAC patient-derived organoid (PDO) model obtained from various PDAC specimens. 2) to find out clinicogenomic factors affecting patients' outcomes. **Methods:** The SMC PDAC Cohort Patients were prospectively enrolled and underwent EUS-guided FNB, metastatic sites (such as liver, ascites, lung, and bone), and surgical resection. PDAC PDOs were comprehensively analyzed for histology, next generation sequencing (NGS), and high-throughput screening (HTS) drug sensitivity tests. **Results:** The 735 PDAC patients were prospectively enrolled in this study. PDAC PDO platform has been trying to establish from the following cancer specimens: ascites, biopsies from bone, liver, lung, and pancreas, or surgical resection. The success rate was as follows according to the source of obtaining site; ascites due to peritoneal seeding (3/3: 100%), bone mets (1/1: 100%), EUS-FNB (195/183: 87.8%), liver mets (7/8: 87.5%), lung mets (1/1: 100%), surgical specimens (394/500: 78.8%) and PDO was successfully established within 8.2 ± 2.6 days. It took approximately 3 weeks to acquire each specimen and generate sufficient PDAC PDOs for the simultaneous HTS drug sensitivity test and NGS. Whole exome or genome sequencing (WES/WGS, n = 357) showed an almost identical concordance between original PDAC tissues and matched PDOs and the increased frequency of genetic alterations in PDOs. The HTS drug sensitivity test (n = 151) revealed the clinical correlation between the PDO response and the actual chemotherapeutic response of the study patients in both palliative and adjuvant in real-world settings (ranging from 84.0~ to 91.2%). In addition, whole transcriptome sequencing (n = 373) identified nab-paclitaxel resistance-associated genes such as ITGB7, ANPEP, and ST3GAL1, and also found early recurrence-related genes including COL2A1, CALB1, and CYP24A1 in the extracellular matrix, calcium signaling, and vitamin D metabolism. **Conclusions:** The PDAC PDO platform may become a valuable tool for personalized medicine and may give us insights into tumor biology. Research Sponsor: None.

Actionable genomic alterations and survival in *KRAS* wild-type pancreatic ductal adenocarcinoma: Analysis of the MSK-CHORD 2024 clinico-genomic cohort with spotlight on *NRG1* fusions. First Author: Ayham Al-Omari, Detroit Medical Center - Wayne State University, Detroit, MI

Background: Pancreatic ductal adenocarcinoma (PDAC) is predominantly driven by KRAS mutations; however, approximately 10% of tumors are KRAS wild-type (KRAS-WT). Among these, NRG1 gene fusions have recently gained heightened clinical relevance following the FDA's accelerated approval of zenocutuzumab for NRG1 fusion–positive PDAC after prior therapy. Contemporary real-world data characterizing actionable alteration yield and outcomes in KRAS-WT PDAC remain limited. **Methods:** We analyzed patients with PDAC (OncoTree: PAAD) from MSK-CHORD 2024. KRAS status was defined by the presence or absence of pathogenic KRAS somatic mutations. NRG1 fusions were identified through structural variant analysis. A predefined clinically actionable alteration set included NRG1 and NTRK1–3 fusions, MSI-H/dMMR, BRCA1/2 or PALB2 alterations, ERBB2 amplification, and BRAF V600E mutation. The primary endpoint was overall survival (OS) from the date of molecular profiling. Secondary endpoints included prevalence of actionable alterations within KRAS-WT PDAC and enrichment of NRG1 fusions by KRAS status. **Results:** Among 2,703 patients with PDAC, 2,424 (89.7%) had KRAS mutations and 279 (10.3%) were KRAS-WT. NRG1 fusions were identified exclusively within KRAS-WT tumors (4/279; 1.43%) and were absent among KRAS-mutant PDAC. As summarized in Table 1, 25 of 279 KRAS-WT PDAC patients (9.0%) had at least one clinically actionable genomic alteration. These included NRG1 and NTRK fusions, MSI-H/dMMR, homologous recombination repair gene alterations, ERBB2 amplification, and BRAF V600E mutation. Median OS differed substantially by KRAS status. Patients with KRAS-WT PDAC demonstrated longer survival compared with those with KRAS-mutant disease (26.3 vs 14.9 months). Patients with NRG1 fusion–positive PDAC had a median OS of 22.9 months, acknowledging limited sample size (n=4). **Conclusions:** KRAS-WT PDAC accounts for approximately one-tenth of cases and is associated with significantly longer overall survival compared with KRAS-mutant disease. Nearly 1 in 10 KRAS-WT tumors harbored clinically actionable genomic alterations, including NRG1 fusions, now linked to an FDA-approved targeted therapy. These findings support routine comprehensive molecular profiling, including fusion detection, in KRAS-WT PDAC and underscore the clinical relevance of precision oncology approaches in this distinct subgroup. Research Sponsor: None.

Genomic characteristics and actionable alterations in KRAS–wild-type PDAC (MSK-CHORD 2024).

Characteristic	KRAS-Mutant PDAC (n=2,424)	KRAS–Wild-Type PDAC (n=279)
Median OS, months	14.9	26.3
Any actionable alteration*	–	25 (9.0%)
NRG1 fusion	0 (0%)	4 (1.43%)
NTRK1–3 fusion	–	3 (1.08%)
MSI-H/dMMR	–	2 (0.72%)
BRCA1/2 mutation	–	6 (2.15%)
PALB2 mutation	–	1 (0.36%)
ERBB2 amplification	–	5 (1.79%)
BRAF V600E	–	7 (2.51%)

Exosomal miRNA signatures as predictors of response to neoadjuvant FOLFIRINOX and GEM/nab-paclitaxel in resectable pancreatic cancer: The PRECEPT study. First Author: Takayuki Noma, Department of Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of City of Hope, Biomedical Research Center, Monrovia, CA

Background: Neoadjuvant chemotherapy (NAC) with FOLFIRINOX or gemcitabine plus nab-paclitaxel (GEM/nab-PTX) is widely used for resectable and borderline-resectable pancreatic ductal adenocarcinoma (PDAC). However, 10–20% of patients experience disease progression or severe toxicity during NAC, leading to loss of opportunity for curative resection. Given substantial differences in treatment responsiveness between regimens, reliable regimen-specific predictive biomarkers are needed to improve preoperative risk stratification and treatment selection. The PRECEPT trial (NCT07226154) aims to develop circulating exosomal microRNA (exo-miRNA)–based predictors of NAC response. **Methods:** Pre-treatment plasma samples were collected from patients with resectable or borderline-resectable PDAC prior to NAC. Exo-miRNAs were profiled by small RNA sequencing in a discovery cohort of 49 patients (FOLFIRINOX, n = 31; GEM/nab-PTX, n = 18) to identify regimen-specific candidate exo-miRNAs, which were subsequently quantified by qRT-PCR in a validation cohort of 73 patients (FOLFIRINOX, n = 43; GEM/nab-PTX, n = 30). Regimen-specific miRNA panels were constructed using stepwise selection followed by Firth penalized logistic regression. To benchmark against conventional biomarkers, multivariable Firth logistic regression models including the panel score and baseline CA19-9 were performed to evaluate the incremental predictive value of the exo-miRNA panels. Predictive performance was assessed by receiver operating characteristic (ROC) analysis. **Results:** In the discovery cohort, exo-miRNA signatures achieved areas under the curve (AUC) of 0.953 for the FOLFIRINOX panel and 1.000 for the GEM/nab-PTX panel. In the qRT-PCR validation cohort, performance remained robust (AUC 0.835 and 0.882, respectively). Higher panel scores were significantly associated with non-response to NAC ($p < 0.01$). In multivariable analyses, the exosome-derived miRNA panels provided predictive information beyond CA19-9 and remained independent predictors of treatment non-response in both therapeutic cohorts, demonstrating incremental value over conventional biomarkers. Both panels showed high sensitivity with low false-negative rates, supporting their clinical utility in identifying patients unlikely to benefit from neoadjuvant chemotherapy for each regimen. **Conclusions:** We developed two regimen-specific circulating exo-miRNA panels capable of predicting response to FOLFIRINOX and GEM/nab-PTX prior to treatment initiation. These panels provide predictive information beyond CA19-9 and may support individualized NAC selection, risk-adapted treatment planning, and improved preoperative decision-making in resectable PDAC. Clinical trial information: NCT07226154. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Phase I clinical trial evaluating dual-targeting CAR-T cells (KD-496) against CLDN18.2 and NKG2DL in advanced gastrointestinal cancers and pancreatic cancers. First Author: Panpan Zhang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Early Drug Development Centre, Peking University Cancer Hospital & Institute, Beijing, Beijing, China

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has shown limited efficacy in gastrointestinal (GI) cancers. Previous studies indicate that bispecific CAR-T cells incorporating tandem single-chain variable fragments (scFvs) demonstrate enhanced therapeutic indices compared to monospecific constructs. We developed novel bispecific CAR-T cells (KD-496) targeting both NKG2D ligands and CLDN18.2, demonstrating promising preclinical antitumor activity and safety profiles. **Methods:** We conducted an open-label, single-arm, "3+3" dose-escalation study (NCT06134960) in patients with treatment-refractory advanced GI cancers. Following lymphodepletion with fludarabine, cyclophosphamide, and nab-paclitaxel, subjects received a single KD-496 infusion at three dose levels: 1×10^8 (DL1), 3×10^8 (DL2), or 5×10^8 (DL3) CAR-T cells. Primary endpoints included safety and toxicity; secondary endpoints comprised efficacy, pharmacokinetics, and immunogenicity. **Results:** Between March 2024 and October 2025 , seven subjects (age range: 43-73 years) received KD-496 treatment (n=3 at DL1; n=3 at DL2; n=1 at DL3). Only one Grade IV possibly treatment-related adverse events (TRAEs) is Neutrophil count decreased (14%); Grade III possibly treatment-related adverse events (TRAEs) included Neutrophil count decreased (14%); Alanine aminotransferase increased (14%); Elevated aspartate aminotransferase (14%); anemia (29%); and White blood cell decreased (57%). Cytokine release syndrome (CRS) occurred in seven subjects, with one case (17%) reaching grade 3; no grade 4/5 CRS or neurotoxicity was observed. The dual-antigen requirement effectively prevented on-target off-tumor toxicity, with no patients experiencing severe gastrointestinal adverse events. No dose-limiting toxicities or serious adverse events were reported. Among evaluable subjects: Those with gastric cancer (n=4), achieved an objective response rate (ORR) of 75%; Among three subjects with pancreatic cancer, disease control rate (DCR) of 66.7% overall; Achieved an objective response rate (ORR) of 33% overall. Notably, the ORR reached 100% for both gastric cancer and pancreatic cancer advanced subjects in the medium-dose group. **Conclusions:** These initial data demonstrate a favorable safety profile for KD-496 CAR-T cells targeting NKG2DL/CLDN18.2. The preliminary efficacy signals warrant further investigation of KD-496, particularly in gastric cancer and pancreatic cancer. Clinical trial information: NCT06134960. Research Sponsor: Nanjing KAEDI Biotherapeutics.

Nab-paclitaxel plus S-1 induction chemotherapy for patients with locally advanced pancreatic cancer: A multicenter, open-label phase 2 study. First Author: Zhe Cao, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: The prognosis of locally advanced pancreatic cancer is dismal. The objective of the present study was to evaluate safety and efficacy of nab-paclitaxel plus S-1 in previously untreated locally advanced pancreatic cancer. **Methods:** This multicenter, single-arm phase 2 study was conducted at 4 centers in China. Patients with Eastern Cooperative Oncology Group performance status of 0-1 received up to 8 cycles of nab-paclitaxel 120 mg/m² (day 1,8) plus 80-120mg/d S-1 (day 1-14 each 21-day cycle). After induction, patients without disease progression or unacceptable adverse events were eligible to receive continued therapy according to investigators' evaluation, including: continued chemotherapy, chemoradiation, or surgery. The primary endpoint was 6-month progress-free survival rate. The secondary endpoints were progress-free survival, overall survival, objective response rate, R0/R1 rate and safety. The reported efficacy outcomes were analyzed in the intention-to-treat population, and safety outcomes were analyzed in the treated population. This trial is registered with ClinicalTrials.gov, NCT03885219. **Results:** Between April 25, 2019, and March 29, 2023, 60 patients were enrolled in the study. 31 (51.7%) of 60 enrolled patients discontinued induction therapy, with reasons including disease progression (13 [21.7%] patients), adverse events (12 [20.0%] patients), alteration in treatment (4 [6.7%] patients), and withdrawal from study (2 [3.3%] patients). 29 (48.3%) of 60 enrolled patients completed induction treatment, 22 (36.7%) patients finished all 8 cycles of treatment, and 11 (18.3%) patients underwent surgery (10 achieved R0/R1 resection status). The 6-month progression-free survival rate was 71.0% (95%CI: 57.6%-80.9%); 12-month progression-free survival rate was 45.0% (95%CI: 32.0%-57.2%) and 12-month overall survival could reach up to 83.3% (95%CI: 70.3%-90.9%). The median progression-free survival was 11.1months (95% CI: 8.1-14.2); median overall survival was 20.2 months (95% CI: 11.2-29.2). During induction, 54 patients achieved disease control and the disease control rate was 90.0% (95% CI: 79.5%-96.2%). 16 patients had a best response of partial response; the objective response rate was 26.7% (95% CI: 16.1%-39.7%). Grade 3 or higher treatment-related adverse events (TRAEs) occurred in 32 (53.3%) patients. The most common grade 3 or higher TRAEs were neutropenia (23 [38.3%] of 60 patients), followed by leukopenia (13 [21.7%]) and fatigue (4 [6.7%]). No treatment-related deaths were reported. **Conclusions:** The data from this trial supports the favorable and efficacy of nab-paclitaxel plus S-1 for locally advanced pancreatic cancer, as well as the possibility of converting unresectable disease into surgically resectable disease. Clinical trial information: NCT03885219. Research Sponsor: None.

Plasma small extracellular vesicle microRNAs as non-invasive biomarkers for the diagnosis of pancreatic ductal adenocarcinoma. First Author: Yue Zhang, The Third Affiliated Hospital of Soochow University, Changzhou, Jiangsu, China

Background: Current non-invasive approaches for the diagnosis of pancreatic ductal adenocarcinoma (PDAC) exhibit inherent limitations in accuracy. Consequently, there exists an urgent and unmet need for novel non-invasive biomarkers exhibiting high sensitivity and specificity to enable PDAC diagnosis. **Methods:** We employed small RNA sequencing to detect microRNA (miRNA) expression in small extracellular vesicles (sEVs) isolated from plasma samples of study participants (n = 208). A diagnostic model was developed (n = 140) and validated (n = 68) to discriminate between patients with PDAC and non-malignant controls (healthy individuals, chronic pancreatitis, intraductal papillary mucinous neoplasms, serous cystadenomas, solid pseudopapillary tumors, pancreatic cysts, and pancreatic abscesses). **Results:** The small RNA sequencing analysis of plasma sEV miRNA identified 32 differentially expressed sEV miRNAs between non-malignant controls and PDAC patients. The diagnostic model with the best performance was constructed using 17 sEV miRNAs. The diagnostic model achieved an area under curve (AUC) of 0.939, a sensitivity of 93%, and a specificity of 90% in the training cohort and an AUC of 0.951, a sensitivity of 95%, and a specificity of 83% in the test cohort. We identified the distinct characteristics of plasma sEV miRNAs among non-malignant controls compared to PDAC patients. Moreover, nine negative miRNAs and one positive miRNA were found significantly associated with the death risk of PDAC (all $p < 0.05$). **Conclusions:** Our findings demonstrates that plasma sEV miRNA exhibits a highly discriminative biomarker for distinguishing non-malignant group from malignant group, making it a promising tool for the diagnosis of PDAC. Research Sponsor: None.

Impact of radiologically identified embryological origin on recurrence patterns and survival in resectable pancreatic head adenocarcinoma. First Author: Imdat Eroglu, Gazi University School of Medicine, Department of Medical Oncology, Ankara, Turkey

Background: The pancreatic head develops embryologically from the fusion of the dorsal pancreatic (Dp) and ventral pancreatic (Vp) buds, which differ in cellular composition. Although histopathology is considered the gold standard for distinguishing these structures, they can also be differentiated radiologically. The prognostic significance of the embryological origin of pancreatic head adenocarcinomas remains unknown. This study aimed to investigate the impact of tumor embryological location on survival outcomes in patients with resectable pancreatic head adenocarcinoma. **Methods:** Patients who underwent surgical resection for pancreatic head adenocarcinoma were retrospectively analyzed. Preoperative conmputed tomography images were used to determine the embryological tumor location. The boundary between Dp and Vp was defined as a line connecting the portal vein/superior mesenteric vein to the anterior margin of the intrapancreatic bile duct. Tumors located predominantly ($\geq$80%) on one side of this boundary were classified accordingly, while tumors without $\geq$80% predominance in either region were classified as mixed. Patients were grouped as Vp, Dp, or mixed pancreatic (Mp) origin. The primary endpoint was overall survival (OS), and the secondary endpoint was progression-free survival (PFS). **Results:** A total of 164 patients were included. Tumor origin was classified as Vp in 74 patients (45.1%), Dp in 63 patients (38.4%), and Mp in 27 patients (16.5%). Mp tumors were associated with a significantly higher rate of grade 3 tumors (48.1% in Mp vs 21.6% in Vp and 23.8% in Dp, p = 0.005) and advanced T stage (T3–T4: 70.3% in Mp vs 32.4% in Vp and 47.6% in Dp, p = 0.009). Other baseline clinicopathological characteristics, and the rates of adjuvant chemotherapy and radiotherapy were similar among groups. Median PFS was 11.2 months (95% CI 10.5–11.9) in Mp, 13.0 months (95% CI 9.3–16.7) in Vp, and 9.8 months (95% CI 7.6–11.9) in Dp (p = 0.032). All recurrences in the Dp group were distant metastases, whereas Mp tumors recurred predominantly as distant metastases (85.7%) and Vp tumors showed a higher proportion of local recurrence (33.3%) ($p < 0.001$). Median OS was significantly longer in the Vp group (Mp: 16.7 months, 95% CI 8.9–27.4; Vp: 25.3 months, 95% CI 11.8–37.8; Dp: 16.7 months, 95% CI 13.2–20.3; p = 0.006). **Conclusions:** The embryological origin of pancreatic head adenocarcinoma is associated with distinct pathological features, survival outcomes, and recurrence sites. Vp-origin tumors demonstrate superior OS but higher local recurrence rates, whereas Dp-origin tumors are characterized by early distant metastasis. Preoperative CT-based identification of tumor origin serves as a non-invasive prognostic tool that may guide personalized adjuvant strategies, such as intensifying systemic therapy for Dp/Mp tumors or optimizing local control for Vp tumors. Research Sponsor: None.

Early detection of pancreatic ductal adenocarcinoma (PDAC) with a multiomic liquid biopsy. First Author: Holly Butler, Dxcover Ltd, Glasgow, United Kingdom

Background: Early diagnosis remains the major unmet challenge in pancreatic ductal adenocarcinoma (PDAC), which accounts for approximately 3% of all cancers but nearly 8% of cancer-related deaths in the United States, reflecting its exceptionally poor prognosis. Overall five-year survival remains below 15%, largely because the majority of patients present with unresectable or metastatic disease at diagnosis. Curative surgical resection is feasible in fewer than 20% of cases. There is a critical need to improve risk stratification and diagnostic triage among high-risk populations, including individuals with pancreatic cystic lesions, chronic pancreatitis, and new-onset diabetes over the age of 50. However, the low short-term incidence of PDAC in these groups limits the feasibility of widespread surveillance using current imaging modalities. **Methods:** In this study, a spectroscopic blood test has been evaluated as an alternative strategy for PDAC detection. This technology employs infrared (IR) spectroscopy to interrogate blood samples, generating disease-specific spectral signatures sensitive to cancer-associated biochemical alterations. When integrated with machine learning, the approach enables detection by capturing global changes across all biomolecular components of the sample. Initially, spectra from 166 patients with PDAC were classified against those from 459 symptomatic patients with non-cancer diagnoses. The trained algorithms are then independently tested on an additional clinical dataset focused on the higher risk population (n = 975). **Results:** The initial receiver operating characteristic (ROC) curve reported an area under the curve (AUC) value of 0.84. The diagnostic algorithm reported 92% sensitivity with 52% specificity. Importantly, the model did not seem to be affected by cancer stage. The detection rates with the sensitivity-tuned model were 88% stage I, 94% stage II, 99% stage III and 95% stage IV. Validation testing provided additional confirmation of diagnostic ability in the intended use population. The ROC curve for PDAC versus all control patients reported an AUC of 0.81, and PDAC classified against high-risk non-cancers produced an AUC of 0.83. **Conclusions:** Earlier detection of PDAC has the potential to substantially improve patient outcomes and survival. While advances in genetic sequencing have enabled the identification of tumor-derived biomarkers—including circulating tumor DNA, exosomes, and microRNA—these approaches are limited in early-stage PDAC due to low tumor burden and weak signal from circulating markers. A spectroscopy-based, multi-omic blood test represents a novel strategy that may overcome these limitations, particularly in high-risk populations. Research Sponsor: None.

A phase II multicenter study of NASOX regimen as adjuvant chemotherapy for patients with resected pancreatic ductal adenocarcinoma. First Author: Kuirong Jiang, Pancreas Center, The First Affiliated Hospital with Nanjing Medical University, Nanjing, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is the fifth leading cause of cancer-related mortality in China, with a 5-year survival rate of only 5%–7%. Surgical resection followed by adjuvant chemotherapy can improve this to 15%–25%, but more effective adjuvant regimens are urgently needed to further prolong survival. The PRODIGE 24/CCTG PA.6 trial demonstrated that the mFOLFIRINOX regimen significantly improved outcomes compared with gemcitabine alone. The NASOX regimen is a modified mFOLFIRINOX regimen, which uses irinotecan hydrochloride liposomes (nal-IRI) instead of irinotecan and oral fluoropyrimidine tegafur instead of fluorouracil, and has demonstrated a favorable safety profile. This study aims to assess the efficacy and safety of NASOX as an adjuvant chemotherapy regimen for patients with resected PDAC. **Methods:** This is a Phase II, single-arm, open-label, multicenter clinical trial to evaluate the efficacy and safety of NASOX as adjuvant chemotherapy in patients with resected PDAC. The primary endpoint is DFS. Secondary endpoints include overall survival (OS), safety, quality of life (QoL), compliance with adjuvant therapy, and nutritional status. Exploratory endpoints will involve genomic, metabolomic, and proteomic analyses to identify biomarkers that may predict response and safety to NASOX regimen **Results:** Between August 2024 and October 2025, 55 patients were screened, with 53 ultimately enrolled. Age ranged from 34 to 73 years (median: 59). Forty-six patients underwent at least one tumor assessment, with 11 experiencing disease recurrence and 3 deaths. Median follow-up was 11.5 months(interquartile range 9.9–15.5), yielding a 9-month DFS rate of 82.7% a 9-month OS rate of 97.7%, with median DFS and OS not yet reached. Treatment-related adverse events (TRAEs) occurred in 52 patients (100%), including grade 3 or 4 adverse events in 28 patients (53.85%). The most common Grade 3–4 treatment-related adverse events were diarrhea (17.31%), neutropenia (17.31%), hypokalemia (11.54%), and gastrointestinal pain (9.62%). **Conclusions:** NASOX regimen demonstrated the anticipated efficacy and safety profile in the adjuvant treatment of PDAC following surgery, warranting further investigation. Clinical trial information: NCT06361316. Research Sponsor: None.

Safety, efficacy, and immunogenicity of adjuvant therapy with personalized cancer vaccine (PCV) RGL-270 in combination with adebrelimab and mFOLFIRINOX in resectable pancreatic ductal adenocarcinoma (PDAC). First Author: Si Shi, Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Tumor specific neoantigens are peptides carrying somatic mutations presented by HLA molecules and recognized by T cells, which subsequently induce specific immune response (IR). The IR could be further boosted when in combination with PD-1/L1 inhibitor. RGL-270 is a lipid nanoparticle (LNP)-encapsulated, mRNA-based PCV, encoding tumor specific neoantigens screened via a proprietary algorithm to induce patient specific IR. This investigator-initiated, open-label, dose escalation and expansion clinical trial was conducted in China, to evaluate the safety, efficacy and immunogenicity of RGL-270 in combination with adebrelimab (anti-PD-L1 mAb) in patients with resectable PDAC. **Methods:** PDAC patients with R0/R1 surgical margins were enrolled. After surgery, RGL-270 was administrated up to 9 cycles, in combination with adebrelimab and followed by modified FOLFIRINOX chemotherapy. The key endpoints included safety, efficacy assessment with recurrence-free survival (RFS), overall survival (OS), 18-month RFS rate, and PCV specific IR evaluation by ELISpot. **Results:** As of 01/15/2026, 16 patients in the dose escalation (n = 7) and expansion (n = 9 at expansion dose level) stage received RGL-270 combo with adebrelimab therapy. Up to date, all dose levels were safe and well tolerated. The most common treatment-related adverse events (TRAEs) were fever, influenza-like illness and injection-site reactions. All TRAEs were CTCAE grade 1~2 and no treatment-related SAE or DLT was reported. Currently, the median follow-up is 18.0 months, with median RFS and OS not reached yet, and the 18-month RFS rate is 100%.The PCV-specific IR positive rate was 100%. Interestingly, IR was also detected in patients who had undergone prior splenectomy (5/16). The primary IR emerged as early as 2 cycles after the first PCV administration, with the best of response (BoR) observed 2~4 cycles post-baseline and, in most cases, persisting until cycle 9, the booster cycle. To date, no dose-dependent manner for IR has been observed. Additionally, concordance between the predicted and immunogenic neoantigens was analyzed, and the resulting insights were fed back to improve the neoantigen screening algorithm. Furthermore, bulk T-cell receptor sequencing was performed to further characterize the PCV specific IR. **Conclusions:** Based on proprietary LNP delivery systems, algorithms for neoantigen identification and immunogenicity prediction, the combination treatment of RGL-270 and adebrelimab demonstrated a favorable safety profile, promising efficacy, and robust immunogenicity. This preliminary result guarantees the further development of PCV-based anti-tumor therapy in the adjuvant setting for PDAC. Clinical trial information: NCT06156267. Research Sponsor: Noncommunicable Chronic Diseases-National Science and Technology Major Project (2024ZD0525500/2024ZD0525505).

Experience of Spanish centers with echoendoscopically implanted ^{32}P microparticles associated with chemotherapy in locally advanced pancreatic adenocarcinoma. First Author: Carmen Guillen-Ponce, Hospital Universitario Ramon y Cajal, Irycis, Madrid, Spain

Background: Phosphorous 32 microparticle (^{32}P) brachytherapy delivered by echoendoscopy (EUS) represents an innovative therapy in pancreatic cancer (PC). The device to implant it is approved in unresectable locally advanced PC in combination with gemcitabine-based chemotherapy. Our aim is to present the preliminary efficacy and safety results of a series that brings together the experience of thirteen centres in Spain. **Methods:** After being assessed by a multidisciplinary committee, patients signed consent to receive intratumoural ^{32}P by EUS. Complications associated with intratumoural 32P injection via EUS, associated adverse events (AEs) and preliminary efficacy results (progression-free survival [PFS], distant and locoregional, and overall survival [OS]) were analysed. **Results:** Fifty one patients (32 females and 19 males; age 65.5 years [range 48, 84]; 36 ECOG 1 and 14 ECOG 0) with unresectable locally advanced PC (30 in head, 5 in uncinate, 5 in neck and 11 in body; tumour size 30.8 mm [range 12, 60]) were included. The median time from tumour diagnosis to procedure was 5.9 months [0, 28.9]. Twenty-four patients (47 %) had received at least one previous line of treatment; four had received two prior lines. Fifty patients (98%) received gemcitabine-based chemotherapy concomitant with intratumoural 32P (42 gemcitabine plus nabpaclitaxel; 8 gemcitabine monotherapy. There were two AEs related to 32P injection by EUS: G1 epigastric pain (1 patient) and G2 asthenia (1 patient). A total of 30 patients (58.8%) had chemotherapy-related AEs, with 8 cases of G3 neutropenia (1 febrile neutropenia) and/or G3 thrombopenia; 22 had G1-2 toxicities: neurotoxicity (5), asthenia (4), neutropenia (3), thrombopenia (2), anaemia (4), nausea (2), diarrhoea (2), anorexia (1), onycholysis (1), mucositis (1), and constipation (1). Seven patients (13,7%) underwent surgery after intratumoural treatment (5 R0 and 2 R1). With a median follow-up of 8.7 months after injection (range: 1.02 months to 40.77 months), 25 patients (49.2 %) have progressed, 19 of them distantly, and nine also locoregionally. The median PFS since 32P injection is 8.5 months (95% CI 5.3, 17). 33 patients are alive at the end of follow-up (64.7%) with a median OS since 32P injection of 15.6 months 95% CI [10.2, 26.9]. **Conclusions:** Our experience suggests that intratumoural 32P associated with gemcitabine-based chemotherapy is safe. Patients after 32P injection achieve long overall survival. Surgical rescue was achieved in a high percentages of initially unresectable cases. Research Sponsor: None.

Distinct multi-omic signatures that underlie *KRAS* variants and survival in *KRAS* G12R pancreatic cancer. First Author: Sargis Hovhannisyan, Cedars-Sinai Medical Center, Los Angeles, CA

Background: KRAS mutations are the dominant oncogenic drivers of pancreatic ductal adenocarcinoma (PDAC). While KRAS G12D/V variants are associated with aggressive disease and poor prognosis, the biological basis for survival differences among KRAS variants remains incompletely defined. We leveraged a comprehensive multi-omics dataset to characterize variant-specific molecular signatures associated with survival. **Methods:** Tissue and plasma samples from 72 patients with Stage I/II resectable PDAC were retrospectively analyzed using the Aseesa Stars multi-modal integrated platform. Multi-omic profiling included targeted DNA sequencing, whole-transcriptome RNA sequencing, tissue and plasma proteomics, lipidomics, and computational pathology, generating 6,363 features linked to overall survival (OS). Analyses focused on KRAS wild-type (n=7) and the most prevalent KRAS variants: G12R (n=12), G12D (n=21), and G12V (n=13). **Results:** Patients with KRAS G12R who underwent upfront resection demonstrated significantly longer OS compared with G12D/V variants (median OS 37.5 vs. 18.9 months; HR 0.50 [95% CI 0.23–1.09]; log-rank p=0.047). Compared with KRAS-WT, combined KRAS-mutant tumors exhibited significant alterations in neutrophil degranulation, apoptosis, protein transport, cell adhesion, and oxidative phosphorylation (OXPHOS) pathways ($p<0.05$). A total of 381 molecular signatures differed significantly ($p<0.05$) between G12R and G12D/V cohorts. In direct G12R vs. G12D comparison, 110 features were unique to high OS ($p<0.05$). KRAS G12R, G12D and G12V shared activation of PI3K/AKT, MET, and PTPN11 signaling, consistent with a common aggressive phenotype. In contrast, KRAS G12R tumors demonstrated significant alterations in major mRNA splicing and OXPHOS pathways ($p<0.05$). Splicing regulators PLRG1 and RBM8A were reduced in G12R patients by 6% ($p<0.03$). Six OXPHOS-related signatures also favored high OS, lipid hexosylceramide 24:1 was decreased by 14.59% (p=0.016). Tissue protein ACADS decreased by 5.38% (p=0.025) in G12R high OS, but increased in G12D high OS. **Conclusions:** KRAS G12R defines a molecularly distinct PDAC subtype with improved survival, characterized by suppressed mRNA splicing signatures and coordinated metabolic remodeling, highlighting variant-specific metabolic and molecular divergence. These findings underscore the importance of KRAS variant stratification for prognostication and future development of variant-specific precision therapeutic strategies. Risk-adapted step-up local therapy for malignant portal vein tumor thrombus from hepatic metastases: A real-world study of microwave ablation with and without iodine-125 seed implantation. First Author: Hoang Tran Pham, Department of Internal Medicine, Trinity Health Ann Arbor Hospital, Ann Arbor, MI

Background: Malignant portal vein tumor thrombus (PVTT) arising from hepatic metastases is associated with poor prognosis, rapid hepatic decompensation, and limited effective local treatment options despite systemic therapy. In real-world practice, local treatment intensity is frequently adapted to disease burden and treatment response. We evaluated outcomes of a risk-adapted, step-up local treatment strategy using microwave ablation (MWA) alone or in combination with iodine-125 (I-125) seed implantation for patients with malignant PVTT. **Methods:** We retrospectively reviewed patients with hepatic metastases treated with MWA with or without I-125 seed implantation between 2023 and July 2025. In clinical practice, MWA alone was preferentially used for patients with relatively limited disease burden, while MWA plus I-125 was employed as an escalation strategy for patients with more advanced PVTT or disease progression following MWA alone. The primary endpoint was PVTT-directed local outcome, defined as portal vein patency and/or local control of tumor thrombus on follow-up imaging. Secondary endpoints included progression-free survival (PFS), overall survival (OS), hepatic function changes, and treatment-related toxicity. Survival analyses were considered exploratory. **Results:** A total of 73 patients were included, of whom 50 were treated with MWA alone and 23 with MWA plus I-125 seed implantation. Patients receiving MWA plus I-125 demonstrated more advanced disease characteristics, including universal presence of PVTT and higher disease stage, consistent with treatment escalation by disease severity. Among patients with PVTT, MWA plus I-125 achieved portal vein patency and/or local control in 65% at first follow-up imaging. Treatment-related toxicities were manageable, with no unexpected grade $\geq$3 adverse events attributable to I-125 implantation. Median PFS was 11.5 months in patients treated with MWA alone and 9.9 months in patients treated with MWA plus I-125, consistent with greater baseline disease burden in the latter group. **Conclusions:** MWA alone and MWA plus I-125 function as complementary components of a risk-adapted, step-up local treatment strategy for malignant PVTT from hepatic metastases. Escalation to MWA plus I-125 appears feasible in patients with advanced or refractory PVTT and demonstrates a potential signal for improved PVTT-directed local control and portal vein patency. Prospective studies focused on PVTT-specific endpoints are warranted. Research Sponsor: None.

Donafenib plus immune checkpoint inhibitors with or without oral fluorouracil chemotherapy drugs (S-1/capecitabine) for patients with resected high-risk biliary tract tumor: A multi-center retrospective study. First Author: Huang Huaiyin, Hunan People's Hospital (Hunan Normal University Affiliated No.1 Hospital), Changsha, China

Background: Chemotherapy combined with Immune Checkpoint Inhibitors (ICIs) and donafenib showed promising efficacy and safety in advanced biliary tract cancer (BTC). Oral fluorouracil chemotherapy drugs S-1 or capecitabine are used as standardized adjuvant therapy for BTC. This study aimed to evaluate the efficacy and safety of donafenib plus ICIs with or without oral fluorouracil chemotherapy drugs as adjuvant therapy in BTC patients with high-risk recurrence factors after radical resection. **Methods:** This multi-center retrospective study enrolled BTC patients with high-risk recurrence factors who underwent surgical resection at Hunan Provincial People's Hospital, Sichuan Provincial People's Hospital, The First Affiliated of Zhengzhou University, Sir Run Run Shaw Hospital and Jiangsu Provincial People's Hospital from Aug 2022 to Nov 2025. All patients exhibited at least one of the following high-risk recurrence factors: macrovascular invasion, lymph node metastasis, satellite lesion, nerve invasion and the maximum diameter of tumors$\geq$5cm. Patients received adjuvant therapy of donafenib plus ICIs with or without S-1/capecitabine after surgery. The primary endpoint was RFS and secondary endpoints included OS and safety. **Results:** A total of 50 patients were enrolled, with a median age of 60.5, included 21 Intrahepatic, 18 hilar cholangiocarcinoma and 11 others. Tumor stage I/II/III/IV, 8/10/25/7; R0/R1 resection, 44/6. All patients exhibited a high risk factor of recurrence at least, the rate of macrovascular invasion, lymph node metastasis, satellite lesion, nerve invasion and the maximum diameter of tumors$\geq$5cm are 40.0%, 42.0%, 6.0%, 70.0% and 34.0%. 20 patients received the adjuvant therapy of S-1/ capecitabine plus donafenib with ICIs, and the other 30 patients were treated with donafenib and ICIs. The median follow-up time was 15.2 months (95%CI: 11.17-18.46), 16 patients relapsed. The median RFS was 14.0 months (95% CI: 11.07-NA), and the one-year RFS rate was 63.8%, two-year RFS rate was 45.1%. T staging of tumor is an independent influencing factor on disease recurrence in the multivariate analysis. The RFS in stage T1/2 patients was significantly higher than stage T3/4. The incidence of grade 3 TEAEs stood at 26.0%, including hand-foot syndrome (44%), anaemia (16%), diarrhea (16%) and rash (12%). No patients encountered grade 5 TRAEs. **Conclusions:** The combination of donafenib plus ICIs with or without oral fluorouracil chemotherapy drugs (S-1/capecitabine) appears to be a promising adjuvant therapy for patients with high-risk biliary tract tumor. Furthermore, no significant safety concerns were observed. Research Sponsor: None.

Deciphering the heterogeneity and cellular interactions of cancer-associated fibroblasts in extrahepatic cholangiocarcinoma by spatial transcriptomics. First Author: Giulia Petroni, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: Cholangiocarcinoma (CCA) is a rare and lethal malignancy characterized by a desmoplastic stroma. containing cancer-associated fibroblasts (CAFs). Although CAFs have been widely studied in intrahepatic CCA, their impact on TME remodeling and chemo-immunotherapy (CIT) efficacy in extrahepatic (e) CCA is not fully elucidated. A compressive characterization of the spatial orchestration of the eCCA TME and of the interaction between CAFs and adjacent tumor cells is needed for the identification of therapies able to improve CIT efficacy, that, so far, is limited in these patients. **Methods:** We employed spatial transcriptomics on tumor specimens from 8 patients with advanced distal (d) or perihilar (p) CCA treated with durvalumab + cisplatin/gemcitabine. 126 microregions were analyzed with the GeoMx Digital Spatial Profiler and classified according to pan-CK and ACTA2/αSMA straining, as follow: $CK^{+}\alpha SMA^{-}$ tumor, $CK^{-}\alpha SMA^{+}$ distant and peritumor CAF-enriched stroma, or $CK^{-}\alpha SMA^{-}$ peritumor stroma. **Results:** αSMA staining showed a high degree of stromal heterogeneity in all eCCA, with some tumor nests surrounded by a dense CAF-enriched stroma and others by αSMA^{-} cells within the same sample. Based on CD45 staining all samples were classified as immune-desert or -excluded, as no immune cells were found intratumorally. Tumor-adjacent CAFs exhibited a distinct extracellular matrix (ECM) remodeling signature marked by the expression of *COL11A1*, *MMP11* and TGFB family members. GSEA showed a positive enrichment of epithelial-mesenchymal transition (EMT) transcripts linked to the downregulation of signatures of immune activation and IFN response, in both peritumoral CAF-enriched regions and adjacent tumor cells. Confirming this data, receptor-ligand interaction modeling performed using the CellChat tool confirmed that CAF-enriched regions exhibited strong interactions with adjacent tumor cells, throughout the secretion of several factors involved in ECM-remodeling and immunosuppression. Intriguingly, a higher expression of EMT-related genes linked to a higher downregulation of pathways of immune activation was observed in dCCA vs pCCA samples, with dCCA patients experiencing a shorter progression-free survival (PFS) from CIT compared to pCCA patients (PFS ranging from 7-12 and 10-24 months, respectively). **Conclusions:** Our findings suggest that $COL11A1^{+}MMP11^{+}$ CAFs might limit CIT efficacy in eCCA by promoting eCCA EMT and, at the same time, by forming a collagen-dense physical barrier that hampers the intratumoral recruitment of immune cells, thus offering novel insights into potential therapeutic targets for interventions. A deeper characterization of CAF features and CAF-tumor interactions is ongoing. Research Sponsor: None.

Real-world outcomes in gastrointestinal cancer patients with targetable genomic alterations identified on serial liquid biopsy. First Author: Linda Albusoul, Henry Ford Cancer Institute, Detroit, MI

Background: Precision oncology in gastrointestinal (GI) cancers relies on identifying targetable genomic alterations (TGA) to guide therapy. Liquid biopsy (LB) using circulating tumor DNA (ctDNA) enables minimally invasive molecular profiling and serial monitoring. As targeted therapies for GI cancers expand, repeat LB is increasingly used to detect emergent alterations. However, the clinical relevance of TGA not previously identified, particularly when detected at low variant allele fraction (VAF) where clonal burden is difficult to infer, remains unclear. **Methods:** GI cancer patients (pts) with >1 LB were identified from the Guardant Health InfinityAI Data Library, a real-world database of insurance claims and de-identified clinical Guardant360 records. Pts without TGA on initial LB, but gained TGA on subsequent LB were included. TGA were defined as biomarkers with cancer-type specific or pan-tumor matched targeted therapy (MTT) approvals: KRAS G12C, ERBB2 amplification (amp), BRAF V600E, IDH1, MSI-H, and NTRK/RET/FGFR2 fusions or with select approved MTT in non-GI cancers: PIK3CA and ERBB2 mutation (mut). When available, methylation-derived tumor fraction (TF), a measure of overall ctDNA burden independent of variant-specific effects, was compared with emergent TGA VAFs, excluding MSI-H and ERBB2 amp. Pts with multiple cancers or prior MTT were excluded. Cox proportional hazards model assessed associations between MTT and real-world overall survival (rwOS), adjusting for age, gender, cancer type, MSI-H status, and number of gained TGA. **Results:** Among 16,435 GI cancer pts with >1 LB and no initial TGA, 2,072 (12.6%) gained TGA on serial LB and were included in the overall cohort. For the survival analysis, 804 pts with gained TGA had treatment and survival data; 13.4% (108/804) received MTT. Colorectal cancer pts had the highest rate of emergent TGA with approved MTT (17%). The most common gained TGA across the overall cohort were PIK3CA mut (62%), ERBB2 mut (11.7%), BRAF V600E (9.5%), KRAS G12C (8.6%), ERBB2 amp (7%), MSI-H (4.4%), FGFR fusions (3%), and NTRK fusions (1.9%). Gained TGA were often detected at low VAF (median 0.2%; 0.01% - 41.4%), and below the TF, suggesting potential subclonal emergence. Cholangiocarcinoma and gastroesophageal cancers had the highest MTT rates (14.2% and 10%, respectively), whereas no anal cancer pts received MTT. Including pts who gained MSI-H status, 12-and 60-month rwOS from LB-detected TGA was 67% and 25% without MTT versus 78% and 44% with MTT, $p<10\text{-}4$; excluding MSI-H, rwOS with MTT was 82% and 34%, p=0.00025. **Conclusions:** Repeat LB identified TGA in a subset of GI cancer pts lacking baseline TGA, many detected at low VAF. MTT receipt for emergent TGA was associated with improved rwOS, supporting serial LB in later-line decision making. Further studies are needed to assess outcomes by TGA type, therapy, clonality, and GI cancer. Research Sponsor: None.

TPS4239 **Poster Session**

Phase II study evaluating ivonescimab in combination with chemotherapy as first- and second-line treatment of advanced or metastatic gastric and gastroesophageal adenocarcinoma patients (UCGI 52 – GRACIE). First Author: Christelle De La Fouchardiere, Cancer Center Institut Paoli-Calmettes, Marseille, France

Background: The prognosis of advanced/metastatic gastroesophageal adenocarcinomas (GEA) has recently improved with new targeted therapies, including immune checkpoint inhibitors, mostly developed in the first-line setting. However, for patients (pts) without actionable biomarkers or for those who become refractory to first-line therapy, a significant unmet need remains for effective therapeutic options. Ivonescimab, a bispecific antibody targeting both VEGF-A and PD-1, appears to be a promising strategy in this setting. **Methods:** This phase 2 multicenter two-cohort, non-randomized study (NCT06846346) is designed to evaluate the efficacy and safety of ivonescimab + chemotherapy in pts with advanced or metastatic GEA, with and without actionable biomarker. Main eligibility criteria are age ≥ 18 years, histologically proven GEA, stage 4 disease, no prior treatment for pts without actionable biomarker (cohort 1) or only one prior line for pts with actionable biomarker (cohort 2), ECOG-PS 0-1, and adequate organs functions. The tumor has to be measurable (RECIST 1.1). Treatment regimens are ivonescimab 20mg/kg IV on D1 Q2W combined with: cohort 1: FOLFOX (oxaliplatin 85mg/m² IV, folinic acid 400 mg/m² IV [or L-folinic acid 200 mg/m²], 5-FU bolus 400 mg/m² then 5-FU 2400 mg/m² as a 46-hours continuous IV infusion on D1 Q2W; oxaliplatin will be stopped after 8 cycles); cohort 2: at investigator discretion, paclitaxel (80 mg/m2 IV at D1, D8 and D15, Q4W for at least 4 cycles) or irinotecan (180 mg/ m2 IV on D1 Q2W). Treatment will be administered until disease progression or unacceptable toxicity. The primary endpoint is ORR by central review. Secondary endpoints include ORR assessed by investigator, duration of response, PFS, OS, safety, time to PS deterioration >2, and quality of life. According to a single stage phase II A'Hern's design, a sample of 33 evaluable pts in cohort 1 and 47 evaluable pts in cohort 2 is required to distinguish between a maximum futility proportion of 0.5 (cohort 1)|0.2 (cohort 2) and a minimum efficacy proportion of 0.75 (cohort 1)|0.4 (cohort 2) with a one-sided significance level of 0.04 and 90% power. 88 patients have to be enrolled to observe a minimum of 80 evaluable patients. Planned accrual duration is 1 year, 12 patients have already been enrolled. Clinical trial information: NCT06846346. Research Sponsor: SUMMIT Therapeutics.

HIPEC combined with NIPS and tislelizumab for conversion therapy in gastric cancer with peritoneal metastasis (P0CY1 or PCI ≤10): A prospective, single-arm, phase II study. First Author: Honghai Guo, The Third Department of Surgery, the Fourth Hospital of Hebei Medical University, Shijiazhuang, China

Background: Peritoneal metastasis, which is common, difficult to diagnose early, and associated with a poor prognosis, is a leading cause of death in pts with advanced gastric cancer. Due to the peritoneal-plasma barrier, traditional systemic chemotherapy is often ineffective for gastric cancer patients with peritoneal metastasis. In recent years, combined systemic and intraperitoneal therapy has gained increasing recognition. The RATIONALE-305 study demonstrated that tislelizumab (TIS) significantly improves outcomes in these patients. This study combines hyperthermic intraperitoneal chemotherapy (HIPEC), normothermic intraperitoneal and systemic chemotherapy (NIPS), and PD-1 inhibitor, exploring a novel conversion therapy regimen for pts with gastric cancer peritoneal metastasis. **Methods:** This is a prospective, single-center, single-arm phase II study aims at evaluate the efficacy and safety of HIPEC combined with NIPS and tislelizumab as conversion therapy for gastric cancer pts with peritoneal metastasis who are either cytology-positive only without macroscopic peritoneal deposits (P0CY1) or Peritoneal Carcinomatosis Index (PCI) ≤10. Key inclusion criteria are: 1) age 18-75 years; 2) ECOG performance status 0-1; 3) HER2-negative confirmed by IHC, and PD-L1 CPS≥1; 4) either P0CY1 or PCI ≤10 without other distant metastases confirmed by laparoscopy; 5) adequate function of major organs. Pts undergo diagnostic laparoscopy for PCI scoring and peritoneal cytology examination. Upon confirmation of eligibility, pts receive three sessions of HIPEC followed by 4 cycles of NIPS combined with systemic therapy. The HIPEC regimen consists of paclitaxel at a dose of 75 mg/m² administered on D1, 3, and 5. After a two-week rest, NIPS combined TIS is initiated. The NIPS regimen includes paclitaxel (20 mg/m², ip, D1,8, Q3W and 50 mg/m², iv, D1,8, Q3W) ,S-1 (40-60mg based on BSA, po, D1-14, Q3W). The dosage and administration of TIS is 200 mg, iv, D1, Q3W. Radiological evaluations are performed every 2 cycles during conversion therapy. Upon completion of conversion therapy, pts undergo a second laparoscopic exploration with peritoneal cytology examination to re-evaluate disease status. Operable pts who achieve R0 resection receive postoperative adjuvant therapy with the same regimen (paclitaxel + S-1 + TIS) for 4 cycles. For inoperable pts or those not achieving R0 resection, subsequent treatment is determined by a multidisciplinary team (MDT). The primary endpoint is the surgical conversion rate. Secondary endpoints include the 1-year progression-free survival (PFS) rate, 2-year overall survival (OS) rate, PFS, OS, and safety. Exploratory endpoints aim to investigate the correlation between efficacy prediction and biomarkers such as PD-L1 expression, CLDN18.2 expression, and microsatellite instability (MSI) status. Clinical trial information: NCT07304258. Research Sponsor: None.

TPS4241 **Poster Session**

A randomized phase II/III trial of intraperitoneal paclitaxel plus systemic treatment vs systemic treatment alone in gastric carcinomatosis: STOPGAP II—ECOG-ACRIN EA2234. First Author: Maheswari Senthil, UC Irvine School of Medicine, Orange, CA

Background: Thirty to forty percent of patients with gastric cancer will develop peritoneal carcinomatosis (PC), the survival of which remains poor despite systemic therapy (ST). Limited drug delivery into PC due to blood-peritoneal barrier is considered to decrease the effectiveness of ST. Hence, there is a critical need to develop novel treatment strategies to improve patient outcomes. Intraperitoneal (IP) paclitaxel (PTX) combined with ST had been studied extensively in Asia. In the US, STOPGAP I, a single institution phase II trial has established the safety and feasibility of IP PTX plus ST in Western patients with gastric PC. Based on these results, we developed STOPGAP II trial, which is designed to evaluate the survival benefits of IP PTX plus ST compared to ST alone in patients with gastric PC. **Methods:** ECOG-ACRIN EA 2234 STOPGAP II is a multicenter randomized phase II/III trial (NCT07001748) evaluating IP PTX plus ST compared to ST alone in patients with gastric PC. Eligible patients must have microsatellite stable gastric/gastroesophageal cancer (Siewert 3) with cytology positive disease or carcinomatosis detected by diagnostic laparoscopy (DL), laparotomy, or radiology and have undergone 3-6 months of first line ST. Patients must not have visceral metastases except ovarian metastases or clinically significant progression of PC. All enrolled patients will undergo DL with peritoneal cancer index (PCI) assessment within four weeks of registration. Patients will be randomized intraoperatively in 1:1 fashion to Arm A- ST or Arm B- IP PTX with ST. In patients randomized to Arm B, an IP port will be placed at the initial DL . Patients in Arm A will continue first line ST and patients in Arm B will receive 40 mg/m2 of IP PTX on days 1 and 8 combined with 50mg/m2 of IV PTX, 5 fluorouracil 400 mg/m2, leucovorin 20mg/m2. Immune checkpoint inhibitors and targeted agents will be continued as per standard of care. Patients will be stratified by PCI (0, 1-6, 7-14, versus $>$15) and first line ST type (chemo + targeted agent or immunotherapy versus chemotherapy alone). In both treatment arms, patients will undergo reevaluation with repeat imaging and if indicated, DL after three months. Patients with stable disease or response will continue the assigned treatment or could be considered for cytoreduction if PCI $<$7. The primary endpoints are progression free survival (phase II) and overall survival (OS) (phase III). Assuming the median OS of IP PTX and that of ST to be 22.5 and 12.5 months respectively, and accounting for attrition, 148 patients will be enrolled to achieve 90% power with a hazard ratio of 0.56 (one-sided type I error of 5%). The study is actively enrolling patients with results expected in 2031. Clinical trial information: NCT07001748. Research Sponsor: NCI CTEP.

TPS4242 **Poster Session**

A phase 1/2 study of BDC-4182, a Claudin 18.2–targeting next-generation immune-stimulating antibody conjugate (ISAC), in patients with advanced gastric and gastroesophageal cancer. First Author: Sophia Frentzas, Department of Medical Oncology, Monash Health, Clayton, VIC, Australia

Background: Claudin 18.2 (CLDN18.2) is a transmembrane tight junction protein with expression restricted to the gastric mucosal epithelia where CLDN18.2 protects against paracellular acid leakage and associated gastritis.[1] CLDN18.2 overexpression has been observed in several tumor types, including gastric, esophageal, and pancreatic cancer.[2,3] Loss of cell polarity in these tumors results in CLDN18.2 localization to surfaces that are more readily accessible to biologics and effector cells. This expression pattern makes CLDN18.2 a compelling target for immune-stimulating antibody conjugates (ISACs) that combine the specificity of tumor-targeting antibodies with the potency and durability of immune activation. BDC-4182 is a next-generation ISAC consisting of a CLDN18.2-targeting antibody covalently attached to a novel toll-like receptor (TLR)7/8 agonist via a non-cleavable linker. In preclinical models, systemic delivery of ISACs has been shown to broadly activate the innate and adaptive immune system, leading to complete tumor regression. A BDC-4182 surrogate induced immunologic memory and epitope spreading as evidenced by rejection of tumor cells that no longer express the target antigen (CLDN18.2) following re-challenge.[4,5] **Methods:** This is a first-in-human Phase 1 dose escalation and Phase 2 expansion study of BDC-4182. Up to 122 patients with advanced gastric and gastroesophageal cancer will be enrolled. To optimize tolerability, BDC-4182 is administered via an intra-patient step-up dosing regimen wherein subjects receive lower initial priming doses prior to the target dose. Primary objectives are to define safety and tolerability and to determine the recommended phase 2 dose (RP2D) of BDC-4182 as a single agent. Secondary objectives will evaluate the preliminary anti-tumor activity of BDC-4182, analyze PK characteristics of BDC-4182, and evaluate the immunogenicity of BDC-4182 as a single agent. Exploratory analyses will also be conducted to explore potential biomarkers in blood and tumor tissue associated with exposure, efficacy, or safety of BDC-4182, and to define CLDN18 expression in tumor tissue. This study is being conducted in Australia, South Korea, and Taiwan. References: 1. Suzuki K, Sentani K, Tanaka H, et al. Cell Mol Gastroenterol Hepatol. 2019;8:119-142. 2. TPS4243 **Poster Session**

Phase II RAINSPOT: A multicentric open label trial of zolbetuximab-paclitaxel-ramucirumab in second-line setting for CLDN18.2-positive gastro-esophageal adenocarcinoma. First Author: Filip Van Herpe, Gastrointestinal Oncology Department, University Hospitals Leuven, Leuven, Belgium

Background: Claudin 18.2 (CLDN18.2) is an emerging therapeutic biomarker in gastro-oesophageal adenocarcinoma. Phase III trials (SPOTLIGHT, GLOW) showed significant overall survival (OS) and progression-free survival (PFS) benefit from adding zolbetuximab to first-line chemotherapy. However, access to zolbetuximab remains limited in Belgium due to lack of reimbursement, and globally for patients receiving immunotherapy first line. Aim: RAINSPOT (NCT06962137) evaluates the efficacy and safety of adding zolbetuximab to standard second-line paclitaxel–ramucirumab in CLDN18.2-positive advanced gastro-oesophageal adenocarcinoma. Secondary objectives include assessing CLDN18.2 expression loss after first-line progression and evaluating zolbetuximab efficacy according to maintained versus lost CLDN18.2 expression. **Methods:** RAINSPOT is a national, multicentre, phase II, open-label study with a prospective single-arm cohort and a matched retrospective cohort across six Belgian centres. The prospective cohort will include 100 patients ($\geq$18 years, ECOG 0–1) with metastatic or locally advanced disease progressing after one prior systemic line. Tumours must be CLDN18.2-positive ($\geq$75% moderate-to-strong membranous staining; Ventana 43-14A assay). A fresh biopsy at progression is obtained when feasible. Treatment consists of zolbetuximab (800 mg/m² loading, then 400 mg/m² q2w), paclitaxel (80 mg/m² weekly $\times$3 q28d) and ramucirumab (8 mg/kg q2w). Treatment continues until progression or unacceptable toxicity. HRQoL is assessed every 4 weeks (EORTC QLQ-C30, QLQ-OG25). The retrospective cohort includes patients treated with second-line paclitaxel–ramucirumab (2021–2023) with archived tissue reassessed for CLDN18.2; only baseline-positive patients are eligible. Propensity score matching (1:1; SMD $\leq$0.05) uses age, sex, tumour location, gastrectomy, peritoneal metastases and centre. This study is supported by Astellas. **Results:** (Trial in Progress) Enrollment began December 2025 and will continue for 24 months, with 24 months' follow-up. Planned analyses include OS, PFS, objective response rate, toxicity and HRQoL. **Conclusion:** RAINSPOT is the first study evaluating zolbetuximab plus paclitaxel–ramucirumab in second-line CLDN18.2-positive gastro-oesophageal adenocarcinoma. By integrating a matched real-world comparator, it aims to generate near-randomized evidence on survival, tolerability and quality of life, informing optimal treatment sequencing. Clinical trial information: NCT06962137. Research Sponsor: None.

TPS4244 **Poster Session**

Combining zanidatamab, FOLFOX, and pembrolizumab as first-line therapy for HER2/PD-L1–positive gastroesophageal adenocarcinoma: The phase II IKF-090/AIO ZANGEA trial with translational analysis. First Author: Joseph Tintelnot, University Cancer Center Hamburg (UCCH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Gastroesophageal adenocarcinoma (GEA) presents a substantial global health challenge as the number of cases continues to rise. The current standard approach for treating previously untreated, metastatic HER2/PD-L1 positive GEA involves a combination of doublet chemotherapy, which consists of a platinum compound and a fluoropyrimidine, in combination with trastuzumab and pembrolizumab. Recently, the phase 3 HERIZON-GEA-01 trial has shown improved survival for zanidatamab in combination with CAPOX or fluoropyrimidine and cisplatin with the PD-1 inhibitor tislelizumab compared to chemotherapy and trastuzumab. Zanidatamab is a bispecific antibody that targets two distinct HER2 epitopes (domains 2 and 4), thereby crosslinking neighboring HER2 receptors and inducing receptor clustering. This leads to enhanced HER2 internalization, reduced downstream signaling, and increased Fc-mediated immune effector functions, compared with trastuzumab. There is currently insufficient evidence regarding the combination of zanidatamab with the frequently used chemotherapy backbone FOLFOX and no available data on combining this regimen with the PD-1 inhibitor pembrolizumab. Furthermore, biomarkers to predict response and toxicities are lacking. **Methods:** The ZANGEA study is an open-label, single-arm, multicenter, translational phase II trial designed to assess the efficacy, safety, tolerability and translational aspects of zanidatamab in combination with FOLFOX and pembrolizumab in patients with 1st line HER2/PD-L1-positive GEA. The primary endpoint is the progression-free survival rate after 12 months. Secondary objectives include safety and tolerability, efficacy in terms of objective response rate, progression-free and overall survival and translational markers, such as blood-based signatures (e.g. inflammatory cytokines), microbiota signatures, dietary patterns or microbiota derived metabolites that may correlate with therapy response or side-effects. In total, 80 patients will be recruited to show an PFS at 12 months of 55% compared to 46% with trastuzumab/pembrolizumab/chemotherapy (KeyNote 811). Enrollment started on 16 Jan 2026. Clinical trial information: NCT07176312. Research Sponsor: The Frankfurt Institute of Clinical Cancer Research (IKF); Jazz Pharmaceuticals.

TPS4245 **Poster Session**

Efficacy and safety of disitamab vedotin (DV) combined with trastuzumab, and tislelizumab versus chemotherapy (CAPOX) combined with trastuzumab ± pembrolizumab for patients with first-line HER2-high advanced gastric/gastroesophageal junction adenocarcinoma (G/GEJA): A randomized controlled phase 3 trial. First Author: Zhi Peng, Department of GI Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Patients (pts) with HER2-high (defined as IHC 3+, or IHC 2+/FISH+ according to Chinese Society of Clinical Oncology Gastric Cancer Guidelines) advanced G/GEJA continue to face a poor prognosis. Although adding pembrolizumab to trastuzumab and chemotherapy significantly improved overall survival in this pts population with a PD-L1 combined positive score (CPS) ≥1 in the first-line (1L) setting, there remains an unmet need for more effective treatment options. DV (anti-HER2 antibody-drug conjugate) is approved as monotherapy for the treatment of pts with HER2 IHC 2+/3+ advanced G/GEJA in China. In the randomized phase 2 part of the RC48-C027 trial, DV + trastuzumab + an anti-PD-1 agent showed a promising objective response rate (ORR) in 1L HER2-high advanced G/GEJA compared with the control (82.4% vs. 68.8%) (Shen et al. J Clin Oncol. 2025). Building on these results, the open-label randomized phase 3 RC48-C040 trial is designed to assess the efficacy and safety of DV + trastuzumab + tislelizumab versus chemotherapy + trastuzumab ± pembrolizumab in pts with previously untreated, HER2-high, advanced G/GEJA (NCT07315750). **Methods:** The key eligibility criteria are pts aged 18-75 years with histologically confirmed unresectable locally advanced or metastatic G/GEJA; central lab-confirmed high HER2 expression; no previous systemic treatment for locally advanced or metastatic gastric cancer; and at least one assessable lesion according to Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Pts with central nervous system metastasis and/or carcinomatous meningitis are ineligible. The planned sample size is 555. Pts will be randomized (2:1) to receive DV (2.5 mg/kg, intravenously [IV], Q2W) + trastuzumab (staring dose of 8 mg/kg followed by 6 mg/kg, IV, Q3W) + tislelizumab (200 mg, IV, Q3W) or to receive CAPOX (oxaliplatin: 130 mg/m², IV, Q3W for up to 6 doses; capecitabine: 1000 mg/m², orally, BID, days 1-14 every 3 weeks) + trastuzumab ± pembrolizumab (200 mg/kg, IV, Q3W) until occurrence of disease progression, intolerable toxicity, or initiation of new anti-tumor treatment. Randomization will be stratified by HER2 expression (IHC 2+/FISH+ or IHC 3+), PD-L1 expression (CPS < 1 or 1≤CPS < 10 or CPS≥10), and liver metastasis (presence or absence). The primary endpoint is progression-free survival (PFS) assessed by the Blinded Independent Review Committee as per RECIST v1.1. The secondary endpoints include overall survival, investigator-assessed PFS, ORR, disease control rate, duration of response, patient-reported outcomes, adverse events, pharmacokinetic parameters, and immunogenicity. This study started in January 2026; enrollment is ongoing in China. Clinical trial information: NCT07315750. Research Sponsor: RemeGen Co., Ltd.

TPS4246 **Poster Session**

A single-arm, phase II study of ivonescimab in combination with FOLFOX in advanced HER2-negative gastroesophageal adenocarcinomas. First Author: Sienna M. Durbin, Mass General Brigham Cancer Institute, Boston, MA

Background: Gastroesophageal adenocarcinoma (GEA) is a major cause of global cancer-related mortality. A common standard of care for frontline advanced GEA is 5-fluorouracil and oxaliplatin (FOLFOX), with the addition of immune checkpoint inhibitors (ICI) in patients with a PD-L1 combined positive score (CPS) of > 1. Adding ICIs improves median overall survival (OS) by 2-4 months, with increased benefit seen with higher CPS scores (Leone et al, *ESMO Open*, 2024). There remains a significant need to improve ICI outcomes and expand the portion of patients who benefit. In GEA, vascular endothelial growth factors (VEGF) are associated with poor prognosis, influencing immune suppression and T cell exhaustion. There is strong mechanistic rationale for cooperativity between anti-VEGF antibodies and ICI in GEA, as well as evidence of clinical benefit in treatment-refractory gastric cancer (Kim et al, *Cancer Immunol Res*, 2025). Ivonescimab is a novel bispecific antibody that simultaneously targets PD-1 and VEGF, in a spatially constrained manner, impairing neoangiogenesis and remodeling the suppressive tumor microenvironment. Ivonescimab has evidence of safety and efficacy in colorectal and hepatocellular cancers and is approved for the treatment of PD-L1+ lung cancer in China (Deng et al, ESMO 2024; Li et al, ESMO 2025; Xiong et al, *Lancet*, 2025). **Methods:** This single-arm, multi-institutional phase II study seeks to evaluate ivonescimab in combination with FOLFOX as frontline therapy in GEA. Adults with locally advanced unresectable or metastatic HER-2 negative GEA are eligible. Patients must have disease that can be evaluated radiographically and may not have received prior systemic therapy for advanced disease. Positive PD-L1 expression is not required for eligibility. We plan to enroll 40 patients. To allow for collection of early immune modulation data, patients will commence therapy with a single dose of ivonescimab 20 mg/kg at discretion of the treating investigator. Subsequent cycles will continue with the addition of FOLFOX (dosed per institutional standards) to ivonescimab, given on day 1 and day 15 of a 28-day cycle. Imaging will be performed every 6 weeks until week 24, at which point imaging will change to every 9 weeks. Treatment will continue until disease progression, withdrawal of consent, or death. The primary objective is to define efficacy of ivonescimab in combination with FOLFOX as measured by the 6-month progression-free survival (PFS) rate. Secondary objectives include safety and tolerability, objective response and clinical benefit rates, median PFS and OS. Translational correlative studies are planned to explore tumor and immunologic determinants of response. This study is currently open and enrolling (NCT07070466). Clinical trial information: NCT07070466. Research Sponsor: None.

TPS4247 **Poster Session**

A multicenter, open-label, single-arm, dose-finding and -expansion phase 1b/2 study to evaluate the safety and tolerability of nesuparib (JPI-547) in combination with irinotecan as a third-line and beyond therapy for recurrent or metastatic gastric cancer. First Author: Sun Young Rha, Department of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Recurrent or metastatic gastric cancer (GC) progressing after standard first- and second-line therapies has limited treatment options, leading to poor survival outcomes. Nesuparib is an orally available, next-generation dual inhibitor of tankyrase and poly(ADP-ribose) polymerase (PARP). It disrupts DNA damage repair and induces a "BRCAness" phenotype by modulating Wnt/β-catenin and Hippo signaling pathways. In a previous phase I study, nesuparib monotherapy demonstrated promising clinical activity with an overall response rate (ORR) of 28.2% and a disease control rate (DCR) of 64.1%. Preclinical models have shown synergistic anti-tumor efficacy when nesuparib is combined with irinotecan. This study aims to evaluate the safety, tolerability, and preliminary efficacy of nesuparib plus irinotecan in patients with advanced GC. **Methods:** This multicenter, open-label, single-arm, dose-finding and expansion phase 1b/2 study enrolls adults with histologically confirmed recurrent or metastatic GC or gastroesophageal junction adenocarcinoma who have progressed after ≥2 prior systemic therapies and have ECOG PS 0–1, measurable disease per RECIST v1.1, and UGT1A1 wild-type genotype. Phase 1b follows a standard 3+3 design with multiple predefined dose levels. Each dose level consists of a fixed combination of (1) a specific nesuparib dose (25–100 mg) administered orally once daily on either a 5-days-on/2-days-off or 3-days-on/4-days-off schedule and (2) irinotecan administered every 2 weeks at 100, 120, or 150 mg/m². The dose-limiting toxicity evaluation window is 28 days. Phase 2 enrolls patients at RP2D to further evaluate anti-tumor activity. The primary endpoint is objective response rate. Secondary endpoints include safety, disease control rate, duration of response, progression-free survival, time to response, and overall survival. Exploratory objectives include population pharmacokinetics, pharmacodynamic biomarkers, homologous recombination deficiency profiling, and circulating tumor DNA analyses. Approximately 43–49 patients are planned (18–24 in phase 1b; 25 in phase 2). Treatment continues until disease progression, unacceptable toxicity, or study withdrawal. Clinical trial information: NCT07364422. Research Sponsor: None.

TPS4248 **Poster Session**

Chemoradiotherapy plus sintilimab versus chemoradiotherapy as neoadjuvant treatment in locally advanced esophageal squamous cell carcinoma (NEOCRTEC2101): A multicenter, randomized, phase III trial. First Author: Mian Xi, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Guangdong Esophageal Cancer Research Institute, Guangzhou, China

Background: Neoadjuvant chemoradiotherapy (NCRT) followed by surgery is the current standard of care for resectable locally advanced esophageal squamous cell carcinoma (ESCC). The integration of immunotherapy is now challenging this established therapeutic paradigm. Our previous phase II trial demonstrated that combining PD-1 inhibitor and NCRT yielded an encouraging pathological complete response (pCR) rate with an acceptable safety profile in ESCC. Therefore, this multicenter, randomized phase III trial (NEOCRTEC2101) aims to compare the efficacy and safety of NCRT combined with sintilimab (a IgG4 anti-PD-1 monoclonal antibody) versus NCRT alone in patients with resectable locally advanced ESCC. **Methods:** This was a multicenter, open-label, randomized, phase III trial. Key eligibility criteria included previously untreated, histologically confirmed, resectable thoracic ESCC clinically staged as T1-4aN1-3M0 or T3-4aN0M0 according to the 8th edition of the UICC staging system, age 18–75 years, Eastern Cooperative Oncology Group performance status of 0 or 1, and adequate hematologic and organ function. Key exclusion criteria included a history of other malignancies, previous antitumor therapy, severe comorbidities, active autoimmune disease, prior non-infectious pneumonitis, or interstitial lung disease. Eligible patients were randomly assigned (1:1) to sintilimab plus NCRT group or NCRT group. All patients received NCRT consisting of concurrent radiotherapy (40 or 45 Gy in 20 fractions) and chemotherapy (paclitaxel 50 mg/m² + cisplatin 25 mg/m² administered on days 1, 8, 15, and 22). Patients randomized to the sintilimab plus NCRT group additionally received sintilimab 200 mg via intravenous infusion on days 1 and 22. Surgical resection was performed 6-8 weeks following the completion of neoadjuvant therapy. The primary endpoint was overall survival, and the secondary endpoints were progression-free survival, pCR rate, R0 resection rate, and treatment-related adverse events. The planned sample size is 422 patients. This study opened to accrual in October 2022 and is currently recruiting patients. Clinical trial information: NCT05357846. Research Sponsor: None.

TPS4249 **Poster Session**

Adjuvant oxaliplatin plus S-1 versus docetaxel plus S-1 for stage III gastric cancer after D2 gastrectomy (DRAGON-Adjuvant): A multicenter, open-label, phase 3, randomized, non-inferiority study. First Author: Chenfei Zhou, De-Department of Oncology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Adjuvant therapy is the standard treatment for stage II-III gastric cancer patients after radical D2 gastrectomy. Neoadjuvant therapy has been demonstrated as an effective strategy for resectable gastric cancer patients, while less than 2% of patients received such treatment in China. Therefore, adjuvant chemotherapy following radical resection is still widely used in current clinical practices. For stage III gastric cancer patients, oxaliplatin or docetaxel combined with oral fluoropyrimidine as adjuvant regimens are recommended by clinical guidelines. Although historical data show comparable efficacy between these regimens, direct comparisons are not feasible due to differences in study design, enrolled populations, and treatment cycles. Regimen selection is mainly based on clinical experience, as high-level evidence is still lacking. Currently, minimal residual disease (MRD) detection based on ctDNA testing can indicate patient prognosis and adjuvant therapy selection in colorectal cancer. The role of ctDNA-based MRD detection in adjuvant therapy of gastric cancer is still under investigation. This study aims to compare the efficacy and safety of oxaliplatin plus S-1 (SOX) versus docetaxel plus S-1 (DS) as adjuvant therapy for stage III gastric cancer, and to explore the role of MRD in adjuvant setting of gastric cancer. **Methods:** DRAGON-Adjuvant (NCT07366528) is a prospective, open-label, multicenter, randomized, non-inferiority study in patients aged from 18 to 80 years who are histologically confirmed adenocarcinoma of the stomach or gastroesophageal junction, with pathological staging at AJCC stage IIIA to IIIC after standard D2 gastrectomy and R0 resection. Patients had no prior neoadjuvant therapy. Eligible patients will be randomized and assigned into experiment group (SOX, n = 193) and control group (DS, n = 194), respectively. Experiment group patients will be treated with eight 3-week cycles of intravenous oxaliplatin (130mg/m^2 on day 1 for each cycle) with orally S-1 on days 1 to 14 of a 3-week cycle. Control group patients will be treated with S-1 on days 1 to 14 of a 3-week cycle (C1), then intravenous infusion of docetaxel (40mg/m^2) on day 1 of each cycle and S-1 on days 1 to 14 of a 3-week cycle (C2 to 7), then S-1 continued on days 1 to 28 of 6-week cycles for up to 1 year. S-1 dose is dependent on body surface area. The primary objective is to assess that 3-year disease-free survival rate of SOX group is not inferior to DS group. Secondary objectives are to compare the 5-year overall survival rate, safety profiles, and recurrence sites in two groups. Exploratory objective is to assess the correlation of MRD with treatment efficacy and patient prognosis. As of January 2026, the DRAGON-Adjuvant is recruiting patients at 5 sites in China. Clinical trial information: NCT07366528. Research Sponsor: Science and Technology Commission of Shanghai Municipality; 25PJD078.

TPS4250 **Poster Session**

Multicenter phase Ib/II study of neoadjuvant zolbetuximab plus docetaxel, oxaliplatin, and S-1 (DOS) followed by adjuvant zolbetuximab/S-1 in patients with CLDN18.2-positive resectable gastric or gastroesophageal junction adenocarcinoma (NEOCLAUD). First Author: Hyung-Don Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Zolbetuximab, a monoclonal antibody targeting claudin 18.2 (CLDN18.2), has demonstrated significant survival benefit in advanced gastric or gastroesophageal junction adenocarcinoma (G/GEJA) in the phase 3 SPOTLIGHT and GLOW trials, validating CLDN18.2 as a therapeutic target. The phase III PRODIGY study demonstrated that neoadjuvant chemotherapy with docetaxel, oxaliplatin, and S-1 (DOS) followed by surgery and adjuvant S-1 chemotherapy improved progression-free survival (PFS) and overall survival (OS) compared with surgery followed by adjuvant S-1 for patients with resectable locally advanced gastric cancer (LAGC). Building on this evidence, we designed NEOCLAUD to evaluate whether adding zolbetuximab to neoadjuvant DOS chemotherapy, followed by adjuvant zolbetuximab/S-1, improves outcomes in patients with CLDN18.2-positive LAGC. **Methods:** This open-label, multicenter, phase Ib/II trial will enroll up to 57 patients with newly diagnosed, resectable G/GEJA positive for CLDN18.2 ($\geq$75% moderate–strong membranous staining by VENTANA 43-14A). Eligible patients must have clinical stage T3–4/N0 or T2–4/N+ disease (AJCC 8th), ECOG 0–1, and no distant metastasis. Primary endpoints are recommended phase II dose (RP2D) (phase Ib) and the pathologic complete regression (pCR) rate (phase II). Phase Ib uses a 3+3 design to determine the RP2D. Phase II will test whether adding zolbetuximab increases the pCR rate from 10% (historical control) to 25%; the primary endpoint will be met if $\geq$8/40 patients achieve pCR (A'Hern single-stage design, α = 0.05, power = 80%). Secondary endpoints include PFS, OS, objective response rate, disease control rate, R0 resection rate, and safety. Exploratory endpoints include artificial intelligence-based histopathology modeling, spatial transcriptomics, single-cell RNA sequencing, and circulating tumor DNA minimal residual disease analysis. Neoadjuvant therapy consists of zolbetuximab 800 mg/m² on cycle 1 day 1 (C1D1) followed by 600 mg/m² on C2D1/C3D1, with DOS (docetaxel 50 mg/m², oxaliplatin 100 mg/m² IV D1; S-1 40 mg/m² PO BID D1–14) every 3 weeks $\times$3 cycles. Surgery (D2 gastrectomy) is performed 1–4 weeks post-neoadjuvant therapy. Adjuvant therapy (initiated 3–8 weeks post-surgery) includes zolbetuximab 600 mg/m² D1/D22 Q6W $\times$8 cycles plus S-1 PO D1–28 Q6W $\times$8 cycles. Enrollment has been ongoing since February 2025 across multiple sites in Korea. Clinical trial information: NCT06732856. Research Sponsor: Astellas.

TPS4251 **Poster Session**

A phase 2, open-label, single-arm study of lirafugratinib in patients with previously treated, unresectable, locally advanced, or metastatic solid tumors (excluding cholangiocarcinoma) with *FGFR2* fusion or rearrangement. First Author: Richard D. Kim, Moffitt Cancer Center Magnolia Campus, Tampa, FL

Background: Tissue agnostic cancer therapies offer the potential to markedly change the treatment landscape by targeting oncogenic drivers rather than the tumor's site of origin. Lirafugratinib is the first highly selective, irreversible inhibitor designed to target oncogenic fibroblast growth factor receptor (*FGFR)2* driver alterations and resistance mutations. In the phase 1/2 ReFocus Trial (RLY-4008-101; NCT04526106),46 subjects (Group 3) with non-cholangiocarcinoma solid tumors harboring FGFR2 fusion/rearrangements (f/r) received lirafugratinib 70 mg once daily. The ORR was 33.3% (95% CI 19.6 - 49.5). However, this sample size was insufficient to support regulatory approval of lirafugratinib for a tissue agnostic indication. **Methods:** The ELE-4008-202, phase 2, open-label, single-arm study (NCT07359820) is designed to further evaluate the efficacy and safety of lirafugratinib 70 mg in 20-30 subjects across 20 sites with FGFR2 f/r, previously treated, unresectable, locally advanced or metastatic, non-CCA solid tumors who have not received prior FGFR inhibitor therapy. The primary endpoint is objective response rate (ORR) by independent review committee (IRC) per RECIST v1.1; key secondary endpoints include duration of response (DOR) by IRC, investigator-assessed efficacy endpoints, safety, pharmacokinetic (PK) parameters, and quality of life (QoL) per EORTC QLQ-C30. Efficacy will also be evaluated for ORR, DOR, disease control rate (DCR), progression-free survival (PFS), overall survival (OS), time to response (TTR), time to progression (TTP) per investigator. Time to discontinuation (TTD) will also be assessed. Exploratory endpoints will include FGFR2 genotype per tissue assessment or liquid biopsy vs ORR and levels of other biomarkers in relationship to clinical activity. An interim analysis of the pooled efficacy dataset from ELE-4008-202 and Group 3 of RLY-4008-101 will be conducted once approximately 65 evaluable subjects with non-CCA tumors have been enrolled across $\geq$7 tumor types ($\geq$5 subjects per tumor type). Enrollment of a tumor type may be capped once it has reached approximately 20% of the total subjects in the pooled data from the two studies. With 65 subjects, observing at least 21 subjects with a complete response (CR) or partial response (PR) (ORR $\geq$32%), will result in a 95% CI (lower bound $>$20%) with the probability of observing $\geq$21 responders assuming a true ORR of 40% is approximately 92%. The results of this analysis will determine whether the pooled evaluable data from RLY-4008-101 and ELE-4008-202 meet regulatory requirements to support a tissue-agnostic indication for FGFR2 f/r non-CCA solid tumors. Clinical trial information: NCT07359820. Research Sponsor: Elevar Therapeutics.

TPS4252 **Poster Session**

A randomized phase III study of gemcitabine plus cisplatin with S-1 versus gemcitabine plus cisplatin with immune checkpoint inhibitor in unresectable biliary tract cancer. First Author: Hiroto Matsui, Oncology Center, Yamaguchi University Hospital, Ube, Japan

Background: Gemcitabine plus cisplatin (GC) has been established as the standard first-line treatment for unresectable biliary tract cancer (BTC). Recent phase III trials have demonstrated the clinical benefit of adding immune checkpoint inhibitors (ICIs) to GC. Meanwhile, GC combined with S-1 has also shown promising efficacy in East Asian populations. However, no randomized phase III trial has directly compared GC plus ICI with GC plus S-1. This study aims to compare the efficacy and safety of GC plus ICI with GC plus S-1 in patients with unresectable BTC. **Methods:** This is an ongoing, multicenter, open-label, randomized phase III trial (UMIN000051689). Eligible patients have histologically confirmed unresectable biliary tract cancer, including intrahepatic cholangiocarcinoma, extrahepatic cholangiocarcinoma, and gallbladder cancer, with no prior systemic therapy. Patients are randomized in a 1:1 ratio to receive either Arm A: gemcitabine plus cisplatin plus S-1 or Arm B: gemcitabine plus cisplatin combined with an immune checkpoint inhibitor. Randomization is stratified by primary tumor site, disease status (recurrence vs primary unresectable), and planned immune checkpoint inhibitor regimen for patients assigned to Arm B. The primary endpoint is overall survival. Secondary endpoints include progression-free survival, objective response rate, disease control rate, safety, and health-related quality of life. The planned sample size is 460 patients (230 per arm), providing 80% power to detect a statistically significant difference in overall survival with a two-sided alpha of 0.05. Current Status: Patient enrollment began in August 2023. As of January 2026, approximately 60% of the planned patients have been enrolled. Enrollment is ongoing, and follow-up continues. **Conclusions:** This randomized phase III trial will clarify the optimal first-line systemic treatment for unresectable biliary tract cancer by directly comparing GC plus immune checkpoint inhibition with GC plus S-1. Clinical trial information: UMIN000051689. Research Sponsor: None.

TPS4253 **Poster Session**

ARTEMIDE-Biliary02: A phase 3, randomized, global study of rilvegostomig or durvalumab with chemotherapy as first-line (1L) treatment for advanced biliary tract cancer (BTC). First Author: Lipika Goyal, Department of Medicine, Stanford Cancer Center, Palo Alto, CA

Background: Biliary tract cancer (BTC) is the second most common hepatic malignancy, comprising 15% of liver tumors. BTC incidence is rising worldwide, and the majority of patients are diagnosed late where the median survival is approximately one year. Chemoimmunotherapy with gemcitabine and cisplatin combined with either durvalumab or pembrolizumab is the current first-line (1L) standard for advanced BTC. To enhance the clinical benefit from immune checkpoint inhibitors, dual blockade of the programmed cell death-1 (PD-1) and T cell immunoreceptor with Ig and ITIM domains (TIGIT) pathways may be an effective strategy. Rilvegostomig, a monovalent, Fc-reduced, bispecific anti-PD-1/anti-TIGIT antibody, has shown promising preliminary efficacy in combination with gemcitabine and cisplatin for 1L treatment of advanced BTC (Zhou J, et al. ASCO 2025 [Abstract 4080]). The phase 3 ARTEMIDE-Biliary02 study (NCT07221253) assesses the efficacy and safety of rilvegostomig or durvalumab in combination with gemcitabine and cisplatin for 1L treatment of advanced BTC. **Methods:** Eligible participants (aged $\geq$ 18 years) have unresectable, locally advanced/metastatic BTC (intrahepatic cholangiocarcinoma [iCCA], extrahepatic CCA [eCCA], or gallbladder cancer [GBC]), previously untreated in the advanced setting, no prior immunotherapy, centrally confirmed programmed cell death ligand-1 (PD-L1) status, and ECOG PS of 0/1. Approximately 1100 participants will be randomized (1:1) to receive rilvegostomig or durvalumab, both in combination with gemcitabine and cisplatin, until radiological progression per RECIST v1.1. Participants will be stratified by PD-L1 expression (tumor area positivity $<$ 1% vs $\geq$ 1%), disease status (initially unresectable vs recurrent), primary tumor site (iCCA vs eCCA vs GBC), and geographic region (Asia vs rest of world). The primary endpoint is overall survival (OS) in the PD-L1 $\geq$ 1% population, defined as time from randomization until date of death due to any cause. Key secondary endpoints include OS in the intent-to-treat (ITT) population and progression free survival (PFS), defined as time from randomization until radiological progression per RECIST v1.1, in both the PD-L1 $\geq$ 1% and ITT populations. Other secondary endpoints include objective response rate, duration of response, PFS rates (defined as time from randomization until earliest progression event) in both the PD-L1 $\geq$ 1% and ITT populations, safety/tolerability, and patient-reported outcomes. OS will be assessed using a stratified log-rank test adjusting for stratification factors. A stratified Cox proportional hazards model will estimate the hazard ratio and associated 95% confidence interval. Enrollment started in December 2025 and is ongoing across Asia, Australia, Europe, and the Americas. Clinical trial information: NCT07221253. Research Sponsor: AstraZeneca.

TPS4254 **Poster Session**

Adjuvant sintilimab plus bevacizumab following curative resection of spontaneously ruptured hepatocellular carcinoma: A prospective exploratory phase II study (CLEAR-2). First Author: Yongjun Chen, Department of General Surgery, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Spontaneous rupture of hepatocellular carcinoma (srHCC) is a life-threatening complication associated with acute hemorrhage, aggressive tumor biology, and an exceptionally high risk of postoperative recurrence. Even after successful hemostasis and curative (R0) resection, outcomes remain poor, with early relapse—particularly peritoneal dissemination—being a dominant failure pattern. Patients with srHCC have been systematically excluded from most pivotal phase III adjuvant trials in hepatocellular carcinoma, resulting in a critical evidence gap for postoperative systemic management. Current adjuvant strategies are largely extrapolated from non-ruptured HCC or based on retrospective analyses, and no prospective studies have specifically evaluated immunotherapy-based adjuvant therapy in this population. Immune checkpoint inhibitor–based combinations with anti-angiogenic agents have demonstrated survival benefits in advanced HCC and have recently been explored in the adjuvant setting for high-risk resected disease. Given the unique biological behavior of srHCC, characterized by tumor cell spillage at rupture and a strong propensity for early systemic and peritoneal relapse, adjuvant systemic therapy targeting micrometastatic disease is biologically rational and urgently needed. The CLEAR-2 study is designed to prospectively explore the efficacy and safety of adjuvant sintilimab combined with bevacizumab following curative resection of srHCC. **Methods:** CLEAR-2 is a prospective, multicenter, single-arm, exploratory phase II study. Eligible patients are adults (18–75 years) with radiologically or intraoperatively confirmed spontaneous rupture of HCC who have undergone curative (R0) hepatic resection, with Child-Pugh A liver function and ECOG performance status 0–1. Preoperative transarterial embolization (TAE) for hemostasis is permitted if performed once and within 2 weeks prior to surgery, without chemotherapeutic agents. A total of 35 patients will be enrolled. Adjuvant treatment is initiated 4–8 weeks postoperatively and consists of sintilimab 200 mg plus bevacizumab 15 mg/kg intravenously every 3 weeks for up to 1 year or until recurrence, unacceptable toxicity, or withdrawal. Radiologic assessment is performed every 12 weeks. The primary endpoint is disease-free survival (DFS). Secondary endpoints include overall survival (OS), safety graded per CTCAE v5.0, and recurrence patterns (intrahepatic, extrahepatic, and peritoneal). Clinical trial information: NCT07331883. Research Sponsor: None.

TPS4256 **Poster Session**

Fatty acid degradation (FAD)–guided comprehensive therapy for unresectable hepatocellular carcinoma: A prospective phase II study (FAD-HCC-01). First Author: Decai Yu, Department of General Surgery, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China

Background: Hepatocellular carcinoma (HCC) exhibits marked molecular and metabolic heterogeneity, leading to variable therapeutic responses and limiting the effectiveness of current systemic treatments. Despite recent advances in immunotherapy and targeted agents, no validated biomarker is available to guide treatment selection in unresectable HCC. We previously established a fatty acid degradation (FAD) pathway-based molecular classification of HCC, revealing that FAD-associated transcriptional programs delineate biologically distinct HCC subtypes with heterogeneous immune microenvironments and differential responses to systemic and locoregional therapies. These findings suggest that FAD-based stratification may enable a more precise, biology-driven treatment strategy. However, the feasibility of implementing FAD-guided treatment allocation in a prospective clinical setting has not been established. FAD-HCC-01 is designed to evaluate the feasibility, safety, and preliminary efficacy of a FAD-guided comprehensive therapy in patients with unresectable HCC. **Methods:** FAD-HCC-01 is a prospective, multicenter, open-label phase II study enrolling patients with unresectable or non-curatively treatable HCC. Eligible patients have histologically or clinically confirmed HCC, BCLC stage B or C disease, Child–Pugh class A to B ($\leq$7), ECOG performance status 0-1, and no prior systemic therapy. Tumors are classified into FAD subtypes (F1, F2, or F3) using transcriptomic profiling with ssGSEA-based FAD scoring; MRI-derived fat fraction may serve as a provisional surrogate when tumor tissue is unavailable. A total of 86 patients will be enrolled, with 43 patients planned for each treatment cohort. Patients are assigned to two parallel cohorts according to FAD subtype. Patients with F1 or F2 tumors receive camrelizumab (200 mg intravenously every 3 weeks) plus rivoceranib (250 mg orally once daily). Patients with F3 tumors receive transarterial chemoembolization (TACE) combined with camrelizumab and rivoceranib, with TACE performed per institutional standards and repeated as clinically indicated. Treatment continues until disease progression, unacceptable toxicity, or withdrawal of consent. The primary endpoint is objective response rate assessed by RECIST v1.1. Secondary endpoints include ORR by mRECIST, disease control rate, progression-free survival, overall survival, duration of response, conversion to curative treatment, and safety. Key feasibility objectives include successful FAD subtyping, adherence to FAD-guided treatment allocation, and integration of molecular or imaging-based classification into routine clinical workflows. Exploratory analyses will assess concordance between MRI fat fraction and FAD subtypes and explore molecular correlates of treatment response. Clinical trial information: NCT07314372. Research Sponsor: Fundings for Clinical Trials from the Affiliated Drum Tower Hospital, Medical School of Nanjing University.

TPS4257 **Poster Session**

CAREFOL: A phase 3, randomized, open-label, multicenter trial of camrelizumab and rivoceranib with or without intravenous FOLFOX chemotherapy as first-line treatment for unresectable hepatocellular carcinoma. First Author: Linhui Peng, Department of Hepatobiliary Surgery, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: The combination of camrelizumab (an anti-PD-1 IgG4 monoclonal antibody) and rivoceranib (a VEGFR2-TKI) is a standard of care, first-line (1L) therapy for advanced hepatocellular carcinoma (HCC). However, immune therapy resistance leads to ineffective initial treatment and difficulty in maintaining long-term efficacy in some patients. Several studies have shown that oxaliplatin and fluorouracil can induce immunogenic cell death in tumor cells and induce antitumor immune response in the body. Intravenous FOLFOX chemotherapy may regulate the liver tumor microenvironment and improve clinical benefit, a hypothesis supported by positive efficacy signals in the Phase II VIC-TRIPLETS study (NCT05412589). Here we present the design of a phase III randomized controlled study. **Methods:** This investigator-initiated, phase III, randomized, open-label, multicenter trial (NCT06280508) aims to compare the efficacy and safety of camrelizumab and rivoceranib combined with (CAREFOL) or without intravenous FOLFOX chemotherapy (CARE) as first-line treatment for unresectable HCC. Eligible patients are aged at least 18 years, with unresectable or metastatic HCC, no previous systemic treatment, with BCLC stage B or C disease (which is not amenable to or had progressed after surgical or locoregional therapy), at least one measurable lesion per RECIST 1.1 criteria, Child-Pugh class A liver function, an ECOG performance status of 0 or 1, and adequate organ function. Approximately 326 Participants will be randomly assigned (1:1) using a centralized interactive response system. Randomization is stratified by presence of extrahepatic metastasis (yes vs no), macrovascular invasion (Vp0-3 vs Vp4), and baseline α-fetoprotein level ($<$ 400 ng/mL vs $\geq$400 ng/mL). The experimental group consisted of camrelizumab 200 mg intravenously every 3 weeks plus rivoceranib 250 mg orally once daily combined with 21-day cycles of intravenous FOLFOX chemotherapy (oxaliplatin 85 mg/m^2, levofolinate 200 mg/m^2, 5-fluorouracil bolus 400 mg/m^2 on day 1, and 5-fluorouracil infusion 2400 mg/m^2 for 46 hours; up to 6 cycles). The control group is camrelizumab plus rivoceranib (same as experimental group). The dual primary endpoints are investigator-assessed progression-free survival per RECIST v1.1 and overall survival. Secondary endpoints include objective response rate, disease control rate, duration of response, surgical conversion rate, time-to-treatment failure, safety. The trial is currently screening eligible patients. Clinical trial information: NCT07267806. Research Sponsor: None.

TPS4258 **Poster Session**

A phase II trial of trifluridine/tipiracil plus oxaliplatin in patients with advanced or metastatic biliary tract cancer following first-line therapy. First Author: Madison Conces, Department of Oncology, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Biliary tract cancers (BTCs) comprising of intrahepatic and extrahepatic cholangiocarcinoma and gallbladder cancer are aggressive and difficult cancers to treat. Most patients present with metastatic or unresectable disease, and systemic therapy is the only therapeutic option. Treatment options are highly limited after progressing on first line therapy with median survival of 6 months. We demonstrated encouraging activity with single agent trifluridine/tipiracil (FTD/TPI) and FTD/TPI plus irinotecan in separate phase 2 trials in patients with refractory BTCs after multiple lines of therapies (NCT03278106 and NCT04072445). Disease control rate (DCR) of 50% was reported with the combination therapy and median OS was 9.1 months. Prior studies have suggested oxaliplatin-based therapy may be more effective than irinotecan-based therapy in BTC. Thus, FTD/TPI plus oxaliplatin may be an active regimen in patients with advanced BTCs. **Methods:** This is a phase II trial evaluating FTD/TPI plus oxaliplatin as second line treatment in patients with advanced BTCs and disease progression on standard of care gemcitabine-based combination therapy. Key inclusion criteria are pathologically confirmed BTC, ECOG performance status 0 or 1, prior gemcitabine-based combination therapy, adequate organ function, signed informed consent. Key exclusion criteria include >1 prior line of systemic therapy for advanced disease (adjuvant therapy not counted) and active autoimmune disease requiring systemic therapy. Participants will be enrolled at Case Comprehensive Cancer Center sites and receive a dose of FTD/TPI of 25 mg/m^2 twice daily on days 1-5 and oxaliplatin 85 mg/m^2 on day 1 of a 14-day cycle until disease progression, intolerable toxicities, or patient declines to continue study. Primary endpoint is DCR, defined as proportion of patients achieving responses or stable disease with trial treatment. The trial is a Simon 2-stage optimal design with a significance level of 0.05 and 80% power. We estimate a DCR of 0.62 compared to historical control of 0.33 in second line setting. If ≤ 2 patients have disease control out of the first 6 patients enrolled, then regimen will be considered ineffective. If >3 patients have disease control, then the study will proceed to stage 2. During stage 2, an additional 18 patients will be enrolled for 24 total evaluable patients. If >12 patients of the 24 evaluable patients have disease control, then the trial will be considered a success and a larger trial will be planned. Secondary endpoints are grade and duration of adverse events, ORR, PFS, OS. Correlative studies are circulating DNA and oral and fecal samples for microbiome testing. The study is supported by the National Comprehensive Cancer Network (NCCN) through a grant provided by Taiho Oncology. Neither NCCN nor Taiho are the sponsor. Clinical trial information: NCT07146646. Research Sponsor: Taiho.

TPS4259 **Poster Session**

Impact of immunonutrition in patients undergoing hepatectomies for liver tumors: A randomized controlled phase II trial. First Author: Shraddha Patkar, Department of Surgical Oncology, Tata Memorial Hospital (HBNI), Mumbai, India

Background: Recent studies have demonstrated that immunonutrition has the potential to improve the host immune state, reduce infectious complications, and shorten the length of hospital stay after major abdominal surgeries. Controversy still persists regarding whether or not perioperative immunonutrition could offer substantial benefits to patients undergoing hepatectomy as compared with standard nutrition. Several biomarker-based indices reflecting the immune as well as nutritional status, have been investigated, to predict postoperative morbidity following major hepatectomies. One such index, validated in a meta-analysis is the prognostic nutritional index (PNI). Prognostic Nutritional Index (PNI) = [(10 $\times$ serum albumin (g/dL)) + (0.005 $\times$ total lymphocyte count)], with higher PNI correlating with improved survival outcomes . Based on this we aim to conduct a randomized controlled trial to evaluate the improvement of PNI, by immunonutritional intervention in patient undergoing major hepatectomies. **Methods:** Study Design: Open labelled, Phase II randomized controlled trial. Eligibility criteria: Inclusion: (1) Patients with liver tumors planned for major hepatectomies (defined as resection of $>/=$ 3 liver segments); (2) Age above 18 years; (3) ASA class I-III. Exclusion: (1) Preoperative severe renal failure (estimated glomerular filtration rate $<$ 30 ml/min); (2) History of hypersensitivity to arginine, omega-3 fatty acids, or nucleotide; (3) Inability to take oral nutrition; (4) Pregnancy; (5) Mental condition rendering the subject unable to understand the nature, endpoints and consequences of the trial. Interventions: Randomization will be carried out centrally at the Clinical Research Secretariat, Tata Memorial Hospital. The trial statistician will generate a permuted-block randomization sequence using variable sized blocks of 2, or 4, without any stratification factors. Participants will be randomly assigned in 1:1 to receive either the intervention or control. Details of Intervention: In addition to their usual intake, patients in the intervention arm will be prescribed for each of the 7 consecutive days preceding surgery 6-9 scoops Immunomax powder (120-180g per day), based on weight. At recruitment, blood samples will be taken for inflammatory and immune status markers. These measurements will be repeated on the day prior to surgery (D-1) and on POD 1, 3, 5 and 7. An additional Creactive protein (CRP) measurement will be taken on POD30. PNI will be calculated before the intervention and on the day prior to surgery. Primary Endpoints: Mean difference in PNI points between intervention and control group. Secondary Endpoints: (1) Incidence of postoperative complication; (2) Incidence of post-hepatectomies liver failure (PHLF); (3) Length of ICU stay; (4) Length of hospital stay; (5) Incidence of 90 days mortality. 100 patients will be enrolled over 2 years. Clinical trial information: CTRI/2025/06/088908. Research Sponsor: Tata Memorial Hospital Intramural Grant.

TPS4260 **Poster Session**

Phase II study of NC410 and FOLFIRINOX in combination with nivolumab with or without ipilimumab in patients with treatment-naive metastatic pancreatic cancer. First Author: Shriram K. Sundararaman, Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, MD

Background: Pancreatic adenocarcinoma (PDAC) is now the third leading cause of cancer-related death in the United States (1). Median overall survival for patients with metastatic PDAC is 11.1 months with first-line FOLFIRINOX chemotherapy (2) and more effective treatments are needed. A major resistance mechanism to immunotherapy in PDAC is the desmoplastic stroma (3). Collagen physically hinders T cell infiltration and suppresses immune cells in the tumor microenvironment (TME) through the Leukocyte Associated Immunoglobulin-like Receptor-1 (LAIR-1) (4). Both collagen and the complement protein C1q, overexpressed in the PDAC TME, are primary ligands for the inhibitory LAIR-1 receptor on myeloid and lymphoid cells, and binding results in immune cell downregulation (5-7). LAIR-2, primarily made by CD4+ T cells, is a competitive inhibitor of LAIR-1 that reverses the immunosuppressive effect (8). NC410 is a dimeric fusion protein of LAIR-2 with human IgG1 Fc that remodels collagen, reduces tumor growth, enhances T cell tumor infiltration, and overcomes neutrophil-mediated T cell suppression in preclinical studies (7,9,10). NC410 binds the collagen-rich PDAC TME with high avidity when compared across tumor types (7). Our group contributed to the recent phase Ib/II study demonstrating clinical activity of NC410 with pembrolizumab in patients with advanced colorectal and ovarian cancer (NCT05572684). Based on these promising results, our study combines NC410 and immunotherapy with FOLFIRINOX in the first-line setting to assess safety and clinical efficacy in patients with metastatic PDAC. **Methods:** This is a single-center, open-label, two-arm phase II study evaluating safety and efficacy of NC410 and FOLFIRINOX in combination with nivolumab with or without ipilimumab in patients with untreated metastatic PDAC. The two arms enroll sequentially. In Cycle 1, NC410 and FOLFIRINOX are given with nivolumab (Arm 1, n =10) or nivolumab + ipilimumab (Arm 2, n = 10). In Cycle 2 and beyond, patients in both arms receive NC410 and FOLFIRINOX every 2 weeks and can continue to receive treatment per investigator discretion. On study scans are obtained every 8 weeks. Eligible patients have untreated metastatic PDAC, measurable disease per RECIST 1.1, and are willing to undergo tumor biopsy at baseline and on treatment. Primary endpoint is safety. Secondary endpoints are disease control rate, objective response rate, progression free survival, and overall survival. Correlative studies will profile circulating neutrophils and markers of immune activation in paired whole blood and tumor biopsy samples at baseline and on-treatment at Cycle 4. Enrollment began in August 2025 and is ongoing. 10 of planned 20 patients have been enrolled; awaiting 8-week primary safety endpoint evaluation in Arm 1. Trial information: NCT06941857. References upon request. Clinical trial information: NCT06941857. Research Sponsor: The Lustgarten Foundation; Swim Across America; Cynthia Boscov Fund for Pancreatic Cancer Research; James and Frances McGlothlin Fellows to Faculty Fund; U.S. National Institutes of Health.

TPS4262 **Poster Session**

Phase 1 faecal microbiota transplantation in patients with advanced pancreatic carcinoma (FMTPanc Trial). First Author: Timothy Jay Price, Queen Elizabeth Hospital, University of Adelaide, Adelaide, Australia

Background: Higher abundance of specific oral, pancreatic and/or gut microbes is correlated with pancreatic cancer occurrence (e.g. *Porphyromonaas gingivalis*, *Malassezia* sp.). Furthermore, the pancreatic tumour microenvironment of long-term survivors ($\geq$ 5 years) shows richer tumoral microbial diversity associated with more active T-cells and fewer immune-suppressing cells than short-term survivors. Preclinical animal studies have also demonstrated that faecal microbiota transplantation (FMT) from a healthy donor or a long-term survivor can significantly decrease the size of pancreatic tumours. These findings demonstrate that manipulations of the gut and/or organ microbiota holds promise as part of cancer treatment. This trial aims to evaluate whether restoring a healthier microbiota can improve symptoms, visceral pain and treatment efficacy in people with non-resectable pancreatic cancer. **Methods:** This study is a Phase 1 double-blind randomised placebo-controlled trial (RCT) assessing the safety and potential benefit of oral FMT in patients with non-resectable pancreatic cancer. FMT will be a co-treatment to the standard of care chemotherapy. The primary outcomes are FMT safety and toxicity and mortality at 3, 6, and 12 months after chemotherapy initiation. Secondary outcomes include: changes in visceral pain and symptoms measured by PAGI-SYM, changes from baseline in blood CA-19-9 levels and reduction in tumour size as surrogate marker of treatment efficacy, and changes in faecal microbiota as a surrogate marker of gut flora restoration and treatment efficacy at 3, 6, and 12 months after treatment initiation. Power calculations were conducted for the main secondary clinical outcome of interest (i.e. the PAGI-SYM tool) that encompasses pain and symptom monitoring using published evidence, an MCID of 0.94, for an alpha of 0.05 and 80% power a minimum of 14 participants per arm is required. The trial aims to recruit a minimum of 28 and maximum of 60participants, 14-30 per arm. Eligible patients will have advanced and unresectable adenocarcinoma of the pancreas suitable for standard chemotherapy (gemcitabine/nab-paclitaxel or FOLFIRINOX) and be treatment-naive. Patients will be randomised 1:1 to FMT or placebo. FMT and placebo capsules will be prepared by BiomeBank (Adelaide South Australia). Stool will be sourced from healthy donors and rigorously screened following criteria specified by the Australian Therapeutic Administration (TGA). FMT/placebo will be provided through two doses (dose 1: 25mg, dose 2: 50mg). Chemotherapy will commence 3 to 14 days after completion of the first FMT dose (week 0). Supportive medication includes pancrelipase (2x25,000U three times a day) to facilitate digestion during FMT treatment. The FMTPanc is open at 3 sites across South Australia and Victoria and as of January 2025 12 patients have been enrolled. Clinical trial information: ANZCTR: ACTRN12624000455561. Research Sponsor: None.

TPS4263 **Poster Session**

TRIDENT: A phase 2 study of relacorilant plus nab-paclitaxel and gemcitabine in patients with previously untreated metastatic pancreatic ductal adenocarcinoma. First Author: Erkut H. Borazanci, HonorHealth Research Institute, Scottsdale, AZ

Background: Metastatic pancreatic ductal adenocarcinoma (mPDAC) has a 5-year survival rate of < 5%. Approved treatment options are limited to combination cytotoxic chemotherapy such as mFOLFIRINOX or nab-paclitaxel + gemcitabine. Cortisol-mediated glucocorticoid receptor (GR) activation provides prosurvival signals to tumor cells that contribute to chemotherapy resistance. The addition of relacorilant, a selective GR antagonist, to paclitaxel + gemcitabine improved tumor growth inhibition over paclitaxel + gemcitabine alone in a PDAC xenograft model (Greenstein *Oncotarget* 2021). Moreover, in a phase 1 study of relacorilant and nab-paclitaxel, 2 durable confirmed partial responses were observed in patients with mPDAC (Munster *Clin Cancer Res* 2022). The combination of relacorilant and nab-paclitaxel prolonged progression-free survival (PFS) and overall survival (OS) in patients with platinum-resistant ovarian cancer in 2 randomized controlled trials, including the phase 3 ROSELLA study (Olawaiye *Lancet* 2025). The combination was well tolerated, with a safety profile that was consistent with nab-paclitaxel monotherapy. Therefore, the combination of relacorilant, nab-paclitaxel, and gemcitabine is deserving of further clinical study to improve outcomes in patients with mPDAC. **Methods:** TRIDENT is a phase 2, single-arm, open-label, multicenter study (NCT07259317) designed to evaluate the combination relacorilant + nab-paclitaxel + gemcitabine as a first-line treatment in mPDAC (target enrollment, N = 60). Key inclusion criteria are confirmed measurable metastatic disease (per Response Evaluation Criteria in Solid Tumors [RECIST] version 1.1), no prior systemic anticancer therapy to treat metastatic disease, Eastern Cooperative Oncology Group performance status of 0 or 1, and adequate organ function. Patients will receive relacorilant 150 mg orally once daily for 3 consecutive days (day before, day of, and day after chemotherapy) in combination with nab-paclitaxel (100 mg/m^2) and gemcitabine (1000 mg/m^2) given on days 1, 8, and 15 of each 28-day cycle. Treatment will continue until disease progression or unmanageable toxicity. The primary endpoint is investigator-assessed PFS per RECIST version 1.1 and will be analyzed using Kaplan-Meier methods. Secondary endpoints are OS, best overall response, objective response rate, clinical benefit rate at 24 weeks, duration of response, cancer antigen 19-9 kinetics, and tolerability/safety. The study is currently enrolling. Clinical trial information: NCT07259317. Research Sponsor: Corcept Therapeutics.

TPS4264 **Poster Session**

S2433: Randomized phase III study of second-line chemotherapy with or without panitumumab for KRAS wild type, locally advanced, or metastatic pancreatic adenocarcinoma. First Author: Rachael A. Safyan, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA

Background: Pancreatic ductal adenocarcinoma (PDA) is characterized by driver mutations in *KRAS*, *TP53*, *CDKN2A*, and *SMAD4*. *KRAS* wild type (WT) tumors, present in 5-10% of PDA, often harbor alternative mitogen-activated protein kinase (MAPK) pathway drivers or other targetable molecular alterations (e.g., microsatellite instability [MSI-high], DNA damage repair mutations), enabling targeted therapy in approximately 30% of cases; however, most lack actionable drivers and require a tailored treatment approach. EGFR is overexpressed in 30%-70% of PDA. Prior studies of EGFR-targeted therapy demonstrated modest overall survival (OS) benefit in unselected populations, with retrospective analyses suggesting benefit confined to *KRAS* WT PDA. Recent data showed survival benefit from the anti-EGFR antibody nimotuzumab when added to 1st line gemcitabine vs gemcitabine alone in *KRAS* WT PDA. These findings provide a strong rationale to evaluate anti-EGFR mAb in combination with multi-agent chemotherapy in *KRAS* WT PDA in the United States. **Methods:** This randomized (1:1) phase III study will enroll 94 pts to investigator choice 2nd-line chemotherapy – 5 fluorouracil (5FU) plus irinotecan or nanoliposomal irinotecan following 1st-line gemcitabine-based therapy, or gemcitabine plus nab-paclitaxel following 1st-line 5FU-based therapy – with or without panitumumab. Eligibility requires *KRAS* WT and *BRAF* V600E WT status by tumor tissue-based next-generation sequencing and no known mutations in *PTEN*, *NRAS*, *EGFR* extracellular domain exons 1-16, no amplifications of *HER2* and *MET*, and no gene fusions of *RET*, *NTRK1*, and *ALK*. One prior line of chemotherapy for locally advanced or metastatic PDA is permitted. Pts with cancers harboring molecular alterations (e.g., MSI-high, ROS fusion) may have received prior targeted therapy, and past maintenance therapy with a PARP inhibitor does not count as a line of therapy. The primary endpoint is OS; secondary endpoints include safety, progression-free survival, overall response rate, disease control rate, and duration of response. Quality of life will be assessed using the Functional Assessment of Cancer Therapy – General (FACT-G), Functional Assessment of Chronic Illness Therapy (FACIT) Item GP5, and selected patient-reported outcome (PRO)-CTCAE items. Blood and tumor samples will be collected for correlative studies. Standard eligibility criteria apply. Assuming panitumumab improves median OS from 6.3 to 12.6 months, 84 eligible patients provide 90% power with a one-sided alpha of 0.05. Kaplan-Meier methods will estimate OS, with early stopping for efficacy or futility. This study is open to accrual (NCT06998940). Clinical trial information: NCT06998940. Research Sponsor: NIH/NCI/NCTN grants U10CA180888, U10CA180819.

TPS4265 **Poster Session**

A prospective single-arm study of irinotecan liposome II combined with adebrelimab, gemcitabine, and nab-paclitaxel for conversion therapy in locally advanced pancreatic cancer. First Author: Wenwen Zhang, Faculty of Hepato-Pancreato-Biliary Surgery, Chinese PLA General Hospital; Institute of Hepatobiliary Surgery of Chinese PLA; Key Laboratory of Digital Hepetobiliary Surgery, PLA, Peking, China

Background: Locally advanced pancreatic cancer (LAPC) has an extremely poor prognosis, with only a minority of patients eligible for radical surgery at initial presentation. Conversion therapy is critical for improving resectability and survival. Currently, no standard conversion regimen exists for LAPC, and gemcitabine plus nab-paclitaxel (AG regimen) is widely used. Irinotecan liposome has favorable tumor targeting and manageable toxicity; the PAN-HEROIC-1 study showed that irinotecan liposome II combined with 5-fluorouracil/leucovorin (5-FU/LV) significantly prolonged overall survival in Chinese advanced pancreatic cancer patients. Adebelimab, a programmed death-ligand 1 (PD-L1) inhibitor, exerts synergistic antitumor effects with chemotherapy in solid tumors. Herein, we evaluate the efficacy and safety of Irinotecan Liposome II plus Adebelimab and AG regimen as conversion therapy for LAPC to improve surgical conversion rates and survival benefits. **Methods:** This prospective, single-arm, open-label study plans to enroll 45 patients with pathologically confirmed locally advanced pancreatic ductal adenocarcinoma. Key inclusion criteria: 18-75 years old; Eastern Cooperative Oncology Group (ECOG) PS 0-1; adequate major organ function; no central nervous system metastasis; effective contraception for reproductive-aged subjects (pregnancy excluded); informed consent. Exclusion criteria: non-ductal pancreatic cancer; active autoimmune diseases; severe infections; major surgery or investigational drugs within 4 weeks prior to enrollment; other investigator-judged ineligibility. Primary endpoint is surgical conversion rate; secondary endpoints include event-free survival, overall survival, R0/R1 resection rate, objective response rate, pathological complete response rate, and safety profile. Treatment Regimen: Irinotecan Liposome II (40 mg/m², IV infusion 90±30 min, Day 1, q2w) + Adebelimab (1200 mg, IV infusion 30-60 min, Day 1, q4w) + gemcitabine (1000 mg/m², IV infusion > 30 min, Days 1,8,15, q4w) + nab-paclitaxel (125 mg/m², IV infusion > 30 min, Days 1,8,15, q4w). Registration Number: ChiCTR 2500108269. Research Sponsor: Hengrui Pharma. Clinical trial information: ChiCTR2500108269. Research Sponsor: None.

TPS4266 **Poster Session**

Using organoids to predict efficacy of adjuvant treatment to improve outcome in resectable pancreatic cancer: UNITEPANC (AIO-PAK-0424), a prospective, multicenter, proof-of-concept trial of the AIO Pancreatic Cancer Group. First Author: Thomas Jens Ettrich, Department of Internal Medicine I, Ulm University Hospital, Ulm, Germany

Background: Pancreatic cancer (PDAC) is a heterogeneous disease and there is a lack of predictive biomarker to guide treatment. Patient tumor derived organoids (PDO) recapitulate key morphological and genetic features and may preserve patient-specific drug response phenotypes **Methods:** UNITEPANC is a prospective, proof of concept, multicenter IIT of the German AIO PDAC Group and funded by the German Cancer Aid. UNITEPANC examines the feasibility of an organoid-educated adjuvant treatment approach with respect to organoid establishment, expansion and characterization and its potential role for selecting an optimal adjuvant treatment in PDAC in a multicenter setting. Preparatory activities like harmonizing SOPs and round-robin-tests for generation of organoids and organoid-based pharmacotyping in the trial centers and the different Organoid Facilities have been completed and evaluated. UNITEPANC examines selection of adjuvant chemotherapy by pharmacotyping of tumor organoids. Options for adjuvant treatment are gemcitabine, gemcitabine/capecitabine, gemcitabine/nab-paclitaxel or mFOLFIRINOX. Major inclusion criteria are R0 or R1 resected, histologically confirmed PDAC and patients in principle, suitable for mFOLFIRINOX treatment in the adjuvant setting, postoperative Ca19-9 < 180 U/ml, and a timely PDO-based chemotherapy recommendation by the UNITEPANC Organoid Board to guarantee a start of the adjuvant treatment within 12 weeks after resection. UNITEPANC is an interventional, prospective, multicenter, single-arm trial. 92 patients shall be allocated to the trial for the generation of organoids, 38 patients shall be enrolled for PDO-based adjuvant treatment and 34 patients need to be analyzed as ITT population in the follow-up period. Efficacy: The efficacy endpoint of the trial is purely descriptive and intended to obtain a signal for further development of the strategy. This requires the proof of an efficient 1) generation and 2) expansion of PDO and 3) a clear sign that an organoid-educated treatment selection is superior to standard treatment with mFOLFIRINOX. For 1) and 2) we have chosen a rate of 75% and 60%, respectively, according to the literature. For 3): The approach would be considered promising, if the true 18-months-DFS rate is 77% (corresponding to a hazard ratio of 0.5 compared to Prodige-24, 80% power, one-sided type I error 0.1. HR-QoL data will be analyzed (QLQ-C30, Pan26). Additionally, an extensive translational program is enclosed. UNITEPANC has started recruitment in Q3/2025. Clinical trial information: 2023-510490-34-00. Research Sponsor: German Cancer Aid.

TPS4267 **Poster Session**

Phase I light-dose escalation study in locally advanced pancreatic ductal adenocarcinoma: Intra-arterial (IA) padeliporfin vascular-targeted photodynamic therapy (VTP). First Author: Nadine Abi-Jaoudeh, University of California Irvine, Division of Vascular & Interventional Radiology, Department of Radiological Sciences, Orange, CA

Background: Locally advanced pancreatic ductal adenocarcinoma (LA-PDAC) with $>$ 180° vascular encasement of major abdominal arteries is considered unresectable and is associated with poor prognosis. Standard-of-care options, including chemotherapy and chemoradiation, achieve limited conversion to resectability with high recurrence rates. Thus, a therapeutic approach that can effectively downstage LA-PDAC to resection is clinically needed. Activation of vascular-targeted photodynamic therapy (VTP) by Padeliporfin illumination at 753nm results in photochemical generation of oxygen and nitric oxide radicals that cause rapid occlusion followed by break down of the tumor vasculature, tumor necrosis and break-down of the extracellular matrix. Photosensitivity at $>$ 6 hours is avoided due to 1.19 hours Padeliporfin half-life without accumulation in epithelial tissue. Padeliporfin-VTP activation by intra-arterial (IA) illumination has the potential to selectively ablate tumor tissue encasing the artery, reducing vascular encasement and enabling subsequent surgical resection. Robust feasibility and safety preclinical studies in normal swine and efficacy in mouse tumor models have demonstrated feasibility of light transmission through the arterial wall at a dose sufficient to induce tumor ablation at the artery interface and acceptable safety profile, supporting clinical translation. **Methods:** NCT05919238 is an ongoing multi-center Phase I light dose-escalation study. Key inclusion criteria are stage III LA-PADC with solid tumor contact $>$ 180° in head/uncinate process of the pancreas for the total encasement length up to 3cm and with target artery internal diameter 5-10 mm. VTP is applied via IA placement of an optical fiber, inside a standard angioplasty balloon, in the target artery adjacent to the tumor. Ten minutes intravenous administration of Padeliporfin at a fixed dose of 4 mg/kg immediately followed by 753nm laser illumination through the inflated balloon, for two 5-minute cycles with 1-minute break. The study is designed to evaluate three light power densities: 200, 400 and 600mW/cm. The primary objectives include determination of Maximum Tolerated light Dose (MTD) and/or recommended phase 2 dose (RP2D) and evaluation of safety. Secondary objectives are to determine rate of surgical downstaging and resectability as well as the pattern of disease progression following VTP treatment, based on pre- and post-VTP contrast computed tomography (CT) scans and tissue specimens, in case surgery is performed. The study comprises two parts: part A with 3+3 light dose escalation schema; part B (expansion cohort) with the RP2D/MTD, derived in Part A. As of 28 October 2025, Cohort 1 of Part A with an LPD of 200mW/cm have been completed without DLTs. Enrolment to cohort 2, with LPD 400mW/cm, began in November 2025. Clinical trial information: NCT05919238. Research Sponsor: Impact Biotech.

TPS4268 **Poster Session**

Durvalumab and oleclumab in resectable pancreatic ductal adenocarcinoma: A window of opportunity trial (DORA). First Author: Erica Sophia Tsang, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: Resectable pancreatic ductal adenocarcinoma (PDAC) comprises $<$ 20% of cases and remains associated with poor outcomes despite surgery and adjuvant chemotherapy. PDAC features a hypoxic, immunosuppressive and "cold" tumor microenvironment (TME). CD73 has emerged as a prognostic biomarker in PDAC, with high expression linked to poor survival. CD73 on tumor cells impairs antitumor T-cell responses and results in tumor immune escape. Inhibition of CD73 could reverse immune suppression by the TME. Preliminary data from the phase I combination trial of durvalumab (anti-PD-L1 antibody) and oleclumab (anti-CD73 antibody) has shown modest antitumor activity in patients in PDAC, colon cancer, and non-small cell lung cancer. A window-of-opportunity (WOO) study allows for rapid early identification of biological activity. We therefore designed a WOO trial to assess the impact of CD73 and PD-L1 blockade in resectable PDAC to test the hypothesis that this strategy would increase CD8+ T cell infiltration and reduce suppressive immune cells as assessed by digital spatial profiling and image mass cytometry. **Methods:** DORA (NCT06060405) is a prospective phase II multicentre WOO trial evaluating the immune activity of combined CD73 and PD-L1 blockade in upfront resectable PDAC. Eligible patients must have ECOG 0–1, histologically confirmed NCCN resectable PDAC, and be immunotherapy-naïve. Patients undergo an upfront EUS for histological diagnosis and for correlative studies, and then receive a single dose of durvalumab 1500 mg IV and oleclumab 3000 mg IV x 2 doses every two weeks prior to surgical resection. Patients receive standard-of-care adjuvant systemic therapy following surgery. The primary objective is to determine the increase in immune cell infiltration, specifically CD8+ T cells, between the paired pre-treatment and surgical resection specimens. Secondary objectives include the percent change in other immune cell populations (CD3/CD45RA/RO T cells, M1 vs. M2 macrophage), and the dynamic changes in immune cell populations as measured by flow cytometry/CyTOF. A total of 22 patients will be enrolled to ensure 20 evaluable subjects who undergo surgical resection. With 20 patients, this provides 80% power to detect an effect size of 0.66 using a two-sided alpha of 0.05. Planned correlatives include serial ctDNA analysis and whole genome and transcriptome sequencing of all surgical resections. This study was activated in January 2024. Clinical trial information: NCT06060405. Research Sponsor: None.

TPS4269 **Poster Session**

ENVELOPE trial (NCCH2412): Enfortumab vedotin in patients with locally advanced or metastatic small bowel adenocarcinoma refractory or intolerant to platinum-based combination therapy—A multicenter, phase II trial (trial in progress). First Author: Hiroyuki Fujii, Department of Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Small bowel adenocarcinoma (SBA) is a rare malignancy with limited systemic options beyond first-line platinum-based combination therapy (FOLFOX/CapeOX) and no established second-line treatment. We recently reported that Nectin-4 is frequently highly expressed in SBA, providing a biological rationale for enfortumab vedotin, a Nectin-4–directed antibody-drug conjugate (ADC). We designed a multicenter phase II trial to evaluate the antitumor activity and safety of enfortumab vedotin in unresectable locally advanced or metastatic SBA refractory or intolerant to platinum-based combination therapy. To our knowledge, this is the first trial to evaluate the efficacy of ADC in this rare cancer. **Methods:** Key eligibility criteria include age $\geq$18 years, histologically/cytologically confirmed SBA, ECOG PS 0–1, prior FOLFOX or CapeOX with progression or intolerance, $\geq$1 measurable lesion (RECIST v1.1) and adequate organ function. If prior testing has identified alterations qualifying for approved tumor-agnostic therapies, patients must be refractory or intolerant to such therapies. Nectin-4 positivity is not required for enrollment. Exclusion criteria include a history of interstitial lung disease and poorly controlled diabetes. Enfortumab vedotin is administered at 1.25 mg/kg intravenously on days 1, 8, and 15 of each 28-day cycle until progression or unacceptable toxicity. Tumor assessments are performed by enhanced CT every 8 weeks up to week 24 and every 12 weeks thereafter. The primary endpoint is the objective response rate (ORR), as determined by blinded independent central review. Representative secondary endpoints include disease control rate, progression-free survival, overall survival, and safety outcomes, as assessed by the Common Terminology Criteria for Adverse Events v5.0. The null ORR is 5%, and the expected ORR is 25%. An exact binomial design (one-sided α = 0.05; 90% power) requires 25 evaluable patients, with the planned sample size of 27 to account for non-evaluable cases. In a prespecified translational study, tumor Nectin-4 expression will be assessed by immunohistochemistry, and its association with the efficacy of enfortumab vedotin will be explored. Biological specimens will be collected at baseline, during treatment, and at progression for multi-omics analysis to investigate mechanisms of response and resistance. The ENVELOPE trial has been approved by the Institutional Review Board of the National Cancer Center Japan. Enrollment opened on October 2025 and will continue through October 2027; follow-up will extend 12 months after the last patient is enrolled. As of December 31, 2025, 5 patients had been enrolled. Clinical trial information: NCT07347314/jRCT2031250424. Research Sponsor: Japan Agency for Medical Research and Development, AMED; Grant number JP25ck0106015h0001.

TPS4270 **Poster Session**

FusionVAC22_02, a phase I clinical trial in progress: Adjuvant *DNAJB1-PRKACA* fusion transcript–based peptide T-cell activator for fibrolamellar hepatocellular carcinoma (FLC) and other tumor entities carrying the oncogenic driver fusion. First Author: Susanne Jung, Clinical Collaboration Unit Translational Immunology, Department of Internal Medicine, Cluster of Excellence iFIT (EXC2180), University Hospital Tübingen, Tübingen, Germany

Background: The DNAJB1-PRKACA fusion transcript was detected as the oncogenic driver of tumor pathogenesis in fibrolamellar hepatocellular carcinoma (FLC) and other cancers, e.g. oncocytic neoplasms of pancreas and bile duct. We and others have shown that the fusion protein can be targeted by T cell-based immunotherapy: Application of Fusion-VAC-XS15 a peptide-based T cell activator including the TLR1/2 agonist XS15 emulsified in Montanide ISA 51 VG in two FLC patients was well tolerated without systemic side effects and induced long-lasting T-cell response accompanied by disease remission with a progression-free survival of up to 80 months and 60 months in both patients (Bauer *et al.* Nat. Commun., 2022). Based on these promising data, Fusion-VAC-XS15 combined with Atezolizumab is currently under evaluation in the advanced or metastatic situation since October 2023 (Hackenbruch *et al.* Front Oncol., 2024; NCT05937295). For localized FLC, surgical resection still represents the only curative treatment option but shows high relapse rates which underscores the high medical need for adjuvant treatment options. We here present the FusionVAC22_02 trial, which evaluates Fusion-VAC-XS15 as an adjuvant therapeutic in FLC patients who have reached complete remission. **Methods:** FusionVAC22_02 is a Phase I open label, multicentric clinical trial evaluating immunogenicity along with safety, toxicity and first signs of clinical efficacy of Fusion-VAC-XS15 as adjuvant treatment, in 20 patients with FLC or other cancers with proven DNAJB1-PRKACA fusion protein, and lacking adjuvant treatment options. One key eligibility criterion is achievement of complete remission (e.g. due to surgery, radiotherapy, local intervention or systemic treatment) according to RECIST1.1. Of note, a history of liver transplantation or prior immune-mediated side effects (e.g. after treatment with checkpoint-inhibitors) are no exclusion criteria. Fusion-VAC-XS15 is applied twice in a 4-week interval, with an optional booster 56 days after the second application, followed by a 6-month follow-up. Primary objectives include assessment of immunogenicity in terms of peptide-specific T cell responses, as well as evaluation of safety and toxicity. Safety assessment is based on the frequency of adverse events according to CTCAE v5.0. Clinical efficacy is determined by RECIST1.1 assessment on imaging. Recruitment started in July 2025, nine FLC patients from various parts of the world have been included and treated so far, four of which have reached the primary endpoint. Clinical trial information: NCT06789198. Research Sponsor: Fibrolamellar Cancer Foundation; Angewandte Klinische Forschung.

TPS4271 **Poster Session**

Sacituzumab govitecan in combination with capecitabine for the treatment of advanced gastrointestinal cancers after progression on standard therapy.

First Author: Maria Diab, Henry Ford Health/Michigan State University, Detroit, MI

Background: Gastrointestinal (GI) malignancies are associated with poor survival and novel therapies are urgently needed. Sacituzumab govitecan (SG) is an antibody-drug conjugate (ADC) that targets the tumor-associated antigen Trop-2 (trophoblast cell-surface antigen 2). SG is covalently bound to the topoisomerase I inhibitor SN-38, which is the active metabolite of irinotecan. Trop-2 is overexpressed in most GI malignancies, including colorectal, gastric, and pancreatic cancers, and is associated with poor prognosis. SG has been approved for the treatment of second-line triple-negative breast cancer and pre-treated hormone-receptor positive metastatic breast cancer but its role in GI cancers is not determined. Furthermore, its combination with capecitabine has never been studied. **Methods:** We are conducting a single arm, single institution, dose escalation phase 1 trial with a 3+3 design of combination SG plus capecitabine. SG dosing will be at three levels: Level -1 at 5mg/kg; Level 0 at 7.5mg/kg; and Level +1 at 10mg/kg. Dosing will start at dose level 0. SG will be administered as an intravenous infusion on Days 1 and 8 of a 21-day cycle. Capecitabine dose is fixed at 825mg/m^2 and will be delivered orally twice a day for 14 days on and 7 days off, starting on Day 1, of the 21-day cycle. Key eligibility criteria include histologically documented metastatic adenocarcinoma of GI origin, including gastroesophageal, colorectal, and pancreaticobiliary, that has failed standard therapy; age $\geq$18years; ECOG performance status 0-1; and adequate end organ function. Key exclusion criteria include previous receipt of topoisomerase 1 inhibitors. The primary endpoint is the Recommended Phase 2 Dose (RP2D). Secondary endpoints include objective response rates, duration of response, progression-free and overall survival. An exploratory endpoint is the correlation between Trop-2 expression in collected archival tissue and clinical outcomes. Optional biopsies will be offered for patients with missing or insufficient archival tissue. This study has been registered under NCT06065371 and is actively enrolling. The trial will enroll up to 20 patients. The trial is funded by Gilead Sciences, Inc. Clinical trial information: NCT06065371. Research Sponsor: None.

4500 Oral Abstract Session

A phase 2 randomized trial of radium-223 dichloride and cabozantinib in patients (pts) with renal cell carcinoma (RCC) with bone metastases (BM): RADICAL (Alliance A031801). First Author: Rana R. McKay, UC San Diego Moores Cancer Center, San Diego, CA

Background: BM occur in ~30% of RCC pts and are associated with poor survival and symptomatic skeletal events (SSEs). Radium-223, an alpha-emitting bone-seeking radioisotope, prolongs survival in advanced prostate cancer. A pilot study of radium-223 with VEGF tyrosine kinase inhibitors (TKI) in RCC with BM showed safety and early efficacy (McKay, CCR, 2018). Cabozantinib is a TKI that showed efficacy in BM. RADICAL (NCT04071223) was designed to investigate cabozantinib ± radium-223 in RCC with BM. **Methods:** This open label multicenter study enrolled RCC pts with ≥1 symptomatic BM not previously irradiated and Karnofsky performance status ≥60%. Prior therapies were allowed; non-clear cell population was limited to 20%. Randomization was 1:1 to cabozantinib with (Arm A) or without (Arm B) radium-223, stratified by osteoclast-targeted therapy (OTT), prior therapy, baseline opioid use, and IMDC risk. In Arm A, cabozantinib was 40 mg daily cycle 1, 60 mg thereafter if tolerated; radium-223 was 1.49 microcurie/kg IV every 28 days for 6 doses. In Arm B, cabozantinib was 60 mg daily. The primary endpoint was SSE-free survival (SSE-FS). Secondary endpoints were safety, objective response rate (ORR), progression-free survival (PFS) and overall survival (OS). The study was designed with 85% power to detect improvement in 6-month SSE-FS from 65% to 78% (one-sided α=0.05), with planned interim futility analysis at 50% of expected events. **Results:** From 12/2019 to 9/2025, 90 pts were enrolled and evaluable for the interim analysis. Median age was 63 years; 74.4% male, 90.0% White, 83.3% clear cell histology. 11.1% were treatment naïve, 80.0% received OTT, 51.1% had baseline opioid use. IMDC risk was 16.7% favorable, 68.9% intermediate, 14.4% poor. Median cabozantinib dose was 31.4 mg (Arm A) and 40.0 mg (Arm B); median radium-223 cycles was 6. Median follow-up was 13.1 (range 0.1-49.4) months with 50 events, 17 SSEs (Arm A: 10; Arm B: 7) and 33 deaths (Arm A: 13; Arm B: 20). Outcomes are in Table. 71 pts were evaluable for response. ORR was 22.2% (Arm A), 22.9% (Arm B). Any grade treatment-related adverse events were 97.7% (Arm A), 93.2% (Arm B); grade ≥3 were 65.9% (Arm A), 56.8% (Arm B). The trial closed after interim analysis as SSE-FS did not meet the prespecified futility boundary (HR≤1). **Conclusions:** Radium-223 did not improve the primary endpoint of SSE-FS when added to cabozantinib but a numerical prolongation in OS was observed. Combination treatment was safe. Alternative radiotherapeutics warrant investigation in RCC. Clinical trial information: NCT04071223. Research Sponsor: National Cancer Institute.

Interim efficacy analysis.

	Arm	Median (95% CI)	HR (95% CI)
Stratified SSE-FS	**A**	17.9 (15.0-NE)	1.24 (0.62-2.48)

4501 Oral Abstract Session

A prospective, multi-center, phase Ib/II trial of first-line cadonilimab plus axitinib in advanced non−clear cell renal cell carcinoma. First Author: Xu Hu, Department of Urology, Institute of Urology, West China Hospital, Sichuan University, Chengdu, China

Background: Non-clear cell renal cell carcinoma (nccRCC) is a rare and heterogeneous disease with limited treatment evidence. Patients with nccRCC generally respond less favorably to systemic immunotherapy than those with clear cell RCC. However,current evidence for the treatment of nccRCC remains limited,underscoring the need for new strategies. Cadonilimab,a bispecific PD-1/CTLA-4 antibody,has shown antitumor activity in various solid tumors, but its efficacy in RCC remains unknown. Here, we report initial results from a phase Ib/II trial of cadonilimab plus axitinib in advanced nccRCC. **Methods:** This open-label, multi-center, single-arm, phase Ib/II trial included patients with metastatic or unresectable treatment-naive nccRCC, regardless of PD-L1 status, to receive cadonilimab plus axitinib 5mg b.i.d. In phasel,a 3+3 dose-escalation design was adopted,starting at 10 mg/kg Q3W of cadonilimab with axitinib to evaluate safety. In phase II, an additional 31 patients were enrolled at the recommended phase II dose (RP2D). The primary endpoints were safety assessment in phase Ib and objective response rate (ORR) by RECIST v1.1 in phase II. **Results:** As of October 1,2025, A total of 37 patients was enrolled (Phase Ib:n=6;Phase II: n=31), with a median follow-up duration of 14.4 months. In phase Ib, no DLTs were observed. AEs were reported in 100.0% (6/6) of cases. Grade≥3 treatment-related adverse events (TRAEs) occurred in 66.7% (4/6) of cases,including proteinuria, hypertriglyceridemia, myasthenia gravis, diarrhea and alanine aminotransferase increased. The RP2D for cadolinimab was 10 mg/kg. For secondary endpoints, ORR was 50% (2/4) and DCR was 100% (6/6). In phase II, the ORR was 51.6%(16/31). DCR was 96.8% (30/31). AEs were reported in100.0% of cases. Grade≥3 treatment-related adverse events (TRAEs) occurred in 58.1% (18/31) of cases. All AEs were expected and manageable. The median PFS was 16.7 (95%CI,11.8-NR). The median OS was NR at the data cutoff. For the total cohort, the median PFS was 17.3(95%CI,12.1-NR). The median OS was NR at the data cutoff. **Conclusions:** Cadonilimab combined with axitinib demonstrated encouraging efficacy and tolerability as first-line therapy in advanced nccRCC across subtypes in this multi-center phase Ib/II study. Clinical trial information: NCT05808608. Research Sponsor: None.

Summary of efficacy analysis and tumor response review per RECIST v1.1.

	Phase Ib	Phase II	Total cohort
Objective response rate, n(%)	2 (50)	16 (51.6)	18 (51.4%)
Disease control rate, n(%)	6 (100)	30 (96.8)	36 (97.2%)
mPFS (95%CI) months	NR (17.3, NR)	16.7 (11.8-NR)	17.3 (12.1-NR)
mOS (95%CI), months	NR (NR, NR)	NR (NR, NR)	NR (NR, NR)

4502 Oral Abstract Session

ctDNA analysis in participants with renal cell carcinoma treated with adjuvant pembrolizumab or placebo in the KEYNOTE-564 trial. First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: In the phase 3 KEYNOTE-564 trial (NCT03142334), adjuvant pembrolizumab (pembro) was superior to placebo (pbo) in participants (pts) with clear cell renal cell carcinoma (ccRCC) at increased risk of recurrence post nephrectomy. We report an analysis of pre-treatment and on-treatment ctDNA (using 2 versions of a ctDNA assay with different sensitivities) with clinical outcomes in KEYNOTE-564. **Methods:** Pts with ccRCC at increased risk of recurrence post nephrectomy were randomized 1:1 to pembro or pbo. ctDNA was evaluated using Natera's Signatera RUO tissue-exome-based 16-plex and 64-plex ctDNA assays. Primary objectives of this analysis were to evaluate the association of baseline ctDNA status and ctDNA status change from baseline to cycle 5 day 1 (C5D1) with disease-free survival (DFS). Significance was prespecified at multiplicity-adjusted α = 0.05. Sensitivity (percentage of ctDNA-positive pts among all pts with a DFS event) and specificity (percentage of ctDNA-negative pts among all pts without a DFS event) to predict DFS were also evaluated. **Results:** 994 pts were randomized to pembro (n = 496) or pbo (n = 498). ctDNA samples from 736 pts (pembro n = 374; pbo n = 362) were analyzed at baseline and from 641 pts at C5D1 (pembro n = 314; pbo n = 327) using both assays. Median study follow-up was 69.5 mo (range 60.2-86.9). In both treatment arms, ctDNA was detectable at baseline in 40 pts (5.4%) using the 16-plex assay and 60 pts (8.2%) using the 64-plex assay. By risk group, using the 16-plex assay, ctDNA was detectable at baseline in 26 of 642 (4.0%) intermediate-high risk pts, 10 of 53 (18.9%) high-risk pts, and 4 of 38 (10.5%) M1 NED pts; using the 64-plex assay, ctDNA was detectable in 44 of 642 (6.9%) intermediate-high risk pts, 11 of 53 (20.8%) high-risk pts, and 5 of 38 (13.2%) M1 NED pts. For both assays, ctDNA positivity was negatively associated with DFS in both pembro and pbo arms (P's < 0.05). ctDNA status at baseline showed low sensitivity and high specificity to predict DFS in both treatment arms (Table). Of pts with detectable ctDNA at baseline and evaluable ctDNA at C5D1, ctDNA clearance at C5D1 occurred in 6 of 10 pts in the pembro arm and 3 of 14 pts in the pbo arm using the 16-plex assay; and 10 of 18 pts in the pembro arm and 9 of 25 pts in the pbo arm using the 64-plex assay. In both assays, ctDNA change from baseline at C5D1 was associated with DFS for both pembro and pbo arms (P's < 0.05). **Conclusions:** While sensitivity was low, ctDNA positivity was associated with worse DFS outcomes irrespective of the ctDNA assay used. ctDNA clearance was higher in the pembro arm than the pbo arm. These data highlight the limitations of these ctDNA assays in ccRCC. Clinical trial information: NCT03142334. Research Sponsor: Funding for this study was provided by Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

% (n/N)	Pembro Sensitivity	Pembro Specificity	Pbo Sensitivity	Pbo Specificity
Baseline ctDNA, 16-plex	12 (17/146)	98 (224/228)	10 (18/173)	99 (188/189)
Baseline ctDNA,64-plex	15 (22/146)	96 (220/228)	15 (26/173)	98 (185/189)

4503 Oral Abstract Session

Intravesical recombinant BCG combined with chemo-immunotherapy (chemo-IO) as perioperative therapy for patients with muscle-invasive bladder cancer (MIBC): Primary analysis of SAKK 06/19. First Author: Richard Cathomas, Division of Oncology, Cantonal Hospital Graubunden, Chur, Switzerland

Background: Perioperative chemo-IO is a new standard for MIBC but pathological complete remission (pCR) rates remain modest. Intravesical Bacillus Calmette Guérin (BCG) is very effective in non-muscle invasive bladder cancer, inducing a local immune response and likely activation of adaptive immunity, with evidence of systemic immune modulation that may enhance downstream immune-oncological effects. The use of BCG in MIBC has not yet been explored, primarily due to concerns about systemic complications. The recombinant BCG vaccine VPM1002BC (rBCG) is associated with enhanced immunogenicity and an improved safety profile. We hypothesize that the combination of intravesical rBCG and chemo-IO in MIBC may act synergistically, augmenting systemic immune activation and hereby improve anti-tumor efficacy without compromising safety. **Methods:** SAKK 06/19 is an open-label single arm phase II trial for cT2-T4a N0-1 MIBC patients (pts) eligible for cisplatin and radical cystectomy with lymphadenectomy (RC). rBCG was instilled weekly x3 (day 1, 8, 15). Atezolizumab (Atezo) 1200 mg was administered on day 1 and then x4 every 3 weeks (q3w). Cisplatin and gemcitabine started on day 22 and were given for 4 cycles q3w followed by RC. Only in case of ≥ ypT2 or ypN+, Atezo q3w was given after surgery for 13 cycles. pCR defined as ypT0 ypN0 and assessed by central pathological review was the primary endpoint. Based on Simon's minimax 2-stage design with H0 pCR ≤ 35% and H1 pCR ≥ 55%, accrual of 46 pts was needed (including 15% dropouts). Secondary endpoints included event free survival (EFS), overall survival (OS), pathological response (PaR, ≤ ypT1N0), feasibility and safety. NCT04630730. **Results:** 47 pts were included between 04/22 and 04/25 at 10 Swiss sites. 7 pts did not undergo RC (6 refused, 1 unfit for surgery). Of the 40 resected pts 53% had cT2, 37% cT3, 10% cT4 and 88% cN0, 12% cN1. rBCG was instilled in 95% of pts, 78% had all 3 doses. 98% received 4 doses of Atezo and 95% had 4 cycles of platinum (20% switched to carboplatin). pCR according to central review was 65% (26/40; one-sided 95% CI lower boundary of 51%) and PaR was 80% (32/40). Overall pCR for all included pts was 55% (26/47). TRAEs overall, G3, G4 were 48%, 9%, 0% to rBCG, 55%, 15%, 2% to Atezo and 98%, 38%, 17% to chemotherapy. No treatment-related deaths occurred. At a median follow-up of 11.8 months 1-year overall EFS was 88% (95% CI 71 - 95) and OS 95% (95% CI 81 - 99). **Conclusions:** This is the first trial to combine intravesical rBCG with chemo-IO in MIBC. The combination was feasible and safe without unexpected toxicities. The centrally assessed pCR rate of 65% and PaR of 80% are among the highest reported in an unselected MIBC population. Integration of intravesical rBCG into novel MIBC treatment regimens appears highly promising, particularly in the context of bladder-preservation approaches. Clinical trial information: NCT04630730. Research Sponsor: Roche; Swiss State Secretariat for Education, Research and Innovation (SERI).

4504 Clinical Science Symposium

Feasibility and safety results from RAD-IO: A multi-stage trial of durvalumab with chemoradiotherapy with 5-fluorouracil and mitomycin C in patients with muscle-invasive bladder cancer. First Author: Nicholas David James, The Institute of Cancer Research and The Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom

Background: Immune checkpoint inhibitors have a defined role peri-operatively and in the adjuvant setting when cystectomy is used as radical definitive treatment (Powles, T., *et al.* 2024, Galsky, M. D., *et al.* 2024). Their role when chemoradiation therapy (CRT) is used as definitive treatment remains to be established. RADIO is a multi-stage partially randomised trial comparing CRT (RT/5FU/mitomycin C) with durvalumab (CRT-D) given prior to, concurrently and 12 months following CRT in localized muscle-invasive bladder cancer. The trial is funded by AstraZeneca. **Methods:** Eligible patients had T2–T4aN0–N2M0 urothelial carcinoma of the bladder. Neoadjuvant chemotherapy was delivered as standard of care, where fit, prior to trial therapy. After randomised feasibility and safety criteria were met, the trial transitioned to a single-arm CRT-D design. Here we report the primary endpoint of 1-year disease-free survival rate (1yDFS) for all evaluable CRT-D participants, plus progression free survival (PFS), disease free survival (DFS), and overall survival (OS). DFS patients with disease present at 3-month imaging are categorised as having never been disease free. The design aimed to detect 1yDFS improvement, based on our previous trials, from 60% (CRT) to 75% (CRT-D) with 80% power and one-sided α=0.10. **Results:** All data are preliminary. Between Oct 2020–Mar 2024, 55 participants (45 male; 10 female) with median age 70 (IQR 62-76) years of whom 40 (73%) had T2N0, 8 (14%) had T3N0 and 7 (13%) had TxN1-2 were enrolled to receive CRT-D. 41 (74.5%) received neoadjuvant CT. Of the 54 participants who started treatment, all completed planned RT (55Gy/20Fr); 47 (87%) within the expected timeframe, 7 (13%) required an extension (2-6 days) (toxicity 3, patient choice 3, other 1). Toxicities extending RT: urinary tract infection, chest pain, and low platelets. At abstract submission, 48/55 were evaluable: 1yDFS 79% (38/18; 95% CI 66%, 88%). 12-month Kaplan-Meier estimates were: PFS 83% (95% CI 73%, 94%), DFS 72% (95% CI 61%, 85%), OS 96% (95% CI 91%, 100%). Safety: 35 SAEs; 17 unrelated SAEs, 12 SARs, 6 SUSARs. 10 SAEs were related to durvalumab, 3 were related to CT, and 5 were related to both durvalumab and CT. 3 SAEs led to discontinuation (5FU 2, durvalumab 1). 168 AESIs have been reported (most common: diarrhoea (19%), rash (12%), creatinine increased (8%)), and an additional 41 grade $\geq$3 AEs. **Conclusions:** Durvalumab combined with CRT demonstrated promising 1-year DFS and survival outcomes compared to our previously reported CRT outcomes (Hall, E., *et al*, 2022) with manageable safety profile. CRT-D is a safe treatment with a side effect profile in keeping with known side effects of CRT and durvalumab. Further investigation is warranted. Clinical trial information: 43698103. Research Sponsor: AstraZeneca UK Limited.

4506 Oral Abstract Session

Perioperative SHR-A2102, a novel nectin-4—targeted antibody-drug conjugate, in combination with adebrelimab for patients (pts) with muscle-invasive bladder cancer: Results from a phase 2/3 study. First Author: Dingwei Ye, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Muscle-invasive bladder cancer (MIBC) is an aggressive disease, with substantial recurrence risk after radical cystectomy and pelvic lymph node dissection (RC + PLND) alone. SHR-A2102 is a nectin-4-targeted antibody-drug conjugate carrying topoisomerase I inhibitor payload. This phase 2/3 study (NCT06879145) evaluates the efficacy and safety of SHR-A2102 in combination with adebrelimab (an anti-PD-L1 antibody) as perioperative treatment for MIBC. Here, we report the preliminary results from the phase 2 study. **Methods:** In the multicenter phase 2 part, pts aged $\geq$18 years, ECOG PS 0-1, with pathologically and radiographically confirmed T2-4aN0M0 or T1-4aN1M0 MIBC, and scheduled for RC + PLND were enrolled. Pts received neoadjuvant treatment with 4 cycles of intravenous SHR-A2102 (8 mg/kg, day 1 Q3W) and adebrelimab (1200 mg, day 1 Q3W), followed by surgical resection and 5 additional cycles of adjuvant SHR-A2102 (8 mg/kg, day 1 Q3W) plus 13 additional cycles of adjuvant adebrelimab (1200 mg, day 1 Q3W). The primary endpoints are the recommended phase 3 dose (RP3D) and investigator-assessed pathological complete response (pCR, defined as pT0N0). **Results:** As of Nov 24, 2025, 37 pts were enrolled; 91.9% were male and the median age was 66 years (IQR 59-74). The ECOG PS was 0 in 24.3% of pts and 1 in 75.7%. Regarding disease stage, 29.7% were classified as T2N0, 51.4% as T3-4aN0, and 18.9% as T1-4aN1. Among 7 pts with target lesions, the neoadjuvant regimen achieved an objective response rate of 71.4% (5/7; 95% CI 29.0–96.3) and a disease control rate of 100.0% (95% CI 59.0–100.0). A total of 27 pts underwent RC + PLND, 13 (48.1%, 95% CI 28.7-68.1) achieved pCR and 16 (59.3%, 95% CI 38.8-77.6) attained pathological downstaging ($<$ pT2N0). Consistent pCR benefits were observed across all predefined subgroups, with creatinine clearance $<$ 60 mL/min showing no discernible effect on pCR rates. Of the 10 pts who refused or were ineligible for radical surgery after neoadjuvant therapy, 5 received transurethral resection of bladder tumor and 3 of whom achieved a complete clinical response (cCR, defined as T0N0M0). With the median follow-up of 4.7 months (IQR 2.1-6.6), 3 event-free survival events were reported. Grade 3 or higher adverse events occurred in 40.5% (15/37) of the pts, primarily decreased neutrophil count (16.2%) and decreased lymphocyte count (10.8%). No patient was ineligible for surgery due to adverse events. **Conclusions:** Perioperative treatment with SHR-A2102 plus adebrelimab showed promising efficacy and was well tolerated in pts with MIBC. This combination holds potential benefit even for pts with renal impairment, suggesting its clinical applicability may extend beyond cisplatin-eligible populations. These results support further investigation for SHR-A2102 plus adebrelimab in this population. Clinical trial information: NCT06879145. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

4507 Oral Abstract Session

Enfortumab vedotin plus pembrolizumab (EV+P) vs chemotherapy for previously untreated locally advanced or metastatic urothelial carcinoma (la/mUC): 3.5-year follow-up and response analyses from the phase 3 EV-302 study. First Author: Thomas Powles, Barts Cancer Centre, Queen Mary University of London, London, United Kingdom

Background: EV+P is the preferred standard of care for previously untreated la/mUC based on the EV-302/KEYNOTE-A39 trial (NCT04223856). We present updated data with 3.5 years of median follow-up, including exploratory subgroup analyses focusing on patients who achieved a complete response (CR) after an initial partial response (PR). **Methods:** Patients were randomized 1:1 to EV 1.25 mg/kg IV (days 1 and 8 of each 3-wk cycle) and P 200 mg IV (day 1) or gemcitabine + cisplatin/carboplatin, with treatment until disease progression, toxicity, or maximum number of cycles. Dual primary endpoints were progression-free survival by blinded independent central review and overall survival (OS); safety was a secondary endpoint. **Results:** With 42.8 months of median follow-up (data cutoff: October 6, 2025), OS benefit favoring EV+P (n=442) vs chemotherapy (chemo; n=444) was maintained (median OS, 33.6 vs 15.9 months; 42-month OS rate, 44.0% vs 24.6%; HR, 0.53 [95% CI, 0.45-0.63]), with no new safety signals. Of responding patients, 45.1% achieved a CR in the EV+P arm (n=295) and 32.8% in the chemo arm (n=195. Data cutoff was Aug 8, 2024. Among patients with confirmed CR in the EV+P arm, 66.2% achieved a PR initially, then converted from a PR to a CR with a median of 5 additional EV cycles (IQR, 3.0-8.0). In this subgroup, mOS was not estimable (NE), and $>$80% of patients were alive after 3.5 years. Longer treatment duration did not lead to new safety concerns. Overall, the most common first subsequent treatment was platinum-based chemo in the EV+P arm (n=135 [30.5%]) and a PD-L1 inhibitor in the chemo arm (n=265 [59.7%]). In the EV+P arm, investigator-assessed responses to subsequent platinum chemo occurred in 28 of 135 evaluable patients (20.7%). **Conclusions:** EV-302 represents the longest follow-up available for EV+P in a phase 3 trial. After 3.5 years of median follow-up, EV+P continues to demonstrate superior efficacy vs chemo, with no new safety signals. Two-thirds of patients achieving CR converted from an initial PR, suggesting that treatment duration is relevant in maximizing outcomes. Clinical trial information: EV-302 NCT04223856. Research Sponsor: Astellas Pharma Inc., Northbrook, IL, USA; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; Seagen Inc., Bothell, WA, USA, which was acquired by Pfizer in December 2023.

4508 Oral Abstract Session

Initial results from NEXUS-01, a phase 1 study of LY4052031, an antibody-drug conjugate targeting Nectin-4, in participants with advanced or metastatic urothelial carcinoma. First Author: Gopa Iyer, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Enfortumab vedotin plus pembrolizumab (EVP) is the current first-line standard of care for locally advanced / metastatic urothelial carcinoma (mUC). However, subsequent treatment options are limited, representing an urgent and growing unmet need. Preclinical data suggest that EV resistance may be payload mediated and consequently Nectin-4 remains a viable target for alternative therapies. LY4052031 is a next generation anti-Nectin-4 ADC, comprising a humanized IgG1 antibody conjugated to Camp98, a novel topoisomerase I inhibitor, via a cleavable peptide linker with homogeneous drug antibody ratio of 8. Here, we report the initial clinical data from the phase 1 dose escalation cohort of NEXUS-01 (NCT06465069). **Methods:** Adults with locally advanced / mUC or other selected solid tumors were eligible. Participants (pts) must have received or were ineligible for available standard therapies, and have ECOG PS 0-1. Dose escalation utilized a Bayesian optimal interval design. Key endpoints were safety, PK, and antitumor activity of LY4052031 per RECIST v1.1. **Results:** As of 25 Nov 2025, 70 pts (47 mUC, 23 non-UC) received LY4052031 doses ranging from 0.6-5.4 mg/kg IV Q3W. Median age was 66 years (range, 31-82); 60% had ECOG PS 1. Among pts with mUC, 70% (33/47) had prior EV (6% [2/33] had discontinued EV due to treatment-related toxicity). LY4052031, total antibody, and Camp98 exhibited mostly linear, dose-proportional PK, except at 4.8-5.4 mg/kg for payload. The most common treatment-emergent AEs (TEAEs) were nausea (43%), alopecia (39%), fatigue (37%), decreased appetite (29%), constipation, diarrhea, dysgeusia, mucositis, vomiting (27% each), and anemia (24%). The most common grade $\geq$3 TEAE was anemia (13%). Low activity scores (AS) for CYP2D6, the metabolic clearance pathway for Camp98, were associated with increased dose-limiting toxicity at higher dose levels. Thus, the study was amended to require CYP2D6 genotyping prior to treatment with dedicated dose finding in pts with low AS ($<$ 0.5). Response was assessed in efficacy evaluable pts, defined as all treated pts who had at least 1 post-baseline response assessment or who discontinued prior to the first post-baseline response assessment. In 21 efficacy evaluable mUC pts (AS $\geq$0.5) treated with 2.4-4.8 mg/kg, ORR was 48% (10/21) and DCR was 81% (17/21) with 1 CR, 9 PR, and 7 SD. Among those who had prior EV (8 EV and 7 EV/P), ORR was 40% (6/15) and DCR was 80% (12/15) with 1 CR, 5 PR, and 6 SD; in the EV naïve pts, ORR was 67% (4/6) and DCR was 83% (5/6) with 4 PR and 1 SD. Median follow-up was 7 months (95% CI, 2.79-NE); median DoR was 7 months (95% CI, 2.7-NE). **Conclusions:** LY4052031 demonstrated promising clinical activity at multiple dose levels, including in EV pre-treated mUC. CYP2D6 AS specific dose optimization is ongoing and updated results will be presented. Clinical trial information: NCT06465069. Research Sponsor: Eli Lilly and Company.

Health-related quality of life (HRQoL) with neoadjuvant and adjuvant (neoadj-adj) enfortumab vedotin (EV) plus pembrolizumab (pembro) in participants (pts) with muscle-invasive bladder cancer (MIBC) who are cisplatin ineligible: Phase 3 KEYNOTE-905 study. First Author: Peter H. O'Donnell, University of Chicago, Chicago, IL

Background: In KEYNOTE-905/EV-303 (NCT03924895), neoadj-adj EV + pembro and radical cystectomy (RC) + pelvic lymph node dissection (PLND) showed significant and meaningful improvements in EFS, OS, and pathologic complete response vs RC + PLND in pts with MIBC who were ineligible for or declined cisplatin (cis) therapy. Prespecified exploratory HRQoL outcomes are reported. **Methods:** Pts with MIBC who were ineligible/declined cis were randomized 1:1 to neoadj-adj EV + pembro and RC + PLND or RC + PLND (control). HRQoL was analyzed in pts who completed ≥1 PRO assessment. EQ-5D-5L and Functional Assessment of Cancer Therapy (FACT)–Bladder-Cystectomy (BI-Cys) with FACT-general (FACT-G) and Bladder Cancer Index (BCI) were assessed predose on D1 of neoadjuvant cycles 1 (baseline [BL]), 2, and 3; pre- and post-surgery; and predose on D1 of adjuvant cycles 1, 2, 4, 8, and 12 in the EV + pembro arm. In the control arm, assessments were at pre- (BL) and post-surgery. In both treatment (Tx) arms, assessments were also done at Tx discontinuation, Q12W for ≤2y, and Q24W thereafter. End points included mean (95% CI) change from BL to post-surgery wk 18 in FACT-G score; FACT–BI-Cys scores (BI-Cys subscale and Trial Outcome Index [TOI]); BCI urinary, bowel, and sexual scores; and EQ-5D-5L visual analog scale (VAS). **Results:** At post-surgery wk 18, completion and compliance rates for all assessments were ≥65% in the EV + pembro arm and >86% in the control arm. Mean changes from BL to post-surgery wk 18 were similar between arms for FACT-G total and FACT–BI-Cys subscale scores; FACT–BI-Cys TOI score; BCI urinary, bowel, and sexual scores; and EQ-5D-5L VAS score (Table). BCI sexual and bowel score diminution was observed in both arms. For all PRO assessments, mean changes from BL over time were similar between Tx. **Conclusions:** The addition of neoadj-adj EV + pembro did not decrease HRQoL 18 wk post-surgery relative to RC + PLND alone; BCI bowel and sexual domains worsened in both arms, consistent with prior reports of RC impact. Given the superior efficacy and manageable safety, these results support the benefit/risk profile of EV + pembro and RC + PLND as Tx for pts with MIBC ineligible for or declining cis. Clinical trial information: NCT03924895. Research Sponsor: The study was conducted by Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA in collaboration with Astellas Pharma Inc., Northbrook, IL, USA and Seagen Inc., Bothell, WA, USA, which was acquired by Pfizer in December 2023.

Mean change from BL to post-surgery wk 18, (95% CI), n	EV + pembro	Control
FACT-G total score	−2.73 (−6.22 to 0.75) n = 102	−2.84 (−6.11 to 0.43) n = 75
FACT–BI-Cys (subscale/symptom index) total score	1.31 (−0.70 to 3.32) n = 102	1.85 (−0.59 to 4.29) n = 75
FACT–BI-Cys TOI	−1.89 (−5.61 to 1.84) n = 102	−0.58 (−4.35 to 3.20) n = 75
BCI urinary	−2.03 (−6.12 to 2.07) n = 101	−0.05 (−5.90 to 5.80) n = 70
BCI bowel	−4.75 (−8.73 to −0.77) n = 101	−4.27 (−7.93 to −0.61) n = 70
BCI sexual	−15.46 (−20.53 to −10.39) n = 94	−17.88 (−24.36 to −11.40) n = 61
EQ-5D-5L VAS	−2.52 (−7.23 to −2.19) n = 102	−0.39 (−5.14 to 4.36) n = 75

Decision regret and toxicity perception following adjuvant pembrolizumab in renal cell carcinoma. First Author: Elizabeth Nally, Barts Cancer Institute, London, United Kingdom

Background: Adjuvant pembrolizumab (pembro) is standard of care in renal cell carcinoma (RCC). We explored whether patients retrospectively regret their decision to receive adjuvant pembro and hypothesised that this is related to long-term toxicity that is not adequately captured by CTCAE criteria. To address this we developed a patient-informed tool, co-designed with patients, focusing specifically on long-term toxicity. **Methods:** Patients with RCC who received adjuvant pembro across three tertiary cancer centres in London between June 2022-Dec 2024 were invited to participate. Eligible patients completed the validated Ottawa Decision Regret Scale (DRS) and a complementary questionnaire exploring factors influencing regret including toxicity and disease recurrence. CTCAE-graded immune-related adverse events (irAEs) were collected and correlated with decision regret (DR). In parallel, patients categorised irAEs as life-changing, significant or non-significant and these were correlated with DR. DRS > 25 was defined as moderate-high regret. Appropriate ethical approval was obtained. **Results:** 104 patients were included post adjuvant pembro (88% pT3N0, 4% pT3N1 and 8% M1 NED). Median follow up was 30 months. 14% patients have relapsed. CTCAE ≥G3 irAEs occurred in 18%. 28% and 11% reported toxicity as significant (S) or life changing (LC) respectively. Patient reported S and LC toxicity did not correlate with ≥G3 CTCAE (p= 0.11), with 33% CTCAE G1-2 events reported as significant. Mean DR score was 14.9 (95% CI 8.5-21.3) with 13% expressing regret. 1/14 patients who had disease recurrence expressed regret (mean DRS = 10.3 [1.4-19.3]). Patients that reported LC & S toxicity expressed more regret (26.9 LC v 26.1 S v 2.1 NS, p= 0.0021). There was no difference in regret between patients that sustained CTCAE G1-2 versus G3-4 irAE (14.9 vs 15.1, p= 0.23). DR was highest with permanent endocrine (n = 24) or musculoskeletal (n = 22) irAEs (endo: DRS 28.8 v 9.5, p= 0.003; MSK: DRS 25.1 v 12.8, p= 0.042). Lower baseline expectations of toxicity correlated with greater DR (p= 0.002). **Conclusions:** DR after adjuvant pembro is driven by long-term, low-grade toxicity rather than disease recurrence. Novel patient-informed tools that capture life-changing or permanent toxicities outperform CTCAE in identifying patients at risk of regret. Improved baseline education on long-term risks may reduce decision regret and improve shared decision-making. Research Sponsor: None.

Health-related quality of life (HRQOL) with pembrolizumab or observation for high-risk muscle-invasive urothelial carcinoma after surgery: Results from the AMBASSADOR randomized trial (Alliance A031501). First Author: Ronald C. Chen, University of Kansas Medical Center, Kansas City, KS

Background: The AMBASSADOR trial (NCT03244381) showed that in patients with high-risk muscle-invasive urothelial carcinoma after radical surgery, adjuvant pembrolizumab for one year improved disease-free survival from 14.2 to 29.6 months (Apolo et al, NEJM 2024). Here we report the HRQOL results. **Methods:** HRQOL was completed by 560 randomized patients and included the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 plus the bladder cancer supplement BLM30, and the EQ-5D-5L, which assesses overall quality of life or health state. Published minimally important difference thresholds for EQ-5D-5L is 0.06, and for EORTC instruments is 5-10 points. For all reported HRQOL data, higher score is better except BLM30 urinary symptoms, where higher score indicates more symptoms. **Results:** Mean changes from baseline to 12 months (corresponding to end of treatment) for each HRQOL measure are summarized in the Table. No statistically significant difference was seen between the observation vs. pembrolizumab arms. Further, numerical differences between arms for these HRQOL measures do not meet (are lower than) the published minimally clinically important difference thresholds. **Conclusions:** Adjuvant pembrolizumab after radical surgery for patients with high-risk muscle-invasive urothelial carcinoma improved disease-free survival without negatively affecting HRQOL. These HRQOL results add further support to adjuvant immune checkpoint blockade therapy in these patients. Support: U10CA180821, U10CA180882, UG1CA189823 (https://acknowledgments.alliancefound.org). MAIN-CAV: Phase III randomized trial of maintenance cabozantinib and avelumab versus avelumab after first-line platinum-based chemotherapy (PBC) in patients (pts) with locally advanced/metastatic urothelial cancer (la/mUC; Alliance A032001). First Author: Shilpa Gupta, Department of Hematology and Oncology, Cleveland Clinic - Taussig Cancer Institute, Cleveland, OH

Background: Maintenance avelumab is a standard of care in patients (pts) with la/mUC who do not progress after first-line PBC. Cabozantinib (CABO) is an oral inhibitor of MET, VEGFR and TAM, active in multiple solid tumors. We hypothesized that an avelumab (Av)-CABO combination would improve outcomes in pts with mUC with an acceptable safety profile compared to avelumab maintenance alone. **Methods:** MAIN-CAV (NCT05092958) is a phase III randomized, multicenter, international trial for la/mUC pts who did not progress after 4-6 cycles of any PBC (gemcitabine-cisplatin, gemcitabine-carboplatin, MVAC, ddMVAC). Pts were randomized 1:1 to Av 800 mg IV every 2 weeks alone or with CABO 40 mg daily for ≤2 years. Stratification factors were response to first-line PBC (complete response [CR] vs partial response [PR] vs stable disease [SD]) and visceral metastases. The primary endpoint was overall survival (OS); secondary endpoints included progression-free survival (PFS), safety and quality of life. The target accrual was 654 pts; the trial closed early after enrollment of 68 pts following adoption of enfortumab vedotin plus pembrolizumab as the new preferred first-line standard in the US. **Results:** From 3/2022 to 3/2024, 68 pts were randomized (Av n = 33; CABO-Av n = 35). Median OS was 24.8 months (mo) with Av and 23.0 mo with Avb-CABO (Hazard ratio 1.41; 95% CI 0.66–3.01; p = 0.186). Median PFS was 4.6 mo with Av vs 6.0 mo with Av-CABO (p = 0.343). Objective response rate among pts with PR or SD after first-line PBC was 20.8% with Av vs 11.5% with Av-CABO (p = 0.424). Grade ≥3 treatment-related adverse events occurred in 24.2% pts on the Av arm vs 39.4% of pts on the Av-CABO arm and CABO dose reductions occurred in 63% of pts. **Conclusions:** Addition of CABO to Av did not improve OS or PFS compared with Av alone in this underpowered, prematurely closed phase III trial; safety was consistent with known profiles. Phase II study of frontline gemcitabine, 5-fluorouracil/leucovorin, and cisplatin (GemFLP) in advanced urachal and non-urachal urinary tract adenocarcinoma. First Author: Emanuele Crupi, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Adenocarcinomas of the urinary tract are rare malignancies with limited prospective data. Outcomes of triplet chemotherapy remain poorly defined. **Methods:** This was a prospective, single-arm, phase II study (NCT00082706) conducted at MD Anderson. Between 2005 and 2010, patients (pts) aged ≥18 years with ECOG 0–2 and metastatic or unresectable urachal (UA) or non-urachal adenocarcinoma (NUA) received frontline GemFLP (5-fluorouracil 200 mg/m² continuous infusion ×5 days with leucovorin 23 mg IV daily ×5; cisplatin 20 mg/m² IV daily ×5; gemcitabine 200 mg/m² IV on days 1 and 5). Best overall response (BOR) was assessed by imaging. Primary endpoints were objective response rate (ORR) and overall survival (OS); secondary endpoint was toxicity. PFS was calculated from treatment initiation and duration of response (DoR) from first CR/PR to progression or death; time-to-event endpoints were estimated by Kaplan–Meier (KM). Post hoc analyses evaluated baseline tumor markers (CEA, CA19-9, CA125, β-hCG) Treatment-related adverse events (TRAEs) were graded per CTCAE v5. **Results:** Forty-six pts were enrolled (28 UA, 18 NUA). Median age was 58 years; 41% were de novo metastatic, and 78% had visceral metastases. ORR was 44% (20/46). Among responders, median DoR was 8.6 months (95% CI 4.6–30.8). median PFS was 3.3 months (95% CI 2.3–8.4) and median OS (mOS) was 21.0 months (95% CI 15.9–35.3) There was no difference in PFS (p=0.39) or OS (p=0.99) between UA and NUA. Baseline CEA, CA19-9, CA125, and β-hCG were not associated with ORR or PFS. Higher baseline CA125 was associated with inferior OS (HR 1.33, 95% CI: 1.12–1.58; p=0.001) Subsequent systemic therapy was administered to 28 pts (60.9%); median number of subsequent treatment lines was 2 (range 1–5). The most common hematologic TRAEs were anemia (28.1%; grade ≥3 [G3] 12.5%), thrombocytopenia (21.9%; G3 12.5%), and neutropenia (12.5%; G3 9.4%). The most frequent non-hematologic TRAEs were dehydration (21.9%; G3: 6.2%), diarrhea (9.4%; G3 6.2%) and catheter-related thrombosis (9.4%; G3 9.4%). No grade 5 events occurred. **Conclusions:** In this prospective phase II study, frontline GemFLP achieved a 44% ORR with durable responses (mDoR 8.6 mo) and 21 mo mOS in advanced UA and NUA. Survival did not differ between UA and NUA subtypes. Baseline CA125 was associated with OS. Toxicity was manageable. These data provide a prospective benchmark for this rare disease. Clinical trial information: NCT00082706. Research Sponsor: None.

4516 **Rapid Oral Abstract Session**

Interim analysis results from Duravelo-2: Zelenectide pevedotin (zele; BT8009) + pembrolizumab in patients (pts) with previously untreated locally advanced/metastatic urothelial carcinoma (la/mUC). First Author: Yohann Loriot, University Paris-Saclay, Gustave Roussy, Villejuif, France

Background: Zele is a highly selective Bicycle Drug Conjugate (BDC) targeting Nectin-4, a protein overexpressed in la/mUC. There remains an unmet need in la/mUC for safer and more tolerable treatments. Here, we report an interim analysis (IA) for zele + pembrolizumab (pembro) dosage selection from the Phase 2/3 Duravelo-2 study (NCT06225596/BT8009-230) in previously untreated (untx) pts with la/mUC. **Methods:** Adults with la/mUC were enrolled into 2 cohorts: previously untx pts eligible for platinum-based chemotherapy (Cohort [Co]1) or pts with ≥1 prior systemic therapy (Co2). IA was conducted to determine the optimized dosage of zele + pembro (Co1) or zele monotherapy (Co2). Herein, we report IA results from Co1. Pts in Co1 were randomized 1:1:1 to: zele 5 mg/m^2 on Days [D]1/8/15 + pembro 200 mg on D1; or zele 6 mg/m^2 on D1/8 + pembro 200 mg on D1; or gemcitabine + cisplatin/carboplatin ± avelumab on a 21-D cycle. Dosage optimization included safety, efficacy, and pharmacokinetic data in pharmacometric and utility score analyses to quantify benefit-risk. **Results:** IA was performed at 27 weeks of follow-up (N=30 each zele dose group). Median zele treatment (tx) duration was 6.21 months. Confirmed ORRs by BICR among randomized, dosed pts with measurable disease at baseline were 55% (16/29; 7 complete responses [CR], 9 partial responses [PR]; 95% CI 35.7–73.6) and 58% (15/26; 8 CR, 7 PR; 95% CI 36.9–76.6) with zele 5 mg/m^2 and 6 mg/m^2, respectively. Zele-related adverse events (AEs) were reported in 97% (47% Gr ≥3) of pts at 5 mg/m^2 and 90% (40% Gr ≥3) at 6 mg/m^2. Gr ≥3 zele-related AEs for 6 mg/m^2 (≥5% pts) included neutropenia (10%), neutrophil count decreased (7%), and anemia (7%). AEs related to pembro were reported in 80% (37% Gr ≥3) and 53% (13% Gr ≥3), respectively. Zele-related AEs of clinical interest (AECIs) for 6 mg/m^2 are summarized in the Table. Notably, no zele-related severe skin reactions of any Gr were reported at the 6 mg/m^2 dosage. Zele dose reductions and discontinuations due to zele-related AEs occurred in 20% and 3%, respectively, for 6 mg/m^2. At Week 27, >50% of pts remained on tx. **Conclusions:** Zele at 5 mg/m^2 on D1/8/15 + pembro and 6 mg/m^2 on D1/8 + pembro on a 21-D cycle demonstrate encouraging response rates and safety profiles with the potential to differentiate from ADCs in previously untx pts. The 6 mg/m^2 D1/8 regimen demonstrated a more favorable benefit-risk profile to meet the need for safer and more tolerable treatments, with substantially reduced toxicity, better tolerability, improved potential for combinability, and enhanced convenience, leading to fewer discontinuations. Clinical trial information: NCT06225596. Research Sponsor: BicycleTx Ltd.

4517 **Rapid Oral Abstract Session**

Initial results from EXCEED, a phase 1 study of LY4101174, an antibody-drug conjugate targeting Nectin-4, in participants with advanced or metastatic urothelial carcinoma. First Author: Xin Gao, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Enfortumab vedotin plus pembrolizumab (EVP) is the current first-line standard of care for locally advanced / metastatic urothelial carcinoma (mUC). However, subsequent treatment options are limited, representing an urgent and growing unmet need. Preclinical data suggest that EV resistance may be payload mediated and consequently Nectin-4 remains a viable target for alternative therapies. LY4101174 is a next generation anti-Nectin-4 ADC comprising a humanized IgG1 antibody conjugated to the topoisomerase I inhibitor, exatecan, via a maleimide-ß-glucuronide poly-sarcosine linker and a homogeneous drug antibody ratio of 8. Here, we report the initial clinical data from the phase 1 dose escalation cohort of EXCEED (NCT06238479). **Methods:** Adults with locally advanced / mUC or other selected solid tumors were eligible. Participants (pts) must have received or were ineligible for available standard therapies, and have ECOG PS 0-1. Dose escalation utilized a Bayesian optimal interval design. Key endpoints were safety, PK, and antitumor activity of LY4101174 per RECIST v1.1. **Results:** As of 3 Dec 2025, 143 pts (86 mUC, 57 non-UC tumors) were treated across 6 dose levels (DLs) of LY4101174 (0.8-3.2 mg/kg Q2W or 2.4-4.0 mg/kg Q3W IV). Median age was 68 (range, 30-85), 60% ECOG PS 1. Median prior lines of therapy was 4 (range, 1-10), 92% of mUC pts had received prior EV (19% [15/79] had discontinued EV due to treatment-related toxicity). LY4101174 and total antibody exhibited mostly linear, dose-proportional PK up to 4.0 mg/kg, and up to 3.2 mg for exatecan. At 3.2 mg/kg Q2W, 3 of 6 pts experienced DLTs (neutropenia [grades 3 and 4], febrile neutropenia, and thrombocytopenia [both grade 3]) prompting a schedule change to 3.2 mg/kg Q3W for continued escalation. The most common treatment-emergent AEs (TEAEs) across Q3W DLs were anemia (71%), fatigue (55%), nausea (49%), neutropenia (36%), thrombocytopenia (31%), diarrhea (26%), vomiting (25%), and decreased appetite (23%). The most common grade ≥3 TEAEs were anemia (47%), neutropenia (29%), thrombocytopenia (21%), febrile neutropenia and leukopenia (10% each); prophylactic granulocyte colony stimulating factor (G-CSF) was required at DL 4.0 mg/kg Q3W. TRAEs led to dose reduction in 24% and discontinuation in 2%. In the 66 efficacy evaluable mUC pts treated with 2.4-4.0 mg/kg Q3W (92% [61/66] EV-pretreated), ORR was 18% (12/66) and DCR was 70% (46/66) with 12 PR (8 confirmed, 4 ongoing and pending confirmation) and 34 SD. Median follow-up was 4.9 months (95% CI, 1.4-NE). **Conclusions:** LY4101174 has demonstrated clinical activity at Q3W dose levels, including in EV pre-treated mUC, suggesting Nectin-4 remains an important therapeutic target. Dose and duration on treatment were mainly limited by grade ≥3 hematologic toxicity requiring the use of prophylactic G-CSF. Clinical trial information: NCT06238479. Bulumtatug fuvedotin (BFv; 9MW2821) plus toripalimab in patients with locally advanced or metastatic urothelial carcinoma (la/mUC): Follow-up results from a phase 1b/2 study. First Author: Xinan Sheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Genitourinary Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Nectin-4 is an adhesion molecule that is highly expressed in variety of solid tumors, especially in urothelial cancer, cervical cancer, esophageal cancer and breast cancer. BFv is a novel site-specific ADC targeting Nectin-4, and Toripalimab is a novel recombinant humanized anti-PD-1 monoclonal antibody. Previous results of BFv and Toripalimab in la/mUC patients have shown promising efficacy and well-tolerable toxicity. Here we report follow-up results of BFv and Toripalimab in la/mUC patients. **Methods:** This is an open-label, multicenter, phase 1b/2 study to evaluate the safety and efficacy of BFv combined with Toripalimab in la/mUC. Patients received BFv (1.0 or 1.25mg/kg) on D1/D8 and Toripalimab (240mg) on D1, 21 days per cycle. Primary objective was safety, and secondary objectives were efficacy, pharmacokinetics and immunogenicity. **Results:** As of 1 Dec 2025 (median follow-up time: 16.0 months), 47 assessable patients with la/mUC were enrolled and received the combination therapy of BFv and toripalimab. 7 of them (3 received BFv 1.0mg/kg; 4 received BFv 1.25mg/kg) have been previously treated for la/mUC and other 40 (all received BFv 1.25mg/kg) were treatment-naïve patients. In the overall population, ORR was 83.0% (95%CI 69.2-92.4), CR rate was 12.8%. All CR patients were still on treatment and the longest treatment duration has already exceeded two years. DCR was 89.4% (95%CI 76.9-96.5), median PFS was 12.9 months (95%CI 6.5-NA) and median DOR was not reach. Median OS also was not reach, OS rate at 18 months was 68.1% (95%CI 52.7-79.4). Subgroup analysis showed significant benefits to all patients, which might indicate that compared to traditional chemotherapy, BFv plus toripalimab could bring patients greater benefits and a longer survival time, especially in those elderly and patients with impaired kidney function. Safety profile was consistent with previous results, and there was no other new safety signals of BFv or toripalimab observed in this study. **Conclusions:** BFv plus toripalimab in patients with la/mUC demonstrated remarkable efficacy and well-tolerated safety profile. A pivotal phase 3 study is ongoing currently. Clinical trial identification: NCT06592326, NCT06079112. Research Sponsor: Mabwell (Shanghai) Bioscience Co., Ltd.

Microbial dysbiosis as predictor of benefit from CBM588 as an adjunct to immune checkpoint blockade (ICB)—based first line therapies in metastatic renal cell carcinoma (mRCC). First Author: Rahul Winayak, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: The *Clostridium butyricum*-based live biotherapeutic, CBM588, demonstrated signals for enhanced clinical activity with first-line ICB combinations in two randomized phase I trials for mRCC. However, impact of microbial dysbiosis on the benefit of CBM588 supplementation is unclear. Herein, we examined prognostic and predictive value of microbial dysbiosis with CBM588. **Methods:** We analyzed clinical outcomes and stool whole-genome sequencing data from a combined cohort from two randomized phase I clinical trials. Both enrolled treatment-naïve patients with mRCC and randomized them to receive nivolumab/ipilimumab (NCT03829111) or nivolumab/cabozantinib (NCT05122546) alone (standard of care [SOC]), or with CBM588 (SOC+CBM588). Baseline TOPOSCORE, a stool metagenomic dysbiosis index linked to ICB outcomes, was analyzed continuously (S score positively correlated with dysbiosis) and categorically (SIG1+ [dysbiosis phenotype] vs SIG2+ [non-dysbiosis]). Associations with progression free survival (PFS) and objective response rate (ORR, per RECIST 1.1) with SOC and SOC + CBM588 were assessed. **Results:** Fifty-nine patients were included: 39 in the SOC + CBM588 arm and 20 in the SOC arm. Median age was 65 (range 36-90), with the majority male (69.5%), clear-cell (88.1%) and intermediate/poor risk (67.8%) mRCC. Baseline clinical characteristics were comparable across arms. ORR was 66.7% in SOC+CBM588 arm versus 20.0% in the SOC arm (p = 0.001). Median PFS was 32.1 months (95% CI 16.6-NR) with SOC+CBM588 versus 3.7 months (95% CI 2.6-17.0) with SOC (HR 0.36 [95% CI 0.19, 0.67], p = 0.001). At baseline, S score was similar across arms (p = 0.16), and SIG1+ was seen in 55.6% of patients in the SOC+CBM588 arm versus 44.4% in the SOC arm (p = 0.441). While differences in PFS were not statistically significant in the SIG2+ cohort between SOC+CBM588 and SOC alone (32.0 vs 10.9 months, HR 0.49 [95% CI 0.19-1.3], p = 0.149), in the SIG1+ setting, a PFS improvement was seen for SOC+CBM588 versus SOC alone (24.9 vs 2.8 months, HR 0.19 [95% CI 0.07-0.53], $p < 0.001$). Notably, S score was associated with response to SOC+CBM588 among patients who received nivolumab/ipilimumab backbone (median S score 0.668 in response vs 0.540 in no response, p = 0.046), while no such association was observed in patients treated with nivolumab/cabozantinib backbone (median S score 0.681 vs 0.821, p = 0.554, respectively). **Conclusions:** Addition of CBM588 to ICB-based first-line combinations conferred a disproportionately greater benefit in patients with a dysbiotic stool phenotype, underscoring actionability of TOPOSCORE as a potential predictive biomarker in this setting. The upcoming phase III randomized placebo-controlled BIOFRONT trial will assess clinical activity of CBM588 and advance microbiome-based predictive biomarker development in mRCC. Research Sponsor: None.

4520 **Rapid Oral Abstract Session**

Prospective clinical activity and preclinical basis of panitumumab-based EGFR blockade in SMARCB1-deficient renal medullary carcinoma (RMC): A collaborative multi-institutional study. First Author: Pavlos Msaouel, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: RMC is a rare, exceptionally aggressive malignancy that predominantly affects young individuals of African descent with sickle cell trait. RMC is typically refractory to standard kidney cancer therapies, including anti-angiogenic agents and immune checkpoint inhibitors. While cytotoxic chemotherapy is the current standard, objective response rates (ORR) remain low (~29%), with a median progression-free survival (PFS) of $\leq$ 4 months in the first-line setting. This study explores wild-type EGFR as a therapeutic dependency in RMC. **Methods:** We characterized EGFR expression and mutation status in primary RMC tumors using whole exome sequencing (WES), CLIA-certified IHC and integrated bulk RNA and histone ChIP-sequencing. Preclinical efficacy was compared between the EGFR antibody panitumumab and the kinase inhibitor erlotinib across two RMC xenograft models. Subsequently, a prospective multi-national registry (N=26) evaluated panitumumab-based therapy (monotherapy or combined with nab-paclitaxel $\pm$ carboplatin) in heavily pretreated patients with RMC. **Results:** No EGFR mutations were detected on WES. RMC tumors demonstrated uniformly high wild-type EGFR protein expression and enhancer-associated activation. In vivo, panitumumab induced profound tumor regressions in both RMC xenograft models, significantly outperforming erlotinib ($p < 0.005$). Mechanistically, panitumumab triggered definitive lysosomal receptor degradation and suppressed AKT and ERK1/2 signaling. The prospective clinical registry (N=26) included 20 (76.9%) males and 6 (23.1%) females, with a median age of 33.5 years (range, 17–67). At treatment initiation, patients had a median of 4 metastatic disease sites (range, 2–6). The cohort was heavily pretreated with a median of 2 prior systemic therapies (range, 0–4); 96.2% had progressed on prior platinum-based chemotherapy. We observed an ORR of 53.9% (14/26 patients), including 4 (15.4%) complete responses. Median PFS was 5.8 months (95% CI: 4.0–8.2) and median OS was 9.5 months (95% CI: 7.6–NE). Treatment was well-tolerated, with manageable grade 1-2 acneiform rash (80.8%), no grade 3+ rash cases observed, and no treatment-related deaths. **Conclusions:** These data establish wild-type EGFR dependency as a foundational vulnerability in RMC. Panitumumab-based therapy yields unprecedented responses in heavily pretreated patients and represents a transformative new systemic standard of care for this lethal disease. Final results of a phase 2 trial of cabozantinib plus nivolumab (CaboNivo) in patients with non–clear cell renal cell carcinoma (nccRCC). First Author: Darren R. Feldman, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY

Background: CaboNivo improved objective response rate (ORR), progression-free survival (PFS), and overall survival (OS) over sunitinib in a phase 3 trial for metastatic clear cell RCC. (Choueiri NEJM 2021). We previously reported on 47 patients (pts) treated on a phase 2 trial of CaboNivo for nccRCC. We now present final results on all 60 pts accrued to the study. **Methods:** Pts had advanced nccRCC, 0 or 1 prior systemic therapies excluding prior immune checkpoint inhibitors and measurable disease by RECIST. Cabo 40 mg/day plus Nivo 240 mg every 2 weeks or 480 mg every 4 weeks was given across two cohorts. Cohort 1: papillary, unclassified, or translocation associated RCC (tRCC); Cohort 2: chromophobe RCC. The primary endpoint was ORR by RECIST; secondary endpoints included PFS, OS, and safety. Cohort 1 was a single stage design that met its primary endpoint and was expanded to produce more precise estimates of ORR. Cohort 2 was a Simon two-stage design that closed early for lack of efficacy and slow accrual. **Results:** Of 60 pts, 53 were included in Cohort 1, of whom 16 had papillary RCC, 16 unclassified RCC with papillary features (UCPF), 8 FH-deficient, 8 unclassified without papillary features (UC), and 5 tRCC. In Cohort 1, 39 (74%) pts were previously untreated, and 14 (26%) pts had 1 prior line: 10 (19%) received prior VEGF-targeted therapy and 8 (15%) received prior mTOR-targeted therapy. For Cohort 1 (Table), the ORR was 43% (95% CI 30-58), including 88% in pts with FH-deficient RCC. Median PFS (mPFS) in Cohort 1 was 11 months (95% CI 8-14), median OS was 28 months (95% CI 21-37), and there were 43 deaths after a median follow-up of 50 months for survivors. 7 pts with chromophobe RCC were enrolled in Cohort 2 with 5 achieving stable disease (SD) but no objective responses observed. Adverse events were similar to the previously reported cohort and cabozantinib and nivolumab were discontinued for toxicity in 22 (42%) and 20 (38%) pts, respectively. **Conclusions:** Final results from this phase 2 trial in nccRCC confirm efficacy and acceptable safety of CaboNivo in pts with metastatic papillary, unclassified, or tRCC histologies with a particularly high ORR in FH-deficient RCC. These results justify CaboNivo as a standard first-line treatment option for these pts. In contrast, objective responses were not observed in chromophobe RCC. Clinical trial information: NCT03635892. Research Sponsor: None.

Artificial intelligence (AI)–augmented analysis of quantitative circulating tumor DNA (ctDNA) burden and longitudinal kinetics to identify prognostic risk stratification in metastatic clear cell renal cell carcinoma (mccRCC). First Author: Eric Martin, Inova Schar Cancer Institute, Fairfax, VA

Background: The relevance of ctDNA burden and longitudinal kinetics in RCC remains poorly defined. We applied AI–based analysis of quantitative ctDNA trajectories to identify prognostically informative patterns beyond baseline detection. **Methods:** We analyzed patients with mccRCC undergoing longitudinal tumor-informed ctDNA testing (Signatera) during first-line immune checkpoint inhibitor–based therapy. Quantitative ctDNA burden in mean tumor molecules per milliliter (MTM/mL) was measured serially and aligned to treatment initiation, with radiographic response classified as complete response (CR), partial response (PR), stable disease (SD), or progressive disease (PD). ctDNA trajectory similarity was independently assessed using dynamic time warping (DTW), trajectory-based K-means clustering, and a neural network sequence autoencoder (TensorFlow) with clustering to learn latent representations of ctDNA kinetics. Cross-method concordance was used to define robust ctDNA kinetic phenotypes. **Results:** Survival and response analyses included 93 patients with mccRCC with longitudinal ctDNA profiling. Baseline ctDNA detectability was not significantly associated with OS. Conversion from ctDNA-positive to ctDNA-negative status during therapy was associated with improved OS ($p<0.05$). Patients with radiographic disease control (CR/PR/SD) had significantly lower peak ctDNA levels than those with progressive disease (median 0.18 vs 8.86 MTM/mL; p=0.007). Increasing peak ctDNA burden was strongly associated with inferior OS (HR 2.21, 95% CI 1.63–3.01; $p<0.001$). A machine learning–based spline-regularized Cox survival model identified a high-risk ctDNA threshold >20 MTM/mL associated with worse OS (p=0.034). Trajectory-based K-means identified an optimal solution at k=4 clusters, independently supported by DTW and autoencoder-based analyses. Four ctDNA kinetic phenotypes repeatedly emerged: early ctDNA clearance, early ctDNA rise, delayed ctDNA clearance, and persistently low-level ctDNA. Autoencoder-derived phenotypes demonstrated strong internal robustness (Adjusted Rand Index, ARI ≈ 0.80) and high concordance with DTW-based clustering. Phenotypes were associated with distinct radiographic response and survival patterns, with early ctDNA rise conferring the poorest OS (p=0.022). **Conclusions:** AI-driven modeling of quantitative ctDNA burden and longitudinal kinetics identifies biologically interpretable and reproducible prognostic phenotypes in RCC, capturing higher-order temporal features of ctDNA dynamics and providing prognostic stratification beyond baseline detectability and burden alone, thereby informing clinical decision-making regarding earlier therapy switching. Research Sponsor: None.

4523 **Poster Session**

Vessel branching patterns quantified by artificial intelligence as a novel prognostic biomarker in advanced renal cell carcinoma: A post-hoc analysis of the CM914 trial. First Author: Hannah Timm, Institute for AI in Medicine, University Hospital Essen, Essen, Germany

Background: Current adjuvant risk stratification in renal cell carcinoma (RCC) relies primarily on TNM-staging. However, disease progression and response to therapy are driven by biological subgroups reflected in tumor vessel architecture. We therefore analyzed vessel branching patterns in 1098 adjuvant RCC patients to evaluate whether an AI-derived biomarker quantifying vascular architecture improves prognostic discrimination beyond TNM. **Methods:** Digital images of representative tumor tissue and oncologic outcomes were obtained from the CM914 trial (NCT03138512). Tumor tissue was annotated by a pathologist to define vessel branching patterns as high-branching (HB) or low-branching (LB) patterns. HB and LB patterns were quantified using a deep learning model as the tumor-wide fraction of HB in digitized H&E whole-slide images from 1098 of 1641 evaluable patients (67%). Based on the tumor-wide HB fraction, patients were classified into risk groups using a data-driven cut-off optimized for Kaplan–Meier survival analysis, allowing comparison with TNM-based risk strata (PT2a, G3/G4, N0, M0 / PT2b, G ANY, N0, M0 / PT3, G ANY, N0, M0; intermediate-high risk, n=1016 vs PT4, G ANY, N0, M0 / PT ANY, G ANY, N1, M0; high risk, n=82). Risk stratification performance for overall survival (OS) and disease-free survival (DFS) was compared between branching pattern–based and TNM-based risk groups using Cox regression, Kaplan–Meier analysis, and concordance indices. **Results:** Higher tumor-wide HB fractions were associated with improved DFS and OS, showing a continuous effect on prognosis. Each 10% increase in HB fraction reduced risk of recurrence and death (DFS HR 0.92, 95% CI 0.89–0.95; OS HR 0.89, 95% CI 0.83–0.95; both $p<0.005$). Kaplan–Meier analyses showed longest survival in the 4th quartile (OS HR 0.39, 95% CI 0.21–0.71, p=0.002; DFS HR 0.47, 95% CI 0.35–0.64, $p<0.0001$). This threshold defined the 75th percentile cutoff for risk stratification, separating patients into intermediate risk (≥74% HB; n=275) vs high risk (<74% HB; n=823) groups. High risk patients had an increased risk of recurrence and death (DFS HR 2.11, 95% CI 1.57–2.84, C-Index 0.57; OS HR 2.57, 95% CI 1.28–4.32, C-Index 0.56, both $p<0.005$). TNM-based risk showed lower prognostic discrimination (DFS: HR 1.95, 95% CI 1.39–2.74, C-Index 0.53; OS: HR 2.55, 95% CI 1.52–4.30, C-Index 0.55, both $p<0.005$). Combining branching-based risk with TNM improved DFS and OS discrimination compared with TNM alone (C-Index 0.59). **Conclusions:** Higher fractions of high-branching vessels are associated with improved DFS and OS, potentially enabling risk stratification beyond conventional TNM criteria in RCC. While prospective validation is required to confirm clinical applicability, these results suggest high-branching vessel architecture represents a promising prognostic feature. Deciphering the genomic landscape of renal cell carcinoma brain metastases. First Author: Betul Gok Yavuz, The University of Chicago, Chicago, IL

Background: Brain metastases from renal cell carcinoma (RCC) remain a major cause of morbidity and mortality, yet the drivers of metastatic dissemination remain poorly understood. **Methods:** Whole-exome sequencing was performed on 72 RCC brain metastasis samples with matched normal. To identify candidate metastatic drivers, the genetic alterations detected in the brain metastases were compared against alterations in extracranial metastases from the MSK-ECM cohort (n=137) and primary RCC tumors from TCGA (n=432) by case-control analyses. Candidate drivers were also identified by matched-pair analyses on the brain metastases vs. matched primary tumors or extracranial metastases from the same patient (n=25). A random survival forest model incorporating the candidate CNA events was developed to predict overall survival. The candidate metastatic drivers were further evaluated using functional experimental data from MetMap and DepMap. Survival analyses were conducted to assess the prognostic significance of the candidate drivers. **Results:** We identified metastatic drivers that were significantly enriched in RCC brain metastases, including 4q loss, 7p gain, 7q gain, 8p loss, 8q gain, 9p21.3 deletion, 12q15 amplification, and 14q loss. These driver events were associated with significantly poorer patient survival among RCC patients. A random survival forest model based on these CNA events stratified TCGA-KIRC patients into prognostically distinct risk groups (C-index = 0.64). Among the drivers, 8p loss, 8q gain, 9p21.3 deletion were associated with increased incidence of brain metastases across multiple primary cancer types in xenograft mouse models. These drivers were also strongly associated with metastatic progression and poor prognosis across RCC, lung adenocarcinoma, breast cancer, and melanoma. **Conclusions:** Somatic copy-number alterations represent key drivers of brain metastasis in RCC and other tumors that frequently metastasize to the brain. These findings indicate a shared genomic basis for brain tropism across cancers and highlight the potential utility of copy-number biomarkers for risk stratification and clinical decision-making. CheckMate-901: Association of tumor and peripheral biomarker profiles with durable disease control in metastatic urothelial carcinoma treated with nivolumab plus ipilimumab. First Author: Matthew D. Galsky, Icahn School of Medicine at Mount Sinai, Tisch Cancer Institute, New York, NY

Background: Patients (pts) with untreated, unresectable, or metastatic urothelial carcinoma (mUC) have limited therapeutic options and poor prognosis. The phase 3, global, open-label, randomized CheckMate 901 trial compared nivolumab plus ipilimumab (NIVO+IPI) vs gemcitabine–carboplatin/gemcitabine–cisplatin (gem–carbo/gem–cis) with previously untreated unresectable or mUC. A subset of pts treated with NIVO+IPI experienced durable disease control. This exploratory analysis seeks to identify biomarkers that might characterize pts deriving particular benefit from NIVO+IPI. **Methods:** Serum samples from CheckMate 901 (NIVO+IPI, n = 288–300; gem–carbo/gem–cis, n = 222–236) underwent multiplex analysis at Myriad RBM using Luminex and Simoa technology. Pts were stratified by progression-free survival (<8 months [early progressor; EP] vs ≥8 months [durable benefit; DB]), and clinical laboratory variables (granulocyte count [GRANC], hemoglobin [HB], thyroid-stimulating hormone [TSH], neutrophil-lymphocyte ratio [NLR]) and cytokine/protein biomarkers (alpha-1 antitrypsin [AAT], beta2-microglobulin [B2M], C-reactive protein [CRP], ferritin [FRTN], interleukin [IL]-2 receptor alpha [IL-2ra], IL-8, vascular cell adhesion molecule-1 [VCAM-1], and von Willebrand factor [vWF]) were compared in EP vs DB pts. In addition, tumor RNA-seq was used for gene signature analysis (NIVO+IPI, n = 134; gem–carbo/gem–cis, n = 117), including 8-gene epithelial–mesenchymal transition (EMT)/stroma core, 9-gene transforming growth factor beta (TGFβ) activation, 13-gene high-risk TGFβ, and cluster of differentiation 4 (CD4). **Results:** Distinct biomarker patterns emerged between EP and DB pts. Pts achieving DB vs EP with NIVO+IPI exhibited significantly lower levels of GRANC, TSH, and NLR, and higher HB (all $P < 0.05$). Similarly, levels of proteins AAT, B2M, CRP, FRTN, IL-2ra, IL-8, VCAM-1, and vWF were significantly lower in NIVO+IPI-treated pts achieving DB vs EP (all $P < 0.05$). RNA-seq analysis showed significant differences between NIVO+IPI-treated pts achieving DB vs EP for 8 EMT/stroma core and 9 TGFβ activation ($P < 0.05$). **Conclusions:** In untreated, unresectable, or mUC, distinct clinical and cytokine/protein biomarker profiles were associated with DB vs EP with NIVO+IPI therapy. Pts with EP exhibit features in the tumor microenvironment and circulation suggestive of tumor-promoting inflammation, several of which have been linked to resistance to immune checkpoint blockade in prior analyses. These findings underscore the heterogeneity of mUC and the potential of routinely measured circulating analytes for risk stratification and treatment decisions. Prospective studies should confirm their clinical applicability. Clinical trial information: NCT03036098. Research Sponsor: Bristol Myers Squibb.

Machine learning–based transcriptomic signatures to predict treatment outcomes across targeted and immunotherapy regimens in renal cell carcinoma. First Author: Peng Li, Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Despite available tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICIs), reliable biomarkers guiding frontline advanced RCC treatment remain limited. Existing signatures lack generalizability across therapeutic regimens. We developed a data-driven machine learning (ML) framework to predict survival outcomes and therapeutic response. **Methods:** Transcriptomic and clinical data were analyzed from 733 patients across two frontline treatment cohorts, sunitinib (n = 376) and avelumab plus axitinib (n = 357), derived from JAVELIN Renal 101. A multi-algorithm feature selection framework was applied to identify transcriptomic signatures associated with progression-free survival (PFS) and overall survival (OS). Prognostic performance was evaluated using the concordance index (C-index). Predictive models for therapeutic response, including disease control, were developed using PFS-derived gene signatures and assessed by area under the curve (AUC). External validation was performed in an independent cohort from The Ohio State University Total Cancer Care (OSU TCC) (n = 114). **Results:** ML-derived transcriptomic models consistently stratified patients into distinct risk groups with improved prognostic discrimination compared with standard clinical classifiers. In the sunitinib cohort, the best-performing models achieved C-indices of 0.72 for PFS and 0.81 for OS, outperforming IMDC (0.59 and 0.66). In the validation set of the sunitinib cohort, high-risk patients exhibited worse outcomes, with hazard ratios of 3.00 for PFS ($P < 0.001$, 95% CI, 2.06–4.39) and 13.42 for OS ($P < 0.001$, 95% CI, 7.78–23.13). In the avelumab plus axitinib cohort, C-indices reached 0.70 for PFS and 0.79 for OS. Consistent risk stratification was observed in the validation set, with hazard ratios of 3.16 for PFS ($P < 0.001$, 95% CI, 2.07–4.83) and 4.69 for OS ($P < 0.001$, 95% CI, 2.65–8.30). For response prediction, the models demonstrated predictive performance, with the Naive Bayes model achieving a validation AUC of 0.83 for disease control in both sunitinib and avelumab plus axitinib cohorts. The model showed significant risk stratification in an external validation cohort (OSU TCC). **Conclusions:** This study presents a multi-cohort transcriptomic framework with prognostic and predictive utility in advanced RCC. By outperforming established clinical risk classifiers and enabling prediction of regimen-specific therapeutic responses, this ML-based approach supports biomarker-informed frontline treatment selection. Efficacy outcomes by patterns of progression in patients with advanced renal cell carcinoma from the phase 3 CLEAR trial. First Author: Viktor Grünwald, University Hospital Essen, Essen, Germany

Background: In CLEAR, lenvatinib + pembrolizumab (L+P) significantly improved efficacy vs sunitinib (S) in treatment-naïve patients with advanced renal cell carcinoma (Motzer 2021, Motzer 2024). We summarize efficacy by patterns of progressive disease (PD) for the L+P arm and report survival per a modified PD classification system (based on patients receiving immunotherapy; data cutoff 31 July 2022). **Methods:** Treatment-naïve patients (n=1069) who had clear-cell advanced renal cell carcinoma were randomized (1:1:1) to receive: L 20 mg PO daily + P 200 mg IV Q3W; or L + everolimus; or S 50 mg PO daily (4 wks on/2 wks off). Methods for post-progression survival/OS analyses were previously reported (Grünwald 2025). A modified system of classifying PD (Saal 2025) is used in new analyses of the L+P arm reported here: low risk (progression of existing lesions); intermediate risk (new lesions without progression of existing lesions); high risk (progression of existing lesions + new lesions). The number of patients with PD was determined by independent imaging review at the data cutoff date. **Results:** At the time of PD, the median tumor burden of target lesions was lower with L+P (−48.1%) vs S (−17.4%). Patients in the L+P arm with larger % decreases in sums of target lesion diameters at PD had longer median post-progression survival (≤-61% [n=59], 35.6 mos [95% CI 28.4−39.2]; >-61%-≤-34% [n=58], 24.4 mos [95% CI 15.5−34.5]; >-34% [n=59], 20.2 mos [95% CI 16.4−26.9]) and OS (Grünwald 2024, 2025). In the L+P arm, most patients had low/intermediate risk PD (Table). Patients with low (HR 0.39; 95% CI 0.22-0.70) or intermediate risk (HR 0.47; 95% CI 0.27-0.81) PD had improved OS vs patients with high risk PD. Patients with low/intermediate risk PD stayed on 1st subsequent anticancer medication longer than patients with high risk PD (Table). **Conclusions:** In the L+P arm, PD was mainly characterized by progression of existing lesions or formation of new lesions without progression of existing lesions (low/intermediate risk PD); these patients had improved OS (vs high risk PD) suggesting prognostic/predictive value of patterns of PD. Patients with low/intermediate risk PD stayed on 1st subsequent anticancer medication longer than patients with high risk PD, implying that 2L therapy can be used effectively upon progression with L+P. These results, together with lower tumor burden seen at PD in the L+P arm (Grünwald 2024), indicate that L+P has robust tumor control, supporting its use as a standard 1L therapy in advanced renal cell carcinoma. Clinical trial information: NCT02811861. Research Sponsor: Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Cabozantinib plus nivolumab (C+N) versus sunitinib (S) in patients with advanced renal cell carcinoma (aRCC) and bone metastasis: Updated subgroup analysis of the phase 3 CheckMate-9ER trial. First Author: Andrea B. Apolo, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: In first-line aRCC, C+N significantly improved progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) vs S in the phase 3 CheckMate 9ER trial (NCT03141177; Motzer et al. *Ann Oncol* 2026). In an exploratory analysis with median 18.1-mo f-u, C+N improved PFS, OS, and ORR vs S in patients with or without bone metastasis at baseline. We performed an updated exploratory analysis of outcomes by baseline bone metastasis status based on the 5-year update and analyzed subgroups with additional metastatic sites. **Methods:** 651 patients with clear-cell aRCC were randomized 1:1 to C (40 mg QD) + N (240 mg Q2W) or S (50 mg QD for 4 weeks of 6-week cycles). Median f-u was 67.6 mo. PFS (primary endpoint) and ORR were per RECIST v1.1 by blinded independent central review. Patient subgroups analyzed here include those with or without bone metastasis at baseline and those with liver, lung, lymph node (LN), or adrenal gland metastasis in addition to bone metastasis. **Results:** 154 patients had bone metastasis at baseline. Baseline characteristics were generally consistent between treatment arms for subgroups with and without bone metastasis. PFS and OS were prolonged with C+N vs S in patients with or without bone metastasis (Table). The ORR was higher and duration of response (DOR) was longer with C+N vs S in both groups. Although outcomes were less favorable in those with vs without bone metastasis, the relative benefit with C+N vs S was consistent across metastatic site subgroups. The safety profile among patients with bone metastasis was generally consistent with the overall population. **Conclusions:** With additional follow-up, a consistent benefit was maintained for C+N vs S in patients with or without bone metastasis. Among patients with bone metastasis, a consistent benefit was observed regardless of concomitant metastasis in liver, lung, LN, or adrenal gland. Clinical trial information: NCT03141177. Research Sponsor: Exelixis, Inc.

An external validation of the IMmotion151 molecular subtypes in patients with advanced renal cell carcinoma using the ORIEN database. First Author: Gautham Prakash, University of Virginia, Division of Hematology/Oncology, Charlottesville, VA

Background: There is a major unmet need for novel biomarkers in advanced renal cell carcinoma (RCC). A promising candidate biomarker is the classification of advanced RCC into 7 distinct molecular subtypes identified in an exploratory analysis of the IMmotion151 trial (Motzer et al., Cancer Cell 2020). These transcriptomic clusters were predictive of treatment outcomes with atezolizumab + bevacizumab vs sunitinib. However, a recent validation study reported that while these clusters were able to be replicated in an external cohort, they failed to stratify survival between avelumab + axitinib vs sunitinib (Saliby et al., Cancer Cell 2024). Given these mixed results, there is a need for further validation of the IMmotion151 molecular clusters. We used a multi-institutional cohort from the Oncology Research Information Exchange Network (ORIEN), an alliance of cancer centers, to replicate these clusters and assess if they were prognostic for 5-year overall survival (OS) in patients with advanced RCC. **Methods:** Patients with RCC metastatic to lymph nodes or a distant site were identified in the ORIEN database. Included patients had mRNA sequencing data available from a metastatic tumor sample. We used methods similar to those used in the IMmotion151 exploratory analysis to attempt to replicate the molecular clusters. Using an unsupervised clustering algorithm called non-negative matrix factorization (NMF) on the top 10% most variable genes in each sample, we derived 7 distinct molecular clusters. To compare our clusters with those identified in IMmotion151, we constructed a heatmap of expression (using z-scores) for pre-specified gene sets across each cluster. We then conducted Kaplan-Meier analysis to assess if our clusters were able to stratify 5-year OS in our patient cohort for a significance level of $p \leq 0.05$. OS was measured from the time of diagnosis with metastatic RCC. **Results:** 155 eligible patients were included in our analysis. We successfully replicated clusters 2 (angiogenic), 3 (complement/Ω-oxidation), 4 (T-effector/proliferative), and 6 (stromal/proliferative). Cluster 7 (snoRNA) was not possible to replicate as our transcriptomic data only included mRNA. Kaplan-Meier analysis did not show any statistically significant difference (p = 0.85) in 5-year OS between our 7 clusters. Cluster 2 had a median OS of 47.5 months, cluster 3 had a median OS of 43.6 months, median OS was not reached for cluster 6, and there were insufficient patients in cluster 4 to be included in the survival analysis. **Conclusions:** While our results show that the IMmotion151 molecular subtypes are robust and replicable even in smaller datasets, the lack of any association between subtypes and survival outcomes casts further doubt on the clinical utility of these biomarkers. Our results may also be influenced by our smaller sample size compared to the IMmotion151 analysis (n = 823). Research Sponsor: Division of Hematology/Oncology, University of Virginia.

4530 Poster Session

Cabozantinib plus nivolumab (C+N) versus sunitinib (S) in patients with advanced renal cell carcinoma (aRCC) and liver metastasis: Subgroup analysis of the phase 3 CheckMate-9ER trial. First Author: Amishi Yogesh Shah, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: In the phase 3 CheckMate 9ER trial (NCT03141177), C+N treatment significantly improved progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) vs S in patients with first-line aRCC, including those with baseline LM (Motzer et al. *Ann Oncol* 2026). We performed exploratory analyses of outcomes in additional subgroups including patients with no LM (NLM) and those with LM plus other metastatic sites. **Methods:** 651 patients with clear-cell aRCC were randomized 1:1 to C (40 mg QD) + N (240 mg Q2W) or S (50 mg QD for 4 weeks of 6-week cycles). PFS (primary endpoint) and ORR were per RECIST v1.1 by blinded independent central review. Median f-u was 67.6 mo. Patient subgroups analyzed included those with LM or NLM at baseline and those with bone, lung, lymph node (LN), or adrenal gland metastasis in addition to LM. **Results:** 129 patients had LM at baseline. Baseline characteristics were generally consistent between treatment arms among patients with LM and NLM. A PFS and OS benefit with C+N vs S was observed in patients with LM and NLM (Table). Both subgroups experienced greater ORR and longer duration of response (DOR) with C+N vs S. Although outcomes were less favorable in those with vs without LM, and least favorable in those with both LM and bone metastasis, the relative benefit with C+N vs S was consistent across metastatic site subgroups. The safety profile among patients with LM was generally consistent with the overall population. Presence of LM did not negatively impact C dose exposure (median daily dose 31.8 mg in LM; 26.3 mg in NLM). **Conclusions:** Treatment with C+N vs S improved efficacy outcomes in patients with first-line aRCC irrespective of LM at baseline. Among patients with LM, a consistent benefit was observed regardless of concomitant metastasis in bone, lung, LN, or adrenal gland. Clinical trial information: NCT03141177. Research Sponsor: Exelixis. Inc.

4531 Poster Session

Efficacy of fruquintinib (F) plus sintilimab (S) versus axitinib (A) or everolimus (E) by scores of IMDC risk factors and PD-L1 expression at baseline in previously treated advanced renal cell carcinoma (RCC): A subgroup analysis of the FRUSICA-2 study. First Author: Kaiwei Yang, Department of Urology, Peking University First Hospital, Beijing, China

Background: FRUSICA-2 (NCT05522231), a randomized, open-label, controlled phase 2/3 study, demonstrated a significant efficacy of F plus S vs A or E in previously treated advanced RCC (BIRC-assessed mPFS 22.21 vs 6.90 mo; HR 0.373, p<0.0001; ORR 60.5% vs 24.3%, OR 4.622, p<0.0001; D Ye, et al; 2025 ESMO). Given the IMDC classification as the most common prognostic model and PD-L1 expression has demonstrated prognostic value across various cancer types, we conducted this exploratory subgroup analysis to evaluate clinical outcomes by baseline scores of IMDC risk factors and PD-L1 expression. **Methods:** Patients (pts) with histologically confirmed advanced RCC previously treated with VEGFR-TKI were randomized 1:1 to receive either F (5 mg QD, 2 weeks on/1 week off) plus S (200 mg iv, every 3 weeks), or investigator's choice of A (5 mg twice daily) or E (10 mg once daily). Efficacy was analyzed by IMDC risk factor scores (0, 1, 2, and ≥3) and PD-L1 combined positive score (CPS≥1, <1, or unknown). Data cutoff was February 17, 2025. **Results:** Among 234 patients in the phase 3 part, IMDC risk scores and PD-L1 CPS distributions are detailed in table. With a median follow-up of 16.56 mo, BIRC-assessed mPFS for F+S vs A/E across IMDC subgroups were: score 0, not estimable(NE) vs 8.31 mo (stratified HR 0.270, p=0.0009); score 1, 24.87 vs 8.25 mo (HR 0.289, p<0.0001); score 2, 13.8 vs 6.9 mo (HR 0.436, p=0.0164); and score ≥3, 9.69 vs 4.21 mo (HR 0.591, p=0.3267). Across PD-L1 expression subgroups, BIRC-assessed mPFS for F+S vs A/E were: CPS ≥1, 22.21 vs 3.22 mo (stratified HR 0.232, p=0.0004); CPS <1, NE vs 8.28 mo (HR 0.350, p<0.0001). An additional 82 patients had unknown PD-L1 CPS status (F+S: n=40; A/E: n=42) and were not included in PD-L1 subgroup analysis. ORR analyses consistently favored F+S over A/E across all subgroups defined by IMDC risk factors and PD-L1 expression, with detailed results presented in table. **Conclusions:** In the exploratory analyses, these findings suggest that the efficacy benefit of F+S vs A/E is maintained across different IMDC risk scores and PD-L1 CPS in previously treated advanced RCC patients, supporting its broad application. Clinical trial information: NCT05522231. Research Sponsor: HUTCHMED Limited.

Emotional health concerns due to kidney cancer (KC) and unmet needs in patient support: Results from the International Kidney Cancer Coalition (IKCC) Global Patient Survey (GPS). First Author: Eric Jonasch, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: KC negatively impacts the emotional well-being of patients, and patient support services are a critical component of care to improve emotional health and patient outcomes. Since 2018, the IKCC and its network have conducted a biennial GPS to assess patient/caregiver experiences on KC burden, diagnosis, and management, determine unmet needs and country variances, and identify opportunities to close gaps. We present global data from the 2025 GPS on emotional well-being and use of patient support resources. **Methods:** An IKCC steering committee of patient advocates, medical experts and the Picker Institute (UK) designed the 2025 GPS targeting KC patients and caregivers. It was cognitively tested, translated into 16 languages, and hosted online and on paper. Data were independently analyzed using cross-tabulations. **Results:** Between Sept 24 and Nov 15, 2024, 2677 responses were received from patients (n=2049) and caregivers (n=628) from 46 countries. Globally, 85% of respondents were impacted emotionally due to KC, with impacts observed across all disease stages. The most common were disease-related anxiety (50%), fear of recurrence (49%), sadness/depression (36%), and fear of dying (35%). Respondents aged 80+ and 66–80 years reported fewer emotional concerns than younger respondents. Globally, only 40%–66% of respondents discussed emotional concerns with a healthcare provider (HCP). Respondents from India and Mexico were more likely to discuss concerns with an HCP, while those from the Republic of Korea were least likely to discuss concerns. Many conversations with HCPs were considered unhelpful; notably, 33% indicated discussions about difficulties navigating the healthcare system were unhelpful. Globally, 50% of respondents accessed a patient support group, either in person or online. Respondents from Japan (19%), Türkiye (24%), France (25%), and Italy (27%) were least likely to access a patient support group, while those from India (90%) and the Republic of Korea (88%) were most likely to access a group. Overall, 47% said support groups were helpful. Patient organization websites (28%) and online support groups (27%) were considered most helpful, with variations observed across countries. Respondents indicated a desire for more counselling and/or psychological support, in-person support, peer-to-peer support, and online support. **Conclusions:** Most respondents experienced an impact on their emotional well-being due to KC; however, many did not discuss their emotional concerns with an HCP or access a patient support group either in person or online. Improved communication is needed between patients/caregivers and HCPs to address emotional concerns. HCPs can improve patient well-being through referrals to counselling/psychological support, and patient organizations in their country. Research Sponsor: None.

Efficacy with fruquintinib plus sintilimab versus axitinib or everolimus in advanced renal cell carcinoma: A post-hoc analysis from FRUSICA-2 trial by baseline tumor burden. First Author: Yuan-Yuan Qu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The multicenter randomized phase 2/3 FRUSICA-2 trial (NCT05522231) demonstrated that fruquintinib plus sintilimab (F+S) significantly improved progression-free survival (PFS) (22.2 months vs 6.9 months) and objective response rate (ORR) (60.5% vs 24.3%) by blinded independent central review (BIRC) assessment compared to axitinib or everolimus (A/E) in Chinese patients (pts) with advanced renal cell carcinoma (aRCC) who had failed prior tyrosine kinase inhibitor therapy (Ye D, et al; 2025 ESMO). Considering that baseline tumor burden may correlate with efficacy outcome, we present the results of a relevant *post-hoc* subgroup analysis. **Methods:** Overall, 234 eligible pts were 1:1 randomized to receive either F+S or A/E. The primary efficacy endpoint was PFS assessed by BIRC per RECIST 1.1; secondary endpoints included investigator-assessed PFS, ORR, disease control rate, duration of response, time to response, and overall survival. This subgroup analysis evaluated BIRC-assessed PFS and ORR across subgroups defined by the number of target lesions (TLs) and metastatic sites (METs) at baseline. **Results:** At baseline, 79, 79, 32 and 44 pts had 1, 2, 3 and ≥4 TL(s), respectively. Metastatic disease was present in 117 (98.3%) pts in F+S arm and 110 (95.7%) pts in A/E arm, with a higher proportion of pts in F+S arm (88, 73.9%) having ≥3 METs than in A/E arm (67, 58.3%). By the data cut-off date of Feb 17, 2025, median follow-up for PFS was 16.6 months. As summarized in the table, F+S demonstrated superior PFS versus A/E across all subgroups, with unstratified hazard ratios (HRs) ranged from 0.28 to 0.50, as well as consistently longer median PFS. Similarly, improvements in ORR were observed across subgroups with odds ratios (ORs) ranged 2.46~7.22. Notably, in F+ S arm, fewer baseline TLs and METs appeared to correlate with longer median PFS, though such trend was not observed for ORR. **Conclusions:** Consistent with the primary analysis, F+S showed superior efficacy compared to A/E in terms of PFS and ORR in the second-line treatment of aRCC, regardless of the amount of baseline TLs or METs. Clinical trial information: NCT05522231. Research Sponsor: HUTCHMED.

A phase 1b, open-label, safety, tolerability, and efficacy study of HC-7366 in combination with belzutifan in patients with locally advanced (inoperable) or metastatic renal cell carcinoma. First Author: Neil J. Shah, Memorial Sloan Kettering Cancer Center, New York, NY

Background: HC-7366 is a novel, selective, potent activator of general control nonderepressible 2 (GCN2) kinase, regulating metabolic stress via the integrated stress response. Our preclinical studies in RCC demonstrated that prolonged GCN2 activation by HC-7366 resulted in antitumor activity accompanied by inhibition of HIFs and cell cycle progression. Furthermore, combination with belzutifan (BEL) results in superior preclinical efficacy, accompanied by inhibition of HIF signaling and cell-cycle progression, supporting clinical evaluation of the combination in RCC. **Methods:** Patients with advanced ccRCC previously treated with ≥1 anti-PD/PD-L1 and ≥1 VEGF-TKI were enrolled into HC-7366 monotherapy (60 mg QD) or a dose-escalation/expansion cohort of HC-7366 (20, 40, 60 mg QD) with BEL (120 mg QD). Primary objectives were safety, tolerability, and investigator-assessed ORR per RECIST v1.1. Enrollment in escalation and expansion is complete; second expansion is ongoing. **Results:** As of the data cutoff 10 Dec 2025, 69 patients received study treatment: 16 monotherapy and 53 combination (7 at 20 mg, 22 at 40 mg, 24 at 60 mg). Median prior therapies were 3 (range 1-5) in monotherapy and 2 (range 1-4) in combination. Most TEAEs were Grade (Gr) 1-2. Gr 3 events were mainly hematological (anemia) and gastrointestinal (nausea and diarrhea), with one DLT (Gr 3 nausea, 40 mg combination). In efficacy-evaluable patients, the 40 mg combination demonstrated the best overall response rate (BORR) of 36.8%, including a confirmed ORR (cORR) of 26.3%, disease control rate (DCR) of 89.5%, and primary progressive disease (PD) rate of 10.5%. The 60 mg combination had a BORR of 31.6%, with a cORR of 31.6%, DCR of 84.2%, and primary PD rate of 15.8%. In monotherapy, BORR of 15.4% and DCR of 61.5% were observed. Early efficacy signals at 40–60 mg align with the preclinical projected maximal efficacious dose range. **Conclusions:** HC-7366, alone or in combination with BEL, was generally well tolerated. Preliminary efficacy analyses indicate favorable disease control, characterized by a high DCR and low primary PD. Clinical trial information: NCT06234605. Research Sponsor: None.

Combining HC-7366 with belzutifan in patients with renal cell carcinoma to alter tumor and microenvironment: Pharmacokinetic and pharmacodynamic (PK/PD) analysis of a phase 1b study. First Author: Benjamin Garmezy, Genitourinary Research Program, Sarah Cannon Research Institute, Nashville, TN

Background: Clear cell renal cell carcinoma (ccRCC), characterized by loss of von Hippel-Lindau (VHL) tumor suppressor function, and constitutive stabilization of hypoxia-inducible factor (HIF) proteins results in activation of genes promoting angiogenesis, metabolic reprogramming including altered lipid metabolism and glycolysis, cell proliferation, and immunosuppressive remodeling of the tumor microenvironment. HC-7366 is a novel, selective GCN2 kinase activator that regulates metabolic stress via the ATF4–driven integrated stress response. Preclinically, GCN2 hyperactivation with HC-7366 enhances belzutifan (BEL) activity, broadly impairing stress adaptation, disrupting tumor metabolism, decreasing HIF expression, inhibiting the cell cycle, and remodeling the tumor immune microenvironment. **Methods:** In this phase 1b study (NCT06234605), 69 patients with advanced ccRCC received HC-7366 monotherapy (60 mg QD; n=16) or HC-7366 (20 mg, n=7; 40 mg, n=22; 60 mg, n=24) plus BEL (120 mg QD). Blood samples for soluble biomarkers and paired biopsies for IHC were collected per IRB-approved guidelines. **Results:** Overall, PK analysis (N=69) demonstrated steady state free exposure of HC-7366 at 40-60 mg doses (Cmax = 5.8 ng/mL, AUC = 75 h*ng/mL) that were consistent with exposures providing maximal BEL combination benefit preclinically. Compared with screening biopsies, all on-treatment biopsies at week 3 (8/8) showed induction of the ATF4 pathway biomarker ASNS (asparagine synthetase). Baseline HIF expression analysis by IHC from 52 patients demonstrated that 33 patients (63%) express mid to high levels of HIF1 and HIF2. HIF1α, but not HIF2α, was reduced consistently with treatment across all cohorts (7/8, 66-98% reduction). Reduced cell cycle biomarkers, including pRB and Ki67 (4/4), and increased frequency of $CD8^+$ $PD1^+$ $TCF1^+$ $Lag3^-$ $Tim3^-$ T-cells (3/3), suggesting ICI responsiveness, were observed in the 40-60 mg combination cohorts. Systemic changes were also observed in serum, including deep and sustained inhibition of EPO, decreases in proangiogenic cytokines like VEGF-A and PDGF-BB, and changes in adipokines that counter RCC progression (Table 1). Low baseline serum levels of KIM-1 predicted response to the combination (p=0.005). **Conclusions:** Early clinical findings suggest HC-7366 + BEL is associated with modulation of angiogenic and immune-related pathways in ccRCC, providing a rationale for the combination with ICIs and/or VEGFR-TKIs. Clinical trial information: NCT06234605. Research Sponsor: None.

Neoadjuvant apatinib plus camrelizumab in renal cell carcinoma with inferior vena cava tumor thrombus: Results of a phase II study. First Author: RuiYang Xie, Department of Urology, Peking University Third Hospital, Beijing, China

Background: Renal cell carcinoma (RCC) with inferior vena cava tumor thrombus (IVCTT) remains a surgically challenging condition, and evidence supporting neoadjuvant systemic therapy is still evolving. We conducted a phase II study to evaluate the efficacy and safety of apatinib combined with camrelizumab as neoadjuvant treatment in this population. **Methods:** This single-arm phase II trial enrolled patients with histologically confirmed, resectable RCC with IVCTT (cT3b-T4, N0-1, M0-1; ECOG performance status 0-1). Patients received camrelizumab 200 mg i.v. every 2 weeks for six cycles plus oral apatinib 250 mg once daily, followed by surgical resection when feasible. The primary endpoint was downgrading of Mayo level of tumor thrombus (TT). Secondary endpoints included TT response (RECIST 1.1), response of primary renal tumor, safety (CTCAE v5.0), progression-free survival, and overall survival. **Results:** Nine patients were included in the intention-to-treat analysis. TT response was observed in 4 patients (44.4%), with disease control achieved in 8 patients (88.9%); one patient (11.1%) experienced progression. Mayo level downgrading occurred in 3 patients (33.3%), all of whom subsequently underwent surgery. Overall, 7 of 9 patients (77.8%) successfully completed neoadjuvant therapy and underwent robotic-assisted radical nephrectomy with thrombectomy. For primary renal tumor, partial response was observed in 1 patient (11.1%), and stable disease in 8 patients (88.9%), resulting in a disease control rate of 100%. Treatment-related adverse events were manageable and consistent with known safety profiles, with grade ≥3 events including hypertension, proteinuria, pneumonitis, and immune-related myasthenia gravis. At a median follow-up of 45 weeks, survival outcomes remain immature. **Conclusions:** Neoadjuvant apatinib plus camrelizumab demonstrated promising antitumor activity and acceptable safety in patients with RCC and IVCTT, achieving meaningful TT response and Mayo level downgrading, thereby facilitating surgical resection. These findings support further investigation of neoadjuvant combination therapy in this high-risk population. Clinical trial information: ChiCTR2300069990. [^{68}Ga] Ga-NYM096 PET/CT in patients with primary and metastatic clear cell renal cell carcinoma: A preliminary study. First Author: Yangyang Xue, Department of Nuclear Medicine, The First Affiliated Hospital of Anhui Medical University, Hefei, China

Background: With limitations of conventional imaging and biopsy, accurate, non-invasive techniques to detect in patients with primary and metastatic clear cell renal cell carcinoma (ccRCC) remain an unmet need. Carbonic anhydrase IX (CAIX) is a tumour antigen highly expressed in ccRCC. NYM096 is a new-generation CAIX targeting small molecule that can be labeled with ^{68}Ga. It has a higher affinity (almost 100-fold) for CAIX compared to NYM005. This study aims to assess the efficacy of [^{68}Ga]Ga-NY096 PET/ CT to identify ccRCC. **Methods:** This is an open-label, multicenter study. Patients with primary and metastatic ccRCC were prospectively recruited in the study. A washout of 7 days was required if the patients were on tyrosine kinase inhibitors. All patients received an intravenous injection of [^{68}Ga]Ga-NYM096 at a dose of 1-7 mCi and underwent whole body PET/CT scan using a total-body PET/CT scanner at 60 min after injection. They were further divided into two groups: group 1, patients with primary renal mass and group 2, patients with suspected/confirmed metastatic ccRCC, who were scheduled for surgery or biopsy. In some patients, ^{18}F-FDG PET/CT was also performed within one week before or after [^{68}Ga]Ga-NYM096 PET/CT. The diagnostic efficacy of ^{68}Ga-NYM096 was compared with that of ^{18}F-FDG. **Results:** A total of 24 patients (mean age, 56.7 years$\pm$14.4, 18 men) were recruited in this preliminary study. Including 23 patients in group 1 and 1 patient in group 2. All patients had ^{68}Ga-NYM096 PET/CT, and all patients also had ^{18}F-FDG PET/CT. The patient-level sensitivity, specificity, and accuracy of [^{68}Ga]Ga-NY096 PET scan was 100%, 90.0%, 95.7% for all patients, and 100%, 90.0%, 95.5% for group 1. One patient in Group 2 was confirmed as a true positive case by histopathological examination. Among patients with positive PET findings, the SUV_{max} of the single most active lesion ranged from 4.9 to 111.8, with a mean ($\pm$ SD) of 52.2 $\pm$ 34.1. This value was significantly higher than the mean SUV_{max} of 5.5 $\pm$ 2.9 observed with ^{18}F-FDG ($p < 0.001$). The tumor-to- kidney ratio was also higher (3.3 $\pm$ 3.0 versus 1.7 $\pm$ 3.0, $p < 0.05$). **Conclusions:** ^{68}Ga-NYM096 PET/CT has high diagnostic efficacy for primary ccRCC patients, and its diagnostic efficacy is significantly better than that of ^{18}F-FDG. It has the potential to become a diagnostic product for both primary and metastatic ccRCC. Research Sponsor: Norroy Bioscience Co., Ltd.

Body composition and quality of life (QOL) with lenvatinib + everolimus (len + eve) versus cabozantinib (cabo) in metastatic clear cell renal cell carcinoma (ccRCC) after PD-1 inhibitor progression: Results from the randomized phase II LenCabo trial. First Author: Julia Moura, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The LenCabo trial (NCT05012371) was the first randomized head-to-head comparison of contemporary second-line or later treatments after progression on PD-1 based immune checkpoint inhibition (ICI). Len + eve significantly improved progression-free survival (PFS). There were numerical, but not statistically significant, differences in treatment discontinuation and ≥ grade 3 adverse events. Although cabo and len share many kinase targets, lenvatinib also blocks FGFR, and its combination with the mTOR inhibitor everolimus may affect body composition through metabolic effects. We sought to investigate how patient QOL and body composition changed after treatment with len + eve and cabo. **Methods:** LenCabo was a multicenter, phase II trial that randomized pts with metastatic ccRCC to len 18 mg/d plus eve 5 mg/d vs cabo 60 mg/d after 1-2 prior lines of treatment, including a PD-1 ICI. Pre-planned, health-related QOL was measured by FKSI DRS at baseline and after 60 days. Post-hoc, body composition was measured using an AI segmentation tool (Voronoi DAFS) at the L3 vertebra from baseline CT scans and after 4 months. Outcomes were compared using proportional odds models adjusting for baseline values and including nonlinear terms as restricted cubic splines. Pre-specified, body composition models additionally adjusted for prior VEGF-targeted therapy, age, IMDC risk category, and sex. **Results:** 86 pts received at least 1 dose of assigned len + eve (n=40) or cabo (n=46). 38 pts completed baseline and day 60 FKSI DRS (len + eve = 20, cabo = 18). The QOL comparison by FKSI DRS at day 60 was inconclusive (OR = 0.51 in favor of cabozantinib, 95% CI 0.16-1.64, p=0.26). 67 pts had body composition measured at baseline and 4 months (len + eve = 30, cabo = 37). After 4 months of treatment, len + eve was associated with a significantly lower odds of having a higher body mass index (BMI), skeletal muscle mass (SMMi), and subcutaneous adiposity (SATi, Table). **Conclusions:** In patients with metastatic ccRCC progressing on PD-1 ICI, len + eve was associated with significantly greater reductions in BMI, skeletal muscle mass, and subcutaneous adiposity compared with cabo at 4 months. The study did not contradict the supposition that the two treatment arms yield the same QOL at day 60. These results suggest that the superior PFS efficacy of len + eve in this setting is accompanied by a more pronounced catabolic effect. Clinical trial information: NCT05012371. Research Sponsor: Eisai.

Body composition measures at 4 months by treatment.

	Adjusted mean of len + eve vs. cabo	Odds ratio for higher measure (95% CI)	P value
BMI	28.5 vs. 29.4	0.36 (0.15 – 0.88)	0.03
SMMi	47.5 vs. 49.7	0.30 (0.11 – 0.79)	0.01
SATi	65.7 vs. 73.4	0.21 (0.08 – 0.55)	0.002

Defining second-line sequencing in advanced renal cell carcinoma: A systematic review and meta-analysis. First Author: Luisana Sisca, Campus Bio Medico, Roma, Italy

Background: In the absence of head-to-head comparative trials, the optimal sequencing of second-line systemic therapy for advanced renal cell carcinoma (RCC) remains undefined. As immune checkpoint inhibitor (ICI) based regimens now represent the dominant first-line standard, second-line treatment decisions increasingly rely on indirect data. We conducted a systematic review and meta-analysis to assess the comparative clinical reliability, defined as consistency of benefit across trials, of commonly adopted second-line strategies in RCC. **Methods:** Randomized phase II–III and prospective trials evaluating second-line systemic therapies in advanced RCC were identified through a systematic literature search. 13 trials encompassing approximately 5,000 patients were included, predominantly post TKI and post immunotherapy. Treatments were grouped by mechanism of action, including tyrosine kinase inhibitor (TKI) based regimens, mTOR inhibitor based therapies, immune-based approaches, and targeted combinations. Hazard ratios (HRs) for overall survival (OS) and progression-free survival (PFS) were pooled using inverse-variance random-effects models, with heterogeneity assessed using the I^2 statistic. **Results:** TKI based strategies demonstrated the most consistent benefit across endpoints, with significant improvement in OS (pooled HR 0.77, 95% CI 0.67–0.87; $p<0.0001$) and favorable PFS (HR 0.56, 95% CI 0.50-0.63; $p<0.0001$). Targeted combination strategies achieved consistent PFS benefit (HR 0.66, 95% CI 0.53–0.81; $p<0.0001$), which did not translate into OS advantage. In contrast, mTOR inhibitor based regimens were associated with modest PFS improvement but failed to demonstrate OS benefit (HR 1.13, 95% CI 0.95–1.35), while immune based approaches showed heterogeneous outcomes. To contextualize these findings within contemporary clinical practice, analyses restricted to patients previously treated with first line ICI based regimens demonstrated a consistent treatment pattern, with TKI based therapies retaining a robust PFS benefit (HR 0.57, 95% CI 0.51–0.64), while targeted combinations maintained a significant PFS improvement without a corresponding OS signal (HR 0.66, 95% CI 0.51–0.85). **Conclusions:** In the absence of head to head sequencing trials, this systematic synthesis of prospective evidence supports TKI based therapies as the most reliable reference second line strategy in advanced RCC, showing consistent benefit across both OS and PFS, including the immunotherapy first setting. In contrast, mTOR inhibitor based approaches and targeted combinations were associated with greater heterogeneity and did not demonstrate a consistent survival benefit despite improvements in PFS. These findings provide clinically actionable guidance for second-line treatment selection after ICI failure and underscore the need for prospective sequencing focused trials. Research Sponsor: None.

Relationships between clinical stage, pathological stage, and disease-free (DFS) survival in renal cell carcinoma as used to inform future neoadjuvant study design: ECOG-ACRIN EA8143 PROSPER analysis. First Author: James Owain Jones, University of Cambridge, Cambridge, United Kingdom

Background: Estimating risk of renal cell cancer (RCC) relapse based only on pre-surgical data is key to future neoadjuvant trial design. The EA PROSPER phase 3 study accrued pts with clinical stage ≥T2 or $T_{any}N+$ RCC of any histology for nephrectomy. Pts were randomized to presurgical nivolumab (nivo) followed by primary tumor resection and 9 cycles of adjuvant nivo, or surgery alone followed by observation. We used PROSPER data to assess how baseline data informs risk. We reviewed cT to pT stage transitions, associated cT stages with outcome, and asked if size in addition to cT stage increases predictive accuracy. **Methods:** Pts with clear cell (cc) RCC were included. cT to pT concordance was assessed by TNM 8th edition. DFS analysis (time from surgery to recurrence, second primary, or any cause death) was performed; pts with no event were censored at date of last assessment. DFS analysis compared cT groups (cT1/cT2 vs cT3/cT4) in the overall eligible study population and within each study arm. A subset DFS analysis by tumor size among cT2a (> 7-8cm vs >8-10cm) and cT3a (< 7cm vs 7-8cm vs > 8cm) was explored. Cox proportional hazards models were used, and log-rank test was reported to represent global p-value of each model. Wald test p-value was reported for individual group comparison (in assessing more than two groups). Two-sided p-values are reported, all p-values were considered significant at 0.05. **Results:** Of 819 pts randomized, 732 ccRCC pts (382 surgery only, 350 nivo + surgery) had data available. DFS was significantly different between cT1/cT2 vs. cT3/cT4 group, favoring cT1/cT2 among all pts (HR [cT1/cT2 as reference]=1.56, two-sided log-rank p < 0.001) and in each of the treatment arms separately (nivo + surgery arm HR=1.48, two-sided log-rank=0.04 ; surgery only arm HR=1.63, two-sided log-rank p=0.007). About half of cT1/T2 pts were upstaged to pT3/4, whereas <10% of cT3a were downstaged to pT1b. Higher grade cT1/T2 were more likely to upstage (p-value < 0.001).119 pts with cT2a and 233 pts with cT3a had tumor size data available. There was no significant DFS difference between tumor size groups in the cT2a subset. In cT3a patients, DFS analysis by tumor size showed a trend of increasing risk for 7-8cm and > 8cm groups when compared to < 7cm group, with a statistically significant difference comparing > 8cm vs < 7cm (HR=3.33, two-sided Wald p < 0.001) signifying worse outcome for pts if tumor size > 8cm. **Conclusions:** In ccRCC pts, baseline cT assessment is associated with DFS outcome. High grade cT1/2 pts risk pathological upstaging to pT3. cT3+ identifies high risk pts, with <10% being downstaged. Pts with cT3a > 8cm have a worse prognosis than patients with < 7cm tumors. These findings should be accounted for in eligibility criteria and risk assessment models for neoadjuvant trials, and explored in other international datasets. Research Sponsor: ECOG-ACRIN.

Genomic and clinical correlates of belzutifan treatment in renal cell carcinoma (RCC): A retrospective analysis of 150 RCC patients. First Author: Harshitha Reddy Dudipala, Department of Medicine, UC San Diego Moores Cancer Center, La Jolla, CA

Background: Belzutifan is a hypoxia-inducible factor-2α (HIF-2α) inhibitor approved for RCC that targets a central driver in RCC pathogenesis; however, predictive biomarkers of response remain poorly defined. **Methods:** Comprehensive DNA (592-gene panel or whole exome) and RNA (whole transcriptome) sequencing were performed by Caris Life Sciences on RCC samples. Clear cell RCC and RCC-NOS with VHL mutations were included. Belzutifan time on treatment (ToT) was derived from insurance claims, and patients were classified as responders or non-responders using the median ToT. **Results:** A total of 150 belzutifan-treated RCC tumors were included in the analysis, of which 29% were primary kidney tumors and the remainder were from metastatic sites. The study population was classified as responders (n=57) or non-responders (n=93) using a median time on treatment of 85 days (95% CI: 71–114). Baseline characteristics were similar, except responders were younger (median age 57 vs 64 years, p=0.007). Transcriptomic analysis showed similar HIF-2α (median 7.78 vs 7.61) and CA9 (4.82 vs 4.54) expression between responders and non-responders without statistical significance. Responders showed enrichment of PTEN (15.8% vs. 3.3%, p=0.03) and PIK3R1 alterations (7.0% vs. 0.0%, p=0.04). Responders demonstrated numerically higher frequencies of PBRM1 (54.4% vs. 44.3%, p=0.46) and PIK3CA mutations (8.8% vs. 3.3%, p=0.24). Alterations in DNA damage response genes were also numerically more common among responders, including TP53 (14.0% vs. 4.9%, p=0.11) and ATM (3.5% vs. 1.6%, p=0.56), although none of these differences reached statistical significance. In contrast, non-responders exhibited numerically higher frequencies of BAP1 (18.0% vs. 8.8%, p=0.10), SETD2 (26.2% vs. 19.3%, p=0.27), and ARID1A (5.1% vs. 1.8%, p=0.30), all of which were also not statistically significant. **Conclusions:** HIF2-α RNA expression alone does not predict belzutifan response in RCC. Responders demonstrated alterations in PBRM1, PI3K/AKT/mTOR, and DNA damage response genes, while non-responders showed numerically higher frequencies of chromatin remodeling mutations including BAP1 and SETD2. Study limitation included small sample size and short follow-up. Larger datasets are required to validate these findings. Research Sponsor: None.

Early detection of kidney cancer using blood-based multi-gene mRNA profiling in a prospective clinical study. First Author: Taigo Kato, Department of Urology, The University of Osaka Graduate School of Medicine, Osaka, Japan

Background: Kidney cancer remains one of the most aggressive and lethal urological malignancies, largely due to late-stage diagnosis and reliance on invasive tissue biopsies. To address this unmet clinical need, we developed and clinically validated the blood-based, cell-free mRNA test. By quantifying circulating tumor-derived transcripts in plasma, this assay provides rapid and precise molecular insights, supporting precision screening, early diagnosis, prognostication, and treatment monitoring. **Methods:** In this prospective clinical study, we evaluated real-time expression levels of 30 kidney cancer–associated genes in plasma samples from 51 subjects, including 41 patients with suspected kidney cancer and 10 healthy controls. The primary objective was to assess the diagnostic and prognostic performance of the Geneverify multi-gene blood-based expression panel. Log_2 fold-change values for individual genes were calculated relative to healthy controls and integrated to generate a composite risk score for each subject. Geneverify scores were compared with biopsy-confirmed diagnoses to assess assay sensitivity. Additional statistical analyses evaluated correlations between Geneverify scores and tumor stage, pathological grade, and treatment status. **Results:** All biopsy-confirmed kidney cancer cases demonstrated Geneverify scores greater than 10. Using an optimized cutoff score of 10, the assay achieved 100% sensitivity for cancer detection. While healthy controls served as the baseline reference, specificity against benign or non-malignant kidney disease could not be fully assessed due to the absence of such cases in this cohort. The majority of patients had early-stage (T1a) kidney cancer. Geneverify scores showed strong correlations with tumor stage, pathological grade, and clinical status. In patients with advanced or metastatic disease undergoing systemic therapy, Geneverify scores declined significantly over time, indicating potential utility for real-time treatment response monitoring. **Conclusions:** This study represents the first real-time clinical validation of a blood-based, cell-free mRNA genomic assay for kidney cancer detection. The Geneverify test demonstrated excellent diagnostic sensitivity, strong concordance with biopsy-confirmed disease, and meaningful prognostic and treatment-monitoring capabilities. These findings establish Geneverify as a powerful non-invasive alternative to tissue biopsy (based on published data 20% biopsies are false negative) for early detection and precision management of kidney cancer, with the potential to reduce invasive procedures and accelerate personalized oncology care. Comprehensive characterization of HIF-2α and carbonic anhydrase IX expression and the genomic landscape in clear cell and *VHL*-altered renal cell carcinoma. First Author: Yu-Wei Chen, Department of Medicine, UC San Diego Moores Cancer Center, La Jolla, CA

Background: Clear cell renal cell carcinoma (ccRCC) is commonly driven by VHL loss, resulting in HIF-2α stabilization and upregulation of targets such as carbonic anhydrase IX (CA9). Clarifying the relationship between CA9 and HIF-2α expression is critical to guide rational therapeutic strategies. **Methods:** DNA (592-gene panel or whole exome) and RNA (whole transcriptome) sequencing was performed on ccRCC and RCC–not otherwise specified, (NOS) tumors with *VHL* alterations via Caris Life Sciences for integrated genomic and transcriptomic profiling. The primary objective was to characterize the expression patterns of HIF-2α and CA9 across RCC tumors and co-occurring genomic alterations. Overall survival (OS) as measured from initial diagnosis. **Results:** A total of 1,935 RCC tumors were analyzed, including 967 (50%) ccRCC and the remainder RCC–NOS with *VHL* alterations; 49% were derived from the primary site. Expression of HIF-2α and CA9 were similar across racial and ethnic subgroups. Compared to primary kidney tumors, lower HIF-2α expression was observed in lymph node and liver metastases (both $p < 0.0001$) and lower CA9 expressions were observed in CNS and bone metastases (both $p < 0.0001$). Increased either HIF-2α or CA9 expressions were associated with high angiogenic and T-effector gene signatures as defined in IMmotion150 (all $p < 0.001$). HIF-2α expression positively correlated with CA9 expression ($r = 0.43$, $p < 0.001$). Tumors with highest quartile HIF-2α expression (Q4) had increased PBRM1 and decreased BAP1, TP53, and TERT mutation frequencies (Table). High CA9 expression (Q4) had increased PBRM1 and decreased TP53 mutations. High HIF-2α (Q4) and CA9 (Q4) expressions were associated with improved OS compared with Q1 (HIF-2α: median OS 97 vs 64.7 months, HR 0.56, $p < 0.0001$; CA9: median OS 90 vs 49 months, HR 0.63, $p = 0.002$). **Conclusions:** High expression of HIF-2α and CA9 identifies a canonical VHL/HIF-driven RCC subtype marked by enrichment of *PBRM1* mutations, depletion of aggressive genomic alterations (*BAP1*, *TP53*, *TERT*), and improved OS. Strong associations with angiogenic and immune-related gene signatures further support a coherent HIF-dependent phenotype. Research Sponsor: None.

Key gene mutation frequency by HIF-2 α/CA9 expression.

	HIF-2α (Q1)	HIF-2α (Q4)	P value	CA9 (Q1)	CA9 (Q4)	P value
PBRM1	33%	48%	<0.001	22%	46%	<0.001
BAP1	29%	8%	<0.001	22%	19%	0.43
TP53	13%	7%	0.012	16%	8%	0.04
TERT	13%	6%	0.005	12%	8%	0.37

A first-in-human phase 1 dose-escalation study of the oral HIF-2α inhibitor JMKX003948 in patients with renal cell carcinoma. First Author: Xieqiao Yan, Peking University Cancer Hospital, Beijing, China

Background: Hypoxia inducible factor-2 alpha (HIF-2α) is a transcription factor and key tumorigenic driver of clear cell renal cell carcinoma (ccRCC). JMKX003948 is a novel, orally administered, selective small-molecule HIF-2α inhibitor that has shown significant antitumor activity in preclinical models of ccRCC. Herein, we present preliminary results from a phase 1 dose-escalation study of JMKX003948 in advanced ccRCC (NCT06321250). **Methods:** In this study, Patients with advanced ccRCC who had received at least 1 prior standard therapy were enrolled in 40, 80, 120, 180, and 270 mg escalating-dose cohorts sequentially, and received JMKX003948 monotherapy once daily (QD) until progression or unacceptable toxicity. The primary endpoints included safety/tolerability, the maximum tolerated dose (MTD), and the recommended Phase 2 dose (RP2D). **Results:** As of Dec 23, 2025, 22 patients (17 male) were enrolled. Median age was 57.5 years (range, 32-73 years). 13 patients (59.1%) have received $\geq$ 2 prior lines of therapy, 20 patients (90.9%) have received immune checkpoint inhibitor, and all patients (100%) have received vascular endothelial growth factor receptor–tyrosine kinase inhibitor (VEGFR-TKI). At data cutoff, the median follow-up was 9.7 months. One dose-limiting toxicity (grade 3 transaminase elevation) was observed at the 120 mg QD dose level, and the MTD was not reached. Treatment-related adverse events (TRAEs) were reported in all patients, with most graded 1-2. The most common TRAEs were anemia (86.4%). Grade 3 TRAEs occurred in 6 patients (27.3%), including hypoxia (13.6%), anemia (9.1%), proteinuria (4.5%), transaminase elevation (4.5%), and hyperkalemia (4.5%). No grade 4 TRAEs occurred. No TRAEs led to treatment discontinuation or death. Of 20 efficacy-evaluable patients, 5 patients (2 patients in 270 mg cohort and 1 patient each in 80, 120, 180 mg cohort) had partial response (PR), and 9 patients had stable disease (SD), objective response rate (ORR) and disease control rate (DCR) per RECIST 1.1 were 25% and 70%, respectively. Mean time to response (TTR) was 3.2 months. Median progression-free survival (PFS) was 7.7 months (95% CI, 1.3-not available). **Conclusions:** JMKX003948 is well tolerated and shows promising antitumor activity in patients with advanced ccRCC. Clinical trial information: NCT06321250. Research Sponsor: Shanghai Jeyou Pharmaceutical Co., Ltd.

Investigating mechanisms of resistance to immune checkpoint inhibitors (ICIs) in renal cell carcinoma (RCC). First Author: Soki Kashima, Center of Molecular and Cellular Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: Though RCC often exhibits substantial CD8 T-cell infiltration, CD8 abundance does not predict clinical benefit from ICIs. We sought to elucidate tumor microenvironment features that uncouple CD8 presence from ICI response and to evaluate strategies to overcome resistance mechanisms. **Methods:** We performed single-cell RNA sequencing on 70 RCC tumors (59 clear-cell; 11 non–clear-cell), including samples obtained during systemic therapy (ICI-based therapy, n = 46; others, n = 24). Best response to ICI-based therapy was assessed according to RECIST: 18 responders (R; CR/PR) and 11 non-responders (NR; PD). Tumor-reactive TCRs were inferred using VDJdive. Non-negative matrix factorization identified gene programs associated with NR. Bulk RNA-seq data from landmark clinical trials (HCRN, JAVELIN Renal 101, CheckMate 9ER, COSMIC-313) were analyzed using Scissor (Sun et al. Nat Biotechnol 2022) to map PFS-associated bulk signals to single-cell states in our reference dataset, with summarized enrichment as an observed-to-expected (O/E) ratio. Ligand–receptor (NicheNet) and pathway analyses implicated upstream drivers. Functional validation was performed using primary human T cells cultured under normoxia or hypoxia, with or without TGFβ1. A TGFβ activation assay was used to evaluate rescue of T-cell function by the clinical-stage latent TGFβ1-selective inhibitor SRK-181. **Results:** We profiled 443,337 high-quality cells including 86,865 CD8 T cells. In NR tumors, a subset with high tumor-specific T-cell abundance (5/11, 45.5%) was enriched for an exhausted CD8 state with a tissue-resident memory program (Tex-rm; $p < 0.01$). Across multiple ICI-treated clinical trial cohorts, we identified Tex-rm cells as most associated with shorter PFS (O/E 1.34–1.82). Ligand–receptor and pathway analyses implicated enhanced TGFβ signaling in Tex-rm compared with other Tex. In vitro, hypoxia plus TGFβ1 increased a Tex-rm–like phenotype ($CD69^+CD103^+PD\text{-}1^+TIM\text{-}3^+$) relative to controls ($p < 0.05$ for each). TGFβ inhibited T-cell IFNγ production, while treatment with the TGFβ inhibitor SRK-181 restored it ($p < 0.05$). **Conclusions:** We identified a Tex-rm program associated with ICI intrinsic resistance in RCC despite high abundance of tumor-specific T cells. Functional data support a role for TGFβ signaling in promoting this dysfunctional state, suggesting that inhibiting TGFβ1 may help restore T-cell function and overcome ICI resistance in some non-responders. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Biomarker-defined outcomes in metastatic clear cell renal cell carcinoma (mccRCC) receiving first-line (1L) immune checkpoint inhibitor-based therapy. First Author: Koral U. Shah, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Dual immune checkpoint inhibitor (IO-IO) and immune checkpoint inhibitor plus VEGF receptor tyrosine kinase inhibitor (IO-TKI) regimens are approved 1L treatments for mccRCC, yet treatment selection remains empiric in the absence of prospective comparisons and validated predictive biomarkers. While prior retrospective studies have linked genomic alterations such as *PBRM1* with favorable immunotherapy outcomes (Miao et al., 2018), the impact of these alterations across IO-IO vs. IO-TKI regimens is not well characterized. We evaluate PD-L1 expression and tumor genomic alterations in relation to clinical outcomes among patients receiving 1L IO-based therapy. **Methods:** Adults with mccRCC diagnosed through 2/4/2025 were identified in ConcertAI's Patient360, a U.S. de-identified database integrating health records, claims, genomics, and mortality data. Patients initiating 1L IO-IO (ipilimumab + nivolumab) or IO-TKI (cabozantinib + nivolumab, pembrolizumab + axitinib, or lenvatinib + pembrolizumab) were included. Molecular testing performed prior to or during 1L therapy was collected. PD-L1 positivity was defined as ≥1% tumor cell staining. Overall survival (OS) and progression-free survival (PFS) were estimated via Kaplan-Meier methods; associations by treatment and biomarker status were assessed using Cox models. **Results:** Among 4,845 patients with mccRCC, 3,225 patients had 1L treatment data, of whom 1,007 (31.2%) received IO-based therapy. IO-based therapy included IO-IO (508 patients; 50.4%) and IO-TKI (499 patients; 49.6%). Among patients receiving IO-based therapy, median age was 62 years, and 63.6% had *de novo* metastatic disease. Tumor genomic alterations were identified in 125 patients, including *VHL* (77.6%), *PBRM1* (50.4%), *BAP1* (28.8%), and *SETD2* (4.8%). Patients with any alterations in *VHL*, *PBRM1*, or *BAP1* demonstrated significantly longer median PFS with IO-TKI compared with IO-IO (37.9 vs. 18.4 months, respectively; p=0.04). In gene-specific analyses, similarly large numerical differences in PFS were observed with IO-TKI vs. IO-IO amongst patients with *VHL* (38.0 vs. 18.4 months) and *PBRM1* (34.4 vs. 18.4 months) alterations. In the overall cohort, median PFS was 32.2 vs. 20.8 months (p=0.06), and median OS was 58.4 vs. 56.7 months (p=0.60) for IO−TKI and IO−IO, respectively. Among 102 patients with available PD-L1 status, 25.5% were PD-L1-positive and 74.5% were PD-L1-negative. Among PD-L1-positive patients, OS and PFS did not significantly differ between regimens. **Conclusions:** Among patients with mccRCC receiving 1L IO-based therapy, those harboring *VHL*, *PBRM1*, or *BAP1* alterations were collectively associated with numerically longer PFS when treated with IO-TKI. These findings represent one of the first and largest biomarker-stratified comparisons of outcomes between IO-TKI and IO-IO regimens. Research Sponsor: None.

First-line tivozanib in favorable- and very favorable−risk metastatic renal cell carcinoma: Real-world evidence from the TIVOREAL-SOGUG study. First Author: Cristina Pernaut Sanchez, Hospital Universitario Severo Ochoa, Leganes, Madrid, Spain

Background: The optimal first-line treatment for favorable-risk metastatic renal cell carcinoma (mRCC) remains debated in the immune checkpoint inhibitor (ICI) era. Real-world data assessing prognostic subgroups treated with VEGFR-TKI monotherapy are limited. **Methods:** TIVOREAL-SOGUG is a retrospective multicenter study including patients with clear-cell mRCC treated with first-line tivozanib between 2017 and 2024 across 14 Spanish centers. Favorable-risk was defined by IMDC criteria (0 risk factors). A very favorable-risk (VFAV) subgroup was identified according to Zarba et al. criteria (time from diagnosis to systemic therapy >3 years, Karnofsky performance status 90–100%, and absence of brain, liver, or bone metastases). The primary endpoint was time to treatment failure (TTF); secondary endpoints included objective response rate (ORR), progression-free survival (PFS), overall survival (OS), subsequent therapies, and safety. **Results:** Among 198 evaluable patients, 84 (42.4%) had favorable-risk disease, including 23 (27.4%) classified as VFAV. In the overall favorable-risk cohort, ORR was 48.8%, including 7.1% complete responses. Median PFS and TTF were 23.7 and 14.7 months, respectively. Median OS was not reached, with 2- and 5-year OS rates of 85.4% and 67.8%. VFAV-risk patients showed higher ORR (65.2%), prolonged PFS (32.2 months) and TTF (31.1 months), and low primary progression. Treatment discontinuation due to toxicity occurred in 9.5% of patients. Most frequent adverse events were grade 1–2 fatigue, diarrhea, mucositis, dysphonia and hypertension, with grade ≥3 events being infrequent and mainly limited to hypertension. After progression, most favorable-risk patients received ICIs, whereas VFAV-risk patients required subsequent therapy less frequently, reflecting more durable disease control. **Conclusions:** In routine clinical practice, first-line tivozanib provides durable disease control and long-term survival in IMDC favorable-risk mRCC, and particularly in VFAV-risk patients. ICI and cabozantinib remain effective salvage options in this setting upon disease progression. Research Sponsor: Recordati Rare Diseases Spain, S.L.U.

Key clinical outcomes by prognostic subgroup.

Outcome	Favorable-risk (n=84)	Very favorable-risk (n=23)
Median TTF, months (95% CI)	14.7 (9.2–20.1)	31.1 (8.0–54.1)
Median PFS, months (95% CI)	23.7 (14.1–33.3)	32.2 (21.1–43.4)
ORR, % (CR %)	48.8 (7.1)	65.2 (13.0)
Primary progressive disease, %	14.3	4.3
2-year OS, % (95% CI)	85.4 (77.2–92.8)	95.7 (88.1–100)
Discontinuation due to toxicity, %	9.5	8.7

TTF and PFS were estimated using Kaplan–Meier methodology; tumor response was assessed according to RECIST 1.1.

LIF expression as a predictive biomarker in metastatic renal cell carcinoma. First Author: Mustafa Saleh, Dana-Farber Cancer Institute, Boston, MA

Background: Clear cell renal cell carcinoma (ccRCC) is biologically heterogeneous, and optimal selection between VEGF-targeted and ICI–based therapies remain an unmet clinical need. Leukemia inhibitory factor (LIF), an IL-6 family cytokine implicated in angiogenesis and immune regulation, is associated with poor prognosis in ccRCC; however, its predictive value for treatment selection has not been defined. **Methods:** Baseline tumor LIF expression was evaluated in 2,026 patients with metastatic ccRCC across 12 clinical and molecular cohorts, including CheckMate 009/010/025/214, JAVELIN Renal 101, IMmotion150, TCGA-KIRC, CPTAC-3, and institutional datasets. RNA-seq data were batch-corrected, normalized, and immune-deconvoluted (CIBERSORTx). Among 1,306 patients with treatment data, 1,058 with complete clinical covariates were included in treatment-by-biomarker interaction analyses. **Results:** LIF-high tumors (median cutoff) were associated with younger age (60 vs 63 years, p<0.001) and increased sarcomatoid features (17% vs 8%, p<0.001). A significant treatment-by-LIF interaction was observed for progression-free survival (PFS; interaction p=0.006). High LIF expression predicted inferior PFS on TKI monotherapy (HR 1.26, p<0.001), while this adverse association was absent with ICI-based regimens (monotherapy or combination; HR 0.70, p<0.001). No significant interaction was observed for overall survival. LIF expression discriminated progressive disease from disease control (p<0.001). Immune deconvolution revealed that LIF-high tumors exhibited an inflamed but immunosuppressive microenvironment, characterized by enrichment of macrophages (M0 and M2), neutrophils, and regulatory T cells, with preserved $CD8^+$ T-cell infiltration. LIF expression correlated strongly with CXCL8 (R=0.45), and more modestly with FGF2 and VEGFA, consistent with VEGF-independent angiogenic signaling. **Conclusions:** LIF identifies a biologically distinct subset of metastatic ccRCC characterized by angiogenic and immunosuppressive features and poor outcomes with TKI monotherapy. These data support LIF as a predictive biomarker to inform treatment selection and highlight the LIF/CXCL8 axis as a potential therapeutic target in advanced RCC. Research Sponsor: None.

Treatment-by-LIF interaction analysis for progression-free survival in metastatic clear cell renal cell carcinoma.

Nivolumab and Ipilimumab (NIVO IPI) as first-line (1L) treatment for patients with metastatic renal-cell carcinoma (mRCC): A real-world benchmarking analysis from the International mRCC Database Consortium (IMDC). First Author: Heber Tomas Reyes-Garcia, Arthur JE Child Comprehensive Cancer Centre, University of Calgary, Calgary, AB, Canada

Background: NIVO IPI has demonstrated durable overall survival (OS) benefit with long-term follow-up in patients with mRCC. Real world outcomes and benchmarks for subgroups as well as conditional survival (CS) are required in the real world. **Methods:** Patients with mRCC treated with 1L NIVO IPI from the IMDC were analyzed, including various subgroups of interest. Outcomes reported will be objective response rates (ORR), median overall survival (mOS) and conditional survival (CS). CS is defined as survival among patients who were alive and on treatment after the requisite 3-month interval landmarks, as estimated using the Kaplan–Meier method. CS was calculated at landmarks while patients were still on treatment, and at landmarks regardless of treatment. **Results:** 2115 patients received 1L NIVO IPI; 148/1042/549 were categorized by IMDC risk group as favorable/intermediate/poor risk; 90% of patients had clear-cell histology, 32% had bone metastases, and 14% had sarcomatoid features. Median follow-up was 34 months (m); median duration of treatment was 4.8 m, and median time to next treatment was 11.2 m. 66% of patients received second-line treatment. ORR was 39.5% (8.3% CR) with primary progression seen in 28 mOS was longer in clear cell (47.8 m) than in non–clear cell (26.3 m) (p<0.001). mOS was significantly shorter in patients with sarcomatoid features (34.2 vs 47.0 m; p=0.02 mOS was also different by IMDC risk group: 53.3 m for favorable, 45.7 m for intermediate and 18.8 m for poor risk patients (p<0.001); and by response: 4-year was OS of 93.6% for patients with CR, 60.1% for PR, 43.6% for SD and 15.4% for patients with PD (p<0.001). CS during 1L NIVO IPI is detailed in Table 1 with greater survival with each successive landmark. **Conclusions:** We provide real-world benchmark survival results for patients with mRCC treated with 1L NIVO IPI, including subgroup analysis regarding the presence of sarcomatoid features, IMDC risk group, and ORR. Conditional survival provides a key understanding of a patient's prognosis after having been on therapy or been alive for at certain time points. This is essential information for patient counselling and clinical trial design. Research Sponsor: None.

Conditional survival (CS) through time landmarks, either on treatment or regardless of treatment.

Extended follow-up (6 years) of the phase 2 LITESPARK-004 study of belzutifan in participants with von Hippel-Lindau disease–associated neoplasms. First Author: Ramaprasad Srinivasan, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Belzutifan, a potent and selective hypoxia-inducible factor 2α inhibitor, is indicated for treatment of patients with von Hippel-Lindau (VHL) disease–associated renal cell carcinoma (RCC), CNS hemangioblastomas (HB), or pancreatic neuroendocrine tumors (pNETs) not requiring immediate surgery based on prior results from the open-label phase 2 LITESPARK-004 study (NCT03401788). We report results from LITESPARK-004 after a minimum of 6 years of follow-up. **Methods:** Participants (pts) with germline *VHL* alterations, $\geq$1 measurable nonmetastatic RCC tumor, no tumor $>$3 cm that required immediate surgery, no metastatic disease, no prior anticancer systemic treatment, and an ECOG PS of 0 or 1 received oral belzutifan 120 mg once daily until disease progression, unacceptable toxicity, or pt withdrawal. The primary end point was objective response rate (ORR) in VHL disease–associated RCC per RECIST v1.1 by independent review committee (IRC). Secondary end points included safety, ORR in non-RCC neoplasms, duration of response (DOR), and progression-free survival (PFS) per RECIST v1.1 by IRC. **Results:** Overall, 61 pts received $\geq$1 dose of belzutifan. Median study follow-up was 73.8 months (range, 72.1-82.1). As of the data cutoff date (April 1, 2025), 34 pts (56%) remained on treatment. ORR was 70% for RCC, 52% for CNS HB, and 91% for pNETs. Additional efficacy results are shown in the Table. Among 14 pts (n = 18 affected eyes by ophthalmic evaluation), retinal HBs in 100% (95% CI, 81-100) of eyes showed improvement. Median DOR in pts with retinal HBs was not reached (NR; 95% CI, 8.5-NR). Within 5 years prior to initiating belzutifan, 46 of 61 pts (75%) had $\geq$1 VHL-related tumor reduction procedure (surgery or radiation therapy; 43 RCC, 39 CNS HB, 12 retinal HB, 3 pNET, 2 other). Since initiating belzutifan treatment, 22 of 61 pts (36%; 14 during treatment and 8 after discontinuing treatment) underwent 25 VHL-related tumor reduction procedures (16 RCC, 3 CNS HB, 5 retinal HB, 1 pNET). Grade 3 treatment-related adverse events (TRAEs) were reported in 12 pts (20%); the most common grade 3 TRAE was anemia (11%). No grade 4 or 5 TRAEs occurred. No additional pts discontinued belzutifan due to TRAEs since the previous analysis. **Conclusions:** After 6 years of follow-up, belzutifan continues to show durable antitumor activity and a manageable safety profile in pts with VHL-associated RCC, CNS HB, and pNETs who do not require immediate surgery. These results continue to support the use of belzutifan in this patient population. Clinical trial information: NCT03401788. Research Sponsor: Funding for this study was provided by Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; the Intramural Research Program of the National Institutes of Health, National Cancer Institute Center for Cancer Research; and a grant (U01 CA236489) from the National Cancer Institute.

Ultrasensitive circulating tumor DNA detection and molecular clearance as a prognostic and predictive marker in advanced renal cell carcinoma. First Author: Juan Ruiz Bañobre, Complejo Hospitalario Universitario de Santiago, Santia, Spain

Background: Renal cell carcinoma (RCC) is characterized by exceptionally low levels of circulating tumor DNA (ctDNA), often falling below the limit of detection for conventional liquid biopsy assays. This low-shedding environment creates a significant unmet need for ultrasensitive strategies to detect molecular residual disease (MRD), improving patient stratification, and enabling longitudinal monitoring of disease evolution in a clinical setting. **Methods:** ctDNA was profiled using NeXT Personal, a tumor-informed WGS-based assay tracking up to ~1,800 patient-specific variants with a limit of detection (LOD) of ~1 part per million (PPM). Baseline and longitudinal (n = 165) plasma from 37 advanced RCC patients were analyzed. The primary analysis evaluated baseline plasma (n = 36) across clinical variables. Prognostic value for progression-free survival (PFS) and overall survival (OS) was assessed in patients treated with immunotherapy or TKIs (n = 35). **Results:** Baseline ctDNA was detected in 84% (31/37) of patients. Notably, 13% (4/31) of these detections occurred in the ultrasensitive range below 100 PPM. Baseline ctDNA PPM levels significantly correlated with IMDC risk group (median PPM: favorable 10.9, intermediate 244.2, poor 2437.0; P=0.005), presence of histological high-risk features (median PPM: low-risk: 40.6 vs high-risk: 1528.0; P=0.025) and stage at diagnosis (median PPM: I-III 35.1 vs IV 1548.3; P=0.006). Median ctDNA levels were significantly lower in patients with surgical site recurrence (5.5 vs. 937.2 PPM; P=0.038). Molecular ctDNA clearance (mCR), defined as ctDNA-negative status at any point during first-line therapy, was highly prognostic. mCR correlated significantly with best overall response (P=0.007), with 100% specificity for disease control; no patients with progressive disease achieved clearance. Patients not achieving mCR had dramatically worse PFS (HR=8.69; P=0.001) and OS (HR=4.70; P=0.044). Among patients with a best response of stable disease (SD) by imaging, mCR provided critical differentiation; those who cleared ctDNA had 100% PFS/OS at 2 years, whereas those who remained ctDNA-positive saw PFS drop to 0% and OS to 33% by year 1. Additionally, achievement of mCR was significantly associated with clinical disease control (PR+SD, 92.3% vs PR+SD, 50.0%; OR 12.0 [95% CI 1.32–108.8], p=0.013). **Conclusions:** Ultrasensitive ctDNA profiling effectively overcomes the low-shedding challenge of advanced RCC, and could provide additional prognostic clarity that complements standard-of-care imaging and IMDC risk models. mCR serves as an effective biomarker for long-term survival, identifying patients with durable responses even among those with radiographically stable disease. These findings support integrating ctDNA monitoring to guide treatment intensification or de-escalation strategies. Impact of time-of-day of immune checkpoint inhibitor infusion on clinical outcomes in patients with metastatic renal cell carcinoma (mRCC). First Author: Soon Khai Low, Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI

Background: Emerging evidence suggests that circadian rhythms may influence the efficacy of immune checkpoint inhibitors (ICIs) by modulating immune cell activity and T-cell trafficking. This study evaluated whether the timing of ICI administration (early vs. late) affects progression-free survival (PFS) and overall survival (OS) in patients with metastatic renal cell carcinoma (mRCC). **Methods:** We conducted a single-center retrospective study of 97 patients with Stage IV mRCC treated with first-line ICIs. Patients were categorized by infusion timing: "Early" (n=68) vs. "Late" (n=29), with the cutoff defined by the median infusion time of 2:00 PM. Treatment regimens included ipilimumab/nivolumab (37%), nivolumab (36%), and pembrolizumab (27%); 23% received ICI in combination with a VEGF-targeted tyrosine kinase inhibitor. Outcomes were analyzed using Kaplan-Meier curves and multivariable Cox regression models, adjusting for age and International Metastatic RCC Database Consortium (IMDC) risk scores. **Results:** The median age was 65 years (IQR 59–71), 77% of patients were male, and 88% had clear cell histology. IMDC risk categories were intermediate (56%), poor (27%), and favorable (18%). At a median follow-up of 54.8 months, early infusion was associated with significantly improved OS (median 54 vs. 29 months; adjusted HR 1.79; 95% CI 1.02–3.12; p = 0.041) and PFS (median not reached; adjusted HR 3.59; 95% CI 1.27–10.20; p = 0.016) after adjustment for age and IMDC risk. Landmark 60-month OS was 40% vs. 31%, and PFS was 79% vs. 60% for the early vs. late groups, respectively. The incidence of any-grade immune-related adverse events (irAEs) was similar (54% in the early group vs. 52% in the late group), and poor IMDC risk remained a significant predictor of OS in the multivariable model (HR 3.09; 95% CI 1.22–7.8; p = 0.017). **Conclusions:** In this mRCC cohort, ICI administration before 2:00 PM was associated with significant improvements in both PFS and OS, including a nearly two-fold increase in median overall survival compared to late-afternoon administration. These findings are hypothesis-generating and suggest that the timing of immunotherapy may be an immediately actionable, high-impact variable in optimizing mRCC treatment. Prospective validation is warranted. Research Sponsor: None.

Correlation between *CARINH* expression and clinical outcomes in metastatic clear-cell renal cell carcinoma (mccRCC). First Author: Wassim Daoud Khatoun, Dana-Farber Cancer Institute, Boston, MA

Background: *CARINH* is an interferon (IFN)-responsive long non-coding RNA that promotes *IRF1* expression and downstream IFN signaling. Higher *CARINH* expression improves outcomes in esophageal cancer through suppressed tumor growth (Huang et al, 2019). Despite the immunogenic nature of RCC, the role of *CARINH* in its immunogenicity remains unexplored. Here, we examine the role of *CARINH* in predicting progression in mccRCC patients (pts) treated with systemic therapy. **Methods:** We included pts with RNA-seq data from 2 first-line clinical trials in mccRCC: Javelin Renal-101 (JR; n = 741) and CheckMate9ER (CM9; n = 403). Transcripts per million (TPM) were log2-transformed and scaled per 1 SD change. IMmotion150 T_{eff} and Myeloid signatures, and tumor inflammatory score (TIS) were computed as means of their log2-transformed genes' TPMs then scaled. Multivariable (MV) Cox models assessed progression-free survival (PFS) per increase in *CARINH* expression and compared PFS for each immune signature with and without *CARINH* expression, using likelihood ratio test (LRT). Log-rank test compared PFS between high and low *CARINH* expression groups with median split. Spearman correlation associated *CARINH* expression and immune signatures. MV logistic regression estimated progression odds ratio between pts who progressed (RECIST 1.1: PD), and those who didn't (CR, PR, SD and NCR/NPD). MV analyses adjusted (adj) for age, sex, treatment arm, IMDC risk and sarcomatoid features. **Results:** In MV Cox analysis, higher *CARINH* was associated with improved PFS in both trials (JR: HR_{adj} = 0.87 - 95% CI: 0.79-0.96, p = 4.5×10^{-3}; CM9: HR_{adj}= 0.82 - 95% CI: 0.73-0.93, p = 1.3×10^{-3}), regardless of treatment arm (LRT p $>$ 0.05). Log-rank test, comparing high and low expression groups, revealed longer PFS with high expression in every cohort and their arms (p $<$ 0.05), except for sunitinib in CM9 (p = 0.18). Higher *CARINH* expression correlated positively with T_{eff} and TIS signatures (ρ = 0.51-0.54) and negatively with Myeloid signature (ρ = -0.14 to -0.10) in both trials (p $<$ 0.05). *CARINH* expression improved PFS prediction over immune signatures in both trials (Table). Higher expression was associated with lower progression odds (JR: OR_{adj}= 0.74 - 95% CI: 0.60–0.91, p = 3.7×10^{-3}; CM9: OR_{adj}= 0.68 - 95% CI: 0.47–0.98, p = 0.04), independent of arm (LRT p $>$ 0.05). **Conclusions:** In mccRCC, higher *CARINH* expression associates with lower progression odds and improved PFS beyond that predicted by immune signatures. Translational efforts to characterize its role in mccRCC pathophysiology and clinical outcomes are ongoing. Research Sponsor: None.

MV Cox for PFS prediction by immune signature after adding *CARINH* expression.

Trial	Immune Signature	HR_{adj} (with CARINH)	95% CI	LRT FDR-adj p-value
JR	TIS	0.86	0.76-0.97	0.02
JR	T_{eff}	0.88	0.79-0.99	0.04
JR	Myeloid	0.87	0.80-0.96	0.02
CM9	TIS	0.84	0.72-0.97	0.02
CM9	T_{eff}	0.81	0.70-0.94	7.2×10^{-3}
CM9	Myeloid	0.82	0.73-0.93	4.6×10^{-3}

A multi-axis biomarker model integrating KIM-1 and MAdCAM-1 in metastatic renal cell carcinoma. First Author: Marc Machaalani, Dana-Farber Cancer Institute, Boston, MA

Background: Kidney injury molecule-1 (KIM-1) and mucosal vascular addressin cell adhesion molecule-1 (MAdCAM-1) have each emerged as prognostic circulating biomarkers in metastatic renal cell carcinoma (mRCC). Whether these biomarkers capture overlapping or complementary aspects of disease biology, and whether their integration improves risk stratification, remains unclear. **Methods:** Baseline plasma KIM-1 and MAdCAM-1 levels were measured in 612 patients with previously untreated mRCC from the JAVELIN Renal 101 trial, including 323 patients treated with avelumab + axitinib and 289 with sunitinib. Biomarker concentrations were analyzed as continuous variables after log10 transformation. Associations with overall survival (OS) and progression-free survival (PFS) were assessed using multivariable Cox models adjusted for IMDC risk, age, and sex. A composite KIM-1−MAdCAM-1 risk score was developed to assess the incremental prognostic value of integrating these biomarkers. **Results:** Both KIM-1 and MAdCAM-1 levels were independently associated with OS and PFS in univariable analyses. In multivariable models including both biomarkers and adjusted for age, sex, and IMDC risk, higher KIM-1 levels remained associated with worse survival (OS: HR 1.57, 95% CI 1.28−1.93), whereas higher MAdCAM-1 levels were associated with improved survival (OS: HR 0.37, 95% CI 0.15−0.92). No significant interaction was observed between KIM-1 and MAdCAM-1, nor between either biomarker and treatment arm for OS or PFS. A composite KIM-1−MAdCAM-1 risk score was strongly associated with clinical outcomes. Patients in the highest-risk quartile had significantly worse PFS (median: 8.3 [5.7−11.1] vs 19.4 [13.8−NR] months) and OS rate (at 18 months: 65.0% [57.3−73.8] vs 90.0% [85.0−95.2]) compared to the lowest-risk quartile, across both treatment arms (Table). A joint KIM-1−MAdCAM-1 model demonstrated improved discrimination compared with either biomarker alone ($p < 0.001$), and the addition of both biomarkers to IMDC significantly improved OS discrimination (C-index 0.73 vs 0.67; $p < 0.001$). **Conclusions:** KIM-1 and MAdCAM-1 provide complementary and non-redundant prognostic information in mRCC. Their integration into a composite risk score significantly improves risk stratification beyond either biomarker alone and beyond IMDC criteria. These findings support a multi-axis circulating biomarker approach to prognostication in mRCC. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; CA258442; Dana-Farber/Harvard Cancer Center Kidney; CA101942-16; Dana-Farber/Harvard Cancer Center; CA006516-56.

Association of KIM-1−MAdCAM-1 composite score quartiles with progression-free and overall survival in the overall study cohort and by treatment arm.

KIM-1−MAdCAM-1 Composite Score	Entire Cohort HR (95% CI)	Avelumab + Axitinib HR (95% CI)	Sunitinib HR (95% CI)
Progression-Free Survival (Q4 vs Q1)	2.12 (1.56−2.87)	2.00 (1.31−3.05)	2.20 (1.41−3.43)
Overall Survival (Q4 vs Q1)	4.67 (2.71−8.05)	3.61 (1.75−7.44)	5.89 (2.54−13.7)

Final analysis of the TiNivo-2 phase 3 trial: Long-term outcome of tivozanib (Tivo) in patients with metastatic renal cell carcinoma (mRCC). First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY

Background: TiNivo-2 results showed that immune checkpoint inhibitor (ICI) rechallenge did not offer benefit to patients with mRCC, regardless of treatment sequencing (*Lancet*, 2024; 404:1309). However, the data highlights activity for Tivo monotherapy in the post-ICI setting. Long term outcomes of the TiNivo-2 study are reported here. **Methods:** TiNivo-2 trial design and primary-endpoint results were previously reported: patients with mRCC were randomized to treatment with Tivo 0.89 mg once daily for 21/28 days plus Nivolumab (Nivo) at 480 mg every four weeks (Tivo/Nivo) or Tivo 1.34 mg once daily for 21/28 days. Here, long term progression free survival (PFS), overall survival (OS), and the safety profile are reported at final analysis. **Results:** At the data cutoff of 17 October 2025, 172 patients were randomized to Tivo (171 treated) and 171 patients were randomized to Tivo/Nivo (168 treated); median (m) follow up was 28.4 mo (95% CI 27.0-29.8) in Tivo versus 27.2 months (mo) (95% CI 26.1-28.5) in Tivo/Nivo. Survival outcomes and hazard ratios (HR) for the ITT population, 2L, and 3L populations are summarized in Table 1. In 2L, mPFS favored Tivo over Tivo/Nivo (9.23 mo [7.29, 11.04] vs 5.95 mo [5.42, 7.95]). Across subgroups, there were no differences in mOS. No new safety signals were observed with prolonged administration; the most common ≥ Grade 3 TEAE was hypertension occurring in 39 (22.8%) and 38 (22.6%) and of patients in the Tivo and Tivo/Nivo groups respectively. Other ≥ Grade 3 TEAEs included diarrhea (2.3% and 3.6%) and palmar-plantar erythrodysaesthesia (0.6% and 1.2%) in the Tivo and Tivo/Nivo groups respectively. Treatment Related SAEs occurred in 15 (8.8%) and 18 (10.7%) of patients in Tivo and Tivo/Nivo groups respectively. **Conclusions:** This final analysis of patients in the TiNivo-2 study highlights the sustained efficacy Tivo in mRCC with a consistent safety profile. Together, these findings support durable clinical benefit and tolerability of Tivo in the post-ICI treatment setting in RCC, an area of high unmet need (NCT04987203). Clinical trial information: NCT04987203. Research Sponsor: AVEO Pharmaceuticals, Inc.

Explainable AI to predict molecular classes of renal cell carcinoma from digital pathology images. First Author: Jordan Krull, Department of Biomedical Informatics, College of Medicine, The Ohio State University, Columbus, OH

Background: There is an unmet need to develop rapidly deployable and reliable biomarkers to guide treatment decisions in clear cell renal cell carcinoma (ccRCC). Transcriptome-based molecular classification is promising in predicting differential clinical outcomes to angiogenesis blockade alone or with an immune checkpoint inhibitor (ICI), but these approaches require molecular profiling that is costly and time-consuming. This study evaluates whether explainable artificial intelligence (AI) can accurately predict molecular classes of ccRCC from diagnostic H&E slides. This approach enables scalable, pathology-based assessment of treatment response−related biology without the need for additional tissue or sequencing. **Methods:** We acquired digital whole slide images of H&E stained primary ccRCC tumors from TCGA, OSU Total Cancer Care Alliance, and an in-house built set of selected biopsies. RNA-Seq cluster assignments from IMmotion151 study were reconstructed from published gene log-fold-change cluster enrichment scores and non-negative least squares regression on matching RNA-Seq of our samples. After assigning samples to their highest scoring group, we trained a multi-group attention-based multiple-instance learning (ABMIL) classifier to predict RNA-Seq groups from digital whole slide images broken into 112um patches and encoded using UNI foundation model embeddings. **Results:** A total of 555 cases with both H&E and RNA-seq data were included. Class prediction from RNA-Seq were 40% Angio-Stromal, 30% Complement-Ox, 16% Angio, 8% Teff-Prolif, 4% Prolif, 2% Stromal-Prolif and 0% snoRNA. Predicting these classes from H&E-stained images, showed AUROC values of 0.76 (Angio-Stromal), 0.78 (Complement-Ox), 0.83 (Angio), 0.85 (Teff-Prolif), 1.00 (Prolif) and 0.91 (Stromal-Prolif) respectively. Similar AUROC values with more modest curves were seen on a hold-out set (10%) where Angio-Stromal/Complement-Ox (0.61/0.61) and Teff-Prolif (0.59) were the lowest AUROC values and Prolif (0.99) was the highest. Importantly, incorrect predictions most often yielded a group prediction where the predicted group shared some biological identity with the ground truth group label (eg. Angio-Stromal and Angio). We also utilized the attention values from ABMIL to evaluate spatial prediction saliency, which showed the model focused primarily on tumor regions, even for predictions of primarily stromal defined classes. **Conclusions:** Our results demonstrate that diagnostic H&E slides contain histologic features that can predict ccRCC molecular subsets using explainable AI. Supporting scalable pathology-based inference of tumor biology linked to treatment response. Research Sponsor: None.

Spatial multiomic profiling to identify de-differentiated tumor phenotypes and exhausted T cell niches in rhabdoid and sarcomatoid RCC. First Author: Zachary Alan Yochum, Center of Molecular and Cellular Oncology, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: Rhabdoid and sarcomatoid (S/R) differentiation are high-grade dedifferentiated states that can arise across renal cell carcinoma (RCC) subtypes. Although associated with poor patient prognosis, S/R RCC paradoxically exhibits increased sensitivity to immune checkpoint blockade. The mechanisms underlying this aggressive, yet immunotherapy-responsive phenotype remain unclear. Spatial multi-omic profiling offers a powerful framework to interrogate tumor-intrinsic and microenvironmental programs that account for this phenotype. Here, we applied spatial multi-omic analyses to treatment-naïve clear cell RCC specimens from seven patients, enabling direct comparison of sarcomatoid, rhabdoid, and clear cell regions captured within the same tissue sections. **Methods:** Hematoxylin and eosin (H&E)−stained sections from seven FFPE patient samples were reviewed and annotated by a genitourinary pathologist to identify discrete regions of sarcomatoid, rhabdoid, or clear cell morphology. Annotated FFPE samples were processed by Singular Genomics using the G4X spatial multi-omic platform, which enables quantification of 315 RNA transcripts, 14 protein targets, and fluorescent H&E imaging. **Results:** Initial spatial multi-omic profiling resolved distinct tumor regions with clear cell biology alongside areas exhibiting rhabdoid or sarcomatoid features. Comparative analysis of immune infiltrates across these regions revealed enrichment of both T cells and B cells within rhabdoid regions. In addition, T cells localized to rhabdoid and sarcomatoid regions displayed distinct phenotypic states compared with those in clear cell regions. Differential gene expression (DGE) analysis of T cells from rhabdoid and sarcomatoid regions relative to clear cell RCC demonstrated upregulation of activation markers (*CD69*, *IL2RA*), exhaustion markers (*LAG3*, *PDCD1*), and cytotoxic genes (*GZMA*, *GZMK*, *NKG7*). Parallel analysis of tumor cell transcriptional programs further highlighted distinct tumor biology across histologic regions. Sarcomatoid tumor cells exhibited increased expression of genes associated with cellular stress, inflammation, and epithelial−mesenchymal transition (EMT), including *IGFBP7* and *FOS*. In contrast, rhabdoid tumor cells showed upregulation of antigen-presentation machinery (*HLA-A*, *TAP1/2*) along with elevated expression of EMT-associated genes (*MET*, *VCAM1*, and *CD44)*. **Conclusions:** Spatial multi-omic analysis of S/R RCC revealed distinct immune and transcriptional programs across sarcomatoid, rhabdoid and clear cell regions. T cells within S/R regions exhibited activated and exhausted phenotypes, while tumor cell characterization of S/R cells reveals upregulation of stress, inflammatory and antigen-presentation machinery, features that may underlie the sensitivity of S/R RCC to immune checkpoint inhibitors. Association of baseline quality of life (QOL) and early death in patients with metastatic renal cell carcinoma (mRCC) in the real-world prospective observational ODYSSEY study. First Author: Michael R. Harrison, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: Baseline QOL has been linked to survival in mRCC therapy clinical trials (Cella, 2024); however, there is a paucity of prospectively collected real-world QOL data across frontline management strategies. We used data from ODYSSEY to examine the relationship between baseline QOL and early death. **Methods:** ODYSSEY is a multi-site, prospective observational study of 468 US pts with mRCC. Pts must have mRCC (any histology); have no prior systemic therapy (ST) or be within 3 months of starting ST; and follow up at a PCORnet study site. Exclusion criteria include treatment for cancer except mRCC. The primary objective is to determine patterns of change in QOL and symptom burden of pts with mRCC. Early death was defined as death within 12 months post-enrollment. All pts with non-missing FKSI-19 or FKSI-DRS at enrollment were included. Cumulative event probabilities as a function of time were stratified by either $<$ or $\geq$ median QoL value and plotted as a step function vs time since enrollment to create cumulative event curves. To determine association between QoL at enrollment and early death, separate Cox proportional hazards models (unadjusted and adjusted) for time-to-first-event as a function of baseline QoL were fit. The adjusted model controlled for the following baseline covariates: IMDC risk (favorable vs intermediate or poor), histology (clear cell vs non). **Results:** As of 1/5/26, 468 pts were enrolled; 425 had non-missing FKSI-19 or FKSI-DRS at enrollment (329 immediate ST, 96 deferred ST [DST]). ST included 129 IO-IO, 108 IO-TKI, 92 Other. DST included 57 Active Surveillance, 22 Local Therapy Planned, 17 Other/Missing. 209 and 190 pts have $<$ median FKSI-19 (score = 59) and FKSI-DRS (score = 29), respectively; 216 and 235 pts have $\geq$ median FKSI-19 and FKSI-DRS, respectively. Those below the median have lower rates of nephrectomy, worse IMDC risk and KPS, shorter time since RCC diagnosis, and higher rates of bone metastasis (all $p<0.05$). Cumulative event probabilities for death at 12 months are 21% and 7% in those $<$ and $\geq$ median baseline FKSI-19, respectively; and 21% and 7% in those $<$ and $\geq$ median baseline FKSI-DRS, respectively. For FKSI-19, the unadjusted hazard ratio (HR) for early death is 0.55 (95% CI: 0.43 – 0.70; $p<0.001$) and adjusted HR is 0.65 (0.49 – 0.85; p = 0.002) per 1 SD higher score. For FKSI-DRS, the unadjusted HR for early death is 0.57 (95% CI: 0.46 – 0.71; $p<0.001$) and adjusted HR is 0.66 (0.51 – 0.86; p =0.002) per 1 SD higher score (higher score indicates better QOL). **Conclusions:** Across management strategies in our ODYSSEY cohort of systemic therapy naïve mRCC patients, better baseline QOL was associated with better survival. This is to our knowledge the largest reported real world mRCC cohort with prospectively collected PROs. Future analyses will focus on association of outcomes with longitudinal PROs. Clinical trial information: NCT04919122. Research Sponsor: Bristol Myers Squibb; Exelixis; Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc.; Pfizer.

Clinical and genomic predictors of outcomes in patients (pts) with advanced urothelial carcinoma (aUC) treated with enfortumab vedotin and pembrolizumab (EVP): UNITE study analysis. First Author: Elise Y. Cai, Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA

Background: EVP is the recommended 1st line (1L) therapy for pts with aUC and is moving into the perioperative setting. There is limited understanding of clinical factors and biomarkers predictive of EVP outcomes. **Methods:** We analyzed pts with aUC treated with EVP in the multi-site retrospective UNITE study. χ^2 test and logistic regression were used to assess observed response rate (ORR) and disease control rate (DCR). Log-rank test and Cox proportional hazard models were used to assess progression-free survival (PFS) and overall survival (OS) from EVP start. Multivariable analysis (MVA) included age, sex, race, ECOG performance status (PS), neutrophil-to-lymphocyte ratio (NLR), albumin, hemoglobin (Hgb), primary tumor site, histology, treatment line, and metastatic sites as covariates. **Results:** A total of 521 pts with aUC from 16 sites received EVP. Median age was 71, 75% were male, 81% were Caucasian, 76% had ECOG PS 0-1, and 72% were treated with 1L EVP. 74% had lower tract primary tumor, 65% pure urothelial histology, 18% liver metastases (mets), 43% non-liver visceral mets, and 28% lymph node (LN)-only mets. At 8.1 mos median follow-up from EVP start, the overall cohort had ORR 55%, DCR 82% [16% complete response (CR), 39% partial response (PR), 27% stable disease (SD)], median PFS (mPFS) 6.5 mos, and median OS (mOS) 19.8 mos. For 1L EVP pts, at 9.8 mos median follow-up, ORR was 59%, DCR 83% (20% CR, 39% PR, 24% SD), mPFS 10.1 mos, and mOS 23.3 mos. In both the overall cohort and 1L EVP pts, clinical factors associated with longer PFS and OS included ECOG PS 0-1, Caucasian race, albumin $\geq$ 3.5 g/dL, Hgb $\geq$ 10g/dL, NLR $<$ 5, and absence of visceral mets. CR was associated with ECOG PS 0-1 (OR 3.6, 95% CI 1.4-12.5, p = 0.02), Hgb $\geq$ 10g/dL (OR 2.3, 95% CI 1.2-4.8, p = 0.02), NLR $<$ 5 (OR 2.7, 95% CI 1.5-5.3, p = 0.002), LN-only mets (HR 3.8, 95% CI 1.7-9.8, p = 0.003), immunotherapy-naive status (OR 4.1, 95% CI 1.4-17, p = 0.02), and 1L EVP for aUC (OR 3.3, 95% CI 1.7-7.3, p = 0.001). Pts with CR had longer mPFS than pts with PR or SD (26.5 vs. 14.5 vs. 7.5 mos, $p < 0.001$) and longer mOS (NR vs. 33.4 vs. 14.5 mos, $p < 0.001$). Among 315 pts with molecular profiling, the most common alterations were in *TERTp* (55%), *TP53* (45%), *FGFR3* (22%), *ARID1A* (19%), *KMT2D* (18%), *PIK3CA* (18%), and *CDKN2A/B* (17%). In MVA, *KMT2D* alterations were associated with lower CR rate (6% vs. 19%, p = 0.05), shorter mPFS (5.0 vs. 8.0 mos, p = 0.04), and shorter mOS (12.0 vs. 20.0 mos, p = 0.04). Very high tumor mutational burden ($\geq$ 15 mut/Mb) was associated with higher DCR (97% vs. 79%, p = 0.04) but no significant difference in PFS or OS. **Conclusions:** In this large real-world cohort, ECOG PS, metastatic site, treatment line, and prior immunotherapy exposure were associated with EVP outcomes. *KMT2D*-altered aUC may represent a high-risk molecular subset with worse outcomes. Further validation in prospective cohorts is needed. Research Sponsor: None.

Real-world overall survival outcomes of belzutifan treatment in advanced renal cell carcinoma. First Author: Elshad Hasanov, Pelotonia Institute for Immuno-Oncology and Division of Medical Oncology, The Ohio State University Comprehensive Cancer Center – James Cancer Hospital and Solove Research Institute, Columbus, OH

Background: Belzutifan, a hypoxia-inducible factor–2α inhibitor, is an emerging therapy for advanced renal cell carcinoma (RCC) that demonstrated significant benefit over everolimus in the LITESPARK-005 trial. We aimed to validate these findings in a real-world setting and identify clinical prognostic factors within a large, multi-institutional cohort. **Methods:** We conducted a retrospective cohort study, using Epic Cosmos, of adults with RCC who initiated Belzutifan on or after the FDA Approval date (December 14, 2023) to Dec 20, 2025, ensuring at least one month of follow-up prior to the query date. Overall survival (OS) was measured from the treatment start date to death, with censoring at the last clinical encounter. Survival was estimated using Kaplan–Meier methods. Associations between baseline clinical and laboratory variables and OS were evaluated using univariable Cox proportional hazards models with false discovery rate (FDR) correction. **Results:** A total of 2,844 patients were included; the median age was 66 years, 72% were male, and 51.2% had documented tobacco use. The OS probabilities were 80.9%, 68.1%, 58.3%, and 53.2% at 6, 12, 18, and 24 months, respectively, and comparable to the LITESPARK-005 trial. Among clinical variables, tobacco use was associated with worse survival (HR 1.24 [95% CI 1.08–1.44], FDR = 0.014), whereas female sex (HR 0.78 [0.66–0.92], FDR = 0.014) and higher BMI (HR 0.96 [0.95–0.98], FDR $<$0.001) were associated with improved outcomes. Markers of nutritional and hematologic reserve were strongly protective, including higher Albumin (HR 0.46 [0.41–0.52], FDR $<$0.001), Total Protein (HR 0.77 [0.70–0.89], FDR $<$0.001), Hemoglobin (HR 0.90 [0.87–0.93], FDR $<$0.001), RBC (HR 0.69 [0.62–0.75], FDR $<$0.001), and MPV (HR 0.90 [0.84–0.96], FDR = 0.002). Inflammatory and immune markers demonstrated divergent effects: higher Lymphocytes (HR 0.53 [0.46–0.61], FDR $<$0.001) and Lymphocyte-to-Monocyte Ratio (HR 0.75 [0.71–0.80], FDR $<$0.001) predicted favorable outcomes. Conversely, worse survival was associated with elevated RDW (HR 1.14 [1.11–1.17], FDR $<$0.001), Monocytes (HR 1.71 [1.34–2.20], FDR $<$0.001), Basophil-to-Lymphocyte Ratio (HR 2.39 [1.20–4.77], FDR = 0.019) and Neutrophils (HR 1.06 [1.04–1.07], FDR $<$0.001),.Higher Corrected Calcium (HR 1.43 [1.30–1.57], FDR $<$0.001) and Total Bilirubin (HR 1.13 [1.04–1.22], FDR = 0.005) were associated with inferior outcomes. **Conclusions:** In the largest real-world cohort to date, overall survival after belzutifan initiation mirrored LITESPARK-005, supporting its effectiveness in routine practice. Baseline nutritional, hematologic, and immune markers were associated with improved survival, while systemic inflammation and metabolic dysfunction predicted worse outcomes, highlighting the prognostic value of routine clinical variables. Real-world clinical outcomes by HER2 expression in locally advanced/metastatic urothelial carcinoma (la/mUC): Results from the global SGNDV-003 retrospective study. First Author: Vadim S. Koshkin, University of California, San Francisco, CA

Background: Approximately 50-80% of patients (pts) with la/mUC have tumors with HER2 protein expression. As HER2-directed therapies enter development, a robust understanding of HER2 prevalence and real-world outcomes with standard-of-care (SOC) therapies across HER2 expression subgroups is needed. SGNDV-003 (NCT05902494) is a global retrospective chart review study in which HER2 status was assessed via central lab testing and outcomes were analyzed by HER2 status in pts with la/mUC. **Methods:** SGNDV-003, conducted 6/2023-7/2025, included pts with la/mUC who received ≥1 prior treatment (tx) (incl. 1 line of platinum-based chemotherapy [chemo]). HER2 status was centrally tested using a UC-specific investigational immunohistochemistry [IHC] and in situ hybridization (ISH) assays. HER2 status was defined as: HER2-positive (IHC3+ or IHC2+/ISH+), HER2-low (IHC2+/ISH- or IHC1+), HER2-expressing (IHC3+, 2+, 1+), and HER2-zero (IHC0). Index line of therapy (LOT) was defined as the first LOT received after platinum-based chemo. Outcomes included real-world objective response rate (rwORR) (per RECIST 1.1 or physician-assessed response) to index LOT, real-world progression-free survival (rwPFS), and overall survival (OS) from start of index LOT. Data was analyzed via descriptive statistics. **Results:** A total of 353 pts with la/mUC and available HER2 status were analyzed (male, 76%; median age, 70 years). 70% of pts were HER2 expressing (19% HER2-positive, 51% HER2-low); 30% were HER2-zero. Disease characteristics were well balanced by HER2 status. Index LOT tx and real-world outcomes are shown in the Table. Immuno-oncology therapies (IO) and enfortumab vedotin (EV) were the most common index LOTs. For IO, rwORRs were 21% for HER2-expressing and 17% for HER2-zero. For EV mono, rwORRs were 36% (HER2-expressing) and 38% (HER2-zero), respectively. **Conclusions:** This global study provides a robust estimate of HER2 distribution in la/mUC based on standardized central lab testing, showing high prevalence of HER2 expression. Real-world outcomes with current SOC therapies were broadly consistent across HER2 subgroups, establishing an important benchmark for the clinical development of HER2-directed therapies in this setting. Research Sponsor: Seagen Inc. Bothell, WA, USA, which was acquired by Pfizer in December 2023.

Zelenectide pevedotin (BT8009) monotherapy in previously treated metastatic urothelial carcinoma (mUC): Update on Duravelo-1. First Author: Oscar Reig Torras, Hospital Clínic de Barcelona, Barcelona, Spain

Background: Zelenectide pevedotin (zele, formerly BT8009) is a highly selective Bicycle Drug Conjugate (BDC) targeting Nectin-4, a protein that is overexpressed in mUC and other cancers. Zele has a lower molecular weight (4.2 kDa) and a shorter plasma half-life (<1 hour) than antibody drug conjugates (ADCs), with potential to rapidly penetrate solid tumors and minimize healthy tissue exposure. Here, we present updated safety and efficacy results of zele monotherapy in enfortumab vedotin (EV)–naïve patients with mUC from the Phase 1/2 Duravelo-1 study (NCT04561362). **Methods:** Eligible patients had previously treated unresectable mUC, creatinine clearance ≥50 mL/min, prior anti-PD-1/PD-L1 exposure, had progressed on or were ineligible for platinum-based chemotherapy, and had not received EV. All patients treated with the recommended Phase 2 dose of zele monotherapy 5 mg/m^2 once weekly across the dose-escalation and dose expansion phases were included in the analysis. **Results:** As of July 1, 2025, 53 patients with a median age of 63 years (range 25–84) and a median of 2 (range 1–7) prior lines of therapy were included. Median time on treatment was 4.4 months and maximum duration was 24.9 months, and median follow-up time was 9.9 months (range 0.5–43.9). Median progression-free survival was 5.4 months (95% CI 2.3–7.1). Confirmed objective response rate (cORR) in all patients was 32% (n=17/53), and disease control rate (DCR) was 66% (n=35/53), including 2 complete responses and 15 partial responses (PR); 3 additional patients had unconfirmed PR. Of the 13 patients who had received prior taxane therapy, cORR was 31% and DCR was 69%, including 4 PR and 5 with stable disease. Median duration of response was 10.0 months (95% CI 5.3–16.6) among patients with confirmed responses (n=17). Nausea (36%), asthenia (28%), and diarrhea (28%) were the most common treatment-related adverse events (TRAEs). TRAEs of Grade ≥3 occurred in 25% of patients and serious TRAEs occurred in 9%. TRAEs led to treatment withdrawal in 4% of patients. Grade 3 TRAEs of clinical interest (AECIs) were single reports of skin reaction and hyperglycemia (n=1 each, 2%). Grade 1–2 treatment-related AECIs of peripheral neuropathy were reported in 47% of patients and were all sensory-based, with 1 patient requiring treatment withdrawal. Grade 1–2 treatment-related skin reaction and eye disorder AECIs were reported in 15% and 13%, respectively. **Conclusions:** Zele monotherapy at 5 mg/m^2 once weekly continues to demonstrate an encouraging efficacy profile and a promising safety profile with the potential to differentiate from ADCs in EV-naïve patients with mUC. Antitumor activity was preserved in patients with exposure to taxanes. Treatment withdrawal resulting from zele-related AECIs was uncommon. A Phase 2/3 study of zele in patients with locally advanced or mUC (NCT06225596; Duravelo-2) is currently active. Clinical trial information: NCT04561362. Research Sponsor: BicycleTx Ltd.

Zelenectide pevedotin (BT8009) plus pembrolizumab in 1L cisplatin-ineligible locally advanced/metastatic urothelial carcinoma: Update on Duravelo-1 B7. First Author: Ignacio Duran, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

Background: Zelenectide pevedotin (zele, formerly BT8009) is a highly selective Bicycle Drug Conjugate (BDC) targeting Nectin-4 and conjugated to MMAE. Zele has a lower molecular weight (4.2 kDa) and a shorter plasma half-life (< 1 hour) than antibody drug conjugates (ADCs), with potential to rapidly penetrate solid tumors and minimize healthy tissue exposure. Preliminary results of zele + pembrolizumab (pembro) in previously untreated, cisplatin-ineligible locally advanced/metastatic urothelial carcinoma (la/mUC) patients (pts) (expansion cohort B7, NCT04561362; Duravelo-1), showed promising antitumor activity and a generally tolerable safety profile (Giannatempo et al., 2025). Here, we present updated results with extended follow-up and further efficacy data. **Methods:** Cisplatin-ineligible pts by Galsky criteria who had received no prior systemic anticancer treatment for la/mUC were eligible. Pts received IV zele 5 mg/m^2 on Days (D)1/8/15 + pembro 200 mg on D1 of a 21-D cycle. The primary endpoint was confirmed objective response rate (cORR) per Investigator using RECIST v1.1. Secondary endpoints included safety and additional efficacy endpoints. Treatment-related adverse events (TRAEs) were determined for all pts who received at least one dose of study drugs. **Results:** As of July 1, 2025, 22 pts were treated: median age 77 years, 45% had ECOG performance status (PS) of 2, and 45% had creatinine clearance < 60 mL/min. Median duration of treatment for zele and pembro was 23.4 weeks (range 1.0–84.1) and 26.9 weeks (range 3.0–85.9), respectively. Median follow-up was 11.8 months (range 1.0–19.4); 14 pts remained on study at the time of data analysis. Median progression-free survival (mPFS) was 13.0 months (95% CI 3.8–NE). cORR was 50% (n = 11/22), and disease control rate was 82% (n = 18/22), including 5 complete responses and 6 partial responses (PR); 2 additional pts had unconfirmed PRs. Median duration of response (mDOR) was not mature. The most common Gr ≥3 TRAEs included ALT increase (18%) and neutropenia and asthenia (14% each). Of AEs of clinical interest (AECIs), treatment-related Gr 3 events included peripheral neuropathy (14%; leading to drug withdrawal in 2 pts) and skin reactions (9%; these events were not serious and did not lead to withdrawal); no Gr 4 or 5 treatment-related AECIs occurred. **Conclusions:** Treatment with zele + pembro has promising clinical benefits in pts with la/mUC and a historically poor prognosis with first-line therapies (~50% ECOG PS of 2), including: mPFS of 13.0 months, 50% cORR, and mDOR not reached. Additionally, zele + pembro demonstrates a safety profile with the potential to differentiate from ADC combinations, including no skin-related serious AEs. These data support the Phase 2/3 study of zele as monotherapy and in combination with pembro versus chemotherapy in pts with la/mUC (NCT06225596; Duravelo-2). Clinical trial information: NCT04561362. Research Sponsor: BicycleTx Ltd.

Effect of on-treatment dose adjustments on the efficacy of enfortumab vedotin and pembrolizumab (EVP) in advanced urothelial carcinoma (aUC): A UNITE analysis. First Author: Jeffrey Yinhong Zhong, Division of Solid Tumor Oncology, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH

Background: EVP is the preferred 1st-line regimen for patients (pts) with aUC. EV-related toxicities are often managed with dose adjustments, such as reductions and holds. Analysis of EV monotherapy trials showed consistent survival outcomes despite dose adjustments. We hypothesized that on-treatment EV dose adjustments would not impact survival in these pts. **Methods:** Pts with aUC treated with EVP in the multisite UNITE study were analyzed. Early dose reductions (DR) and holds were defined as occurring < 9 weeks from EVP start, with the remainder classified as late. Pts with DR at treatment start were excluded. Survival endpoints were progression-free survival (PFS) and overall survival (OS) from EVP start, assessed by Kaplan-Meier analysis and Cox models. Multivariable Cox analysis (MVA) included age (≥ 75 vs < 75), ECOG performance status (0-1 vs 2-3), Hgb level (< 10 vs ≥ 10) and liver metastases (present vs not). A time-dependent covariate was used to reduce immortal time bias. Complementary MVA landmark analyses were performed, aligned to the total number of treatment cycles received, with six analyses from cycles 2 to 7. **Results:** 360 pts from 17 sites were included (median age 70; 78% Caucasian; 76% male; 27% upper tract primary; 35% histology subtype component; 17% with liver metastasis; 78% frontline); median follow-up was 11.7 months (95% CI [10.79, 13.08]). Median number of cycles was 6 in pts with DR and 3 with no DR. Early DRs (100 pts [28%]) and holds (18 pts [5%]) were most commonly due to rash (28% of all early DRs and holds). Late DR (75 pts [21%]) and holds (50 pts [14%]) were most commonly due to neuropathy (52% of all late DRs and holds). Pts with early or late DR had longer PFS and OS vs those who did not (Table); however, there was no significant PFS or OS difference with dose hold vs no hold (PFS HR 0.65, 95%CI (0.40, 1.05), p = 0.08; OS HR 0.70, 95%CI (0.39, 1.27), p=0.24). In landmark analyses, about 50% of pts had DR; no significant difference in PFS or OS was observed at most landmarks, except for longer OS in the DR cohort at cycle 4 (HR 0.53, 95% CI (0.29, 0.98), p = 0.042) and cycle 5 (HR 0.43, 95% CI (0.19, 0.99), p = 0.048). **Conclusions:** In this real-world retrospective analysis, EVP efficacy was maintained despite DR and dose holds. Survival difference noted in the time-dependent analyses were not consistently reproduced in landmark analyses, suggesting exposure-related selection bias rather than causal effect. Prospective studies are warranted to validate these hypothesis-generating findings. Research Sponsor: None.

Association of EV DR with PFS/OS (time-dependent analyses).

Interim analysis results from Duravelo-2: Zelenectide pevedotin (zele; BT8009) in patients (pts) with previously treated locally advanced/metastatic urothelial carcinoma (la/mUC). First Author: Daniel P. Petrylak, Yale School of Medicine, New Haven, CT

Background: Zele is a highly selective Bicycle Drug Conjugate (BDC) targeting Nectin-4, a protein overexpressed in la/mUC. There remains an unmet need in la/mUC for safer and more tolerable treatments. Here, we report an interim analysis (IA) for zele monotherapy dosage selection from the Phase 2/3 Duravelo-2 study (NCT06225596/BT8009-230) in previously treated pts with la/mUC. **Methods:** Adults with la/mUC were enrolled into 2 cohorts: previously untreated pts eligible for platinum-based chemotherapy (Cohort [Co]1) or pts with ≥1 prior systemic therapy (Co2). IA was conducted to determine the optimized dosage of zele + pembrolizomab (Co1) or zele monotherapy (Co2). Herein, we report IA results from Co2. Pts in Co2 were randomized 1:1 to zele 5 mg/m^2 on Days [D]1/8/15 or zele 6 mg/m^2 on D1/8 on a 21-D cycle. Dosage optimization included safety, efficacy, and pharmacokinetic data in pharmacometrics and utility score analyses to quantify benefit-risk. **Results:** IA was performed at 27 weeks of follow-up (N=30 each zele dose group). Median zele treatment (tx) duration was 4.80 months. Confirmed ORRs by BICR among randomized, dosed pts with measurable disease at baseline were 28% (8/29; 2 complete responses [CR], 6 partial responses [PR]; 95% CI 12.7–47.2) and 30% (8/27; 3 CR, 5 PR; 95% CI 13.8–50.2) with zele 5 mg/m^2 and 6 mg/m^2, respectively. Zele-related adverse events (AEs) were reported in 93% (47% Gr ≥3) of pts at 5 mg/m^2 and 93% (52% Gr ≥3) at 6 mg/m^2. Gr ≥3 zele-related AEs for 6 mg/m^2 (≥5% pts) included neutrophil count decreased and neutropenia (10% each) and anemia, asthenia, and ALT increase (7% each). No zele-related Gr 5 AEs were reported at either dosage. Zele-related AEs of clinical interest (AECIs) for 6 mg/m^2 are summarized in the Table. Notably, no zele-related severe skin reactions of any Gr were reported at either dosage. Zele dose reductions and discontinuations due to zele-related AEs occurred in 24% and 0%, respectively, for 6 mg/m^2. At Week 27, a third of pts remained on tx. **Conclusions:** Zele monotherapy at 5 mg/m^2 on D1/8/15 and 6 mg/m^2 on D1/8 on a 21-D cycle demonstrate encouraging response rates and safety profiles with the potential to differentiate from ADCs in previously treated pts. The 6 mg/m^2 D1/8 regimen provides a more favorable benefit-risk profile to meet the need for safer and more tolerable treatments, with enhanced potential for combinability and convenience, leading to fewer discontinuations. Clinical trial information: NCT06225596. Research Sponsor: BicycleTx Ltd.

Zele-related AECIs in pts with previously treated la/mUC treated with zele 6 mg/m^2 on D1/8 (N=30).

Identifying optimized dosage for zelenectide pevedotin in locally advanced/metastatic urothelial carcinoma (la/mUC) using quantitative analyses. First Author: Yasong Lu, Bicycle Therapeutics, Cambridge, MA

Background: Zelenectide pevedotin (zele; BT8009) is a Bicycle Drug Conjugate (BDC) comprising a highly selective bicyclic peptide targeting Nectin-4 linked to the cytotoxin monomethyl auristatin E (MMAE) via a cleavable linker. Zele demonstrated preliminary antitumor activity and a generally tolerable safety profile in patients (pts) with la/mUC in the Phase 1/2 Duravelo-1 trial (NCT04561362) [Reig, 2024; Giannatempo, 2025]. Zele is being evaluated in a randomized Phase 2/3 study at 2 dosages, 5 mg/m^2 on Days (D)1/8/15 and 6 mg/m^2 on D1/8 of a 21-D cycle, each as monotherapy or combined with pembrolizumab (P) in pts with la/mUC (NCT06225596, Duravelo-2) [Loriot, 2025]. After 30 pts in each dosage arm had 27 weeks follow-up (N=120 total), an interim analysis was conducted to select the optimized dosage for further development. **Methods:** Pharmacometric (PMx) and utility score analyses were conducted to quantify the benefit-risk comprehensively. For the PMx analysis, all pharmacokinetic (PK), overall response rate [ORR, assessed by investigator (INV) and/or blinded independent central reviewer (BICR)], and adverse event (AE) data [zele-related and treatment-emergent (TE) Gr ≥3 AE, Gr ≥3 neutropenia, Gr ≥2 gastrointestinal disorders, Gr ≥2 peripheral neuropathy, any Gr skin reactions, dose modifications] from Duravelo-1 and -2 were pooled and analyzed using population PK (PopPK) and exposure-response (ORR, AE) modeling. Simulations for ORR and AE probabilities were then generated for comparing dosages with balance of relevant pt characteristics. The utility score analysis was mainly based on Gr ≥3 zele-related TEAEs and ORR by BICR regardless of confirmation in Duravelo-2, with sensitivity analyses based on alternative safety and/or efficacy endpoints (TEAEs, confirmed ORR by BICR). **Results:** The datasets for PopPK, ORR, and AE analysis included 434, 203 (203 INV assessed, 114 BICR assessed), and 394 pts, respectively, mostly treated at the 5 or 6 mg/m^2 dosages. Modeling of ORR did not detect a significant difference between the dosages studied. ORR was impacted positively by P combination, negatively by baseline tumor size, but not by the assessor (INV vs BICR). The AE rates were significantly correlated with exposures of zele and/or MMAE. Between 5 mg/m^2 D1/8/15 and 6 mg/m^2 D1/8, ORR did not differentiate them; safety favored 6 mg/m^2 D1/8 as its predicted AE probabilities were mostly lower. For AEs favoring 6 mg/m^2 D1/8, predicted probabilities were lower by 0.1% – 15.5% as monotherapy and by 0.1% – 19.1% in combination. The utility score analysis favored 6 mg/m^2 D1/8 consistently for zele combined with P and remained neutral between the dosages for monotherapy. **Conclusions:** 6 mg/m^2 D1/8 was identified as the optimized zele dosage for monotherapy and in combination with P based on the overall benefit-risk informed by the comprehensive quantitative analyses. Clinical trial information: NCT06225596. Research Sponsor: BicycleTx Ltd.

Avelumab + sacituzumab govitecan (Ave + SG) vs avelumab monotherapy (Ave mono) as first-line (1L) maintenance treatment for advanced urothelial carcinoma (aUC): Updated subgroup analyses of JAVELIN Bladder Medley based on metastatic sites. First Author: Petros Grivas, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA

Background: Ave 1L maintenance is a recommended treatment option for patients (pts) with aUC without progression after 1L platinum-based chemotherapy (PBC). In the JAVELIN Bladder Medley phase 2 trial (NCT05327530), 1L maintenance with Ave + SG (Trop-2–directed antibody-drug conjugate) improved progression-free survival (PFS) vs Ave mono (primary endpoint). In pts with aUC, presence of visceral metastases (including liver or lung) is associated with poorer prognosis. We report updated subgroup analyses from the primary analysis of JAVELIN Bladder Medley based on metastatic site. **Methods:** Pts with unresectable locally advanced or metastatic UC without progression after 4-6 cycles of 1L PBC were randomized 2:1 to receive Ave + SG or Ave mono, stratified by presence of visceral metastases at start of 1L PBC. Primary endpoints were investigator-assessed PFS (measured from randomization) and safety; overall survival (OS) was a secondary endpoint. For visceral and nonvisceral subgroups, PFS and OS data in the Ave mono arm were extended per protocol using propensity score–weighted data from the JAVELIN Bladder 100 phase 3 trial; extended data were not available for other subgroups. **Results:** At the start of 1L PBC, of 74 and 37 pts in the Ave + SG and Ave mono arms, respectively, 37 (50.0%) and 19 (51.4%) had visceral metastases, 20 (27.0%) and 11 (29.7%) had lung metastases, 17 (23.0%) and 7 (18.9%) had liver metastases, 17 (23.0%) and 11 (29.7%) had bone metastases, and 26 (35.1%) and 11 (29.7%) had lymph node–only disease. At data cutoff (Apr 28, 2025), in the Ave + SG and Ave mono arms, respectively, median follow-up for PFS was 15.7 and 25.1 mo. Across all subgroups, PFS was prolonged with Ave + SG vs Ave mono (Table); OS analyses were immature. In the Ave + SG and Ave mono arms, respectively, grade ≥3 treatment-related adverse events occurred in 72.2% and 5.6% of pts with visceral metastases, 57.9% and 0% of pts with lung metastases, 82.4% and 0% of pts with liver metastases, 82.4% and 0% of pts with bone metastases, 70.3% and 5.6% of pts with nonvisceral metastases, and 76.9% and 9.1% of pts with lymph node–only metastases. **Conclusions:** In the primary analysis of JAVELIN Bladder Medley, Ave + SG as 1L maintenance improved PFS vs Ave mono, irrespective of metastatic site. Clinical trial information: NCT05327530. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Longitudinal tumor-informed ctDNA monitoring and clinical outcomes in advanced urothelial carcinoma treated with enfortumab vedotin ± pembrolizumab. First Author: Adanma Ayanambakkam, Stephenson Cancer Center, University of Oklahoma Health Sciences, Oklahoma City, OK

Background: Enfortumab vedotin plus pembrolizumab (EV±P) is standard-of-care for patients (pts) with locally advanced/metastatic urothelial carcinoma (la/mUC), although not all pts experience durable benefit. Tumor-informed circulating tumor DNA (ctDNA) assays enable a personalized, real-time assessment of disease kinetics, and early ctDNA dynamics (<12 weeks) have been linked to EV±P radiographic response and survival outcomes. However, the prognostic relevance of ctDNA dynamics relative to durable clinical benefit is not well defined. **Methods:** We conducted a multicenter, retrospective real-world analysis of pts with la/mUC who received ≥1 cycle of EV±P and ≥1 commercial plasma ctDNA test using a clinically validated, personalized, tumor-informed assay (Signatera, Natera, Inc.). Associations between ctDNA features and progression-free survival (PFS) and overall survival (OS) were evaluated using Cox proportional hazards models. **Results:** A total of 110 pts with 545 plasma samples were analyzed. All pts had ≥1 ctDNA test (median: 4 tests/pt) immediately prior to and/or after EV±P initiation, with median time between serial ctDNA collections of 7.3 (IQR: 5.4-12.0) weeks. In this cohort, 69% (76/110) of pts had ≥1 ctDNA test (355 total) beyond 12 weeks post-EV±P initiation. Among these 76 pts, 31.5% (24/76) were persistently ctDNA negative (≥2 consecutively negative samples with no positives), while 65.8% (50/76) were anytime ctDNA-positive. Time-varying covariate analysis incorporating all serial results after 12-weeks reaffirmed that ctDNA-positivity was associated with worse PFS and OS (PFS: HR: 36.8, p<0.005; OS: HR: 17.7, p=0.01). Serial ctDNA negativity within 4-24 weeks (i.e. ≥2 consecutively negative samples with no positives) was strongly associated with durable OS/PFS beyond 24 weeks (PFS: HR=0.05, 95% CI: 0.01-0.42, p=0.005; OS: HR=0.046, 95% CI: 0.0004-0.33 [Firth], p=0.0002). Furthermore, single-timepoint ctDNA positivity evaluated at 12–24 weeks (HR: 11.8; 95% CI: 2.72–51.60; p=0.001) and >24 weeks (HR: 6.8; 95% CI: 2.5–18.6; p=0.0002) was strongly associated with inferior PFS. Findings were similar for OS (12-24wk: HR: 7.2, 95% CI: 1.7-31.3; p=0.008; >24wk: HR=3.8, CI: 1.2-12.3; p=0.03). **Conclusions:** Longitudinal ctDNA dynamics are strongly prognostic in pts with la/mUC treated with EV±P, even when assessed beyond 12 weeks from treatment start. Sustained ctDNA negativity further identifies pts with durable clinical benefit. These findings support ctDNA as a potentially complementary biomarker to standard imaging in this clinical context. Untreated advanced urothelial carcinoma (aUC) in the modern treatment era: Patterns of care from a decade-long national cohort. First Author: Melanie Mayer, Department of Biostatistics, Epidemiology, & Informatics, University of Pennsylvania, Philadelphia, PA

Background: Over the past decade, the therapeutic landscape for locally advanced/unresectable and de novo metastatic urothelial cancer (aUC) has transformed with the introduction of immune checkpoint inhibitors (ICIs) and antibody-drug conjugates (ADCs). These agents offer a more favorable benefit-risk and superior efficacy vs historical chemotherapy. We hypothesized that the proportion of untreated patients with aUC has declined over time, reflecting increased uptake of novel therapeutics. **Methods:** We analyzed the U.S. Flatiron Health EHR-derived de-identified database. We included patients diagnosed with aUC between Jan 1, 2011 and April 30, 2025. Patients were classified as treated if they received first-line (1L) systemic therapy within 6 months of advanced diagnosis. Calendar time was divided into three clinically relevant eras: pre-ICI approval (2011-2016), post-ICI but pre-ADC approval (2017-2019), and post-ADC approval (2020-2025). Outcomes included proportion untreated and time to treatment initiation (TTI) from advanced diagnosis. We estimated the cumulative incidence of treatment initiation using competing-risk methods, treating death before initiating as a competing event. Subgroup analyses evaluated patients with de novo stage IV disease at initial diagnosis. **Results:** We identified 12,849 patients with aUC (median age 73, 72.9% male, 78.7% white, 57.5% cis-ineligible, 78.3% bladder primary site). The proportion remaining untreated 6 months post advanced diagnosis declined across therapeutic eras: 36.8% untreated in the pre-ICI era, 27.4% in the post-ICI, pre-ADC era, and 22.7% untreated in the post-ADC era. Year-specific analysis showed steady improvement in treatment uptake: treatment within 6 months rose from 56% in 2011 to 79% in 2024 (Table). In the TTI analysis, overall, 25.1% had not initiated 1L therapy before death or data cutoff. Median TTI shortened across eras (63 days, 49 days, 45 days) and competing-risk cumulative incidence initiating therapy increased over time. For example, the probability of initiating 1L therapy within 90 days of aUC diagnosis across eras was 55.9% (pre-ICI), 66.1% (post-ICI, pre-ADC) and 70.7% (post ADC). **Conclusions:** In a large national cohort, untreated rates among patients with aUC declined markedly from 2011-2025 paralleling the introduction of ICIs and ADCs. Novel, better-tolerated therapies appear to have expanded real-world treatment eligibility and reduced early attrition. Characterizing the immune effects of enfortumab vedotin and pembrolizumab (EV+P) on peripheral blood mononuclear cells (PBMCs) in metastatic urothelial cancer patients (mUC). First Author: Aditi Gupta, Memorial Sloan Kettering, New York, NY

Background: Enfortumab vedotin improves response and outcomes over chemotherapy in mUC, with further benefit when combined with pembrolizumab. Although EV alone has limited immune-activating effects, we hypothesize that the combination of EV+P modulates peripheral T-cell activation states and correlates with clinical response. **Methods:** We conducted a retrospective analysis of mUC patients treated with EV+P at Memorial Sloan Kettering Cancer Center. PBMCs were isolated from patients on C1D1 and C2D1 of EV+P (n=33) and analyzed with a 32-color spectral flow cytometry panel. Immune subsets were compared between responders (complete [CR] or partial response [PR]) and non-responders (stable [SD] or progressive disease [PD]) using Wilcoxon rank sum test. Response was determined by a radiologist's assessment of the best-overall response on EV+P according to RECIST v1.1. **Results:** Among 33 patients, median age was 71 years and 48% were male. 12.1% (4/33) received prior platinum chemotherapy and 18.1% (6/33) received prior PD-1/PD-L1 immunotherapy. The objective response rate was 67% (CR=10; PR=12); eight patients had SD and three had PD. At C1D1, CD8+ T cell frequencies did not differ by response. At C2D1 however, circulating CD8+ T cells were significantly higher in non-responders ($p < 0.05$). From baseline to C2D1, CD8+ T cells showed increased expression of CTLA4+ ($p < 0.0001$), Ki67+ ($p < 0.01$) and HLA-DR+ ($p < 0.01$), with higher expression of each marker at C2D1 significantly correlated with response (all $p < 0.05$, Table 1). At C2D1, CD4+ effector T cells showed increased expression of Ki67+ and HLA-DR+ (both $p < 0.05$), both significantly higher in responders (both $p < 0.05$). CD4+ regulatory T cells showed increased CTLA4+ ($p < 0.001$), Ki67+ ($p < 0.01$) and HLA-DR+ ($p < 0.01$) expression from C1D1 to C2D1, with significantly higher expression in responders (CTLA4+ $p < 0.05$, Ki67+ $p < 0.0001$, HLA-DR+ $p < 0.001$). Across all T cell subtypes, PD1+ expression significantly decreased ($p < 0.05$) from C1D1 to C2D1, but this decrease did not correlate with response. The frequencies of circulating memory CD8+ and CD4+ T cells did not change on treatment or correlate with response at either timepoint. **Conclusions:** EV+P induces early peripheral T cell activation in mUC, with increased expression of activation and proliferative markers in responders at C2D1. Ongoing studies are investigating correlation between TCR specificity, immune activation and responses to EV+P. Research Sponsor: Bladder Cancer Advocacy Network.

Peripheral CD8+ T cell frequencies (median) at C1D1 and C2D1 from mUC patients on EV+P.

CD8+ T Cell	C1D1	C2D1	p-value	C2D1 in Responders	C2D1 in Non-Responders	p-value

Genomic determinants of metastatic burden and survival in metastatic urothelial carcinoma. First Author: Milit S. Patel, The University of Texas at Austin, Austin, TX

Background: Metastatic urothelial carcinoma (mUC) has variable outcomes. Metastatic site count (MSC) correlates with prognosis; the genomic landscape underlying metastatic burden and survival is poorly characterized. We investigated associations among somatic alterations, metastatic patterns, and survival in a large clinical-genomic cohort. **Methods:** We analyzed 1,157 patients with metastatic bladder cancer by integrating genomic data from the AACR Project GENIE Cohort v18.0-public with clinical annotations and metastatic site information from the MSK-MET database. Associations between 428 genomic alterations and MSC were assessed using Mann-Whitney tests. Survival analyses (n=1,153; 364 events) used Kaplan-Meier estimation, log-rank tests, and Cox regression. Models were adjusted for age, MSC (stratified), and location (lymph, liver, lung). FDR correction was applied, and proportional hazards assumptions verified. **Results:** Median age was 68.7 years; median OS was 15.8 months. MSC stratification revealed survival differences: 0-1 sites (n=515, median OS not reached), 2-4 sites (n=415, median OS 62.8 months), and >=5 sites (n=223, median OS 13.1 months; log-rank $p < 2.5 \times 10^{-19}$). Each increase in MSC category was associated with worse OS (FDR $p < 0.001$). MSC predicted 2-year survival with an AUC of 0.78 (95% CI: 0.75–0.82). Six alterations were significantly associated with lower MSC (FDR < 0.05): *ERCC2* (n=122; d=0.50, FDR p=5.6 x 10^{-6}), *STAG2* (n=128; d=0.40, FDR p=1.9 x 10^{-4}), *FBXW7* (n=96; d=0.36, FDR p=7.1 x 10^{-3}), *FGFR3* (n=291; d=0.17, FDR p=8.1 x 10^{-3}), *TP53BP1* (n=35; d=0.59, FDR p=4.3 x 10^{-2}), and *ARID2* (n=70; d=0.41, FDR p=4.6 x 10^{-2}). *ERCC2* mutation frequency was 15.7% in 0-1 sites and 4.0% in >=5 sites. Conversely, *CDKN2A/B* deletions were enriched in patients with >=5 sites (28.3%/27.9%) compared with 0-1 sites (16.5%/15.9%; FDR $p < 0.01$). Five alterations were independently associated with OS in univariable analysis (FDR < 0.05): *CDKN2B* deletion (HR 1.81, 95% CI: 1.43–2.28, FDR p=1.7 x 10^{-4}), *CDKN2A* deletion (HR 1.79, 95% CI: 1.42–2.26, FDR p=1.7 x 10^{-4}), *ERCC2* mutation (HR 0.39, 95% CI: 0.24–0.62, FDR p=1.1 x 10^{-2}), *CREBBP* mutation (HR 0.53, 95% CI: 0.37–0.75, FDR p=3.1 x 10^{-2}), and *KDM6A* mutation (HR 0.66, 95% CI: 0.52–0.84, FDR p=4.4 x 10^{-2}. In multivariable analysis adjusting for age, MSC, and location, no genomic alterations retained independent significance, suggesting MSC mediates these prognostic effects. Penalized regression confirmed MSC as the dominant prognostic variable (HR 1.39 per site increase). **Conclusions:** DNA damage repair and chromatin modifier mutations are associated with oligometastatic phenotypes and favorable survival, whereas *CDKN2A/B* deletions correlate with polymetastatic disease. The attenuation of genomic effects after MSC adjustment suggests that metastatic burden is a key mediator. These findings support using genomic profiling to guide mUC prognosis. CXCL9:SPP1 ratio: Macrophage polarization and outcomes with pembrolizumab or enfortumab vedotin plus pembrolizumab in metastatic urothelial cancer. First Author: Saad Omar Atiq, Mount Sinai Tisch Cancer Center, New York, NY

Background: Enfortumab vedotin plus pembrolizumab (EV+P) is standard first-line treatment for metastatic urothelial cancer (mUC), yet responses vary considerably. Identifying resistance mechanisms may guide patient selection and inform novel therapeutic strategies. Single-cell RNA sequencing (RNA-Seq) across tumor types has revealed dichotomous tumor-associated macrophage (TAM) populations: SPP1+ TAMs exhibit tumor-promoting programs while CXCL9+ TAMs express programs associated with anti-tumor immunity. The CXCL9:SPP1 gene expression ratio (CS ratio) from bulk RNA-Seq captures this balance and correlates with outcomes across solid tumors (Bill et al, Science, 2023). We explored the CS ratio's association with outcomes in mUC patients receiving pembrolizumab monotherapy or EV+P. **Methods:** We retrospectively analyzed mUC patients who underwent molecular profiling at Caris Life Sciences using NGS (592-gene panel, DNA WES, or RNA WTS). CS ratios were calculated and patients stratified into quartiles (Q1–Q4; Q4=highest ratio). PD-L1 expression was assessed by IHC (22c3, positive (+) CPS $\geq$ 10%) while TMB-High was defined as $\geq$ 10 Mut/Mb. TME composition was inferred using quanTIseq. Real-world overall survival (rwOS) was derived from insurance claims and calculated from biopsy to last contact or time on treatment (TOT) using Kaplan-Meier analysis while Hazard ratio (HR) was calculated by Cox proportional hazard method. Mann-Whitney U and χ^2/Fisher exact tests were applied with adjustment for multiple comparisons. **Results:** Among 6,708 mUC patients, 1,299 received pembrolizumab and 561 received EV+P. Lower CS ratios (SPP1+ TAM predominance) were associated with shorter time on treatment and rwOS (Table 1). Low CS ratio was also associated with reduced PD-L1 expression (15.5% vs 66.7%, $p < 0.001$) and TMB-H prevalence (34.6% vs 52.3%, p = 0.006). Low CS ratio tumors demonstrated reduced immune infiltration except for neutrophil enrichment. **Conclusions:** Lower CS ratios associate with shorter time on treatment and rwOS with both pembrolizumab and EV+P. To our knowledge, this is the first analysis linking macrophage transcriptional states with EV+P resistance. Further validation of the CS ratio in patients treated with EV + P or P is warranted. Research Sponsor: None.

CS ratio and associated outcomes with pembrolizumab monotherapy and EV+P.

	Pembrolizumab Monotherapy		EV + P	
CS Ratio	TOT (months)	OS (months)	TOT (months)	OS (months)
CS-Q1	2.7 (2.1-3.0)	5.7 (4.4-8.2)	7.6 (6.2-8.8)	17.8 (13.8-19.8)
CS-Q2	3.1 (2.2-4.1)	7.2 (5.4-8.8)	6.9 (6.0-8.0)	16.4 (13.2-19.4)

The role of NECTIN4 in shaping the tumor microenvironment and potentiating the efficacy of immunotherapy in bladder cancer. First Author: Kazuki Nishimura, Harvard Medical School, Brigham and Women's Hospital, Boston, MA

Background: The EV-302 trial established enfortumab vedotin plus pembrolizumab (EV/P) as first-line therapy for metastatic urothelial carcinoma (UC). Although EV/P is administered without NECTIN4 testing based on the assumption of uniform NECTIN4 expression, real-world data have identified NECTIN4-low tumors associated with inferior responses to EV, highlighting the need for NECTIN4-based precision therapy. We aimed to define the molecular and immunologic roles of NECTIN4, identify predictive biomarkers of EV/P outcomes, and explore rational therapeutic strategies for NECTIN4-low UCs. **Methods:** We performed multi-omics analyses of 817 UC cases integrating whole-exome sequencing, RNA-seq, multiplex immunofluorescence, and spatial single-cell profiling (CODEX). We evaluated associations among NECTIN4 status, molecular subtype, tumor microenvironment (TME), survival, and response to immune checkpoint inhibitors. Basal bladder cancer (BC) cell lines and orthotopic MB49 bladder cancer models with NECTIN4 overexpression (OE) or control were used to assess tumor biology and therapeutic response. **Results:** Clustering by NECTIN4 H-score and molecular subtype revealed that basal/squamous (Ba/Sq) muscle-invasive BCs with low NECTIN4 had significantly worse survival outcomes than NECTIN4-high tumors in both our cohort (P=0.001) and the IMvigor210 trial (P=0.019). In vitro, NECTIN4 OE in basal BC cells suppressed proliferation and migration through downregulation of inflammation-related signaling pathways. CIBERSORTx and EcoTyper analysis of RNA-seq data indicated a more immune-inflamed TME in NECTIN4-high Ba/Sq tumors. Spatial single-cell profiling showed increased CD8+ T cells, particularly CD8+/TIGIT+ cells, in NECTIN4-high Ba/Sq UCs. Moreover, in orthotopic mouse models, NECTIN4-OE tumors exhibited reduced growth and increased CD8+ T-cell infiltration. Clinically, NECTIN4-high Ba/Sq tumors showed higher objective response rate (ORR) to pembrolizumab/avelumab than NECTIN4-low tumors (55.5% vs 0%, P=0.002) in our cohort; in IMvigor210, NECTIN4-high Ba/Sq patients also had superior ORR (38.5% vs 15.6%, P=0.025). Additionally, in orthotopic mouse models, EV/P showed limited efficacy in NECTIN4-low tumors, whereas NECTIN4-OE tumors responded well. Transcriptomic analyses identified histone deacetylases (HDAC) as potential targets in NECTIN4-low tumors; accordingly, HDAC inhibitors demonstrated greater efficacy in NECTIN4-low basal BCs in vitro and vivo. **Conclusions:** NECTIN4 influences tumor progression and shapes the TME, thereby impacting immunotherapy efficacy. NECTIN4 is a potential predictive biomarker for survival and for outcomes with immunotherapy and EV/P in Ba/Sq UCs. NECTIN4-low Ba/Sq tumors may require alternative strategies, and HDAC inhibition represents a rational therapeutic approach for NECTIN4-low Ba/Sq UC patients. Research Sponsor: None.

Outcomes with first-line (1L) platinum-based chemotherapy (PBC) and avelumab 1L maintenance in locally advanced or metastatic urothelial carcinoma (la/mUC) by *NECTIN4* and *HER2* RNA expression: Exploratory analyses from JAVELIN Bladder 100. First Author: Niklas Klümper, University Hospital Bonn, Bonn, Germany

Background: Nectin-4 and HER2 are relevant therapeutic targets and potential biomarkers for the treatment of la/mUC. *NECTIN4* and *HER2* RNA expression are heterogeneous in UC tumors, with highest expression observed in luminal molecular subtypes. We report exploratory biomarker analyses from the JAVELIN Bladder 100 phase 3 trial evaluating response to 1L PBC and survival outcomes with avelumab administered as 1L maintenance treatment in subgroups defined by tumor *NECTIN4* and *HER2* RNA expression. **Methods:** In JAVELIN Bladder 100 (NCT02603432), patients (pts) with unresectable la/mUC without progression after 4-6 cycles of 1L PBC were randomized 1:1 to receive avelumab + best supportive care (BSC) or BSC alone. Biomarker analyses were performed using existing whole transcriptome profiles generated using RNA sequencing, and transcript levels were quantified using Personalis ACE technology. *NECTIN4* and *HER2* RNA expression were assessed as continuous variables for subgroups defined by response to 1L PBC and as dichotomous variables (median and lower quartile split) for stratified survival analyses. **Results:** In biomarker-assessable pts (n=560) who had complete response (CR; n=149), partial response (n=261), or stable disease (SD; n=150) to 1L PBC, no significant differences in tumor *NECTIN4* RNA expression were observed, whereas slightly higher tumor *HER2* RNA expression was observed in pts who had CR vs SD. Overall, when defined by median split, 201 pts (35.9%) had high *NECTIN4*/high *HER2* RNA expression, 202 (36.1%) had low *NECTIN4*/low *HER2*, 78 (13.9%) had high *NECTIN4*/low *HER2*, and 79 (14.1%) had low *NECTIN4*/high *HER2*. Molecular subtype was non-luminal in 20.4%, 87.1%, 55.1%, and 50.6%, respectively. The table shows overall survival (OS) with avelumab + BSC vs BSC alone in subgroups defined by combined high or low *NECTIN4*/*HER2* expression. OS improvements with avelumab + BSC vs BSC alone were observed across subgroups defined by high or low *NECTIN4*/*HER2* RNA expression alone. **Conclusions:** Exploratory analyses from JAVELIN Bladder 100 showed that pts with low *NECTIN4* and low or high *HER2* RNA expression had pronounced OS with avelumab 1L maintenance vs BSC alone. Results are hypothesis generating. Clinical trial information: NCT02603432. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Treatment-free survival (TFS) in patients with advanced urothelial carcinoma (aUC) treated with enfortumab vedotin (EV)–based therapy. First Author: Salvador Jaime-Casas, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: EV as monotherapy or with pembrolizumab (EVP) has shown robust efficacy in patients with aUC. Despite lack of data, treatment breaks (TB) with EV are frequently utilized due to toxicity or patient/physician preference. In this retrospective real-world analysis, we evaluated TFS after temporary or permanent EV discontinuation in patients with aUC. **Methods:** A multicenter cohort of patients with aUC treated with EV/EVP between 01/2015 through 12/2025 were included. Patients were categorized in groups with or without TB (defined as ≥6 weeks between EV doses without progression). Baseline characteristics were summarized using descriptive statistics, and comparison was performed using the chi-square test/Fisher's exact and t-test, as appropriate. TFS was estimated using the Kaplan–Meier method among TB+ patients. Overall survival (OS) and progression-free survival (PFS) were estimated for both cohorts using the Kaplan-Meier method and compared using the log-rank test. Univariable and multivariable models adjusted for baseline variables evaluated factors associated with TFS, OS and PFS. **Results:** From a total of 172 patients eligible for inclusion, 25 (14%) received TB and 148 (86%) did not. Median age was 72.5 years. Most patients were White (76.3%), had primary bladder cancer (89%), and received EVP (63%). Overall, 30% had ≥1 prior line of therapy. Baseline characteristics did not differ significantly between patients with and without TB. Most common reason for TB was treatment toxicity (52%) and a minority (20%) continued pembrolizumab during their break. The median TFS was 3.6 months (95% CI 3.0, 8.3), with 28% experiencing a TFS ≥24 weeks. TB did not compromise outcomes, and patients with a TB demonstrated longer median PFS (13.5 vs. 7.7 months, p=0.05) and OS (not reached vs 21.8 months, p=0.008). Prior radiation therapy (OR 0.18 (95% CI 0.06-0.53, p=0.002) and prior adjuvant chemoimmunotherapy (OR 0.18 (95% CI 0.04-0.77, p=0.02) were independently associated with decreased odds of experiencing a TB. **Conclusions:** Treatment break on EV therapy did not compromise outcomes and resulted in TFS lasting ≥6 months in a subset of patients. Rational treatment de-escalation strategies in selected patients need to be prospectively investigated to mitigate long-term toxicity in patients with aUC undergoing EV-based therapy. Research Sponsor: None.

Quantitative pre-cystectomy ctDNA levels for identification of ctDNA-positive patients with surgically curable loco-regional disease versus those with occult micrometastatic progression. First Author: Ruveyda Ayasun, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Radical cystectomy (RC) is a life-altering operation associated with substantial morbidity. Despite its curative intent for muscle-invasive urothelial carcinoma (MIUC), approximately 50% of patients experience metastatic recurrence after surgery. Identifying patients destined to relapse despite RC could help spare them from the morbidity of surgery and instead direct them toward alternative systemic therapies. While ctDNA-positive assays post-neoadjuvant therapy (NAT) but pre-cystectomy are associated with a poor prognosis, a subset of patients with ctDNA positive assays pre-cystectomy "clear" ctDNA with cystectomy alone (Powles, ASCO, 2025). We hypothesized that quantitative pre-cystectomy ctDNA thresholds may therefore distinguish local, surgically curable, bladder cancer versus micrometastatic disease. **Methods:** We conducted a retrospective single-institution cohort study of patients undergoing RC who had tumor-informed ctDNA (Signatera) assays ≤60 days pre-surgery and within ±30 days of a 3-month postoperative landmark. The primary outcome was ctDNA positivity at this landmark. The analyses proceeded in two steps: (1) association between log-transformed pre-cystectomy ctDNA and 3-month ctDNA positivity, assessed using logistic regression; and (2) derivation of the maximal quantitative preoperative ctDNA threshold >0.02 Mean Tumor Molecules per Milliliter (MTM/ml) using constrained optimization (target sensitivity ≥80%, specificity ≥50%), with internal validation via Efron-Gong bootstrap resampling. **Results:** Of 45 patients with MIUC meeting inclusion criteria, 10 (22.2%) received NAT. Higher pre-cystectomy ctDNA correlated with ctDNA positivity at the post-cystectomy landmark timepoint (odds ratio per 10-fold increase 1.6, 95% CI 1.2–2.4; p=<0.01). A pre-cystectomy ctDNA threshold ≥0.06 MTM/ml (95% CI 0.04–2.475) demonstrated optimal performance characteristics and was confirmed on bootstrap validation (sensitivity 81.6% [95% CI 61.1–88.9%], specificity 66.4% [95% CI 51.9–96.3%], positive predictive value [PPV] 63.8% [95% CI 55.2–91.7%], and negative predictive value [NPV] 85.1% [95% CI 78.8–88.9%]). **Conclusions:** Higher pre-cystectomy ctDNA values correlate with a higher likelihood of a persistent ctDNA-positive assay at 3 months post-cystectomy. In this dataset, a ctDNA threshold of ≥0.06 MTM/ml identified patients with high sensitivity and NPV for post-operative micrometastatic disease. Further validation of these findings, and threshold, in larger cohorts (with or without NAT) are needed to refine MIUC care by testing strategies involving (alternative) NAT versus proceeding with cystectomy. Outcomes with enfortumab vedotin (EV) rechallenge after disease progression in metastatic urothelial carcinoma. First Author: Michal Sternschuss, Memorial Sloan Kettering Cancer Center, New York, NY

Background: EV, alone (mono) or with pembrolizumab (EVP), is an established therapy for metastatic urothelial carcinoma (mUC). However, the activity with EV rechallenge after prior exposure and subsequent disease progression is not well defined. **Methods:** A retrospective institutional database of patients (pts) treated with EV mono (n=395) or EVP (n=256) for mUC was reviewed to identify pts who received EV rechallenge after disease progression. EV-free interval (EVFI) was defined as the time from last EV1 (initial) dose to first EV2 (rechallenge) dose. Investigator-assessed objective response rate (ORR; CR/PR), progression free survival (PFS), overall survival (OS), and duration of response (DoR, from first documented response) were summarized descriptively. **Results:** Of 42 pts identified, EV1 regimen was mono for 62% (n=26; EV1-mono) and EVP for 38% (n=16; EVP1). Median age was 77, 76% were male, and 45% had upper tract primary. Most pts (n=35; 83%) discontinued EV1 for toxicity, predominantly peripheral neuropathy. Median follow up from EV2 initiation was 26 mo (95% CI 17-NR). At rechallenge, 10 pts (24%) switched EV regimens (EV1-mono to EVP2, n=5; EVP1 to EV2-mono, n=5). EV2 was initiated at 1.25 mg/kg in four pts (9.5%), 1.0 mg/kg in 13 pts (31%), and ≤0.75 mg/kg in 25 pts (60%). Among response-evaluable pts (n=39), ORR to EV2 was 21% (8/39; 95% CI 9%-36%), including 2 CRs (5%), both with prior CR to EV1. No responses were observed in pts with SD/PD to EV1 (0/8; 0%), or those with EV1 PFS <6 mo (0/11; 0%). Among pts with long (>12 mo) or intermediate (6-12 mo) EVFI, ORR to EV2 was 33% (4/12) and 31% (4/13), respectively. No responses were reported with short (<6 mo) EVFI (0/14; 0%). EV2 was initiated at 0.75 mg/kg in 5/8 pts with CR/PR. Median PFS and OS estimated from EV2 start were 2.8 and 18.5 mo. Among pts with CR/PR, median DoR was 7.0 mo (95% CI 3.5-NR). At last follow up, three pts remained on EV2; 39 pts discontinued EV2 due to progression (74%, n=29), toxicity (23%, n=9) or pt preference (2.6%, n=1). **Conclusions:** In a real-world cohort, EV rechallenge demonstrated modest activity, primarily in pts with prior benefit from EV and EVFI >6 mo. These observations underscore the need for further studies to clarify the effects of repeated EV exposure and optimize patient selection. This is particularly relevant given efforts to mitigate toxicity and the emerging issue of recurrent disease after perioperative EVP. A phase 1b study of SYS6002 in advanced solid tumors. First Author: Yao Zhu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: SYS6002 is a next-generation Nectin-4-targeting antibody-drug conjugate (ADC) utilizing a novel site-specific enzymatic conjugation technology to link monomethyl auristatin E (MMAE) with a uniform drug-antibody ratio of 2. This design aims to enhance linker stability, minimize free payload release, and improve the therapeutic window. **Methods:** This phase 1 study (ChiCTR2200066256) included dose escalation (0.2–4.5 mg/kg Q3W; 2.4–2.7 mg/kg Q2W), pharmacokinetic (PK) expansion, and cohort expansion phases. Eligible patients had advanced solid tumors refractory to standard therapies. The primary endpoints were safety and recommended phase 2 dose (RP2D). Secondary endpoints included PK profile and efficacy, with the latter reported herein were specific to the pretreated advanced urothelial carcinoma (aUC) cohort. **Results:** As of Dec 19, 2025, 150 patients were enrolled (dose escalation n=32; PK expansion n=70; cohort expansion n=48). The maximum tolerated dose was not reached up to 4.5 mg/kg. The RP2D in aUC patients was determined as 3.6 mg/kg Q3W. SYS6002 exhibited a manageable safety profile in all 150 patients. With a median follow-up of 11.5 months (IQR 6.5-15.5), 2 (1.3%) patients discontinued treatment due to treatment-related adverse events (TRAEs) and no TRAE led to death. The most common TRAEs were ocular disorders (e.g., corneal disorder, dry eye), which were predominantly Grade 1-2. While ocular events were frequent (consistent with on-target effects), they were reversible and effectively managed with prophylaxis, resulting in no treatment discontinuations due to ocular toxicity. Notably, TRAEs typically associated with payload shedding were characterized by low incidence, with peripheral neuropathy reported in 11.3% of patients (no Grade ≥3) and rash in 20.7% (2.0% Grade ≥3), which compared favorably to historical data of other MMAE-based ADCs. Furthermore, no Stevens-Johnson Syndrome or Toxic Epidermal Necrolysis reported. In 85 efficacy-evaluable aUC patients across all tested doses, the objective response rate (ORR) was 37.6% (95%CI 27.4-48.8) and disease control rate (DCR) was 77.6% (95%CI 67.3-86.0), with a median duration of response of 6.2 months (95%CI 4.3-10.4) and median overall survival of 13.2 months (95%CI 10.6-14.9). At the RP2D (n=39), the ORR reached 41.0% (95%CI 25.6-57.9). Encouragingly, in heavily pretreated patients with prior MMAE-based ADC exposure (n=25), SYS6002 maintained activity with an ORR of 24.0% (95%CI 9.4-45.1) and DCR of 72.0% (95%CI 50.6-87.9), suggesting potential to overcome resistance. **Conclusions:** SYS6002 demonstrated a distinct safety profile from other Nectin-4 ADCs. Its promising efficacy in aUC patients, extending to those progressing on prior MMAE-based ADCs, supports further phase 3 trials. Clinical trial information: ChiCTR2200066256. Research Sponsor: CSPC Megalith Biopharmaceutical Co., Ltd.

Proteomic profiling of circulating tumor cells (CTCs) in metastatic urothelial cancer (mUC) as associated with upregulation of EGFR, HER2, and B7-H3 in patients (pts) progressing on enfortumab vedotin (EV) plus pembrolizumab. First Author: Wadih Issa, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Pts with mUC have poor prognosis, and while EV/pembro have improved outcomes, therapeutic targets arising after EV-pembro treatment are elusive. Proteomic profiling of circulating tumor cells (CTCs) offer a minimally invasive approach to capture tumor biology changes in real-time. We evaluated CTC burden and proteomic changes in relation to treatment response in mUC. **Methods:** Pts with mUC were prospectively enrolled at UT Southwestern Medical Center. Peripheral blood samples were collected at baseline, 4 weeks, and 12 weeks of treatment, as well as progression of disease. CTCs were isolated using a dendrimer-based microfluidic chip assay functionalized with antibodies against EpCAM, Trop-2, Nectin-4, and FGFR3, identifying nucleated CTCs (DAPI+/CK+, CD45-). After CTCs were selected within regions of interest, spatial proteomic profiling was performed via the Nanostring GeoMx Immuno-Oncology Proteome Atlas panel. CTC variation and surface proteomics after treatment were primary objectives. CTC changes were considered concordant if they decreased >10% in pts with complete or partial response (CR or PR), remained stable (within 10% of baseline) in pts with stable disease (SD), or increased >10% in pts with progressive disease (PD), as defined by RECIST 1.1. One pt underwent post-treatment biopsy with IHC analysis. **Results:** Thirty pts with mUC were enrolled, with a median age of 71.5 years, predominantly male (26/30, 87%) and Caucasian (24/30, 80%). Most received EV/pembro (26/30, 86.7%), while the rest were treated with chemotherapy (3/30, 10%) or SG (1/30, 3%). Median CTC counts (cells/ml) were assessed at baseline (30.3, IQR 18.5–62.9), at week 4 (22.3, IQR 6.0–37.0), and at week 12 (29.5, IQR 15.2–44.5). Twenty-two pts had sufficient radiographic and clinical follow up. CTC changes were concordant with treatment responses in 77% (17/22) of pts, including 12/22 pts with CR/PR, 3/22 with SD, and 7/22 with PD. Proteomic profiling of serial CTCs from 9 pts treated with EV/pembro revealed dynamic proteomic changes from baseline to week 12 and at disease progression. Together, these pts demonstrated upregulation of activated EGFR (phospho-Y1068), HER2 (phospho-Y877), STAT5, FAK, and vimentin. Pts with primary PD (n=3) showed B7-H3 upregulation on CTCs, whereas pts with secondary PD(n=2) showed higher expression of vimentin, c-MET, and MHC class I on CTCs. IHC of a post-EV/pembro progression bone metastasis confirmed increased HER2 expression (2+). **Conclusions:** CTCs with proteomic profiling can serve as a dynamic, noninvasive biomarker in mUC, identifying distinct therapeutic targets for pts progressing on EV/pembro. The emergence of actionable pathways, including EGFR, HER2, c-MET, and B7-H3, suggests opportunities for rational, biomarker-driven therapeutic strategies. Responses to trastuzumab deruxtecan (T-Dxd) in HER2 IHC spectrum 2+ versus 3+ urothelial carcinoma across lines of therapy. First Author: Sara El Sarout, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: The role of HER2 as a therapeutically actionable target has been validated with the DESTINY-PanTumor02 trial demonstrating meaningful clinical benefit to T-DXd across HER2-expressing bladder malignancies leading to the FDA approval in the immunohistochemical (IHC) 3+ population. We explore the clinical outcome of real-world patients with urothelial carcinoma (UCa) on T-DXd and its correlation with molecular and pathological findings across all the HER-2 IHC scores (e.g., 0 to 3+). **Methods:** We reviewed the clinical, pathologic, and molecular data of 29 patients with UCa, who received T-DXd between April 2024 and November 2025. Baseline clinical variables included age, sex, ECOG performance status, visceral metastases, line of therapy, and HER2 IHC score (adapted from gastric cancer scoring). Available genomic data included tumor mutational burden (TMB ≥10 mut/Mb), ERBB2 amplification and mutation, DNA damage response (DDR), FGFR alterations, and microsatellite instability (MSI) status. Outcomes of interest included Objective Response Rate (ORR), Disease Control Rate (DCR), and progression-free survival (PFS) and overall survival (OS) which were estimated using Kaplan–Meier methods and compared across groups using the log-rank test. Cox proportional hazards models were used to estimate hazard ratios. **Results:** Higher HER2 IHC scores were associated with greater clinical activity and higher ORR in IHC 2+ (n=7; 42.9; 95% CI = 9.9–81.6%) tumors and HER2 IHC 3+ (n=20; 55.0; 95% CI =31.5–76.9%). However, no response was seen in HER2 IHC 1+ (n=2). Median duration of response was 15.6 months in HER2 IHC 2+ and 11.6 months in HER2 IHC 3+ (15/30 patients received T-DXd in ≥3 lines). PFS and OS appeared comparable between HER2 2+ and HER2 3+ tumors, with no statistically significant difference by log-rank test (p = 0.67, p = 0.79 respectively). Elevated TMB was observed in 6/12 cases. ERBB2 amplification was detected in 3/10 of cases and ERBB2 mutation in 5/13 of cases. Alterations in DDR related genes and FGFR were identified in patients 2/11 and 1/12 respectively, while MSI-H was not observed in any case. Responses were numerically higher when T-DXd was given in 2nd line (53.3%, 95% CI 26.6–78.7%) than in further lines (42.9%, 95% CI 17.7–71.1%) and so was DCR 93% (95% CI 68.1–99.8%) in 2nd line than 71.4% (95% CI 41-91.6%) in further (≥3) lines. **Conclusions:** T-DXd demonstrated meaningful clinical activity not only in IHC 3+ but in IHC 2+ tumors as well, which is consistent with the results of the DESTINY-PanTumor02 trial. In this limited sample size, there was no statistically significant association between genomic features and patient outcomes. Larger studies are needed to further find predictors across different levels of IHC expression. Research Sponsor: None.

HER2 IHC Score	n	Responders (CR/PR)	ORR (%)	95% CI
1+	2	0	0.0	0.0–84.2%
2+	7	3	42.9	9.9–81.6%
3+	20	11	55.0	31.5–76.9%

Circulating tumor DNA (ctDNA) dynamics as early biomarkers of response to enfortumab vedotin plus pembrolizumab (EVP) in advanced urothelial carcinoma (aUC). First Author: Mohammad Jad Moussa, Internal Medicine Residency Program, Baylor College of Medicine, Houston, TX

Background: Radiographic assessment of treatment response remains challenging in aUC. ctDNA testing offers a sensitive, noninvasive measure of real-time treatment response. With EVP established as a frontline standard, we hypothesized that ctDNA dynamics correlate with radiographic response and survival. **Methods:** We retrospectively analyzed an institutional cohort of 302 patients (pts) with aUC treated with EVP at MD Anderson; 79 pts with baseline and serial ctDNA testing using a tumor-informed assay (Signatera) (08/23–01/26) were included. ctDNA dynamics were evaluated in two ways: (1) early on-treatment change (baseline vs. first on-treatment ctDNA) for association with radiographic response, and (2) time-dependent modeling as a covariate in Cox proportional hazards analyses of progression-free survival (PFS) and overall survival (OS) to account for immortal-time bias. **Results:** All pts had a median of 4 ctDNA tests (range: 1-9). Baseline ctDNA was obtained before or at EVP start in 67 (84.8%). Among these patients, first ctDNA clearance occurred in 46.3%, decrease in 26.9%, and increase in 19.4%; 6% had persistently undetectable ctDNA and 1.5% was lost to follow-up. Median time to first ctDNA reduction (clearance or decrease) was 48 days [IQR: 40–86]. Pts without baseline ctDNA prior to EVP (12, 15.2%) were non-evaluable. The best overall response rate to EVP was 53/79 (67.1%), including complete in 13.9% and partial responses in 53.2%. Objective responses were highest among pts with first ctDNA clearance (87.1%), lower with first ctDNA decrease (55.6%), and uncommon with first ctDNA increase (38.4%) (χ^2 test, p=0.003). In the overall cohort (n=79), median PFS from EVP start was 20.4 months (mo) [95% CI: 8–NE] and median OS from EVP start was 30.3 mo [95% CI: 26.3–34.3], with a median follow-up of 12.1 mo [95% CI: 9.1–14.9]. In time-dependent Cox models accounting for immortal-time bias, increasing ctDNA levels over time were associated with inferior PFS (HR 1.49 [95% CI: 1.11–2]; p=0.007) and OS (HR 1.41, [95% CI: 0.96–2.08], p=0.08). **Conclusions:** Early ctDNA dynamics provide a clinically meaningful measure of response to EVP in aUC and correlate with imaging outcomes. ctDNA clearance identifies pts with deep and durable benefit, while lack of clearance flags early resistance. Longer follow-up will evaluate ctDNA-guided monitoring to inform treatment de-escalation or maintenance approaches. Research Sponsor: None.

Baseline characteristics of cohort (n=79).

Variable	Measure
Age at aUC diagnosis, median [IQR]	71 [65 – 76]
Sex, male, n (%)	56 (70.9%)
Tumor Origin, n (%)	
Bladder	61 (77.2%)
Upper Tract	18 (22.8%)
Visceral mets, n (%)	34 (43%)
Nodal-only mets, n (%)	40 (50.6%)
Baseline ctDNA before/at EVP start (MTM/mL), median [IQR]	
All (n=67)	12.9 [1.1 – 105.5]
Visceral mets (n=30)	12.8 [1.3 – 140.2]
Nodal-only mets (n=33)	16.9 [1.4 – 96]

Comparison of cisplatin/gemcitabine or carboplatin/gemcitabine on efficacy, toxicity, and quality of life from the randomized DISCUS trial. First Author: Syed A. Hussain, Division of Clinical Medicine, University of Sheffield, School of Medicine and Population Health, Sheffield, United Kingdom

Background: The DISCUS trial compared 3 versus 6 cycles (3C versus 6C) of chemotherapy followed by avelumab in 267 patients receiving first-line treatment for metastatic urothelial cancer. It showed 3 cycles of chemotherapy followed by maintenance avelumab was associated with better QoL than six cycles (NCT06892860). Efficacy outcomes of the two arms appeared similar. Here we compare the cisplatin (cis) or carboplatin (carbo) chemotherapy subsets in the 3C and 6C arms. **Methods:** Patients were randomized to receive either 3 or 6 cycles of chemotherapy. Cisplatin or carboplatin was allocated by physician choice. Progression free survival (PFS), Overall survival (OS), response rates, patient-reported outcomes (PROs) and treatment related adverse events were collected (TRAEs) were collected. The analysis was exploratory and p values nominal. **Results:** 267 were included of whom 55 received 3C/cis, 55 6C/cis, 78 3C/carbo and 79 6C/carbo. Patients receiving carboplatin had poor performance status (ECOG $>$=1 in 17% cis vs 35% carbo). Table 1 showed similar efficacy outcomes with potentially marginally superior OS with cisplatin. The comparison of efficacy and QOL endpoints for 3 vs 6 cycles of carboplatin showed many similarities. Six cycles of cisplatin-based chemotherapy was associated with a major drop in QOL compared to 3 cycles without showing any clear benefits in efficacy endpoints. **Conclusions:** The QoL benefits of shorter chemotherapy appear to be more marked in patients receiving cisplatin than carboplatin. The efficacy results for 3 cycles of cisplatin were impressive. This study was not powered for non-inferiority. Clinical trial information: NCT06892860. Research Sponsor: Merck; 10.13039/100009945.

Risk and patterns of recurrence for patients (pts) with advanced urothelial carcinoma (aUC) metastatic to liver after response to enfortumab vedotin + pembrolizumab (EVP). First Author: Rishi Raju Patel, University Hospitals Cleveland Medical Center, Cleveland, OH

Background: EVP is the preferred frontline regimen in pts with aUC. Despite initial response to treatment, many pts treated with EVP ultimately have progression. We hypothesized that recurrence patterns would differ between pts with and without baseline liver metastases. **Methods:** UNITE is a multi-institutional retrospective database capturing clinical and treatment characteristics of pts with aUC receiving systemic therapies. We queried this database to identify pts who achieved an observed response (OR) to EVP. Pts were grouped by initial metastatic sites using a non-mutually exclusive approach. Descriptive statistics were used to summarize observed response rates (ORR) and recurrence patterns at time of progression. Progression-free survival (PFS) from start of EVP was estimated using the Kaplan-Meier method. The effect of liver metastases on PFS was assessed via multivariable Cox regression. Median-follow up time was estimated using the reverse Kaplan-Meier method. Statistical analyses were conducted in RStudio. **Results:** We identified 464 pts treated with EVP (median age 72; 74% male, 80% White). Best ORR in pts with baseline liver metastases (n=77) were complete response 9%, partial response 35%, stable disease 18%, and progressive disease 21%, compared with 18%, 37%, 27%, and 18%, respectively, in pts without baseline liver metastases (n=325). The estimated median follow-up time was 52 weeks (95% CI 48-62). Among pts with initial OR to EVP, those with baseline liver metastases showed a non-significant trend toward shorter PFS (HR 1.35; 95% CI 0.67–2.75; p=0.40) versus those without baseline liver metastases. Among pts with initial OR to EVP and subsequent progression the distribution of sites of recurrences at progression for those with (n = 10) and without (n = 40) baseline liver metastases were: liver (50% vs. 10%), lymph nodes (60% vs. 55%), lungs (50% vs. 38%), bone (20% vs 20%), and primary tumor (20% vs 25%). EVP responders with baseline liver metastases had a numerically higher rate of site-specific metastasis resolution at progression versus those with lymph node or lung metastases (Table). **Conclusions:** Our analysis suggests that liver metastases may be associated with shorter PFS among EVP responders, though these pts frequently do not retain liver metastases at time of progression. Study limitations include retrospective analysis, investigator-assessed response, small sample size, selection and confounding biases. Patterns of recurrence following EVP merits further evaluation. Research Sponsor: None.

Metastatic Site	Pts with Site-Specific Baseline Metastases (n)	Pts with Resolution of Site-Specific Metastases at Progression, n (%)	Pts without Baseline Metastases at Site (n)	Pts who Remained Free of Site-Specific Metastases at Progression, n (%)
Liver	10	5 (50%)	40	36 (90%)

Long-term survival update of TRUCE-01: A phase 2 study of preoperative tislelizumab combined with low-dose nab-paclitaxel for muscle-invasive bladder cancer (MIBC). First Author: Zhouliang Wu, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: The TRUCE-01 study (NCT04730219) previously met its primary endpoint, demonstrating that preoperative tislelizumab combined with low-dose nab-paclitaxel achieved a high clinical complete response (cCR) rate of 52% and a favorable safety profile in patients with muscle-invasive bladder cancer (MIBC). Here, we report the long-term survival outcomes after 4 years of study follow-up. **Methods:** Eligible patients with cT2-4aN0M0 MIBC received three cycles of tislelizumab (200 mg, day 1) plus low-dose nab-paclitaxel (200 mg, day 2) every 3 weeks, followed by radical cystectomy (RC) or maximal transurethral resection of bladder tumor (mTURBT) based on response assessment. The primary endpoint was cCR. Secondary endpoints included event-free survival (EFS), overall survival (OS), disease-specific survival (DSS), and metastasis-free survival (MFS). **Results:** At the clinical data cutoff of October 2025, the median follow-up was 47.4 months (IQR 24.8–53.3). Among the intention-to-treat population (n = 62), 25 patients experienced clinical events, including 15 recurrences and 20 deaths (13 due to disease progression, 7 due to non-disease-related causes). Notably, among the 24 patients who elected for bladder preservation, a bladder preservation rate of 75% was achieved(4 due to recurrence requiring salvage radical cystectomy, 2 due to disease progression). The 4-year EFS and OS rates were 59.7% and 67.8%, respectively. Survival analysis stratified by response showed that patients achieving a cCR had significantly superior long-term outcomes compared to non-cCR patients. The cCR group demonstrated a robust and significant benefit in OS (HR 0.28, 95% CI 0.09–0.83, p = 0.0212), DSS (HR 0.10, 95% CI 0.02–0.46, p = 0.0029), and MFS (HR 0.19, 95% CI 0.06–0.63, p = 0.0068). No new safety signals or late-onset immune-related adverse events were observed with extended follow-up. **Conclusions:** With approximately 4 years of median follow-up, preoperative tislelizumab combined with low-dose nab-paclitaxel continues to demonstrate robust and durable survival benefits for patients with MIBC. Paired Nectin4 expression analysis pre and post enfortumab vedotin and pembrolizumab in urothelial carcinoma. First Author: Michal Sternschuss, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Enfortumab vedotin and pembrolizumab (EVP) transformed the treatment of urothelial carcinoma (UC), yet resistance remains a challenge. Mechanisms of resistance including changes in target expression are poorly defined. **Methods:** We analyzed an institutional retrospective cohort of patients (pts) who had paired tissue samples obtained pre- and post-EVP. Membranous (mNectin4) and cytoplasmic (cNectin4) expression were measured by immunohistochemistry (H-score). mNectin4 was categorized as negative (<15), weak (15-99), moderate (100-199) or strong (200-300). Changes in Nectin4 were assessed as absolute differences (post−pre) and as scaled log change (%) [100xlog((post + c)/(pre + c))] to capture relative expression changes. Nectin4 dynamics were compared between primary (resistant disease ≤6 months from EVP initiation) and acquired resistance (>6 months) using Wilcoxon rank-sum and fisher's exact tests. **Results:** Of 46 pts with paired samples, 40 had evaluable Nectin4 IHC. Median age was 72, 70% were men, and 30% had upper tract primary. Median H-scores were similar pre- and post-EVP for both mNectin4 (195 [IQR 115, 260] vs 200 [IQR 85, 230]; p=0.5) and cNectin4 (0 [IQR 0, 40] vs 0 [IQR 0, 60]; p >0.9). Post-EVP mNectin4 was moderate/strong in 29 pts (73%). Complete loss of mNectin4 was uncommon: of five pts (13%) with negative mNectin4 post-EVP, two were negative at baseline and three had weak expression pre-EVP. Post-EVP samples obtained on EV (≤21d from last dose; n=21) vs off EV (>21d; n=19) showed similar changes from pre-EVP for mNectin4 (p=0.3) and cNectin4 (p=0.4). Nectin4 changes differed by resistance pattern, with primary resistance (n = 14) showing a greater relative decrease in mNectin4 expression (median log change −57 vs 3; p = 0.035) and a relative increase in cNectin4 expression (median log change 52 vs 0; p = 0.029) compared with acquired resistance (n = 21). Paired analyses of *NECTIN4* copy number by FISH will be reported. **Conclusions:** In a paired analysis, most tumors retained substantial mNectin4 expression post-EVP and complete loss was rare, supporting the rationale for Nectin4-targeted strategies in the post-EVP setting. Distinct Nectin4 dynamics suggest greater relevance of target expression changes in primary vs acquired resistance; further studies are needed. Clinical outcomes for patients (pts) with synchronous versus metachronous metastatic urothelial cancer (mUC) treated with enfortumab vedotin and pembrolizumab (EV-P). First Author: Libin Yan, Division of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Synchronous versus metachronous metastases in mUC has prognostic significance, and EV-P has emerged as standard first-line therapy for pts with mUC. How primary disease in synchronous mUC should be best treated remains unclear. This study evaluated clinical outcomes of pts with synchronous vs metachronous mUC treated with EV-P. **Methods:** A retrospective analysis of all consecutive pts with mUC treated EV−P at UTSW was performed. Patients were grouped by synchronous mUC or metachronous mUC. Baseline characteristics were compared using Wilcoxon rank-sum and Chi-squared tests. Overall survival (OS) and progression-free survival (PFS) were analyzed using Cox proportional hazards models. **Results:** For 159 pts with mUC treated with EV-P between 9/2020 and 12/2025, 40 had synchronous mUC and 119 had metachronous mUC. Baseline characteristics were similar with median age 71.5 years vs 73.0 years (p=0.90), male 75% vs 94%(p=0.76), and visceral metastases (20% vs 26%, p=0.58). In metachronous mUC, 76 (63.9%) had prior cystectomy and 42 (35.3%) had prior radiation as definitive treatment. Patients with metachronous mUC demonstrated a median PFS of 16.0 months vs not reached (NR) for patients with synchronous mUC (HR 1.95, 95% CI 1.05–3.62; p = 0.035). Similarly, the median OS was 21.9 months for metachronous mUC vs not reached in the synchronous mUC (HR 2.61, 95% CI 1.24–5.49; p = 0.011). Median cycles of EV-P was 13.5 for synchronous mUC vs 10 for metachronous mUC. For synchronous mUC, 22 (55.0%) underwent cystectomy and 8 (20.0%) underwent radiation as consolidative treatment. **Conclusions:** Synchronous and metachronous mUC treated with EV-P have significantly different disease courses on EV-P. Metachronous mUC has earlier progression on EV-P, needing more treatment options in refractory disease. Consolidation treatment for synchronous mUC needs further prospective trials for optimal outcomes. Research Sponsor: None.

Use of *NECTIN4* expression inferred from circulating chromatin to predict response and survival to enfortumab vedotin (EV) in metastatic urothelial carcinoma. First Author: Rashad Nawfal, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: APEX (Associating Plasma Epigenomics with eXpression) is a machine-learning framework that infers genome-wide gene expression in cancer from plasma cell-free chromatin Immunoprecipitation sequencing (cfChIP) by integrating signal from multiple histone marks and fragmentomic features, enabling enhanced transcriptional readouts from liquid biopsy without tissue sampling. We investigated whether APEX can noninvasively quantify *NECTIN4* expression to predict outcomes with EV, a NECTIN4-targeted antibody-drug conjugate, in metastatic bladder cancer. **Methods:** Baseline plasma (1 mL) was collected from patients with metastatic bladder cancer within 90 before to 8 days after start of EV monotherapy and profiled by cfChIP-seq, followed by APEX-based tumor gene-expression inference. APEX-inferred *NECTIN4* expression was dichotomized into high and low groups by the cohort median and tested for association with objective response (CR/PR vs SD/PD). Progression-free survival (PFS) and overall survival (OS) were analyzed using log-rank test and multivariable Cox regression model, accounting for the presence of bone or liver metastases and cfDNA tumor fraction. APEX performance was then compared against *NECTIN4* locus signal from individual histone marks, plasma tumor fraction, and *NECTIN4* copy-number status/amplification. **Results:** In the EV-treated cohort (*n*=24), baseline APEX-inferred *NECTIN4* expression was significantly higher in responders versus non-responders (p = 0.002) and outperformed *NECTIN4* estimates derived from single histone-mark features, tumor fraction, and *NECTIN4* copy number. Patients with high plasma-inferred *NECTIN4* had an objective response rate of 58%, whereas no responses were observed among those with low inferred *NECTIN4*, supporting strong negative predictive value. High baseline APEX-inferred *NECTIN4* was also significantly associated with improved progression-free and overall survival (HR = 0.22, 95%CI: 0.08 – 0.65, p = 0.005 and HR = 0.27, 95%CI: 0.10 – 0.75, p = 0.008, respectively), with stronger associations than plasma tumor fraction, *NECTIN4* copy number/amplification, or individual histone-mark coverage. In multivariable Cox models, APEX-inferred *NECTIN4* remained independently associated with survival. Moreover, responders were enriched for urothelial luminal genes known to associate with *NECTIN4* expression and favorable outcomes, while non-responders showed increased activation of epithelial-mesenchymal transition-related genes, known to associated with worse outcomes. **Conclusions:** A machine learning framework for plasma-based inference of tumor gene expression identifies plasma-based *NECTIN4* as a clinically actionable, expression-based biomarker that predicts EV response and survival in metastatic bladder cancer. Research Sponsor: None.

Cost-effectiveness analysis of first-line (1L) therapies for advanced urothelial carcinoma (aUC) from a U.S. payer perspective. First Author: Prateek Jain, Sinai Hospital Baltimore, Baltimore, MD

Background: Recent years have seen a shift in aUC management following approval of enfortumab vedotin−pembrolizumab (EV-P) and gemcitabine/cisplatin plus nivolumab (GC-NIVO) as first-line therapies. Despite improved clinical outcomes, their relative economic value remains uncertain. Herein, we conducted a cost-effectiveness analysis of current 1L regimens in aUC from a U.S. payer perspective using 2026 pricing. **Methods:** A partitioned survival model with three health states (progression-free [PF], progressed disease [PD], and death) was developed over a 10-year horizon from a U.S. payer perspective. Analyses focused on cisplatin-eligible patients. Survival data were reconstructed from published Kaplan−Meier curves and extrapolated using parametric survival models. Treatment dosing, schedules, and duration were modeled according to trial protocols. Patients receiving gemcitabine/cisplatin without progression were modeled to receive avelumab maintenance (GC→AVEL). Subsequent-line therapy costs were applied at incident progression, and grade ≥3 adverse event costs and disutilities were applied as one-time events. Drug acquisition costs (2026 USD) were based on average sales prices from the Centers for Medicare & Medicaid Services. Costs and quality-adjusted life years (QALYs) were discounted at 3% annually. Incremental cost-effectiveness ratios (ICERs) and net monetary benefit (NMB) were evaluated at willingness-to-pay (WTP) thresholds of $100,000, $150,000, and $200,000 per QALY. Parameter uncertainty was characterized using probabilistic sensitivity analysis. **Results:** In the base-case analysis, total discounted costs and QALYs were $90,269 and 1.62 for GC→AVEL, $131,836 and 2.09 for GC-NIVO, and $1,451,885 and 2.77 for EV-P. Compared with GC→AVEL, GC-NIVO gained 0.46 QALYs at an incremental cost of $41,567, resulting in an ICER of $89,501 per QALY and positive NMB across all evaluated WTP thresholds. Compared with GC→AVEL, EV-P gained 1.15 QALYs at an incremental cost of $1.36 million (ICER $1.19 million per QALY). Compared with GC-NIVO, EV-P gained 0.68 QALYs at an incremental cost of $1.32 million (ICER $1.93 million per QALY), exceeding all evaluated WTP thresholds. In a scenario analysis limiting EV-P to 10 treatment cycles, total costs decreased to $287,360, with ICERs of $172,000/QALY versus GC→AVEL and $225,000/QALY versus GC-NIVO, remaining above the $150,000/QALY threshold. **Conclusions:** Using updated 2026 pricing, GC-NIVO is likely to be the most cost-effective first-line regimen for cisplatin-eligible patients with aUC. EV-P offers the greatest clinical benefit but is not cost-effective at current prices. A major limitation of this study is cross-trial variability in study populations and design, limiting the validity of head-to-head economic comparisons. Research Sponsor: None.

A novel oncolytic vaccinia virus armed with IL-21 and 4-1BBL for intravesical treatment of NMIBC: Preclinical efficacy and first-in-human safety evaluation. First Author: Shun Zhang, Department of Urology, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Oncolytic viruses are emerging cancer immunotherapies. For non–muscle-invasive bladder cancer (NMIBC), intravesical delivery allows high local exposure with limited systemic toxicity. This study was conducted to evaluate anti-tumor efficacy, mechanism and safety of KM1, a novel developed oncolytic vaccinia virus modified with tyrosine kinase deletion, L025 and A46R gene deletion, and armed with interleukin 21 and 4-1BBL in murine models and human. **Methods:** In vitro assays assessed virus replication, cytotoxicity, and transgene expression in human and murine bladder cancer cell lines and organoids. In vivo studies assessed immune activation, toxicity, and antitumor efficacy in murine subcutaneous and orthotopic bladder tumor models. An investigator-initiated phase 1a trial enrolled NMIBC patients who had failed prior BCG therapy or declined further BCG. This multicenter, single-arm study used 3+3 dose-escalation with primary endpoints of safety and tolerability (AE and DLTs). Planned dose levels were 2×10^9 PFU (DL1), 5×10^9 PFU (DL2), and 1×10^{10} PFU (DL3) per instillation. Following completion of DL1 and DL2, the protocol was amended to discontinue further dose escalation (DL3 was not opened) and to enroll an expansion cohort at DL1 (additional n=3) to further characterize safety/tolerability and PK/PD at the putative recommended dose. The induction regimen consisted of bladder irrigation with sucrose monolaurate, followed by intravesical KM1 retained for 2 hours, given twice weekly for 3 weeks and then once weekly for 3 weeks. Subsequent maintenance therapy comprised three intravesical KM1 instillations every 3 months. **Results:** KM1 selectively replicated in human and murine bladder cancer cells, induced high IL-21 and 4-1BBL secretion. Supernatant from KM1-infected cells activated $CD8^+$ T cells and enhanced tumor-killing *in vitro*. *In vivo*, KM1 showed better antitumor efficacy than BCG, increased $CD8^+$ T and NK cell infiltration and function. Depletion of either population diminished efficacy. In the phase 1a study, 12 patients received intravesical KM1 (DL1, n=9 [including n=3 expansion]; DL2, n=3) and were evaluable. Ten TEAEs were reported, predominantly grade 1–2; the most common were noninfective cystitis (5/12, 41.7%) and urinary tract pain (4/12, 33.3%). One DL1 patient experienced a DLT of transient, likely treatment-related grade 3 liver injury that resolved within 1 week without sequelae. No KM1 DNA was detected in saliva, blood, or feces at any assessed time point. At a median follow-up of 10.1 months, all patients remained recurrence-free by 6 months (CR 12/12; 100%). **Conclusions:** KM1 showed selective replication, oncolysis, and immune activation in preclinical models. Early clinical data suggest favorable safety and promising antitumor activity of intravesical KM1 in NMIBC. Clinical trial information: ChiCTR2400086709. Research Sponsor: Shenzhen Huayao Kangming Biopharmaceutical Co., Ltd.

Keratin 19 (KRT19) as a circulating biomarker to measure disease burden and guide treatment in urothelial cancer. First Author: Eric James Miller, Mount Sinai Tisch Cancer Center, New York, NY

Background: Circulating tumor DNA (ctDNA) has emerged as a valuable biomarker in urothelial cancer but remains limited by cost and turnaround time. Keratin 19 (KRT19) is a cytoskeletal protein that is highly and specifically expressed in urothelial tumor tissue in The Cancer Genome Atlas (TCGA) urothelial cancer cohort. Based on this tumor specific expression, we hypothesized that circulating KRT19 levels could serve as a rapid, inexpensive measure of disease burden to guide systemic therapy for urothelial cancer. **Methods:** Two patient cohorts from completed clinical trials were analyzed. HCRN GU16-257, a phase 2 trial of gemcitabine, cisplatin, and nivolumab as organ-sparing treatment for localized muscle-invasive bladder cancer, included 76 patients evaluable for KRT19 with median follow-up of 30 months. HCRN GU14-182, a phase 2 switch maintenance trial of pembrolizumab versus placebo following first-line chemotherapy for metastatic urothelial cancer, included 46 patients evaluable for KRT19 in the pembrolizumab arm with median follow-up of 12.9 months. Serum KRT19 levels were quantified using Olink proteomics technology alongside 91 additional proteins. Cox proportional hazards models assessed associations between KRT19 expression and clinical outcomes, with adjustment for multiple comparisons using false discovery rate correction. **Results:** In the GU16-257 cohort, among 92 peripheral blood analytes tested at baseline (C1D1), KRT19 demonstrated the strongest association with overall survival. Elevated baseline KRT19 was independently associated with inferior overall survival (HR 2.62, adjusted p=0.016) and metastasis-free survival (HR 3.01, adjusted p=0.001). A decrease in KRT19 from C1D1 to C3D1 was associated with improved overall survival (HR 0.59, unadjusted p=0.024) and metastasis-free survival (HR 0.60, unadjusted p=0.041). In GU14-182, elevated baseline KRT19 was associated with inferior overall survival (HR 2.11, adjusted p=0.034) and progression-free survival (HR 1.57, unadjusted p=0.024). Optimal KRT19 cutpoints enabled significant risk stratification for mortality and disease progression in both cohorts. Analysis of an independent peripheral blood single-cell RNA sequencing cohort from patients with urothelial cancer confirmed epithelial cells as the predominant source of circulating KRT19. **Conclusions:** KRT19 represents a promising, readily measurable serum biomarker with specificity for urothelial cancer. Both baseline levels and on-treatment changes correlate with disease progression and survival. Further validation of KRT19 as a tool to assess disease burden and guide treatment decisions in urothelial cancer is warranted. Research Sponsor: Conquer Cancer, the ASCO Foundation.

Preliminary results of a single-arm, muti-center, prospective clinical study of disitamab vedotin combined with toripalimab and pelvic lymph node dissection for bladder preservation in patients with cT2-4aN0M0 bladder urothelial carcinoma and HER2 expression ≥ 2+ after maximal TURBT. First Author: Tianhang Lan, The Second Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China

Background: With the evolution of different treatment eras, the clinical complete response (cCR) rate of bladder cancer has been progressively increasing, while the lymph node metastasis rate has still not improved significantly. Particularly, patients with HER2 overexpression are at a higher risk of lymph node metastasis, which poses a major challenge to bladder-sparing therapy for patients with muscle-invasive bladder cancer (MIBC). This study aims to establish a novel bladder-preserving treatment model by combining local therapy enhanced with pelvic lymph node dissection (PLND) and systemic therapy with Disitamab Vedotin and Toripalimab. **Methods:** Patients with cT2-4aN0M0 MIBC and HER2 expression $\geq$2+ were enrolled, The primary endpoint was 2-year bladder-intact disease-free survival rate. After maximal transurethral resection of bladder tumor (TURBT), patients received Toripalimab (3mg/kg, Q2W) combined with Disitamab Vedotin (2mg/kg, Q2W) for 6 cycles, followed by TURBT and PLND. Those with cCR or partial response (PR) continued the combined therapy for another 6 cycles. Patients achieving cCR after 12 cycles of combined therapy received maintenance Toripalimab (240mg, Q3W) for 1 year. Non-cCR patients received comprehensive treatment or salvage radical cystectomy(RC). **Results:** As of December 2025, 21 patients were enrolled, with a median age of 66 years (range: 37–82). The primary endpoint was not yet reached. Efficacy assessment was performed in 14 patients at Week 12: 10/12 (85.8%) achieved cCR, while 1 patient had stable disease (SD) and 1 had progressive disease (PD). Among 10 patients who underwent TURBT and PLND, pathological complete response (pT0N0M0) was achieved in 90.0%, and 1 patient was postoperatively staged as pT0N1M0. Patients with SD or PD underwent RC. All patients experienced treatment-related adverse events (TRAEs) of any grade. The most common TRAEs were pruritus (75.00%), paresthesia (68.75%), and elevated ALT (43.75%), all of which were Grade 1–2. One patient developed a Grade 3 adverse event (AE), which was severe urinary tract infection. No TRAEs of Grade $\geq$4 were observed. **Conclusions:** The novel bladder-sparing modality of Disitamab Vedotin combined with Toripalimab plus PLND after maximal TURBT currently demonstrates favorable efficacy and safety. Long-term outcomes warrant further investigation. Clinical trial information: ChiCTR2400081555. Urinary tumor DNA–guided de-escalation of systemic immunotherapy in extensive very high risk non–muscle-invasive bladder cancer. First Author: Yunkai Qie, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: Non-muscle-invasive bladder cancer (NMIBC) has entered the era of systemic immunotherapy. Large randomized trials, including CREST, POTOMAC, and ALBAN, have explored long-term systemic immunotherapy in NMIBC, yet the clinical benefit remains heterogeneous and is often accompanied by substantial toxicity. Urinary tumor DNA (utDNA) has emerged as a promising biomarker for molecular response assessment, yet its role in guiding treatment de-escalation has not been established. We evaluated whether utDNA negativity after complete response (CR) could support safe early treatment cessation of systemic therapy in patients with extensive very-high-risk NMIBC (VHR-NMIBC). **Methods:** Patients with extensive VHR-NMIBC who achieved CR after initial systemic therapy with the PD-1 inhibitor tislelizumab plus low-dose paclitaxel were included from a prospective cohort. After CR assessment, some patients underwent low-coverage utDNA testing as part of routine clinical decision-making following clinician–patient discussion. Patients with negative utDNA completed three additional cycles and subsequently stopped systemic therapy (utDNA-guided de-escalation group), whereas those who continued treatment beyond this point were categorized as the longer treatment-exposure group. Efficacy and safety outcomes included survival endpoints and adverse events (AEs) with exposure-adjusted incidence rates. **Results:** With a median follow-up of 42.8 months, 54 patients achieving CR were evaluable. Among them, 21 with negative utDNA status completed three additional cycles and underwent planned treatment cessation, while 33 continued systemic therapy with longer treatment exposure. Across key efficacy endpoints, outcomes were comparable between the utDNA-guided de-escalation and longer treatment–exposure groups, with no significant differences in recurrence-free survival (RFS; HR 1.37, 95% CI 0.21–8.87, P = 0.73), overall survival (OS; HR 2.48, 95% CI 0.12–53.7, P = 0.51), or duration of response (DOR; HR 1.33, 95% CI 0.21–8.50, P = 0.76). A difference in radical-cystectomy–free survival was observed (short vs long: HR 4.97, 95% CI 1.03–23.9, P = 0.03). Long-course treatment was associated with a higher cumulative incidence of any-grade AEs (88.1% vs 72.5%) and more AE types (median 5 vs 2, $P < 0.001$). Exposure-adjusted AE rates per cycle were lower in the long-course group (IRR 0.50, 95% CI 0.42–0.60, $P < 0.001$), while grade $\geq$3 AEs occurred in 2.9% and 9.5% of patients in the short- and long-course groups, respectively, predominantly during later treatment phases. **Conclusions:** UtDNA negativity after complete response may provide a molecular basis for individualized treatment duration, highlighting the potential role of liquid biopsy in guiding precision treatment tailoring and warranting prospective validation in larger biomarker-driven studies. Clinical trial information: NCT04730232. Research Sponsor: None.

Evidence implicating human papillomavirus in bladder carcinogenesis: A case-control study. First Author: Xueying Zhang, Jilin Cancer Hospital, Changchun, Jilin, China

Background: The etiology of high-risk oncogenic human papillomavirus (HPV) subtypes with signature cytomorphological changes such as koilocytosis in bladder cancer (BCa) carcinogenesis still remains controversial and insufficiently investigated. We evaluated the diagnostic concordance rate between HPV-DNA test with urine HPV related cytomorphological findings in BCa urine samples. **Methods:** A retrospective case-control study was conducted. A total of 172 HPV-positive urine cytology specimens from patients with primary BCa treated at our hospital between January 2020 and December 2024 were included as the study group. During the same period, of 172 HPV - negative urine cytology specimens from primary BCa were selected as the control group. HPV DNA was detected by in situ hybridization was utilized. Immunohistochemistry (IHC) was performed to assess $p16^{INK4a}$ protein expression as a surrogate marker of functional HPV activity. Cytomorphologic changes that had concurrent liquid-base cytology were identified using The Paris System for Reporting Urinary Cytology (TPS) criteria. Statistical analyses were performed using chi-square tests and fisher's exact tests. **Results:** Overexpression of $p16^{INK4a}$ was observed in 82.2% (140/172) of the HPV-positive group and showed a high level of concordance with HPV infection status (Kappa=0.812, $p<0.001$). Among the HPV-positive group, high-risk HPV types accounted for 88.9% (152/172) with HPV-16 (114/152,75.6%) and HPV-18 (38/152,24.4%) being the predominant subtypes. A p16INK4a protein expression from HPV-negative group was detected which was significantly lower than in the positive group (13/172, 7.56%, $p<0.001$). HPV infection cytomorphology was identified, with 48.6% (83/172) koilocytes (52/172, 30.23%) either alone or in addition to basaloid clusters (16/172, 9.3%) and atypical squamous cells (ASCs) (15/172, 8.72%) identified using TPS from the HPV-positive group, and a significantly lower rate of 6.1% (10/172, $p<0.001$) was identified from the HPV-negative group. **Conclusions:** HPV plays an etiological role in carcinogenesis and contributes to a worse prognosis for patients with BCa development. The identification of cytomorphologic changes in urine cytology is a significant and underutilized piece of etiological evidence supporting a role for HPV in bladder carcinogenesis. It provides a reliable direct and visible link between the viral cytopathic effect and the urothelial cells. Integrating routine cytological assessment with modern molecular testing in urine samples could better define its role as an oncogenic driver in specific BCa variants. Recognizing this association has implications for risk stratification, screening in high-risk populations, and potential therapeutic avenues. Clinical outcomes with *ERBB2* gene amplification and activating mutations in muscle-invasive bladder cancer patients treated with neoadjuvant chemotherapy. First Author: Earle F. Burgess, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC

Background: Activating ERBB2 mutations (mut) are associated with improved pathologic response (pCR) to neoadjuvant chemotherapy (NAC) in patients with muscle-invasive bladder cancer (MIBC). However, the impact of ERBB2 gene amplification (amp) on pCR and of aggregate ERBB2 gene variants (amp and mut) on relapse and survival is unknown. We previously reported that high tumor mutational burden (TMB) is associated with improved pCR and relapse-free survival (RFS) in a cohort of MIBC patients treated with cisplatin-based NAC followed by cystectomy (Burgess et al. GU ASCO '26). In the current analysis, we assessed the impact of ERBB2 gene variants on clinical outcomes in the previously reported cohort. **Methods:** 91 patients with MIBC who received cisplatin-based NAC followed by radical cystectomy underwent genomic analysis of diagnostic transurethral resection of bladder tumor specimens with the Tempus xT platform. Sample size was prespecified by statistical design. Correlation of ERBB2 gene variants with TMB and clinical outcomes was performed using logistic regression, Cox proportional hazards models, and Kaplan-Meier techniques. **Results:** Median follow for the cohort was 63.6 months. pCR was achieved in 31.9%. Thirty-eight (41.8%) patients relapsed. Only 4 (4.4%) received adjuvant immune checkpoint inhibition (ICI). ERBB2 mut and amp were exclusively found in 4 (4.4%) and 13 (14.3%) patients, respectively. All ERBB2 mut were p.S310F. pCR occurred in 3 (75%) patients with mut and 6 (46.2%) patients with amp. In those with amp and no pCR (7), 4 were ypTaN0 or ypT1N0. In aggregate, the presence of ERBB2 gene variants (mut + amp, n = 17) was associated with an improved pCR rate compared to no ERBB2 gene variant (OR = 3.038, p = 0.048). ERBB2 variants (mut + amp) were not clearly associated with a TMB $>$ 10 Mut/Mb (OR = 2.217, p = 0.178). Five patients with ERBB2 gene variants relapsed (29.4%, OR = 0.518, p = 0.288). Three (75%) mut and ten (76.9%) amp patients remain alive. The median RFS for patients with and without ERBB2 gene variants in aggregate is 124.1 and 54.7 months (HR = 0.460, p=0.094). The median overall survival (OS) for patients with and without ERBB2 gene variants is Not Reached and 107.6 months (HR = 0.381, p=0.098). **Conclusions:** The impact of ERBB2 gene variants (mut + amp) on survival in MIBC-patients treated with NAC has not been previously reported. In this cohort collected before widespread use of peri-operative ICI, the presence of ERBB2 gene variants was associated with improved pCR rates and showed strong trends for improved RFS and OS but not clearly associated with high TMB. These findings establish a prognostic role for ERBB2 amp in addition to previously reported ERBB2 mut in patients with MIBC. Whether peri-operative use of ICI or ERBB2-targeted agents may influence these findings warrants further investigation. Research Sponsor: Atrium Health Foundation.

Impact of FGFR3 pathway activation in patients with muscle-invasive bladder cancer treated with neoadjuvant chemotherapy. First Author: Earle F. Burgess, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC

Background: The prognostic value of FGFR3 pathway activation in patients with muscle-invasive bladder cancer (MIBC) treated with neoadjuvant chemotherapy (NAC) has not been established. Activation of FGFR3 signaling drives a subset of urothelial bladder cancers and classically results from pathogenic gene mutations (mut) or fusions (fus). Additionally, an RNA signature (FGFR-PRS) representing activation of the FGFR3 pathway independent from pathogenic FGFR3 mut or fus has been identified (Eisner et al. Clin Can Res 2024). We previously reported that high tumor mutational burden (TMB) may be associated with improved pathological complete response (pCR) and survival in a cohort of MIBC patients treated with cisplatin-based NAC (Burgess et al. GU ASCO '26). In the current analysis, we assessed the impact of FGFR3 pathway activation detected by either FGFR3 gene mut/fus or FGFR-PRS (+) on clinical outcomes in the previously reported cohort. **Methods:** 91 patients with MIBC who received cisplatin-based NAC followed by radical cystectomy underwent genomic analysis of diagnostic transurethral resection of bladder tumor specimens with the Tempus xT platform. Sample size was prespecified by statistical design. A subset of 61 patients had sufficient RNA for FGFR-PRS analysis. Correlation of FGFR3 molecular status with TMB and clinical outcomes was performed using logistic regression, Cox proportional hazards models, and Kaplan-Meier techniques. **Results:** Median follow up for the cohort was 63.6 months. pCR was achieved in 31.9%. 41.8% of patients relapsed. FGFR3 mut were found in 8 (8.8%) and included p.R248C (n = 2), p.S249C (n = 5), and p.G370C (n = 1). One (1.1%) patient had a FGFR3-TACC3 fus. In the subset with RNA analysis (n = 61), FGFR-PRS (+) was detected in 33 (54.1%), of which 28 (84.8%) were FGFR3 wild type (wt) without detected mut/fus. pCR occurred in 12.5% and 33.7% with and without FGFR3 mut [OR 0.281, p = 0.428]. pCR was similar regardless of FGFR-PRS status [OR 1.372, p = 0.602]. All tumors with FGFR3 mut/fus (n = 9) had TMB $<$ 10 Mut/Mb. Nineteen (57.6%) tumors with FGFR-PRS (+) had TMB $<$ 10 compared to 13 (46.4%) of FGFR-PRS (-) tumors. Six (75%) patients with FGFR3 mut [OR 3.188, p = 0.064] and 10 (30.3%) with FGFR-PRS (+) [OR 1.087, p = 0.999] relapsed. Patients with FGFR3 mut had inferior relapse-free survival (RFS) [HR 2.58, p = 0.028], but those with FGFR-PRS (+) did not [HR 1.37, p = 0.451]. **Conclusions:** The presence of FGFR3 mutations was associated with an inferior relapse rate and RFS in this MIBC cohort treated with cisplatin-based NAC. FGFR3 pathway activation by RNA signature (FGFR-PRS+) was not associated with inferior outcomes. Whether peri-operative FGFR3 inhibition improves prognosis in MIBC patients with FGFR3 mutations should be studied. Research Sponsor: Atrium Health Foundation.

PUNCH03: Preliminary results from a phase II study of disitamab vedotin combined with tislelizumab and Bacillus Calmette-Guerin (BCG) in Her2-positive high-risk non-muscle-invasive bladder cancer (HR NMIBC). First Author: Zongren Wang, Department of Urology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Disitamab vedotin (RC48) was a novel antibody drug conjugate that targets the Her2 protein. The KEYNOTE-057 study has supported the benefits of PD-1 inhibitor in HR NMIBC patients (pts). Our study was established to evaluate the efficacy and safety of RC48 combined with tislelizumab and BCG as a bladder-preserving treatment for Her2-positive HR NMIBC pts. **Methods:** This open-label phase II study enrolled BCG-naïve HR NMIBC pts with multiple papillary tumors (high-grade Ta or T1 tumors), and all pts were Her2-positive (IHC 2+ or 3+). Firstly, the papillary tumors should be removed all visible lesions by transurethral resection of bladder tumor (TURBT). Secondly, pts were administered RC48 (2.0 mg/kg, ivgtt), every 2 weeks for 1 cycle, and were administered tislelizumab (200 mg, ivgtt), every 3 weeks for 1 cycle. Then, pts received second TURBT. Finally, pts received at least 1 year of tislelizumab (200 mg, Q3W, ivgtt). Meanwhile, pts were administered 3 - 5 cycles of RC48 (2.0 mg/kg, Q2W, ivgtt) and received 18 instillations of BCG. Specifically, pts were started on an induction course of BCG with 6 instillations every week, followed by maintenance with 3 instillations every 2 weeks and 9 instillations every 4 weeks. The primary end point was recurrence-free survival (RFS) rate at 12 months (defined as no reappearance of high grade or T1 tumors or clinical stage development after the therapy). Secondary end points were bladder-preservation rate, OS and safety. Our study estimated a RFS rate at 12 months was no less than 85% and the study would enroll 38 pts. **Results:** By Aug. 2025, 24 eligible pts were enrolled and analyzed (male 87.5%; median age 63 years (38-85); IHC 2+ =58.3%, IHC 3+ =41.7%; tumor size$\geq$3 cm (50%); cT1=100.0%; 75.0% multiple papillary tumours. Median follow-up was 6.1 months (3.1-14.2), the median number of tislelizumab cycles was 10 (4-16) and RC48 cycles was 6 (4-8). All pts completed tislelizumab and RC48 treatment during the induction therapy. During the follow-up, only two pts showed reappearance and one pt received radical cystectomy. The bladder-preservation rate was 95.8% (95%CI, 90.7%-100%). The common treatment related adverse events (TRAEs) of any grade were fatigue (54.2%), alopecia (33.0%), anorexia (33.0%) and peripheral neuropathy (16.8%). None 3-5 grade of TRAEs were observed. **Conclusions:** Our preliminary results supported the use of disitamab vedotin combined with tislelizumab and BCG as a bladder-preserving therapy for Her2-positive HR NMIBC pts. Clinical trial information: ChiCTR2400093839. Research Sponsor: None.

4598 Poster Session

Cost-effectiveness analysis in the era of systemic immunotherapy for BCG-naive high-risk non–muscle-invasive bladder cancer in the United States, the United Kingdom, and China. First Author: Zihan Xue, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: Non–muscle-invasive bladder cancer (NMIBC) has entered the era of systemic immunotherapy, with randomized trials evaluating the addition of systemic immunotherapy to BCG to improve disease control. The cost-effectiveness of combining immune checkpoint inhibitor (ICI) with BCG in BCG-naive high-risk NMIBC (HR-NMIBC) remains unclear. We therefore conducted a multinational cost-effectiveness analysis in the United States, United Kingdom, and China based on the CREST and POTOMAC studies. **Methods:** We developed a Markov model to evaluate treatment strategies for patients with BCG-naive HR-NMIBC over a 5-year time horizon from healthcare payer perspectives, with health outcomes measured in quality-adjusted life-years (QALYs). Total costs, QALYs, and incremental cost-effectiveness ratios (ICERs) were calculated for each strategy. Model robustness was assessed using deterministic and probabilistic sensitivity analyses. **Results:** Health outcomes were comparable across strategies, with BCG, durvalumab plus BCG, and sasanlimab plus BCG yielding 4.11, 4.31, and 4.18 QALYs, respectively. In the US, durvalumab plus BCG increased costs by $159,021 compared with BCG, resulting in an ICER of $827,706 per QALY, exceeding the willingness-to-pay (WTP) threshold of $150,000 per QALY. In the UK, the corresponding ICER was £503,944 per QALY, far above the WTP threshold of £20,000 per QALY. In China, the ICER reached ¥3,860,692 per QALY, exceeding the threshold defined as three times the national per-capita GDP (¥257,145). Sasanlimab plus BCG was strictly dominated by durvalumab plus BCG in all settings. Consequently, neither systemic immunotherapy–based strategy was cost-effective under the evaluated WTP thresholds. BCG was optimal in all probabilistic simulations, and ICI prices were the primary drivers of cost-effectiveness for systemic immunotherapy–based strategies. **Conclusions:** Despite modest clinical benefits, the high cost of systemic immunotherapy plus BCG precludes cost-effectiveness across health care systems, with BCG alone remaining the preferred strategy under current pricing. Future efforts should focus on drug price reductions and precision patient selection to improve the value proposition of early systemic immunotherapy. Research Sponsor: None.

	Costs ($; US)	Costs (£; UK)	Costs (¥; China)	Incremental costs ($; US)	Incremental costs (£; UK)	Incremental costs (¥; China)	Effectiveness (QALYs)	ICER ($/QALY; US)	ICER (£/QALY; UK)	ICER (¥/QALY; China)
BCG	48,828	21,307	119,383	-	-	-	4.11	-	-	-
Durvalumab + BCG	207,849	118,126	861,110	159,021	96,819	741,728	4.31	827,706	503,944	3,860,692
Sasanlimab + BCG*	309,654	138,329	932,331	260,826	117,023	812,948	4.18	3,726,091	1,671,751	1,1613,542

*The Sasanlimab plus BCG strategy is strictly dominated by the Durvalumab plus BCG strategy (higher cost and lower effectiveness).

Final results from a phase II study of tislelizumab combined with radiotherapy as bladder-preserving treatment for high-risk non–muscle-invasive bladder cancer patients unresponsive to Bacillus Calmette-Guerin. First Author: Zhiyong Li, Department of Urology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Radical cystectomy (RC) was the standard of care for high-risk non-muscle-invasive bladder cancer (HR NMIBC) patients with Bacillus Calmette-Guerin (BCG)-unresponsive papillary tumors. Clinical unmet need was to explore non-surgical treatment options for patients who were ineligible for or declined RC. Our study was established to evaluate the efficacy and safety of tislelizumab combined with radiotherapy as bladder-preserving treatment for HR NMIBC patients unresponsive to BCG. **Methods:** This open-label, single arm phase II study enrolled HR NMIBC patients with BCG-unresponsive papillary tumors (high-grade Ta or T1 tumors without carcinoma in situ). The papillary tumors should be removed all visible lesions by transurethral resection of bladder tumor (TURBT). Within 2 weeks after TURBT, eligible patients received tislelizumab 200 mg in day 1 (D1), every 21 days for eight cycles and a total radiotherapy dose of 60-66 GY in 30-33 fractions over seven weeks. The primary endpoint was disease-free survival (DFS) rate at 12 months (defined as no reappearance of high grade or T1 tumors or clinical stage development after the therapy). Secondary endpoints were bladder-preservation rate, OS and safety. Our study estimated a DFS rate at 12 months was no less than 50% and the study would enroll 32 patients to meet the primary endpoint. **Results:** Between September 4, 2020, and December 11, 2024, 32 patients (26 [81.2%] men and 6 [19.8%] women) who had received a median of eleven (IQR 7-22) previous BCG instillations were enrolled. Patients received a median of 8 cycles (IQR 8–8) of tislelizumab and of radiotherapy doses of 62.0 GY (IQR 62.0–64.0) . Median follow-up was 28.8 months (19.7-43.8). The DFS rate at 12 months was 90.6% (95%CI, 79.8%-99.6%), at 24 months was 70.2% (95%CI, 50.1%-83.4%). The bladder-preservation rate at 24 months was 93.2% (95%CI, 75.4%-98.3%). The OS rate at 24 months was 100% (95%CI, 100%-100%). The OS rate at 36 months was 90.5% (95%CI, 67.0%-97.6%). Treatment-related adverse events (TRAEs) occurred in 27 (84.4%) of 32 patients, 7 (21.9%) patients had a grade 3 TRAEs. The most common 3 TRAEs were diarrhea (9.4%), radiocystitis (3.1%), leukopenia (3.1%) and liver function damage (3.1%) without grade 4-5 TRAEs. **Conclusions:** Our final results supported the use of tislelizumab combined with radiotherapy as a promising bladder-preserving therapy for BCG-unresponsive HR NMIBC patients who were ineligible for or decline RC. Clinical trial information: ChiCTR2000035275. Research Sponsor: None.

Prognostic value of post-operative circulating tumor DNA (ctDNA) in real-world treatment and outcomes among patients (pts) with muscle invasive (MIBC) and locally advanced (LA) bladder cancer (BC). First Author: Khilna Patel, Flatiron Health, Durham, NC

Background: BC has high recurrence risk despite curative intent surgery and perioperative therapy. As ctDNA guided strategies are investigated in trials, evidence from routine practice is needed to understand treatment decisions and how post-surgery ctDNA status relates to outcomes. This study evaluated real-world survival outcomes and treatment patterns by post-surgery ctDNA status among pts with MIBC/LA BC and assessed prognostic value beyond pathologic response (pCR). **Methods:** This retrospective study used the US-based, EHR-derived deidentified Flatiron Health Research Database (cutoff 08/31/25). Pts with MIBC or LA BC diagnosed on or after January 2015 who underwent surgery and ctDNA testing were included. Pt characteristics were summarized, including ctDNA testing patterns. Adjuvant therapy initiation was described by post-surgery ctDNA status. Real-world overall survival (rwOS) and disease-free survival (rwDFS) were estimated from the date of surgery using Kaplan–Meier methods, stratified by pCR status and post-surgery ctDNA status (results within 90 days post-surgery), and summarized descriptively with landmark survival probabilities. **Results:** Among 388 pts in the study population who underwent surgery and received ctDNA testing, median age at diagnosis was 70 years (IQR: 63.8-75.0); 63% received neoadjuvant therapy, 49% received adjuvant therapy, and 11% had residual disease post-surgery. Use of ctDNA testing increased substantially over time in the study cohort, from 2.6% (10/388) in 2021 to 57% (223/388) in 2025. Of ctDNA-tested pts, 97 pts had evaluable post-surgery ctDNA results (ctDNA+: 10.3% [n=40]; ctDNA−: 14.7% [n=57]). Of these, adjuvant therapy was given to 43% of post-surgery ctDNA+ pts and 35% of ctDNA− pts. The 12-month rwOS (95% CI) was 69.4% (53.8%-89.6%) for ctDNA+ vs 96.5% (91.8%-100.0%) for ctDNA−; 12-month rwDFS (95% CI) was 34.4% (20.8%-56.8%) vs 72.7% (61.2%-86.4%), respectively. Stratified by pCR, outcomes were favorable among pts achieving pCR. Although limited by small sample sizes, ctDNA status appeared to further differentiate prognosis within each stratum, particularly among pts without pCR, where ctDNA+ pts had worse rwOS (43.2% vs 100.0%, $P < .01$) and worse rwDFS (9.9% vs 64.2%, $P = .014$) over time compared with ctDNA− pts. **Conclusions:** Rapid growth in ctDNA testing highlights increasing clinical adoption. Post-surgery ctDNA positivity was linked to worse rwOS/rwDFS in pts with MIBC/LA BC and further stratified prognosis beyond pCR. Importantly, ctDNA may complement pathologic response in identifying pts at highest risk for recurrence and informing post-surgical management. Future work is needed to translate these findings into clinically actionable insights and treatment strategies. Research Sponsor: Flatiron Health, Inc.

Assessing responses to UGN-102 across EORTC recurrence score groups in patients with recurrent low-grade intermediate-risk NMIBC (ENVISION trial). First Author: Sandip M. Prasad, Morristown Medical Center/Atlantic Health System and Garden State Urology, Morristown, NJ

Background: The ENVISION phase 3 study (NCT05243550) treated patients with recurrent low-grade intermediate-risk non-muscle-invasive bladder cancer (LG-IR-NMIBC) with UGN-102, a reverse thermal hydrogel administered intravesically containing 75 mg mitomycin. Complete response (CR) rate at 3 months was 79.6% (95% confidence interval [CI]: 73.9, 84.5) with a 72.2% (95% CI: 64.1, 78.8) probability of remaining in response 24 months later. The European Organization for Research and Treatment of Cancer (EORTC) recurrence score tables provide estimates of recurrence based on baseline prognostic factors. We conducted a post-hoc analysis of CR and duration of response (DoR) by EORTC recurrence score subgroup. **Methods:** 240 patients with recurrent LG-IR-NMIBC received ≥1 dose of UGN-102. CR was assessed at 3 months using cystoscopy, urine cytology testing, and for-cause biopsy. Patients achieving CR entered the follow-up period and are being assessed for recurrence or progression for up to 5 years. CR at 3 months and probability of maintaining CR at 24 months in patients with EORTC recurrence scores of 1–4, 5–9, and 10–17 were calculated. DoR was calculated using the Kaplan–Meier (KM) estimation method. **Results:** The median (range) EORTC recurrence score was 7 (2–13). CR rate at 3 months was 83.9%, 81.2%, and 60.0% for patients with recurrence scores of 1–4 (n=31), 5–9 (n=191), and 10–17 (n=15), respectively. Of the patients with CR at 3 months, 26.9%, 23.9%, and 33.3% (for recurrence scores of 1–4, 5–9, and 10–17) experienced recurrence of LG disease, progression (either in stage or grade), or death by 24 months. The KM estimate of median DoR was not estimable for any group due to the low event rates. **Conclusions:** UGN-102 demonstrated robust complete response rates across all EORTC recurrence score subgroups, including patients with higher baseline recurrence risk. The majority of patients remained recurrence-free at 24 months. Despite the post-hoc design and small subgroup sizes, these findings suggest UGN-102 provides durable and clinically meaningful disease control in recurrent LG-IR-NMIBC. Clinical trial information: NCT05243550. Research Sponsor: UroGen Pharma, Inc.

	EORTC recurrence score group		
	1–4 N=31	5–9 N=191	10–17 (N=15)
CR at 3 months, n (%)	26/31 (83.9)	155/191 (81.2)	9/15 (60.0)
CRR (95% CI)	83.9 (66.3, 94.5)	81.2 (74.9, 86.4)	60.0 (32.3, 83.7)
Recurrence 24 months[a], n (%)	7/26 (26.9)	37/155 (23.9)	3/9 (33.3)
Recurrence of LG disease	5/26 (19.2)	27/155 (17.4)	3/9 (33.3)
Progression	0	7/155 (4.5)	0
Death	2/26 (7.7)	3/155 (1.9)	0
Probability of remaining in response at 24 months, %, 95% CI[b]	67.4 (43.2, 83.1)	73.7 (64.6, 80.8)	66.7 (28.2, 87.8)
Median duration of follow up, months, 95% CI[c]	23.29 (23.03, 23.92)	23.72 (23.66, 23.92)	23.90 (23.72, NE)

[a]24 months after 3-month CR.

Patient experiences with UGN-102 for recurrent low-grade intermediate-risk non-muscle invasive bladder cancer (LG-IR-NMIBC): Insights for shared decision making. First Author: Ruchika Talwar, Department of Urology, Vanderbilt University Medical Center, Nashville, TN

Background: Recurrent LG-IR-NMIBC can be managed using various approaches, including repeat transurethral resection of bladder tumor (TURBT) and non-surgical intravesical therapies. One option is UGN-102, a reverse thermal hydrogel containing 75mg mitomycin. Given LG-IR-NMIBC tends to recur, understanding patients' experiences/preferences across management strategies is essential to support clinical shared decision making. **Methods:** The ENVISION study (NCT05243550) assessed patient-reported outcomes via EORTC-QLQ-NMIBC24. Patients with biopsy-confirmed LG-IR-NMIBC and ≥1 previous NMIBC episode at baseline had 6 once-weekly intravesical instillations of UGN-102 in an outpatient setting. 32 US-based patients had semi-structured prospective phone interviews that compared experiences of prior TURBT (at enrollment) vs UGN-102 at 3 months. **Results:** 232 patients were included; 94.8% received all 6 doses of UGN-102. Mean change from baseline (CfB) scores at 3- and 12-months post-treatment did not reach minimal clinically important difference (MCID) thresholds for any of the EORTC-QLQ-NMIBC24 domains (Table). Patients perceived more interference with routines/responsibilities with TURBT vs UGN-102, similar urinary symptoms, expressed concern regarding more bleeding with TURBT, and would recommend UGN-102 as a less invasive, painful, and time-consuming procedure than TURBT. A small number of patients preferred surgery as a 1-day procedure vs 6 weekly intravesical instillations. **Conclusions:** UGN-102 maintained stable quality-of-life scores across NMIBC24 domains and was generally preferred by patients over surgical resections. These important insights support shared decision making, enabling clinicians to discuss trade-offs between procedural convenience and treatment invasiveness in recurrent LG-IR-NMIBC management. Clinical trial information: NCT05243550. Research Sponsor: UroGen Pharma, Inc.

EORTC-QLQ-NMIBC24 domain	MCID	Baseline, mean (SD) n	3-month CfB, mean (SD) n	12-month CfB, mean (SD) n

Influence of low-coverage whole-genome sequencing–based urinary tumor fraction and chromosomal instability on recurrence risk stratification in systemic immunotherapy-treated non–muscle–invasive bladder cancer. First Author: Yunkai Qie, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: Urinary tumor DNA (utDNA) is increasingly explored for prognostic assessment in bladder cancer, but most studies rely on a simple positive/negative classification, and its prognostic value in patients receiving systemic immune checkpoint inhibitors (ICIs) remains unclear. Low-coverage whole-genome sequencing (LC-WGS) of urine enables low-cost quantitative assessment of tumor fraction (TF) and chromosomal instability (CIN), providing richer molecular information than conventional binary utDNA status. We evaluated whether LC-WGS–derived TF and CIN improve prognostic stratification in ICI–treated high- and very high-risk non–muscle–invasive bladder cancer (NMIBC). **Methods:** Patients with high- or very high-risk NMIBC were enrolled in a prospective cohort treated with ICI tislelizumab plus low-dose nab-paclitaxel. Pretreatment urine samples were collected and analyzed using LC-WGS to derive TF and CIN. Clinicopathologic variables were collected at baseline. The primary endpoint was 2-year recurrence-free survival (RFS). Prediction models were constructed using clinicopathologic features (tumor size, number, concomitant carcinoma in situ, lymphovascular invasion) alone and in combination with TF and CIN. **Results:** A total of 35 patients were included. After a median follow-up of 27.3 months, 11 patients experienced disease recurrence. Models based on clinicopathologic features alone demonstrated limited discrimination for 2-year RFS (AUC = 0.61). Higher urinary TF and CIN were significantly associated with increased recurrence risk (TF: HR 2.18, 95% CI 1.29–3.97, p = 0.004; CIN: HR 2.74, 95% CI 1.41–5.32, p = 0.002). Incorporation of TF improved discrimination (AUC = 0.71), and further addition of CIN achieved the highest performance (AUC = 0.80; ΔAUC = 0.19 vs clinical model, p = 0.01). Patients classified as high molecular risk based on combined TF and CIN had significantly lower 2-year RFS than those at low molecular risk (HR 3.92, 95% CI 1.62–9.48, p = 0.002). Notably, the molecular-only model incorporating TF and CIN demonstrated discrimination comparable to the clinicopathologic-integrated model (AUC = 0.79 vs 0.80, p = 0.68), suggesting that urinary genomic features alone may provide sufficient information for recurrence risk stratification in this setting. **Conclusions:** Urinary TF and CIN derived from cost-effective LC-WGS substantially improved recurrence risk stratification beyond conventional tumor characteristics in NMIBC patients treated with systemic immunotherapy. These findings suggest that urine-based molecular profiling may offer a practical and scalable complement to conventional clinicopathologic risk assessment for baseline risk stratification and post-therapy management. UTOPIA: A phase 3 trial of UGN-103, an intravesical mitomycin reverse thermal hydrogel, in recurrent low-grade intermediate-risk non-muscle invasive bladder cancer. First Author: Abhishek Srivastava, Carolina Urologic Research Center, Myrtle Beach, SC

Background: Management of recurrent low-grade (LG), intermediate-risk (IR) non-muscle invasive bladder cancer (NMIBC) remains challenging due to frequent recurrence following standard surgical management with transurethral resection of bladder tumor (TURBT). UGN-102 is an intravesical mitomycin reverse thermal hydrogel, approved by the Food and Drug Administration for treatment of adults with recurrent LG-IR-NMIBC based on the Phase 3 ENVISION trial demonstrating a complete response (CR) rate of 80% (95% confidence interval [CI]: 74, 85) at 3 months, with an 82% (95% CI: 76, 87) probability of remaining in response 12 months from initial CR. UGN-103 is a novel formulation of UGN-102 developed to simplify drug preparation and shorten manufacturing time. **Methods:** UTOPIA (NCT06331299) is an ongoing, multicenter, single-arm, Phase 3 study evaluating UGN-103 as primary treatment for adults with recurrent LG-IR-NMIBC. Eligible patients provided written informed consent and received six once-weekly intravesical instillations of UGN-103 (mitomycin 75 mg in 56 mL admixture). Disease assessment was performed 3 months after start of treatment. Patients with no detectable disease entered a follow-up period, with evaluations every 3 months until recurrence, progression, death, or completion of follow-up (12 months after the 3-month visit). The primary endpoint was CR rate (defined as the proportion of patients assessed as having no evidence of disease at the 3-month visit) based on cystoscopy, for-cause biopsy, and urine cytology. Secondary endpoints include durability of response, safety and tolerability, and pharmacokinetics. Data cut off: September 3, 2025. **Results:** A total of 99 patients received ≥1 instillation of UGN-103; of these, 97% (n=96) received all 6 instillations. At baseline, median patient age was 71 years (range 46, 93), with 78% (n=77) being ≥65 years old. Most patients were male (72%; n=71) and 99% (n=98) were White. Most patients had multiple tumors (90%; n=87), with the longest tumor diameter being ≤3 cm in 96% (n=93). At 3 months, 77 of 99 patients in the intent-to-treat population achieved CR (CR rate: 78% [95% CI: 68, 86]). Non-CR outcomes included residual disease in 16% (n=16) and progression to high-grade disease in 4% (n=4). Two (2%) patients had missing/indeterminate responses. Treatment-emergent adverse events (TEAEs) were reported in 60% of patients (n=59), with the most common TEAE (≥10%) being dysuria (19%; n=19). Two (2%) patients had a total of 3 serious TEAEs, including atrial fibrillation, osteoarthritis, and respiratory failure; none were treatment related. No TEAE led to death. **Conclusions:** UGN-103 demonstrated a safety and efficacy profile similar to that observed with UGN-102 in patients with recurrent LG-IR-NMIBC, supporting continued evaluation of UGN-103 as an intravesical treatment option. Clinical trial information: NCT06331299. Research Sponsor: UroGen Pharma, Inc.

Preliminary results of a phase II study to evaluate the efficacy and safety of disitamab vedotin (RC48-ADC) in combination with radiotherapy for adjuvant therapy in upper tract urothelial carcinoma. First Author: Zihao Tao, Department of Urology, Peking University First Hospital, Peking University, Beijing, China

Background: Although postoperative platinum-based adjuvant chemotherapy improves disease-free survival (DFS), many upper tract urothelial carcinoma (UTUC) patients (pts) were ineligible for cisplatin after radical nephroureterectomy (RNU). UTUCs did not seem to benefit from adjuvant immunotherapy. Previous evidence demonstrated adjuvant radiotherapy improvesd cancer-specific survival in HR UTUCs. Further exploration of alternative adjuvant treatment strategies is needed. This study aims to evaluate the therapeutic potential of RC48-ADC in combination with radiotherapy in HER2 overexpressing UTUCs. **Methods:** This is an open-label, phase II, non-randomised study to evaluate the efficacy and safety of disitamab vedotin (RC48-ADC), a humanized anti-HER2 antibody, in combination with radiotherapy as a novel adjuvant therapy strategy in UTUC. We recruited cisplatin-intolerant pts with HER2-overexpressing (Immunohistochemistry, IHC 2+, 3+) UTUC after nephroureterectomy staged as pT2N0M0 with high-grade/multifocal disease/positive surgical margin, pT3-4 N0 M0 or pTany N1-2 M0. Pts who declined any adjuvant therapy were assigned to the surveillance group. Pts in adjuvant therapy group received RC48-ADC (2.0 mg/kg D1 Q2W, 6 months) and radiotherapy (45-50Gy/25f/5w, lymphatic drainage regions; 62.5Gy/25f/5w, enlarged lymphnode). The therapy was initiated within 90 days of surgery. The primary end point was DFS. Secondary end points were overall survival (OS), metastasis-free survival (MFS), local-recurrence free survival (LRFS) and safety. The trial is registered with ClinicalTrials.gov, NCT06210490. **Results:** As of January 2026, 54 patients out of the planned 60 pts have been enrolled in the study. Thirty pts were assigned to adjuvant therapy group and 24 in surveillance. In therapy group, 17 pts completed adjuvant therapy, while 13 pts were undergoing treatment. At a median follow-up of 12.4 months, one recurrence was observed in the therapy group, while 9 patients in surveillance experienced recurrence. The 1-year disease-free survival rates were 95% (95% CI 85.9–100) in the adjuvant therapy group and 69.6% (95% CI 53.1–91.2) in the surveillance group. As of now, the most common (≥20%) treatment-related adverse events (TRAEs) were peripheral sensory neuropathy (40%), increased AST (28%), asthenia (28%) and alopecia (20%). Grade ≥ 3 TRAE was observed in 2 patients (8%), the patients experienced gastrointestinal hemorrhage and peripheral sensory neuropathy, respectively. **Conclusions:** This study is the first to evaluate the efficacy and safety in adjuvant treatment of ADC plus radiotherapy in UTUCs. The combination of RC48-ADC and radiotherapy as a new adjuvant therapy demonstrated a tolerable safety profile in pts with HER2-overexpressing UTUC. Clinical trial information: NCT06210490. Research Sponsor: RemeGen.

Adjuvant nivolumab in high-risk muscle-invasive urothelial carcinoma: Real-world evidence from the SOGUG-NIADY study of the Spanish Oncology Genitourinary Group (SOGUG). First Author: Sara Perez Ramirez, Hospital Gregorio Marañón, Madrid, Spain

Background: Adjuvant nivolumab significantly improved disease-free survival (DFS) in patients (pts) with high-risk muscle-invasive urothelial carcinoma (MIUC) after radical surgery in the phase III CheckMate-274 trial. Based on these results, since august 2023, the Spanish National Health System reimburses postoperative nivolumab in high-risk, positive programmed death ligand 1 (PDL1) MIUC. The aim of the PrInCIS-NIADY study was to assess the effectiveness and safety of adjuvant nivolumab in real-world clinical practice after its approval in Spain. **Methods:** PrInCIS is a nationwide multicentre, non-interventional epidemiological study with retrospective patient inclusion and prospective follow-up. The NIADY cohort included pts with high-risk PDL1+ MIUC treated with adjuvant nivolumab in routine practice, was conducted across 65 hospitals belonging to the Spanish Oncology Genitourinary Group (SOGUG) in 16 Spanish regions. Baseline characteristics, treatment patterns, safety, and outcomes were analysed and compared against CheckMate-274. **Results:** A total of 395 evaluable pts were included, 95.7% were PD-L1 positive. Median age was 69.5 years, (74.9% aged ≥65 years); 91.4% had bladder cancer and 8.6% had upper tract disease. Predominant histology was urothelial carcinoma (79.2%). 51.2% pts received neoadjuvant platinum-based chemotherapy (NAChT) (48.9% cisplatin vs. 2.3% carboplatin) (Table). With a median follow-up of 13 months, 27.3% of pts had disease recurrence. Treatment after recurrence was platinum-based ChT in 8.8% and enfortumab vedotin in 6.6% of pts. Median DFS and overall survival (OS) were not reached. The estimated 18-month DFS and OS probability were 65.6% and 78.3% respectively. Nivolumab was well-tolerated: Treatment delays or dose reductions occurred in 37.3% of pts. Most common (>10%) grade 1-2 immune-related adverse events were fatigue, pruritus and diarrhea, while grade 3–4 toxicity was infrequent (>1%), mainly consisting in hepatic enzyme and creatinine elevation. **Conclusions:** Outcomes and effectiveness of adjuvant nivolumab in this large Spanish real-world cohort were consistent with the Checkmate-274 results, with a manageable safety profile despite an older population. In spite of short-term follow-up, these findings externally validate the results of the pivotal trial reinforcing the role of adjuvant nivolumab in daily clinical practice for high-risk MIUC. Research Sponsor: SOGUG: Spanish Oncology Genitourinary Group.

Magnitude and timing of clinical benefit associated with pathologic complete response in perioperative muscle-invasive bladder cancer: A reconstructed IPD analysis of NIAGARA trial. First Author: Andrea Malgeri, Medical Oncology 1, IRCCS National Cancer Institute Regina Elena, Rome, Italy

Background: Pathologic complete response (pCR) is widely used as an early efficacy endpoint in neoadjuvant or perioperarive bladder cancer trials. However, formal surrogacy analyses linking pCR to long-term clinical outcomes are lacking. In particular, the magnitude and timing of clinically meaningful benefit associated with pCR remain poorly defined. We aimed to quantify the absolute benefit and temporal emergence of event-free survival (EFS) and overall survival (OS) associated with pCR in NIAGARA trial. **Methods:** Individual patient data (IPD) were reconstructed from the most recent publicly available Kaplan-Meier curves of the NIAGARA trial, including stratification by pCR and non-pCR status for each treatment arm. The primary analysis compared outcomes between pCR and non-pCR patients within each treatment arm. Restricted mean survival time differences (ΔRMST) were estimated at 24 months for EFS and 36 months (mo) for OS. Time to benefit (TTB) was defined as the earliest time point at which ΔRMST reached ≥1 mo for EFS and ≥2 mo for OS. Exploratory analyses compared outcomes within pCR patients and within non-pCR patients between treatment arms, to explore whether the clinical benefit associated with pCR is purely prognostic or reflects treatment-related modulation within pathological response strata. **Results:** At 24 months, pCR was associated with a large and early EFS benefit across treatment arms. Among patients receiving durvalumab + cisplatin-gemcitabine (CG), pCR was associated with a ΔRMST of +5.87 mo (95% CI 4.78-6.96; $p<0.0001$) compared with non-pCR, with a TTB of 9 mo. Similar results were observed in the CG arm (ΔRMST of +5.63 mo, 95% CI 4.49-6.77; $p<0.0001$), with a TTB of 9 mo. At 36 months, pCR was also associated with a substantial OS benefit. In the durvalumab + CG arm, pCR was associated with a ΔRMST of +5.32 mo (95% CI 3.89-6.74; $p<0.0001$) versus non-pCR, with a TTB of 22 mo. Comparable findings were observed in the CG arm (ΔRMST +5.89 mo, 95% CI 4.30-7.47; $p<0.0001$), and a TTB of 20 mo. In exploratory analyses, no significant EFS or OS differences were observed between treatment arms among pCR patients (ΔRMST <1 month), with a TTB of 38 mo for EFS and not reached within 60 mo for OS. Among non-pCR patients, treatment-related differences were similarly modest (ΔRMST ~1 month), with delayed TTB (19 mo for EFS and 50 mo for OS). **Conclusions:** Using reconstructed IPD from NIAGARA, pCR identifies a large, early EFS benefit and a later OS benefit, informing, in the absence of formal surrogacy validation, a quantitative and temporal clinical interpretation of pCR. In contrast, no additional treatment-related survival benefit was observed within pCR or non-pCR subgroups, raising the hypothesis that survival differences may be largely attributable to pCR rather than to treatment-related modulation within response strata. Progress of phase II study of MVR-T3011, an IL-12/anti-PD-1 armed oncolytic HSV-1, in high-risk BCG-unresponsive CIS and papillary NMIBC. First Author: Dingwei Ye, Fudan University Shanghai Cancer Center, Shanghai, China

Background: MVR-T3011 is a novel Phase II oncolytic immunotherapy candidate based on herpes simplex virus type 1 (HSV-1). It combines potent tumor lysis with co-expression of anti-PD-1 antibody and IL-12. MVR-T3011 is being evaluated as monotherapy in patients with non-muscle invasive bladder cancer (NMIBC), including both BCG-unresponsive and BCG-naïve populations. Herein, we report the latest Phase II results of MVR-T3011 in BCG-unresponsive carcinoma in situ (CIS) and papillary NMIBC. **Methods:** In this ongoing trial, MVR-T3011 is administered intravesically in 50 mL without prewash. This simplified procedure utilizes the virus's natural ability to bind to glycosaminoglycans (GAGs) on the urothelial surface as attachment receptors. Patients were assigned to two groups: 1) 2×10^9 PFU, administered weekly for 12 weeks during the induction phase, followed by maintenance treatment every 2 weeks; 2) 1×10^{10} PFU, administered weekly for 6 weeks for induction, then every 3 weeks of treatment for maintenance. Both continued for up to 2 years. Efficacy was assessed every 3 months via cystoscopy, cytology, biopsy, and imaging. Primary endpoints were complete response rate (CRR) for CIS and recurrence-free survival (RFS) for papillary disease. The safety was fully evaluated. **Results:** As of Dec 31, 2025, a total of 43 patients were enrolled, 14 with CIS and 29 with Papillary. Among 13 evaluable CIS patients, 7 were treated at 2×10^9 PFU dose level, achieving 6-month CRR of 71.4% (5/7), 3 patients maintained CR for 12 months, and 1 patient remained in CR for 18 months. 6 patients treated at 1×10^{10} PFU dose level, all achieved complete responses, with 100% CRR at 3 months (6/6), 6 months (5/5), and 9 months (3/3). Among 26 evaluable papillary patients, 16 were treated at the 2×10^9 PFU dose level. The RFS rate was 80.8% (95% CI: 51.4–93.4) at 6 months, 74.0% (95% CI: 44.6–89.4) at both 12 and 15 months, and 64.8% (95% CI: 34.0–84.0) at both 18 and 21 months. 10 patients treated at 1×10^{10} PFU dose level, the 3-month and 6-month RFS rates were both 88.9%% (95% CI: 43.3–98.4). Assessment of the safety data revealed that most treatment-related adverse events (TRAEs) were grade 1. Common events included hematuria (25.0%), urinary tract infection (11.4%), proteinuria (9.1%), pollakiuria (6.8%), and rash (6.8%; immune-related). Only two grade 3 TRAEs were reported, both of which were urinary tract infections. No higher-grade TRAE or SAE occurred. **Conclusions:** MVR-T3011 is being evaluated as mono or combination therapy across multiple solid tumors. In this study, MVR-T3011 demonstrates suitability for intravesical administration, plus promising efficacy and a favorable safety profile. Durable complete responses were observed in CIS patients and encouraging 12-month RFS rates in papillary disease. These findings support its potential as a bladder-sparing option for BCG-unresponsive NMIBC. Clinical trial information: NCT06427291. Research Sponsor: None.

Bulumtatug fuvedotin (BFv; 9MW2821) plus toripalimab in perioperative patients with muscle-invasive bladder cancer (MIBC): Results of cohort A from a phase 2 study. First Author: Zhuowei Liu, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Radical cystectomy with pelvic lymph node dissection (RC+PLND) has always been the standard treatment for MIBC. Perioperative treatment, especially cisplatin-based neoadjuvant therapy, could reduce the risk of tumor recurrence effectively and prolong the survival of patients. BFv, a novel Nectin-4 antibody-drug conjugate, combined with toripalimab, has demonstrated promising efficacy and safety profile in advanced urothelial cancer patients. This provides possibilities for the perioperative treatment of MIBC. Here we report the preliminary results of BFv plus toripalimab in patients with perioperative MIBC (cohort A). **Methods:** Patients with MIBC (cT2-4aN0-1M0) can be enrolled in cohort A. Eligible patients will receive BFv plus toripalimab for 4 cycles in neoadjuvant stage, and then proceed with RC+PLND. After surgery, patients will receive BFv plus toripalimab for 6 cycles and toripalimab only for the next 11 cycles in the adjuvant stage. The primary endpoint was pathological complete response (pCR). Main secondary endpoints were pathological downstaging (PDS) rate and disease-free survival (DFS), overall survival (OS) and safety. **Results:** As of 4 Jan 2026, 32 patients were enrolled in the cohort A. 7 patients had completed neoadjuvant therapy and 6 of them were performed with RC+PLND. One patient achieved CR in the neoadjuvant stage and refused to undergo the surgery. pCR rate was 66.7% (4/6, 95%CI 22.3-95.7), PDS rate was 83.3% (5/6, 95%CI 35.9-99.6). DFS and OS were not mature. Safety profile was consist with previous study. No new safety signals of BFv or toripalimab were observed in this study. **Conclusions:** This study showed remarkable preliminary efficacy of BFv plus toripalimab in perioperative patients with MIBC. It may offer a new choice for MIBC patients and deserve to be further investigation. Clinical trial information: NCT07314723. Research Sponsor: Mabwell (Shanghai) Bioscience Co., Ltd.

Survival and treatment patterns of patients with metastatic urothelial cancer in France: Results of a cohort study using the French National Healthcare database (SNDS). First Author: Philippe Barthelemy, Institut de Cancérologie Strasbourg Europe, Strasbourg, France, Strasbourg, France

Background: Despite the increasing number of available treatment options, metastatic urothelial cancer (mUC) remains a challenging disease, characterized by high mortality and substantial rates of undertreatment worldwide. In this study, we aimed to describe treatment patterns and survival among patients with mUC in France. **Methods:** This retrospective study included adult patients with incident mUC between January 2017 and December 2023. The overall study cohort was divided into two subcohorts: treated, defined as initiating any systemic treatment within 120 days after index date and untreated (defined as not initiating any treatment within 120 days after index date). The index date was defined as diagnosis (first recorded ICD-10 code for metastasis) or start of systemic anticancer treatment. Overall survival (OS) was estimated using Kaplan-Meier method, calculated from the index date for the overall cohort and untreated subcohort, and from the initiation of first line (1L) treatment for the treated subcohort. Baseline characteristics including sex, age, and age-adjusted Charlson Comorbidity index (CCI) were compared between treated and untreated subcohorts using $\chi 2$ and Wilcoxon tests. **Results:** The study included 24,912 patients, male (77.8%), mean (SD) age was 75 (11) yrs, and median (IQR) age-adjusted CCI was 4 (2-5). Median (IQR) follow-up was 2.5 (1-10) months. Mortality was 90.8%, primarily due to malignant tumors (88.6%) among the recorded causes of death. Overall, 1L treatment was initiated in 10,562 pts (42.4%), with increasing annual rates from 2017 (38%) to 2023 (47%). Chemotherapy was the predominant 1L treatment (75.4%) followed by immune-oncology (IO) agents (24.5%). Of 7,960 pts receiving 1L chemotherapy, 4,193 (53%) did not receive any further treatment, and 2,184 (27%) patients received chemotherapy, 1,359 (17%) IO, and 224 (3%) antibody-drug conjugates in second line. Mean (SD) time from index date to 1L initiation was 18 (25) days and mean (SD) duration of 1L was 101 (155) days. Median OS was 2.5 (95% CI 2.4-2.6), 7.6 (7.4-7.8) and 1.1 (1.1-1.1) months for the overall cohort, treated and untreated subcohorts, respectively. It decreased with higher CCI scores: from 3.99 months for patients with CCI 0 to 1.54 months for those with CCI $\geq$5. Sex, age and CCI were significantly different between treated and untreated patients ($p<0.0001$). **Conclusions:** This nationwide population-based study showed that more than half of patients with mUC treated in real-world clinical practice in France did not receive 1L systemic treatment. Untreated individuals were mainly elderly, male, comorbid, and experienced poor survival. These findings underscore the importance of the early utilization and optimization of available therapies to improve outcomes, especially among untreated patients with mUC. Real-world effectiveness of disitamab vedotin plus PD-1 inhibitor versus platinum-based chemotherapy as postoperative adjuvant therapy in high-risk upper tract urothelial carcinoma: A comparative study. First Author: Yudong Cao, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Urology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Currently, gemcitabine–platinum combination chemotherapy represents the standard adjuvant regimen following radical surgery for high-risk upper tract urothelial carcinoma (UTUC), as it reduces the risk of disease progression in approximately half of all patients. Nevertheless, a substantial proportion of patients are ineligible for this standard regimen due to post-surgical complications like renal insufficiency. Disitamab vedotin (DV), an antibody–drug conjugate targeting HER-2, has recently been shown to yield superior outcomes in advanced urothelial carcinoma when combined with PD-1 inhibitor immunotherapy. Therefore, based on real-world data, this study aims to evaluate the efficacy of the DV plus PD-1 inhibitor versus standard gemcitabine–platinum chemotherapy in the operative adjuvant treatment of UTUC. **Methods:** A retrospective cohort analysis was conducted using data from UTUC patients at Peking University Cancer Hospital between January 2015 and June 2025. The study included UTUC patients diagnosed as $pT_{2-4a}N_0M_0$, who received either 4–6 cycles of DV combined with PD-1 inhibitors or gemcitabine–platinum (cisplatin or carboplatin selected based on postoperative renal function) combination chemotherapy. The primary endpoint was disease-free survival (DFS), the key secondary endpoint was treatment-related adverse events (TRAEs). **Results:** A total of 105 UTUC patients were enrolled, with a median follow-up of 45.7 months. Of these, 34 patients were treated with DV combined with PD-1 inhibitors (DV group), and 71 patients received chemotherapy. Compared with chemotherapy, the DV plus PD-1 inhibitor significantly prolonged DFS, with a hazard ratio of 0.29 (95% CI 0.09–0.98; P = 0.047). The estimated 3-year DFS rates were 83.1% (95% CI 66.8–100.0) in the DV group and 64.9% (95% CI 54.3–77.7) in the chemotherapy group. Regarding safety, grade $\geq$ 3 TRAEs occurred more frequently in the chemotherapy group than in the DV group (36.6% vs. 12.9%), mainly comprising hematologic toxicities. **Conclusions:** Disitamab vedotin combined with PD-1 inhibitor immunotherapy might improve DFS compared with standard chemotherapy as adjuvant therapy for UTUC. Supported by favorable efficacy and safety outcomes, this combination represents a promising postoperative treatment option. Research Sponsor: None.

Real-world treatment patterns and clinical outcomes among US patients with non-muscle invasive bladder cancer (NMIBC) during the BCG shortage. First Author: Suzanne Biehn Merrill, Colorado Urology Group, Lakewood, CO

Background: Bladder cancer is diagnosed in 80,000 US patients (pts) annually; 70% present as non-muscle invasive (NMIBC). Guidelines are risk-based; treatment for high risk (hr) disease includes tumor resection (TURBT) and intravesical therapy, commonly Bacille Calmette Guérin (BCG). Delivery of indicated treatment remains challenged, especially by ongoing (acutely since 2017) BCG shortages. We describe recent real-world (rw) patient characteristics, treatments (BCG, TURBT use), and clinical outcomes for NMIBC pts by risk group. **Methods:** We analyzed demographic, clinical and treatment data from electronic health records in N-Power Medicine's Real-World Analytical Dataset, largely based in the Midwest. Adults diagnosed with NIMBC between 1/2017 - 6/2022 were included and followed through 2022. Pts were classified as hr (Y/N) by AUA definition. Kaplan-Meier (KM) curves estimated BCG maintenance (MTX) duration, rw MIBC and metastatic free survival (modified PFS), cystectomy free survival (CFS), overall survival (OS), and recurrence free survival (RFS). Logistic and Cox regression was used to identify predictors of MTX start and discontinuation among hr pts including demographics, diagnosis year, smoking status, Charlson comorbidity index (CCI) and physician specialty. **Results:** Among 3,516 NMIBC pts (median age at diagnosis 72 years), 2,634 (75%) had hrNMIBC; most were non-Hispanic White (88%) and male (75%). Over a median follow-up of 2.7 years, 29% of hrNMIBC pts received BCG induction (IDX); 12% received BCG MTX and median MTX duration was 7.7 months (95% confidence interval [CI]: 6.8-9.2). For hr pts who received IDX, those diagnosed in 2019-2020 were less likely to initiate MTX (2019 vs 2017: OR 0.4; 95% CI [0.2-0.7], 2020 vs. 2017: OR 0.6 CI [0.4-1.0]). Hr pts with higher CCI (>2 vs 0: HR 2.2 [1.2-4.2]) were more likely to discontinue MTX. Most (95%) BCG recipients received no other therapy after BCG. Nearly all pts (>99%) received TURBT. Clinical outcomes (rwmPFS, rwCFS, rwOS) were less favorable for hr pts (Table). **Conclusions:** We examined treatment during the BCG shortage. BCG IDX and MTX were low among hrNMIBC pts. Clinical outcomes during the shortage highlight the potential to improve outcomes, especially for hr pts, and the need for alternative treatment strategies. Research Sponsor: AstraZeneca.

Neoadjuvant and adjuvant (neoadj-adj) enfortumab vedotin (EV) plus pembrolizumab (pembro) in participants with cisplatin-ineligible muscle-invasive bladder cancer (MIBC): An analysis of clinically relevant subgroups in KEYNOTE-905. First Author: Nabil Adra, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Background: Results from the phase 3 KEYNOTE-905/EV-303 study (NCT03924895) showed that neoadj-adj EV + pembro and radical cystectomy with pelvic lymph node dissection (RC + PLND) led to superior event-free survival (EFS; HR 0.40; 95% CI 0.28-0.57), overall survival (OS; HR 0.50; 95% CI 0.33-0.74), and pathological complete response (pCR) rate (57.1% vs 8.6%) vs RC + PLND alone in participants (pts) with MIBC who were ineligible for or declined cisplatin. We report efficacy in subgroups of clinical interest, including advanced age, ECOG PS, cisplatin eligibility status, and baseline clinical tumor stage. **Methods:** Adults with stage T2-T4aN0M0 or T1-T4aN1M0 MIBC by central review who were cisplatin-ineligible or declined cisplatin were randomly assigned 1:1 to neoadj-adj EV + pembro and RC + PLND vs RC + PLND alone (control). EFS by BICR, OS, and pCR (pT0N0) rate by central review were analyzed in subgroups by age ($\geq$65 to <75 vs $\geq$75 yr), ECOG PS (0-1 vs 2), cisplatin-ineligibility status (ineligible vs declined), and clinical stage (T2N0 vs T3-T4aN0 vs T1-4aN1). The analyses were exploratory; no formal statistical testing was performed. **Results:** 170 pts were assigned to EV + pembro and 174 to control. Median follow-up at data cutoff (Jun 6, 2025) was 25.6 mo (range 11.8-53.7). 30 pts in the EV + pembro arm and 32 in the control arm had stage T2N0 MIBC; 133 and 132 pts had stage T3-T4aN0; 7 and 10 had stage T1-4aN1. In pts with T2N0 MIBC, median EFS was not reached (NR) with EV + pembro vs NR with control (HR 0.26; 95% CI 0.08-0.80), and pCR rate was 60.0% vs 18.8%. In pts with T3-T4aN0 MIBC, median EFS was NR with EV + pembro vs 17.2 mo with control (HR 0.43; 95% CI 0.29-0.63); median OS was NR vs 41.7 mo (HR 0.54; 95% CI 0.35-0.82); pCR rate was 57.1% vs 6.8%. In pts with T1-4aN1 MIBC, median EFS was 36.7 vs 7.2 mo (HR 0.35; 95% CI 0.09-1.40); pCR rate was 42.9% vs 0%. OS for T2N0 and T1-4aN1 will be assessed after additional follow-up (currently <10 events). Outcomes by age, ECOG PS, and cisplatin eligibility are shown in the Table. **Conclusions:** An efficacy benefit was observed with neoadj-adj EV + pembro added to RC + PLND vs RC + PLND alone across clinically relevant subgroups, consistent with the ITT population. Results further support EV + pembro as a potential new standard treatment for pts with cisplatin-ineligible MIBC. Clinical trial information: NCT03924895. Neoadjuvant and adjuvant enfortumab vedotin plus pembrolizumab for participants with muscle-invasive bladder cancer who are eligible for cisplatin: Randomized, open-label, phase 3 KEYNOTE-B15 study. First Author: Christopher J. Hoimes, Duke University Medical Center, Durham, NC

Background: Enfortumab vedotin (EV) + pembrolizumab (pembro) is the established first-line standard of care for locally advanced/metastatic urothelial carcinoma and represents a novel neoadjuvant and adjuvant treatment strategy for patients with muscle-invasive bladder cancer (MIBC) who are ineligible for cisplatin-based chemotherapy. The randomized phase 3 KEYNOTE-B15/EV-304 study (NCT04700124) evaluates neoadjuvant EV + pembro followed by radical cystectomy plus pelvic lymph node dissection (RC + PLND) and adjuvant EV + pembro vs neoadjuvant chemotherapy followed by RC + PLND in participants (pts) with MIBC who are eligible for cisplatin-based therapy. **Methods:** Pts with clinical stage T2-T4aN0M0 or T1-T4aN1M0 MIBC (confirmed by central pathology and central imaging assessment) who were eligible for cisplatin-based chemotherapy and RC + PLND were randomized 1:1 to receive either 4 cycles neoadjuvant EV 1.25 mg/kg IV on days 1 and 8 + pembro 200 mg IV on day 1 Q3W, followed by RC + PLND, and adjuvant 5 cycles EV + 13 cycles pembro (EV + pembro arm) vs 4 cycles neoadjuvant gemcitabine 1000 mg/m^2 on days 1 and 8 + cisplatin 70 mg/m^2 on day 1 Q3W, followed by RC + PLND (cis + gem arm). The primary endpoint was event-free survival (EFS) by blinded independent central review. Key secondary endpoints were pathological complete response (pCR) rate by blinded central pathological review and overall survival (OS). Safety was a secondary endpoint; AEs of special interest were based on distinct prespecified lists for each drug. **Results:** A total of 405 and 403 pts were randomized to EV + pembro and cis + gem, respectively. Median time from randomization to the data cutoff date of October 27, 2025 was 33.6 months (range, 22.5–53.6). Baseline characteristics were generally balanced between groups. EV + pembro significantly improved EFS (median NR vs 48.5 mo; 24-mo estimated EFS rate 79.4% vs 66.2%; HR 0.53, 95% CI 0.41–0.70; 1-sided $P<.0001$), OS (median NR vs NR; 24-mo estimated OS rate 86.9% vs 81.3%; HR 0.65, 95% CI 0.48–0.89; 1-sided $P=.0029$), and pCR rate (55.8% vs 32.5%; estimated difference 23.4%, 95% CI 16.7–29.8; 1-sided $P<.0001$) vs cis + gem. Grade ≥3 treatment-emergent AEs occurred in 75.7% of pts with EV + pembro and 67.2% with cis + gem. Most common grade ≥3 drug-related AE of special interest for EV was skin reactions (14.1%); most common grade ≥3 AE of special interest for pembro was severe skin reactions (13.9%). **Conclusions:** Neoadjuvant and adjuvant EV + pembro significantly improved EFS, OS, and pCR rate compared with neoadjuvant gem + cis in pts with MIBC who were eligible for cisplatin-based chemotherapy. The safety profile of EV + pembro was consistent with prior experience with the combination. These results support EV + pembro as an effective perioperative treatment option in this setting. Clinical trial information: NCT04700124. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA, Astellas Pharma Inc., Northbrook, IL, USA and Seagen Inc., Bothell, WA, USA, which was acquired by Pfizer in Dec. 2023.

Adjuvant or rescue disitamab vedotin for high-risk non–muscle invasive bladder cancer with HER2 overexpression: A phase II multi-center study. First Author: Junru Chen, Department of Urology, Institute of Urology, West China Hospital, Sichuan University, Chengdu, China

Background: Disitamab vedotin (DV), a HER2-targeted antibody–drug conjugate (ADC), has shown efficacy in metastatic urothelial carcinoma. However, its role in high-risk non-muscle-invasive bladder cancer (HR-NMIBC) patients with HER2 overexpression remains unexplored. We report preliminary findings from an ongoing phase II trial evaluating DV as adjuvant or rescue therapy in this population. **Methods:** Two cohorts were enrolled: patients receiving adjuvant therapy following transurethral resection (cohort A) and those undergoing rescue therapy after BCG failure (cohort B). Eligible patients had HR-NMIBC with HER2 overexpression. DV was administered at 120 mg intravenously every 2 weeks for up to 10 cycles. The primary endpoints were safety, 12-month recurrence-free survival (RFS) in cohort A, and 3-month clinical complete response (cCR) rate in cohort B. Secondary endpoints included 6-month RFS (cohort A) and duration of response (DOR, cohort B). Exploratory analyses evaluated the prognostic value of urinary tumor DNA (utDNA) using samples collected at baseline, end of treatment, and at the time of disease recurrence. This study is registered with ClinicalTrials.gov (NCT05996952). **Results:** Between September 2023 and October 2025, 28 patients were enrolled—22 in cohort A (median age 62 years [range, 33–75]; 3 women [13.6%]) and 6 in cohort B (median age 66 years [range, 60–72]; all men). Median follow-up was 13.4 months (range, 2.1–24.2) for cohort A and 17.0 months (range, 1.8–22.9) for cohort B. In cohort A, 6- and 12-month RFS rates were 95.2% and 73.4%, respectively. In cohort B, the 3-month cCR rate was 100%, and the median DOR was not reached (range, 1.7–19.7 months). All patients experienced treatment-related adverse events (TRAEs); 4 patients (14.3%) had grade ≥ 3 TRAEs. The most common TRAEs were elevated alanine aminotransferase (42.9%), alopecia (42.9%), and fatigue (35.7%). Exploratory analysis of baseline utDNA status demonstrated significant prognostic stratification, with positive patients exhibiting inferior 1-year RFS compared to those with negative status (50% vs. 91%, P=0.043). **Conclusions:** DV demonstrated a manageable safety profile and encouraging efficacy in patients with HR-NMIBC and HER2 overexpression in both adjuvant and rescue settings. The trial is ongoing, following a Simon two-stage optimal design, with a target enrollment of 52 patients in cohort A and 25 in cohort B. Study initiation was in May 2023. Clinical trial information: NCT05996952. Research Sponsor: None.

Molecular characterization of residual disease post-neoadjuvant sacituzumab govitecan (SG), pembrolizumab, or their combination in patients with muscle-invasive bladder cancer (MIBC). First Author: Andrea Necchi, Department of Medical Oncology, IRCCS San Raffaele Hospital, Comprehensive Cancer Center; Vita-Salute San Raffaele University, Milan, Italy

Background: In patients (pts) with MIBC, we tested the activity of neoadjuvant SG (SURE-01, NCT05226117), SG + pembrolizumab (SURE-02, NCT05535218) and pembrolizumab alone (PURE-01, NCT02736266), followed by surgery. We aimed to molecularly characterize the residual post-neoadjuvant therapy (NAT) MIBC and its changes from baseline samples. **Methods:** Post-NAT samples (ypT≥2) were available for transcriptome analyses from 12 pts in SURE-01, 24 in SURE-02, and 26 post-pembrolizumab alone. Decipher bladder genomic subtyping classifier (GSC) expression profiling assay (Veracyte) was used to compare molecular subtyping distributions and genes/signatures expressions between matched pre-post NAT samples, including 192 locked transcriptomic signatures in GRID (v3.1) and prespecified therapeutic target genes. FGFR3-active tumors were determined using a previously-developed long non-coding RNA (lncRNA)-based classifier. The clinical primary endpoint was event-free survival (EFS). **Results:** Post-NAT molecular subtyping identified Luminal (L) vs non-Luminal (NL) tumors in: 17% (2/12) vs 83% (10/12) (SURE-01), 21% (5/24) versus 79% (19/24) (SURE-02), and 8% (2/26) versus 92% (24/26) (PURE-01). In total, 21 pts from SURE studies and 22 from PURE-01 had matched pre-post NAT samples. Consensus molecular subtyping revealed a concordance in 86% (6/7) of pts in SURE-01, 57% (8/14) in SURE-02 and 36% (8/22) in PURE-01. Stroma-rich tumors were found in 17% (2/12), 29% (7/24) and 50% (13/26) of post-NAT samples. After NAT, we found a decrease in L subtypes in SURE-01 (57% → 29%) and in SURE-02 (36% → 14%) vs an increase in stroma-rich (Consensus) subtype in SURE-02 (7% → 36%) and in PURE-01 (14% → 50%). Elevation of TGF-beta signaling hallmark (p=0.02) and immune exclusion (p=0.02) scores characterized post-NAT samples in SURE-01, while in SURE-02 we found elevated stromal gene scores (p=0.004) and lower DNA repair hallmark scores (p=0.03) after NAT. Comparing matched samples from SURE-01 and 02, we found significantly decreased TROP2 expression scores (p=0.03) and lower HER2 (p=0.06) and NECTIN4 expression (p=0.07). Application of the lncRNA-based FGFR3-activity classifier revealed a total of 10/36 (28%) FGFR3-active tumors post-NAT in SURE-01 and SURE-02, all without EFS events during follow-up. For SURE-02, we found 4/24 (17%) pts harboring claudin-low tumors post-NAT, who did not experience EFS events following adjuvant pembrolizumab, similar to the low EFS rate observed in PURE-01 (N=7, 22%). **Conclusions:** This study expands our knowledge on residual MIBC after various NAT, displaying a noteworthy plasticity and significant changes post-NAT that are important to unveil the biology of these tumors and putative biomarkers for sequential therapies. TRUCE-11: An open-label, single-arm, multicenter phase II study of tislelizumab combined with nab-paclitaxel for muscle-invasive urothelial bladder carcinoma. First Author: Zhouliang Wu, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: Neoadjuvant tislelizumab plus nab-paclitaxel may enhance pathologic response in muscle-invasive bladder cancer (MIBC), and TRUCE-11 evaluates its efficacy and safety prior to radical cystectomy (RC). **Methods:** TRUCE-11 is a multicenter phase II neoadjuvant study for eligible MIBC pts who had pure or mixed urothelial carcinoma of the bladder (cT2–4aNxM0). Pts received nab-paclitaxel 125 mg/m² IV on day 1, followed 2 h later by tislelizumab 200 mg IV (Q3W) for 2–3 cycles, then underwent RC with pathologic assessment. Imaging and urine cytology were performed at baseline and post-treatment. The primary endpoint was pathologic complete response (pCR). Secondary endpoints included pathologic downstaging rate (PaIR, ≤pT1), adverse events (AEs), and overall survival (OS). Exploratory analyses evaluated radiomics features (bladder MRI, PET/CT, and contrast-enhanced ultrasound) and serum biomarkers, including peripheral blood tumor whole-genome chromosomal aberration assay (PB-TWGCA). Transcriptomic biomarker discovery further highlighted GRHL1 using bulk RNA-seq and paired baseline/RC tumor scRNA-seq. **Results:** Between March 2024 and January 2026, 27 pts were enrolled; 21 underwent RC after neoadjuvant therapy. Among RC pts (n=21), 11 pts achieved pCR (52%) and 13 achieved PaIR (≤pT1, 62%). The most common grade 1–2 AEs were alopecia (86%), fatigue (76%), rash (43%), decreased appetite (38%), and fever (14%). No grade 3–4 AEs (CTCAE) were observed. After a median follow-up of 247 days (range, 65–677), all pts were alive. Among pts achieving pCR, pre-cystectomy MRI (DWI/ADC) showed no residual diffusion restriction and/or PET/CT showed no malignant findings, concordant with pathology. In 6 pCR pts with contrast-enhanced ultrasound, 5 (83%) demonstrated marked reduction or disappearance of tumor hypervascularity during treatment. In 5 pts, PB-TWGCA r-score was consistent with tumor burden. Transcriptomic analyses further suggested that tumor-cell GRHL1 expression might be underlying markers that predict adverse outcomes for the pCR and non-pCR pts cohorts in this crew. **Conclusions:** Neoadjuvant tislelizumab plus nab-paclitaxel achieved a high pCR and downstaging rate with no grade 3–4 AEs in pts with MIBC undergoing RC. Multimodal imaging and circulating/transcriptomic biomarkers (PB-TWGCA r-score and tumor-cell GRHL1) may aid response evaluation and require confirmation in larger cohorts. Clinical trial information: NCT05328336. Research Sponsor: Scientific Research Project of Tianjin Municipal Education Commission; grant no. 2024KJ192.

Neoadjuvant sacituzumab govitecan in patients with muscle-invasive bladder cancer: Final results and biomarker analyses of the SURE-01 trial. First Author: Brigida Anna Maiorano, Department of Medical Oncology, IRCCS San Raffaele Hospital, Milano, Italy

Background: To evaluate neoadjuvant sacituzumab govitecan (SG), followed by radical cystectomy (RC), in patients with muscle-invasive bladder cancer (MIBC) who are ineligible for/refuse neoadjuvant chemotherapy (NAC). We report the results of the primary analysis and final biomarker analyses of the open-label, phase 2 SURE-01 trial (NCT05226117). **Methods:** Patients aged ≥18 years, ECOG PS 0-1, with histologically confirmed cT2-T4aN0M0 MIBC, ineligible/refusing NAC, and scheduled for RC received 4 cycles of SG 10 mg/Kg on D1 and D8, every three weeks (Q3W), followed by RC. The primary outcome measure was the pathological complete response (pCR) rate. Transcriptome-wide analyses and comprehensive genomic profiling assays were performed on baseline tumor samples. **Results:** From 03/22 to 07/25, 44 patients were treated and efficacy evaluable. After the initial 8 patients enrolled, the protocol was amended with a SG dose of 7.5 mg/Kg, with primary prophylaxis for neutropenia, due to the occurrence of two deaths (one treatment-related). Subsequent Grade 3-4 treatment-related adverse-events (TRAE) occurred in 5 pts (13.9%). Twenty-six patients (59.1%) had a cT3-4 stage, 20 (45.5%) had a variant histology. Fourteen patients (31.8%) refused to undergo RC and underwent a repeated transurethral resection of the bladder tumor. The median follow-up was 22 months (interquartile range: 15-26). In the intention-to-treat population: the ypT0N0-x rate was 29.5% (95% confidence interval [CI]: 16.7-45.2). We observed an enrichment of ypT0 responses in non-Luminal subtypes (46% vs 14% of Luminal), with the Infiltrated Luminal subtype having the highest proportion of ypT0 (62%). Variance by subtype revealed that TOP1 had the lowest scores in the Infiltrated Luminal subtype. A few signatures involving metabolism and tumor microenvironment were statistically significantly associated with a lower odds ratio of ypT0, whereas TROP2 expression (p=0.72) was not. The 24-month event-free survival (EFS) rate was 71.4% (95%CI: 58-87.8) and the 24-month overall survival (OS) rate was 80.2% (95%CI: 67.7-95). Longer EFS was observed for participants with lower TOP1-expressing tumors (p=0.04). **Conclusions:** To our knowledge, SURE-01 is the first to report results of an antibody-drug conjugate monotherapy targeting TROP2 in the neoadjuvant setting for patients with MIBC. Neoadjuvant SG at the reduced dose of 7.5mg/kg demonstrated compelling activity and survival estimates, with a manageable safety profile, corroborating TROP2 as a suitable target for MIBC. Molecular biomarkers pointing to the payload were associated with neoadjuvant SG activity. Clinical trial information: NCT05226117. Research Sponsor: None.

Association of GLP-1 receptor agonist therapy with BCG response in high-risk non–muscle invasive bladder cancer. First Author: Benyamin Yaniv, UMass Chan Medical School, Worcester, MA

Background: Observational studies suggest glucagon-like peptide-1 receptor agonists (GLP-1RAs) are associated with reduced cancer incidence and improved survival in patients with established malignancies. Cohort data in lung cancer also suggest improved outcomes with immune checkpoint inhibitor therapy among patients receiving GLP-1RAs, raising the possibility of enhanced anti-tumor immunity. Intravesical Bacillus Calmette–Guérin (BCG) remains the mainstay treatment for high-risk (HR) non-muscle invasive bladder cancer (NMIBC). We hypothesized that GLP-1RA exposure during BCG therapy is associated with more favorable clinical outcomes in HR-NMIBC. **Methods:** Patients with HR- NMIBC treated between November 1st 2015 to November 1st 2025 were evaluated retrospectively using the TriNetX US Research Network. Patients were stratified by GLP-1RA exposure before BCG initiation (with or without overlap during BCG) versus no exposure. Cohorts were propensity score–matched for demographics and comorbidities, and outcomes were evaluated using multivariable logistic regression. The primary outcome was mortality; secondary outcomes included recurrence, progression to muscle-invasive bladder cancer (MIBC), cystectomy, and distant metastasis. **Results:** A total of 12,423 patients were evaluated, of which 791 (7%) received GLP-1RAs, while 11,630 (93%) did not. After propensity score matching, 787 patients were analyzed in each group. The average age in both cohorts was 73 years. Majority of patients were white (85%), male (80%), and non-Hispanic (85%). The distribution of GLP-1RAs use included semaglutide (67%), dulaglutide (37%), tirzepatide (21%), liraglutide (17%), exenatide (8%), and lixisenatide (1%). Patients who received GLP-1RAs demonstrated a significant reduction in 10-year mortality (RR 0.65; 95% CI 0.45 – 0.93, p = 0.017) and a lower risk of developing MIBC (RR 0.43; 95% CI 0.26 – 0.89; p = 0.018). No significant changes were noted in the risk of disease recurrence, radical cystectomy or distant metastasis (Table 1). **Conclusions:** In this real-world, retrospective, multi-cohort analysis we found that patients who received GLP-1RAs prior to BCG treatment are at a decreased risk of all-cause mortality, and less likely to develop progression to MIBC. This study underscores the need for further evaluation of GLP-1RAs in patients with NMIBC treated with BCG. Research Sponsor: None.

Outcomes comparing HR-NMIBC patients exposed to GLP-1RA prior to BCG therapy versus those without exposure.

Outcome	Risk Ratio (95% CI)	p-value
Mortality	0.65 (0.45 – 0.93)	0.017
MIBC progression	0.43 (0.26 – 0.89)	0.018
NMIBC recurrence	0.98 (0.89 – 1.09)	0.84
Radical cystectomy	0.94 (0.72 – 1.22)	0.65
Distant metastasis	0.83 (0.62 – 1.11)	0.19

4621 **Poster Session**

Rethinking the role of tumor size in bladder preservation: Comparing survival outcomes of radical cystectomy (RC) and tri-modality therapy (TMT). First Author: Dawood Hasan Syed, Geisinger Health System, Wilkes-Barre, PA

Background: TMT (maximal TURBT followed by chemoradiation) is typically reserved for bladder cancer (BC) patients with solitary tumors less than 6 cm, no extensive carcinoma in situ, and no or unilateral hydronephrosis. The National Comprehensive Cancer Network (NCCN) guidelines specify that optimal candidates for bladder preservation with chemo-radiotherapy have tumors less than 6 cm; larger tumors are less likely to be completely resected and have poorer local control and survival outcomes with bladder-sparing approaches. We aimed to analyze outcomes of BC patients receiving multimodal therapy and further categorizing outcomes of RC versus TMT based on tumor sizes. **Methods:** We analyzed patients with T1–T4, N0–N3, M0 urothelial carcinoma of the bladder using the NCDB (2010–2022). Patients were grouped as: RC, neoadjuvant chemotherapy (NAC) plus RC, RC followed by adjuvant chemotherapy (AC), and TMT. Overall survival (OS) was estimated with Kaplan–Meier methods and multivariable Cox regression adjusted for common confounders for these four groups. We also further analyzed the role of tumor size for patients who received either RC or TMT. Tumor size was divided in three groups; less than 3cm, 3 to 6cm, and more than 6cm. **Results:** Among 33,836 patients (median age 68y), treatment groups were as follows: RC alone (34%), NAC-RC (23%), RC-AC (21%) and TMT (22%). BC specific prognostic factors like tumor size more than 6cm vs 3cm (HR 1.70 (1.62–1.77) ($p < 0.001$)) and lymphovascular invasion (LVI) (HR 1.94 (1.87–2.00), $p < 0.001$)) were independently associated with poor OS. In our analysis, NAC-RC (HR 0.67 (0.64–0.70, p = 0.001) followed by RC-AC (HR 0.72 (0.69–0.75, p = 0.001) conferred the heaviest OS benefit. When tumor size was investigated as a prognostic factor comparing RC versus TMT, multivariate analysis showed that for both tumors less than 3cm (HR = 1.27 (1.16–1.39), p = 0.001) and 3cm to 6cm (HR 1.08(1.03–1.14), p = 0.003), RC was significantly superior in terms of OS. Interestingly, for tumors more than 6cm (HR = 0.97 (0.88–1.06), p = 0.468), the analysis revealed no significant difference in OS between RC and TMT. **Conclusions:** Despite NAC-RC offering the greatest overall survival (OS) benefit and being the standard of care, it is frequently underutilized as many patients are not candidates for chemotherapy. Consequently, bladder preservation strategies (BPS) are essential. Our analysis shows tumor size may dictate the optimal curative approach. For smaller tumors (< 3 cm and 3cm to 6cm), Radical Cystectomy (RC) is significantly superior to TMT in terms of OS. Conversely, for large tumors (> 6cm) RC provided no significant OS benefit over TMT. This suggests that the inherent aggressiveness of large lesions overrides any surgical advantage. Therefore, BPS must be strongly considered for tumors $>$ 6cm when other TMT contraindications (e.g., hydronephrosis) are absent. Research Sponsor: None.

Exploration of biomarkers for TRUCE-01: Development of a urine-based efficacy prediction model. First Author: Yuda Lin, The Second Hospital of Tianjin Medical University, Tianjin, China

Background: Preliminary results from the TRUCE-01 phase II trial (NCT04730219) indicate encouraging antitumor activity and a manageable safety profile for the combination of the immune checkpoint inhibitor tislelizumab and nab-paclitaxel in patients with T2-4a N0/X M0 muscle-invasive bladder cancer (MIBC) of predominant urothelial carcinoma histology. To identify patient subgroups that may derive particular benefit, we conducted a comprehensive biomarker analysis. **Methods:** We performed whole-exome sequencing (WES) on baseline tumor tissue from 44 patients. Concomitantly, urine samples were collected during treatment. Baseline urine from 44 patients was subjected to 808-panel circulating tumor DNA (ctDNA) detection, and low-depth whole-genome sequencing (WGS) was performed across three time points (pre-treatment, during treatment, and post-treatment) for 47 patients. **Results:** The classic biomarker PD-L1 expression failed to predict complete response (CR) Urine-derived biomarkers showed high concordance with tissue-based mutation profiles. Specifically, urinary mutations in RB1, ERCC2, and AR were associated with CR, while mutations in ELF3, KDM6A, and TP53 were linked to non-clinical response (NCR). Baseline ctDNA levels (p=0.016) and baseline (p=0.011)/post-treatment (p=0.0011) WGS scores were significantly higher in the NCR versus CR group, potentially reflecting higher tumor burden. Interestingly, only two patients who achieved CR later experienced disease progression; both showed a rising trend in WGS scores during treatment, suggesting that CR does not ensure long-term favorable prognosis and that dynamic urine monitoring may be crucial during treatment. Finally, we developed a predictive model integrating urinary WGS scores, ctDNA scores, and efficacy-associated mutation genes. This integrated model achieved an area under the curve (AUC) of 0.930, significantly outperforming models based on WGS score alone (AUC=0.695) or ctDNA score alone (AUC=0.749). **Conclusions:** Urine-based biomarker assays show promise for predicting response to chemo-immunotherapy in MIBC. Further studies with expanded sample sizes and multi-center validation are warranted to confirm these findings and assess their clinical utility in broader patient cohorts. Clinical trial information: NCT04730219. Research Sponsor: None.

Chemoablation with oral erdafitinib in recurrent *FGFR3*-altered non–muscle-invasive bladder cancer: A phase II window-of-opportunity trial. First Author: Muhammad Hassan Alkazemi, Urologic Oncology Service, New York City, NY

Background: Non-muscle invasive bladder cancer (NMIBC) frequently recurs despite intravesical treatments, necessitating repeated transurethral resections of bladder tumors (TURBT). FGFR3 alterations are common in NMIBC and may be a potential therapeutic target. Erdafitinib, a pan-FGFR inhibitor, is approved for metastatic urothelial cancer, but its efficacy as a chemoablative agent in recurrent NMIBC is not yet established. This trial evaluates the efficacy of oral erdafitinib as a chemoablative treatment in patients with recurrent FGFR3-altered NMIBC. **Methods:** Patients with recurrent NMIBC and FGFR3 alterations detected with MSK-IMPACT were given oral erdafitinib (6 mg daily) for ~28 days before TURBT. Tumor response was assessed using RECIT-Bladder criteria, and tissue, blood, and urine samples were collected for pharmacodynamic analyses and biomarker exploration. Toxicities were graded using CTCAE v5.0. **Results:** A total of 20 patients with recurrent NMIBC and confirmed FGFR3 mutations were enrolled in the study. The most common mutations were S249C (n=12), Y373C (n=3), and R248C (n=3). Most patients (70%) had a history of low-grade Ta (LG Ta) tumors. All patients had received at least one prior intravesical therapy, with 55% having undergone multiple courses of BCG, gemcitabine, mitomycin, or combination regimens. The objective response rate (ORR) was 75% (15/20), with complete response (CR) achieved in 11 patients (55%). No grade ≥3 toxicities were observed. **Conclusions:** Oral erdafitinib demonstrated efficacy in reducing tumor burden in select FGFR3-altered NMIBC in this window-of-opportunity trial. Clinical trial information: NCT04917809. Research Sponsor: Janssen; ASCO YIA.

Durvalumab (D) in combination with BCG induction and maintenance (I + M) therapy for BCG-naive, high-risk non–muscle-invasive bladder cancer (NMIBC): 5-year overall survival (OS) analysis and patient-reported outcomes (PROs) from POTOMAC. First Author: Maria De Santis, Department of Urology, Charité Universitaetsmedizin Berlin, Berlin, Germany and Department of Urology, Medical University of Vienna, Vienna, Austria

Background: In the Phase 3 POTOMAC study (NCT03528694), 1 year of D in combination with BCG (I + M) resulted in a statistically significant and clinically meaningful improvement in disease-free survival vs BCG (I + M) alone, with a manageable safety profile, in patients (pts) with BCG-naive, high-risk NMIBC. We report a planned updated 5-year OS analysis and PROs. **Methods:** Eligible pts were randomized 1:1:1 to D + BCG (I + M), D + BCG (I only), or BCG (I + M). Secondary endpoints included 5-year OS and PROs, evaluated every 8 weeks by EORTC QLQ-C30 and every 4 weeks by EORTC QLQ-NMIBC24 and PRO-CTCAE. Prespecified priority subscales were global health status/quality of life (GHS/QoL), physical functioning, and fatigue for QLQ-C30; and urinary symptoms, intravesical treatment (tx) issues, future perspective/worries, and sexual functioning for QLQ-NMIBC24. Change from baseline (CFB; mixed model for repeated measures) was assessed; a ±10-point score was considered clinically meaningful. **Results:** At data cutoff Oct 3, 2025 (median follow-up 72 months), the OS HR was 0.81 (95% CI, 0.54–1.19) with a 5-year OS rate of 87.6% (95% CI, 83.5%–90.8%) for D + BCG (I + M) vs 86.3% (95% CI, 82.1%–89.6%) for BCG (I + M). Median OS was not reached in either arm. For PRO analyses (data cutoff Apr 3, 2025), QLQ-C30 and QLQ-NMIBC24 baseline compliance rates were ≥74% and ≥79%, respectively, with similar baseline scores between arms. Overall, both arms showed deterioration in QLQ-C30 adjusted mean CFB scores, with suggested clinically meaningful deterioration for fatigue with D + BCG (I + M); however, the difference between arms was small (Table). Overall QLQ-NMIBC24 adjusted mean CFB scores were numerically small and similar between arms (Table). PRO-CTCAE measures were similar between arms. **Conclusions:** Addition of 1 year of D to BCG (I + M) continued to show no detriment to OS at >5.5 years of follow-up and had no major impact on PROs for pts with BCG-naive high-risk NMIBC. Clinical trial information: NCT03528694. Research Sponsor: AstraZeneca.

Subscales	D + BCG (I + M) Adjusted mean CFB (95% CI)[a]	BCG (I + M) Adjusted mean CFB (95% CI)[a]	Estimated difference of means (95% CI)
QLQ-C30			
GHS/QoL[b]	−7.6 (−9.19, −6.07)	−4.9 (−6.46, −3.41)	−2.7 (−4.85, −0.54)
Physical functioning[b]	−5.5 (−6.76, −4.15)	−2.8 (−4.11, −1.56)	−2.6 (−4.43, −0.81)
Fatigue[c]	10.1 (8.32, 11.90)	6.1 (4.37, 7.88)	4.0 (1.50, 6.46)
QLQ-NMIBC24			
Urinary symptoms[c]	1.7 (−0.06, 3.41)	0.4 (−1.27, 2.15)	1.2 (−1.19, 3.65)
Intravesical tx issues[c]	1.5 (−0.38, 3.28)	2.7 (0.89, 4.50)	−1.2 (−3.79, 1.29)
Future perspective/worries[c]	−5.5 (−7.54, −3.39)	−3.2 (−5.29, −1.19)	−2.2 (−5.11, 0.66)
Sexual functioning[b]	2.2 (0.47, 3.91)	1.1 (−0.60, 2.80)	1.1 (−1.30, 3.48)

[a]Higher scores indicate better health (GHS/functioning) or greater burden (symptoms).
[b]Positive difference favors D + BCG (I + M).
[c]Negative difference favors D + BCG (I + M).

4626 **Poster Session**

Updated efficacy and safety of SHR-1501, an IL-15RαFc superagonist, with or without Bacille Calmette Guerin (BCG) for high-risk non-muscle invasive bladder cancer (NMIBC): A phase 1/2 study. First Author: Zhisong He, The First Hospital of Peking University, Beijing, China

Background: SHR-1501, an IL-15 agonist fusion protein composing of a humanized antibody Fc region fused with IL-15 and IL-15Rα sushi domain, demonstrated promising efficacy, well tolerance, and acceptable safety in alone or in combination with BCG in patients with BCG-naive and BCG-unresponsive high-risk NMIBC (*ASCO 2025*). Here, we report the updated results of this phase 1/2 study (NCT05410730). **Methods:** In the dose-escalation phase 1a and 1b parts, SHR-1501 monotherapy (200, 400, and 600 μg) or SHR-1501 (600 μg) in combination with BCG (120 mg) was administered to patients with high-risk NMIBC. In the phase 2 part, patients with BCG-naive NMIBC (cohort A), BCG-unresponsive NMIBC carcinoma in situ (CIS; cohort B), and BCG-unresponsive high-grade Ta/T1 NMIBC without CIS (cohort C) were enrolled to receive SHR-1501 (600 μg) plus BCG (120 mg). During the induction phase, all patients received weekly intravesical study treatment for 6 weeks. In the maintenance phase, instillations were administered weekly for three weeks at months 3, 6, 12, 18, and 24 following the initial induction dose. Primary endpoints were dose-limiting toxicity (DLT), maximum tolerated dose (MTD), and recommended phase 2 dose in phase 1a and 1b parts; and was complete response (CR) rate for cohort B and 12-mo disease-free survival (DFS) rate for cohorts A and C in phase 2 part. **Results:** As of Oct 31, 2025, 112 patients were enrolled (n=8 in phase 1a; n=6 in phase 1b; n=30, 25, and 43 in cohorts A, B, and C in phase 2). The median follow-up duration was 23.0 months (range 3.5-25.6) in patients with BCG-naive NMIBC, 6.5 months (range 2.6-21.2) in patients with BCG-unresponsive NMIBC CIS, and 13.5 months (range 2.5-23.1) in patients with BCG-unresponsive high-grade Ta/T1 NMIBC without CIS. In cohort B, the overall CR rate was 80.0% (20/25), the median DFS was 12.0 months (95% CI 6.0-NR). The 12-mo DFS rate was 90.3% (95% CI, 72.8-96.8) in patients with BCG-naive NMIBC and 62.7% (95% CI, 44.9-76.1) in patients with BCG-unresponsive high-grade Ta/T1 NMIBC without CIS. The 18-mo DFS rates were 90.3% (95% CI, 72.8-96.8) and 58.2% (95% CI, 39.6-72.9), respectively. Treatment-related adverse events (TRAEs) and grade 3 TRAEs occurred in 90 (86.5%) and 19 (18.3%) of 104 patients with SHR-1501 + BCG. The most common TRAEs were urinary tract infection (62.5%) and pollakiuria (35.6%). No TRAEs led to death. **Conclusions:** This updated analysis confirms the promising efficacy and manageable safety profile of SHR-1501 monotherapy or in combination with BCG in BCG-naive and BCG-unresponsive high-risk NMIBC patients. Two randomized, controlled phase 3 trials are underway in both BCG-unresponsive and BCG-naïve, high-risk NMIBC populations, with the recommended dose of 600 μg SHR-1501 plus BCG. Clinical trial information: NCT05410730. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co. Ltd.

Patient-reported outcomes from IMvigor011: A phase 3 study of circulating tumor (ct)DNA–guided adjuvant atezolizumab vs placebo in muscle-invasive bladder cancer (MIBC). First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute and Harvard University, Boston, MA

Background: IMvigor011 (NCT04660344) showed that serial ctDNA-based molecular residual disease (MRD) monitoring can identify patients (pts) with MIBC at very high risk of recurrence who benefit from adjuvant atezolizumab (atezo), demonstrating statistically significant and clinically meaningful improvements in DFS and OS vs placebo (pbo) in pts who tested ctDNA+. Pts who persistently tested ctDNA− had low risk of recurrence or death without adjuvant treatment (tx; Powles *NEJM* 2025). Here we report pt-reported outcomes (PROs). **Methods:** Pts with MIBC and no radiographic disease were enrolled and underwent serial ctDNA monitoring for up to 1 year after cystectomy; pts who tested ctDNA+ and remained disease-free were randomized to atezo or pbo every 4 weeks (wk) for 12 cycles or up to 1 year. PROs were assessed on Day (D)1 of Cycle (C)1, C3, C5, C7, C9, and C11, and at tx discontinuation. Time to confirmed deterioration (TTCD) analysis of physical functioning (PF), role functioning (RF), and global health status/quality of life (GHS/QoL) were secondary endpoints. Symptoms, functioning, and GHS/QoL per EORTC QLQ-C30, and tx side-effect burden per EORTC IL46, were exploratory endpoints. Relevant adverse events (AEs) were graded per NCI CTCAE v5. **Results:** Eligible pts who tested ctDNA+ (n=250) were randomized to atezo (n=167) or pbo (n=83). QLQ-C30 completion was >94% at C1D1 and >87% during tx, and >72% and >90%, respectively, for IL46. C1D1 completion rates were similar between arms. TTCD in PF, RF, and GHS/QoL showed no evidence of a difference between arms (Table). There was no clinically meaningful difference in mean change from C1D1 in symptoms, functioning, and GHS/QoL over time through C11D1 and between arms. From C1D1 to C11D1, >90% of pts reported little or no tx side-effect burden in both arms. Relevant safety data showed consistency between AEs and PROs. **Conclusions:** ctDNA-guided adjuvant atezo provided clinically meaningful DFS and OS benefit without negatively impacting pt-reported QoL. Clinical trial information: NCT04660344. Research Sponsor: F. Hoffmann-La Roche Ltd.

Molecular classification of neuroendocrine carcinoma of the bladder. First Author: Shijia Li, Bridgeport Hospital, Bridgeport, CT

Background: Neuroendocrine carcinoma (NEC) of the bladder is a rare and aggressive cancer with limited treatment options. Recent studies reported molecular subtypes resembling small cell lung cancer (SCLC), specifically those associated with transcription factors (TFs) ASCL1, NEUROD1, and POU2F3. A subset of bladder NEC remains unclassified. ATOH1 was recently identified as a TF associated with a minority of SCLC tumors. **Methods:** The Tempus Lens Platform (Tempus AI, Inc., Chicago, IL) was used to query the multimodal de-identified database and establish a cohort of 121 patients with bladder NEC. We analyzed the genomic and transcriptomic profiles using tempusverse and custom code. K-means consensus clustering of gene expression was used to identify molecular subtypes; subsequently, tumor genetic alterations (single-nucleotide variants [SNVs], indels, and copy number alterations [CNAs]) and gene expression profiles were compared across these subtypes. Fisher's exact test was used to compare the frequency of events across categorical groups. limma-trend and empirical Bayes statistics were used for differential gene expression analysis. The Cox proportional hazards model and the Kaplan-Meier method were used for survival analysis. consensusMIBC was used for the consensus molecular classification. **Results:** Within the cohort, 103 were classified as neuroendocrine (NE)-like using consensusMIBC and were further analyzed in this study. The median age at diagnosis was 71 years (interquartile range, 63–76), with a male predominance (77%). Using the four SCLC TFs (ASCL1, NEUROD1, POU2F3, and ATOH1; YAP1 was excluded as it was recently found to be expressed in the non-NE components of mixed bladder NECs), we identified a five-type system that classifies most samples: ASCL1+/NEUROD1- (n=37; 36%), ASCL1-/NEUROD1+ (n=23; 22%), ASCL1+/NEUROD1+ (n=16; 16%), POU2F3+ (n=23; 22%), and ATOH1+ (n=4; 4%). Each subtype was associated with a distinct gene expression profile with representative markers: ASCL1, SOX2, and DLL3 (ASCL1+/NEUROD1-); NEUROD1, NEUROD4, and SSTR2 (ASCL1-/NEUROD1+); ETV1, NKX2-1, and NKX2-2 (ASCL1+/NEUROD1+); POU2F3, GFI1B, and POU2AF2 (POU2F3+); ATOH1, POU4F3, and USH2A (ATOH1+). POU2F3+ tumors expressed low NE markers and high PLCG2 and ERBB3; ATOH1+ tumors often expressed NE markers and tended to overexpress ALK. No statistically significant tumor SNVs, indels, or CNAs were differentially observed across the subtypes; TP53 (92%), TERT (82%), and RB1 (62%) were the most frequently altered genes in the entire cohort. Univariate analysis showed a worse real-time overall survival of ASCL1+/NEUROD1+ (hazard ratio [HR]=3.1, p=0.01), POU2F3+ (HR=3.4, p=0.001), and ATOH1+ (HR=8.4, p=0.0003), compared with ASCL1+/NEUROD1- tumors. **Conclusions:** We report an effective, clinically relevant molecular classification system for bladder NECs, including the newly described ATOH1+ subtype. Research Sponsor: University of California San Francisco.

TPS4629 **Poster Session**

A phase II trial of neoadjuvant zanzalintinib (ZANZA) plus nivolumab (NIVO) in patients with locally advanced and/or surgically challenging clear cell renal cell carcinoma (EXPLORE-RCC). First Author: Qian Qin, Department of Internal Medicine, Division of Hematology and Oncology, UT Southwestern, Dallas, TX

Background: Immunotherapy doublet combinations (+/- vascular endothelial growth factor receptor-tyrosine kinase inhibitor [VEGFR-TKI]) are established for front-line treatment of metastatic, clear cell renal cell carcinoma (ccRCC). However, their role in the perioperative setting for locoregional ccRCC remains to be defined. We designed the EXPLORE-RCC trial to evaluate neoadjuvant ZANZA (novel, next generation VEGFR-TKI with short half-life) plus NIVO (PD-1 inhibitor) in patients with locally advanced ccRCC, where the combination has the potential to shrink the primary tumor, increase resectability, and/or allow a partial nephrectomy or minimally invasive approach. **Methods:** In this multisite, phase 2, open-label, single-arm trial coordinated by the Hoosier Cancer Research Network, subjects will receive ZANZA 60mg orally once daily plus NIVO intravenously per standard of care (SOC) dosing for 12 weeks (w), followed by restaging scans and an adaptive approach: (1) subjects who are deemed operable will undergo resection (Cohort A); (2) subjects who remain inoperable can receive up to 48w total of ZANZA plus NIVO (Cohort B1) with the option to undergo resection when deemed operable; or (3) subjects who have disease progression will stop protocol mandated therapy and receive subsequent SOC treatment (Cohort B2). The main inclusion criteria include age $\geq$ 18 years, ECOG Performance Status of 0-1, histologically confirmed ccRCC, and locally advanced (cT3/4, N0-1, with or without tumor thrombus) disease and/or deemed surgically challenging per surgeon discretion. Non-measurable metastasis per RECIST 1.1 criteria, including soft tissue metastasis with longest diameter $<$10mm or distant lymph nodes $<$15 mm in short axis are allowed. Main exclusion criteria are non-clear cell histology, measurable metastatic disease per RECIST 1.1 criteria, and prior systemic treatment for ccRCC. The primary endpoint is overall response rate (ORR) after 12w of therapy. This single arm trial is powered to detect an improvement in ORR from a historical rate of 30% to 45%, with 80% power and a 0.05 one-sided type I error. Estimating 10% drop out, 69 subjects will be enrolled. Key secondary/exploratory endpoints include efficacy outcomes (conversion to operable, disease free survival, overall survival, pathologic response), safety, surgery-related complications (including Clavien-Dindo), and biomarker correlatives. The trial is actively enrolling (ClinicalTrials.gov NCT06794229) at UT Southwestern and opening at Ohio State, Fox Chase Cancer Center, Virginia Commonwealth, Northwestern University, and Washington University in St Louis. Clinical trial information: NCT06794229. Research Sponsor: Exelixis.

TPS4630 **Poster Session**

A multicenter randomized controlled clinical study of neoadjuvant combination of axitinib plus toripalimab to improve disease-free survival of patients with renal cell carcinoma. First Author: Zhiling Zhang, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: Clear cell renal cell carcinoma (ccRCC) is the most common subtype of renal cell carcinoma, accounting for 75-80% of cases worldwide and 60-85% in China. High risk ccRCC includes tumors larger than 7 cm (T2 stage) or those at advanced stages ($\geq$T3 or N1). Surgical resection is standard, but 30% may have recurrence, with a 2-year disease-free survival rate of 68%. Neoadjuvant therapy with axitinib and toripalimab may enhance antitumor immunity and improve prognosis for high risk patients. **Methods:** This is an open-label, multicenter, phase III randomized controlled study to assess whether neoadjuvant axitinib plus toripalimab improves disease-free survival (DFS) compared with surgery alone in patients with ccRCC at high risk of recurrence. The study is designed to enroll 298 patients with high risk ccRCC (T2G4 or T3-4 or N1) scheduled for nephrectomy. Patients must provide an adequate tumor tissue sample at screening for molecular and immune profiling. Patients will be randomly assigned to the control group or the neoadjuvant group at a 1:1 ratio. Both groups will undergo nephrectomy, while the neoadjuvant group will additionally receive preoperative treatment with axitinib plus toripalimab. Axitinib will be given for 3 months, 5 mg twice daily, orally. Toripalimab will be administered at 240 mg intravenously every 3 weeks for 4 cycles (one cycle every 3 weeks). Blood samples are collected before and after neoadjuvant treatment for exploratory molecular analysis. CT or MRI assessments will be conducted after 2 cycles of medication and before surgery. Radical nephrectomy (or partial nephrectomy, if applicable) will be performed within 1-28 days after completion of neoadjuvant therapy. For both groups, if postoperative pathology meets high recurrence risk criteria per Keynote-564—specifically, T2G4, T2 with sarcomatoid differentiation, T3, T4, any T stage with lymph node metastasis, or M1 with no evidence of disease—1 year of adjuvant toripalimab is recommended according to NCCN and EAU guidelines. Eligible patients must be diagnosed as ccRCC or RCC with a predominant clear cell component through histopathological examination. Clinical staging via CT or MRI must indicate T2, while biopsy pathology should show either nuclear grade 4 or sarcomatoid differentiation, or a classification of T3-4 or N1. Additional inclusion criteria include: signed informed consent, age $\geq$18 and $<$ 80 years old, adequate organ function, ECOG of 0 or 1 point. The primary endpoint is 2-year DFS, defined as the time from randomization to disease recurrence or death from any cause. Secondary endpoints include cancer-specific survival, overall survival, objective response rate, major pathological response, and safety profile. Enrollment began in April 2023, and 112 of the planned 298 patients have been enrolled. Clinical trial information: NCT05738694. Research Sponsor: None.

TPS4631 **Poster Session**

Phase 3 study to assess the safety and efficacy of ^{177}Lu-girentuximab in advanced, relapsed, or recurrent ccRCC (LUTEON). First Author: David Cade, Telix Pharmaceuticals, North Melbourne, VIC, Australia

Background: A high unmet need remains for treatments that provide durable disease control while preserving quality of life in patients with advanced clear-cell renal cell carcinoma (ccRCC). Girentuximab is a monoclonal antibody targeting carbonic anhydrase IX (CAIX), which is expressed on $>$95% of ccRCC cells with limited expression in healthy tissues. Radiolabeling girentuximab with β emitting luteium-177 (^{177}Lu-girentuximab) enables targeted delivery to CAIX-expressing tumor cells. Phase 1 - 2 data of ^{177}Lu-girentuximab in patients with metastatic ccRCC suggest favorable safety, tolerability, and efficacy profile.[1,2,3] LUTEON is a Phase 3 study designed to assess safety and efficacy of ^{177}Lu-girentuximab in patients with advanced, relapsed or recurrent ccRCC. **Methods:** LUTEON is a 2-part, randomized, open-label, multicenter study to determine the optimal activity and schedule of ^{177}Lu-girentuximab (Part 1), and evaluate efficacy and safety of ^{177}Lu-girentuximab versus an approved monotherapy standard-of-care (SOC) comparator (Part 2). Eligible patients are aged $\geq$18 years, have relapsed or recurrent, locally advanced or metastatic, histologically or cytologically confirmed ccRCC, and have received 2-3 prior lines of systemic therapies (including a PD-1/PD-L1 inhibitor and a VEGF/VEGFR-targeting agent) for locally advanced or metastatic ccRCC. Patients must have CAIX-positive cancer as determined by ^{89}Zr-girentuximab PET (performed during screening). In Part 1, patients will be randomized 1:1 ($\leq$20/arm) to receive either 3 IV infusions of 1887 MBq ^{177}Lu-girentuximab every 8 weeks or 6 infusions of 1258 MBq ^{177}Lu-girentuximab every 4 weeks. Unacceptable toxicity is managed with predefined, clinically appropriate measures. In Part 2, patients will be randomized 1:1 to receive ^{177}Lu-girentuximab at the optimal regimen identified in Part 1 or an SOC comparator. In both parts, the end of treatment (EOT) visit occurs 3 $\pm$1 week after the last infusion or within 30 days of discontinuing treatment. After EOT, efficacy assessments occur every 8 $\pm$2 weeks for 6 months; patients will undergo tumor assessments according to RECIST 1.1 and will receive a contrast-enhanced CT and/or MRI of the chest, abdomen, and pelvis. In Part 2, after the first 6-month follow-up visits, patients continue follow-up every 12 $\pm$2 weeks for up to 24 months after the EOT visit or until progression of disease, death, or the initiation of new systemic anticancer therapies, whichever occurs first. The primary endpoints of Part 1 are incidence and severity of TEAEs, patient discontinuation due to TEAEs, and dosing delays due to TEAEs. The primary endpoint of Part 2 is progression-free survival, defined as time from randomization to first disease progression according to RECIST 1.1 or death due to any cause. This study is sponsored by Telix Pharmaceuticals. Clinical trial information: NCT07197580. Research Sponsor: Telix Pharmaceuticals.

TPS4633 **Poster Session**

LITESPARK-033: Phase 3 study of belzutifan plus zanzalintinib versus cabozantinib for recurrent clear cell renal cell carcinoma during or after adjuvant anti–PD-(L)1 therapy. First Author: Cristina Suárez, Vall d´Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d´Hebron, Vall d´Hebron Barcelona Hospital Campus, Barcelona, Spain

Background: Adjuvant pembrolizumab is standard of care for patients with renal cell carcinoma (RCC) at increased risk for recurrence after nephrectomy. However, treatment options are needed following adjuvant anti–PD-(L)1 therapy because none of the currently available treatments for advanced RCC were evaluated in this setting. Belzutifan, a potent and selective hypoxia-inducible factor 2α inhibitor, is approved for advanced RCC following a PD-(L)1 inhibitor and vascular endothelial growth factor tyrosine kinase inhibitor (VEGF-TKI). Zanzalintinib is a multitargeted kinase inhibitor of VEGF receptors, MET, and the TAM family of kinases (TYRO3, AXL, and MER). VEGF-TKIs, such as cabozantinib, are approved as first-line treatment for advanced RCC and in patients who have received subsequent lines of therapy. Promising antitumor activity has been observed in phase 2 studies when combining a VEGF-TKI with belzutifan for advanced clear cell RCC. The randomized, multicenter, open-label phase 3 LITESPARK-033 study (NCT07227402) is designed to evaluate the efficacy and safety of belzutifan plus zanzalintinib versus cabozantinib in participants with advanced clear cell RCC who experienced recurrence during or after anti–PD-(L)1 adjuvant therapy. **Methods:** Eligible participants are aged $\geq$18 years with histologically confirmed, unresectable, advanced (stage IV) RCC with a clear cell component; have measurable disease per RECIST v1.1 as assessed by investigator; received adjuvant anti–PD-(L)1 therapy after nephrectomy; and experienced recurrence during or up to 24 months from the last dose of adjuvant therapy. Approximately 904 participants will be randomly assigned 1:1 to receive belzutifan 120 mg orally once daily plus zanzalintinib 60 mg orally once daily or cabozantinib 60 mg orally once daily. Treatment will continue until unacceptable toxicity or disease progression. Randomization will be stratified according to time of recurrence after adjuvant anti–PD-(L)1 therapy ($\leq$6 months vs $>$6 months after the last dose), International Metastatic RCC Database Consortium risk (favorable vs intermediate vs poor), and presence of sarcomatoid features (yes vs no). Primary end points are progression-free survival per RECIST v1.1 as assessed by blinded independent central review (BICR) and overall survival. Secondary end points are objective response rate and duration of response per RECIST v1.1 as assessed by BICR, and safety. The study is open and currently enrolling as of November 26, 2025. Clinical trial information: NCT07227402. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS4634 **Poster Session**

ZAMBONI: A phase II study of zanzalintinib for metastatic clear cell renal cell carcinoma with bone metastases previously treated with immune checkpoint inhibitors. First Author: Kelly N. Fitzgerald, University of California, San Francisco, San Francisco, CA

Background: Bone metastases (BM) in metastatic renal cell carcinoma (mRCC) are associated with aggressive disease behavior and poor prognosis, particularly following progression on immunotherapy (IO)-based treatment regimens. Oral vascular endothelial growth factor receptor (VEGFR)-targeting tyrosine kinase inhibitors (TKIs) have demonstrated efficacy in mRCC with BM and have been shown to modulate production of osteoclastogenic factors in the tumor microenvironment. Zanzalintinib is a novel oral VEGFR-targeting TKI that has demonstrated a tolerable safety profile in phase I studies; its broad multikinase targeting profile and short half-life of 16-22 hours may enhance efficacy and tolerability compared with other VEGFR-targeting TKIs. However, the efficacy of zanzalintinib in patients with BM is unknown. **Methods:** This is a single-institution, phase II trial of zanzalintinib plus investigator-choice bone modifying agent (BMA) in patients with metastatic clear cell RCC with BM that has been previously treated with immunotherapy (IO). Eligible patients will have primarily clear cell histology, at least three BM including at least one BM not previously treated with radiation therapy (RT), and prior disease progression on 1-3 prior lines of therapy including at least one IO-based therapy administered in either the adjuvant or metastatic setting. Measurable disease based on Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 is not required. Patients will receive zanzalintinib 60mg by mouth daily in 28-day cycles; treatment will be continued until disease progression or unacceptable toxicity occurs. Dose reduction, re-escalation, or interruption of up to 6 weeks is allowed for patients experiencing adverse events. Investigator-choice BMA may include zoledronic acid, pamidronate, ibandronate, or denosumab, will be administered at a standard dose/interval starting within 30 days of cycle 1, day 1 (C1D1), and continued until criteria for discontinuation of BMA or removal from study are met. RT and/or steroid therapy for symptomatic metastases, including BM, is allowed per investigator discretion. Patients will be radiologically evaluated starting 8 weeks after C1D1 and every 12 weeks thereafter. Adverse events will be monitored throughout the study and for 30 days following cessation of study treatment. Enrollment will continue until 20 patients evaluable for primary endpoint are enrolled, or up to a maximum of 24 patients. The primary endpoint is 12-month landmark progression-free survival and will be evaluated in patients with RECIST-measurable disease at baseline; key secondary endpoints include overall survival, rate of skeletal-related events, and rate of osteonecrosis of the jaw and will be measured in all patients. Clinical trial information: NCT07043608. Research Sponsor: Exelixis.

TPS4635 **Poster Session**

First-in-human study of [^{111}In] XYIMSR-01 SPECT/CT, a novel carbonic anhydrase IX small molecule in patients with metastatic clear cell renal cell carcinoma. First Author: Yasser Ged, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD

Background: Clear cell renal cell carcinoma (ccRCC) accounts for approximately 75% of renal cancers and is characterized by von Hippel–Lindau (VHL) inactivation and subsequent upregulation of hypoxia-inducible factor-2α (HIF-2α), leading to overexpression of carbonic anhydrase IX (CAIX) in over 95% of tumors. CAIX represents an attractive theranostic target for molecular imaging and radioligand therapy. XYIMSR-01 is a novel low-molecular-weight CAIX-targeted molecule engineered for rapid clearance, high tumor to background contrast, and potential same-day imaging. Preclinical studies demonstrated strong tumor uptake, favorable biodistribution, and selective retention in CAIX-expressing ccRCC xenografts, supporting clinical translation. Based on these findings, a first-in-human study of indium-111 labeled XYIMSR-01 using single photon emission computed tomography (SPECT/CT) imaging has been initiated in patients with metastatic ccRCC. **Methods:** This is an investigator-initiated, single-center, phase I study conducted at the Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, designed to evaluate the safety, tolerability, and feasibility of [^{111}In]XYIMSR-01 SPECT/CT imaging in patients with metastatic ccRCC. Eligible patients must have histologically confirmed ccRCC, $\geq$2 measurable metastatic lesions (size of each lesion at least $\geq$1.5 cm), treatment naïve, and have adequate organ and marrow function. Following informed consent, patients receive a single intravenous injection of 10.5 $\pm$ 1 mCi of [^{111}In]XYIMSR-01, followed by whole-body planar and regional SPECT/CT imaging at 2-4, 24 $\pm$ 1, and 48 $\pm$ 1 hours post-injection. Blood samples are collected at multiple time points up to 48 hours to assess pharmacokinetics, clearance, and metabolic profile. Radiation dosimetry is calculated from serial imaging to estimate absorbed doses to tumor and normal organs. The primary objective is to assess the safety, tolerability, and feasibility of imaging with [^{111}In]XYIMSR-01. Secondary objectives include characterization of biodistribution, radiation dosimetry, and pharmacokinetics. Exploratory analyses will evaluate concordance between [^{111}In]XYIMSR-01 SPECT/CT with standard CT or MRI for lesion detection. The planned sample size is up to 10 patients. Successful completion of the study may support the development of future CAIX-targeted theranostic strategies in ccRCC. Clinical trial information: NCT07062549. Research Sponsor: None.

TPS4636 **Poster Session**

PEAK-1: A randomized, double-blind, active-control, multicenter phase 3 trial of casdatifan and cabozantinib versus placebo and cabozantinib in patients with advanced clear cell renal cell carcinoma. First Author: Toni K. Choueiri, Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: For patients (pts) with advanced or metastatic clear cell renal cell carcinoma (ccRCC) who have relapsed post anti-PD-1/PD-L1 treatment, second line treatment options remain limited, consisting primarily of tyrosine kinase inhibitors (TKI) monotherapy. Hypoxia-inducible factor 2 alpha (HIF-2α) inhibition represents a promising target as its mechanism of action has been clinically validated in ccRCC and is distinct from that of TKIs without overlapping toxicities. Casdatifan (cas) is an orally bioavailable, selective HIF-2α inhibitor that has a potentially improved pharmacodynamic profile relative to other members of the therapeutic class (Ghasemi 2025). Combining cas with a TKI (cabozantinib [cabo]) that targets VEGFR, MET, and AXL may yield enhanced antitumor activity beyond the individual agents. Preliminary efficacy data from the Phase 2 ARC-20 Study demonstrated promising antitumor activity with the combination (cas + cabo; Choueiri 2025). PEAK-1 is currently the only Phase 3 that examines the efficacy and safety of a HIF-2α inhibitor in combination with a TKI in ccRCC. **Methods:** PEAK-1 (NCT07011719) is an ongoing Phase 3, randomized, active-control, double-blind, 2-arm, global, multicenter study in adult pts with confirmed advanced or metastatic ccRCC who have experienced progression on or after anti-PD1 or anti-PD-L1 treatment. Approximately 720 pts will be enrolled and randomized 2:1 to treatment with 100 mg QD cas + 60 mg QD cabo (experimental arm) or placebo + 60 mg QD cabo (comparator arm). Crossover is not allowed. Stratification factors include by region (North America vs Western Europe vs rest of world); prior VEGFR-TKI (yes vs no); and International Metastatic RCC Database Consortium risk score (favorable vs intermediate/poor). Key eligibility requirements include adults ($\geq$ 18 years) who have received anti-PD-1 or anti-PD-L1 treatment as part of the most recent regimen (either adjuvant monotherapy or first line in combination with anti-CTLA-4 or VEGFR-TKI), with $\leq$ 1 prior regimens in the metastatic setting. Pts must have a Karnofsky Performance Status score $\geq$ 80%, at least 1 target lesion measurable by computed tomography/magnetic resonance imaging per RECIST 1.1, and adequate organ and marrow function. Key exclusion criteria include prior treatment with a HIF-2α inhibitor or cabo, receiving ongoing concomitant treatment with moderate or strong CYP3A4 inducers, and uncontrolled or poorly controlled hypertension (sustained blood pressure $>$140/90 mm Hg on $\geq$ 3 antihypertensives). The primary endpoint of the study is PFS BICR according to RECIST 1.1. Secondary endpoints include safety, overall survival, overall response rate, duration of response, and disease control rate. Pt reported outcomes using NFKSI-DRS will also be assessed. Enrolment is ongoing as of 1 Oct 2025. Clinical trial information: NCT07011719. Research Sponsor: Arcus Biosciences, Inc.

TPS4637 **Poster Session**

Phase II study of cemiplimab ± fianlimab following SBRT for oligometastatic clear-cell RCC (LAG-BOOST). First Author: Abhirami Das, Department of Internal Medicine, College of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Oligometastatic clear-cell renal cell carcinoma (ccRCC) is a biologically distinct, often indolent state where metastasis-directed therapy, including metastasectomy or SBRT, provides durable local control and delays systemic therapy. Randomized prospective trial evidence demonstrates a survival benefit with adjuvant programmed cell death-1 (PD-1) inhibition following surgical metastasectomy in oligometastatic ccRCC. However, the role of adjuvant PD-1 inhibition following stereotactic body radiation therapy (SBRT) has not been prospectively evaluated. SBRT induces immunogenic tumor cell death, enhances tumor antigen presentation, and promotes T-cell priming, providing a strong biologic rationale for evaluating PD-1 inhibition following SBRT. Beyond PD-1 blockade alone, lymphocyte activation gene-3 (LAG-3) is an inhibitory immune checkpoint expressed on tumor-infiltrating lymphocytes in ccRCC and contributes to T-cell exhaustion and immune evasion. Dual PD-1 and LAG-3 blockade has demonstrated promising antitumor activity with acceptable tolerability in early-phase studies, supporting investigation of strategies to enhance the efficacy of adjuvant PD-1 inhibition following SBRT in oligometastatic disease. **Methods:** LAG-BOOST is a 1:1 randomized, prospective, multicenter, investigator-initiated phase II trial. Eligible patients have histologically confirmed oligometastatic ccRCC, defined as $\leq$5 metastatic lesions by RECIST v1.1, all amenable to SBRT. Following SBRT to all visible lesions, patients are randomized to receive one year of adjuvant PD-1 inhibition (cemiplimab) alone or combined PD-1 and LAG-3 inhibition (cemiplimab and fianlimab). Treatment continues for up to one year or until disease progression, unacceptable toxicity, or withdrawal of consent. Patients must be naïve to systemic therapy for metastatic RCC; prior adjuvant therapy for non-metastatic RCC is permitted in the absence of radiographic disease progression within 12 months of treatment completion. Stratification is based on International Metastatic RCC Database Consortium (IMDC) risk and metastatic burden: (1) favorable or intermediate IMDC risk with 3 or fewer metastatic lesions and no brain metastases versus (2) poor IMDC risk or 4–5 metastatic lesions or the presence of brain metastases. The primary endpoint is 1-year progression-free survival (PFS). Secondary endpoints include safety and tolerability (treatment-related adverse events per CTCAE v5.0), objective response rate by RECIST v1.1, duration of response, disease control rate, and overall survival. As of submission, 2 of the planned 72 patients have been enrolled. The study is powered for H_0: 65% versus H_a: 85% 1-year PFS, with α = 0.05 and power = 0.8. ClinicalTrials.gov identifier: NCT07223541. Clinical trial information: NCT07223541. Research Sponsor: Regeneron Pharmaceuticals.

TPS4638 **Poster Session**

A phase I, first-in-human study to evaluate the safety, tolerability, pharmacokinetics, and preliminary anti-tumor activities of GenSci139 in patients with solid tumors. First Author: Jinming Yu, Shandong Cancer Hospital, Jinan, China

Background: HER2 and EGFR are frequently co-expressed in solid tumors. Bispecific targeting of these receptors can produce synergistic enhancement in cell binding and internalization, potentially overcoming monotherapy resistance and maintaining efficacy in low antigen-expression settings. GenSci139 is a bispecific antibody-drug conjugate (ADC) directed against both EGFR and HER2, incorporating a cleavable linker to deliver a topoisomerase I inhibitor. In preclinical studies, GenSci139 demonstrated broad-spectrum efficacy, surpassing ENHERTU in HER2-low tumor models. It also displayed a favorable pharmacokinetic and a tolerable safety profile. These findings support further clinical evaluation of GenSci139 in urothelial carcinoma (UC), non-small cell lung cancer (NSCLC), gastric cancer (GC), triple-negative breast cancer (TNBC) and other EGFR/HER2-driven malignancies. **Methods:** This first-in-human, open-label study (NCT07230977) comprises a dose escalation phase with backfill (Part 1) and a dose expansion phase (Part 2). Part 1 employs an accelerated titration followed by a "3+3" design to determine the maximum tolerated dose (MTD) and/or recommended dose for expansion (RDE). Backfill cohorts will be enrolled at selected dose levels according to predefined criteria. Part 2 will further evaluate preliminary antitumor activities in predefined cohorts. Key eligibility criteria include advanced solid tumors, measurable disease per RECIST1.1, adequate hematologic and organ function, being able to provide tumor tissues. GenSci139 is administered intravenously every 3 weeks until disease progression, unacceptable toxicity, withdrawal of consent, initiation of alternative anticancer therapy, or other discontinuation criteria are met. Primary endpoints in Part 1 include the incidence of dose-limiting toxicities (DLTs), treatment-emergent adverse events (TEAEs). After determination of the MTD/RDE, Part 2 will evaluate the preliminary anti-tumor activity of GenSci139, with primary endpoints including objective response rate (ORR), disease control rate (DCR) and Duration of response (DoR). The study initiated in December 2025 and is currently recruiting. Clinical trial information: NCT07230977. Research Sponsor: None.

TPS4639 **Poster Session**

An open-label phase 1 study of DCC-2812 monotherapy in patients with advanced genitourinary cancers. First Author: Ildefonso I. Rodriguez Rivera, NEXT Oncology, San Antonio, TX

Background: The integrated stress response (ISR) is a major adaptive cellular response pathway that cancer cells depend on to survive in the context of oncogenic pathway activation and high proliferative demand. The ISR is tightly regulated by stress-sensing kinases, including general control nonderepressible 2 (GCN2). Under a controllable level of cellular stress, moderate activation of GCN2 promotes adaptation to nutrient and oxygen deficiency, supporting cancer cell survival. In contrast, excessive GCN2 activation in response to unresolvable stress leads to the induction of pro-apoptotic genes and cancer cell death, making pharmacologic activation of this pathway a promising therapeutic strategy. DCC-2812 is an investigational, potent, and selective activator of GCN2 and the ISR pathway in cancer cells. In preclinical studies, DCC-2812 upregulated the ISR pathway and demonstrated single-agent antitumor activity in a variety of cancer cell lines, including those of renal and urothelial origin. DCC-2812 also inhibited tumor growth in vivo in xenograft models of renal cell carcinoma (RCC) and urothelial cell carcinoma. Here, we describe an ongoing phase 1 study evaluating DCC-2812 as a monotherapy in patients with advanced genitourinary cancers. **Methods:** This is a multicenter, open-label, phase 1 dose-escalation study evaluating the safety and preliminary antitumor activity of DCC-2812 in adult patients ($\geq$18 years) with histologically or cytologically confirmed advanced or metastatic RCC, urothelial cancer, or castration-resistant prostate cancer (NCT06966024). Eligible patients must have experienced disease progression on or be intolerant of standard-of-care therapies and must have adequate organ function as well as the ability to take oral medication. Individuals will be excluded if they received any anticancer therapy (other than luteinizing hormone–releasing hormone agonists/antagonists for prostate cancer) or investigational therapy within a specified timeframe prior to the first dose of DCC-2812, have impaired cardiac function, or had major surgery within 28 days of the first dose of DCC-2812. Enrolled patients will receive DCC-2812 orally in 28-day cycles. The primary outcome measures are the number of patients with dose-limiting toxicities during cycle 1, treatment-emergent adverse events (TEAEs) and serious adverse events, and dose modifications due to TEAEs. Secondary outcome measures include radiographic objective response rate and radiographic duration of response per Response Evaluation Criteria in Solid Tumors version 1.1 and Prostate Cancer Working Group 3 criteria, if applicable, as well as pharmacokinetics. The study is currently recruiting patients at multiple sites in the United States. Clinical trial information: NCT06966024. Research Sponsor: Deciphera Pharmaceuticals, LLC, a member of ONO Pharma.

TPS4640 **Poster Session**

RNDO-564-001: A first-in-human, phase 1/1b study of RNDO-564, a costimulatory bispecific antibody for the treatment of advanced bladder cancer and other Nectin-4–positive solid tumors. First Author: John D. Powderly II, Carolina BioOncology Institute PLLC, Huntersville, NC

Background: RNDO-564 is a novel CD28 x Nectin-4 bispecific antibody (bsAb) with high affinity Nectin-4 binding and optimized CD28 costimulatory arms designed to maximize the therapeutic window. RNDO-564-001 (NCT07218003) is an ongoing, open label, multicenter, phase 1/1b dose escalation and dose optimization study of RNDO-564 as monotherapy, and in combination with pembrolizumab (anti-programmed death PD-1 monoclonal antibody), in adults with relapsed/refractory (R/R), locally advanced or metastatic urothelial cancer (la/mUC) and other Nectin-4 positive solid tumors. **Methods:** The objectives of the study are to assess the safety, tolerability, and to determine the recommended phase 2 dose (RP2D) of intravenous RNDO-564 monotherapy given on Days 1, 8, and 15 of a 21-day cycle. Monotherapy dose escalation will include an accelerated titration component using four single participant (pt) cohorts, followed by more gradual dose increments using a Bayesian Optimal Interval (BOIN) with backfill design. Pts with R/R la/mUC, cervical, head and neck, esophageal, gastric, gastroesophageal, non-small cell lung, or triple negative breast cancer, who have exhausted, are ineligible for, or declined available standard treatment options, are eligible for the dose escalation phase of the study. Pts must have an ECOG performance status of 0-1. Pts with prior Nectin-4 directed therapies and Monomethyl Auristatin E (MMAE) exposure and those with ongoing Grade $\leq$ 2 peripheral neuropathy are eligible. Pts with a history of, or with active, inflammatory skin conditions are ineligible. Enrollment into Cohorts 1 and 2 have been completed without dose limiting toxicity (DLT). Enrollment to cohort 3 opened in January 2026. Safety endpoints include incidence of adverse events per CTCAE v6.0. Secondary endpoints include clinical activity, pharmacokinetics, and incidence of anti-drug antibody development. Retrospective assessment of Nectin-4 expression on tumor tissue by immunohistochemistry (IHC), and measurement of CD28 receptor occupancy, T cell activation, and serum cytokines in peripheral blood will be performed as exploratory endpoints. To determine the optimal RP2D in R/R la/mUC, up to two 20 pt dose optimization cohorts at two different dose levels will be enrolled. Separate dose escalation and optimization stages in combination with pembrolizumab will be conducted to assess safety, clinical activity, and RP2D for further development of combination treatment. Based on emerging clinical data, additional monotherapy and/or combination therapy expansion cohorts may be opened for pts with non-UC Nectin-4 positive solid tumors. **Conclusions:** RNDO-564-001 is an ongoing phase 1/1b study to determine the safety, tolerability, clinical activity, and RP2D of RNDO-564 in R/R la/mUC and other Nectin-4 positive solid tumors. Clinical trial information: NCT#07218003. Research Sponsor: Rondo Therapeutics, Inc.

TPS4641 **Poster Session**

A phase III randomized trial of pembrolizumab in combination with sacituzumab govitecan vs standard of care in anti–PD-(L)1–resistant advanced urothelial cancer: ECOG-ACRIN EA8231. First Author: Monika Joshi, Penn State Cancer Institute, Hershey, PA

Background: Patients (pts) with locally advanced or metastatic urothelial carcinoma (la/mUC) who progress after anti-PD-(L)1 therapy (CPI-R) and enfortumab vedotin (EV) have relatively limited treatment options and poor outcomes. SG, a TROP-2–directed antibody–drug conjugate (ADC), has meaningful efficacy in previously treated la/mUC, while SG plus pembro achieved 41% overall response rate (ORR; 20% complete response rate) in platinum-refractory la/mUC. With rapidly evolving treatment paradigms and earlier use of EV and anti-PD(L)1, the frequency of CPI-R la/mUC is expected to increase; therefore, newer combinations and the role of anti-PD(L)1 re-challenge should be prospectively evaluated in previously treated la/mUC. We hypothesized that SG/pembro combination would improve outcomes over standard chemotherapy (SOC) in pts previously treated with anti-PD(L)1. **Methods:** EA8231 is an open-label, multicenter, randomized phase III trial enrolling adults with unresectable la/mUC. Key eligibility criteria: a) ECOG PS 0-2 b) Prior anti-PD(L)1 given in any disease setting but no cancer progression within 12 weeks from starting prior anti-PD(L)1initiation c) Prior exposure to EV unless contraindicated d) $\geq$1 lines of systemic therapy for la/mUC [*FGFR3* altered tumors must have received prior FGFR inhibitor unless contraindicated] e) Bellmunt score 0-2 f) No prior exposure to SG or other TROP-2 directed therapies or drugs containing topo-isomerase I inhibitor. Treatment: Pts are randomized 1:1 to Arm A SOC (platinum-gemcitabine or taxane Q3 week cycle) OR Arm B pembro/SG (Pembro 200mg on day 1 + SG 10mg/kg on days 1, 8 of a 21-day cycle with G-CSF support). Pts are stratified by Bellmunt score (0-1 vs 2), prior lines of therapy ($\leq$2 vs $>$2), prior exposure to platinum-based chemotherapy (yes vs no prior exposure and platinum-eligible vs no prior exposure and platinum-ineligible), duration of prior anti PD-(L)1 therapy ($\leq$6 vs $>$6 months). G-CSF primary prophylaxis is strongly recommended, esp. with SG. *Endpoints*: Primary endpoint: overall survival (OS); secondary endpoints: progression-free survival, ORR, clinical benefit rate, duration of response, safety/tolerability, health related QOL (NFBISI-18; FACIT-Fatigue; EQ-5D-5L). Statistical plan: Trial is designed to demonstrate 42.5% improvement in median OS [platinum-ineligible cohort: median OS increase from 9 to 12.8 months; platinum-eligible cohort: median OS increase from 10.3 to 14.7 months]; 80% power with 1-sided 0.025 type I error rate; HR (pembro+SG/SOC) 0.70, N=320. Trial Status: Activation date: 10/23/2025 (1 patient accrued as of Jan 6, 2026; 28 approved sites, additional sites pending). Clinical trial information: NCT06524544. Research Sponsor: National Cancer Institute of the National Institutes of Health under award numbers: U10CA180820, U10CA180794, U10CA180821, UG1CA233180, UG1CA233196, UG1CA233328, UG1CA233339, and UG1CA233373.

TROPION-Urothelial03: A phase 2/3 study of datopotamab deruxtecan (Dato-DXd) + platinum chemotherapy (CT) vs gemcitabine + platinum CT in participants with locally advanced or metastatic urothelial carcinoma (la/mUC) with progression on or after enfortumab vedotin (EV) + pembrolizumab. First Author: Matthew D. Galsky, Icahn School of Medicine at Mount Sinai, Tisch Cancer Institute, New York, NY

Background: Although first-line (1L) EV + pembrolizumab has improved outcomes for patients with la/mUC, most experience disease progression, highlighting an unmet need for novel therapies. TROP2 is a glycoprotein highly expressed in several epithelial tumors, including UC. Dato-DXd is a TROP2-directed antibody–drug conjugate comprising an anti-TROP2 monoclonal antibody, a tetrapeptide-based cleavable linker, and a topoisomerase I inhibitor payload (DXd), designed to induce selective tumor-cell death and reduce systemic exposure to the payload. Dato-DXd has demonstrated durable efficacy and a manageable safety profile in patients with la/mUC both as monotherapy (TROPION-PanTumor01 [NCT03401385]) and in combination with immunotherapy (TROPION-PanTumor03 [NCT05489211]). We describe a Phase 2/3 trial comparing the efficacy and safety of Dato-DXd + platinum CT (carboplatin or cisplatin) vs gemcitabine + platinum CT in participants with la/mUC with disease progression on or after EV + pembrolizumab. **Methods:** TROPION-Urothelial03 (NCT07129993) is a global, multicenter, randomized, open-label, Phase 2/3 trial. In Part A (Phase 2), ~60 participants will be randomized 1:1 to receive Dato-DXd 4 or 6 mg/kg + platinum CT. In Part B (Phase 3), ~570 participants will be randomized 1:1 to receive Dato-DXd at the recommended Phase 3 dose (determined using Part A data) + platinum CT vs gemcitabine + platinum CT. Randomization in Part A is stratified by assignment of platinum CT (carboplatin vs cisplatin), and in Part B, by assignment of platinum CT, presence vs absence of liver metastasis at screening, and time to progression on 1L EV + pembrolizumab ($<$6 vs $\geq$6 months). Study treatment continues until disease progression, unacceptable toxicity, withdrawal of consent, death, loss to follow-up, or other reasons per protocol. Radiographic tumor assessments occur every 6 weeks for 54 weeks, then every 12 weeks. The primary endpoint of Part A is objective response rate (ORR) by investigator per Response Evaluation Criteria in Solid Tumours, version 1.1 (RECIST 1.1). The dual primary endpoints of Part B are progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1 and overall survival (OS). Secondary endpoints include duration of response by investigator per RECIST 1.1 (Part A), and PFS by investigator per RECIST 1.1 and ORR by BICR and investigator per RECIST 1.1 (Part B). In Part A, ORR will be summarized with 2-sided 95% exact confidence intervals using the Clopper–Pearson method by trial group. In Part B, PFS and OS will be compared between trial groups using a log-rank test stratified by randomization stratification factors, with hazard ratios from the stratified Cox regression model. Clinical trial information: NCT07129993. Research Sponsor: Daiichi Sankyo, Inc.

TPS4643 **Poster Session**

Advancing treatment of low-grade upper tract urothelial carcinoma (LG UTUC) with padeliporfin vascular-targeted photodynamic therapy (VTP): The ENLIGHTED phase 3 trial. First Author: Vitaly Margulis, Department of Urology, UT Southwestern Medical Center, Dallas, TX

Background: Padeliporfin VTP is a drug-led combination therapy consisting of IV Padeliporfin activated by a low-power near-infrared (753 nm) laser–fiber system. A non-contact cylindrical fiber positioned near the tumor provides circumferential illumination, inducing vascular occlusion and coagulative tumor necrosis while preserving tissue structure. Safety and efficacy were shown in a Phase 1 UTUC study (NCT03617003). We report emerging efficacy, durability, and safety from the ENLIGHTED Phase 3 trial in LG UTUC (NCT04620239). **Methods:** ENLIGHTED is an open-label Phase 3 study conducted in the US, EU, and Israel, evaluating the efficacy, durability, and safety of padeliporfin VTP in LG UTUC. Eligible patients (pts) may have new or recurrent disease, be treatment-naïve or previously treated, and have up to two biopsy-confirmed LG lesions (5–15 mm kidney or 5–20 mm ureter) without high-grade cells on instrumented cytology. VTP is performed via retrograde upper tract endoscopy under anesthesia and low-light conditions. Padeliporfin is administered IV, and an optical fiber with a 20–40 mm diffuser is positioned near the tumor through the scope, followed by 10 minutes of laser illumination. Treatment consists of an Induction Treatment Phase (ITP) of 1–3 VTP sessions at 4-week intervals until complete response (CR) or treatment failure at Primary Response Evaluation (PRE). Pts achieving CR enter a 12-month Maintenance Treatment Phase (MTP) with quarterly endoscopic surveillance and retreatment for treatable recurrences, followed by long-term follow-up up to 48 months. The primary endpoint is CR at PRE (28 $\pm$ 3 days post last ITP treatment), defined by absence of visible tumor on endoscopy and negative instrumented cytology. A total of 100 pts are to be enrolled. As of January 19, 2026, 78 pts were enrolled and 63 completed ITP. Response rates were: CR 73.0%, PR 17.7%, DR 3.2%, PD 4.8%, and stable disease 1.6%. Among pts with CR at PRE, 39.5% had completed MTP by data cutoff, with 88.2% maintaining CR in the treated area (TA) for $\geq$12 mos. Median Duration of Response in the TA was not reached and is $\geq$23.9 mos. Most pts remains in MTP or follow-up. The most common treatment-emergent adverse events were hematuria (10.6%), flank pain (8.6%), nausea (5.5%), procedural pain (4.5%), abdominal pain (4.1%), dysuria (4.1%), vomiting (3.4%), and fatigue (3.1%), all Grade 1–2 with a median duration of 5 days. 23 serious adverse events (7.7%) were reported, mostly unrelated to treatment. One Grade 3 SAE (renal colic related to VTP) resolved within 2 days. Padeliporfin VTP demonstrates favorable preliminary efficacy, durable responses, and a safety profile consistent with prior experience. Enrollment is ongoing, and final outcomes are anticipated to support regulatory approval of an organ-preserving therapy for LG UTUC. Clinical trial information: NCT04620239. Research Sponsor: Steba/Impact biotech.

Selective bladder-sparing trial with sasanlimab as maintenance treatment based on clinical response to neoadjuvant treatment in molecularly categorized muscle invasive bladder cancer patients: SASAN-SPARING trial. First Author: Elena Sevillano, HM Sanchinarro Centro Integral Oncologico Clara Campal (CIOCC), Madrid, Spain

Background: Muscle-invasive bladder cancer (MIBC) is an aggressive disease with a high risk of progression, for which radical cystectomy (RC) remains the standard of care. Adaptive bladder-sparing strategies based on post-neoadjuvant clinical restaging are increasingly explored to maintain oncologic control while preserving quality of life. SASAN-SPARING evaluates sasanlimab, a PD-1 inhibitor, as maintenance therapy in patients achieving a clinical response after neoadjuvant cisplatin-based chemotherapy. **Methods:** SASAN-SPARING (HM-8788561; NCT06623162) is an ongoing, single-arm, multicenter, phase II trial enrolling patients aged $\geq$18 years with treatment-naïve, localized MIBC (pT2–T4a, N0, M0) eligible for neoadjuvant chemotherapy. All patients receive four cycles of cisplatin (70 mg/m^2 on day 1) plus gemcitabine (1000 mg/m^2 on days 1 and 8) every 3 weeks, followed by comprehensive clinical restaging. Patients achieving a clinical response (cT0/Ta/T1/Tis, negative cytology, and negative imaging) are eligible for bladder preservation with sasanlimab 300 mg administered subcutaneously every 4 weeks for up to 12 cycles. Non-responders ($\geq$cT2) undergo RC. During maintenance, restaging is performed every 12 weeks, and RC may be considered upon loss of response or disease progression. The primary endpoint is bladder-intact overall survival at 12 months after the first dose of sasanlimab. Secondary endpoints include disease-free survival, metastasis-free survival, overall survival, safety, and health-related quality of life. The study incorporates an ambitious biomarker analysis, including whole-genome sequencing of tumour tissue and plasma, the use of ctDNA in plasma and urine for tumour assessment and molecular dynamics, and the study of the gut microbiome in stool. Biomarker-correlative studies will provide a valuable tool for personalized treatments and inform treatment decisions in adaptive strategies such as SASAN-SPARING. The Expected sample size is 70 patients, assuming a 12-month biOS of 81% (H0) and an increase with sasanlimab up to 93% (H1) (one-arm survival test; α=0.05 β=0.8).Recruitment began in December 2024. As of January 2026, 62 patients have been enrolled across 10 centers, and 21 started sasanlimab maintenance therapy. Enrollment is ongoing.SASAN-SPARING explores an adaptive, biomarker-integrated bladder-sparing strategy which aims to generate prospective evidence to support organ-preservation strategies in MIBC. Clinical trial information: NCT06623162. Research Sponsor: None.

Clinico-transcriptomic risk stratification to guide abiraterone treatment intensification in high-risk prostate cancer: A combined analysis of NRG/RTOG 9202, 9413, 9902, and 0521. First Author: Krishnan R. Patel, Radiation Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Outcomes for some patients with ≥high-risk localized prostate cancer (HR-PCa) who receive radiation therapy (RT) remain poor. Current guidelines recommend intensification with abiraterone/prednisone (AAP) in select patients; however, the current guideline-defined candidate population may be suboptimal. **Methods:** This is a secondary analysis of available biopsy samples from NRG/RTOG 9202, 9413, 9902, and 0521. The primary objective was to determine if a specific subgroup of ≥HR-PCa patients had sufficiently poor prognoses to derive a clinically meaningful benefit from AAP intensification. The prognostic impact of the Decipher 22-gene genomic classifier (GC; Veracyte, San Diego, CA) was first evaluated for metastasis-free survival (MFS, primary), overall survival (OS), and distant metastases (DM). GC scores were analyzed using both continuous (per 0.1 GC units) and pre-specified categorical cutpoints: ≤ intermediate transcriptomic risk (IR-PCa, GC≤0.6), HR-PCa (GC:0.6-0.85), and very high risk (VHR-PCa, GC > 0.85). A tree-based model was then used to combine clinical and transcriptomic risk category. **Results:** This study characterized outcomes of 427 patients (64% NCCN HR-PCa; 36% NCCN VHR-PCa) with a median follow-up of 10.4 years. Continuous GC score was observed to discriminate risk when adjusted for age, PSA, grade, T-stage, and treatment received for the endpoints of MFS (HR_{GC}:1.19 [95% CI:1.10-1.29], $p < 0.001$), DM (HR_{GC}:1.31 [95% CI:1.13-1.51], $p < 0.001$), and OS (HR_{GC}: 1.18 [95% CI: 1.09-1.28], $p < 0.001$). MFS and OS were estimated using the Kaplan-Meier method by pre-specified GC subgroup within each NCCN risk group (HR-PCa, VHR-PCa). Based on outcomes by subgroup, a novel clinico-transcriptomic risk stratification system was constructed, where patients receive 1 point for NCCN/GC HR categorization and 2 points for NCCN/GC VHR categorization. The combined risk score ≥3 subgroup had a prognosis similar to the STAMPEDE M0 control arm, whereas the combined score ≤2 subgroup had a substantially better prognosis. Utilizing this system could enhance the specificity of AAP recommendations, increasing the candidate pool eligible for AAP intensification by approximately 20% and identifying approximately 25% of NCCN VHR in whom the therapeutic ratio of AAP may be less favorable. **Conclusions:** This study defines a novel clinico-transcriptomic risk stratification system to augment current clinical eligibility for AAP intensification. This system may increase the population who benefit from AAP by approximately 20% and simultaneously identify approximately 25% of NCCN VHR patients who may avoid AAP intensification. Assessment of the ability of Decipher Prostate Genomic Classifier (DGC) >0.85 to identify patients who benefit from adding docetaxel (DOC) to androgen deprivation therapy (ADT) plus enzalutamide (ENZ): Level 1B evidence from the ENZAMET study. First Author: Christopher Sweeney, South Australian Immunogenomics Cancer Institute, Adelaide University, Adelaide, SA, Australia

Background: DGC predicts overall survival (OS) benefit from DOC when added to ADT while the benefit of adding DOC to ADT and ENZ is unknown. We hypothesized in a locked prespecified statistical analysis plan that higher GC score (> 0.85, the locked threshold on clinical test report) will identify patients who benefit from addition of DOC to ADT plus ENZ independently of metastases volume and timing. **Methods:** DGC scores were generated from transcriptome profiling using a clinical test (Veracyte) on tumor index cores from participants (pts) randomised on ENZAMET study (N = 1,125) 1:1 ADT with NSAA or ENZ with clinical discretion to add DOC as part of standard of care. Primary tumor samples were available from 764 pts. Differential DOC OS benefit was assessed by testing the marker-by-treatment interaction term in propensity score-weighted Cox models, with weights based on factors associated with planned DOC use. Prognostic effects of DGC were estimated using Cox for age, WHO PS, Gleason, randomized arm +/- planned DOC, metastases volume and timing, with adjusted hazard ratios (aHR) and 95% CIs. Analyses were prespecified and conducted independently by two statisticians. **Results:** DGC scores were available for 634 (83%) unique pts (median follow-up 5.6 years) with clinical factors representative of the overall trial. Median age was 68 yrs with 50% HV, 62% synchronous presentation, and 44% with planned DOC. Planned DOC was associated with younger age, high volume and synchronous presentation (all p≤0.002). Median DGC score was 0.88 (IQR 0.75-0.96) and 55% had DGC > 0.85 (62% in pts with DOC planned, 49% in others). Overall, higher GC was significantly associated with poorer OS (aHR 1.37 [1.06-1.78], p = 0.02). DOC benefit differed by GC level [higher vs lower] in pts treated with ADT plus ENZ (p-interaction 0.043). Higher DGC was associated with worse OS in pts treated with ADT plus ENZ (aHR 2.31 [95% CI 1.26-4.21], p = 0.007) while pts treated with DOC added to ADT plus ENZ showed no significant difference by DGC (aHR 1.08 [0.63–1.86]). Effects were more pronounced in pts with high vs. low volume disease. **Conclusions:** DGC > 0.85 is predictive of benefit from adding DOC to ADT plus ENZ as it negated the poor prognostic outcome of DGC > 0.85 with ADT plus ENZ alone, whereas there was no evidence of benefit for adding DOC for pts with GC ≤0.85. Research Sponsor: Nantional Cancer Institute; Movember Foundation; Australian Department of Health; Astellas and Pfizer; Veracyte.

Spatial transcriptomics–guided computational pathology model to stratify docetaxel benefit in metastatic hormone-sensitive prostate cancer: CHAARTED trial (ECOG-ACRIN E3805). First Author: Md Mamunur Rahaman, School of Computer Science and Engineering, University of New South Wales, Sydney, NSW, Australia

Background: The CHAARTED trial demonstrated improved overall survival (OS) with the addition of docetaxel (DTX) to androgen deprivation therapy (ADT) in metastatic hormone-sensitive prostate cancer (mHSPC), but many patients do not benefit and experience significant toxicity. Clinical factors (e.g., metastatic burden) are suboptimal for predicting DTX benefit, indicating a need for better biomarkers. We developed ST-DoxPCa (Spatial Transcriptomics–Guided Docetaxel Therapy Stratification in Prostate Cancer), an artificial intelligence (AI)-driven biomarker that infers intratumoral gene expression from routine H&E slides (via virtual spatial transcriptomics) to stratify patients by likelihood of benefiting from DTX. **Methods:** ST-DoxPCa was developed using paired H&E and spatial transcriptomics from the HEST1K prostate cohort to train a Vision Transformer–based regressor to predict a 208-gene panel at spot/patch level; predictions were distilled into a biologically informed 26-gene signature and summarized into patient-level features capturing expression level and heterogeneity. In CHAARTED, a Cox model for overall survival (OS) was trained and internally validated in the ADT-only arm (n = 154; 50/50 split: n = 77 train, n = 77 validation) to derive an ST-DoxPCa risk score and fixed median threshold. This locked model was then applied to the ADT validation cohort (n = 77) and the held-out ADT+DTX arm (n = 129), and OS was compared between treatment arms within biomarker-defined risk groups using Kaplan–Meier estimates and Cox hazard ratios. **Results:** ST-DoxPCa stratified patients into biomarker-defined risk groups using aggregated spatial-expression features from a biologically informed gene panel; key genes included AR, PTEN, FASN, FOXA1, and ACPP. In ST-DoxPCa-positive (high-risk) patients, adding DTX to ADT significantly improved OS versus ADT alone (HR = 0.53, 95% CI 0.31–0.90; p = 0.018), with no benefit in ST-DoxPCa-negative (low-risk) patients (HR = 1.32, 95% CI 0.74–2.34; p = 0.34). **Conclusions:** ST-DoxPCa is a novel spatial transcriptomics guided histology biomarker that predicts differential benefit from docetaxel in mHSPC. ST-DoxPCa identified a subset of patients who achieve substantial survival gains from upfront DTX and another subset with no benefit, enabling personalized treatment intensification. ST-DoxPCa has the potential to spare low-risk patients unnecessary chemotherapy while directing therapy to those most likely to benefit. Clinical trial information: NCT00309985. Research Sponsor: National Cancer Institute (NCI), National Institutes of Health (NIH); United States Department of Veterans Affairs; U.S. Department of Defense (DoD) – Prostate Cancer Research Program.

A phase 2 trial of androgen deprivation therapy interruption in patients responding exceptionally to androgen receptor pathway inhibitor in metastatic hormone-sensitive prostate cancer (A-DREAM / Alliance A032101). First Author: Atish Dipankar Choudhury, Dana-Farber Cancer Institute, Boston, MA

Background: Patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC) treated continuously with testosterone suppression (TS) plus an androgen receptor pathway inhibitor (ARPI) can experience cumulative toxicity. We conducted this single-arm phase 2 trial (NCT05241860) to test the hypothesis that pts who achieve favorable response to TS + ARPI can have prolonged treatment-free interval with testosterone recovery after treatment interruption (TI). Here we report on the primary endpoint. **Methods:** Eligible pts had mHSPC by conventional imaging with prostate-specific antigen (PSA) $\geq$ 5 ng/ml and testosterone $\geq$ 150 ng/dl prior to starting TS+ARPI, with PSA $<$ 0.2 ng/ml and testosterone $<$ 50 ng/dl at the time of enrollment after having received TS for 540-750 days and ARPI for $\geq$ 360 days. Prior local therapy, radiation to metastases and docetaxel were permitted. After enrollment, pts discontinued TS and ARPI and were followed with PSA and testosterone levels every 3 months (mo), CT/MRI and bone scan at least every 6 mo, and FACT-P questionnaire for patient-reported outcomes (PROs) every 6 mo. Treatment was resumed for PSA $\geq$ 5 ng/ml, radiographic change (progressive disease [PD] per RECIST 1.1 on CT/MRI or unconfirmed PD per PCWG3 on bone scan), or prostate cancer-related symptoms. The primary endpoint was proportion of men remaining treatment-free 18 mo after TI with eugonadal testosterone ($>$ 150 ng/dl). Target enrollment was 75 pts to differentiate 18-mo treatment-free rates of 0.30 (H_0) and 0.45 (H_a). **Results:** Of 79 pts enrolled between 07/2022 and 03/2024, 78 were eligible and underwent TI. Among these 78, median PSA prior to starting TS+ARPI was 19 (range 5-6759), 27 (35%) had high volume disease, 31 (40%) never received local therapy, and 55 (71%) did not receive radiation to metastases. By 18 mo after TI, 67% (52/78) recovered testosterone and 58% (45/78) remained treatment-free; 41% (32/78) remained treatment-free with testosterone recovery (80% CI 33.5-48.9%, one-sided p 0.0249). At median follow-up of 21.2 mo, 35% (27/78) resumed initial TS+ARPI after meeting re-initiation criteria (of whom 1 required treatment switch for PD 9 mo later); 5% (4/78) resumed prior to meeting criteria; 9% (7/78) pursued alternative therapy instead of resuming TS+ARPI per protocol; 5% (4/78) withdrew; 1 died of myocardial infarction prior to resuming treatment. 4 pts died, 1 of prostate cancer. **Conclusions:** The primary objective was achieved with 41% of favorable responders to TS+ARPI remaining treatment-free with testosterone recovery at 18 mo after TI. Analyses of biomarkers and PROs are in progress, and pts will be followed for long-term outcomes. Cognitive effects of darolutamide vs enzalutamide: Results of ARACOG (AFT-47), a randomized clinical trial from the Alliance for Clinical Trials in Oncology. First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Androgen receptor pathway inhibitors (ARPIs) may have distinct central nervous system (CNS) penetration and differential effects on cognition or quality of life (QOL). AFT-47, "ARACOG" is a prospective, randomized open-label phase 2 trial comparing objective and patient-reported cognitive and QOL outcomes between patients with metastatic hormone sensitive prostate cancer (mHSPC), metastatic castration-resistant prostate cancer (mCRPC) or non-metastatic castration-resistant prostate cancer (nmCRPC) treated with darolutamide (DAR) or enzalutamide (ENZ). **Methods:** Between 8/17/2021 and 3/11/2025, 111 pts were enrolled and randomized 1:1 to treatment with ENZ or DAR. CANTAB, a validated computer-based platform evaluating 5 cognitive domains (PALFAM-memory recall, SWM- spatial working memory, SSP-short-term visual memory, working memory, RVP-rapid visual processing, and OTSMCC- executive function), was performed at baseline, 12, 24, and 48 weeks. Crossover (Xover) was allowed at 12 or 24 weeks for significant pre-specified decline in cognitive testing or patient reported outcome measures (PROMs), or for CNS-associated adverse events, including falls. The primary endpoint was the percent change in the maximally changed cognitive domain (MCCD) from baseline to 24 weeks and was compared between groups with the Wilcoxon rank sum statistic. Patients crossing over prior to 24 weeks were evaluated at the time of Xover and analyzed with their randomized arm. Secondary endpoints included comparison of Xover rates. **Results:** Among 111 pts, 55 received DAR and 56 received ENZ; median age was 71, 83% White. 95 pts (48 DAR, 47 ENZ) were evaluable for the primary endpoint. Baseline CANTAB was similar between groups. Median cognitive change in MCCD between baseline and 24 weeks was -15.8% and -36.1% for the DAR and ENZ pts, respectively (p = 0.009) (Table). Individual cognitive domains suggest possible learning effect (increased scores) for DAR and are stable or show mild decline for ENZ treated patients at 24 weeks. 32 DAR (58%) and 33 ENZ (59%) participants were eligible for Xover by 24 weeks, and 23 pts crossed over by 24 weeks. All Xover was pts randomized to ENZ (crossed to DAR), with the most common causes being decline in objective (N = 14) or subjective (N = 11) cognitive testing. **Conclusions:** In this US randomized trial comparing DAR to ENZ, the primary endpoint of differential cognitive effects was met. ENZ showed significantly greater cognitive score decline than DAR at 24 weeks in the MCCD after treatment initiation. Learning effect was seen with DAR but not ENZ. Longer term follow-up of cognitive change and PROM analyses are ongoing. Clinical trial information: NCT04335682. Research Sponsor: Prostate Cancer Foundation; Alliance Scholar Award; Bayer; https://acknowledgments.alliancefound.org.

Percent change in maximally changed cognitive domain by treatment.

	DAR (N=48)	ENZ (N=47)	Wilcoxon Rank Sum Test Result
CANTAB domain	PALFAM	SWM	
Degree of change	-15.8 (-38.8, -2.6)	-36.1 (-59.3, -16.7)	P=0.009

5006 **Oral Abstract Session**

Final results from ZZFIRST: A randomized phase 2 trial of enzalutamide (EZ) and talazoparib (TALA) in metastatic hormone-naïve prostate cancer (mHNPC). First Author: Joaquin Mateo, Vall d´Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d´Hebron, Barcelona, Spain

Background: ADT plus AR pathway inhibition (ARPI) improves outcomes in mHNPC, yet responses remain heterogeneous. AR–PARP cotargeting has shown enhanced clinical activity in prostate cancer, but the underlying mechanisms are incompletely defined. ZZFIRST evaluated enzalutamide (EZ) plus talazoparib (TALA) in mHNPC, including the study of tumor adaptation response to ADT+ARPI through biopsies obtained on therapy. **Methods:** ZZFIRST (NCT04332744) is an open label, randomized academic phase 2 trial that included patients (pts) with high-volume (HV)-mHNPC (CHAARTED), ECOG PS $\leq$1, PSA$\geq$4 ng/mL. All pts received standard ADT and started EZ 160 mg/day. After two 28-day cycles, pts were randomized 2:1 to EZ+TALA 0.5 mg/day or continue EZ alone until progressive disease (PD), unacceptable toxicity, or withdrawal. Randomization was stratified by DDR mutation status. Primary endpoint was confirmed PSA $<$ 0.2 response rate (PSA $<$ 0.2-RR) at 12 months (mo) for EZ+TALA. Key secondary endpoints included rPFS, time to PSA-PD, time to castration resistance, and safety. The study was powered (80%, one-sided α = 5%) to detect improved PSA $<$ 0.2-RR (H0: 20%; H1$\geq$40%) for EZ+TALA. Between-arm comparisons were exploratory. Spatial transcriptomics (Visum HD) was performed on baseline (BL) and Cycle 2-Day 1 (C2D1) on-treatment tumor biopsies. **Results:** 54 pts were enrolled (37 EZ+TALA, 17 EZ). 7 pts harbored HRR alterations by tumor tissue NGS (13%; 5 EZ+TALA, 2 EZ). Visceral metastases were present in 17 pts (32%); 51 pts (94%) had *de novo* M1 disease. Median follow-up was 3.6 years. The primary endpoint was met, with a 73% 12-mo PSA $<$ 0.2-RR for EZ+TALA (95%CI, 55.9%-86.2%, p $<$ 0.001); the rate was 64.7% for EZ. Median rPFS was 45.3 mo (29.4-NR) for EZ+TALA vs 31.1 mo (13.5-NR) for EZ (HR = 0.62; 95%CI, 0.28-1.37). Median time to PSA-PD was not reached (30.4-NR) for EZ+TALA vs 30.7 mo (6.6-NR) for EZ (HR = 0.47; 95%CI, 0.21-1.04). Median TTCR was 30.4 mo (23.0-NR) for EZ+TALA vs 22.8 mo (6.3-45.4) for EZ (HR = 0.62; 95%CI, 0.30-1.26). In TALA+EZ, common treatment-emergent AEs were fatigue (any grade: 83.8%; G$\geq$3: 13.5%) and anemia (67.6%; G$\geq$3: 40.5%). 14 (38%) pts required TALA dose reductions. Two pts on EZ+TALA developed acute myeloid leukemia (AML) 26.0 and 32.8 mo after study entry. Transcriptomics analysis on C2D1 vs BL biopsies showed induction of cell cycle arrest, with downregulation of AR and DDR signatures and upregulation of IFN-related and inflammatory response signatures upon ADT+EZ. **Conclusions:** EZ+TALA demonstrated promising antitumor activity in HV-mHNPC. The toxicity profile was consistent with prior AR+PARP trials, although two cases of AML were observed with prolonged TALA exposure. Paired tumor biopsies revealed mechanisms of tumor adaptation to ADT+EZ inhibition, supporting a biologically informed rationale for AR+PARP treatment intensification strategies in mHNPC. Clinical trial information: NCT04332744. Research Sponsor: Pfizer S.L. and Astellas Pharma Europe LTD.

TALAPRO-3: Talazoparib (TALA) + enzalutamide (ENZA) compared with placebo (PBO) + ENZA for the treatment of patients (pts) with metastatic castration-sensitive prostate cancer (mCSPC) harboring homologous recombination repair (HRR) gene alterations. First Author: Neeraj Agarwal, Huntsman Cancer Institute (NCI-CCC), University of Utah, Salt Lake City, UT

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

5008 Oral Abstract Session

Fuzuloparib combined with abiraterone acetate and prednisone (AA-P) as first-line (1L) treatment for metastatic castration-resistant prostate cancer (mCRPC): Interim results from the FUZUPRO trial. First Author: Dingwei Ye, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The combination of PARP inhibitors with standard AA-P may offer enhanced antitumor activity over AA-P. We conducted FUZUPRO, an international, randomized, double-blind, placebo-controlled phase 3 trial, to compare the efficacy of fuzuloparib, a novel PARP inhibitor, plus AA-P vs AA-P as 1L treatment for mCRPC. **Methods:** 1L mCRPC patients were randomized (1:1) to orally receive fuzuloparib 150 mg BID plus AA-P (abiraterone acetate 1000 mg QD; prednisone 5 mg BID) or placebo plus AA-P. Randomization was stratified by DNA-repair gene defect (DRD) status (positive vs negative/unknown) and other factors. Primary endpoint was blinded independent central review (BICR)-assessed radiographic progression-free survival (rPFS) per RECIST v1.1 and PCWG3. As of March 23, 2025, 259 (85% of total expected) BICR-assessed rPFS events occurred, and a prespecified interim analysis was conducted. **Results:** 496 patients were randomized to fuzuloparib-AA-P (n = 249) or AA-P (n = 247). Median follow-up was 33.3 mo. Fuzuloparib-AA-P significantly prolonged rPFS compared with AA-P (median, 24.8 mo vs 19.9 mo; HR 0.71, 95% CI 0.55-0.91; 1-sided p = 0.0034). rPFS benefit with fuzuloparib-AA-P was generally consistent across clinically relevant subgroups. Among DRD-positive patients (n = 116), median rPFS was 27.7 mo and 13.9 mo in the fuzuloparib-AA-P and AA-P groups, respectively (HR 0.51, 95% CI 0.31-0.85; 1-sided p = 0.0039). Subgroup analysis suggested improved rPFS among DRD-positive patients regardless of their *BRCA1/2* mutation status. Among DRD-negative/unknown patients (n = 380), median rPFS was 22.8 and 21.2 mo, respectively. Overall survival showed a benefit trend in favor of fuzuloparib-AA-P (Table). Treatment-related adverse events (TRAEs) were reported by 81.9% and 76.0% of patients in the two groups, respectively. The most common grade ≥3 TRAEs were mainly hematological toxicities, including anemia (20.1%), decreased white blood cell count (5.6%), decreased platelet count, and decreased neutrophil count (5.2% for each). **Conclusions:** Fuzuloparib plus AA-P as 1L treatment significantly prolonged rPFS in patients with mCRPC. The combination showed acceptable safety and tolerability with no new safety signals identified. Clinical trial information: NCT04691804. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

Safety and dosimetry of ^{177}Lu-rosopatamab tetraxetan plus SoC in patients with metastatic castration-resistant prostate cancer: Preliminary results from part 1 of phase 3 ProstACT Global study. First Author: Pedro C. Barata, University Hospitals Seidman Cancer Center, Cleveland, OH

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

5010 Clinical Science Symposium

AcTION: Phase 1 study of [^{225}Ac]Ac-PSMA-617 (^{225}Ac-PSMA-617) in men with metastatic castration-resistant prostate cancer (mCRPC) with or without prior [^{177}Lu]Lu-PSMA (^{177}Lu-PSMA) radioligand therapy (RLT). First Author: Louise Emmett, Kinghorn Cancer Centre, St Vincent's Hospital, Sydney, NSW, Australia

Background: AcTION is the first prospective dosage escalation study of ^{225}Ac-PSMA-617, an alpha-emitting, PSMA-targeted RLT in patients (pts) with mCRPC (NCT04597411). **Methods:** This study enrolled pts with progressive, PSMA-positive mCRPC in 3 groups (Gps). Gp A: prior chemotherapy (ChT) and an androgen receptor pathway inhibitor (ARPI) but no prior ^{177}Lu-PSMA RLT; Gp B: no prior ChT, ARPI, or ^{177}Lu-PSMA RLT (ChT/ARPI-naive); Gp C: prior ^{177}Lu-PSMA RLT. Dosage escalation of ^{225}Ac-PSMA-617 used a Bayesian logistic regression model with administered activities of 4, 6, 8 or 10 MBq given intravenously for ≤6 cycles every 8 weeks. Primary objective was to identify the recommended phase 2 dosage (RP2D), based on dosage-limiting toxicities (DLTs) within the first 6 weeks of ^{225}Ac-PSMA-617 administration. This analysis includes all 101 treated pts per 13 Nov 2025. **Results:** Gp A pts had a median of 3 prior systemic therapies and median baseline [BL] PSA 73.4 (range 1-3320) ng/mL. At a median follow-up [FU] of 7.46 months (mos), PSA50 response rate (PSA50) was 20/34 (58.8%; 95% CI 40.7, 75.4) and PSA90 was 15/34 (44.1%; 95% CI 27.2, 62.1). Gp B pts had BL PSA 223.4 (5-12308) ng/mL. At a FU of 13.24 mos, PSA50 was 23/27 (85.2%; 95% CI 66.3, 95.8) and PSA90 was 22/27 (81.5%; 95% CI 61.9, 93.7). Gp C pts had 5 prior systemic therapies and BL PSA 85.5 (5-1760) ng/mL. At a FU of 8.57 mos, PSA50 was 21/40 (52.5%; 95% CI 36.1, 68.5) and PSA90 was 7/40 (17.5%; 95% CI 7.3, 32.8). Across all 3 Gps, there were no DLTs and a maximum tolerated dosage was not reached. No Grade [G] 4/5 TRAEs occurred. No dosage-dependent safety signals were observed. Dry mouth (G1/2 only) was the most common treatment-related (TR) adverse event (AE), observed in > 90% of pts across all Gps and mostly reported as not resolved at data cut off. Two TRAEs led to treatment discontinuation (G2 dry mouth at 8 MBq, and G3 anemia at 10 MBq; both occurring in Gp C). The RP2D for all 3 Gps was 10 MBq. Additional efficacy data will be presented. **Conclusions:** ^{225}Ac-PSMA-617 demonstrated an acceptable safety profile and promising anti-tumor activity up to 10 MBq in pts with mCRPC regardless of prior ^{177}Lu-PSMA RLT. Two phase 3 trials, AcTFirst (NCT06855277) and PSMAcTION (NCT06780670), are currently recruiting. Clinical trial information: NCT04597411. Research Sponsor: Endocyte, Inc., A Novartis Company.

5011 Clinical Science Symposium

CONVERGE-01 part 3: Ac-225 rosopatamab tetraxetan (CONV01-α) in Lu-PSMA-pretreated metastatic castration-resistant prostate cancer (mCRPC). First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Ac-225 rosopatamab tetraxetan (CONV01-α, Convergent Therapeutics, Cambridge, MA), an alpha-emitting radionuclide conjugated to a PSMA-targeting monoclonal antibody, has demonstrated safety and encouraging activity in prior investigator-initiated trials (Tagawa et al. JCO 2024, Nauseef et al. AACR 2023). This phase 2 Convergent Therapeutics-sponsored multi-center CONVERGE-01 trial is evaluating the safety and efficacy of CONV01-α in pts with mCRPC, including those previously treated with Lu-PSMA-617 or -I&T (Lu-PSMA), in a dose-escalation (DE) and in an Initial Expansion (IE) cohort. **Methods:** Eligible pts had PSMA PET-positive (VISION criteria) mCRPC with previous exposure to ≥1 ARPI, 0-1 taxane regimens, and 1-6 cycles of Lu-PSMA. CONV01-α was administered in a single cycle of two doses (D1 & D15). Dose escalation used a BOIN design protocol (dose levels [DLs]: 45 and 55 kBq/kg, with optional IE). Primary endpoints: safety (CTCAE v5, all pts) and proportion of patients with decline in PSA of 50% or greater (PSA50) (at recommended phase 2 dose [RP2D]). Secondary endpoints: biodistribution and pharmacokinetic profile. Exploratory endpoints: bPFS, rPFS, genomic and imaging biomarkers. Enrollment into DE and IE cohorts of Part 3 was conducted between 8/2024 and 12/2025. Data within reflect current status and are subject to change with continued follow up and analysis. **Results:** DE was completed without DLTs in all evaluable pts (n=3 at DL45, n=6 at DL55). This was followed by an IE at both DLs (total n=22, incl pts in DE; DL45: n=12, DL55: n=10). ECOG: PS 0 - 12/22, PS 1 - 10/22. 21/22 pts were taxane exposed (19 for CRPC). Common grade (Gr) ≥3 treatment emergent adverse events (TEAEs) (occurring in >1 pt) are in shown Table. Among all TEAE at DL45: thrombocytopenia occurred in 5/12 patients (Gr 1 3/12, Gr 2 2/12), without clinical sequelae. Dry mouth was limited to Gr 1 (5/12) and Gr 2 (1/12). Among pts at who were evaluable for PSA change, 45.4% (5/11) achieved a PSA50 at DL45, with several pts experiencing ongoing PSA declines including pts who were primarily refractory to Lu-PSMA. Based on the combined safety and activity profile, DL45 was chosen as RP2D and Subsequent Expansion is underway. **Conclusions:** CONV01-α at the RP2D of DL45 is well-tolerated and shows promising activity in a heavily pretreated and Lu-PSMA-exposed population where there are limited therapeutic options available. Subsequent Expansion continues for pts exposed to Lu-PSMA (Part 3) at RP2D of DL45. A pivotal study is planned. Clinical trial information: NCT06549465. Research Sponsor: Convergent Therapeutics, Inc.

Genomic classifier–driven NCCN risk reclassification to track distinct transcriptomic signatures in early prostate cancer. First Author: Daniel Keizman, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: NCCN clinicopathologic risk stratification in early prostate cancer (EPC) may under- or overestimate biologic risk and contribute to over- or undertreatment. The RNA-based Decipher genomic classifier (DGC), endorsed by NCCN, frequently drives NCCN risk reclassification, yet the transcriptomic biology that tracks with reclassification remains incompletely defined. We investigated whole-transcriptome signatures underlying DGC-based risk stratification and NCCN risk reclassification in a real-world EPC cohort. **Methods:** We performed a retrospective, real-world analysis, of prostate biopsy Decipher testing of 1,272 men with EPC, using the Decipher genomic classifier clinical database (Veracyte, San Diego, CA) and the GRID RWD registry (NCT02609269). Associations between NCCN risk reclassification and clinicopathologic variables (PSA, clinical T stage, and Gleason Grade Group) were evaluated, along with genomic risk scores, transcriptomic signatures, and a panel of gene expression signatures associated with adverse molecular features, including androgen receptor (AR) signaling, PAM50 subtype (Luminal B), inferred TP53/PTEN activity, and pathways related to proliferation, DNA repair, and immune response. **Results:** By DGC, 21% of tumors were classified as low risk, 34% as intermediate risk, and 45% as high risk. Decipher testing resulted in NCCN risk up-classification in 38% and down-classification in 19%, while 43% remained in the same NCCN risk category. Whole-transcriptome analysis revealed distinct molecular patterns across reclassification groups. Tumors that were up-classified exhibited a shift toward a more proliferative, less androgen-dependent phenotype, with significant increases ($p < 0.05$) in proliferation, DNA-repair, and immune-related pathways, increased Luminal B prevalence, reduced androgen receptor (AR) signaling, and decreased TP53 and PTEN activity. In contrast, down-classified tumors demonstrated significant downregulation of proliferation, DNA-repair, and immune-related pathways, with preservation of AR signaling and PTEN activity ($p < 0.05$). **Conclusions:** Genomic classifier–driven NCCN risk reclassification tracks coherent transcriptomic patterns that extend beyond clinicopathologic stratification. Higher genomic risk and up-classification align with Luminal B enrichment, reduced AR signaling, and loss of TP53/PTEN activity, supporting the clinical and biological validity of genomic risk refinement beyond conventional NCCN classification. Research Sponsor: None.

A phase 1, first-in-human (FIH) study evaluating the safety, pharmacokinetics, and efficacy of ABBV-969 in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Tanya B. Dorff, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Prostate-specific membrane antigen (PSMA) and six-transmembrane epithelial antigen of prostate 1 (STEAP1) are overexpressed in >80% of metastatic prostate cancer tumors. ABBV-969 is a first-in-class PSMA/STEAP1 dual-targeting antibody drug conjugate with a topoisomerase 1 inhibitor (Top1i) payload. We report results from the completed dose escalation part of the phase 1, FIH study (NCT06318273) evaluating ABBV-969 in patients (pts) with mCRPC. **Methods:** Pts were ≥18 years with confirmed metastatic prostate adenocarcinoma, had an ECOG performance score ≤1, a serum prostate-specific antigen (PSA) level ≥1.0 ng/mL, and hemoglobin ≥9 g/dL at study entry. Pts received ≥1 novel hormone agent (NHA) and ≥1 taxane (unless unable to receive or declined taxane), and progressed on prior NHA. Pts received 1 mg/kg–12.5 mg/kg of ABBV-969 monotherapy every 3 weeks until disease progression or intolerable toxicity. Primary objective was to determine safety and tolerability. Secondary objectives were preliminary efficacy, pharmacokinetics, and recommended phase 2 dose. **Results:** As of Jan 2026, 49 pts with mCRPC received ABBV-969 in the dose escalation part of the study. Median follow-up was 11.1 months (95% CI, 8.4–13.2), and median number of prior lines was 5 (range 1–9). Pt demographics and safety results are shown in Table 1. Thirty-one (63%) pts had Grade (G) ≥3 TEAEs, primarily G3 anemia (n=24). Dose and exposure responses were observed, with durable PSA and objective responses noted at all dose levels ≥3 mg/kg. At dose levels ≥3 mg/kg, confirmed PSA50 and PSA90 responses were 67% (95% CI, 52–81) and 28% (95% CI, 15–44), respectively. Among 29 pts with RECIST-evaluable disease, the confirmed ORR, as assessed by investigator, was 45% (95% CI, 26–64). At data cut, 26 pts were receiving ongoing treatment. Radiographic PFS will be presented. **Conclusions:** ABBV-969 demonstrated promising antitumor activity and a manageable safety profile in heavily pretreated pts with mCRPC. Dose optimization is ongoing. Clinical trial information: NCT06318273. Research Sponsor: AbbVie Inc.

Phase 2 study of YL201, an anti-B7H3 antibody–drug conjugate (ADC), in heavily pretreated metastatic castration-resistant prostate cancer (mCRPC). First Author: Dingwei Ye, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The treatment of mCRPC remains challenging, especially for patients who progressed on androgen receptor axis-targeted therapy (ARAT) with or without taxane-based chemotherapy. YL201 is a B7H3-targeting ADC with promising activity in advanced solid tumors. Here, we report the safety and preliminary efficacy of YL201 monotherapy in heavily pretreated mCRPC patients from a phase 2 study. **Methods:** Patients with mCRPC who had an ECOG PS of 0 or 1 and progressed on ≥1 prior line of ARAT and ≤2 lines of chemotherapy were enrolled and treated with YL201 intravenously Q3W at 2.0 or 2.4 mg/kg until disease progression or unacceptable toxicity. Primary endpoints were objective response rate (ORR) and radiographic progression-free survival (rPFS) per RECIST v1.1 and PCWG3 criteria. Secondary endpoints included PSA_{50} response rate, duration of response (DoR), overall survival (OS), and safety. **Results:** As of 12 December 2025, 82 patients were enrolled (34 at 2.0 mg/kg; 48 at 2.4 mg/kg) with a median follow-up of 12.2 months (95% CI: 11.2–13.4). The median age was 67.0 years, 65.9% had an ECOG PS of 1, and 43.9% had visceral metastases (22.0% with liver metastasis) at study entry. Patients had a median of 4 prior line of therapy (range: 1–8), with 100% having received ARAT and 70.7% having received taxane-based chemotherapy. Across both dose levels, confirmed PSA_{50} response rate was 38.5% (95% CI: 27.7–50.2), with a median duration of PSA response of 13.6 months (95% CI: 6.9–NR). Confirmed ORR was 29.5% (95% CI: 18.5–42.6), with a median DoR of 9.9 months (95% CI: 6.5–NR). Median rPFS was 9.1 months (95% CI: 7.4–12.0), while median OS remained immature. Higher PSA_{50} response rate, ORR and rPFS were observed at 2.4 mg/kg compared with 2.0 mg/kg (48.9% *vs*. 24.2%, 33.3% *vs*. 24.0%, 11.8 *vs*. 9.0 months, respectively). Notably, in patients with baseline visceral metastases, YL201 still showed encouraging efficacy with a confirmed PSA_{50} response rate of 54.5%, confirmed ORR of 28.6%, and median rPFS of 11.8 months at 2.4 mg/kg. Membrane B7H3 expression was detected in most tumor samples (median H-score: 185; range: 0–290), with no association observed between response and B7H3 expression level. Treatment-related adverse events (TRAEs) of grade ≥3 occurred in 43.9% of patients. The most common grade ≥3 TRAEs included neutropenia (29.3%), anemia (22.0%), leukopenia (18.3%), and thrombocytopenia (9.8%). No interstitial lung disease or pneumonitis was observed. The rate of treatment discontinuation due to TRAEs was 1.2%, and no treatment-related deaths were reported. **Conclusions:** YL201 showed promising antitumor activity and manageable safety profile in heavily pretreated mCRPC patients. These findings support further development of YL201 in mCRPC, especially for those who progressed after ARAT with or without taxane-based chemotherapy, and those with visceral metastases. Clinical trial information: NCT06241846. Research Sponsor: MediLink Therapeutics.

5016 Rapid Oral Abstract Session

Phase 2 multicenter trial of chemoimmunotherapy for patients with neuroendocrine or aggressive variant metastatic prostate cancer (CHAMP). First Author: Andrew J. Armstrong, Division of Medical Oncology, Duke University Medical Center, Duke Cancer Institute, Duke University, Durham, NC

Background: Platinum-doublet chemotherapy is effective in pts with neuroendocrine small cell neuroendocrine or aggressive-variant prostate cancer (NEPC/AVPC), but responses have limited durability. PD-1/PD-L1 inhibition in small cell lung cancer with chemotherapy is standard of care, but chemoimmunotherapy has not been tested in patients with NEPC/AVPC. **Methods:** We conducted a multicenter, phase II trial evaluating cabazitaxel, carboplatin, ipilimumab, and nivolumab (NCT04709276) in patients with metastatic NEPC/AVPC defined by histologic, clinical, or molecular features. Ipilimumab was dosed at 1 mg/kg q6w and nivolumab 360 mg q3w w/ongoing ADT. Cabazitaxel 20-25 mg/m2 + carboplatin AUC4 with GCSF was given q3w up to 10 cycles but could be stopped early for response or toxicity, followed by maintenance immunotherapy. Primary endpoint was immune modified iRECIST/PCWG3 radiographic progression-free survival (rPFS), hypothesizing a 55% 6-mo rPFS rate for cabazitaxel/carboplatin (1-sided α 0.1, 85% power) based on historic data. Secondary endpoints: overall survival (OS), rPFS, objective responses, safety. **Results:** We enrolled 40 patients across 3 centers in the Department of Defense Prostate Cancer Clinical Trials Consortium from 7/2021-8/2025, including 12 (32%) with NEPC and 28 (68%) with AVPC, with 38 evaluable for efficacy. Median age was 65 yrs, median PSA 2 ng/dl (range 0-807), and 75% with any visceral metastases including 58% with liver and 33% with lung metastases. The % with elevated serum CEA, LDH, or CgA was 88%; 85% had prior ARPI and 70% prior chemo. With a median f/u of 17 mo, CHAMP met its primary endpoint of improving 6-mo rPFS vs. cabazi/carbo with a 6-mo PFS rate of 78% (90% CI 69-100%); median rPFS was 12 mo. See Table for efficacy. We observed 20 G3 (50%) and 7 G4 (18%) toxicities related to treatment on a per patient basis. Two patients are free of disease and off therapy at 30+ mo. Most common overall G3-4 toxicities were anemia (n=15), neutropenia (n=5), sepsis (n=5), thrombocytopenia (n=5), colitis (n=5), febrile neutropenia (n=4), and UTI (n=4), with no treatment-related deaths. **Conclusions:** Dual PD-1/CTLA4 immune checkpoint blockade with platinum doublet chemotherapy is effective in patients with AVPC/NEPC, resulting in greater efficacy than expected with historic platinum chemotherapy alone, and with acceptable toxicity given disease risk. These results support randomized controlled clinical trials of chemoimmunotherapy in patients with NEPC/AVPC. Clinical trial information: NCT04709276. Research Sponsor: Bristol-Myers-Squibb.

Primary Endpoint (n=38)	Outcome (95% CI)

5017 Rapid Oral Abstract Session

PROTRACT: A randomized phase II trial comparing ctDNA-guided biomarker directed therapy vs patient/clinician's choice for metastatic castration resistant prostate cancer (mCRPC) progressing after abiraterone plus prednisone (AAP). First Author: Corinne Maurice-Dror, BC Cancer - Vancouver Centre, Vancouver, BC, Canada

Background: A subset of mCRPC patients (pts) will benefit from enzalutamide (ENZA) following disease progression on AAP. Preliminary data suggests that higher plasma ctDNA/total cfDNA fraction (ctDNA%) post-AAP predicts poor response to ENZA but preserved sensitivity to docetaxel (DOC). We hypothesize that ctDNA%-guided selection of enzalutamide or docetaxel in chemotherapy-naïve mCRPC post-abiraterone will improve clinical outcomes versus patient/clinician's choice of treatment. **Methods:** A multi-centre, open-label, phase II trial randomized mCRPC pts progressing after AAP 1:1 to biomarker-directed therapy (Arm A: ctDNA% $\geq$2% receives DOC; ctDNA% $<$2% receives ENZA) or clinician's choice of ENZA or DOC (Arm B, ctDNA% blinded). Baseline ctDNA% was assessed at screening using somatic mutations and genome-wide ploidy models. At progression, eligible pts could cross over to the alternative therapy. The primary endpoint was progression-free survival (PFS) defined as the time from treatment initiation to first documented disease progression (clinical, radiological, or PSA) or death from any cause. PFS was estimated using the Kaplan-Meier method and compared between arms using the log-rank tests. Secondary endpoints included PSA50 response (PSA decline $\geq$50% from baseline) and overall survival (OS). **Results:** Between October 2020 and June 2025, 56 pts were screened and 42 randomized 1:1 to Arm A (n=17) or Arm B (n=25). The trial was terminated due to slow accrual prior to the planned enrollment of 100 patients. At data cut-off (January 7, 2026), median follow-up was 38.0 months, and 94% (Arm A) and 92% (Arm B) had experienced disease progression or death. Baseline characteristics were balanced. ctDNA% $<$2% was observed in 35.3% and 32% of pts in Arm A and B, respectively. In Arm A, 11 pts were assigned to and received DOC (ctDNA% $\geq$2%) and 6 pts to ENZA (ctDNA $<$2%). In Arm B patient/clinician choice was DOC in 4 patients (3 pts with ctDNA $\geq$2%) and ENZA in 21 patients (7 pts with ctDNA $<$2%). PFS, OS and PSA50 all favoured biomarker directed therapy (Arm A) (Table). **Conclusions:** In this clinical utility study, ctDNA% to guide ENZA or DOC selection in patients previously treated with AAP led to superior PFS and OS compared to patient/clinician-selected therapy. These hypothesis-generating results illustrate the potential for ctDNA% as a predictive biomarker to assist in clinical decision making and support further studies. Clinical trial information: NCT04015622. Research Sponsor: Prostate Cancer Canada, Canadian Cancer Society.

Circulating tumor DNA–based clinical-genetic (CG) prognostic model for radiographic progression-free survival (rPFS) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC): Analysis of Alliance A031201. First Author: Susan Halabi, Department of Biostatistics and Bioinformatics, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: mCRPC is characterized by marked molecular heterogeneity and variable clinical outcomes. Circulating tumor DNA (ctDNA) profiling provides a noninvasive approach to capture tumor genomic alterations with potential prognostic value. We developed and validated a ctDNA-based prognostic model for rPFS using data from the Alliance A031201 (NCT01949337) trial, distinct from our published CG model of overall survival (Halabi et al. Eur Urol 2025). **Methods:** We analyzed ctDNA from 776 pts enrolled in the A031201 trial that randomized men with chemotherapy-naïve mCRPC to enzalutamide +/- abiraterone acetate and prednisone. Baseline cell free DNA samples from 776 pts were sequenced using the AR-ctDETECT assay. The primary endpoint of this analysis was rPFS. Proportional hazards model was used to assess the association of each genetic alterations and clinical variables with rPFS. Random survival forest (RSF) incorporating CG and clinical (C) variables only were trained and evaluated using 10-fold cross-validation. Model performance was assessed using integrated time-dependent area under the ROC curve (itAUC) and net reclassification improvement (NRI). **Results:** Higher ctDNA aneuploidy fraction, ctDNA positivity, and multiple pathogenic genomic alterations were associated with worse rPFS. Among prevalent alterations, *AR* enhancer gain and *AR* gain were strongly prognostic, with median rPFS of 13.7 vs 27.3 months (mos) and 13.5 vs 27.0 mos for pts with and without alterations, respectively. The rPFS prognostic model included gains in *AR, AR enhancer, MYC, CCND1,* and *FOXA1*, and losses in *PTEN, TP53,* and *LRP1B* based on RSF. *PTEN* loss, gains in *AR enhancer, MYC,* along with hemoglobin, PSA and alkaline phosphatase showed the largest contribution to risk prediction. Mean itAUC for C model was 0.66 (95% confidence interval [CI] 0.62-0.70), mean itAUC for CG model was 0.73 (95% CI: 0.69–0.77). At 22 mos (median rPFS), NRI comparing CG model with C model was 0.30 (95% CI: 0.19-0.36). Pts were stratified into low-, intermediate-, and poor-risk groups and showed markedly distinct rPFS outcomes, with median rPFS of 39.2, 25.2, and 12.8 mos, respectively. The hazard ratios for low vs poor risk was 0.25 (95% CI: 0.20–0.31) and for intermediate vs poor risk 0.46 (95% CI: 0.38-0.55). **Conclusions:** A ctDNA-based prognostic model integrating CG features robustly stratifies rPFS risk in pts with mCRPC treated with first line AR pathway inhibitor therapy. This approach may support individualized risk assessment and inform trial design around treatment intensification combinations and therapeutic decision-making. External validation in independent cohorts is warranted. Support: U10CA180821, U10CA180882; R01CA256157; R01CA174777; https://acknowledgments.alliancefound.org. 5019 Rapid Oral Abstract Session

Canadian Cancer Trials Group (CCTG) study PR21 (PLUDO): Results of crossover treatment from a randomized trial of ^{177}Lu-PSMA-617 (LuP) vs docetaxel (DOC) in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Kim N. Chi, University of British Columbia, BC Cancer, Vancouver Cancer Centre, Vancouver, BC, Canada

Background: The PLUDO trial randomized patients with mCRPC to receive either LuP or DOC, with cross-over permitted at radiographic progression (RP). At the primary analysis, there was no significant difference in the primary endpoint of 1st line radiographic progression free survival (rPFS) (HR 1.01, 90% CI: 0.77, 1.31). However, overall survival (OS) was in favor of patients randomized to receive docetaxel first (HR 1.64, 95% CI: 1.14, 2.35) (KN Chi, et al. ESMO Congress, 2025). To provide insights into potential reasons for the survival difference, we report the prespecified secondary objective of rPFS after cross-over therapy. **Methods:** Multi-centre open-label randomized phase II trial. 199 patients with chemotherapy-naïve, PSMA-PET positive mCRPC progressing after ARPI therapy were randomized 1:1 to receive either LU-P 7.4 GBq IV q6 weeks or DOC 75 mg/m2 IV q3 weeks, with cross-over permitted at progression. rPFS2 was measured from randomization to RP or death after cross-over therapy, "2nd line rPFS" was from time of start of cross-over therapy to RP or death, OS was defined from time of initial randomization to death, and "2nd line OS" was from time of cross-over therapy to death. **Results:** 159 patients had an rPFS event on 1st line therapy (LuP: n = 79, DOC: n = 80) including 24 deaths (LuP: n = 16, DOC: n = 8). At the time of 1st rPFS, there were no substantive differences between arms for grade 3-4 adverse events, but patients on LuP reported better quality of life (FACT-P). Of the 135 patients alive, 104 received cross-over therapy (LuP → DOC: 42, DOC → LuP: 62). There were no clinically relevant differences in baseline characteristics of patients who had cross-over therapy between treatment arms. OS was worse for patients that did not cross-over compared to those who did cross-over (LuP arm: HR 3.18 (95% CI 1.93, 7.42); DOC arm: HR 4.73 (95% CI 1.96, 11.38)). For the 104 patients who received both lines of therapy, there was no differences in efficacy outcomes for 2nd line rPFS, rPFS2, OS, or 2nd line OS (TABLE). PSA decline $\geq$ 50% was higher with cross-over Doc than LuP (69% vs 40%, P = 0.004). There were 9 grade 3 adverse events related to cross-over therapy in each arm. **Conclusions:** In the PLUDO study, there was no difference in first-line or cross-over rPFS between LuP and DOC. In patients who received cross-over therapy, this analysis shows no OS difference, suggesting that imbalance in cross-over from LuP to Doc likely impacted the OS difference in the ITT population and emphasizes the importance of both treatments on efficacy outcomes. Clinical trial information: NCT04663997. Research Sponsor: Canadian Cancer Society; 707213; Novartis; Prostate Cancer Canada.

Subgroup analyses by disease volume and *de novo*/recurrent mHSPC in the PSMAddition study of [^{177}Lu]Lu-PSMA-617. First Author: Fred Saad, Centre Hospitalier de l'Université de Montréal, University of Montreal, Montreal, QC, Canada

Background: In the phase 3 PSMAddition study (NCT04720157), combining [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) with ADT + ARPI significantly improved rPFS in patients with PSMA+ mHSPC vs ADT + ARPI at rPFS interim analysis (data cut off Jan 13, 2025), with a HR of 0.72 (95% CI 0.58, 0.90; p = 0.002). **Methods:** Patients had treatment-naive/minimally treated mHSPC diagnosed by CT/MRI/bone scan and ≥1 PSMA+ metastatic lesion on [^{68}Ga]Ga-PSMA-11 PET/CT. Patients were randomized 1:1 to ^{177}Lu-PSMA-617 (7.4 GBq ± 10% q6w, 6 cycles) + ADT + ARPI (^{177}Lu-PSMA-617 arm) or ADT + ARPI (control arm). The primary endpoint of rPFS (centrally assessed rPD per PCWG3/RECIST v1.1 or death) and selected secondary efficacy, safety, and patient-reported outcomes (PROs) were assessed in subgroups of high/low disease volume (DV) per CHAARTED criteria (locally assessed by CT/MRI/bone scan; prespecified) and *de novo*/recurrent mHSPC (AJCC stage ≥/<IVb; *post hoc*). **Results:** Of 572 patients randomized to the ^{177}Lu-PSMA-617 arm and 572 to the control arm, 68.0% and 68.2% had high DV, and 52.1% and 47.9% had *de novo* mHSPC. Efficacy and PRO HRs for the ^{177}Lu-PSMA-617 arm vs control arm were generally similar in the overall population and DV and mHSPC subgroups (rPFS HR 0.72–0.74; time to PSA progression HR 0.29–0.51) (Table). Incidences of AEs, grade ≥3 AEs, serious AEs, and selected safety topics of interest (cytopenias, dry mouth) were similar across subgroups within each treatment arm. **Conclusions:** In patients with PSMA+ mHSPC, combining ^{177}Lu-PSMA-617 with ADT + ARPI improved rPFS vs ADT + ARPI across high/low DV and *de novo*/recurrent mHSPC subgroups. Other efficacy outcomes, PROs, and the safety profile were generally consistent across subgroups. Clinical trial information: NCT04720157. Research Sponsor: Novartis.

Validation of prostate-specific antigen (PSA) decline among the Latin American subgroup of LIBERTAS: A phase 3 study of apalutamide (APA) plus continuous versus intermittent androgen deprivation therapy (ADT) in metastatic castration-sensitive prostate cancer (mCSPC). First Author: Andrea Juliana Gomes, Liga Norte Riograndense Contra o Câncer, Natal, Brazil

Background: APA in combination with continuous ADT showed rapid and deep PSA decline in participants (pts) with mCSPC in the TITAN study, and this deep PSA decline was associated with improved overall survival. LIBERTAS (NCT05884398), a global phase 3 study, is evaluating APA + intermittent ADT as an ADT de-escalation strategy for pts with mCSPC who achieve an undetectable PSA (< 0.2 ng/mL) after 6 months on APA + ADT. In the initial treatment phase of LIBERTAS, 6 months of APA + continuous ADT resulted in deep PSA responses in the majority of pts with mCSPC. **Methods:** Pts with mCSPC were eligible if they had ≤3 months of prior ADT, ECOG PS 0–1 and confirmed metastases by conventional or next-generation imaging. In the initial 6-month treatment phase, all pts received APA 240 mg/day + ADT. In the main treatment phase, pts with < 0.2 ng/mL were randomized 1:1 to APA 240 mg/day + intermittent or continuous ADT. Co-primary endpoints were radiographic progression-free survival (rPFS), measured by the 18-month event-free survival rate, and reduction of hot flash burden, measured by the 18-month severity-adjusted hot flash score. Here, we present an analysis of the Latin American (LATAM) subgroup evaluating PSA response results following the initial treatment phase. **Results:** From Dec 2023 to July 2024, 118 LATAM pts were enrolled (87 pts from 7 sites in Brazil, and 31 pts from 4 sites in Mexico). Racial distribution in LATAM pts was 60.2% White, 10.2% Black, 9.3% Multiple, and 17.8% other. LATAM pts were younger (median age 67 years [range: 48–86]) and had more advanced disease (89.0% with M1 disease at diagnosis; 39.8% with ECOG PS 1, 66.1% with high volume disease; median baseline PSA 22.95 ng/mL [IQR: 3.18–87.00]) compared with the overall study population. Among 109 pts who completed the 6-month initial treatment phase, 104 (95.4%) achieved a ≥50% PSA decline (PSA50), 90 (82.6%) achieved a ≥90% decline (PSA90), and 66 (60.6%) achieved PSA < 0.2 ng/mL (PSA0.2), of which 62 (56.9%) pts were randomized to the main treatment phase. Median time to response was 1.87 months for PSA50, 1.91 months for PSA90, and 3.14 months for PSA0.2. No new safety signals were observed in the LATAM subgroup. **Conclusions:** LATAM pts in LIBERTAS were younger on average and had more advanced disease compared with the overall study population. Despite having higher baseline PSA levels, LATAM pts with mCSPC demonstrated rapid and deep PSA responses to APA + ADT, consistent with the results from the global analysis. The safety profile of APA was consistent with previous studies. The LIBERTAS study remains on track for the primary readout. Clinical trial information: NCT05884398. Research Sponsor: None.

Real-world genetic testing patterns in prostate cancer assessed via artificial intelligence: Implications for NCCN guideline implementation. First Author: Mitchell Singstock, Hunstman Cancer Institute at The University of Utah, Salt Lake City, UT

Background: Germline and somatic genomic testing in prostate cancer guide both targeted therapy selection and identification of heritable cancer risk. Although NCCN guidelines define testing eligibility based on disease risk and stage, real-world testing remains suboptimal. Population-level data indicate that only one-third of men with metastatic prostate cancer undergo genomic testing. As part of a larger effort to improve testing rates, we evaluated three consecutive years of prostate cancer care to quantify testing utilization and assessed artificial intelligence (AI) performance for risk stratification and testing eligibility. **Methods:** We conducted a retrospective chart review of patients with advanced prostate cancer treated at a large multi-site community oncology practice between 2023 and 2025. Clinical data were manually reviewed to assign disease stage, NCCN risk stratification, and eligibility for germline and somatic testing. In 2023, a rules-based AI applied explicit NCCN guideline logic (v1.2023). In 2024 and 2025, an untrained general-purpose AI model (ChatGPT 5.2) was provided NCCN guideline text (v1.2024 and v1.2025) and tasked with inferring risk category and testing eligibility. Primary outcomes included observed annual germline and somatic testing rates and AI concordance with manual review. Temporal trends in germline and somatic testing adoption were assessed using the Cochran-Armitage trend test. **Results:** Across 2023–2025, NCCN-indicated germline and somatic testing was inconsistently performed (Table 1), with significantly increasing rates from 2023 to 2025 (Cochran–Armitage trend test, germline $p < 0.001$, somatic $p < 0.001$). Testing outside of NCCN guidelines was ordered by clinicians in 10 (4%), 22 (9%), and 31 (18%) patients each year, respectively. **Conclusions:** In a large community oncology setting, NCCN-indicated germline and somatic testing for prostate cancer was frequently underutilized, despite significant improvement over time. Ongoing analyses seek to clarify which interventions contributed to increased testing rates and whether testing performed outside NCCN guidelines reflects broader clinical awareness of indications not consistently captured in structured data. AI-based guideline interpretation of NCCN guidelines demonstrated consistently high concordance with manual review and may offer a scalable approach to systematically identify patients eligible for genetic testing using structured data. Research Sponsor: AstraZeneca; Pfizer.

Year	Charts Reviewed	Germline Eligible	Germline Tested	Somatic Eligible*	Somatic Tested	AI Risk Stratification	AI Testing Recommendation Concordance
2023	259	194	54 (28%)	91	24 (26%)	Not assessed	Germline 97%; Somatic 100%

Image-only and multimodal AI digital pathology biomarkers to demonstrate risk stratification across standard prostate cancer management strategies. First Author: Xinglei Shen, University of Kansas Medical Center, Kansas City, KS

Background: Reliable risk stratification across standard treatment pathways is essential for the clinical adoption of precision medicine biomarkers in localized prostate cancer. We previously developed and validated a multimodal artificial intelligence (MMAI) model that integrates digitized hematoxylin and eosin (H&E) prostate biopsy slides with clinical variables to prognosticate distant metastasis (DM) and prostate cancer specific mortality (PCSM). To evaluate the independent prognostic signal derived from routine histopathology alone without clinical variables, we built an Image-only artificial intelligence model. In this study, we validate the prognostic ability of the new Image-only and existing MMAI models in a multi-institutional cohort of nonmetastatic prostate cancer patients receiving guideline-concordant standard-of-care treatments. **Methods:** The Image-only model was trained to estimate the risk of 10-year distant metastasis (DM) without clinical inputs. Both the Image-only and MMAI models were evaluated in a cohort of men from 3 institutions with non-metastatic prostate cancer treated with active surveillance (AS), radical prostatectomy (RP), or radiation therapy (RT). The primary endpoint was 10-year risk of DM, with prostate cancer–specific mortality (PCSM) as a secondary endpoint. Prognostic associations were evaluated within each treatment subgroup using Fine–Gray models. **Results:** Among 886 patients with Image-only scores and 911 with MMAI scores, approximately 36% were managed with AS, 41% with RP, and 23% with RT. The Image-only model continuous raw scores were consistently associated with DM risk across treatment modalities, including AS (subdistribution hazard ratio [sHR] 2.38, $p < 0.001$), RP (1.99, $p < 0.001$), and RT (sHR 2.84, $p < 0.001$). Similarly, the Image-only model calibrated scores showed significant prognostic association with DM across all treatment groups. The MMAI showed consistent prognostic performance for DM using both calibrated and raw scores (raw scores: AS sHR 2.87, $p < 0.001$; RP sHR 2.12, $p < 0.001$; RT sHR 2.73, $p < 0.001$). Both Image-only and MMAI scores were significantly associated with PCSM despite low event rates. **Conclusions:** Both Image-only and MMAI biomarkers demonstrate consistent prognostic performance across standard prostate cancer management strategies, including AS, RP, and RT, supporting their utility for risk stratification regardless of ultimate treatment selection. These findings highlight the robustness of image-derived prognostic information and demonstrate that routinely available H&E pathology alone captures clinically meaningful risk information that generalizes across treatment contexts. Together, these results support the use of AI-based digital pathology biomarkers for prognostication in localized prostate cancer. Research Sponsor: Artera Inc.

AI-assisted preoperative communication in prostate cancer: A prospective, single-blinded, randomized phase II trial. First Author: Zheng Liu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: To evaluate whether AI-assisted preoperative communication reduced patient anxiety, and physician workload compared with standard preoperative communication in patients undergoing radical prostatectomy. **Methods:** We conducted a prospective, randomized, single-blinded, phase II trial in newly diagnosed prostate cancer patients undergoing radical surgery, excluding those with severe psychiatric or cognitive disorders. Upon hospital admission, patients were randomized at the room level to receive either standard or AI-assisted preoperative communication. After baseline assessment, the AI-assisted group received individualized responses generated by a locally deployed large language model–based AI system prior to routine physician-led face-to-face preoperative communication, while physicians remained blinded to group allocation. The primary outcomes were patient anxiety (GAD-7) and physician workload (NASA-TLX). Comparisons were conducted using non-parametric rank-sum tests. The trial was registered at ClinicalTrials.gov (NCT07082049). **Results:** Between April and November 2025, 268 patients were randomized to the control group (n = 130) or the AI-assisted group (n = 138). A total of 3,507 questions were collected (avg. 13.08 per patient). After routine preoperative communication, patients in the AI-assisted group reported lower anxiety levels than those in the control group (GAD-7 median [IQR], 3.5 [2.5–5.0] vs. 7.5 [6.5–9.0]; $P < 0.001$). Physician workload was also reduced in the AI-assisted group, as reflected by lower NASA-TLX scores (median [IQR], 37.0 [27.0–46.0] vs. 54.0 [35.0–73.0]; $P < 0.001$), accompanied by a substantial reduction in preoperative communication time (12.60 vs. 21.90 minutes; $P < 0.001$). Patients in the AI-assisted group reported more favorable emotional status, lower negative illness perceptions, and higher satisfaction, while exploratory analyses indicated that AI-assisted communication alone improved anxiety, emotional status, and disease-related perceptions prior to physician face-to-face preoperative communication. The observed reductions in physician workload and communication time suggest potential applicability in resource-constrained clinical settings where clinical manpower and consultation time are limited. **Conclusions:** AI-assisted preoperative communication reduced patient anxiety, and physician workload compared with standard communication, supporting its role as a supplementary approach to routine preoperative care in prostate cancer, including settings involving older adults and limited clinical resources. Implementation of serum microRNA-371a-3p testing for testicular germ-cell tumors in a pathology department: Real-world data from a comprehensive cancer center. First Author: João Lobo, Portuguese Oncology Institute of Porto (IPO-Porto), Porto, Portugal

Background: The classical serum tumor markers for testicular germ cell tumor (TGCT) patients show limited sensitivity and specificity in some clinical settings. In the last years, serum miR-371a-3p testing has been shown to have superior performance for the detection and follow-up of TGCT patients. A commercial test with IVD approval is already available for use in the clinic. In this work we demonstrate our experience with the clinical implementation of this liquid biopsy test, comparing its performance with the one of AFP, HCG and LDH. **Methods:** The M371 test (serum) was implemented at the Department of Pathology of our Comprehensive Cancer Center in August 2024, for patients presenting with testicular masses and for TGCT patients during follow-up. Simultaneous collection of AFP, HCG and LDH was performed at the different timepoints, following the guidelines for diagnosis and follow-up of TGCT patients. Blood was collected on the recommended Serum-Gel 7.5mL tubes and processed to serum within 3h of collection. The RTqPCR test and analysis followed the manufacturer's closed protocol (IVDR approved). Clinical charts and CT scans were reviewed to determine disease status, and results were correlated with histology. **Results:** A total of 128 M371 tests were performed at the Department of Pathology during 16 months, including several contexts of the disease (pre-orchiectomy, follow-up, pre-RPLND, pre and post-chemotherapy). The mean turnaround time for the test (from receiving the blood sample to issuing the report) was of 5.6 days. The median patient age was 35 years (19-81 years). The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were as follows: 0.43, 0.96, 0.76 and 0.85 for AFP; 0.57, 0.98, 0.89 and 0.88 for HCG; 0.37, 0.91, 0.55 and 0.82 for LDH; 0.80, 0.92, 0.77 and 0.93 for the combination of AFP+HCG+LDH; and 0.96, 0.96, 0.87 and 0.99 for M371 test alone. Additional collections/testing and subanalyses based on disease setting and histologic findings are ongoing. **Conclusions:** The M371 IVD serum test alone showed a superior diagnostic performance for detecting active TGCT in an unselected, consecutive cohort of TGCT patients representing different settings of the disease, when compared to the classical serum tumor markers AFP, HCG and LDH, isolated or in combination. The sensitivity of AFP, HCG and particularly LDH isolated (0.43, 0.57 and 0.37) were outperformed by the sensitivity of the M371 test (0.96). The high NPV of the M371 test (0.99) may aid in the decision of de-escalating intervention (treatment or follow-up measures) of young TGCT patients. These real-world data underscore the potential advantages of adding microRNA testing as a an additional test to combine with classical serum tumor markers and imaging. Research Sponsor: None.

Comparative transcriptomic analysis of chemotherapy-naive and post-chemotherapy germ cell tumors. First Author: Michal Mego, Department of Oncology, Faculty of Medicine, Comenius University and National Cancer Institute, Bratislava, Slovakia

Background: Cisplatin-based chemotherapy is highly effective in testicular germ cell tumors (GCTs); however, the presence of viable tumor after first-line chemotherapy is associated with chemoresistance and poor clinical outcome. The transcriptional programs distinguishing chemotherapy-naïve and post-chemotherapy viable GCTs remain incompletely characterized. **Methods:** Tumor samples from 50 GCT patients treated between 2010 and 2022 were analyzed, including 30 chemotherapy-naïve tumors and 20 post-chemotherapy viable GCTs resected from the retroperitoneum. Five normal testicular tissue samples served as controls. Formalin-fixed paraffin-embedded samples were profiled using the HTG EdgeSeq Oncology Biomarker Panel. Differential gene expression analysis was performed using DESeq2, adjusted for histology, with significance defined as adjusted p-value < 0.1 and $|\log2 \text{ fold change}| > 1$. Functional enrichment analysis was conducted to identify deregulated biological pathways. **Results:** Compared with normal testicular tissue, chemotherapy-naïve GCTs and post-chemotherapy viable GCTs exhibited 1,010 and 720 differentially expressed genes, respectively. Direct comparison between chemotherapy-naïve and post-chemotherapy tumors identified 424 differentially expressed genes. Post-chemotherapy viable GCTs demonstrated marked downregulation of genes associated with pluripotency and embryonal stem cell identity, including *POU5F1*, *UTF1*, *DPPA4*, and *PRDM14*. In contrast, post-chemotherapy tumors showed upregulation of immediate early stress response genes, inflammatory and cytokine signaling pathways, EGFR-related growth factor signaling, and metabolic stress adaptation. **Conclusions:** Post-chemotherapy viable GCTs are characterized by loss of pluripotent transcriptional programs and acquisition of stress-responsive, inflammatory, and adaptive signaling pathways. These transcriptional changes provide insight into the biology of chemotherapy resistance in GCTs and may have prognostic and therapeutic implications. Genomic determinants of cisplatin resistance in germ cell tumors. First Author: Vincent D'Andrea, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cisplatin-based chemotherapy achieves complete remission in 70-80% of patients with germ cell tumors (GCTs), but a subset are cisplatin-resistant and progress after first-line therapy. Prior studies have linked *TP53* and *MDM2* alterations and chromosome 3p25.3 gain to cisplatin resistance and worse outcomes in GCT. We sought to validate this and identify additional genomic determinants of cisplatin response in a large GCT cohort. **Methods:** Patients who received first-line cisplatin-based chemotherapy for GCT of any primary site with genomic analysis of the tumor were eligible. Cisplatin resistance was defined as: (1) incomplete response to chemotherapy, (2) non-teratomatous progression after chemotherapy, or (3) viable non-teratomatous GCT at post-chemotherapy surgery; all other patients were considered sensitive. Next-generation sequencing was performed using the MSK-IMPACT assay and association between genomic alterations and resistance was assessed using Fisher's exact test. Cytoband analysis was completed using the FACETS algorithm to calculate chromosomal alterations, with a required cytoband coverage of 75%. The association between cytoband alterations and resistance was assessed using relative risk with a robust variance estimator. **Results:** The cohort of 556 patients included 79% testicular, 15% mediastinal, 4% ovarian, and 1.5% tumors of other primary site. 79% were non-seminomatous germ cell tumors and 21% pure seminoma. Among these, 336 (60%) were cisplatin-resistant. *TP53* mutations were more common in resistant than sensitive tumors (16% vs 2%), as were *MDM2* and *CRKL* amplifications (7% vs 1% and 4% vs < 1%, respectively). *KIT* was more frequently mutated in cisplatin-sensitive tumors (5% in resistant vs 14% in sensitive) (Table 1). *TP53* mutations occurred predominantly in mediastinal primary tumors (89%) whereas *MDM2* alterations were confined to testicular primaries. Of 472 patients who underwent cytoband 3p25.3 analysis, chromosome 3p25.3 gain was associated with cisplatin resistance (relative risk 1.23; 95% CI: 1.00, 1.49; p = 0.04). **Conclusions:** In this large GCT cohort, *TP53* and *MDM2* alterations and chromosome 3p25.3 gains were associated with cisplatin resistance, consistent with prior reports. We also found that *CRKL* amplifications were associated with cisplatin resistance whereas *KIT* mutations were associated with cisplatin sensitivity. These latter findings are the first reports of the association of these genes with cisplatin response and warrant further mechanistic investigation to define how these alterations influence cisplatin sensitivity. Research Sponsor: None.

Genomic alterations corresponding to cisplatin response in GCT.

Alteration	Resistant (n=336)	Sensitive (n=220)	p-value

Prognostic significance of teratoma components in germ cell tumor patients undergoing high-dose chemotherapy and autologous stem cell transplantation. First Author: Nurlan Mammadzada, Ankara Gülhane Eğitim ve Araştirma Hastanesi, Ankara, Turkey

Background: The prognostic significance of a teratoma component in relapsed or refractory germ cell tumors (GCT) treated with high-dose chemotherapy followed by autologous stem cell transplantation (HDCT-ASCT) remains unclear. While teratoma has been extensively studied in earlier treatment lines, data specifically addressing its impact in the transplant setting are limited. Identification of factors influencing outcomes after HDCT is critical for patient selection and treatment optimization. **Methods:** This single-center retrospective study included 132 GCT patients who underwent autologous stem cell–supported HDCT. Primary tumor specimens were re-evaluated by an experienced pathologist for the presence of a teratoma component. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan–Meier method and compared between teratoma-positive and teratoma-negative groups. Univariate Cox regression and predefined subgroup analyses were performed to identify factors associated with survival outcomes. **Results:** Baseline pathological data were available for 132 patients; 59 (44.7%) had a teratoma component and 73 (55.3%) did not. Baseline clinicopathological characteristics, including age, primary tumor site, stage, IGCCCG risk group, metastatic pattern, biomarker status, and response to first-line therapy, were comparable between groups. After a median follow-up of 55.6 months, median PFS was 6.8 months (95% CI, 4.1–9.6). Median PFS was significantly shorter in teratoma-positive patients compared with teratoma-negative patients (5.6 vs 10.0 months; log-rank p = 0.011). The 2-year PFS rates were 34% and 50%, respectively. Teratoma presence was associated with inferior PFS in univariate analysis (HR 1.77, 95% CI 1.13–2.77; p = 0.013). Median OS was not reached overall; median OS was 68.9 months in teratoma-positive patients and not reached in teratoma-negative patients, with no significant difference between groups (p = 0.986). The 2-year OS rates were similar (64% vs 67%). Subgroup analyses showed numerically poorer OS with teratoma across most strata, without statistical significance. **Conclusions:** In relapsed or refractory GCT patients undergoing HDCT, the presence of a teratoma component was associated with inferior disease control but not with a statistically significant OS disadvantage, possibly due to limited follow-up. Teratoma status may help identify patients requiring more intensive transplant strategies and early post-transplant treatment optimization. Prospective studies with longer follow-up are warranted. Integrated clinical and genomic analysis of mediastinal germ cell tumors (GCT) with somatic transformation (SM): A multi-institutional cohort study. First Author: Zachariah Thomas, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: SM of GCT is a rare but lethal entity largely described in the context of testicular primaries. The distinct clinical and genomic features of SM that arise from anterior mediastinum are less defined. **Methods:** A multi-institutional study was conducted by integrating data from Indiana University and the MD Anderson Cancer Center, including patients(pts) with SM arising from mediastinal GCT treated between 2016 and 2025. Electronic health records were queried to obtain clinical, pathologic and genomic data when available. SM was classified as "de novo" if detected prior to disease relapse; all others were "evolved". In the absence of elevated markers or concomitant GCT elements, isochromosome12p testing confirmed GCT ancestry. Descriptive statistics were used. Cox regression and Kaplan Meier analysis were used for overall survival(OS) and reverse KM for follow-up. OS measured from the time of transformation to date of last follow-up. The study was under protocol PA16-0736. **Results:** 40 pts were identified. All were male; median age at GCT diagnosis was 25 yrs (IQR:22-35); First detection of SM was by diagnostic biopsy in 14(35%) instances and surgical excision in 24(60%). Sarcoma was the most common histology detected in 33(82%), notably rhabdomyosarcoma and angiosarcoma- 8(20%) each. More than one SM pathology in 6(15%) pts and hematolymphoid SM was detected in 4(10%). Of 23/40 (57%) pts with genomic testing, 17(74%) were performed on the primary specimens, 5(22%) on metastatic deposits and 1(4%) on peripheral blood. TP53 and PTEN/AKT pathway mutations were seen in 16(70%) and 14(61%) respectively. De novo SM was seen in 32(80%). 9(28%) had baseline metastatic disease. Elevated AFP and beta-hCG in 28/32(84%) and 14/32(44%); 6(19%) were marker negative. 24(75%) received conventional GCT regimens. All marker negative pts had histology-driven therapy. Response data in Table. 26(81%) received surgical consolidation. For full cohort, median follow-up was 2.9 yrs, 2yr OS- 62%(95%CI:46.9-81.9) and 5yr OS- 52%(95%CI: 35.6-75.4). For de novo SM, surgical consolidation was associated with longer survival (mOS 8 yrs vs 0.6 yrs, HR-0.09, 95%CI:0.02-0.3, p-0.0003). **Conclusions:** The vast majority of mediastinal SM are sarcomas, that can be detected de novo. Conventional tumor markers are frequently elevated at presentation and may reflect concomitant non-teratoma GCT. TP53 and PTEN/AKT pathway mutations characterize the most common alterations and can be detected in primary and metastatic specimens. Research Sponsor: None.

Response to first-line therapy	GCT Therapy (n= 24) (%)	Histology driven therapy (n=7) (%)
Complete Remission (without resection)	4 (17)	1 (14)
Partial Remission	8 (34)	3 (42)
Stable Disease	5 (22)	2 (29)
Progressive Disease	6 (26)	1(14)
Not available	1 (4)	
Marker Response		
Elevated at presentation	23 (96)	1 (14)
Normalization of markers	15 (63)	1 (14)

Regional trends in testicular cancer burden among adolescents and young adults (15–39 years), 1990–2023: A Global Burden of Disease analysis. First Author: Vanshika Singh, King George's Medical University, Lucknow, India

Background: Testicular cancer is the most common solid malignancy in adolescent and young adult (AYA) males. Contemporary long-term regional trends in incidence and health loss among AYAs remain incompletely described. We quantified trends in testicular cancer burden among ages 15–39 years from 1990–2023 across World Health Organization (WHO) regions. **Methods:** Using annual Global Burden of Disease (GBD) estimates (1990–2023) for ages 15–39 years, we assessed trends in incidence, prevalence, deaths, disability-adjusted life years (DALYs), years of life lost (YLLs), and years lived with disability (YLDs). For each WHO region and measure, we fit log-linear models (ln[rate] = $\beta \times$year) and calculated annual average percent change (AAPC) as $100 \times (e^{\beta} - 1)$, with 95% confidence intervals (CI) derived from the regression. **Results:** Incidence showed an upward trend in all regions, ranging from 0.62%/year in the African Region (95% CI 0.28–0.96) to 3.15%/year in the Eastern Mediterranean Region (2.98–3.33). Prevalence rose across regions, highest in the South-East Asia Region (6.04%/year, 5.82–6.26) and Eastern Mediterranean Region (5.22%/year, 5.09–5.34). Mortality trends varied across regions. Deaths declined in the Western Pacific (-1.69%/year, -1.99 to -1.39), Europe (-1.43%/year, -1.49 to -1.36), and Africa (-0.89%/year, -1.20 to -0.58), were stable in South-East Asia (-0.07%/year, p=0.44), and increased in the Americas (1.68%/year, 1.49–1.87) and Eastern Mediterranean (0.42%/year, 0.32–0.51). DALYs and YLLs followed similar patterns (declining in Europe/Western Pacific, rising in the Americas). **Conclusions:** From 1990–2023, testicular cancer incidence and survivorship-related burden increased across all WHO regions among AYAs, while mortality-related metrics improved in Europe/Western Pacific but worsened in the Americas and Eastern Mediterranean. These findings support urgent investigation of drivers of rising incidence and targeted strategies to reduce regional inequities in timely diagnosis and curative treatment for AYAs. Research Sponsor: None.

Metabolic and inflammatory marker elevations and associations with hormone therapy usage in prostate cancer patients of the All of Us Research Program cohort. First Author: Yuanchu J. Yang, Vanderbilt University Medical Center, Nashville, TN

Background: The development of cardiovascular disease (CVD) involves an interplay of inflammatory and metabolic factors. While hormone therapy (HT) is associated with increased CVD risk in prostate cancer (PCa) patients, the underlying mechanism remains unclear. Prior studies suggest an association between hypogonadism and systemic inflammation, but the specific effect of HT is poorly understood. Utilizing the All of Us Research Program, we investigated the effects of HT on metabolic and inflammatory markers. **Methods:** Our study examined All of Us participants who were diagnosed with PCa and were either treated or not treated with HT (GnRH agonists, GnRH antagonists, and/or anti-androgens), as well as those who received HT for non-PCa indications. We used ANCOVA to evaluate the effect of HT on metabolic and inflammatory labs after adjusting for pre-PCa baseline values. Among HT-treated PCa patients without prior CVD (myocardial infarction, stroke, or heart failure), we used Gray's test to compare CVD time-to-event between participants with and without elevated inflammatory labs (CRP $>$ 10, ESR $>$ 20, or Ferritin $>$ 300) after HT treatment. In the non-PCa cohort, paired T-tests compared pre-HT and post-HT values. **Results:** The study included 7124 participants with PCa (1480 with HT; 5644 controls) and 2683 participants without PCa who received HT. After adjustment for baseline values, HT usage was associated with increased HgbA1c ($P<0.001$), HDL ($P<0.001$), triglycerides ($P<0.001$), ESR (P=0.006), CRP (P=0.009), and ferritin (P=0.006). Similar trends were seen in the non-PCa cohort (Table). In our survival analysis, HT-treated PCa patients with elevated inflammatory labs had higher CVD risk ($P<0.001$). **Conclusions:** Our study demonstrated associations between HT usage and metabolic dysregulation, while also suggesting a pro-inflammatory effect of HT in PCa patients. These trends reinforce prior studies and were similar among those without PCa, suggesting a drug-class effect. Our study also observed an increased risk of CVD among HT-treated PCa patients with elevated inflammatory labs. Future research should explore the role of HT associated inflammation in CVD, as well as identify targets for risk mitigation. Research Sponsor: None.

Lab	HT Treatment EMM (SE)	No HT Treatment EMM (SE)	P-value (ANCOVA)	Non-PCa Pre-HT Mean	Non-PCa Post-HT Mean	P-Value (Paired T-test)

Burden, mortality patterns, and treatment disparities of prostate cancer across G20 countries: Insights from the Global Burden of Disease 2023 study. First Author: Kashish Magnani, Westchester Medical Center, Valhalla, NY

Background: Prostate cancer is the leading male malignancy in G20 nations, yet cross-national disparities in detection, treatment, and outcomes remain insufficiently characterized. This study examines incidence, mortality, and treatment patterns across G20 countries, with attention to socioeconomic and health system factors. **Methods:** We analyzed prostate cancer incidence, mortality, and disability-adjusted life years (DALYs) in all 20 G20 member states from 1990 to 2023 using GBD 2023 data. Analysis focused on men aged ≥50 years. Age-standardized rates were calculated, and incidence-to-mortality ratios were used as a proxy for early detection and treatment access. Radical treatment rates (surgery, radiotherapy) and PSA screening availability were correlated with survival patterns. Country-level economic estimates included diagnostic, therapeutic, and end-of-life expenditures. **Results:** In 2023, G20 countries reported 3.24 million new prostate cancer cases and 512,000 deaths, resulting in 11.8 million DALYs. Age-standardized incidence rates ranged from 23.4 to 112.6 per 100,000 men—a 4.8-fold variation—strongly associated with national healthcare development index ($r = 0.78$, $p < 0.001$). High-income G20 nations reported incidence-to-mortality ratios between 4.2:1 and 5.8:1, while middle-income countries such as India, Indonesia, and Mexico ranged from 1.3:1 to 1.8:1. India and Indonesia together accounted for 24% of G20 prostate cancer deaths despite contributing only 18% of total incident cases. Radical treatment rates spanned from 8% in India to 68% in the USA, correlating with long-term survival trends. Average healthcare expenditure per prostate cancer death ranged from $2,100 in low-resource settings to $89,400 in high-income countries. Within high-income nations, men in the lowest socioeconomic quintile experienced 2.1 times higher mortality than those in the highest quintile. **Conclusions:** Marked disparities in prostate cancer burden and treatment access persist across G20 nations, shaped by income level and healthcare system capacity. Strategic expansion of PSA-based screening and curative treatment in middle-income settings could substantially reduce preventable deaths and narrow the outcome gap. Research Sponsor: None.

Real-world overall survival outcomes of lutetium (Lu^{177}) vipivotide tetraxetan treatment in prostate cancer. First Author: Elshad Hasanov, Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: After FDA approval on March 23, 2022, lutetium (Lu^{177}) vipivotide tetraxetan became an established treatment option for advanced prostate cancer, but real-world survival outcomes and prognostic factors remain incompletely described. **Methods:** We conducted a retrospective cohort study in Epic Cosmos with the largest to date reported cohort of patients with prostate cancer who initiated lutetium Lu^{177} vipivotide tetraxetan after FDA approval to Dec 20, 2025, ensuring at least one month of follow-up prior to the query date. OS was measured from the medication start date to death, or censoring at last encounter. Kaplan–Meier methods were used for survival analysis. Univariable Cox proportional hazards models, adjusted for false discovery rate (FDR), were used to assess associations between OS and clinical variables. **Results:** The cohort included 6464 patients with a median age of 74.0 years (IQR: 38–100). The cohort was predominantly White (75.2%) and Black/African American (19.9%). Kaplan-Meier analysis showed OS probabilities of 85.4%, 67.2%, 42.8%, and 23.8% at 6, 12, 24, and 36 months, respectively, comparable to results reported in the Phase 3 VISION trial. Worse survival was significantly associated with a history of tobacco use (HR 1.22 [1.11–1.33], FDR <0.01) and higher Charlson Comorbidity Index scores (HR 1.04 [95% CI 1.02–1.06], FDR <0.01). Conversely, higher BMI (HR 0.98 [0.97–0.99], FDR <0.01) was associated with improved survival. Baseline laboratory markers of nutritional and hematologic reserve were strongly protective, including higher Albumin (HR 0.39 [0.35–0.43], FDR <0.01), Total Protein (HR 0.81 [0.74–0.89], FDR <0.01), Hemoglobin (HR 0.77 [0.75–0.79], FDR <0.01), RBC count (HR 0.53 [0.49–0.57], FDR <0.01), and MCHC (HR 0.88 [0.86–0.91], FDR <0.01). Inflammatory and immune markers showed distinct prognostic value: higher Eosinophils (HR 0.38 [0.25–0.58], FDR <0.01) and Lymphocytes (HR 0.69 [0.64–0.76], FDR <0.01) were associated with better outcomes, while higher Basophil-to-Lymphocyte Ratio (HR 2.10 [1.17–3.78], FDR = 0.02), RDW (HR 1.16 [1.14–1.19], FDR <0.01), and Neutrophils (HR 1.06 [1.04–1.08], FDR <0.01) were associated with worse survival. Higher electrolytes (Sodium, Chloride, Potassium, Bicarbonate) were generally associated with lower hazard, likely reflecting better physiologic homeostasis. **Conclusions:** In this large real-world cohort of prostate cancer patients treated with Lu^{177} vipivotide tetraxetan, overall survival was strongly influenced by tobacco use, comorbidity burden, and baseline laboratory markers reflecting nutritional status, hematological reserves, and immunity. These findings highlight the importance of physiologic reserve and inflammatory state in shaping outcomes with this radioligand therapy and may inform risk stratification and care strategies in routine clinical practice. Efficacy and safety of disitamab vedotin combined with toripalimab for cisplatin-refractory advanced penile cancer: A prospective single-center study (SAVE). First Author: Fang Yuan, Chongqing University Cancer Hospital, Chongqing, China

Background: Patients with advanced penile cancer progressing on cisplatin-based chemotherapy have limited options. Anti-EGFR therapy has not demonstrated significant survival benefit, and immune checkpoint inhibitors (ICIs) remain uncommon. Preclinical evidence suggests HER-2-targeted antibody-drug conjugates (ADCs) may synergize with ICIs by redirecting immune cells to the tumor microenvironment and overcoming immunosuppression. The HER-2 ADC (Disitamab Vedotin, DV) has shown preclinical activity in HER-2-positive and cisplatin-resistant penile cancer models. This study evaluated DV plus a PD-1 inhibitor (Toripalimab, T) in the cisplatin-resistant and advanced penile cancer patients. **Methods:** In this single-arm prospective study, patients received DV (2.0 mg/kg every 2-3 weeks) plus T (240 mg every 3 weeks) until progression or unacceptable toxicity. Tumor assessments tested by CT/MRI were performed every 8-12 weeks for RECIST v1.1. PD-L1 by combined positive score (CPS), tumor mutational burden (TMB) and HER-2 expression were analyzed. Follow-up continued until death or December 31, 2025. **Results:** Eight patients (median age 52 years; range 38-66) were enrolled, all previously treated with ≥4 cycles of cisplatin chemotherapy and 3 had received ICIs as second-line therapy (1 with ICIs plus cetuximab). Baseline staging included T4 (n = 2), N3 (n = 7), and M1 (n = 5); all target lesions were > 5 cm (perineal/inguinopelvic). After ≥3 treatment cycles and first scan at 8 weeks, best responses were partial response (PR) in 3 patients (1 patient achieved at first assessment, with ongoing response at 18 months and conversion of ctDNA from positive to negative; 1 with sustained response for 17 months, accompanied by reduction in circulating tumor cells; 1 with PR followed by treatment discontinuation and survival of 4 months), stable disease (SD) in 1, and progressive disease (PD) in 4 (median overall survival 5 months). Objective response rate (ORR) was 37.5% (3/8) and disease control rate (DCR) 50% (4/8). Median PFS and mOS were 3 and 5 months, respectively (Kaplan-Meier estimate). One grade ≥3 adverse event occurred (immune-mediated colitis with hematochezia). Grade 1-2 toxicities included leukopenia (n = 2), infusion-related fever (n = 1), sinus tachycardia (n = 1), fatigue (n = 6), rash (n = 1), and peripheral neuropathy (n = 5). Notably, HER-2 expression was assessed as negative in all patients. The patient with clearance of ctDNA had high TMB but low PD-L1 expression; others evaluable tumors had PD-L1 CPS > 40 (TMB not assessed). **Conclusions:** The combination of DV and T shows promising antitumor activity and a manageable safety profile in cisplatin-refractory advanced penile cancer patients, independent of HER-2 or PD-L1 status. These findings support further evaluation in this patients with high unmet clinical need. Clinical trial information: ChiCTR2400086605. Research Sponsor: None.

Spatial immune architecture as used to define progression and treatment response in penile squamous cell carcinoma. First Author: Firas Hatoum, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Penile squamous cell carcinoma (PSCC) is a rare, aggressive malignancy with limited treatment options and poor outcomes. Although immunotherapy has shown activity in a subset of patients, the spatial immune mechanisms underlying disease progression and treatment resistance remain unknown. We hypothesized that clinical behavior in PSCC is driven by spatial organization of the tumor microenvironment (TME), rather than immune cell abundance alone. **Methods:** We conducted the first and largest longitudinal, multi-omics study of PSCC, integrating spatial transcriptomics (NanoString CosMx 6K panel) and single-cell RNA sequencing across 81 patients spanning all disease stages. Spatial profiling was performed on a tissue microarray of 35 primary tumors from 31 patients, capturing >390,000 spatially resolved cells. Patients were stratified by progression status, HPV, stage, and chemotherapy response (n=12) per RECIST 1.1. Spatial architecture was quantified using neighborhood Enrichment Analyses, Spatial cell–cell proximity and Ripley K AUC analyses. **Results:** Two distinct and clinically divergent TME architectures were identified. Tumors with favorable clinical behavior exhibited organized, antigen-driven immune surveillance. HPV-positive (n=18) and non-progressed tumors (n=17) showed coordinated neighborhoods involving myeloid cells, dendritic cells, T cells, and endothelium. Proliferative tumor programs were spatially proximal to DCs, and effector CD8 T cells maintained close coupling to tumor states, with preserved CD8–DC interactions. In contrast, HPV-negative (n=17), progressed (n=18), and chemotherapy non-responders (n=4) converged on a dysregulated inflammatory state characterized by B cell–macrophage and CAF-associated neighborhoods, EMT–hypoxia tumor programs, and immune–stromal self-clustering. These tumors showed reduced tumor-directed immune engagement and loss of organized immune domains. Notably, chemotherapy non-responders were not immune-depleted but instead exhibited dense innate and antigen-presenting cell infiltrates that were spatially confined to stromal and vascular compartments, with limited tumor-directed immune engagement. **Conclusions:** This study establishes the first spatially resolved atlas of PSCC, integrating spatial and single-cell multi-omics to uncover distinct immune and stromal architectures linked to progression and therapy resistance. Distinct TME architectures define progression and treatment resistance, supporting spatial biomarkers for patient stratification and therapeutic optimization. Research Sponsor: None.

5036 Poster Session

HRS-1167 (M9466), a PARP1 inhibitor, combined with abiraterone acetate and prednisone in metastatic castration-resistant prostate cancer: A phase 1b/2 study. First Author: Chaochao Liang, The First Affiliated Hospital of Anhui Medical University, Hefei, China

Background: PARP inhibitors combined with novel hormonal agents (NHAs) have shown improved progression-free survival in metastatic prostate cancer compared to NHA alone. HRS-1167 (M9466) is a novel highly selective PARP1 inhibitor with established antitumor activity in advanced solid tumors. This multicenter, open-label, dose-finding and efficacy expansion phase 1b/2 study assessed the safety, tolerability and preliminary efficacy of HRS-1167 combined with AA-P in mCRPC (ClinicalTrials.gov, NCT06689163). **Methods:** Chinese adult mCRPC patients with homologous recombination repair mutations who were previously treated were enrolled. Eligible patients received oral HRS-1167 at 30 mg QD or 50 mg QD, combined with AA-P (abiraterone acetate 300 mg QD; prednisone 5 mg BID). Primary objectives were safety and tolerability. **Results:** As of Oct 31, 2025, 58 patients were enrolled and treated (HRS-1167 30 mg, n = 33; HRS-1167 50 mg, n = 25; prior NHA, 100%; *BRCA* mutation, 44.8%). Median follow-up was 3.0 months and 6.2 months in the 30 mg and 50 mg cohorts. Preliminary efficacy was summarized in the Table. Among patients with evaluable efficacy (n = 47), prostate-specific antigen response (PSA50) rate was 36.4% (8/22) in the 30 mg cohort and 52.0% (13/25) in the 50 mg cohort. Confirmed objective response rate (cORR) was 37.5% and 14.3%, and disease control rate (DCR) was 81.8% and 92.0%, respectively. HRS-1167 plus AA-P demonstrated particularly encouraging efficacy in patients with *BRCA* mutations: PSA50 rate was 100% (6/6) in the 30 mg cohort and 81.8% (9/11) in the 50 mg cohort, and cORR was 100% (2/2) and 33.3% (1/3), respectively. DCR was 100% in the *BRCA*-mutated subgroup. Treatment-emergent adverse events (TEAEs) were reported by 26 (78.8%) and 25 (100%) patients in the 30 mg and 50 mg cohorts (grade ≥3, 18.2% and 44.0%; serious, 9.1% and 32.0%). There were no TEAEs leading to death. The most common (≥5% of patients) grade ≥3 TEAEs were hematologic toxicities (anemia, 9.1% and 24.0%; decreased platelet count, 6.1% and 8.0%; decreased white blood cell count, 0% and 12.0%; decreased neutrophil count, 3.0% and 8.0%). **Conclusions:** HRS-1167 combined with AA-P showed promising efficacy in patients with mCRPC, especially those with *BRCA* mutations. The combination was well-tolerated with no new safety signals identified. Clinical trial information: NCT06689163. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

	Overall		*BRCA*m	
	30 mg (N = 22)	50 mg (N = 25)	30 mg (N = 6)	50 mg (N = 11)
PSA50, n (%)	8 (36.4)	13 (52.0)	6 (100)	9 (81.8)
Time to PSA progression, months, median (95% CI)	NR (3.7, NR)	6.5 (5.5, NR)	NR (4.6, NR)	6.5 (3.8, NR)
cORR, n/N* (%)	3/8 (37.5)	1/7 (14.3)	2/2 (100)	1/3 (33.3)
DCR, n (%)	18 (81.8)	23 (92.0)	6 (100)	11 (100)

N = efficacy evaluable patients; N* = patients with target lesions at baseline. PSA and tumor responses were confirmed.
PSA, prostate-specific antigen; cORR, confirmed objective response rate; DCR, disease control rate; NR, not reached.

Evaluation of the safety, efficacy and dosimetry of TRC003 in metastatic castration-resistant prostate cancer: A prospective, open-label, single-arm study. First Author: Suping Li, Affiliated Hospital of North Sichuan Medical College, Nanchong, China

Background: TRC003 (also named as ^{225}Ac-PSMA-313) is a novel molecule of targeted alpha therapy (TAT) that administers alpha-particle radiation to cancer cells expressing Prostate Specific Membrane Antigen (PSMA). In this study, we plan to investigate preliminary safety, efficacy and dosimetry of TRC003 in patients with metastatic castration-resistant prostate cancer (mCRPC). **Methods:** This is a prospective, open-label, single-arm, single center study in accordance with ICH GCP guidelines. The patients with progressive PSMA-positive mCRPC who have been treated with androgen receptor pathway inhibitors (ARPIs) and/or taxane-based chemotherapy were recruited and received TRC003 treatment intravenously at 200 μCi (7.4 MBq) doses administered every 8 weeks per cycle for 4 cycles followed by expanded 4 cycle treatment if the participants continued to be benefit from the treatment. Adverse events, ORR, PSA response, bPFS, rPFS and OS were evaluated. In addition, the SPECT images were acquired with noncircular orbit, 120 project views over 360° at 4, 24, 48 and 96 hours after administration for dosimetry analysis. **Results:** From Feb 2024 to Jan 2026, 15 patients were included with an average age of 67.1 yr and median baseline PSA of 98.6 ng/mL. 11 (73.3%) participants received ARPI and taxane-based chemotherapies while 4 (26.7%) participants received only ARPI previously. Median baseline SUVmax and SUVmean on PSMA-PET were 32.7 (14.7-60.26) and 18.2 (9.51-34.73), respectively. A total of 63 cycles of TRC003 were administered, with a median of 4 cycles per patient. The most common AE was anemia (80%) and dry mouth (73.3%). Grade 3 treatment-related adverse events occurred as anemia (20%), lymphocytopenia (13.3%), weight loss (13.3%), thrombocytopenia (6.7%), and vomiting (6.7%). No treatment-related Grade ≥4 AE were observed. No kidney related toxicities were observed. The ORR of all patients was 45.5%, whereas the ORR reached 57.1% in the subset of patients who had received prior treatment of ARPIs and taxanes. The median tumor absorbed dose was 2.40±3.33 Gy (soft lesions: 5.03±5.51 vs bone: 1.65±2.19 Gy). The absorbed doses of kidneys, liver and spleen were 1.56±0.38, 1.07±0.19 and 0.54±0.29 Gy, respectively. The absorbed dose coefficients of tumors, kidney and liver were 0.36±0.50 (soft lesions 0.75±0.82 vs bone 0.25±0.33), 0.23±0.07, 0.16±0.03 Gy/MBq. **Conclusions:** TRC003 was safe and well-tolerated, and exhibited efficacy for mCRPC patients who were resistant to ARPI or chemotherapy. Overall TRC003 is a promising radiopharmaceutical agent for the treatment of mCRPC. Clinical trial information: ChiCTR2400083275. Research Sponsor: C-Ray therapeutics.

5038 Poster Session

Safety and preliminary efficacy of M9466 (HRS-1167) in combination with abiraterone acetate and prednisone/prednisolone (AA-P) in patients (pts) with metastatic prostate cancer in the phase 1 DDRiver 501 study. First Author: Valentina Boni, Hospital Universitario Quironsalud Madrid, NEXT Madrid, Madrid, Spain

Background: M9466 (HRS-1167) is a highly potent, selective next-generation PARP1 inhibitor being investigated in pts with locally advanced/metastatic solid tumors. Here we report safety and preliminary efficacy data from Module 3 of the DDRiver 501 study, a Phase 1, open-label, global multicenter study, evaluating M9466 with AA-P in pts with metastatic prostate cancer (NCT06421935). **Methods:** DDRiver 501 Module 3 enrolled eligible pts with metastatic castration-resistant prostate cancer (mCRPC) or metastatic hormone-sensitive prostate cancer (mHSPC), irrespective of prior anticancer therapy received. Pts received M9466 (either 50 or 100 mg once-daily) with AA-P until disease progression. Primary objective was safety. Additional objectives included efficacy (objective response rate [ORR], PSA50 [confirmed decrease in prostate-specific antigen levels of >50% from baseline]), pharmacokinetics (PK), molecular responses (e.g. >50% reduction from baseline of methylation-based tumor fraction in circulating tumor DNA [ctDNA]) and tumor genetic profiling. **Results:** As of Nov 21, 2025, Module 3 enrolment was complete (N=21; M9466 50 mg n=10, 100 mg n=11; mHSPC n=1, mCRPC n=20; prior treatment included: PARP inhibitors n=0, androgen receptor pathway inhibitors [ARPI] n=21). Thirteen (62%) pts carried HRR gene mutations, including four (19.0%) with *BRCA1/2* mutations, by ctDNA analysis. Pts received M9466 for a median (range) of 18.1 (6.0–30.1) and 26.9 (6.0–42.0) weeks (50 and 100 mg arms respectively). Safety outcomes are presented (table). No dose-limiting toxicities or serious treatment-related adverse events to any study intervention were observed. Across pts with baseline RECIST measurable disease, confirmed ORR was 18.8% (3/16, 95% CI: 4.0, 45.6). Two of the three responders had RAD50 loss of function mutations. In pts with baseline PSA ≥2 ng/mL, 3/17 (17.6%) achieved a PSA50 response. Molecular response and PK data will also be presented. **Conclusions:** Preliminary data from DDRiver 501 Module 3 demonstrate M9466 with AA-P is generally well tolerated and demonstrates antitumor activity in ARPI-pretreated pts with mHSPC/mCRPC. Clinical trial information: NCT06421935. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Safety overview.

n (%)	M9466 50 mg (n=10)	M9466 100 mg (n=11)
Any TEAE	9 (90.0)	11 (100)

Cell-free DNA nucleosome and genomic signatures as predictors of outcomes with radium-223 in metastatic castration-resistant prostate cancer. First Author: David Dawei Chen, Fred Hutch Cancer Center, Seattle, WA

Background: Radium-223 (Ra-223) is a bone-seeking alpha emitter that induces double-stranded DNA breaks. Previous studies have shown Ra-223 can prolong survival of men with mCRPC with symptomatic bone metastases and no visceral metastases. However, clinical outcomes are heterogeneous, and predictive biomarkers for lack of benefit or progression with visceral disease are lacking. We evaluated whether genomic and epigenetic features derived from cell-free DNA (cfDNA) could identify tumor characteristics associated with favorable or unfavorable outcomes with Ra-223 therapy. **Methods:** Pre-treatment plasma cfDNA was analyzed from 137 mCRPC patients who received Ra-223. Ultra-low pass and deep whole genome sequencing were performed. Tumor fraction and copy number alterations were estimated using ichorCNA. Transcription factor (TF) activity was derived by nucleosome profiling of cfDNA fragments around transcription starts sites (TSS) and TF binding sites using the tools Griffin and TritonNP. Genomic and epigenetic features were associated with clinical outcomes including completion of six Ra-223 cycles, overall survival, and development of new nodal, visceral, or liver metastases. A multimodal binary classifier integrating copy number variation and TF activity was constructed using LASSO feature selection and XGBoost with repeated, nested 5-fold cross-validation. External validation was performed using independent cohorts of mCRPC patients treated with docetaxel (n=46) or other agents (n=142) for the prediction of new metastatic involvement. **Results:** Higher pre-treatment tumor fraction and TF activity at specific loci including HIF3A, ZNF770, and PRDM6 were associated with adverse outcomes. A binary classifier predicting completion of Ra-223 demonstrated strong discrimination in cross-validation, with similar performance for prediction of liver metastasis progression. External validation in independent cohorts demonstrated moderate discrimination, supporting generalizability across treatment contexts. **Conclusions:** Our findings demonstrate that analysis of cfDNA-derived genomic and epigenomic features can identify biologically relevant tumor characteristics associated with benefit from Ra-223 in mCRPC. These findings support the development of minimally invasive biomarkers to refine patient selection and risk stratification. Our ongoing analyses look to integrate mutations, amplifications, and deletions in key disease-related genes to further explore tumor genotype-phenotype associations with Ra-223 outcomes. Research Sponsor: Dana-Farber Cancer Institute; Fred Hutch Cancer Center; Bayer.

5040 **Poster Session**

Quality of life analysis from a multicenter, randomized, phase 2, investigator-initiated ETCTN trial of olaparib + radium-223 versus radium-223 in metastatic castration-resistant prostate cancer with bone metastases (COMRADE). First Author: Rana R. McKay, UC San Diego Moores Cancer Center, San Diego, CA

Background: Radium-223 is an α-emitting radioisotope that improves overall survival in men with metastatic castration resistant prostate cancer (mCRPC) and bone metastases (BM). In the ALSYMPCA trial, radium-223 was also associated with improved quality of life (QOL), delayed time to first opioid use, and pain palliation. We previously reported superior radiographic progression free survival (rPFS) with the addition of olaparib to radium-223 in the randomized phase 2 COMRADE study (NCT03317391). We now report patient-reported QOL outcomes from the trial. **Methods:** Patients were randomized 1:1 to olaparib 200 mg twice daily plus radium-223 (Arm A) or radium-223 alone (Arm B). QOL was assessed using the Functional Assessment of Cancer Therapy-Prostate (FACT-P) and Brief Pain Inventory (BPI) at baseline and every 12 weeks. Mixed-effects ANCOVA models assessed treatment effects on QOL changes from baseline, adjusting for baseline score, timepoint, age, and Eastern Cooperative Oncology Group performance status. Least-squares (LS) mean changes were reported for each arm with between-arm differences and 95% confidence intervals. Analysis was limited to patients with baseline and $\geq$1 post-baseline assessment within 24 weeks. **Results:** Of 114 treated patients, 74 (65%) were evaluable for QOL analysis (Arm A, n = 40; Arm B, n = 34), including 71 (62%) for FACT-P and 72 (63%) for BPI pain severity and pain interference. Baseline characteristics were well balanced: median age was 70 and 72 years, ECOG PS 1 was present in 60% and 62%, prior docetaxel was received by 55% and 50%, $>$ 20 bone metastases were present in 45% and 47%, and pain medication use at baseline was reported in 60% and 72% of patients in Arms A and B, respectively. There were no significant differences in LS mean change from baseline in FACT-P total score between arms at week 12 (Arm A: -5.09 vs Arm B: -0.23; difference -4.87, 95% CI -13.4 to 3.62) or week 24 (Arm A: -1.41 vs Arm B: -3.20; difference 1.79, 95% CI -8.28 to 11.9). Similarly, no significant between-arm differences were observed in LS mean changes in BPI pain severity at week 12 (difference 0.44, 95% CI -0.44 to 1.33) or week 24 (difference -0.20, 95% CI -1.32 to 0.93). Arm B showed greater improvement in BPI pain interference at week 12 (LS mean change: Arm A +0.21 vs Arm B -0.88; difference 1.09, 95% CI 0.14 to 2.05), but this difference was not sustained at week 24 (difference -0.27, 95% CI -1.37 to 0.82). **Conclusions:** In this phase 2 trial, the addition of olaparib to radium-223 achieved superior rPFS without significant detriment to patient-reported QOL or pain compared to radium-223 alone, supporting the tolerability of this combination in mCRPC patients with BM. Clinical trial information: NCT03317391. Research Sponsor: National Cancer Institute.

Clinical validation of circulating tumor cell synaptophysin and androgen receptor expression in metastatic prostate cancer phenotypes. First Author: Ethan Lo, Fred Hutch Cancer Center, Seattle, WA

Background: Chronic exposure to androgen receptor (AR) targeted therapies can drive lineage plasticity, promoting the emergence of neuroendocrine (NE) prostate cancer (NEPC) and treatment resistance. NEPC is characterized by a phenotypic shift, with loss of AR expression and emergence of markers (e.g., synaptophysin, SYP). To definitively diagnose NEPC, a metastatic biopsy is typically required; however, there are numerous barriers to obtaining a timely tissue diagnosis. As such, there is an unmet need for blood-based assays that can accurately identify treatment-emergent NEPC. In this study, we evaluate concordance between circulating tumor cell (CTC) SYP and AR expression patterns in patients with and without evidence of NE differentiation on tissue histology. **Methods:** Blood for CTC analysis was prospectively collected from patients with advanced prostate cancer. Patients were retrospectively assigned to either an adenocarcinoma (AR-positive) or NE differentiated (SYP-positive) group based on clinical and patho-genomic factors. Amphicrine PC was included in NE differentiated cohort. The RareCyte system was used to generate slides for CTC-based immunofluorescent (IF) analysis for SYP and AR. Associations between CTC SYP and AR expression, PSA at time of CTC collection, and overall survival (OS) were assessed for patients with $\geq$ 5 CTCs using Wilcoxon rank-sum test, Fisher's exact test, and Kaplan-Meier analyses. **Results:** We enrolled 52 patients with metastatic castration-resistant prostate cancer (mCRPC); 26 were classified as NE differentiated and 26 as AR-positive adenocarcinoma. Median time between biopsy and CTC collection was 10.6 months (IQR 4.1–34.3) and 19.4 months (IQR 3.5–66.4) for the NE differentiated and AR-positive adenocarcinoma cohorts respectively. NE differentiated patients had a significantly higher fraction of SYP-positive CTCs (median 28.6 % vs 0%, p = 0.0084), whereas patients in the adenocarcinoma cohort had a higher fraction of AR-positive CTCs (median 96.7% vs 0.0%, p = 0.0004). Phenotype classification based on high AR or SYP expression ($>$ 80% of CTCs positive) significantly differentiated cohorts and was strongly associated with tissue histology (p = 0.0048). PSA level at the time of CTC collection was significantly lower in the NE differentiated cohort (median 3.8 vs 486.9 ng/mL, p = 0.0001). There was no difference in OS from time of diagnosis or time of metastasis between groups. **Conclusions:** SYP and AR CTC expression demonstrated strong concordance with tissue histology and established clinical features of NEPC and AR-positive adenocarcinoma. These early findings support the feasibility of CTC expression profiling to identify NE biomarker expression. However, results are only hypothesis-generating and prospective validation with matched tissue biopsy in a larger cohort with adequate follow up is warranted. Research Sponsor: None.

5043 **Poster Session**

Impact of baseline demographics on therapy management in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with talazoparib (TALA) + enzalutamide (ENZA) in the TALAPRO-2 study: Extended follow-up. First Author: Ugo De Giorgi, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) Dino Amadori, Meldola, Italy

Background: The randomized, Phase 3 TALAPRO-2 trial showed improved radiographic progression-free survival (rPFS) and overall survival (OS) in pts with mCRPC treated with TALA + ENZA vs placebo + ENZA in two cohorts: unselected and homologous recombination repair (HRR)-deficient pts. Median TALA duration of treatment (DoT) was 19.7 mo (unselected) and 20.3 mo (HRR-deficient). Study protocol required dose reduction for pts with reported Grade 3 or 4 hematologic adverse events (AEs); 55% of pts in both cohorts had a TALA dose reduction due to AEs at final analysis. We analyze the impact of baseline demographics on TALA dose reductions and clinical outcomes in the TALA + ENZA arm. **Methods:** Pts in the TALA + ENZA arm received TALA 0.5 mg (in case of moderate renal impairment [30–59 mL/min/1.73 m^2] 0.35 mg) + ENZA 160 mg PO QD. Time-to-event endpoints were summarized by the Kaplan–Meier method and compared by log-rank test. **Results:** In both cohorts, pts with a TALA dose reduction due to any cause (AEs and other reasons) were more likely to be older, be of Asian ethnicity, have lower bodyweight (BW), and have mild renal impairment vs pts without a TALA dose reduction (Table). Fewer pts with a TALA dose reduction than without discontinued treatment before wk 16 in the unselected (6.1% vs 20.0%) and HRR-deficient (2.7% vs 13.8%) cohorts. Median TALA DoT was longer in pts with a TALA dose reduction in the unselected cohort and similar between groups in the HRR-deficient cohort (Table). No clinically meaningful differences were observed in rPFS or OS in pts with a TALA dose reduction vs without in both cohorts (unselected: rPFS HR 0.94; 95% CI 0.70–1.25; OS HR 0.90; 95% CI 0.68–1.20; HRR-deficient: rPFS HR 0.96; 95% CI 0.64–1.44; OS HR 0.98; 95% CI 0.64–1.49; Table). **Conclusions:** Pts with specific baseline demographics (older, Asian ethnicity, lower BW, mild renal impairment) were more likely to have a TALA dose reduction. TALA dose reduction did not negatively impact TALA DoT or efficacy in pts who received TALA + ENZA in the TALAPRO-2 trial. Clinical trial information: NCT03395197. Research Sponsor: This study was funded by Pfizer Inc. Astellas Pharma Inc. provided enzalutamide.

Genomic landscape of *TP53* Y220C–mutated clinically advanced prostate carcinoma (CAPC). First Author: Varun Nandakumar, University of Utah, Salt Lake City, UT

Background: The *TP53* Y220C base substitution mutation has become a significant therapeutic target with the development of reactivator drugs that restore TP53 function with a regulatory function in the cell cycle. However, its real-world prevalence and associated genomic landscape is not established in CAPC. Data on concurrent genomic alterations (GA) may guide the development of combinatorial therapeutic strategies. **Methods:** 26,156 cases of CAPC underwent hybrid capture-based comprehensive genomic profiling (CGP) to study all classes of GA including base substitutions, short insertions, deletions, copy number changes, rearrangements and fusions. Microsatellite instability (MSI) status and tumor mutation burden (TMB) were determined from the sequencing data; comparisons utilized the Fisher Exact method. **Results:** 144 CAPC (0.6%) of CAPC cases featured *TP53* Y220C mutation (*TP53* Y220C+). Patients with *TP53* Y220C+ CAPC had slightly higher median age (70.0 vs 68.2; p = 0.020) and numerically lower frequency of *TMPRSS2* GA (33.0% vs 39.4%; Not significant (NS)). GA potentially associated with CAPC primary hormonal-based therapy response more frequently found in *TP53* Y220C+ cases included *SPOP* (10.5% vs 1.4%; p $<$ 0.0001) with *AR* GA (13.6% vs 11.3%; NS) being similar in both groups. GA linked to PARP inhibitor response slightly more frequent in *TP53* Y220C+ cases included *BRCA2* GA (8.7% vs 3.5%; p = 0.0003) and *ATM* GA (5.9% vs 4.2%; NS). GA in *RAD21* were slightly higher in *TP53* Y220C- CAPC (14.8% vs 8.3%; p = 0.029). GA in *PIK3CA* (6.6% vs 7.0%) and *PTEN* (32.4% vs 34.5%) were similar in the two groups. Biomarkers likely associated with benefit with anti-PD1/L1 agents were very low in both groups, included higher frequency of *CDK12* GA (5.4% vs 0.7%; p $<$ 0.0001) in *TP53* Y220C+ cases and higher frequencies of MSI-High status (2.7% vs 0.0%; p = 0.045), mean TMB (3.8 vs 2.1 mutations/Mb; p $<$ 0.0001) and TMB $>$ 10 mutations/MB (4.4% vs 0.0%; p = 0.010) in *TP53* Y220C- cases. **Conclusions:** *TP53* Y220C is a rare finding in CAPC, but it may offer a potential therapeutic avenue for these patients whose tumors feature such a mutation. In addition, *TP53* Y220C+ cases appear to be genomically relatively distinct from *TP53* Y220C- CAPC cases and may feature genomic signatures that could influence treatment selection and trial design. Study limitations include a retrospective, descriptive design, a lack of clinical data annotation, and selection and confounding biases, so our findings are hypothesis-generating. Research Sponsor: None.

Selective GA in *TP53* Y220C+ vs *TP53* Y220C- in patients with CAPC.

	TP53 Y220C+ CAPC (144 cases)	*TP53* Y220C- CAPC (26,012 cases)	P Value

Clonal hematopoiesis-related outcomes associated with radioligand therapy in prostate cancer: A "real-world" analysis. First Author: Robert Yuan, UMass Memorial Medical Center, Worcester, MA

Background: Radioligand therapy with radium-223 (Rad) and lutetium-177 (Plu) demonstrates notable hematologic toxicities in patients (pts) with prostate cancer (PC), including myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). Delivery of ionizing radiation to the bone microenvironment is a known risk factor for accelerating clonal hematopoiesis, although the incidence of clonal cytopenias with these agents is not well characterized. We hypothesized that pts treated with Rad and/or Plu would have higher risk of clonal cytopenia of undetermined significance (CCUS) vs matched controls in the "real-world". **Methods:** We performed a retrospective study using de-identified aggregate data from the TriNetX US Research Collaborative Network from January 2010 to December 2025. Adult males with PC who received ≥1 administration of Plu and/or Rad were included; pts with prior myeloid malignancy were excluded. Primary outcomes were incidence of CCUS and MDS. Propensity score matching (PSM) was performed based on age, race, prior diagnosis of leukopenia, anemia, thrombocytopenia, or pancytopenia. Risk ratios (RR) with 95% confidence intervals (CI) were calculated. **Results:** We identified 2,569 pts treated with Plu alone and 2,007 treated with Rad alone and compared them with pts with advanced PC without exposure to either agent (unexposed control) (Table 1). After PSM, the incident risk of CCUS was greater in Rad-exposed pts (RR 2.62, 95% CI 1.45 – 4.73, $p<0.001$) while Plu was not associated with a significant increase in CCUS or MDS. Direct comparison after PSM (n=1,433) demonstrated lower risk of pancytopenia (RR 0.46, 95% CI 0.37 – 0.56, $p<0.001$) and CCUS (RR 0.41, 95% CI 0.20 – 0.81, $p=0.008$) in Plu vs Rad. In unadjusted analysis, pts receiving both Plu and Rad had increased incidence of CCUS vs Plu alone (RR= 3.64, 95% CI 1.87 - 7.07, $p<0.001$) and higher risk of MDS vs either agent alone. **Conclusions:** This "real-world" analysis demonstrates that compared with unexposed controls, Rad – but not Plu – is associated with an increased risk of CCUS. Treatment with Plu and Rad portends a higher risk of CCUS than Plu alone, as well higher risk of MDS than either drug alone. Study limitations include its retrospective nature, missing/ unknown data (e.g. bone marrow and mutation analysis), and potential selection and confounding biases. As treatment sequencing evolves for pts with metastatic PC, further evaluation of clonal hematopoiesis, MDS/AML with adequate sample size and follow up in this population is warranted. Research Sponsor: None.

Safety and efficacy of QLC5508 (MHB088C) in heavily-treated patients with metastatic castration-resistant prostate cancer: Updated data from a phase 1/2 trial. First Author: Xinan Sheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Genitourinary Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: QLC5508 (MHB088C), a novel B7-H3-targeted antibody-drug conjugate with high cell-binding activity and internalization rate, contains SuperTopoi payload which is 5 to 10 times more potent than Dxd. The preliminary data of a phase 1 study indicated the promising anti-tumor activity and tolerability of QLC5508 in patients (pts) with solid tumors, including metastatic castration-resistant prostate cancer (mCRPC). Here we report the updated results of efficacy and safety in pts with mCRPC. **Methods:** This multi-center phase 1/2 trial consisted of dose-escalation stage and dose-expansion stage. In dose-escalation stage, QLC5508 was administered via intravenous infusion at dosage ranging from 0.8 mg/kg to 4.0 mg/kg every two (Q2W) or three weeks (Q3W) in pts with various advanced solid tumors. Then, pts with mCRPC were recruited if they failed or intolerable to standard treatment, including second-generation androgen receptor pathway inhibitors (ARPIs) and/or taxane-based chemotherapy. Dose levels of 1.6 mg/kg Q2W, 2.0 mg/kg Q2W, and 2.4 mg/kg Q3W were selected. The primary endpoints were safety and tolerability. The secondary endpoints were objective response rate (ORR), disease control rate (DCR), and radiological progression-free survival (rPFS) per RECIST v1.1 and PCWG3, and prostate-specific antigen (PSA) response rate. **Results:** As of Nov 30, 2025, 59 pts were enrolled (≥3 lines of prior treatment: 74.6%; ≥3 lines of prior second-generation ARPIs: 28.8%; prior taxane: 84.7%; ≥2 lines of prior taxane: 16.9%). Grade ≥3 treatment-emergent adverse events (TEAEs) with incidence of > 20% were neutrophil count decreased (25.4%), anemia (23.7%), and white blood cell decreased (20.3%). Grade ≥3 gastrointestinal TEAEs occurred in two (3.4%) pts, both unrelated to the treatment. Intestinal lung disease occurred in one (1.7%) patient from 1.6 mg/kg Q2W dose level. TEAEs leading to treatment discontinuation and dose reduction occurred in one (1.7%) and six (10.2%) pts, respectively. The median rPFS was not reached (95% confidence interval [CI], 13.11-not evaluable [NE]), and the 12-month rPFS rate was 71.7% (95% CI, 52.55%-84.26%). In 38 pts at 2.0 mg/kg Q2W dose level, the median rPFS was not reached (95% CI, 13.11-NE), and 12-month rPFS rate was 78.6% (95% CI, 50.67%-91.80%). In 31 pts at 2.0 mg/kg Q2W dose level who had received prior second-generation ARPIs and taxane, the median rPFS was 13.11 months (95% CI, NE-NE). In 31 pts with target lesion at baseline, confirmed ORR and DCR was 22.6% (95% CI, 9.6%-41.1%) and 96.8% (95% CI, 83.3%-99.9%), respectively. Thirteen pts (22.8%) achieved PSA_{50} response. **Conclusions:** QLC5508 showed prolonged rPFS as well as manageable safety profile in heavily treated pts with mCRPC. A phase 3 study is currently being planned. Clinical trial information: NCT07102004. Research Sponsor: Qilu Pharmaceutical Co., Ltd.; Minghui Pharmaceutical.

Phase 1, multicenter, open-label study of HSK46575 in patients with metastatic castration-resistant prostate cancer progressing after next-generation hormonal agents and chemotherapy. First Author: Qiang Wei, West China Hospital, Sichuan University, Chengdu, China

Background: The development and progression of prostate cancer are regulated by steroid hormones. HSK46575 Tablet is a novel oral small-molecule inhibitor of cytochrome P450 11A1 (CYP11A1), which can block the production of all downstream steroid hormones and their precursors, thereby reducing the activation of the androgen receptor (AR) signaling pathway and inhibiting tumor progression. Herein, we report the safety and efficacy of HSK46575 in patients with metastatic castration-resistant prostate cancer (mCRPC). **Methods:** This multicenter, open - label Phase I clinical trial had two parts: Phase Ia (dose escalation and expansion) and Phase Ib (dose optimization). Eligible patients were mCRPC patients who failed at least one NHA treatment and either failed, were intolerant to, or refused at least one line of chemotherapy. Phase Ia's dose escalation used a "3 + 3" design to explore four doses (3 mg, 10 mg, 30 mg, 60 mg), and dose expansion was done at 30 mg due to good safety and preliminary efficacy.The primary endpoints were safety and the recommended Phase II dose (RP2D). **Results:** As of November 4, 2025, 27 subjects were enrolled, with a median follow-up of 3.7 months and a median age of 68 years (range: 51-82 years). Among them, 15 (55.6%) had AR ligand -binding domain (AR-LBD) mutations, and 12 (44.4%) had received taxane-based chemotherapy before. No dose-limiting toxicities were observed in any dose group. Treatment-related adverse events (TRAEs) occurred in 18 subjects (66.7%), most of which were Grade 1-2. The most common TRAEs were alanine aminotransferase elevation (18.5%), sinus bradycardia (11.1%), and nausea (11.1%).No adverse events leading to permanent treatment discontinuation or death were observed. Prostate-specific antigen (PSA) assessment was available for 26 subjects, with PSA response rates confirmed after at least 3 weeks. The PSA_{30} and PSA_{50} response rates were 42.3% and 34.6% in the total population, 71.4% and 57.1% in AR-LBD mutant subjects (n = 14), and 75% and 58.3% in the 30 mg dose group with AR-LBD mutations (n = 12). The PSA_{50} response rate was 12.5% (1/8) in the 30 mg dose group with AR-LBD wild-type. Fourteen subjects were eligible for soft tissue assessment, 8 of whom had AR-LBD mutations. One partial response (PR) was seen during treatment in an AR-LBD mutant patient in the 30 mg dose group, leading to an objective response rate (ORR) of 14.3% in this population. . The radiographic progression-free survival (rPFS) has not been reached. The 6-month rPFS rates were 67.5% in the total population and 76.2% in the AR - LBD mutation population. **Conclusions:** HSK46575 shows a manageable safety profile and preliminary antitumor activity, especially in the population with AR - LBD mutations. These findings support further exploration in the mCRPC population. Clinical trial information: NCT07007910. Research Sponsor: None.

Integrated clinical and molecular characterization of WNT pathway alterations in metastatic castration-resistant prostate cancer (mCRPC) liver metastases (mets). First Author: Elise Y. Cai, Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA

Background: mCRPC patients (pts) with liver mets (LM) have an aggressive clinical course and poor response to established treatments. LM frequently exhibit low PSMA expression, limiting the utility of PSMA-targeted therapies. The mechanisms driving hepatic organotropism and therapy resistance in advanced disease are poorly understood. **Methods:** We analyzed metastatic biopsies with matched transcriptional and genomic profiling from 4 independent mCRPC cohorts from the Stand Up To Cancer/Prostate Cancer Foundation (SU2C/PCF) West Coast Dream Team, SU2C/PCF East Coast Dream Team, University of Washington rapid autopsy program, and Weill Cornell Medicine. Tumors were classified by *FOLH1* gene expression tertile and by androgen receptor (AR) and neuroendocrine (NE) gene signature expression. Individual cohorts were assessed for differential gene expression and validated between cohorts. Cohorts were pooled for genomic and survival analyses. Multivariable Cox proportional hazard models were used to assess outcomes. **Results:** 595 mCRPC biopsies were analyzed, comprising 88 (15%) liver, 130 (22%) non-liver visceral, 166 (28%) bone, and 211 (35%) lymph node mets. 54% of pts had prior androgen receptor pathway inhibitor (ARPI) exposure and 29% had prior taxane chemotherapy. LM had lower *FOLH1* expression (log2FC = -1.5, $q < 0.001$) than non-LM. Amongst *FOLH1*-low LM, 32% had elevated NE gene expression, with high histological concordance (80% NE prostate cancer [NEPC], 9% adenocarcinoma with NE features). WNT pathway mutations in *APC* or *CTNNB1* were enriched in LM compared to non-LM (20% vs. 10%, p = 0.01) and *FOLH1*-low compared to *FOLH1*-high mets (16% vs. 6%, p = 0.006). Notably, in *FOLH1*-low LM, *APC* mutations were exclusively found in tumors with low NE gene expression (28% vs. 0%, p = 0.02). In contrast, NE LM were enriched for alterations in *RB1* (71% vs. 15%, $p < 0.001$) and homologous recombination repair genes (41% vs. 15%, p = 0.04). Compared to NE LM, non-NE *FOLH1*-low LM demonstrated persistence of AR signaling, enrichment for inferred ß-catenin transcription factor activity, and upregulation of adaptive metabolic pathways including HIF-1α mediated hypoxia signaling and unfolded protein response. ß-catenin downstream targets including *CCND1, MYC, MSX2, AXIN2,* and *LEF1* were transcriptionally upregulated, while AR targets *STEAP1* and *KLK2* remained highly expressed. In the overall cohort, WNT pathway mutations were associated with shorter treatment duration on first-line ARPI (HR 2.2, 95% CI 1.04-4.8, p = 0.03) and inferior overall survival from start of first-line ARPI (HR 1.7, 95% CI 1.04-2.7, p = 0.03). **Conclusions:** WNT pathway alterations are enriched in a clinically aggressive PSMA-low subset of non-NE mCRPC that maintains luminal markers, suggesting distinct clonal evolution from NEPC and clinical actionability with emerging therapies. Research Sponsor: Prostate Cancer Foundation.

Phase I dose-escalation results of ^{177}Lu-NYM032 in patients with progressive metastatic castration-resistant prostate cancer (mCRPC). First Author: Yanjuan Wang, Department of Nuclear Medicine, Affiliated Hospital of Jiangnan University, Wuxi, China

Background: ^{177}Lu-NYM032 is a novel prostate-specific membrane antigen (PSMA)-targeted radioconjugate with optimized properties. Phase I dose-escalation study evaluated its safety, tolerability, pharmacokinetics, radiation dosimetry and preliminary antitumor activity in patients with mCRPC. **Methods:** Eligible patients had PSMA-positive mCRPC confirmed by ^{68}Ga-NYM032 PET/CT, no discordant lesions on ^{18}F-FDG PET/CT, progression after ≥1 AR-targeted therapy and 1–2 prior taxane regimens (or unsuitability/refusal), ECOG 0–2, and no prior radioisotope therapy. A modified 3+3 dose-escalation design was used (^{177}Lu-NYM032: 1.9–7.4 GBq). Pharmacokinetics and dosimetry were evaluated using sequential blood samples and SPECT/CT imaging post-administration (Cycle 1: 2h, 24h, 48h, 7d, 14d; Cycles 2–4: 48h). Primary objectives were safety and maximum tolerated dose (MTD); secondary objectives included pharmacokinetics, dosimetry, and antitumor activity. **Results:** Eleven patients were enrolled across four dose levels: 1.9 GBq (n = 1), 3.7 GBq (n = 4), 5.55 GBq (n = 3), and 7.4 GBq (n = 3). Ten patients completed the study and one patient (3.7GBq) withdrew consent and discontinued the study prior to DLT evaluation. Ten Patients received 2–6 treatment cycles (at 6-week intervals) of ^{177}Lu-NYM032. Four patients were administered up to 6 cycles at 7.4 GBq per cycle, reaching a total cumulative activity of 44 GBq. Treatment was well tolerated; with most treatment-emergent adverse events being grade 1-2. Grade≥3 TEAEs related to ^{177}Lu-NYM032 were limited to anemia, decreased lymphocyte count, and hypokalemia. No dose-limiting toxicities were observed. Clearance of ^{177}Lu-NYM032 from the kidney occurs rapidly (half-life: 18.37-38.66 hours). Physiological distribution of the radiopharmaceutical was observed including in the salivary glands, lacrimal glands, liver, spleen, kidneys, and intestines–consistent with known PSMA expression patterns. While the mean tumor absorption dose (7.73 Gy/GBq in cycle 1) decreased over time, mean absorbed doses per cycle to kidneys and salivary glands remained relatively stable across the administered dose range (1.9-7.4 GBq): kidney doses were 0.47-0.64 Gy/GBq in cycle 1 and 0.42-0.63 Gy/GBq in cycles 2–4; salivary gland doses were 0.42-1.34 Gy/GBq in cycle 1 and 0.43-0.83 Gy/GBq in cycles 2-4. Among 10 evaluable patients, objective response rate was 20% and disease control rate was 80%. Of 3 RECIST v1.1 measurable, 2 (66.7%) partial responded, 1 (33.3%) stable. PSA50 and PSA90 responses were observed in 60.0% and 20.0% of patients, respectively. Median rPFS was 6.5 months; median overall survival was not reached. **Conclusions:** ^{177}Lu-NYM032 demonstrated a favorable safety profile and promising antitumor activity in patients with mCRPC, supporting further evaluation in Phase II studies. Clinical trial information: NCT06383052. Research Sponsor: None.

ProTACT: Preliminary data from a first-in-human, phase 1 study evaluating the safety, tolerability, and anti-tumor activity of [^{225}Ac]Ac-FL-020, a PSMA-targeted radioconjugate, in patients with mCRPC. First Author: Alison Yan Zhang, Macquarie University, Sydney, NSW, Australia

Background: [^{225}Ac]Ac-FL-020 is a next-generation, prostate-specific membrane antigen (PSMA) alpha radioconjugate developed using the proprietary UniRDC linker-chelator technology designed to optimize biodistribution. [^{225}Ac]Ac-FL-020 is intended for treating patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) and aims to enhance tumor uptake while sparing radiosensitive organs, such as salivary glands, thus potentially leading to an improved therapeutic window. **Methods:** ProTACT (FL-020-001) is a first-in-human, open-label, multicenter Phase 1 study investigating the safety, tolerability, and preliminary anti-tumor activity of [^{225}Ac]Ac-FL-020 in pts with advanced PSMA-positive mCRPC. This study consists of: Bayesian dose escalation (Part 1) and dose expansion (Part 2). Eligible pts must have: histologically confirmed mCRPC, evidence of disease progression, and ≥1 PSMA-positron emission tomography positive lesion (uptake higher than liver). Prior androgen receptor signaling inhibitors or CYP17 inhibitors and ≥1 taxane-based chemotherapy is required, unless declined by the pt. Prior Lu-177 is allowed. Pts with extensive PSMA-negative disease are excluded. Dose cohorts of 1 to 3 pts (for Cohorts 1 and 2) and dose cohorts of 3 to 6 pts (for Cohorts 3+) will evaluate ascending dose levels from 1 to 10 MBq (intravenous; every 6 weeks; x 6 cycles) to determine the maximum tolerated dose and/or recommended Phase 2 dose (RP2D). Once the RP2D is established, 18 additional pts will be enrolled in Part 2 to further assess safety and early signals of efficacy. **Results:** As of 2 Jan 2026, 15 eligible pts have received [^{225}Ac]Ac-FL-020 (maximum dose/cycle: 5 MBq). No dose-limiting toxicities have been observed. Most frequent adverse events (AEs) were fatigue (10 pts), nausea and dry mouth (7 pts each), constipation and anemia (4 pts each). Grade (G)3+ AEs were reported for 6 pts, all G3+ AEs occurred in one pt each. One pt at 1 MBq had G3 anemia and 1 pt at 5 MBq had G3 anemia and G3 thrombocytopenia, both considered related to disease progression with bone marrow infiltration and unrelated to [^{225}Ac]Ac-FL-020. As of the cutoff date, 11 pts remain on treatment and 4 pts discontinued treatment prematurely, 3 due to disease progression and 1 due to G2 dry mouth. Another 6 pts reported dry mouth, all were G1. No renal toxicities or decline in renal function was observed. As of 6 Jan 2026, 1 of 3 pts at 3 MBq showed a reduction in baseline prostate-specific antigen (PSA) > 80% after 3 cycles and 2 of 6 pts at 5 MBq showed a reduction in PSA > 50% after 1 cycle. **Conclusions:** These initial findings support the feasibility and tolerability of [^{225}Ac]Ac-FL-020 administration in heavily pretreated pts with mCRPC with a few notable PSA responses. The RP2D has not yet been reached, and dose escalation continues. Clinical trial information: NCT06492122. Research Sponsor: Full-Life Technologies.

Analysis of genomic and clinical predictors of overall survival and PSA response: Results from the PRECISION registry. First Author: Hyotae Kim, Department of Biostatistics & Bioinformatics, Duke University, Durham, NC

Background: Outcomes in advanced prostate cancer vary substantially according to clinical and genomic characteristics among patients with metastatic castration-resistant prostate cancer (mCRPC). We sought to identify predictors of overall survival (OS) and prostate-specific antigen (PSA) response using data from the PRECISION real-world registry of mCRPC patients treated with poly(ADP-ribose) polymerase inhibitors (PARPi). **Methods:** Patient-level data from five centers (Dana Farber Cancer Institute, Thomas Jefferson University, University of British Colombia, University of Washington, Yale University) were aggregated, including demographics, clinical characteristics, genomic alterations, treatments, and clinical outcomes. OS was defined as the time from the first date of PARPi treatment to death or the last date the patient was known to be alive. PSA response was defined as a confirmed ≥50% decline from the PSA level measured closest to the start of PARPi treatment. Ten candidate variables per endpoint were selected via a random forest-based feature selection. Cox models stratified by study were used for OS, and logistic regression models with study included as an additional covariate were used for PSA response. Similarly, non-*BRCA* mutation status was defined as the presence of any observed mutation in genes other than *BRCA*, including *ATM*, *CHEK2*, *MSH2*, *PALB2*, *BRIP1*, and *BARD1*. **Results:** The combined dataset included n = 327 patients, with heterogeneity in baseline characteristics and treatments across studies. The prevalence of *BRCA* (*BRCA1* or *BRCA2*) and non *BRCA* mutations was 39% and 37% respectively. Median OS for patients with *BRCA* mutations was 21 months (95% CI:16–28), compared with 15 months (95% CI: 14–18) for those without *BRCA* mutations. No difference in median OS was observed between patients with and without non-*BRCA* mutations: 16 months (95%CI: 14-22) and 17 months (15-21), respectively. Cox models identified age, N stage, PSMA–lutetium therapy, PARPi use within a clinical trial, prior taxane treatment (docetaxel or cabazitaxel), and *BRCA* as important predictors of OS. The corresponding hazard ratios with 95% confidence intervals are shown in the table below. **Conclusions:** These results from real-world data highlight the importance of incorporating genomic information and treatment-specific variables when predicting outcomes in advanced prostate cancer and demonstrate the utility of multi-study integrative analyses. Research Sponsor: Prostate Cancer Foundation.

Predictor	Hazard Ratio (95% CI)
Age	1.02 (1.01–1.04)
N stage	1.91 (1.18–3.12)
PSMA–lutetium therapy	0.35 (0.20–0.62)
PARPi use (within clinical trial)	0.68 (0.48–0.98)
Prior taxane treatment (docetaxel or cabazitaxel)	1.44 (1.02–2.02)
BRCA mutation	0.50 (0.36–0.69)

Association between smoking, tumor genetics, and outcomes in men with metastatic prostate cancer. First Author: Christopher Choi, Duke University Medical Center, Durham, NC

Background: Smoking has been associated with increased metastatic prostate cancer (mPC) mortality, but the mechanisms behind this association are largely unknown. We hypothesized that smoking promotes genetic alterations associated with aggressive disease and/or the transformation to neuroendocrine prostate cancer (NEPC). **Methods:** We utilized the Prostate Cancer Precision Medicine Multi-institutional Collaborative Effort (PROMISE) clinical genomic database for this retrospective analysis. We examined associations between patient characteristics and tumor genetic data with smoking exposure at diagnosis (current, former, never and pack years) and with clinical outcomes, including overall survival (OS) from diagnosis, OS from metastasis, and NEPC status. Patients with unknown smoking status or incomplete/empty/insufficient NGS entries were excluded from analysis. **Results:** We identified 2353 men with mPC and next generation somatic tumor sequencing available for analysis in PROMISE, including 8.1% current, 39.5% former, and 52.4% never smokers. Current smokers were more likely to be younger, present with metastatic (M1 or N1) disease at diagnosis, and were less likely to have prior local therapy (all $p<0.001$). Current smoking was associated with worse OS from diagnosis (99.9 mo in current vs 137 mo in former, and 139.4 mo in never smokers; p=0.008), which remained significant after adjusting for disease characteristics (HR 1.27 95% CI 1.01-1.59). No differences in OS from metastasis were observed for amongst the three groups (current 68.1mo, former 60.3 mo, and never 64.2 mo; p=0.86) We also found no difference in the percentage of NEPC at initial diagnosis or at any time between current, former, and never smokers (p=0.8). However, positive associations were observed between smoking status and genetic alterations in SPOP (current: 15%, former 6.7%, never 3.8%; p= 0.018), FGFR1 (current 10%, former 0.4%, never 1.1% p=0.001), and ARID1A (current 5.1%, former 2.2%, never 0.4%; p=0.035) in mHSPC. No other associations between smoking status and genes of interest were identified. **Conclusions:** Active smoking is associated with worse overall and prostate cancer specific survival as compared to never/former smoking and was associated with specific tumor genetic alterations but not small cell/NEPC transformation. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Association of tumor genetics with smoking status; alterations detected in hormone sensitive tissue only.

Regional disparities in prostate cancer mortality in the African Union: A retrospective analysis (1980-2023). First Author: Abubakar Nazir, King Edwards Medical University, Mayo Hospital, Lahore, Pakistan

Background: Prostate cancer represents a substantial health burden among men in Africa and is an important contributor to cancer-related mortality, with considerable variation observed across African regions. This study uses data from the Global Burden of Disease (GBD) project to evaluate regional variations in prostate cancer age-standardized death rates (ASDR) from 1980 to 2023. **Methods:** Prostate cancer mortality data were extracted from the GBD 2023 database for the period 1980–2023. Age-standardized death rates (ASDRs) per 100,000 population were obtained for African regions as defined by the GBD classification, including Northern Africa, Central Africa, Eastern Africa, Western Africa, Southern Africa and the African Union aggregate. Temporal patterns from 1980 to 2023 were evaluated using joinpoint regression analysis, and average annual percentage change (AAPC) estimates were calculated to quantify long-term trends. Statistical significance was determined using corresponding p-values (less than 0.05) and 95% confidence intervals. **Results:** From 1980 to 2023, a gradual rise in the ASDR per 100,000 was observed in the African Union with substantial regional variations. It gradually increased from 8.78 per 100,000 in 1980 to 11.44 per 100,000 in 2023 (AAPC: 0.68; 95% CI: 0.51 to 0.84; $p < 0.000001$). The highest ASDR were observed in Central Africa. It increased from 13.72 per 100,000 in 1980 to 18.63 per 100,000 in 2023 (AAPC: 0.77; 95% CI: 0.62 to 0.91; $p < 0.000001$). This was followed by Western Africa increasing from 10.64 per 100,000 in 1980 to 16.06 per 100,000 in 2023 (AAPC: 0.96; 95% CI: 0.82 to 1.09; $p < 0.000001$). A slight increase was also observed in Southern Africa rising from 10.70 in 1980 to 12.07 (AAPC: 0.26; 95% CI: -0.0045 to 0.543; $p < 0.053$). Eastern Africa showed a slight increase in ASDR from 8.95 per 100,000 in 1980 to 10.36 per 100,000 in 2023 (AAPC: 0.43; 95% CI: 0.24 to 0.62; $p < 0.000009$). Northern Africa had consistently the lowest ASDR. It rose from 2.35 per 100,000 in 1980 to 4.32 per 100,000 in 2023 (AAPC: 1.41; 95% CI: 1.27 to 1.56; $p < 0.000001$). **Conclusions:** Prostate cancer remains the leading cause of cancer-related death among men in the African Union, particularly in Central Africa. High mortality is driven by limited healthcare access and late-stage diagnosis. Strengthening screening programs and improving specialized care can reduce this rising burden. Research Sponsor: None.

Trends in age standardized death rate (ASDR) per 100,000 due to prostate cancer in the African Union.

Region	ASDR 1980 (per 100,000)	ASDR 2023 (per 100,000)	AAPC (95% CI)
African Union	8.79	11.45	0.68* (0.51 - 0.84)
Central Africa	13.72	18.63	0.77* (0.62 - 0.92)
Eastern Africa	8.95	10.36	0.44* (0.24 - 0.63)
Northern Africa	2.35	4.33	1.42* (1.27 - 1.57)
Southern Africa	10.70	12.08	0.26* (-0.01 -0.54)
Western Africa	10.64	16.06	0.96* (0.82 - 1.10)

AAPC = Average Annual Percentage Change; *$p < 0.05$.

Impact of prior treatment setting on the efficacy of rucaparib vs physician's choice in *BRCA*-mutated castration-resistant prostate cancer (mCRPC) in TRITON3. First Author: Srikala S. Sridhar, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Rucaparib significantly improved radiographic progression-free survival (rPFS) versus physician's choice of docetaxel or an androgen-receptor pathway inhibitor (ARPI) (abiraterone or enzalutamide) in men with BRCA mutations who were chemotherapy-naïve in the mCRPC setting and had received one prior ARPI in the phase 3 TRITON3 trial (NCT02975934). This post-hoc analysis evaluated whether the timing of prior ARPI therapy impacted the efficacy of rucaparib. **Methods:** Patients were randomized 2:1 to rucaparib (600 mg BID) or physician's choice of docetaxel or ARPI, after progression on 1 prior second-generation ARPI in any setting. The primary endpoint was rPFS. Outcomes were analyzed according to whether patients received the prior ARPI in the metastatic castration sensitive (mCSPC) or castration resistant (mCRPC) setting. Data cutoff was August 25, 2022. **Results:** Of the 302 BRCA1/2 patients, 68 received prior ARPI in the mCSPC setting (42 rucaparib; 26 physician's choice) and 234 in the mCRPC setting (159 rucaparib; 75 physician's choice). Baseline characteristics were generally similar. Prior treatments in the mCSPC and mCRPC groups, respectively, included abiraterone (73.5% vs 53.0%), enzalutamide (29.4% vs 48.3%), and docetaxel (17.6% vs 24.8%). Median rPFS favored rucaparib over physician's choice in both groups (mCSPC: 13.6 vs 8.2 months; HR 0.60 [95% CI, 0.32–1.15]; mCRPC: 11.2 vs 5.8 months; HR 0.43 [95% CI, 0.30–0.61]). Median OS was similar between treatments in both settings (mCSPC: 23.2 vs 21.7 months; HR 0.81 [95% CI, 0.47–1.41]; mCRPC: 23.2 vs 21.0 months; HR 0.91 [95% CI, 0.66–1.25]). Treatment-related adverse events occurred at comparable rates (89.6% vs 86.1%). **Conclusions:** Rucaparib demonstrated efficacy in patients with BRCA-mutated mCRPC, regardless of whether prior ARPI was administered in the mCSPC or mCRPC setting. Clinical trial information: NCT02975934. Research Sponsor: Clovis Oncology and pharmaand GmbH.

Phase 1b/2 study of pembrolizumab plus lenvatinib or pembrolizumab coformulated with vibostolimab in participants (pts) with metastatic neuroendocrine prostate cancer (NEPC): KEYNOTE-365 cohorts F and H. First Author: Gunhild Von Amsberg, University Medical Center Hamburg-Eppendorf; Martini Clinic, Hamburg, Germany

Background: Effective therapy for NEPC is an unmet need due to poor prognosis and no established standard of care. The phase 1b/2 KEYNOTE-365 study (NCT02861573) evaluated the efficacy and safety of pembrolizumab (pembro) + lenvatinib (lenva; cohort F) or coformulated pembro/vibostolimab (vibo; cohort H) in pts with NEPC. **Methods:** Pts with pathologically confirmed treatment-emergent neuroendocrine (t-NE) or de novo metastatic NEPC (small cell carcinoma, large cell neuroendocrine carcinoma, or mixed morphology per central review), progression ≤6 mo before screening, and an ECOG PS of 0 or 1 were enrolled. Prior androgen deprivation therapy for metastatic disease was required for pts with t-NE. Prior chemotherapy regimens (≤2) for metastatic castration-resistant prostate cancer and second-generation hormonal agents (≤2) were permitted. Pts in cohort F received pembro 200 mg IV Q3W + lenva 20 mg PO QD. Pts in cohort H received pembro/vibo 200 mg/200 mg IV Q3W. Pembro or pembro/vibo were given for ≤35 cycles; lenva was given until discontinuation criteria were met. Primary end points were safety, ORR per RECIST v1.1 by blinded independent central review (BICR), and confirmed prostate-specific antigen (PSA) response rate (≥50% decrease from baseline measured twice ≥3 weeks apart). Secondary end points included ORR, time to PSA progression, radiographic PFS (rPFS) per Prostate Cancer Working Group 3 (PCWG3)–modified RECIST (mRECIST) v1.1 by BICR, DOR and DCR per RECIST v1.1 by BICR, and OS. **Results:** As of August 25, 2025, 14 and 20 pts received ≥1 dose of study treatment in cohort F or cohort H, respectively. Median follow-up was 25.6 mo (range, 22.9-35.1) and 31.4 mo (range, 23.2-45.9), respectively. Among pts with RECIST-measurable disease, confirmed ORR was 23.1% (3/13; 95% CI, 5.0-53.8) in cohort F and 12.5% (2/16; 95% CI, 1.6-38.3) in cohort H. Additional efficacy results are shown in the table. Treatment-related adverse events (TRAEs) occurred in 85.7% of pts in cohort F (64.3% grade 3 or 4) and 55.0% of pts in cohort H (25.0% grade 3 or 4). No grade 5 TRAEs occurred in either cohort. In cohorts F and H, TRAEs resulted in treatment discontinuation in 21.4% and 10.0% of pts, respectively, and immune-mediated AEs occurred in 35.7% and 15.0%. **Conclusions:** Pembro + lenva or pembro/vibo had a manageable safety profile and only modest antitumor activity in pts with NEPC. Clinical trial information: NCT02861573. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

5056 Poster Session

Can TGF-β inhibition (galunisertib) enhance response to enzalutamide in metastatic castration-resistant prostate cancer (mCRPC)?: Results from a randomized phase II trial. First Author: Nicole Metri, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University School of Medicine, Baltimore, MD

Background: Resistance to androgen receptor (AR)-directed therapies is a major challenge in advanced prostate cancer, and enzalutamide shows limited activity after progression on abiraterone. Aberrant transforming growth factor-β (TGF-β) signaling promotes prostate cancer progression and contributes to resistance to AR-directed therapies. Preclinical studies suggest TGF-β inhibition may overcome resistance to enzalutamide. We hypothesized that combining TGF-β receptor I kinase inhibitor, galunisertib, with enzalutamide may delay enzalutamide resistance in patients with mCRPC who have progressed on abiraterone. **Methods:** This multicenter, randomized phase II trial enrolled chemotherapy-naïve mCRPC patients with disease progression on abiraterone. There was a cycle 1 safety run-in for the first 6 patients, followed by a randomized phase with patients assigned 3:2 to receive galunisertib plus enzalutamide or enzalutamide alone. The primary endpoint was radiographic progression-free survival (rPFS). Secondary endpoints included PSA response, overall survival (OS), safety, and tolerability. rPFS and OS were compared between arms using Cox regression, with medians estimated by Kaplan-Meier method. **Results:** Of 61 patients randomized, 60 received treatment: 23 with enzalutamide and 37 with galunisertib plus enzalutamide. There was no significant difference in rPFS between the combination and enzalutamide arms (HR 1.23; 95% CI: 0.72, 2.11; p=0.44), with a median rPFS of 5.6 and 7.3 months, respectively. The OS was also similar between the two groups (HR 1.00; 95% CI: 0.55, 1.83, p=1.00), with a median OS of 21.6 months in the combination arm and 24 months in the enzalutamide arm. PSA30 response was seen in 22% of patients in the combination arm vs. 35% in the enzalutamide arm (p=0.30), and PSA50 response in 19% vs. 26%, respectively (p=0.50). The most common treatment-related adverse events (AEs) were fatigue, anorexia, and nausea. Grade 3-4 treatment-related AEs occurred in 11% of patients in the combination arm vs. 13% in the enzalutamide arm. **Conclusions:** The addition of galunisertib to enzalutamide did not improve the rPFS, OS, or PSA response compared to enzalutamide alone in patients with chemotherapy-naïve mCRPC with disease progression on abiraterone. These findings do not support further development of galunisertib plus enzalutamide in patients with mCRPC. Clinical trial information: NCT02452008. A randomized phase Ib/II study of enzalutamide (Enza) with and without ribociclib (Rib) in patients with metastatic castrate-resistant prostate cancer (mCRPC) that retains RB expression: RiboX study. First Author: Kevin Kayvan Zarrabi, Thomas Jefferson University, Philadelphia, PA

Background: RB function is often attenuated in tumors through hyperphosphorylation; thus, RB activity can be "re-awakened" in RB+ tumors by suppressing key kinases that phosphorylate RB (CDK4/6). We report a phase Ib/II trial to determine the safety, tolerability and antitumor activity rib with enza in patients (pts) with mCRPC (NCT02555189). **Methods:** RiboX was a multicenter, phase Ib/II, open label trial which enrolled taxane-naïve pts with progression to mCRPC and retained RB expression. For phase Ib, a traditional 3x3 dose-escalation was used to establish the RP2D for the phase II portion. Pts received rib at 200, 400 or 600mg once daily (QD) Days (D) 1-21 in combination with fixed dose enza (160mg QD D1-28). In phase II, pts were randomized 1:1 to enza monotherapy (Arm A) or enza + rib (Arm B). The study was later modified to a single arm Simon two-stage design using the RP2D of 600mg rib with 160mg enza. The primary phase II endpoint was the proportion of pts a PSA50 response at 12 weeks. The null hypothesis was that the PSA50 response was ≤78% and 31 responses were required to reject the null hypothesis. Secondary endpoints were rPFS, PSA PFS, OS and safety. **Results:** 12 pts were enrolled in the phase Ib portion across three dose levels upon confirmation of RB expression on tumor biopsy. No DLTs were observed in dose-escalation and the RP2D was established at rib 600mg QD D 1-21 + enza 160mg QD D 1-28. The phase II portion included 12 pts treated with enza mono; 28 phase II pts and 6 phase 1b pts yielded 34 pts treated with combination at RP2D. The PSA50 response at 12 weeks was 75% (95% CI, 43-95) for enza mono and 82% (95% CI, 65-93) for the combination, failing to reject the null hypothesis. Median rPFS for evaluable pts was 10.9 mo (95% CI, 2.5-45.9) for enza mono (n = 12) and 27.0 mo (95% CI, 11.3-37.0) for combination (n = 30). PSA PFS was 10.1 months (95% CI, 1.8-33.1) for enza mono (n = 12) and 14.8 mo (95% CI, 6.7-35.9) for combination (n = 34). OS was 31.2 mo (95% CI, 15.0-NA) for enza mono (n = 12) and 58.1 mo (95% CI, 33.4-NA) for combination (n = 34). Four pts treated with combination were included for PSA PFS but did not have data for rPFS. Among pts treated at RP2D in the combination arm, the most common TEAE's included fatigue 59%, nausea 26.9%, neutropenia 26.7% (grade 3, 12%), diarrhea 20.9%, dizziness 14.7%, arrhythmia 2.9%, seizure 2.9%. **Conclusions:** The combination of enza + rib was well tolerated; however, no significant difference in PSA50 response was observed, and the primary endpoint was not met. A disease-stabilizing effect was observed in a subset of patients treated with the enza + rib combination, with evidence of prolonged survival. Further investigation into this disease-stabilizing effect and refinement of patient selection criteria beyond RB expression may be warranted. Funding: Novartis Pharmaceuticals and DOD (W81XWH-22-2-0020). Clinical trial information: NCT02555189. Research Sponsor: Novartis.

Belzutifan in docetaxel-pretreated metastatic castration-resistant prostate cancer (mCRPC): Phase 1b/2 KEYNOTE-365 cohort J. First Author: Jose Angel Arranz Arija, Gregorio Marañón General University Hospital, Madrid, Spain

Background: Hypoxia-inducible factor 2α (HIF-2α) is an established oncogenic driver, and HIF-2α expression in prostate cancer is positively correlated with aggressive disease. Belzutifan is a selective HIF-2α inhibitor approved for use in clear cell renal cell carcinoma. Cohort J of the multicohort, phase 1b/2 KEYNOTE-365 study (NCT02861573) evaluated the safety and efficacy of belzutifan in participants (pts) with mCRPC. **Methods:** Eligible adults had histologically or cytologically confirmed adenocarcinoma of the prostate without small cell histology, had an Eastern Cooperative Oncology Group performance status score of 0 or 1, and had received prior docetaxel for mCRPC. Prior treatment with 1 other chemotherapy and ≤2 second-generation hormonal agents were allowed. Pts received oral belzutifan 120 mg daily. Primary end points were safety and tolerability, prostate-specific antigen (PSA) response rate (PSA decline ≥50%), and objective response rate (ORR) per RECIST v1.1 by blinded independent central review (BICR). Secondary end points included time to PSA progression, ORR, and radiographic progression-free survival (rPFS) per PCWG3-modified RECIST v1.1, duration of response and disease control rate (DCR; complete response + partial response + stable disease ≥6 mo) per RECIST v1.1 and PCWG3-modified RECIST v1.1 by BICR, and overall survival (OS). **Results:** A total of 21 pts were allocated to receive belzutifan. Median age was 69.0 y (range, 56-84). Median study follow-up was 17.6 mo (range, 15.9-21.8). All pts discontinued treatment as of the data cutoff (August 25, 2025), most commonly due to progressive disease (n = 12; 57%). Median duration of belzutifan therapy was 2.8 mo (range, 0.7-8.7). Treatment-related adverse events (AEs) occurred in 20 pts (95%); grade 3 or 4 treatment-related AEs occurred in 11 pts (52%), most commonly anemia (n = 8; 38%). A total of 2 pts (10%) discontinued treatment, and no pts died due to treatment-related AEs. Among pts with a baseline PSA measurement (n = 20), PSA response rate was 0% (95% CI, 0-17) and median time to PSA progression was 3.0 mo (95% CI, 2.8-not reached [NR]). Among 12 pts with RECIST-measurable disease, ORR and DCR per RECIST v1.1 were both 0%; ORR and DCR per PCWG3-modified RECIST v1.1 were 0% and 8%, respectively. In all pts, median rPFS was 3.7 mo (95% CI, 1.9-NR) and median OS was 16.9 mo (95% CI, 10.8-NR). **Conclusions:** In cohort J of the KEYNOTE-365 trial, belzutifan monotherapy had a manageable safety profile but did not show meaningful antitumor activity in mCRPC. Future research is needed to determine effective treatments for pts with mCRPC. Clinical trial information: NCT02861573. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Utidelone in heavily pretreated metastatic castration-resistant prostate cancer progressing after docetaxel and novel hormonal agents: Results of a completed phase II trial. First Author: Meiting Chen, Department of Medical Oncology, State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Patients with metastatic castration-resistant prostate cancer (mCRPC) who have progressed after both docetaxel and novel hormonal agents (including abiraterone and/or androgen receptor pathway inhibitors [ARPIs]) have a poor prognosis with limited treatment options. This study aimed to evaluate the efficacy and safety of utidelone, a genetically engineered epothilone analogue with antitumor activity in taxane-resistant cancers, in these patients. **Methods:** In this prospective, single-arm, phase II clinical trial, eligible male patients were aged 18 to 75 years with mCRPC who had progressed on docetaxel and at least one prior ARPI or abiraterone. Patients received utidelone monotherapy (30 mg/m²/day intravenously for 5 days, every 3 weeks) until progression, intolerable toxicity, or death. Recruitment has been completed with 43 patients enrolled at Sun Yat-sen University Cancer Center from March 23, 2022, to December 10, 2025. The primary endpoint was prostate specific antigen (PSA) response rate, defined as a 50% or greater reduction in serum PSA. Secondary endpoints included radiographic progression-free survival (rPFS) according to PCWG3 criteria, OS, and safety. **Results:** Analysis was performed on the full cohort. The median age was 66 years, and patients had received a median of 4.0 (range, 2-8) prior lines of treatment. All patients were pre-treated with docetaxel and 97.7% with abiraterone; 90.7% patients had progressed after ARPI, and 14.0% after radionuclide therapy. Visceral metastases were present in 32.6% patients, and 67.4% had de novo metastatic disease. Among 28 patients with available genetic data, BRCA1/2 mutations were identified in 3 (10.7%). By the data cut-off (January 4, 2026), the PSA50 response rate (≥50% decline) was 23.3%, and 32.6% of patients achieved a PSA30 response (≥30% decline). The median rPFS was 6.7 months, and median OS was 11.4 months. Most of the treatment-related adverse events (TRAEs) were grade 1 or 2 and were considered manageable. Grade 3/4 TRAEs consisted of anemia (14.0%), peripheral sensory neuropathy (2.3%), vomiting (2.3%), and diarrhea (2.3%). No treatment-related deaths occurred. **Conclusions:** Utidelone monotherapy exhibits promising antitumor activity and manageable safety profile in heavily pretreated mCRPC patients, including those who have progressed on ARPIs, abiraterone, and docetaxel. The study results support further investigation of this regimen. Clinical trial information: ChiCTR2200061635. Research Sponsor: Beijing Biostar Pharmaceuticals Co., Ltd.

Rad2Nivo: Phase IB study of radium-223 (Rad) with nivolumab (Nivo) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). First Author: Georges Gebrael, Huntsman Cancer Institute at The University of Utah, Salt Lake City, UT

Background: Rad is an α-emitting calcium-mimetic radiopharmaceutical that is FDA approved for pts with mCRPC with symptomatic bone metastasis (mets) and no visceral mets. Preclinical data suggest that radiation might enhance the anticancer effect from PD-1 therapy [PMID 25274032, 29137877]. Nivo is a PD-1 immune checkpoint antagonist. Few pts experience PSA reduction with Rad, and objective responses in bone mets cannot be assessed. We hypothesized that Rad+Nivo would be safe and result in decreased ctDNA variant allele frequency (VAF) as a marker of clinical efficacy. **Methods:** In this phase IB, prospective, open-label, single-center, single-arm study (NCT04109729), pts with symptomatic bone-metastatic mCRPC without visceral mets were eligible. Participants received intravenous Rad (55 kBq/kg IV) monotherapy for 6 cycles. Nivo (480mg IV) was introduced starting with cycle 3 and continued for up to 2 years. ctDNA collected at baseline, cycle 3 and 6 weeks after. Primary endpoints: (1) frequency of grade ≥3 non-hematologic treatment-emergent adverse events (TEAEs) and (2) change in ctDNA VAF from baseline compared to after 6 weeks of nivolumab therapy. Mean VAF was defined as average VAF of all somatic mutations present at baseline at a VAF 1%. Null hypothesis: proportion of pts with a non-zero ctDNA reduction is ≤ 20%. A one-sided exact binomial test was used to evaluate whether the proportion of pts demonstrating a decrease in mean VAF on-treatment exceeded 20%. With 36 pts, there will be 83% power at one-sided $\alpha = 0.05$ to detect an alternative proportion of subjects with ctDNA reduction = 40%. **Results:** Overall, 39 pts were enrolled trial between 9/2020 and 1/2025, and 35 pts were treated with both Rad+Nivo. Median age was 71 years (54-84), median PSA at study entry was 13.9 ng/dL (0-3245). 22 pts (56.4%) had Gleason score ≥8 (unavailable for 3 pts). Median number of prior lines of therapy was 3 (1-7). 53.9% (n = 21) of pts had received prior chemotherapy. 61% (n = 24) of pts completed 6 doses of Rad (range 2-6). The median number of Nivo cycles was 4 (0-25). Dose holds or delays occurred in 26% (n = 10) and 31% (n = 12) of pts receiving Rad and Nivo, respectively. 38% (n = 15) of pts experienced at least one grade 3-5 TEAE regardless of attribution. Grade 3-4 TEAE related to Rad and Nivo occurred in 15% (n = 6) and 18% (n = 7) of pts, respectively. No dose-limiting toxicities were observed. Serious adverse events related to Rad and Nivo occurred in 5% (n = 2) and 2.6% (n = 1) of pts, respectively. Paired molecular data was available for 25 pts. VAF was measurable in all patients who had samples collected and reduction was observed in 15 of 25 pts (60%, one-sided 95% CI, 41.7%-100%; $p < 0.01$). **Conclusions:** The study met its primary endpoints. Rad+Nivo appears to be safe and VAF was decreased in 60% of patients tested. Survival outcomes and clinical correlation data with VAF will be presented at the meeting. Clinical trial information: NCT04109729. Research Sponsor: Bristol Myers Squibb.

Mortality trends and disparities in prostate cancer with co-occurring cardiometabolic disorders among U.S. men aged ≥ 55 years, 1999–2024. First Author: Mian Muinuddin Jamshed, Aga Khan University Hospital, Karachi, Pakistan

Background: Prostate cancer (PCa) survivors are at significant risk for cardiometabolic disorders (CMD) including hypertension, diabetes, and cerebrovascular diseases which often act as competing causes of death. While PCa survival with CMD has improved but trends in deaths remain poorly characterized across demographic and geographic strata. This study evaluates longitudinal trends to identify success in management and remaining inequities in men aged ≥ 55. **Methods:** We analyzed U.S. mortality data (1999–2024) from the CDC WONDER database for men aged ≥ 55 years with PCa as the underlying cause of death (UCOD) and CMD as the multiple cause of death (MCOD). Age-adjusted mortality rates (AAMR) per 100,000 and joinpoint regression were used to estimate Annual Percent Change (APC) and Average Annual Percent Change (AAPC). Stratified analyses were performed by race, census region, and urbanization. **Results:** A total of 151,108 deaths were identified (cumulative AAMR: 18.78). Overall mortality demonstrated a significant declining trend (1999–2024; AAPC: -2.48%, $p < 0.001$). Significant declines were observed across all racial groups. Black or African American men experienced the highest mortality burden but also the most rapid decline (AAPC: -6.01%, $p < 0.001$), narrowing the gap with White men (AAPC: -4.33%, $p < 0.001$). While all regions showed improvement, the Southern U.S. demonstrated the slowest rate of decline (AAPC: -4.13%, $p < 0.001$) compared to the Northeast, which saw the most substantial reduction (AAPC: -5.76%, $p < 0.001$). Recent trends (2019–2024) showed sharp decreases across regions, including the South (APC: -11.28%, p = 0.002). Declines were consistent across the rural-urban continuum. Micropolitan (non-metropolitan) areas showed a significant overall decline (AAPC: -1.72%, $p < 0.001$). However, segments of transient increase were noted between 2015–2020 in Medium Metro (APC: +3.77%, p = 0.004) and Large Fringe Metro (APC: +3.55%, p = 0.005) areas before resuming a downward trend. **Conclusions:** Mortality for prostate cancer with contributing cardiometabolic causes is significantly decreasing among U.S. men aged ≥ 55. The accelerated decline among Black men and in the Northeast reflects improvements in integrated oncological and cardiovascular care. However, the slower decline in the South and transient increases in specific metropolitan areas underscore the necessity for targeted cardio-oncology interventions. Continued focus on equitable access to cardiometabolic risk management is vital to sustaining these positive trends and eliminating geographic and racial disparities in PCa survivorship. Efficacy, safety, and quality of life outcomes of 177Lu-PSMA-617 in metastatic castration-resistant prostate cancer: A GRADE-assessed systematic review, meta-analysis, and trial sequential analysis of randomized controlled trials. First Author: Moosa Mubarika, Nishtar, Multan, Pakistan

Background: 177Lu-PSMA-617 radioligand therapy (RLT) offers a targeted approach for metastatic castration-resistant prostate cancer (mCRPC). However, its consolidated impact on survival, patient-reported outcomes, and safety requires rigorous validation. We conducted a systematic review, meta-analysis, and trial sequential analysis (TSA) to evaluate the robustness of evidence regarding efficacy, toxicity, and quality of life (QoL). **Methods:** We systematically searched PubMed, Cochrane, and Embase for prospective randomized controlled trials (RCTs) comparing 177Lu-PSMA-617 versus standard-of-care (SOC) in mCRPC. Primary outcomes included overall survival (OS), radiographic progression-free survival (rPFS), and PSA response. Secondary outcomes included QoL (FACT-P scores, pain intensity) and adverse events (AEs). TSA was performed to assess the conclusiveness of the cumulative evidence. Data were pooled using a random-effects model. **Results:** Six prospective RCTs comprising 2,113 patients (1,263 Lu-PSMA; 850 SOC) were included. Lu-PSMA significantly improved overall survival (HR 0.76; P = 0.02) and radiographic progression-free survival (HR 0.55; $P < 0.00001$) compared to SOC. QoL metrics significantly favored Lu-PSMA, including mean difference in QoL scores (MD 2.93; $P < 0.00001$), time to deterioration of FACT-P (RR 0.58; $P < 0.00001$), and worsening of pain intensity (OR 0.61; P = 0.002). TSA demonstrated conclusive evidence for PSA response (RR 2.33; P = 0.001), as the Z-curve crossed the monitoring boundary. However, TSA for ORR and PFS remained inconclusive despite favorable point estimates. Regarding safety, Lu-PSMA was associated with higher risks of Grade 1-2 dry mouth (RR 9.75), Grade ≥3 thrombocytopenia (RR 6.20), and Grade 1-2 dry eyes (RR 6.66). **Conclusions:** 177Lu-PSMA-617 demonstrates a significant survival benefit and conclusively improves PSA response rates in mCRPC. Crucially, it preserves quality of life by delaying the deterioration of physical function and pain. While effective, the therapy carries specific toxicity risks, notably xerostomia and high-grade thrombocytopenia, necessitating careful patient monitoring. Research Sponsor: None.

Outcome	Effect Estimate (95% CI)	P-Value	I^2	TSA Status
Overall Survival	HR 0.76 (0.59–0.96)	0.02	68%	-
Radiographic PFS	HR 0.55 (0.43–0.71)	<0.00001	67%	Inconclusive
PSA Response Rate	RR 2.33 (1.38–3.93)	0.001	93%	Conclusive
Objective Response Rate	RR 2.94 (1.55–5.55)	0.0009	72%	Inconclusive
Quality of Life (MD)	MD 2.93 (1.80–4.07)	<0.00001	20%	-
Time to Det. FACT-P	RR 0.58 (0.51–0.66)	<0.00001	0%	-
Worsening Pain Score	OR 0.61 (0.44–0.84)	0.002	81%	-
Dry Mouth (Grade 1-2)	RR 9.75 (6.85–13.88)	<0.00001	91%	-
Thrombocytopenia (G≥3)	RR 6.20 (2.18–17.65)	0.0006	0%	-
Dry Eyes (Grade 1-2)	RR 6.66 (2.79–15.91)	<0.0001	0%	-

A phase I study of [225Ac]Ac-PSMA-XT, a novel alpha-particle–emitting radioligand therapy, in patients with metastatic castration-resistant prostate cancer. First Author: Xiaorong Sun, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Ji'Nan, China

Background: Targeted alpha therapy (TAT) is an emerging modality for metastatic castration-resistant prostate cancer (mCRPC), offering the potential for precise tumor cell eradication with limited off-target exposure. [225Ac]Ac-PSMA-XT (XT381) is a PSMA-targeted alpha-emitting radiopharmaceutical designed to deliver high linear energy transfer radiation. This single-center, open-label Phase I study (NCT07135102) in China aims to assess the safety, tolerability, and preliminary efficacy of [225Ac]Ac-PSMA-XT in heavily pretreated mCRPC. **Methods:** Patients with PSMA-positive mCRPC (confirmed by THERP trial criteria, ≥1 lesion with SUV_{max}> 20 on PSMA PET/CT imaging, and all measurable lesions with SUV_{max} > liver SUV_{mean}) who progressed after ≥1 line of androgen receptor pathway inhibitor were enrolled. A standard "3 + 3" design was used across five dose levels (25, 50, 75, 100 and 125 kBq/kg), with up to 6 cycles administered every 6 weeks. Primary endpoints were safety/tolerability (CTCAE v5.0). Key secondary endpoints inclued PSA50 response (≥50% decline), radiographic progression-free survival (rPFS), objective response rate (ORR) by RECIST 1.1, and disease control rate (DCR). Enrollment has completed through the 75 kBq/kg cohort, the 100 kBq/kg cohort is ongoing. **Results:** As of December 12, 2025, 12 paitents were dosed (cohorts 25-100 kBq/kg, n = 3 each). All patients received at least one dose of [225Ac]Ac-PSMA-XT. No dose-limiting toxicities have been observed. Grade 3 or 4 treatment-related adverse events (TRAEs) occurred in 2 patients. The most common TRAEs were xerostomia and grade 1-2 hematologic toxicities, including anemia (55.6%, 5/9), leukopenia (44.4%, 4/9), lymphopenia (22.2%, 2/9), neutropenia (11.1%, 1/9), and thrombocytopenia (11.1%, 1/9). Among 9 evaluable patients (≥6 weeks follow-up), 7 (77.8%) achieved a PSA50 response, and 4 (44.4%) achieved a PSA90 response. The 6-month progression-free survival (PFS) rate was 71.4 (5/7). In 5 patients with RECIST-measurable disease, ORR was 60% (3 partial responses). Overall DCR was 67%. **Conclusions:** [225Ac]Ac-PSMA-XT shows a favorable and manageable safety profile with no DLTs observed up to 100 kBq/kg. Early efficacy signals are highly encouraging, with deep PSA declines and durable disease control observed in this heavily pretreated mCRPC population. These data support continued dose escalation and further development of this alpha-emitting PSMA-targeted therapy. Clinical trial information: NCT07135102. Research Sponsor: Beijing Sinotau International Pharmaceutical Technology Co. Ltd.

Genomic biomarkers of sensitivity to bipolar androgen therapy (BAT) in metastatic castration-resistant prostate cancer (mCRPC). First Author: Diogo Assed Bastos, Hospital Sírio-Libanês, São Paulo, Brazil

Background: In most cases, mCRPC remains driven by persistent androgen receptor (AR)-signaling. BAT has shown benefit in a subset of patients (pts) with mCRPC through multiple mechanisms of action, including modulation of AR activity, induction of DNA double-strand breaks and cell cycle arrest. There is a need for predictive biomarkers to identify patients most likely to benefit from BAT. **Methods:** This retrospective multicenter study included pts with mCRPC treated with BAT who had undergone tumor genomic profiling up to one month prior to BAT initiation. Somatic alterations were correlated with PSA50 response rates (≥50% decline in PSA from baseline), time to treatment failure (TTF) and overall survival (OS). PSA50 associations were assessed using Fisher's exact test and logistic regression. Time-to-event outcomes were analyzed using Kaplan–Meier and Cox models. Independent predictors were evaluated using multivariable logistic regression and Cox models. **Results:** We identified 104 pts for inclusion. The median age was 72 years and 49.4% of pts presented with metastases at diagnosis. PSA50 was achieved in 39.4% overall. Median TTF and OS were 3.7 (95% CI: 3.0–4.9) and 28.5 (95% CI: 23.5–35.1) months, respectively. AR amplification, *TP53* alterations and double-hit tumor suppressor alterations involving *TP53*/*RB1*/*PTEN* were all strongly associated with better PSA50 (Table). In multivariable analysis (MVA), AR amplification (OR 4.00, 95% CI 1.23–13.01; p = 0.021) and *TP53* alterations (OR 5.18, 95% CI 1.71–15.71; p = 0.0037) remained independently associated with PSA50 In survival analyses, AR ligand-binding domain mutations that reduce testosterone binding affinity (low-affinity AR-LBD mutations: L702H, W742C, T878A/S) were linked to shorter TTF and remained independently associated in MVA (HR 2.19, 95% CI 1.15–4.18; p = 0.017), together with metastatic disease at diagnosis (HR 1.82, 95% CI 1.17–2.84; p = 0.008). **Conclusions:** Distinct genomic alterations are associated with sensitivity to BAT in mCRPC patients. AR amplification, *TP53* alterations and *TP53/RB1/PTEN* double-hit status were all associated with increased likelihood of PSA response, while low-affinity AR-LBD mutations identify patients at risk for early treatment failure. These findings are in line with prior studies and support genomic profiling to refine patient selection for BAT. Research Sponsor: None.

	PSA50		TTF		OS	
	OR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value

Early chemo-induced TME alterations as a predictor of response to PD-1 blockade in AVPC: Single-cell data from C3NIRA. First Author: Anthos Christofides, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Aggressive variant prostate cancer (AVPC) criteria enrich for androgen-indifferent disease that is highly aggressive and has limited therapeutic options. Single-agent immune checkpoint inhibitors have not demonstrated activity in prostate cancer patients. The C-COLA study (NCT03263650) showed that Cabazitaxel/Carboplatin (CabCarb) elicited inflammatory signaling in responsive patients with AVPC. Based on these findings, we hypothesized that chemotherapy-induced inflammation in the tumor microenvironment (TME) may prime tumors for immunotherapeutic approaches. **Methods:** The C3NIRA trial (NCT04592237) employed one cycle of CabCarb, followed by the addition of the PD-1 blocker Cetrelimab, from cycle 2 for up to 6 cycles of induction treatment in patients with AVPC. Among 120 enrolled men, 20 discontinued due to toxicities and 40 due to progression during induction. Sixty patients completed induction and were subsequently randomized to Niraparib maintenance with or without Cetrelimab. The 30 randomized to Niraparib with Cetrelimab had significantly longer progression free (PFS) and overall survivals than the 30 randomized to Niraparib alone. To investigate whether treatment-induced alterations in the TME could predict immunotherapy response, biopsies were obtained at baseline, and after cycles 1, 3 and 9 for single-cell RNA sequencing (scRNAseq). **Results:** scRNAseq analysis of tumor biopsies showed a high proportion of $GZMK^+$ $CD8^+$ T cells and $CD8^+$ T effector memory clusters, and a low proportion in $FOXP3^+$ $CD4^+$ T regulatory cells, in the TME of responders (PFS≥10months) after cycle 1 of CabCarb, which was not seen in progressors. Similarly, $SPP1^+$ macrophages scoring high immunosuppressive signatures were reduced in responders after CabCarb but not in progressors. Consistent with these suppressive and effector cell changes, $LAG3^+$ $TIGIT^+$ $CD8^+$ T exhausted cells gradually accumulated in progressors from baseline through CabCarb and Cetrelimab treatment, while remaining unchanged in responders over the same interval. **Conclusions:** One cycle of CabCarb induction altered the TME in a subset of AVPC tumors, with reduction of suppressive myeloid and T cell populations and expansion of anti-tumor effector cells associated with clinical responses. These early TME changes may predict benefit from the addition of PD-1 blockade and help refine patient selection for immune checkpoint inhibition. Ongoing analyses are identifying additional therapeutic vulnerabilities in the TME that can be targeted to further improve outcomes in men with AVPC. Clinical trial information: NCT04592237. Research Sponsor: U.S. Department of Defence; W81XWH-20-1-0257; Janssen Scientific Affairs, LLC.

5066 Poster Session

Genomic predictors of response to cabazitaxel in metastatic castration-resistant prostate cancer (mCRPC): A real-world analysis from the PROMISE registry. First Author: Peter D. Zang, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Cabazitaxel (Cabazi) is an important treatment for refractory mCRPC, but responses are heterogeneous. Homologous recombination repair (HRR) and tumor suppressor gene (TSG alterations (alt) can predict aggressive behavior in patients (pts) with mCRPC. We hypothesize that Cabazi has enhanced efficacy in pts with these aggressive alt. **Methods:** The multi-institutional PROMISE clinical-genomic database was queried for patients who had undergone tumor next-generation sequencing prior to initiating Cabazi monotherapy for mCRPC. We evaluated the association of select gene alt HRR (*BRCA1, BRCA2, ATM, BRIP1, CDK12, CHEK2, PALB2, RAD51, RAD51B/CD*), TSG (*RB1, PTEN* loss, *TP53*) and other common alt in mCRPC with PSA response and clinical Progression to Cabazi. Comparisons of PSA50 responses were made using Fisher's exact tests, and associations between genetic alterations and both OS and PFS were conducted using log-rank tests. **Results:** Among 383 pts who met inclusion criteria median age was 61 years, with 283 (74%) Caucasian pts, 71 (19%) African-American/Black pts, 9 (2%) Asian pts, and 20 (5%) Hispanic pts. 302 (79%) had prior docetaxel, 23 (6%) had received PARP inhibitor, and 16 (4%) had received Lu-177 PSMA. The most frequent alt noted were: TSG in 204 (53%) pts, TP53 in 164 (43%), AR alt in 130 (34%) pts, and HRR alt in 91 (24%) pts. No significant difference was noted in PSA50 responses in pts with TSG or HRR alt relative to wild-type, though there was a difference noted in pts with PIK3CA alt (Table). Progression-free survival (PFS) on Cabazi was shorter in pts with TP53 alt [HR 1.55 (1.19 – 2.04), p=0.001), any TSG alt [HR 1.51 (1.15 – 1.98) p=0.003], RB1 [HR 2.34 (1.38 – 3.99), p-=0.005], and AR alt [HR 1.37 (1.04 – 1.79) p=0.03). There was no difference in pts with HRR alt [HR 0.83 (0.60 – 1.15), p=0.26)]. Overall survival (OS) was prolonged in pts with HRR alt [HR 0.69 (0.59 – 0.92), p=0.009)] and worse in pts with TP53 alt [HR 1.54 (1.20 – 1.98) p<0.001)], any TSG alt [HR 1.36 (1.07 – 1.74), p=0.01], or RB1 alt [HR 1.94 (1.18 – 3.18) p=0.02]. **Conclusions:** Common genomic alt including TSG, HRR, and PI3KA were not predictive of Cabazi response in mCRPC. TSG alt were associated with worse outcomes, consistent with aggressive disease biology. Improved OS in pts with HRR alt likely reflects PARP inhibitor or platinum use rather than Cabazi efficacy. Research Sponsor: None.

Association between genomic alterations and cabazitaxel response in mCRPC.

Genetic Alteration	PSA50 Response	PFS (HR)	OS (HR)
Any TSG	26.8% vs 25.4% (p=0.80)	**1.51 (p=0.003)**	**1.36 (p=0.01)**
AR	20.8% vs. 28.6% (p=0.16)	**1.37 (p=0.03)**	1.19 (p=0.19)
Any HRR	31.8% vs. 24.6% (p=0.27)	0.83(p=0.26)	**0.69 (p=0.009)**
PTEN	35.7% vs. 24.0% (p=0.09)	1.12 (p=0.50)	0.98 (p=0.92)
PIK3CA	**5.6% vs. 27.4% (p=0.05)**	1.53 (p = 0.22)	1.27 (p = 0.36)

Correlation between dual FDG/PSMA PET mismatch and ctDNA genomic profiling in metastatic castration-resistant prostate cancer (mCRPC) patients screened for 177Lu-PSMA. First Author: Louise Lazerges, Department of Medical Oncology, Gustave Roussy, Villejuif, France

Background: 177Lu-PSMA radioligand therapy is now a standard treatment for patients (pts) with mCRPC. Dual-tracer FDG/PSMA PET imaging mismatch (i.e. FDG+ and PSMA- lesions) is currently the main selection criterion used to predict 177Lu-PSMA response. However, this approach is time-consuming, resource-intensive and may not fully capture tumor biological aggressiveness. More accessible and biologically informative biomarkers are therefore needed. **Methods:** This retrospective, single-center study included pts diagnosed with mCRPC who underwent FDG and PSMA PET for 177Lu-PSMA screening and circulating tumor DNA next-generation sequencing (ctDNA) as part of the STING program (NCT04932525) at Gustave Roussy. A tumor suppressor gene alterations (TSalt) signature was defined by ≥ 2 alterations among *TP53, PTEN* and/or *RB1*. Univariate logistic and linear regression models were used along with area under the curve (AUC) to assess associations between genomic and mismatch as well as PET-derived parameter. Progression-free survival (PFS, PCWG3 criteria) and overall survival (OS) were analyzed using univariate Cox models. **Results:** Among the 110 pts with available ctDNA and dual-tracer imaging, 18 (16.4%) exhibited mismatch. TSalt+ tumors were identified in 24 pts (21.8%) and were enriched in the mismatch group (50.0 vs 16.3%, p = 0.004) and in case of liver metastases (33.3% vs 10.5%, p = 0.011). TSalt was associated with mismatch (p = 0.003, AUC = 0.625). TSalt predicted higher total lesion glycolysis (TLG; $p < 0.001$, AUC = 0.720), increased ratio TLG/total lesion activity (TLA; p = 0.008, AUC = 0.657), larger FDG+ tumor volume (p = 0.008, AUC = 0.720), and lower PSMA+ tumor volume ($p < 0.001$, AUC = 0.725). TSalt+ pts had significantly shorter OS compared with TSalt- pts (median 5.7 vs 16.5 months; HR 3.31, 95% CI [1.93–5.69], $p < 0.001$). Similarly, pts with mismatch had inferior OS (median 4.7 vs 16.3 months; HR 3.17, 95% CI [1.69–5.95], $p < 0.001$). Among the 79 pts treated with 177Lu-PSMA, TSalt+ status (n = 14, 17.7%) was associated with shorter median PFS (3.5 vs 5.1 months; HR 2.37, 95% CI [1.29–4.34], p = 0.004) and OS (5.5 vs 15.3 months; HR 4.19, 95% CI [2.17–8.10], $p < 0.001$). Patients with mismatch (n = 3, 3.8%) also experienced inferior outcomes, with shorter PFS (2.5 vs 4.9 months; HR 3.80, 95% CI [1.14–12.7], p = 0.02) and OS (5.6 vs 15.1 months; HR 4.97, 95% CI [1.48–16.7], p = 0.004). **Conclusions:** The TSalt genomic signature was associated with FDG/PSMA PET mismatch, adverse metabolic imaging features, and poorer survival in patients with mCRPC, including those treated with 177Lu-PSMA. These findings suggest that ctDNA genomic profiling may help identify molecular imaging mismatch, associated with biologically aggressive disease, such as lineage plasticity phenotypes. Prospective studies are warranted to validate its clinical utility. Research Sponsor: None.

5068 Poster Session

Predicting response to ^{177}Lu-PSMA-617 in metastatic prostate cancer (mPC) using plasma-derived extracellular vesicles (EVs). First Author: Albert Jang, Division of Medical Oncology, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: ^{177}Lu-PSMA-617 (LuPSMA) is a groundbreaking therapy for mPC, but biomarkers are urgently needed to improve patient selection. Plasma-derived EVs are emerging blood-based markers of tumor burden. Here, we analyzed levels of EVs of 123 patients (pts) from 4 cohorts: a pre- and during LuPSMA treatment for a contemporary prospective Mayo Clinic cohort, pre-treatment plasma levels of EVs for a historical Tulane cohort, localized prostate cancer (LPC) after radical prostatectomy (RP), and male healthy donors (HD). **Methods:** Blood samples were collected from 51 pts pre-cycles (pre-C) 1-3 of LuPSMA at Mayo Clinic from 12/2024-12/2025 and 26 pts pre-C1 at Tulane Cancer Center between 12/2018-1/2025. Small and large EVs were incubated with fluorescently conjugated antibodies (PSMA, STEAP1, CEACAM5, and TROP2) and enumerated using nanoscale flow cytometry. EVs from blood samples of 10 HD and 36 LPC post-RP from 6/2020-8/2024 at Mayo Clinic as controls. AUC-ROC and logistic regression analyses were performed to identify marker signatures associated with PSA50 response. **Results:** Baseline demographics are shown in the table. Median levels of PSMA, STEAP1, CEACAM5, and TROP2 EV/milliliter (mL) were all significantly higher for pts with mPC (pooled Tulane and Mayo cohorts) compared to LPC post-RP ($p<0.001$) and HD ($p<0.001$). In the Mayo cohort, 10 of 51 pts (20%) had undetectable PSA pre-C1. There were no significant differences in median pre-C1 plasma EV levels for these 4 different types of EVs comparing pts with undetectable vs detectable PSA. For 41 Mayo pts with detectable PSA pre-C1, 20 achieved PSA50 response at time of data cutoff (49%), while 7 pts (17%) had persistent PSA rise on LuPSMA. For pts who achieved PSA50, there was a significant decline in both CEACAM5 and TROP2 EVs/mL pre-C1 compared to pre-C3 (19 x 10^6 vs 5.8 x 10^6, p=0.003 and 16 x 10^6 vs 5.5 x 10^6, $p<0.001$, respectively), while no significant changes occurred for the 7 pts with no PSA response. A composite score of pre-C1 CEACAM5 and TROP2 EVs (large- and small-sized EVs) demonstrated the strongest association with PSA50 response (OR=2.96, 95% CI: 1.27-6.44, p=0.038), achieving AUC of 0.73. PSMA and STEAP1 EVs did not show any significant changes from pre-C1 to pre-C3. **Conclusions:** Plasma-derived EVs are a promising biomarker to identify patients who will benefit from LuPSMA. Longer follow-up and enrolling a larger cohort are underway. Clinical trial information: NCT06200103. Research Sponsor: Mayo Clinic Comprehensive Cancer Center Vranos Family Career Development Award.

Final results of Alliance A031902: A phase III trial of enzalutamide plus rucaparib as first-line therapy in metastatic castration-resistant prostate cancer (CASPAR). First Author: Charles J. Ryan, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Inhibition of androgen receptor (AR)-signaling results in increases in double-strand DNA breaks and genomic instability. PARP inhibitors (PARPi) are a standard treatment option for patients (pts) with homologous recombination repair mutations (HRRm). Combinations of PARPi and AR pathway inhibitors (ARPI) are associated with synthetic lethality in multiple pre-clinical studies. Clinical trials have suggested potential benefits with co-targeting PARPi and ARPI in pts with and without HRRm. **Methods:** Alliance A031902 compared radiographic progression-free survival (rPFS) and overall survival (OS) as co-primary endpoints with enzalutamide and rucaparib (Enz/Ruca) versus enzalutamide plus placebo (Enz/Plac) for pts with metastatic castration resistant prostate cancer (mCRPC) regardless of BRCA/HRRm status. This trial was conducted by the Alliance for Clinical Trials in Oncology in 36 centers in the US. Target sample size was 1,002 patients. Eligibility required mCRPC with or without measurable metastatic disease and was agnostic regarding HRRm status. The trial was discontinued in 10/2023 due to changes in the treatment landscape for this pt population. **Results:** Between 10/21 and 4/23, 61 pts were randomized to Enz/Ruca (n=30) or Enz/Plac (n=31). Known BRCA1/2 or PALB2 mutations were present in 1 pt (3.3%) in the Enz/Ruca arm and 1 pt (3.2%) in the Enz/Plac arm; wildtype in 14 (46.7%) vs 15 (48.4%), and unknown in 15 (50%) vs 15 (48.4%), respectively. Three patients (11.5%) in the Enz/Ruca arm discontinued due to an adverse event (AE) vs 0 in the Enz/Plac arm. Among response-evaluable pts, 7/26 (27%) in the Enz/Ruca arm discontinued due to disease progression vs 10/31 (33%) in the Enz/Plac arm. Most common grade 3+ AEs were anemia (33% vs 3%) and hypertension (17% vs 10%) in the Enz/Ruca arm and Enz/Plac arm, respectively. All 61 pts were evaluable for response assessment. PSA declines ≥50% and ≥90% were observed in 79% vs 45% and 60% vs 43% of pts receiving Enz/Ruca versus Enz/Plac, respectively. Median PFS in the Enz/Ruca vs Enz/Plac arms was 17.1 vs 14.2 mos, respectively (HR 1.13 [95% CI: 0.42-3.01], p=0.81), median rPFS (inclusive of unequivocal clinical progression) was 17.1 vs 11.7 mos (HR 0.72; 95% CI: 0.31-1.67, p = 0.44), and median OS was not reached vs 27.0 mos (HR 0.65; 95% CI: 0.29-1.45, p=0.29). **Conclusions:** In this prematurely terminated phase III study, Enz/Ruca was generally well tolerated, with the safety profile consistent with prior PARPi/ARPI combinations. Efficacy outcomes for rPFS and OS are inconclusive due to limited sample size. Definitive conclusions regarding the clinical benefit of this combination cannot be determined from this study. Clinical trial information: NCT04455750. Research Sponsor: Alliance for Clinical Trials In Oncology.

Initial results of a phase 1 dose exploration and expansion study of xaluritamig plus abiraterone acetate (AA) in patients (pts) with mCRPC. First Author: Christopher Joseph Sumey, Sanford Cancer Center, Sioux Falls, SD

Background: Xaluritamig (xalu) is a STEAP1 x CD3 T-cell engager, that has shown potent, durable monotherapy activity in pts with mCRPC progressing on taxane chemotherapy. This activity may be further enhanced when given in combination with an androgen receptor pathway inhibitor (ARPI) prior to chemotherapy or radioligand therapy. We therefore evaluated xalu + AA in chemotherapy-naïve pts with mCRPC as a potential chemo-sparing strategy. Here, we report initial safety and efficacy findings. **Methods:** This open-label, multicenter phase (ph) 1 dose exploration and expansion study (NCT04221542) enrolled pts who were taxane-naïve in mCRPC and had received ≤ 2 prior ARPIs (no prior AA permitted). In dose exploration, xalu was administered at a target dose of 0.3, 0.75 or 1.5 mg weekly (QW) via 1-, 2- or 3-step up regimen with 1000 mg AA and predniso(lo)ne daily. Expansion cohort was 3-step up dosing to target dose of 1.5 mg QW then 1.5 mg Q2W. Primary endpoints were safety and tolerability; secondary endpoints were pharmacokinetics and antitumor activity. **Results:** As of data cutoff (15 Oct 2025), 39 pts were enrolled with a median age of 68 years (range: 43–81). Patients received a median of 2 prior therapies, including 56% with prior taxane for mHSPC. Most common treatment-emergent adverse events (all grade [G]/ ≥G3) were myalgia (92.3%/41%), cytokine release syndrome (CRS; 64.1%/7.7%), and anemia (46.2%/12.8%); there were 2 G4 (decrease in lymphocyte count and blood calcium) and no G5 treatment-related AEs reported. Dose-limiting toxicities (n=4) were reported across all dose levels (soft tissue swelling and CRS, 0.3 mg; myalgia n=2, 0.75 and 1.5 mg). Escalation completed at the planned 1.5 mg QW target dose and 1.5 mg Q2W was selected for dose expansion to align with RP3D monotherapy regimen. In the expansion cohort (n=20), confirmed PSA50, PSA90, and objective response rates (RECIST v1.1) were 58%, 47%, and 43%, respectively (Table). Median PSA response duration and radiographic progression free survival were 6.7 (95% CI: 3.8–not estimable [NE]) and 10.5 (95% CI: 8.1–NE) months, respectively. Median OS was not yet reached with 12 months median follow up (95% CI: 11.8–12.3). Seven pts across escalation and expansion remained on treatment. **Conclusions:** Xalu + AA demonstrated manageable safety and promising antitumor activity in taxane- naive mCRPC and is now being evaluated in the randomized ph3 XALience study (NCT07213674). Clinical trial information: NCT04221542. Research Sponsor: Amgen Inc.

Real-world use of olaparib in US veterans with metastatic castration-resistant prostate cancer: Treatment patterns and outcomes. First Author: Christelle McFarland, Section of Urology, Durham VA Health Care System, Durham, NC

Background: Olaparib, a targeted therapy for metastatic castration-resistant prostate cancer (mCRPC), has demonstrated clinical benefits in patients with homologous recombination repair (HRR) gene alterations, as shown in the PROfound trial. As the largest integrated healthcare system in the US, the Veteran's Health Administration (VHA) offers insights into olaparib use among a diverse population. We characterized the treatment patterns and outcomes of patients with mCRPC treated with olaparib. **Methods:** We identified all VHA patients with mCRPC who received olaparib between May 2020 and December 2023. We then performed a retrospective chart review of data from May 2018 to June 2025 to capture pre- and post-treatment data. Demographics, baseline characteristics, biomarker testing and treatment sequencing were summarized. We analyzed time to event outcomes: time to next therapy (TTNT), and overall survival (OS) via Kaplan-Meier methods, both starting from olaparib initiation. **Results:** We identified 477 mCRPC patients receiving olaparib. Median age at initiation was 75, older than subjects in PROfound (median age 69). Most patients were non-Hispanic White (69%), followed by Black/African American (20%) and Hispanic/Latino (6%). Between 2020 and 2023, olaparib was most commonly initiated in ≥5th line after prostate cancer diagnosis (46%), followed by 4th (25%), 3rd (22%), and 2nd line (6.5%). All patients had received an androgen receptor pathway inhibitor prior to olaparib. Median time from HRR testing to olaparib initiation was 5 months. Median TTNT was 7 months; OS was 12 months. Use of olaparib in an earlier line post first NHA was associated with numerically longer OS (17 months for 1st line vs. 8 months for 4th or later). **Conclusions:** Within the VHA, olaparib showed favorable outcomes despite older age and late-line use, supporting effectiveness in routine practice and in a more diverse population with substantially higher representation of Black/African American and Hispanic/Latino individuals than in clinical trials. Understanding these treatment patterns provides insight into clinical practice and helps guide towards optimal integration of olaparib into management of mCRPC. Research Sponsor: AstraZeneca; Merck.

Sequencing of PARP inhibitors and taxane chemotherapy in HRR-altered metastatic castration-resistant prostate cancer: A real-world VA analysis. First Author: June K. Corrigan, VA Boston Healthcare System, Boston, MA

Background: Taxane-based chemotherapy (taxane) and poly(ADP-ribose) polymerase inhibitors (PARPi) are established life-prolonging therapies for patients with homologous recombination repair (HRR)–altered metastatic castration-resistant prostate cancer (mCRPC), particularly tumors with BRCA1/2 alterations. However, data informing the optimal sequencing of PARPi and taxane chemotherapy in this patient population is limited, especially because subsequent treatments may not be captured in reports of clinical trials. Real-world evidence may help describe treatment sequencing patterns and outcomes. **Methods:** We conducted a retrospective cohort study using the nationwide Veterans Affairs (VA) healthcare system. Patients with mCRPC and HRR alterations treated with either PARPi or taxanes for mCRPC were included. HRR mutation status was ascertained from genomic results captured within the VA database and included different platform/assays. Baseline characteristics were assessed at mCRPC treatment initiation. The primary endpoint was overall survival (OS) from the initiation of PARPi or taxane. Secondary analyses included OS comparisons by initial treatment class and OS from initiation of second-line therapy among patients who received both PARPi and taxane chemotherapy. Survival was estimated using Kaplan–Meier methods and compared using Cox proportional hazards models with inverse probability of treatment weighting (IPTW) to adjust for baseline differences. **Results:** Between Jan 2014 - May 2025, a total of 418 patients (26.8% non-Hispanic Black, median age 74.5 years), with HRR-altered mCRPC (31.3% BRCA2, 26.8% ATM, 21.1% CDK12, 13.4% CHEK2) were included in the final analysis. Metastatic involvement included bone metastases in 80.9% of patients, and visceral metastases in 11.2%. Median PSA was 30.2 ng/mL. Prior to mCRPC, 58.6% of patients had received ARPIs and 14.1% had received taxane chemotherapy. With a median follow-up of 14.1 months, patients received PARPi (N=211) or taxane (N=207), and 30.1% received both treatments for mCRPC. OS was similar between patients initially treated with PARPi versus taxane for mCRPC (HR 1.09, 95% CI 0.84-1.41). Among patients who received both therapies, OS did not differ based on treatment sequence (PARPi→taxane vs taxane→PARPi; HR 0.90, 95% CI 0.41-1.85). **Conclusions:** In this real-world VA cohort of HRR-altered mCRPC, overall survival was similar whether PARP inhibitors or taxanes were used as initial therapy and did not differ by subsequent treatment sequence. Treatment crossover was observed in routine clinical practice. Research Sponsor: VA Office of Research and Development.

Dissecting metastatic castration-resistant prostate cancer using regulatory network analysis of tumor transcriptomes. First Author: Aaron Timothy Griffin, Department of Internal Medicine, NYU Langone Medical Center, New York, NY

Background: Metastatic castration-resistant prostate cancer (mCRPC) is characterized by profound clinical and biological heterogeneity, including variable dependence on androgen receptor signaling, frequent genomic instability, lineage plasticity, and highly divergent clinical outcomes. Despite the widespread use of genomic profiling and expression-based signatures, robust patient-level risk stratification and biologically grounded disease subtyping remain limited. We hypothesized that inference of transcriptional regulatory programs underlying tumor state, integrated with genomic and clinical features, would improve prognostication in mCRPC. **Methods:** We analyzed genomic, transcriptomic, and clinical data from mCRPC tumors in the Stand Up To Cancer (SU2C) cohort. A transcriptional regulatory network was reverse-engineered using the latest version of the Algorithm for the Reconstruction of Accurate Cellular Networks (ARACNe3) and transcriptional regulator activity was inferred using Nonparametric analytical Rank-based Enrichment Analysis (NaRnEA). We constructed a novel prognostic machine learning model using a random survival forest integrating regulatory activity features, canonical genomic alterations, and clinical variables. **Results:** Samples were stratified by RNA-sequencing library preparation method into polyA-purified (training, n=150) and exon-capture (testing, n=100). Our model demonstrated strong and statistically significant performance in both the training cohort (out-of-bag Cox PH $p=4.63\times10^{-8}$, AUROC = 0.7711) and the independent test cohort (Cox PH $p=2.92\times10^{-5}$, AUROC = 0.7413). The most informative features included inferred activities of key transcriptional regulators implicated in proliferation, lineage programs, and neuroendocrine differentiation (E2F1, MYC, SOX2, AR, REST), canonical genomic alterations relevant to mCRPC biology (AR, TP53, RB1, FOXA1, APC, PI3K pathway), and select clinical variables (prior therapy, Gleason score, age, metastatic site). Our model also outperformed several widely used gene expression signatures (AR, NEPC, Cell Cycle Progression, RB1 Loss). Regulatory activity–based analyses also revealed substantially greater biological structure and cluster coherence than gene expression–based analyses in subsequent analyses, highlighting distinct and clinically aggressive regulatory states in this dataset. **Conclusions:** Integrating regulatory network–inferred transcriptional programs with genomic and clinical features enables robust, independently validated prognostication in mCRPC that outperforms widely used expression-based signatures. This approach exposes clinically relevant biological heterogeneity underlying aggressive and treatment-resistant disease states and provides a framework for improved risk stratification in advanced prostate cancer. Clinical outcomes of sequential androgen receptor pathway inhibitors (ARPIs) versus novel therapies in metastatic castration-resistant prostate cancer after progression on second-generation ARPIs: A systematic review and meta-analysis. First Author: Rohan Garje, Miami Cancer Institute, Miami, FL

Background: Most recent pivotal, randomized controlled trials (RCTs) testing novel therapies in ARPI pretreated mCRPC patients have incorporated sequential ARPI as the comparator. Given that sequential ARPI could be an inferior control arm based on CARD data, we conducted a meta-analysis to quantify the treatment effect of novel agents vs sequential ARPI and to evaluate whether sequential ARPI constitutes an appropriate control arm for future trials. **Methods:** A systematic search of PubMed, Europe PMC, and ClinicalTrials.gov up to August 14, 2025, identified 2,904 records. After removal of duplicates and exclusions, 17 RCTs met the inclusion criteria. Eligible studies enrolled patients with mCRPC who had progressed after prior exposure to second-generation ARPIs, comparing a novel agent (chemotherapy, targeted therapy, Immunotherapy and radioligands) with sequential ARPI treatment. Three independent reviewers screened the studies and extracted data in accordance with PRISMA guidelines. The primary endpoints were overall survival (OS) and progression-free survival (PFS), and the hazard ratios (HRs) were pooled using a random-effects model. **Results:** We included a total of 6,725 patients in this meta-analysis, with 3,579 (53.2%) receiving novel agents and 3,146 (46.8%) receiving ARPIs. Analysis revealed the pooled HR for OS was 0.86 (95% CI: 0.76–0.96; $p<0.01$). Substantial heterogeneity was observed (I2= 64.05%). This heterogeneity reflects the inclusion of trials with different novel agents and molecular selection criteria, with some highly selective trials (e.g., PROfound HR 0.58) showing greater benefit than others (e.g., ERA 223 HR 1.22). In addition, the pooled PFS analysis demonstrated a highly significant clinical advantage for novel therapies, resulting in a pooled HR of 0.72 (95% CI: 0.61–0.86; $p<0.01$). This PFS analysis exhibited very high heterogeneity (I2= 84.44%), driven by exceptional outcomes observed in trials targeting specific biomarkers. **Conclusions:** Across RCTs, novel therapies consistently outperform sequential ARPI for both OS and PFS in post-ARPI mCRPC. These pooled effects, and their amplification in biomarker-selected populations, suggest that sequential ARPI is a suboptimal control arm in this setting. Future trials should consider more appropriate, biomarker-driven or guideline-concordant active comparators, enabling fairer tests of clinical benefit and more generalizable results Research Sponsor: None.

Androgen receptor (AR) gene dynamics in ctDNA post-abiraterone/enzalutamide: Longitudinal study in mCRPC with germline results. First Author: Minqi Huang, Tulane University, New Orleans, LA

Background: Approximately 10–15% of men with metastatic prostate cancer harbor germline mutations. Circulating tumor DNA (ctDNA) provides a non-invasive approach to identifying AR mutations as resistance mechanism after abiraterone and enzalutamide initiation. In this study, we report longitudinal ctDNA profiling in patients with metastatic castration-resistant prostate cancer (mCRPC) who had germline testing. **Methods:** A retrospective review was conducted at Tulane Cancer Center to identify mCRPC patients with serial ctDNA after starting abiraterone and/or enzalutamide and germline test results. Germline testing was performed using a multi-gene cancer panel from Invitae, covering 50–86 genes, while somatich alterations in ctDNA were assessed through Guardant360, which included 70–83 genes. Linear mixed-effects models (LMMs) with random intercepts were used to model AR gene allele fraction and AR amplification copy number as continuous outcomes. Fixed effects included serial ctdna timepoints and germline gene pathogenicity, and random effects accounted for repeated measure using patient-specific intercepts. Cox Proportional Model was used to analyze the time from initiation of ARPi to AR amp and/or AR mutation in ctDNA. Analyses were performed using the R version 4.4.2. **Results:** From 2015-2025, 341 mCRPC patients with germline test results received an average of 2.96 ctDNA tests post abiraterone or enzalutamide. In this cohort, 47 patients had germline pathogenic mutations (14%) and 294 patients had germline non-pathogenic mutations (86%). Among those with pathogenic germline findings, there were 29 patients with mutation in homologous recombination repair genes (62%) and 18 patients with mutation in other genes. Overall, 55.7% patient in this cohort developed either AR amplification or AR pathogenic mutation in ctDNA. In linear mixed models, germline pathogenicity and pathogenic HRR mutations were not associated with AR copy number, AR allele frequency, or occurrence of somatic AR alterations. Serial ctDNA timepoints following baseline assessment are associated with a significant increase in AR amplifications copy numbers in ctDNA($p=0.003$). AR amplification copy number increases by 0.12 for each subsequent timepoint from baseline. Only 318 patients were included in survival analysis due to missing ARPi start date. Time to ctDNA AR amplification or mutation after 1st ARPi initiation was shorter in mCRPC patients without pathogenic HRR germline mutations compared to those with pathogenic HRR mutations (median: 38 vs 58 months, $p = 0.049$). **Conclusions:** Later serial timepoints correlated with a significant increase in AR amplifications copy numbers but not correlated with highest AR mutant allele frequency. mCRPC patients without germline HRR mutations will find ctDNA AR amplification or mutation sooner than those with germline HRR mutations. Research Sponsor: None.

Effect of frailty measures on overall survival in prostate cancer: A systematic review and meta-analysis. First Author: Nicole Sequeira, Department of Internal Medicine, University of Connecticut Health Center, Farmington, CT

Background: Prostate cancer at all stages is associated with a favorable prognosis and treatment is generally well tolerated, including in the elderly. Frailty screening tools such as the Geriatric 8 (G8) have been associated with decreased survival across different cancers. However, the effect of frailty on overall survival (OS) in prostate cancer is poorly understood. **Methods:** A comprehensive search of PubMed, Embase, and Scopus was performed through December 2025 for studies evaluating the impact of frailty on OS in patients with prostate cancer. Data were analyzed in two distinct cohorts: patients with metastatic castration-resistant prostate cancer (mCRPC) and those with unspecified prostate cancer (PC) (at any stage). Meta-analysis was performed using a random-effects model to calculate pooled hazard ratios (HR) and 95% confidence intervals (CI). Statistical heterogeneity was assessed using the I^2 statistic and Chi² test. **Results:** Of the twelve studies that met the inclusion criteria, two were excluded due to non-availability of survival statistics for analysis. Four studies could not be included in the meta-analysis as hazard ratios were not reported. A total of 7120 patients across seven studies were included in the meta-analysis. In the mCRPC cohort (n=4 studies), frailty was a significant predictor of mortality, associated with a pooled HR of 2.16 (95% CI: 1.34–3.49; P = 0.002). Moderate-to-high heterogeneity was observed in this group (I^2 = 65%). In the unspecified PC cohort (n=2 studies), the association between frailty and OS did not reach statistical significance, yielding a pooled HR of 1.74 (95% CI: 0.69–4.40; P = 0.24). Heterogeneity for the unspecified PC group was I^2 = 61%. **Conclusions:** Frailty is associated with increased mortality in elderly patients with metastatic castration-resistant prostate cancer. This effect of frailty was not statistically significant when the population was expanded to include early-stage prostate cancer. These results highlight the importance of geriatric screening for prognostic assessment in elderly patients with prostate cancer, especially in those with metastatic castration-resistant disease. Research Sponsor: None.

Transient prostate-specific antigen flare induced by lutetium Lu 177 vipivotide tetraxetan in patients with metastatic castration resistant prostate cancer. First Author: Tiewei Cheng, University of Kansas Medical Center, Westwood, KS

Background: Prostate-specific antigen (PSA) flare, an initial rise in PSA that subsequently falls, is a well-known phenomenon in prostate cancer patients treated with hormone therapy and chemotherapy. However, its incidence, chronology, and clinical significance for treatment outcome of patients undergoing lutetium Lu 177 vipivotide tetraxetan (Lu-177), a newly FDA-approved radiopharmaceutical agent for metastatic castration-resistant prostate cancer (mCRPC), is uncertain. Our retrospective study, included mCRPC patients treated with Lu-177 between June 2022 and March 2025 at University of Kansas Cancer Center, aims to evaluate the association of PSA flare with clinical outcomes in patients with mCRPC undergoing Lu-177. **Methods:** PSA flare was defined as any initial increase in PSA level from baseline before start of 3rd cycle followed by a decrease in PSA level of any degree or a decrease to less than baseline PSA level. The primary endpoint was progression-free survival (PFS). The secondary endpoints were overall survival (OS), PSA50 response, and disease control rate (DCR). The log-rank test was applied to compare PFS and OS between patient group with PSA flare and patient group without PSA flare. **Results:** The data from 158 patients were analyzed. The median age was 73.5 years old (range: 52-100). The median number of Lu-177 cycles received was 4 (range: 1-6). Forty five patients (28.5%) experienced PSA flare. The median time from treatment initiation to onset of PSA flare was 3 weeks (range: 1-9); whereas the median interval between PSA flare and PSA nadir was 14 weeks (range: 2-72). The median increase in PSA from baseline to flare was 39.1% (range: 3.3-1,133%); whereas the median decrease in PSA from flare to nadir was 70.1% (range: 8.4-98.4%). There was no statistically significant difference in PFS and OS between patient group with PSA flare and patient group without (median PFS: 8.2 vs. 5.6 months, p=0.20; median OS: 14.3 vs. 12.5 months, p=0.29). PSA50 response was observed in total of 76 patients (48.1%). In patient group with PSA flare, 48.9% of the patients achieved PSA50 response. Similarly, 48.7% of the patients achieved PSA50 response in patient group without PSA flare. Majority of patients were also assessed for radiographic response (n=139). Between patient group with PSA flare and group without PSA flare, DCR was achieved in 60% and 49.5% of the patients respectively (RR = 1.21, 95% CI: 0.88 to 1.67, p=0.26). **Conclusions:** The PSA flare phenomenon is not rare in mCRPC patients treated with Lu-177. Our study suggests the clinical outcome appears consistent regardless of the PSA flare. Therefore, Lu-177 should not be withdrawn early and prematurely in mCRPC patients who have an initial but isolated PSA rise following the therapy. Further studies are warranted to validate our findings. Research Sponsor: None.

Post-ARPI sequencing in mCRPC: A propensity-matched real-world comparison of ^{177}Lu-PSMA-617 versus docetaxel for early clinical outcomes. First Author: Sooraj Srirangadhamu Gopu, New York Medical College, Landmark Medical Center, Woonsocket, RI

Background: Treatment sequencing in metastatic castration-resistant prostate cancer (mCRPC) after ADT and ARPI exposure varies in practice. While ^{177}Lu-PSMA use is expanding in routine practice, real world head to head comparisons with docetaxel in ARPI-exposed mCRPC are limited, particularly for short-term outcomes and treatment related acute care utilization. **Methods:** Using TriNetX, adults > 18 years of age with metastatic prostate cancer and prior ARPI exposure who initiated ^{177}Lu-PSMA or docetaxel were identified (index = first administration). Cohorts were balanced with 1:1 propensity score matching (PSM) on demographics and baseline comorbidities. Outcomes from day 1–180 post-index included all-cause mortality (primary), hospitalization, acute kidney injury (AKI; ICD-10 N17), and thromboembolic/ischemic events (ICD-10 I21/I26/I63/I82). For each outcome, patients with prior documentation of that outcome were excluded. Outcomes are reported as risks and risk ratios (RR) with 95% confidence intervals. **Results:** Before matching, 563 patients initiated ^{177}Lu-PSMA-617 and 8,749 initiated docetaxel; after 1:1 PSM, 497 patients per cohort were analyzed. At 180 days, all-cause mortality was 7.3% (36/494) with ^{177}Lu-PSMA-617 versus 12.2% (60/491) with docetaxel (RR 0.60, 95% CI 0.40–0.88). Hospitalization occurred in 7.2% (21/290) versus 21.1% (52/247) (RR 0.34, 95% CI 0.21–0.55). In a separate matched renal-safety analysis (480 per cohort), AKI occurred in 2.8% (11/390) versus 9.0% (36/399) (RR 0.31, 95% CI 0.16–0.60). Thromboembolic/ischemic events were 3.8% (15/394) versus 6.4% (26/404) (RR 0.59, 95% CI 0.32–1.10). **Conclusions:** In ARPI-exposed mCRPC, ^{177}Lu-PSMA was associated with lower 180-day mortality risk and substantially fewer hospitalizations than docetaxel, with a lower risk of AKI. These findings highlight a potential short-term effectiveness and acute-care utilization advantage of ^{177}Lu-PSMA in routine practice and support further prospective evaluation. Research Sponsor: None.

Key 180-day outcomes after matching.

Outcome	^{177}Lu-PSMA	Docetaxel	Effect estimate (180 days)
All-cause mortality	36/494 (7.3%)	60/491 (12.2%)	RR 0.596 (0.402-0.884)
Hospitalization	21/290 (7.2%)	52/247 (21.1%)	RR 0.344 (0.213-0.554);
Acute kidney injury (AKI)*	11/390 (2.8%)	36/399 (9.0%)	RR 0.312 (0.163-0.595)
Thromboembolic/ischemic†	15/394 (3.8%)	26/404 (6.4%)	RR 0.592 (0.318-1.100)

*AKI analysis used a separate matched run (480 per cohort).

Real-world characteristics, homologous recombination repair mutation (HRRm) testing, treatment patterns, and outcomes of patients with metastatic castration-sensitive prostate cancer (mCSPC) in the US community oncology setting. First Author: Manojkumar Bupathi, Rocky Mountain Cancer Centers, Littleton, CO

Background: Homologous recombination repair mutation (HRRm) testing is recommended by NCCN guidelines for metastatic castration-sensitive prostate cancer (mCSPC). The real-world CAPTURE study is one of the first to associate HRRm carriers with worse outcomes. However, real-world data to quantify prognostic and predictive value of HRRm in mCSPC are limited and heterogeneous, especially for patients treated within US community oncology settings. **Methods:** This was a retrospective observational cohort study of patients with documentation of HRRm testing who initiated systemic therapy for mCSPC (index) between 1/1/2019-3/31/2024 in The US Oncology Network or non-Network practices. Stratified random samples of 150 patients with HRRm and 150 patients without HRRm were selected for chart abstraction to collect patient characteristics within 60 days prior to index and prostate cancer treatments (androgen deprivation therapy, ADT; androgen receptor pathway inhibitors, ARPi; docetaxel, DOC) through the end of follow-up (3/31/2025). Somatic and/or germline testing results for a 12-gene HRRm panel (ATM, ATR, BRCA1, BRCA2, CDK12, CHEK2, FANCA, MLH1, MRE11A, NBN, PALB2, RAD51C) were recorded from all available records. Descriptive Kaplan-Meier analyses of overall survival (OS) and real-world progression-free survival (rwPFS) were assessed per HRRm, de novo metastatic and high-volume disease (HVD) status. **Results:** Overall, 300 patients were selected with median (IQR) age of 69 (63-77) years and median (IQR) follow-up of 25 (15-36) months. Among patients with available data at baseline, most were Gleason ≥8 (79% of 181) and PSA >4 ng/mL (85% of 274). In the HRRm cohort (N=150), 70 (47%) patients were BRCAm and 80 (53%) patients had non-BRCAm HRRm mutations. De novo mCSPC was identified in 97 (65%) patients with HRRm and 100 (67%) patients without HRRm. HVD was observed in 85 (57%) patients with HRRm and 96 (64%) without HRRm. Frontline (index) systemic therapies for mCSPC in the HRRm/non-HRRm subgroups included ADT (28%/22%), ADT+ARPi (39%/47%), ADT+DOC (15%/15%) and ADT+ARPi+DOC (15%/15%). Outcomes are summarized below. **Conclusions:** Patients with HRRm mCSPC experienced numerically shorter OS and rwPFS than non-HRRm patients. This highlights an important need for early HRRm testing and targeted treatment strategies within earlier disease settings. Research Sponsor: None.

Outcome, median (95% CI), months	HRRm (N=150)	No HRRm (N=150)
OS, overall	44.0 (36.8-55.2)	48.5 (40.2-NR)
rwPFS, overall	17.5 (14.4-22.1)	22.6 (17.9-33.4)
N (%), de novo	97 (65)	100 (67)
OS, de novo	41.7 (30.6-44.9)	48.5 (33.4-69.4)
rwPFS, de novo	15.4 (13.0-23.1)	22.0 (17.2-32.3)
N (%), HVD	85 (57)	96 (64)
OS, HVD	44.4 (36.8-55.2)	42.5 (33.4-69.4)
rwPFS, HVD	17.7 (12.0-27.3)	19.2 (16.3-30.3)

Comparative efficacy and safety of systemic therapies in high-risk hormone-sensitive prostate cancer: A network meta-analysis of 13 phase III randomized trials. First Author: Neel Ketankumar Parikh, Zydus Medical College and Hospital, Dahod, India

Background: Treatment intensification improves survival in hormone-sensitive prostate cancer (HSPC). However, direct comparisons between triplet therapies consisting of androgen-deprivation therapy, docetaxel, and an androgen receptor pathway inhibitor (ADT+Docetaxel+ARPI) and ARPI doublets are limited. In addition, available evidence remains fragmented between high-risk non-metastatic (nmHSPC) and metastatic (mHSPC) disease states. We conducted a network meta-analysis (NMA) to rank treatment regimens and inform clinical decision-making. **Methods:** We analyzed 13 phase III RCTs including approximately 13,000 patients with high-risk HSPC, encompassing metastatic and high-risk non-metastatic disease. Treatment strategies included ADT alone, docetaxel (DOC), abiraterone (ABI), enzalutamide (ENZ), apalutamide (APA), darolutamide (DARO), and triplet combinations. A frequentist random-effects NMA was performed with overall survival (OS) as the primary endpoint. Secondary efficacy endpoints included progression-free survival (PFS) and time to castration resistance (TTCR). Safety was assessed using treatment-emergent grade ≥3 AEs, assuming network transitivity. **Results:** For the primary endpoint (OS), triplet therapies ranked highest, including ADT+DOC+DARO (HR 0.55 [95% CI 0.43–0.69]) and ADT+DOC+ABI (HR 0.60 [95% CI 0.45–0.81]) compared with ADT alone. ARPI doublets also demonstrated robust OS benefits, including ABI (HR 0.63 [0.58–0.69]), APA (HR 0.67 [0.51–0.89]) and ENZ (HR 0.69 [0.51–0.94]). No statistically significant OS difference was observed between triplets and ARPI doublets, although triplets numerically favored higher efficacy. For PFS (I^2 = 86.5%), triplet therapies remained superior, with ADT+DOC+DARO showing the greatest benefit (HR 0.24 [0.13–0.45]), followed by the ENZ doublet (HR 0.40 [0.27–0.60]). Secondary endpoints (TTCR, PSA-PFS) consistently favored ARPI-based regimens. Regarding safety, triplet therapies significantly increased the odds of Grade ≥3 AEs versus ADT (OR ~2.6–3.7), driven primarily by docetaxel-associated fatigue and ABI-related hypertension. Conversely, APA, ENZ, and DARO doublets demonstrated favorable safety profiles, with no significant increase in overall Grade ≥3 AEs compared with ADT alone (ORs 1.02–1.06). Benefits were consistent across nmHSPC and mHSPC subgroups (p for interaction = 0.66). **Conclusions:** Triplet therapy represents the efficacy standard for fit patients with high-volume mHSPC. However, ARPI doublets offer a compelling alternative with comparable survival benefits and a superior safety profile, making them the preferred choice for high-risk nmHSPC and patients prioritizing tolerability. Clinical selection should stratify based on disease volume and fitness for docetaxel-associated toxicity. Research Sponsor: None.

Independent validation of a model to predict early favorable PSA response (NADIR model) in enzalutamide-treated patients of the ARCHES trial. First Author: Soumyajit Roy, Department of Radiation Oncology, UH Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Our group recently trained and independently validated a multivariable logistic regression model (NADIR model) to predict early favorable PSA response (≤0.2 ng/mL) in metastatic hormone sensitive prostate cancer (mHSPC) patients (pts) within 6 months of treatment initiation with androgen receptor pathway inhibitor (ARPI). In this work, we independently validated the NADIR model in the enzalutamide (enza) treated patients from the ARCHES trial. **Methods:** ARCHES is a phase III randomized controlled trial where patients with mHSPC were randomly assigned to ADT versus ADT plus enzalutamide. The locked model was applied to patients in the enza arm and model discrimination was assessed using area under the receiver operating curve (AUC) with 95% confidence intervals (CI) from 5000 bootstrap iterations. Additional performance metrics included Index of prediction accuracy (IPA) relative to null model, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and positive likelihood ratio (PLR) and negative likelihood ratio (NLR). A Cox proportional hazard model was applied in a 6-month landmark population to determine the hazard of death in middle and lower tertile relative to upper tertile when stratified by tertiles of predicted probability from the NADIR model. **Results:** 1125 patients with non-missing data were included in this independent validation cohort of whom 559 patients were treated with enza. Approximately 64% (n=360) achieved PSA ≤0.2 ng/mL within 6 months of treatment initiation. The AUC was 0.80 [95% CI 0.76-0.83] and IPA was 23%. The sensitivity, specificity, PPV, NPV, PLR, and NLR were 0.82 [0.77-0.86], 0.56 [0.49-0.63], 0.77 [0.72-0.81], 0.63 [0.55-0.70], 1.85 [1.57-2.17], and 0.33 [0.26-0.42], respectively. The early favorable PSA response rates in patients stratified by decreasing order of tertiles of predicted probability of PSA response from the NADIR model were 92% [88-96], 64% [57-71], and 37% [30-45], respectively. Compared to those in the upper tertile, patients in the middle tertile (HR 1.97 [1.33-2.91]) and lower tertile (HR 2.18 [1.48-3.21]) had significantly worse OS. Among patients with <3 months of ADT before ARPI initiation, the AUC was 0.79 [0.75-0.83] with IPA of 22%. **Conclusions:** In this independent validation using the ARCHES trial, the NADIR model showed strong discriminatory performance and effectively stratified enzalutamide-treated patients by early favorable PSA response and overall survival. With prospective validation, this model may provide a useful tool for early prognostication in patients with mHSPC receiving ARPI therapy. Research Sponsor: None.

Comeback from long-course ADT with relugolix (rel) and darolutamide (daro) in hormone-sensitive prostate cancer (PC) (CLEARED). First Author: Atish Dipankar Choudhury, Dana-Farber Cancer Institute, Boston, MA

Background: The oral luteinizing hormone releasing hormone antagonist rel and androgen receptor pathway inhibitor (ARPI) daro are approved for treatment of advanced PC but the combination has not been prospectively investigated, and kinetics of testosterone (T) recovery after 2 years of rel have not been reported. Here we report pharmacokinetics (PK) as well as initial safety and reduction in T and PSA from a phase 2 trial of rel plus daro in high risk localized (HRL), lymph node-positive (N+) or low volume metastatic (LV) PC. **Methods:** Eligible patients (pts) had PSA > 0.02 ng/ml, T ≥ lower limit of normal (LLN) and were planned for 2 years of ADT+ARPI for HRL, N+ or LV PC. Prior ADT±ARPI was permitted if T recovered to ≥ LLN, but pts with high volume metastatic PC, prior PSA rise with castrate T, or on medications with significant predicted drug-drug interactions with rel or daro were excluded. Pts received rel 360 mg ×1 on day 1 (D1) followed by 120 mg QD and daro 600 mg BID starting on D1, and elected for PK sampling at 0h, 2h, 4h, 8h on D1 (cohort 1) or pre-dose on D1, 2, 8 and 29 (cohort 2). Radiation therapy to local and/or metastatic sites was delivered per standard of care. Pts receive up to 26 28-day treatment cycles with PSA/T monitoring every 3 months (mo) until 18 mo after end-of-treatment (EOT). The primary endpoints are rate of T recovery to > LLN by 18 mo after EOT and safety/adverse events (AEs). Secondary endpoints include PK, rate of treatment discontinuation, and pt-reported outcomes. **Results:** 33 pts enrolled: 8 with HRL, 11 with N+ and 14 with LV PC. 21 chose cohort 1 and 12 chose cohort 2. Single dose maximum concentrations (C_{max}) on D1 for rel and daro, and D29 pre-dose trough level (C_{trough}) for rel were similar to historical monotherapy comparators (comp) with geometric mean ratios (GMR) between 0.80-1.25 (Table), while D8 C_{trough} for daro was slightly outside this range. By cycle 7 (C7) D1, 15 pts experienced Grade ≥3 AEs: 12 lymphopenia (3 possibly related to daro), with the remainder not treatment-related. 0 pts discontinued rel or daro; 3 dose-reduced daro. 33/33 (100%) pts achieved castrate T < 50 ng/dl and 32/33 (97%) achieved profound castrate T < 20 ng/dl (1 with T 24 ng/dl on C7 D1). PSA decline of ≥50% was achieved in 33/33 (100%) and decline ≥90% in 32/33 (97%) by C7 D1. **Conclusions:** The combination of rel and daro was safe and well-tolerated during the 1st 6 treatment cycles, with PK parameters similar to historical monotherapy comparators. Appropriate initial T and PSA reduction were observed, and pts will be followed after EOT for the primary endpoint of T recovery (NCT06463457). Clinical trial information: NCT06463457. Research Sponsor: NCCN; Sumitomo Pharma America; Pfizer; Bayer.

PK for rel and daro.

	Geometric Mean	Coefficient of variation (%)	GMR
rel D1 C_{max} (N=19) [comp]	141.5 ng/ml [125]	145.2% [220%]	1.13
rel D29 C_{trough} (N=11) [comp]	6.34 ng/ml [7.54]	62.6% [91.9%]	0.84
daro D1 C_{max} (N=18) [comp]	2.10 μg/ml [1.77]	29.0% [26.4%]	1.19
daro D8 C_{trough} (N=11) [comp]	2.52 μg/ml [1.82]	24.7% [32.8%]	1.38

Remote activity monitoring to detect physical function decline and unexpected medical events in patients with prostate cancer undergoing androgen deprivation therapy. First Author: Brandon Noorvash, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Among patients with prostate cancer (PC), treatment with androgen deprivation therapy (ADT) is associated with reduced physical function, which can result in diminished quality of life and the occurrence of adverse medical events. The use of wearable activity monitors allows for remote monitoring of daily activity to potentially detect early functional decline and predict significant medical events such as hospitalization, serious adverse events, and premature death. This study evaluated whether wearable activity monitoring could serve as an early indicator of functional decline and impending adverse events in patients with PC undergoing ADT. **Methods:** PC patients receiving ADT at Cedars-Sinai and Durham VA who enrolled in the DigiPRO trial (NCT04575402) wore a Fitbit Charge over 12 weeks to track quantitative physical activity and sleep data for prediction of the occurrence of unexpected medical events (composite of hospitalization, premature death, or fall) and significant patient-reported physical function decline (> 5 NIH PROMIS T score points) within 6-months follow-up. **Results:** 40 patients were included in the analysis (median age 70, range 51-87, 37% Black and 63% White; 10% identified as Hispanic). On average, PC patients walked 5,189 steps/day, were sedentary 16 hours/day, and slept 5.8 hours/night. A clinically meaningful decline in daily steps (> 500 steps) within the first 3 months of initiating ADT was associated with higher odds of experiencing an unexpected medical event (hospitalization, death, fall) (OR = 3.03; 95% CI 1.6-5.9, *p = 0.001*) and clinically meaningful decline in patient-reported physical function (> 5 PROMIS T score points) occurring within 6 months from study completion (OR = 5.2, 95% CI; 1.3-11.7, *p = 0.02*). **Conclusions:** These findings suggest remote activity monitoring may serve as a novel early warning system to identify patients who are at increased risk of unexpected medical events and clinically meaningful physical function decline in PC patients undergoing ADT. Use of this early warning system could lead to targeted interventions in high-risk patients to reduce morbidity and perhaps even prolong survival in patients undergoing ADT. Clinical trial information: NCT04575402. Research Sponsor: U.S. Department of Defense.

Cognition of apalutamide + ADT treatment responders versus non-responders. First Author: Arun Azad, Peter MacCallum Cancer Center, Melbourne, Australia

Background: LIBERTAS (NCT05884398) evaluates intermittent androgen deprivation therapy (ADT) with apalutamide monotherapy in metastatic castration-sensitive prostate cancer (mCSPC). ADT is known to affect cognitive domains such as visuospatial ability and executive function. However, links between cognition and treatment responses remain unclear. LIBERTAS offers an opportunity to examine this relationship in participants with mCSPC. **Methods:** All 410 participants received apalutamide and continuous ADT during the initial treatment phase, 144 without prior ADT exposure (ADT naive). Participants with PSA <0.2 ng/mL at 6 months were considered responders, otherwise they were non-responders. Cognition was assessed by two tasks from Cambridge Cognition's CANTAB battery: Paired Associates Learning (PAL; visual memory) and Spatial Working Memory (SWM; executive function) at baseline (C1), 2 months (C3), and 4 months (C5). Outcomes included PAL First Attempt Memory Score (PALFAMS28, higher=better), PAL Total Errors Adjusted (PALTEA28, lower=better), and SWM Between Errors (SWMBE468, lower=better). At each visit, group differences were evaluated using the Mann-Whitney U test. Longitudinal change within and between groups were assessed using linear mixed effect models adjusted for age and testosterone. **Results:** At all visits, responders had higher PALFAMS28, lower PALTEA28, and lower SWMBE468 than non-responders in the entire sample (Table 1). In ADT-naïve participants, responders (N=100) had higher PALFAMS28 than non-responders (N=44) at C3 (10.48 ± 4.74 vs. 8.59 ± 5.00, p=0.01). SWMBE468 was lower in ADT-naïve responders than ADT-naïve non-responders at C1 (14.25 ± 9.12 vs. 19.30 ± 8.37, p=0.001) and C5 (15.42 ± 8.58 vs. 19.77 ± 11.06, p=0.01). Among all participants and within the ADT-naïve group, only the responders' performance changed over time: PALFAMS28 increased and PALTEA28 decreased from C1 to C5 and SWMBE468 increased from C1 to C3 (p <0.01). No significant time-by-group interaction emerged. **Conclusions:** Analyzed in retrospect, responders outperformed non-responders in visual memory and executive function at baseline and throughout initial treatment, maintaining a cognitive advantage. Though not tested, we hypothesize early cognitive performance could be considered among a constellation of clinical factors to prognosticate treatment response, support patient stratification and personalize treatment strategies. Clinical trial information: NCT05884398. Research Sponsor: Johnson & Johnson.

Significant differences between responders and non-responders.

Measure	Visit	Responders (N=266): Mean ± SD	Non-Responders (N=144): Mean ± SD	P value
PALFAMS28	C1	9.43 ± 4.53	8.18 ± 4.08	0.005
	C3	9.78 ± 4.65	8.07 ± 4.30	<0.001
	C5	10.16 ± 4.85	8.47 ± 4.80	0.003
PALTEA28	C1	28.52 ± 17.94	32.92 ± 17.83	0.02
	C3	26.74 ± 17.90	31.90 ± 18.83	0.007
	C5	25.74 ± 18.40	31.80 ± 20.00	0.004

Evaluation of concomitant medications in advanced prostate cancer patients receiving apalutamide: TITAN and SPARTAN post-hoc analysis. First Author: Neeraj Agarwal, University of Utah Health Hospitals and Clinics, Salt Lake City, UT

Background: Apalutamide (APA) is an androgen receptor pathway inhibitor (ARPI) approved for use with androgen-deprivation therapy (ADT) in patients with metastatic castration-sensitive prostate cancer and nonmetastatic castration-resistant prostate cancer based on data from the phase 3 TITAN and SPARTAN trials. APA induces cytochrome (CYP) 3A4/2C19 and P-glycoprotein, which may alter the pharmacokinetics of commonly used medications, raising the possibility for adverse events (AEs) or serious adverse events (SAEs) due to drug-drug interactions (DDIs). **Methods:** A post-hoc analysis was conducted to evaluate the incidence of AEs associated with select concomitant medication classes—antihypertensives, antidiabetics, statins, proton pump inhibitors (PPIs), and corticosteroids, among patients treated with APA + ADT or placebo + ADT in the TITAN and SPARTAN trials. The selected drug classes include some of the most frequently prescribed agents with significant CYP 3A4/2C19 activities. This analysis was also done in comparison to non-recipients of concomitant medications. **Results:** See Table. **Conclusions:** In this exploratory post-hoc analysis of >2,200 patients from TITAN and SPARTAN, concomitant use of commonly prescribed medications (antihypertensives, antidiabetics, statins, PPIs, and corticosteroids) was frequent and reflected routine real-world practice. Across medication classes, we observed no clinically meaningful increase in serious or loss-of-efficacy adverse events among apalutamide-treated recipients compared with placebo or with non-recipients of the class. These findings suggest that co-administration of apalutamide with routine concomitant therapies is safe and feasible under standard clinical monitoring. Clinical trial information: NCT02489318 and NCT01946204. Research Sponsor: Johnson & Johnson.

Incidence of side effects for selected classes of concomitant medications by study and treatment actually received.

Medication Class	Treatment	TITAN Recipients (%)	TITAN TEAS (%)	TITAN TE SAEs (%)	SPARTAN Recipients (%)	SPARTAN TEAEs (%)	SPARTAN TE SAEs (%)
Antihypertensives	APA+ADT	41 (34.3)	41.9	1.9 (1.7)	42.8 (41)	49.4	0.9 (0.6)
	(PBO+ADT)		(39.2)			(36.8)	
Antidiabetics	APA+ADT	12.2	34.4	1.6 (1.8)	12.2 (9.3)	42.9 (27)	3.1 (0)
	(PBO+ADT)	(10.8)	(33.3)				
Statins	APA+ADT	23.9	12 (11)	0 (0)	33.9	10.7 (6.3)	0 (0)
	(PBO+ADT)	(15.6)			(31.7)		
PPIs	APA+ADT	17.6	6.5 (1.3)	0 (0)	26 (21.6)	8.6 (9.3)	0 (1.2)
	(PBO+ADT)	(14.6)					
Corticosteroids	APA+ADT	14.9	12.8	1.3 (0)	10.7 (8.3)	18.6	1.2 (0)
	(PBO+ADT)	(11.2)	(18.6)			(15.2)	

Treatment-emergent AEs (TEAEs) and SAEs deemed attributable to the pharmacologic class of the concomitant medication are classified as class-related side effects and included in the analysis. Percentages of TEAEs and SAEs are calculated based on recipients of a given class of concomitant medication.

EMBARK: Testosterone recovery to >250 ng/dL following treatment suspension. First Author: Stephen J. Freedland, Department of Urology, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles; Durham VA Medical Center, Durham, CA

Background: The phase 3 EMBARK trial demonstrated significantly longer metastasis-free survival and overall survival for enzalutamide plus leuprolide (enzalutamide combination) vs leuprolide alone in patients with prostate cancer and high-risk biochemical recurrence (hrBCR). In EMBARK, patients with prostate-specific antigen (PSA) < 0.2 ng/mL at week 36 suspended treatment at week 37. Androgen deprivation-related testosterone suppression has been linked to adverse health outcomes, whereas testosterone recovery while off treatment has been associated with improved quality of life. The objective of this post hoc analysis was to assess testosterone recovery to > 250 ng/dL during treatment suspension in patients treated with enzalutamide combination. **Methods:** Eligible patients had hrBCR, with a PSA doubling time of ≤9 months. Patients were randomized 1:1:1 to enzalutamide + leuprolide, leuprolide alone, or enzalutamide monotherapy. Patients who suspended treatment at week 37 reinitiated treatment upon PSA increase to protocol-defined levels. Testosterone levels were assessed every 12 weeks. **Results:** In the enzalutamide combination group, 320 patients suspended treatment. During treatment suspension, testosterone recovery to > 250 ng/dL occurred in 108 patients (33.8%) (Table). Among those who recovered their testosterone, median and mean time to recovery was 5.6 months and 6.8 months, respectively, although some patients had delayed recovery (Table). **Conclusions:** Testosterone recovery to > 250 ng/dL during treatment suspension was observed in approximately one-third of patients treated with enzalutamide combination. While average time to testosterone recovery among those who recovered was ~6 months, recovery was delayed in some patients. Disclosure: Pfizer's generative AI tool MAIA was used in developing this abstract; the authors reviewed, edited, and take full responsibility for the content. Clinical trial information: NCT02319837. Research Sponsor: The study was sponsored by Pfizer Inc. and Astellas Pharma Inc., the co-developers of enzalutamide. Medical writing support was provided by Kathleen Richter and Rosie Henderson of the Prime Group of Companies (Knutsford, UK), funded by the sponsors.

	Enza combination(N=320)
Patients who reached testosterone recovery, n (%)	108 (33.8)
Time to testosterone recovery >250 ng/dL, months[†]	
Median (range)	5.6 (0.0–22.1)
Mean (SD)	6.8 (2.87)

The data cutoff date was January 31, 2023.
[†]Time to testosterone recovery during treatment suspension is based on the number of patients who reached testosterone recovery, and was defined as the time from the date of the start of treatment suspension to the date of the first occurrence of testosterone >250 ng/dL. The summary is based on testosterone records during treatment suspension from patients who had treatment suspension and non-missing testosterone records after treatment suspension. For patients who reinitiated treatment, testosterone records after reinitiation were not considered.

Genomic and transcriptomic correlates of deep PSA response in patients with metastatic hormone-sensitive prostate cancer (mHSPC). First Author: Emmanuel S. Antonarakis, University of Minnesota-Twin Cities, Masonic Cancer Center, Minneapolis, MN

Background: Despite advances in mHSPC treatment with combination therapies, patient outcomes remain heterogeneous. Achieving an undetectable PSA level is a strong prognostic marker for improved overall survival (OS). Baseline molecular predictors of deep PSA response are lacking. We aimed to identify genomic and transcriptomic determinants associated with undetectable PSA using a large clinical-genomic cohort. **Methods:** The Tempus Lens Platform was used to query the de-identified Tempus multimodal database and analyze a cohort of patients with mHSPC who underwent DNA (Tempus xT) and RNA (Tempus xR) clinical sequencing. Patients were restricted to those with stage IV disease within 90 days of sample collection. Samples collected within 12 months prior to or within 3 months of androgen deprivation therapy (ADT)-based therapy initiation were considered hormone-sensitive (n = 525). Patients were classified as PSA-low (< 0.1 ng/mL, n = 285) or PSA-high (≥0.1 ng/mL, n = 240) based on the PSA level at 6 months (±45 days) post-treatment initiation. Genomic alterations, gene expression, and transcriptomic signatures were compared between PSA groups. Real-world OS was defined as the time from ADT start to death or loss to follow-up. Hazard ratios (HR) were estimated using Cox regression and adjusted for age. Significance was calculated using a Wald test at $p < 0.05$. **Results:** Median age at diagnosis was 67.5 years; 69.7% were White and 18.5% were Black/African American. The majority (91%) had de novo metastatic disease. First-line treatments included ADT+androgen receptor pathway inhibitor (ARPI) (65% vs 64%), ADT alone (15% vs 18%), ADT+ARPI+docetaxel (19% vs 15%), and ADT+docetaxel (1.3% vs. 3.5%) for PSA-low vs PSA-high, respectively. Baseline PSA was lower in patients with PSA-low vs PSA-high status (median 24 vs 36 ng/mL, p = 0.01). Somatic alterations in *SPOP* (17% vs 11%, p = 0.04) and *ZFHX3* (2.5% vs 6%, p = 0.05) differed between patients with PSA-low and PSA-high, respectively. No significant differences in expression of actionable novel targets including PSMA, TROP2, B7-H3, or STEAP1 were observed between cohorts. Median OS was not reached for patients with PSA-low and was 47 months for patients with PSA-high, with 36-month landmark OS of 83% vs 66%, respectively. On multivariable analysis, PSA-low was independently associated with improved OS (HR 0.51, 95% CI 0.31-0.85, p = 0.01). **Conclusions:** In a real-world cohort, deep PSA response at 6 months portends significantly improved OS in patients with mHSPC and is associated with more *SPOP* and fewer *ZFHX3* alterations. No transcriptomic differences in emerging therapeutic targets were identified. Validation in independent cohorts is warranted. Research Sponsor: None.

5090 Poster Session

Rezvilutamide (Rez) versus bicalutamide (Bic) plus androgen-deprivation therapy (ADT) in high-volume, metastatic, hormone-sensitive prostate cancer (mHSPC): 5-year outcomes of the phase 3 CHART trial. First Author: Dingwei Ye, Fudan University Shanghai Cancer Center, Shanghai, China

Background: In the CHART trial, Rez plus ADT significantly improved radiographic progression-free survival (rPFS) and overall survival (OS) compared with Bic plus ADT in patients (pts) with high-volume mHSPC (Gu et al., Lancet Oncol 2022). Here, we present updated outcomes ~5 years after the enrollment of the last pt. **Methods:** Pts with high-volume mHSPC and without previous chemotherapy or other localized treatment for PC were eligible to be enrolled. Pts were randomized 1:1 to receive ADT plus either Rez (240 mg) or Bic (50 mg) orally once daily. Final analysis for OS was planned after 325 deaths were reported. **Results:** Between Jun 28, 2018, and Aug 6, 2020, 654 pts were randomized to receive Rez plus ADT (n=326) or Bic plus ADT (n=328). As of data cutoff (Jun 6, 2025), with a median follow-up of 72.8 months (IQR 69.1-77.4), there were 141 (43.3%) deaths in Rez plus ADT group and 194 (59.1%) in Bic plus ADT group. OS was improved with Rez plus ADT versus Bic plus ADT (median 78.8 months [95% CI 68.3-not reached (NR)] vs 44.8 months [95% CI 37.1-57.4]; HR 0.59 [95% CI 0.47-0.73]; 2-sided $p<0.0001$). Risk of progression or death in Rez plus ADT group was reduced by 62% compared with Bic plus ADT group (HR 0.38 [95% CI 0.30-0.48]). Other efficacy outcomes also favored Rez plus ADT (Table). Rez plus ADT improved patient-reported quality of life. No new safety signals were observed. **Conclusions:** Rez plus ADT continued to show meaningful survival benefits with manageable toxicities after long-term follow-up, further supporting Rez plus ADT as frontline treatment for pts with high-volume mHSPC. Clinical trial information: NCT03520478. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Does a statin a day keep prostate cancer (PC) away?: Statin use and disease progression in patients receiving androgen deprivation therapy (ADT) after radical prostatectomy (RP) in SEARCH. First Author: Maria P. Mogollon, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Prior studies suggest statin use may improve PC outcomes, including PC specific mortality (PCSM) and disease progression in patients receiving ADT. However, prior studies compared patients taking vs not taking statins at the time of ADT, ignoring that many statin non-users initiate statins later on. We evaluated the association between statin use and PC outcomes using both baseline (yes/no) and time-dependent exposure definitions in patients initiating ADT after RP. **Methods:** We conducted a retrospective cohort study of 9,931 patients with PC treated with RP between 1988 and 2020 at 9 VA hospitals from SEARCH Database. Patients who received ADT for biochemical recurrence after 2000 were included. Those with known metastasis prior to ADT or missing covariates of interest were excluded. Characteristics at ADT were stratified by statin use at time of ADT and compared with rank-sum for continuous variables and chi-square for categorical. Univariable and multivariable Cox models tested associations between statin use at ADT and time to metastasis, castration-resistant PC (CRPC), PCSM and all-cause mortality (ACM), adjusted for clinicopathological variables. As ~50% of non-statin users initiated statins after ADT, additional models treated statin use as time-dependent covariate. **Results:** Among 1,274 patients treated with ADT, 784 (62%) used statins at time of ADT. Users were older (median 67 vs 65), initiated ADT in more recent years (median 2013 vs 2010), had longer time from RP to ADT (median 39 vs 21 months), and had higher obesity rates (38% vs 25%). PC characteristics were similar between groups, except users had lower rates of positive nodes (11% vs 17%) and seminal vesicle invasion (28% vs 33%). Statin use at ADT was not significantly associated with time to metastasis, CRPC, PCSM or ACM, though HRs indicated lower risk for statin users (all HRs 0.89-0.98, all $p>0.2$; see table). On time-dependent multivariable analysis, statin use was significantly associated with lower risk of CRPC (p=0.019), PCSM (p=0.020) and ACM ($p<0.001$). Similar results were seen for metastases, though this did not reach significance (p=0.058) (see table). **Conclusions:** Statin use at ADT was not associated with PC outcomes after RP. However, accounting for statin initiation during ADT, statin use was associated with notably lower rates of CRPC, PCSM and ACM, with a trend towards reduced metastasis. These findings support the potential role of statins in slowing PC progression and highlight the need for prospective randomized trials of statins in patients initiating ADT. Research Sponsor: None.

Efficacy and safety of enzalutamide (ENZA) in patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC) and cardiometabolic comorbidities (CMDs) and/or related concomitant medications (meds): ARCHES post hoc. First Author: Arnulf Stenzl, Department of Urology, University of Tübingen, Tübingen, Germany

Background: In ARCHES, ENZA improved radiographic progression-free survival (rPFS; primary: data cutoff, Oct 14, 2018) and overall survival (OS; prespecified secondary: data cutoff, May 28, 2021; 5-yr follow-up; data cutoff: Jul 31, 2024) vs placebo (PBO) in mHSPC. Our objective was to evaluate efficacy/safety of ENZA in pts with CMDs on related concomitant meds. **Methods:** We examined two groups: 1) full CMD (fCMD): pts with CMDs or on concomitant CMD meds; 2) confirmed CMD (cCMD): pts on CMD-related meds + confirmed CMD diagnosis, validated by medical history captured in concomitant med domain. CMDs included hypertension, cardiac disorders, dyslipidemia, diabetes mellitus. Related concomitant meds were diabetes meds, vasoprotectives, cardiac meds, lipid-modifying agents, antithrombotics, antihypertensives. Primary endpoint: rPFS (fCMD population; data cutoff: Oct 14, 2018). Other endpoints: OS, safety (fCMD population; data cutoff: May 28, 2021). Kaplan–Meier used for time-to-event analysis, with treatment (tx)-group comparisons assessed by stratified log-rank test and hazard ratios (HRs) relative to PBO using Cox proportional hazard models. Sensitivity analysis with cCMD population evaluated rPFS and OS, with OS adjusted for crossover with rank-preserved structure failure time model. **Results:** Of 1150 pts, 938 (82%) were categorized as fCMD and 756 (66%) as cCMD. In the fCMD group, ENZA showed an association with improved rPFS and OS, with similar results for all sensitivity analyses (Table). Similar results also seen in all concomitant med subgroups. At 2021 data cutoff, median tx duration was 41 mo in the ENZA arm, 14 mo in the PBO arm. Tx-emergent adverse event (TEAE) rates (per 100 pt-yr) were similar with ENZA (313.8) and PBO (468.0). TEAEs of special interest rates (per 100 pt-yr) with ENZA vs PBO: fatigue (14.4 vs 18.0); falls (6.2 vs 2.6); fractures (7.3 vs 5.4); select cardiovascular events (2.5 vs 1.6); convulsions (0.2 vs 0.5). No new safety signals were identified. **Conclusions:** Similar to the overall mHSPC study population, ENZA was efficacious and tolerable in pts with CMD. Optimizing CMD may further enhance outcomes for pts with mHSPC, but ENZA remains a front-line option for all mHSPC pt subgroups. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma Inc.; Pfizer Inc.

Predictors of treatment (tx) duration in patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC) treated with enzalutamide (ENZA): A post hoc analysis of ARCHES. First Author: Andrew J. Armstrong, Center for Prostate & Urologic Cancers, Duke Cancer Institute, Durham, NC

Background: In ARCHES (NCT02677896), ENZA + androgen-deprivation therapy (ADT) significantly improved radiographic progression-free survival (primary: data cutoff, Oct 14, 2018) and overall survival (prespecified secondary: data cutoff, May 28, 2021; 5-year follow-up: data cutoff, Jul 31, 2024) vs placebo + ADT in mHSPC. This post hoc analysis explored factors associated with different ENZA tx durations (5-year follow-up). **Methods:** Reasons for tx discontinuation (DC) including toxicity and progression, and baseline and on-treatment factors underlying tx persistence, were compared descriptively among pts with short (0–2 years [y]; STx), medium (2–5 y; MTx), and long Tx duration (> 5 y; LTx) (STx pts represent non-responders; MTx/LTx pts represent tx responders). **Results:** Of 572 ENZA-treated pts, 204 (36%) were STx; 140 (24%) MTx; 228 (40%) LTx. STx pts were more likely to be older vs MTx and LTx, with high-volume disease (HVD) and Eastern Cooperative Oncology Group performance status (ECOG PS) 1, although 55.3% of LTx had HVD and 73.2% had synchronous metastases. Progressive disease and tx-emergent adverse events (TEAEs) were the most common reasons for tx DC. Drug-related TEAEs (per 100 pt-y) were more common in STx (156.0) vs MTx (89.5) and LTx (47.1), as were those leading to tx DC (STx: 12.4; MTx: 1.5; LTx: 0.1). Rates (per 100 pt-y) of TEAEs leading to ENZA dose reduction were higher in STx (6.2) vs MTx (5.8) and LTx (2.0). The rate (per 100 pt-y) of drug-related TEAEs of special interest were generally higher in STx vs MTx and LTx: convulsions (1.0 vs 0.0 vs 0.0); fatigue (19.0 vs 10.7 vs 4.8), select cardiovascular events (1.0 vs 0.6 vs 0.1); falls (2.4 vs 3.2 vs 1.1); fractures (0.5 vs 1.5 vs 0.5). **Conclusions:** Our findings demonstrate that LTx and MTx tended to have more favorable pt and disease characteristics vs STx, although majority of LTx had adverse prognostic features. While progressive disease was the most common reason for DC, AEs/withdrawals were the second most common. Most TEAEs of special interest were more frequent in STx. Reasons for AE-related tx changes are multifactorial, and optimal management of AEs and comorbidities, as well as dose modifications, can optimize ENZA tx. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma Inc.; Pfizer Inc.

Outcomes with androgen-deprivation therapy (ADT) plus androgen receptor pathway inhibitors (ARPIs) in veterans with de novo metastatic castration-sensitive prostate cancer (mCSPC) who were elderly, frail, or had high comorbidity: A subgroup analysis of enzalutamide and high-volume disease. First Author: Martin W. Schoen, Medicine Service, Veterans Affairs St. Louis Healthcare System, St. Louis, MO

Background: Clinical trials show significant overall survival (OS) benefits of combining ADT with ARPIs (abiraterone, apalutamide, darolutamide, or enzalutamide [ENZA]) vs ADT in mCSPC. The effects of ADT + ARPI in patients (pts) who are elderly, frail, or have high comorbidity burden remain unclear due to underrepresentation in clinical trials. This observational cohort study examined OS in two subgroups of this population: pts who received ENZA and those with high-volume disease (HVD). **Methods:** Veterans Health Administration records were used to assess OS in pts with de novo mCSPC treated with ADT + ARPI ± nonsteroidal antiandrogen (NSAA; ADT + ARPI group) or ADT ± NSAA (ADT group). Pts were aged ≥75 years (y) or had Veterans Affairs Frailty Index (VA-FI) > 0.2 or Charlson Comorbidity Index (CCI) ≥3. Subgroups comprised pts who: 1) initiated ADT + ENZA (HVD or low-volume disease); or 2) had HVD with any ARPI. Pts were indexed on first ADT date (Jun 1, 2017–Dec 31, 2022) and followed until censoring (Jun 1, 2025) or death. Mortality risk was estimated using a multivariable, time-varying Cox model to account for time between ADT + ARPI initiation adjusted for volume of disease, age, body mass index, CCI, and prostate-specific antigen level. **Results:** Of 1,629 pts, 272 (16.7%) received ADT + ENZA and 1,357 (83.3%) received ADT; median follow-up was 34.1 and 23.4 months (mo), respectively. Compared with ADT, the ADT + ENZA subgroup was younger (median age 77.5 vs 81.2 y, standardized mean difference [SMD]: −0.34) with similar frailty (VA-FI > 0.2: 67.3% vs 71.5%, SMD: 0.09) and more HVD (71.7% vs 61.5%, SMD: 0.22). ADT + ENZA was associated with significantly lower risk of death vs ADT (adjusted hazard ratio [aHR] 0.70; 95% CI: 0.60–0.83; $P<0.001$; Table). Among 1,541 pts with HVD, 706 (45.8%) received ADT + ARPI and 835 (54.2%) received ADT; median follow-up was 29.1 and 18.8 mo, respectively. Pts who received ADT + ARPI were younger (median age 77.1 vs 81.9 y, SMD: −0.44) and had less frailty (VA-FI > 0.2: 66.2% vs 72.9%, SMD: 0.15). ADT + ARPI was associated with significantly lower risk of death vs ADT (aHR: 0.73; 95% CI: 0.65–0.83; $P<0.001$). **Conclusions:** In this real-world cohort analysis of pts with de novo mCSPC who were elderly, frail, or had high comorbidity, ADT + ENZA was associated with prolonged survival compared with ADT. In pts with HVD, ADT + ARPI was associated with longer survival vs ADT. Research Sponsor: Astellas Pharma Inc.; Pfizer Inc.

Classification tree phenotypes for early treatment-limiting toxicity after androgen receptor pathway inhibitor initiation in metastatic hormone-sensitive prostate cancer from the IRONMAN registry. First Author: Alexandra Larkin, Department of Medicine, Section of Hematology/Oncology, The University of Chicago, Chicago, IL

Background: Androgen receptor pathway inhibitors (ARPIs) improve survival in metastatic hormone-sensitive prostate cancer (mHSPC), but early treatment-limiting toxicity remains common. Using the IRONMAN (International Registry for Men with Advanced Prostate Cancer; NCT03151629) registry, we developed an interpretable classification tree that yields simple rule-based 1-year risk strata for a composite adverse outcome (AO) after ARPI initiation. **Methods:** Men with mHSPC initiating first-line ARPI with at least 12 months follow-up or AO within 365 days were included (n=583). AO was the first serious adverse event (SAE) or ARPI discontinuation for toxicity or other non-progression reasons; progression-attributed events were not counted. Candidate peri-ARPI initiation predictors (demographics, labs, treatments/medications, patient-reported outcomes) were screened for missingness, imbalance, and collinearity, reduced by stepwise logistic regression, and entered a recursive-partitioning classification tree with restricted depth and node size. Discrimination was summarized by area under the receiver operating characteristic curve (AUC) and repeated 3-fold cross-validation. Terminal nodes were collapsed into low, intermediate, and high-risk strata by predicted 1-year AO. **Results:** Overall, 122/583 men (20.9%) had AO within 1 year (85 SAEs; 37 discontinuations [28 toxicity, 9 other non-progression]). AO-free survival did not differ by ARPI agent (log-rank p=0.40); ARPIs were pooled. Peri-ARPI docetaxel exposure (triplet therapy) was uncommon (2.4%). The final tree retained nine predictors, including European Organization for Research and Treatment of Cancer global health rating (1-7), hemoglobin, worst pain (0-10), lactate dehydrogenase (LDH), age, docetaxel, and opioid agonist and systemic steroid use. In-sample AUC was 0.76 (95% CI 0.71-0.81); cross-validated AUC was 0.60 (95% CI 0.55-0.65). Collapsed strata showed distinct 1-year AO risk (Table 1). High-risk phenotypes reflected poor health/symptoms with anemia and/or elevated LDH, and a treatment-intensity phenotype with triplet therapy plus opioids and steroids. **Conclusions:** A small classification tree identified three clinically transparent phenotypes of early AO after ARPI initiation in mHSPC and can be applied as simple decision rules to support monitoring and shared decision-making. External validation is needed. Research Sponsor: Movember Foundation; Sanofi; Prostate Cancer Clinical Trials Consortium (PCCTC); Amgen; Astellas; AstraZeneca; Bayer; Janssen; Merck; Novartis.

Tree risk strata and 1-year AO risk.

Risk stratum	n (%)	1-year AO %, (95% CI)
Low	422 (72)	10.7 (7.7–13.6)
Intermediate	80 (14)	26.3 (16.6–35.9)
High	81 (14)	69.1 (59.1–79.2)

Correlation of baseline testosterone (T) level with survival outcomes in patients (Pts) with metastatic hormone-sensitive prostate cancer (mHSPC): Analysis of patient (pt)–level data from SWOG 1216 study. First Author: Georges Gebrael, Huntsman Cancer Institute at The University of Utah, Salt Lake City, UT

Background: Retrospective data suggest that low baseline serum T may be associated with inferior survival outcomes in mHSPC [PMID: 38444678]. Whether this relationship persists in rigorously controlled, randomized clinical trial populations remains unclear. We examined the prognostic impact of baseline T using patient-level data from the phase 3 SWOG 1216 trial which randomized pts with mHSPC in 1:1 to ADT + bicalutamide (standard arm) or ADT + orteronel (experimental arm). **Methods:** Patients treated on SWOG 1216 trial with available baseline T levels were eligible and included in this secondary analysis. Baseline T was summarized by median (IQR) and dichotomized at the median as $\leq$ median vs $>$ median. Overall survival was the primary endpoint; progression-free survival (PFS) and prostate-specific antigen (PSA) response were secondary endpoints. PSA response rates were divided into complete response (CR; PSA $<$0.2 ng/mL), partial response (PR; PSA between 0.2 and 4.0 ng/mL), and no response (NR; PSA $>$4.0 ng/mL) at a 7-month landmark following randomization. OS and PFS were estimated by Kaplan-Meier within each arm, with median survival (95% CI) and number of events reported. Comparisons were performed using the log-rank test. PSA response was summarized as n (%), and groups were compared using Pearson's chi-squared test. All tests were two-sided with alpha = 0.05. **Results:** Of 1279 pts, 218 pts had baseline T levels. Median T level was 312.5 ng/ml (IQR 89.25 - 462 ng/ml). In both experimental and standard arms, there was no significant difference in OS, PFS, or PSA response between patients with baseline T levels above vs below the median (Table). Similarly, in both arm, there was no difference in outcomes based on baseline T levels grouped by quartiles, as well as baseline T levels as a continuous variable (data will be presented at the conference). **Conclusions:** In this patient-level analysis of a phase 3 trial, there was no statistically significant association between baseline T and outcomes in mHSPC. Based on these data, baseline T may not be used for prognostication or treatment selection in patients receiving systemic therapy in mHSPC. Limitations include a small sample size. These hypothesis-generating data require external validation before clinical application. Outcomes of radical radiotherapy in de novo low-burden metastatic hormone-sensitive prostate cancer vs prostate radiotherapy alone. First Author: Kelvin Yan, Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: The current standard of care (SoC) for metastatic hormone-sensitive prostate cancer (mHSPC) is androgen deprivation + systemic therapy. Oligometastatic HSPC, however, represents a unique disease entity following the STAMPEDE trial, where de novo mHSPC patients with a CHAARTED-defined low disease burden (DN-mHSPC-LV) had a hazard ratio of death of 0.68 after prostate radiotherapy (PRT). Despite the SABR-COMET results of a survival benefit with stereotactic RT on metachronous oligometastatic sites of predominantly prostate patients, radical RT (RRT) in the DN-mHSPC-LV setting has not been studied. This study analysed the outcomes of such patients receiving RRT to all disease sites vs PRT alone. **Methods:** DN-mHSPC-LV patients receiving RRT to the prostate and all oligometastatic sites (Arm A) vs PRT alone (Arm B) in a Hong Kong tertiary hospital between 1st January 2012 and 1st January 2023 were reviewed. Outcomes of progression-free survival (PFS), overall survival (OS) and treatment-related toxicity (TrT) were analysed using the Kaplan-Meier and multivariable Cox-proportional hazards models. **Results:** 127 eligible patients (60 in Arm A & 67 in Arm B) were identified. The median numbers of oligometastatic sites of 1-3 and = $>$ 4 were balanced between the two arms. The median Gleason score was 8 in both arms. Median T/N/M staging was mostly balanced but more patients in Arm B had N1 disease. Presenting PSA (ng/mL) was higher in Arm A (38.5) than Arm B (27.9). Arm A received up to 76Gy/38# to the prostate + a boost of up to 67.5Gy or stereotactic RT to the oligometastatic sites. Arm B received 55-60Gy/20# to the prostate alone. Patients were started on long-term androgen deprivation therapy. Median follow-up was 40.2 months and 30.3 months in Arms A and B, respectively. Median PFS was not reached (NR) in either of the treatment arms. On multivariate analysis, 5-year PFS was 86.1% vs 50.3% in Arms A and B, respectively (*P* = 0.0173; HR 0.213; 95% CI 0.059-0.761). OS data were not yet mature and there was no difference in TrT between the arms. **Conclusions:** To our knowledge, this is the first study comparing radical RT against the SoC of prostate RT alone in DN-mHSPC-LV. Radical RT was well tolerated and is significantly cheaper than next-generation hormone agents in prostate cancer. 5-year PFS was significantly better with radical RT vs prostate RT alone. PFS is an established surrogate for OS in prostate cancer. This study therefore justifies prospective studies on RRT for DN-mHSPC-LV. More importantly, as prospective trials with an OS endpoint in prostate cancer will take close to a decade to mature, this study provides interim evidence to support radical treatment in this group of patients, in whom cure or long-term control may be achieved, where prospective trials are anticipated to take much longer to complete. Impact of a whole-food plant-based diet (WFPBD) on weight and metabo-inflammation in men with prostate cancer (PC) receiving androgen deprivation therapy (ADT): A multi-center randomized control trial. First Author: Nicole Jacobs, Weill Cornell Medicine, New York, NY

Background: Obesity promotes a chronic inflammatory state associated with PC progression. ADT can cause weight gain, accumulation of body fat, insulin resistance and increased risk of diabetes and cardiovascular disease. A WFPBD promotes weight loss, decreases inflammation, and shifts the gut microbiome to promote insulin sensitivity. We hypothesized that a WFPBD and behavioral intervention will promote weight loss and a reduction in adiposity in overweight/obese patients with PC on ADT. **Methods:** Pts with PC with BMI $\geq$ 27 receiving ADT with an LHRH/GnRH analogue for $>$24 wks pre-study (+ AR pathway inhibitor allowed if stable dose for $>$3 mos) with plan $>$26 more wks were eligible. 60 patients were randomized 1:1. WFPBD group: 12 prepared and home delivered WFPBD meals per wks 1-4, 6 meals wks 5-8 and coaching to assist in self-prepping plant-based meals (wks 9-26); Control group: counseling on a general healthful diet from a Registered Dietician weekly for 8 wks, then monthly (wks 9-26). Baseline and serial measurements (pre-intervention, wks 4, 8 and 26): weight, body composition assessment via dual energy x-ray absorptiometry (DXA), and biomarkers of inflammation and metabolism were collected. Primary endpoint was weight loss at 4 weeks (with an 80% power to detect an effect size 0.74 standard deviations with a 2-sided significance level of 0.05 using a two-sample t-test). Secondary objectives were change in body composition, biomarkers of metabolic disorders and cardiovascular risk and quality of life measurements. **Results:** 60 pts were randomized (31 control, 29 WFPBD). Median age was 73; Race: 65% white, 28% Black, 2% Asian, 5% other/unknown; Median baseline weight 98 kg; No difference in baseline HbA1c or lipid profile between groups. Mean weight loss (kg) at 4, 8 and 26 wks: WFPBD: 3.9, 5.3 and 6.1 kg; Control 1.3, 1.6, 2.1 kg, respectively (each timepoint pair p$<$0.001). DXA measured BMI change at 4 and 26 wks: WFPBD: -1.1 and -1.93 kg/m^2, Control: 0.35 and 0.25 kg/m^2 (each timepoint pair p$<$0.001). DXA measured mean lean (LM), fat (FM) and total mass (TM) showed declines at 4 wks in WFPBD versus Control (LM -2.4 vs -0.64 (p$<$0.001); FM -1.3 vs -0.35 (p=0.023); TM -3.61 vs -0.88 (p$<$0.001), whereas at 26 weeks only FM and TM remained significantly less (LM -2.2 vs -1.4 (p=0.143); FM -5.3 vs -0.8 (p=0.001); TM -6.7 vs -2.2 (p$<$0.001). No significant differences were seen in HbA1c or lipid profiles at 6 mos. **Conclusions:** Compared with nutritional counseling, obese men with PC on ADT subjected to a home-delivered WFPBD for 2 mos and behavioral coaching experienced significantly greater weight loss, BMI reduction and decreases in total and fat mass that persisted for 6 months. Biomarkers of metabo-inflammation, insulin levels, fecal microbiota and metabolites, and serum for metabolomics collected are undergoing analyses. Clinical trial information: NCT05471414. Germline genetic correlates in metastatic hormone-sensitive prostate cancer (mHSPC) treated with androgen deprivation therapy (ADT) plus non-steroidal anti-androgen (NSAA) or enzalutamide (ENZA): Correlative study of ENZAMET (ANZUP 1304). First Author: Anis Hamid, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The international, randomized, phase III ENZAMET trial (n=1125) showed improved overall survival (OS) with ADT plus ENZA vs ADT plus NSAA for mHSPC. Observational studies showed that the mHSPC genetic landscape is comparable to castration resistant prostate cancer (CRPC). Prognostic and predictive impact of inherited pathogenic variants (PVs), including those affecting *BRCA1*, *BRCA2* and other DNA damage and repair (DDR) genes, on androgen receptor pathway inhibitor (ARPI)-treated mHSPC is under investigation. **Methods:** Whole exome sequencing of germline DNA prospectively obtained from ENZAMET pts. Variant annotation and effect prediction identified PVs (altered "+" vs wild-type "-"). Prognostic effect of PVs was assessed within arms. Endpoints: clinical progression-free survival (PFS) and OS by Kaplan-Meier method. Hazard ratios (HRs) were estimated using Cox models. Multivariable analyses (MVA) adjusted for Gleason score (GS), volume (vol), metachronous vs synchronous and docetaxel (D) use. **Results:** All 847 available samples were successfully sequenced. 123 PVs were identified in 117 (13.8%) pts, of which 46 (5.43%) pts harbored a PV in ≥1 DDR gene. The rate of pathogenic germline *BRCA1*/*BRCA2* (BRCA) PVs was 2.13% (39.1% of DDR PVs). Proportions of arm, D use, vol and visceral disease were similar between DDR+ vs DDR- and BRCA+ vs BRCA-. Synchronous mHSPC in DDR+ vs DDR- and BRCA+ vs BRCA- was 41.3% vs 63.0% and 44.4% vs 62.2%, respectively. PFS and OS estimates were similar between BRCA+ and BRCA- groups in the overall cohort (5-yr OS: 55.6% vs 61%; 3-yr PFS: 50% vs 53.5%, respectively) and in the ENZA arm, but differed in the NSAA arm (Table). BRCA+ treated with ADT+NSAA (67% D use) had shortest PFS (median PFS: 11.3m vs 24.9m [BRCA-], HR 1.85, 95% CI: 0.95-3.6). D use associated with poorer outcomes. In MVA, the HR(PFS) for BRCA+ in NSAA arm was 1.47 (95% CI 0.71-3.04, p=0.3) vs ENZA arm: HR 0.98, (95% CI 0.31-3.08, p=0.97). Vol and GS were independently significant in both arms. **Conclusions:** In one of the largest germline genetic studies from a phase III mHSPC trial, we observed recurrent DDR and BRCA PVs at a lower rate than institutional cohorts. Germline BRCA PVs are associated with a shorter PFS on ADT+NSAA – an effect which may be mitigated by ENZA. Validation in independent trial cohorts is ongoing. Research Sponsor: National Cancer Institute; Movember Foundation; Australian Department of Health; Astellas and Pfizer; US Department of Defense.

Outcomes by arm/docetaxel and BRCA status.

	n	5y-OS % (95% CI)	3y-PFS % (95% CI)
NSAA only BRCA-	238	56.6 (50.0-62.7)	42.9 (36.5-49.1)
NSAA only BRCA+	3	66.7 (5.4-94.5)	66.7 (5.4-94.5)
NSAA+D BRCA-	176	54.7 (47.0-61.8)	32.5 (25.7-39.6)

Prognostic value of PSA nadir ≤0.2 ng/mL in metastatic castration-sensitive prostate cancer: A systematic review and meta-analysis. First Author: Arjun Pon Avudaiappan, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: The treatment landscape for metastatic castration-sensitive prostate cancer (mCSPC) has changed substantially with the adoption of early treatment intensification using androgen-receptor pathway inhibitors (ARPI) and chemotherapy, in addition to traditional androgen deprivation therapy (ADT). PSA nadir has long been used to support prognosis and inform treatment decisions; however, the historical thresholds were established based on patients treated solely with ADT and may not fully reflect outcomes in the modern era of combination therapy. Although emerging evidence suggests that a PSA nadir of < 0.2 ng/dl is associated with improved disease control and survival, a systematic evaluation across available mCSPC trials is needed to clarify the prognostic value of PSA nadir and its potential role in guiding treatment decisions. **Methods:** A systematic search of PubMed, Cochrane Library, and ClinicalTrials.gov was conducted through October 31, 2025, to identify studies reporting outcomes by PSA nadir category in men with mCSPC. Eligible studies included patients initiating systemic therapy with ADT alone or in combination with ARPI and/or chemotherapy. The reported hazard ratios (HR) for time-to-event endpoints stratified by PSA nadir (=< 0.2 ng/dl) were analyzed to get pooled HR. The primary outcome was overall survival (OS). **Results:** A total of eight trials comprising 6,582 patients were included. The pooled HR for the primary endpoint, overall survival (OS), was 0.27 (95% CI: 0.21–0.36; I^2 = 88.1%), indicating a clinically meaningful survival advantage among patients achieving PSA nadir. Consistent findings were observed for secondary outcomes. Achieving a PSA nadir ≤0.2 ng/mL was associated with longer radiographic progression-free survival (HR 0.23; 95% CI: 0.12–0.45; I^2 = 87.8%) and longer PSA progression-free survival (HR 0.19; 95% CI: 0.08–0.45; I^2 = 92.6%). A PSA nadir ≤0.2 ng/mL also correlated with a delayed onset of castration resistance (HR 0.31; 95% CI: 0.16–0.61; I^2 = 93.5%). Assessment of publication bias using Begg's and Egger's tests revealed no significant evidence of small-study effects for any endpoint. **Conclusions:** Across contemporary mCSPC trials, achieving a PSA nadir of ≤0.2 ng/mL consistently predicts improved survival and delayed disease progression. These findings establish PSA nadir as a clinically meaningful and cost-effective biomarker that can help guide treatment-intensification and de-intensification strategies in routine practice. Research Sponsor: None.

Clinical impact and molecular profiling of *PTEN* loss and *TMPRSS2:ERG* fusion in metastatic hormone-sensitive prostate cancer. First Author: Carme Crous, Department of Medical Oncology, IDIBAPS, Hospital Clínic, Barcelona, Barcelona, Spain

Background: *PTEN* loss in prostate cancer (PC) is associated with aggressive disease and resistance to conventional treatments. *TMPRSS2:ERG* fusion (TE+) is one of the most frequent genomic alterations in PC and frequently co-occurs with *PTEN* loss, yet the clinical impact of this association remains unclear. The aim of the present study is to evaluate clinical outcomes in metastatic hormone-sensitive PC (mHSPC) patients (pts) stratified by TE and *PTEN* status and to characterize associated gene expression signatures. **Methods:** We conducted a multicenter ambispective study enrolling mHSPC pts receiving different treatment strategies. The primary objective was to evaluate castration resistant PC-free survival (CRPC-FS) according to *PTEN* and TE. TE fusion and *PTEN* status were assessed in FFPE tumor samples using mRNA expression profiling by nCounter. $PTEN_{low}$ was defined with a previously validated cut-off (Jimenez, *Eur Urol Onc* 2023). RNA-seq analysis was performed to molecularly characterize $PTEN_{low}$ and TE associated transcriptional profiles using gene set variation analysis. **Results:** A total of 295 pts were included; median age was 72.9 years, 46.1% had high-volume disease and 66.8% presented *de novo* stage IV disease. Treatment consisted of androgen deprivation therapy (ADT) plus abiraterone (n=97), apalutamide (n=157), enzalutamide (n=41). Overall, 74 pts were $PTEN_{low}$ and 90 pts were TE+. There were no significant differences in baseline characteristics according to *PTEN* or TE. Among $PTEN_{low}$ pts, 33 (44.6%) were TE+. There was a positive correlation between $PTEN_{low}$ and TE+ (p=0.01). With a median follow-up of 31.9 months (range 0.8 – 91.3), 32% of pts progressed to CPRC and 31.2% died. In the overall cohort, $PTEN_{low}$/TE- tumors (14.1%) were associated with the poorest clinical outcomes, showing significantly inferior CRPC-free survival (HR 2.1, p=0.0027) and overall survival (HR 2.1, p=0.0058). Within the $PTEN_{low}$ subgroup, TE+ tumors demonstrated significantly improved CRPC-FS compared with TE- negative tumors (HR 0.45, p=0.04), with a non-significant trend toward improved overall survival (HR 0.48, p=0.07). In the 35 pts with RNA-seq analysis, $PTEN_{low}$/TE- tumors were characterized by enrichment of DNA repair and neuroendocrine and EZH2 signatures (p=0.04 and p=0.03 respectively). $PTEN_{low}$/TE+ had enrichment of *PI3K* signaling (p=0.01) and epithelial differentiation (p=0.05). Androgen-response hallmark was infraexpressed in $PTEN_{low}$ tumors regardless of TE status. **Conclusions:** $PTEN_{low}$/TE- tumors exhibited the worst clinical outcomes, while TE+ in $PTEN_{low}$ disease partially rescued the adverse phenotype. Combined *PTEN* and TE stratification may therefore inform risk-adapted treatment escalation and intensification strategies. Quantitative results from PSMAtrack: A prospective study evaluating changes in PSMA-PET during initial systemic therapy for metastatic hormone-sensitive prostate cancer (mHSPC). First Author: Praful Ravi, Dana-Farber Cancer Institute, Boston, MA

Background: PSA <0.2 ng/mL after 6 months (m) of therapy with androgen deprivation therapy (ADT) and an androgen receptor pathway inhibitor (ARPI), ± docetaxel is strongly prognostic in patients (pts) with mHSPC. This prospective, single-institution pilot study aimed to investigate PSMA-PET for assessing early dynamic changes in PSMA expression and tumor volume in response to treatment for mHSPC and to determine if changes in quantitative PSMA-PET parameters are associated with 6m PSA response. **Methods:** Key eligibility was mHSPC by conventional imaging with plan to start ADT and ARPI ± docetaxel. Primary or metastasis-directed radiotherapy was not permitted during the first 6m. F18-flotufolastat PSMA-PET was performed at baseline within 21 days of ADT start and after 6m of ADT+ARPI±docetaxel. PSMA-PET scans were qualitatively reviewed for PSMA-avid prostate cancer, (i.e., PSMA uptake > background blood pool in a pattern consistent with prostate cancer). Quantitative PSMA-PET parameters were collected including PSMA-avid total tumor volume (TTV, voxel SUV>3), TTV SUVmean and TTV SUVmax (aPromise, EXINI Diagnostics; LesionID MIM software, GE Healthcare). PSA values at baseline and after 6m of therapy were collected. Descriptive statistical analyses, Wilcoxon test, and Pearson correlations were used. **Results:** 20/21 enrolled pts (median age 70 years [range 60-95]) had evaluable baseline and 6m PSMA-PET scans. 12 (60%) received ADT+ARPI, 8 (40%) received ADT+ARPI+docetaxel, and median baseline PSA was 55ng/mL (range 2-3,696); 13 (65%) had high-volume mHSPC by CHAARTED criteria. At 6m, median PSA was 0.29 ng/mL (range <0.02-177), and 9 pts (45%) had a PSA ≤0.2 ng/mL. All 20 pts had residual PSMA-avid disease at 6m by qualitative review, with most (n=17, 85%) having residual disease outside the prostate; 2 pts (10%) had new lesions seen on 6m PSMA-PET. At 6m, median TTV and SUVmax, but not SUVmean, were significantly lower for those with PSA ≤0.2 than PSA >0.2 ng/mL (Table); baseline TTV was strongly correlated with 6m PSA (r=0.74, p<0.01). PSA and TTV were well correlated at baseline (r=0.68, p=0.001) and at 6m (r=0.81, p<0.01), as were changes in PSA and TTV from baseline to 6 m (r=0.67, p=0.001). **Conclusions:** Persistent PSMA-avid disease was seen in all pts with mHSPC after 6m of ADT+ARPI±docetaxel, regardless of PSA at 6m. Pts with 6m PSA >0.2ng/mL had significantly higher TTV and SUVmax at 6m PSMA-PET, and TTV best correlated with PSA levels at baseline and 6 m. Using 6m PSMA-PET could identify mHSPC pts with suboptimal initial response to standard therapy for consolidative therapeutic strategies. Clinical trial information: NCT06479187. Research Sponsor: Blue Earth Diagnostics.

	6m PSA ≤0.2 ng/mL, median (range)	6m PSA >0.2 ng/mL, median (range)	P
TTV (mL)	7.7 (0.4-79.9)	147 (5.9-3440)	<0.01
SUVmax	8.7 (4.8-39.2)	47.4 (11.7-162)	<0.01
SUVmean	5.3 (4.0-8.8)	6.4 (4.2-16.8)	0.14

Prostate-specific antigen outcomes of darolutamide and androgen deprivation therapy in patient subgroups by age, comorbidities, and concomitant medications: ARANOTE post hoc analyses. First Author: Fred Saad, Urology Department, University of Montreal Hospital Center, Montreal, QC, Canada

Background: Darolutamide (DARO) + androgen deprivation therapy (ADT) significantly improved radiological progression-free survival (HR 0.54, 95% CI 0.41–0.71; P<0.0001) vs placebo (PBO) + ADT in patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC) in the phase 3 ARANOTE (NCT04736199) trial, with a favorable safety profile. Here, we report the impact of age, comorbidities (comorbid), and use of concomitant medications (conmeds) ongoing at baseline on prostate specific antigen (PSA) outcomes in pts treated with DARO or PBO. **Methods:** Pts were randomized 2:1 to DARO 600 mg orally twice daily or PBO, both with ADT. Pts were grouped by age and number/type of comorbid or conmeds reported at baseline. Descriptive statistics (*post hoc*) summarized baseline demographics, disease characteristics, and PSA outcomes by age, comorbid, and conmed subgroups. **Results:** Baseline demographics and disease characteristics were generally similar between DARO (n=446) and PBO (n=223) across all subgroups by age (<65, 65–74, or ≥75 years [yrs]), comorbid (<5 or ≥5), and conmeds (<5 or ≥5), respectively. Rates of reaching PSA <0.2 ng/mL at any time were consistently higher with DARO vs PBO across all age (<65 yrs, 62% [n=69/112] vs 21% [n=13/63]; 65–74 yrs, 62% [n=116/187] vs 21% [n=19/89]; ≥75 yrs, 64% [n=81/126] vs 12% [n=7/59]), comorbid (<5, 66% [n=160/244] vs 21% [n=26/122]; ≥5, 66% [n=86/130] vs 14% [n=10/71]), and conmed (<5, 67% [n=115/173] vs 22% [n=21/96]; ≥5, 62% [n=93/151] vs 16% [n=11/71]) subgroups. With DARO, rates of reaching PSA <0.2 ng/mL at any time were consistent among pts with metabolic disorders with or without corresponding conmeds (71% [n=43/61] vs 69% [n=29/42]). The rate of reaching PSA <0.2 ng/ml was slightly lower in patients with cardiovascular disorders who were not receiving corresponding conmeds at baseline (51% [n=22/43]) compared with those receiving corresponding conmeds (64% [n=119/187]). A substantially lower rate of PSA progression was observed with DARO (8% [n=22/266]) vs PBO (33% [n=13/39]) among pts that reached PSA <0.2 ng/mL. Median time to PSA progression among patients that reached PSA <0.2 ng/mL was 421 days (range, 85–702) and 256 days (range, 85–514) for DARO and PBO, respectively. **Conclusions:** Overall, an efficacy benefit was observed with DARO, irrespective of age, and number of comorbidities or concomitant medications reported at baseline in pts with mHSPC, including those with cardiovascular or metabolic disorders, with or without corresponding conmeds, respectively. These results support the use of DARO in mHSPC, even in pts with older age, substantial comorbidities, and greater use of concomitant medications. Clinical trial information: NCT04736199. Prognostic potential of PROSTest for predicting outcome in ADT-treated Black South African prostate cancer patients. First Author: Susanna Elizabeth Nagel, University of Pretoria School of Medicine, Pretoria, South Africa

Background: Prostate cancer (PCa) is the second most common cancer in men with disproportionately aggressive disease observed in black African and Caribbean men. Androgen deprivation therapy (ADT) is commonly used as treatment but there is no personalized strategy to guide patient selection. We investigated the prognostic value of PROSTest before ADT initiation and after the first ADT cycle. **Methods:** We performed a descriptive study of PROSTest with cross-sectional and longitudinal arms in black PCa patients receiving or intended to receive ADT. An ADT-naïve PCa cohort (*n*=50) intended to start ADT was enrolled as well as an ADT-exposed cohort (*n*=80) 6-12, 12-24 or >24 months after starting ADT. Goserelin acetate alone or in combination with cyproterone acetate was administered. The cohorts were followed up 4-monthly for 36 months with evaluation of survival and treatment response (responding, in remission, recurrence, progression, castration resistance). PSA levels were measured using the Architect Total PSA chemiluminescent immunoassay. Whole blood samples were collected into deproteinizing RNA-buffered tubes for determination of the PROSTest activity score using a multiplexed PCR assay. Statistical analysis used non-parametric statistics and Fisher's exact test in GraphPad Prism v8. **Results:** Untreated metastatic PCa patients had the highest baseline PROSTest scores (71.8-85.3). Untreated patients with organ-confined disease were subdivided into group A (PROSTest scores ≤32) and group B (PROSTest scores ≥70). ADT-treated patients enrolled after starting ADT were subdivided into group C (PROSTest scores 9.8-58.3) and group D (PROSTest scores 70.0 – 90.2). Groups A and C showed improved survival and lower rates of recurrence, progression and castration resistance at 36 months compared to groups B and D (p<0.05). Patients that required treatment re-initiation or escalation due to rising PSA all had high enrolment PROSTest scores ≥70. The groups did not differ significantly in terms of age, CAPRA score, Gleason grade, PSA levels, nadir PSA, time to nadir or SUVMAX (*p*>0.05). **Conclusions:** The PROSTest activity score determined pre- or post-ADT (first cycle) identifies PCa patients at risk for poor treatment outcomes. Overall survival in veterans with metastatic hormone sensitive prostate cancer by initial therapy and STRATOS-P somatic tumor classification. First Author: Robert Wilson, Saint Louis University School of Medicine, St. Louis, MO

Background: The STRATOS-P somatic tumor classification stratifies patients with metastatic hormone-sensitive prostate cancer (mHSPC) into favorable, intermediate, or unfavorable risk groups based on tumor comprehensive genomic profiling (CGP). Currently, no studies have compared the mortality benefits or overall survival (OS) differences between mHSPC treatments in these risk categories. **Methods:** Veterans within the Veterans Health Administration with mHSPC diagnosed between December 2018 and September 2024 were included if tumor CGP was completed within 6 months of diagnosis. Patients were grouped based on STRATOS-P genomic classification (favorable vs. intermediate/unfavorable). With each group, OS was analyzed by initial therapy: androgen deprivation therapy (ADT) alone, ADT+androgen receptor pathway inhibitor (ARPI), ADT+docetaxel, or triple therapy with ADT+ARPI+docetaxel. Survival was analyzed using Kaplan-Meier and Cox proportional hazards models, adjusting for baseline differences in age, PSA, Charlson comorbidity index, race, and metastatic volume. **Results:** Of 2,820 veterans with mHSPC, 1,109 (39.3%) had risk classified as favorable per STRATOS-P and 1,711 (60.7%) as intermediate/unfavorable. Initial therapy distribution differed moderately between groups (p=0.046). The favorable group had more patients receiving ADT monotherapy (55.5% vs. 52.0%) and fewer receiving ADT+docetaxel or triple therapy (3.0% vs. 4.7%, 4.4% vs. 5.4%, respectively). The intermediate/unfavorable group had a higher max PSA (median 37.7 vs 23.7, p<0.001) lower percentage of African American patients (27.5% vs 36.0%, p<0.001), and a higher percentage of patients with high volume of disease (28.9% vs. 19.7% p=0.002). In the favorable group, OS did not significantly differ by treatment; however, in a pairwise comparison, ADT+ARPI showed a modest decrease in mortality risk versus ADT alone (aHR [95% CI]: 0.745 [0.561 – 0.989]). In the intermediate/unfavorable group, median OS differed by therapy (ADT monotherapy: 30.7 months, ADT+ARPI: 36.8 months, ADT+docetaxel: 27.9 months, Triple Therapy: 37.6 months; p<0.001). Further, ADT+ARPI and triple therapy were associated with a decreased risk of mortality compared to ADT alone (aHR [95% CI]: 0.638 [0.541 – 0.753], 0.542 [0.360 – 0.817], respectively). **Conclusions:** In patients with intermediate/unfavorable STRATOS-P genomic risk, choice of initial therapy can lead to differences in OS, with ADT+ARPI and triple therapy associated with decreased mortality compared to ADT alone. In favorable risk, choice of initial therapy had smaller effect on OS, and only ADT+ARPI was associated with a modest decrease in mortality. These findings highlight the role of early genomic testing in mHSPC and that high risk tumors may benefit more from combination therapy than those with favorable risk. STRATOS-P clinical model for prognosis and selection of patients with metastatic hormone sensitive prostate cancer (mHSPC) for intermittent therapy. First Author: Martin W. Schoen, Medicine Service, Veterans Affairs St. Louis Healthcare System, St. Louis, MO

Background: Current trials use prostate-specific antigen (PSA) response of ≤0.2 ng/mL at 6-12 months as a prognostic marker and identify patients for intermittent therapy. Clinico-genomic assessment can increase prognostic accuracy and patient selection for intermittent therapy, which would improve quality of life and decrease adverse events associated with mHSPC combination therapies without impacting survival. **Methods:** Retrospective study of veterans diagnosed with mHSPC between 2018-2024. PSA response at 6-12 months and volume of disease were determined. DNA alterations were classified by Somatic Tumor Risk Assessment for Overall Survival-Prostate (STRATOS-P) genomic system, a validated method of risk stratification. PSA response was grouped into ≤0.2, >0.2-<2, 2-<10, and ≥10 ng/mL. Charlson comorbidity index (CCI) high was defined as ≥3. PSMA-PET based staging was determined if PSMA-PET performed within 100 days of mHSPC diagnosis. Multivariable Cox model-based weights were used to create the STRATOS-P mHSPC clinical risk score to prognosticate overall survival and select patients for intermittent therapy. Kaplan-Meier analysis was used to estimate Overall Survival (OS) and time to death or castration resistance from diagnosis, a real-world progression-free survival (rwPFS) surrogate. **Results:** In 3094 Veterans identified, 937 (30.3%) had DNA-based genomic testing within 6 months of diagnosis. There were 1349 patients (43.6%) with a PSA of ≤0.2 who had a median OS of 74.6 months. Of patients with genomic testing, 459 (49.0%) were STRATOS-P Clinical low risk with a median OS that was not reached and rwPFS of 72.1 months, moderate risk with median OS of 37.1 months and rwPFS of 21.6 months, and high risk with median OS of 19.1 months and rwPFS of 12.1 months. There were 66 (13.0%) patients that were STRATOS-P Clinical low risk but did not achieve ≤0.2% and 116 (22.8%) patients that achieved PSA ≤0.2 but were considered STRATOS-P clinical moderate risk. Approximately 497 patient (53%) could be considered for intermittent therapy and had a median OS of 77.9 months and rwPFS of 56.2 months, similar to patients with PSA≤0.2. **Conclusions:** STRATOS-P Clinical model in mHSPC is prognostic for OS and rwPFS and can identify patients for intermittent therapy to achieve similar OS and rwPFS compared to selection using PSA ≤0.2 at 6-12 months. Future trials should incorporate clinico-genomic assessments to improve risk stratification and selection of therapy. Major adverse cardiovascular events in androgen receptor signaling inhibitor–treated patients with metastatic castration-sensitive prostate cancer. First Author: Linden Huhmann, US Department of Veterans Affairs, Washington, DC

Background: Cardiovascular disease is highly prevalent in the predominantly older male population with metastatic castration-sensitive prostate cancer (mCSPC). Androgen receptor pathway inhibitors (ARPIs) form the backbone of contemporary doublet and triplet treatment strategies, but—as with any systemic therapy—may influence patients' underlying cardiovascular risk. This study compares the incidence of major adverse cardiovascular events (MACE) in real-world mCSPC patients treated with darolutamide versus abiraterone. **Methods:** This retrospective cohort study included patients in the nationwide VA healthcare system initiating doublet or triplet abiraterone or darolutamide for newly diagnosed mCSPC. After inverse probability of treatment weighting (IPTW), 1-year cumulative MACE incidence was estimated via Kaplan-Meier analysis. Doubly robust multivariable Cox regression using IPTW and multivariable competing risk regression with death as a competing risk assessed the association between treatment and MACE. All analyses were adjusted for age, race, prior MACE, NCI Charlson Score, smoking status, and prior hypertensive combination treatment. **Results:** Among 11,788 patients initiating darolutamide or abiraterone for mCSPC, 9,952 received abiraterone doublet, 936 received darolutamide doublet, 374 received abiraterone triplet, and 526 received darolutamide triplet therapy. In the weighted cohort, the 1-year cumulative incidence of MACE was lower in patients receiving darolutamide (7.2%, 95% confidence interval [CI] 5.6-9.0%) versus abiraterone (10.7%, CI 10.0-11.4%) doublet therapy. For triplet therapy, 1-year MACE incidence was 5.3% (CI 3.4-7.4%) with darolutamide and 9.6% (CI 5.9-13.6%) with abiraterone. In doubly robust multivariable Cox models, darolutamide doublet was associated with a lower hazard of MACE compared to abiraterone doublet (hazard ratio [HR] 0.78, CI 0.62-0.96, P=0.03). For triplet, patients receiving darolutamide had a HR of 0.73 for MACE (CI 0.39-1.31, p=0.29) compared to patients receiving abiraterone triplet therapy. Competing risk models showed consistent results. **Conclusions:** Darolutamide, particularly in doublet therapy, was associated with lower MACE risk than abiraterone. A similar point estimate in triplet therapy warrants validation in larger cohorts. These findings may inform treatment selection or prophylactic management to improve cardiovascular outcomes in mCSPC. Research Sponsor: Bayer.

Homologous recombination repair (HRR) genes and overall survival prognosis within the STRATOS-P classification in metastatic hormone-sensitive prostate cancer (mHSPC). First Author: Kara N. Maxwell, Corporal Michael Crescenz VA Medical Center, Department of Medicine, Hematology and Oncology, Perelman School of Medicine and Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA

Background: DNA repair genomic alterations are associated with worse overall survival (OS) in patients with metastatic hormone sensitive prostate cancer (mHSPC). It is less clear whether other genomic alterations may affect prognosis of actionable homologous recombination repair (HRR) and mismatch repair (MMR) genes in mHSPC. **Methods:** Retrospective cross-sectional study of veterans diagnosed with mHSPC (n=4401). Tumors with no alterations in HRR/MMR genes (DDRneg) were classified by the Somatic Tumor Risk Assessment for Overall Survival-Prostate (STRATOS-P) genomic system which stratifies patients into favorable, intermediate and unfavorable survival groups based on oncogenic alterations: Favorable, *SPOP* or no alterations; Intermediate, alterations in *AR, BRCA2, CCND1, CDK12, FGF19, FGF3, FGF4, LYN, MYC, PTEN, RAD21,* or *TP53*; Unfavorable, alterations in *FGFR1, PRCK1, RB1*,or both *TP53* and *PTEN*. OS from metastatic diagnosis was determined using a multivariate Cox model controlling for age, Charleston comorbidity index (CCI) and PSA at diagnosis. **Results:** Among 4401 mHSPC patients, 1027 (23%) patient tumors had at least one oncogenic alteration in an HRR or MMR gene. Of 3374 DDR-Neg tumors, 1593 were classified as STRATOS-P-Favorable, 1357 as STRATOS-P-Intermediate, and 424 as STRATOS-P-Unfavorable. Comparing patients with tumors with oncogenic alterations in an HRR or MMR gene to patients with DDR-neg tumors showed that prognosis was worse in patients with tumor alterations in *ATM, BRCA2, CHEK2, CDK12, ATR, PALB2, NBN* and MMR genes compared to patients with STRATOS-P-Favorable tumors (Table). Prognosis was better in patients with tumor alterations in *ATM, BRCA2, CHEK2, CDK12, BRCA1, FANCA* and Lynch genes compared to STRATOS-P-Unfavorable tumors (Table). **Conclusions:** In patients with mHSPC, patients with HRR and MMR altered tumors have a worse prognosis compared to patients with STRATOS-P favorable tumors and better prognosis compared to patients with STRATOS-P unfavorable tumors. Overall, HRR and MRR gene alterations impact prognosis of mHSPC patients within the STRATOS-P classification and should be classified as intermediate risk. Research Sponsor: Veterans Affairs Office of Research and Development; I01CX002946; Prostate Cancer Foundation; 22CHAL02.

Optimal prostate-specific antigen cutoff for prostate cancer detection: A prospective cohort study. First Author: Yun-Gyoo Lee, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Serum prostate-specific antigen (PSA) testing is crucial for detecting early stage and low-risk prostate cancer. However, standard and uniform PSA thresholds may underestimate risk in males with smaller prostate volumes and distinct epidemiologic characteristics. We aimed to evaluate data-driven, age-specific PSA thresholds for short-term prostate cancer detection in a large screening cohort. **Methods:** We analyzed 512,992 PSA measurements from 123,607 asymptomatic males undergoing annual or biennial health checkups in Kangbuk Samsung Cohort Study (KSCS) from 2011 to 2020. Incident prostate cancer within 1-year of each PSA measurement was identified through linkage to the Korea National Cancer Incidence Database. The dataset was randomly partitioned into training (70%) and test (30%) subsets. To estimate cancer risk, logistic regression models incorporating synthetic minority oversampling technique were used. Optimal PSA thresholds were determined using the Youden index in test datasets. Performance was evaluated by accuracy, precision, recall, and F1-score with bootstrap validation. Associations between risk factors and prostate-cancer risk were evaluated using Cox regression models. **Results:** During follow-up, 224 men developed prostate cancer. The optimal PSA cutoff in the overall population was 2.96 ng/mL. Age-specific thresholds increased with age, with males in their 40s, 50s, 60s, and age $\geq$70 years demonstrating cutoff values of 1.62, 2.54, 2.76, and 3.79 ng/mL, respectively. These thresholds demonstrated high discriminative performance (accuracy, 0.97; F1-score, 0.92) (Table). PSA values exceeding age-specific thresholds were associated with a 20.7-fold elevated risk of prostate cancer (HR 20.65; 95% CI, 16.33–26.12; P$<$0.001). Older age, family history of prostate cancer (HR 2.27; 95% CI, 1.58–3.27), and dyslipidemia medication use (HR 2.04; 95% CI, 1.49–2.80) were additional independent predictors. **Conclusions:** In this large prospective Asian cohort, age-specific PSA thresholds between 1.6 and 3.8 ng/mL provided robust short-term risk discrimination and identified male at substantially higher 1-year prostate cancer risk than those below the thresholds. Implementing age-adjusted PSA reference values may improve the precision and efficiency of early detection strategies in Asian male and better inform risk-adapted screening and diagnostic pathways. To determine their effect on long-term clinical outcomes, prospective validation is warranted. Research Sponsor: None.

Age-specific PSA cutoffs and performance metrics.

	Cutoff value	Accuracy	Precision	Recall	F1-score
Overall	2.96	0.97	0.89	0.96	0.92
40 ≤ Age < 50	1.62	0.93	0.70	0.99	0.82
50 ≤ Age < 60	2.54	0.95	0.80	0.95	0.87

Large language model protein set generation for interpretable serum proteomics in localized prostate cancer. First Author: Nicholas Robert Rydzewski, Washington DC VA Medical Center, Washington, DC

Background: High-plex serum proteomics can track prostate cancer biology and treatment response beyond PSA, but interpretation is limited by high dimensionality. Pathway analysis can help, but incomplete overlap between legacy pathway libraries and assay panels can yield hard-to-interpret enrichments dominated by a few measured proteins. We evaluated an automated large language model (LLM) workflow using protein annotations to build protein sets containing only measured proteins. **Methods:** Serum from 88 individuals was profiled with an aptamer-based ~7,000-protein assay (SomaScan 7K; SomaLogic, USA). The cohort included localized prostate cancer treated with radiotherapy (RT) with or without androgen-deprivation therapy (ADT) with serial sampling (pre-RT n = 76, end-RT n = 72, ~1-month follow-up n = 76), plus metastatic (n = 4) and normal controls (n = 8). Assay fidelity was assessed by correlating PSA aptamers with clinical PSA. Protein-level analyses tested ADT effects and paired within-patient changes across RT. For program-level analysis, UniProt annotations for each measured protein were processed with an LLM to generate structured summaries, converted to embeddings, and clustered into protein sets restricted to SomaScan proteins. Set coherence and assay coverage were compared to Gene Ontology (GO) and Reactome mappings. Protein-set enrichment comparing ADT vs no ADT identified candidate programs and were evaluated for association with biochemical recurrence among high-risk ADT-treated patients (n = 50; 20 events) using Cox models adjusted for pre-treatment PSA. **Results:** PSA aptamers correlated with clinical PSA (Spearman r = 0.66–0.77). ADT suppressed reproductive-axis proteins (LH, FSH, hCG) and prostate-lineage proteins (PSA, PAP, TGM4); RT contrasts captured acute epithelial injury/lymphoid suppression followed by remodeling and stress responses. LLM protein sets showed higher set name/protein description coherence (median cosine similarity 0.59) than GO (0.30) or Reactome (0.36) and covered all measured proteins; GO/Reactome sets averaged ~50% member coverage. Pre-RT ADT enrichment identified histone programs (NES 2.13–2.18; FDR $<$ 0.01), summarized as a Histone H2 score. Histone H2 score increased across no ADT, ADT, and metastatic samples (Kruskal–Wallis p = 0.003; all pairwise FDR $<$ 0.05). In high-risk ADT-treated patients, pre-RT Histone H2 score was associated with recurrence (HR 0.53, FDR = 0.024), and remained significant in a bivariate model with pre-treatment PSA (Histone H2 HR 0.49, FDR = 0.013; PSA HR 2.78, FDR $<$ 0.001). Non-H2 histone score (H1/H3) showed no ADT-associated shift (Wilcoxon p = 0.70), supporting specificity of the Histone H2 signal. **Conclusions:** LLM-derived protein sets restricted to measured proteins improved interpretability of serum proteomics and revealed an ADT-associated Histone H2 program complementary to PSA. Spatial transcriptomics-guided pathology biomarker as a predictor of benefit of adjuvant docetaxel in high-risk localized prostate cancer: NRG/RTOG 0521 (NCT00288080). First Author: Md Mamunur Rahaman, School of Computer Science and Engineering, University of New South Wales, Sydney, NSW, Australia

Background: The NRG/RTOG 0521 trial evaluated adding adjuvant docetaxel (DTX) to standard radiotherapy plus androgen deprivation therapy (ADT) in high-risk localized prostate cancer. Adjuvant DTX modestly improved overall survival (OS) in the trial, but the benefit was limited and not all patients benefited. Thus, biomarkers are needed to identify patients most likely to benefit from chemotherapy intensification. ST-DoxPCa (Spatial Transcriptomics–Guided Docetaxel Therapy Stratification in Prostate Cancer) is a novel artificial intelligence (AI) driven histology biomarker that predicts gene expression from H&E slides (virtual spatial transcriptomics). We assessed whether ST-DoxPCa can stratify patients in RTOG 0521 for differential benefit from adjuvant DTX. **Methods:** A Vision Transformer trained on paired histology–spatial transcriptomics (HEST1K) predicts a 208-gene prostate panel at spot level; predictions are distilled into a biologically informed 26-gene signature and aggregated into patient-level features. A prognostic Cox model and fixed median threshold were developed independently in a Cleveland Clinic radical prostatectomy cohort (CCF, n=352; endpoint: biochemical recurrence-free survival). This locked model and threshold were applied unchanged (no refitting or recalibration) to digitized pretreatment diagnostic biopsies from NRG/RTOG 0521 (n=350; RT+ADT n=169, RT+ADT+DTX n=181) to stratify patients into ST-DoxPCa-positive (high-risk) and ST-DoxPCa-negative (low-risk) groups. Overall survival (OS) was compared between treatment arms within each stratum. **Results:** ST-DoxPCa stratified patients into biomarker-defined risk groups using aggregated spatial-expression features from a biologically informed gene panel; key genes included PTEN, NKX3-1, ACPP, FASN and TMPRSS2. ST-DoxPCa-positive (high-risk) patients experienced a significant OS benefit from adding DTX to RT+ADT versus RT+ADT alone (HR=0.38, 95% CI 0.18−0.83; p=0.012), whereas ST-DoxPCa-negative (low-risk) patients derived no OS benefit (HR=1.05, 95% CI 0.67−1.63; p=0.84). **Conclusions:** The ST-DoxPCa model identified a subgroup with substantial OS benefit from adjuvant DTX and a subgroup with no benefit within RTOG 0521, supporting risk-aligned chemotherapy intensification using routine histology. External validation of new prostate cancer risk groups by PSMA-PET (PPP3). First Author: Wolfgang Peter Fendler, Department of Nuclear Medicine, University of Duisburg-Essen, and German Cancer Consortium (DKTK), University Hospital Essen, Essen, Germany

Background: Previously, we proposed novel risk group definitions for prostate cancer patients based on Prostate-Specific Membrane Antigen (PSMA) targeted positron emission tomography (PET). PSMA-PET pan-stage nomograms (PPP3) were developed using the international, multicentre PROMISE registry (NCT06320223) to prognosticate overall survival (OS). Here, we present an external validation of PPP3. **Methods:** Eligible patients enrolled into our PROMISE registry database after the PPP3 data cap were included into this external validation study. Included patients had histologically proven prostate cancer and underwent PSMA-PET at hospitals in Turkey, Cyprus, Italy, China, South Africa or Germany between 2015 and 2022. PSMA-PET was standardized by PROMISE version 2 (V2); total lesion count, total tumor volume, PSMA expression score and OS follow-up were obtained as per local site practice. PPP3 nomograms were applied to calculate risk groups and Harrell´s C-indices for the external validation cohort. Calibration curves were measured for 5-year OS. Head-to-head comparison between the visual PPP3 nomogram and the simplified risk stratification table was examined by area under the receiver operating characteristics curve (ROC-AUC). **Results:** 1855 male patients across all disease stages with 179 (9.6%) reported deaths and median OS follow-up of 4.8 years (IQR 3.7-6.1) were analysed. In the external validation cohort C-indices (95% CI) were 0.71 (0.67-0.76) for the visual nomogram and 0.73 (0.69-0.77) for the quantitative nomogram, respectively. By simplified risk stratification table, 77 of 1855 patients (4.2%) were underestimated and 16 (0.9%) were overestimated, when compared with visual nomograms. Prognostic accuracy was comparable using both methods (AUC Nomogram: 0.64 vs. AUC Table: 0.63, p = 0.02). **Conclusions:** PPP3 nomograms were validated in an external multi-site patient cohort. Prognostication was accurate (C-indices $>$ 0.70) for both PPP3 nomograms. Clinical trial information: NCT06320223. Is language barrier a mere proxy?: Psychological distress among non–English-speaking prostate cancer patients receiving radiation therapy—A prospective cohort study. First Author: Teresia M. John, Boston University School of Medicine, Boston, MA

Background: Cancer patients experience depression and anxiety at elevated rates, with minority and non-English-speaking populations disproportionately affected. Prior research at our institution demonstrated elevated distress among Spanish-speaking breast cancer patients undergoing radiation therapy. However, limited data exist on language-related disparities in prostate cancer patients undergoing radiation therapy. We investigated this while exploring the mediating role of social determinants of health (SDOH). **Methods:** We enrolled prostate cancer patients initiating radiation therapy at an urban safety-net hospital. We assessed anxiety (GAD-2), depression (PHQ-2), and SDOH including food and housing insecurity, and transportation barriers at baseline and treatment completion. Comparisons used t-tests and Mann-Whitney U tests; correlations used Spearman coefficients with statistical significance $p < 0.05$. **Results:** Of 84 patients enrolled (mean age 70.3$\pm$8.0 years), 49 (58.3%) were English-speaking and 35 (41.7%) were non-English-speaking (Spanish n = 20, Haitian Creole n = 13, Portuguese n = 2). The sample was predominantly Black/Caribbean (64.3%). Non-English speakers had fewer years in the US (41.1 vs. 50.3 years, p = 0.016) and lower educational attainment (25.7% vs. 0% elementary school only, p = 0.006). At baseline, non-English speakers showed numerically higher anxiety (GAD-2: 1.31$\pm$2.13 vs. 1.08$\pm$1.72) and depression (PHQ-2: 1.09$\pm$1.87 vs. 0.84$\pm$1.57), though this was not statistically significant ($p > 0.50$). Notably, Spanish-speaking patients demonstrated the highest distress (GAD-2: 2.00$\pm$2.45; PHQ-2: 1.40$\pm$1.98), with 30.0% screening positive for clinical anxiety vs. 16.3% of English speakers. SDOH factors were significantly correlated with distress: housing insecurity (ρ = 0.42, $p < 0.001$), food insecurity (ρ = 0.37, p = 0.001), and transportation worry (ρ = 0.38, $p < 0.001$). In multivariable regression adjusting for age, stage, race, ethnicity, and education, language was not independently associated with anxiety (B = -0.64, 95% CI: -1.76 to 0.48, p = 0.26). Among 73 patients with paired data, distress remained stable from baseline to treatment completion. **Conclusions:** While non-English-speaking prostate cancer patients reported higher psychological distress during radiation therapy, SDOH factors emerged as the strongest predictors of distress regardless of language. Interventions targeting social vulnerability may be more impactful than language services alone. SDOH screening should be integrated into oncology care at safety-net institutions serving diverse populations. Research Sponsor: None.

Assessing the clinical and biological associations between multimodal artificial intelligence (MMAI) and 22-gene genomic classifier (GC) in localized prostate cancer (PCa). First Author: Boon Hao Hong, National Cancer Centre, Singapore, Singapore

Background: MMAI and GC are clinically validated prognostic tools for localized PCa, and are incorporated into NCCN guidelines as treatment-decision aids. However, their clinical and biological relationships remain unclear, especially in Asian populations where comparative study is limited. **Methods:** Patients with newly-diagnosed localized PCa from a single institution in Singapore were enrolled into a prospective protocol (NCT04340024), and underwent image-guided radiotherapy with or without hormonal therapy. All subjects had paired GC and MMAI scores. However, colored marker annotations were present on the H&E slides, which could negatively impact MMAI performance. Associations between GC and MMAI scores with metastasis-free survival (MFS) were evaluated using Cox proportional hazards models. Pearson's correlation was used to assess associations between risk scores and cancer hallmark pathways. **Results:** 144 men were included, comprising 142 (99%) with NCCN intermediate (int) to high-risk, and 2 (1%) with low-risk disease; median follow-up duration was 78.5 (interquartile range: 68.2–95.3) mo. MMAI and GC scores were correlated (R = 0.55), but differed in risk stratification; 12/144 (8%), 54/144 (38%), and 78/144 (54%) were MMAI low-, int-, and high-risk, respectively, compared with 51/144 (35%), 32/144 (22%), and 61/144 (43%) by GC in the same order. We observed the largest discordance in the GC low-risk subgroup (n = 51), where 29/51 (57%) and 14/51 (28%) were classified as MMAI int- and high-risk, respectively. Of note, 16/32 (50%) of GC int-risk men were classified as MMAI high-risk. Nonetheless, both tests were prognostic for MFS (MMAI: hazard ratio [HR] of 2.6 [95% CI: 1.0–6.4], P= 0.035; GC: HR of 3.4 [95% CI:1.5–7.6], P= 0.002), although the difference in HR should be interpreted with caution, as it is attributable to a limited sample size with longer follow-up. Next, we investigated for molecular pathway enrichment of GC and MMAI high-risk groups. Proportions of known prostate cancer molecular subtypes were comparable between the respective GC and MMAI risk-groups (GC high vs MMAI high: PAM50 Basal 51% vs 58%, P= 0.419; Luminal B 46% vs 39%, P= 0.377; PTEN loss 25% vs 22%, P= 0.698; AR lower activity 49% vs 44%, P= 0.512). GC high versus GC low/int tumors however showed positive enrichment in E2F, oxidative phosphorylation, and mTORC1 pathways; negative enrichment in P53 and estrogen pathways. MMAI high was only negatively enriched for fatty acid metabolism. **Conclusions:** While MMAI and GC provide differing risk categorization, both tests were significantly associated with MFS in men with localized prostate cancer who underwent radiotherapy. Known prostate cancer-associated transcriptomic subtypes were comparable between the respective MMAI and GC risk groups. Research Sponsor: None.

A prospective study of mpMRI-guided salvage radiotherapy with lesion-directed dose escalation after radical prostatectomy: 10-year follow-up results (MRI Study: UMIN 000009823). First Author: Kenshiro Shiraishi, Teikyo University, Tokyo, Japan

Background: Salvage radiotherapy (SRT) after radical prostatectomy (RP) has traditionally been delivered as uniform dose distribution of the prostate bed without lesion visualization. We prospectively implemented an image-guided salvage strategy integrating high-resolution multiparametric MRI (mpMRI) and lesion-directed dose escalation. Here we report long-term oncologic outcomes of this pioneering approach. **Methods:** This prospective, single-arm clinical study was registered in the UMIN database in 2013. Patients with biochemical recurrence (BCR, PSA $\geq$0.2 ng/mL) after RP and no evidence of distant metastasis were enrolled. All patients underwent 3 Tesla mpMRI with an endorectal coil prior to SRT. When a focal recurrent lesion was identified, intensity-modulated radiotherapy (IMRT) with simultaneous integrated boost (SIB) was delivered (70 Gy to the MRI-defined lesion and 66 Gy to the prostate bed in 33 fractions). Patients without visible lesions received prostate-bed irradiation alone. Treatment failure after SRT was defined as PSA $>$ 0.2 ng/mL. Long-term clinical outcomes were analyzed. **Results:** A total of 40 patients completed protocol treatment. mpMRI identified focal recurrence sites in 11 patients (27.5%), all of whom received lesion-directed SIB-IMRT. After a median follow-up of 10.6 years, treatment failure occurred in 13 patients (32.5%). Among patients treated with SIB-IMRT, 4 of 11 developed BCR, whereas among 29 patients without mpMRI-detectable recurrence at the time of SRT, 9 developed BCR. There was no statistically significant difference in BCR rates between the two groups. Importantly, no patient developed radiologically evident local recurrence within the irradiated prostate bed, including those treated with SIB in their disease course. All but one patient with treatment failure received subsequent systemic salvage therapy. Distant metastases developed in 3 patients, and 1 patient died from prostate cancer. One patient without SIB experienced grade 3 perforation of the sigmoid colon. During follow-up after SRT, secondary malignancies were diagnosed in 10 patients. **Conclusions:** In this prospective study with long-term follow-up, mpMRI-guided SRT achieved excellent durable local control. Although second BCR occurred in a subset of patients, the absence of in-field local failures regardless of mpMRI detectability at the time of SRT supports the biological and clinical validity of lesion-directed salvage intensification. Our findings underscore individualized SIB approach and highlight the need for future studies to refine patient selection and treatment intensification strategies in salvage settings, including androgen deprivation therapy and/or elective pelvic nodal irradiation. Clinical trial information: UMIN000009823. Research Sponsor: None.

Survival outcomes and subgroup efficacy analysis of Ga-68-NGUL and Lu-177-DGUL (pocuvotide satetraxetan) in patients with mCRPC: Results from a phase 1/2 study. First Author: Chang Wook Jeong, Seoul National University Hospital, Seoul, South Korea

Background: Ga-68-NGUL and Lu-177-DGUL (Pocuvotide Satetraxetan) is a novel PSMA-targeting radiopharmaceutical. This study reports the survival outcomes and identifies clinical factors associated with therapeutic response in patients with metastatic castration-resistant prostate cancer (mCRPC). **Methods:** In this phase 1/2 study (NCT05547061), mCRPC patients progressing after ARPI treatment received Lu-177-DGUL (200 mCi every 6 weeks, up to 6 cycles). Efficacy was evaluated using both RECIST v1.1 and PCWG3-modified RECIST v1.1. Key endpoints included ORR, overall survival (OS), and radiographic progression-free survival (rPFS). **Results:** A total of 91 patients were enrolled. Overall Survival: The median OS was 13.31 months (95% CI: 12.02–17.38). The median rPFS was 11.04 months (95% CI: 8.28–14.29) for the entire cohort. Subgroup Analysis by Metastatic Site: Significant differences in ORR were consistently observed across both criteria. Per RECIST v1.1, the ORR was significantly higher in patients with lung metastases (100% vs. 32.43%, p = 0.0144) and lymph node involvement (48.08% vs. 11.54%, p = 0.0015) compared to those without. These findings align with PCWG3-modified RECIST v1.1 results (Lung: 100% vs. 37.84%, p = 0.0252; LN: 51.92% vs. 19.23%, p = 0.0057). Furthermore, the presence of liver metastases was associated with significantly shorter rPFS compared to those without liver involvement, consistently across RECIST v1.1 (median 5.55 vs. 11.04 months; p = 0.0386) and PCWG3-modified criteria (median 2.76 vs. 8.38 months). Impact of Treatment Cycle on ORR and rPFS: Treatment intensity significantly influenced clinical outcomes across both evaluation criteria (all p $<$ 0.0001). For ORR, under RECIST v1.1 criteria, the ORR was 0% for $<$ 4 cycles, 30% for 4 cycles, and 59.46% for $>$ 4 cycles. Similarly, per PCWG3-modified RECIST v1.1, the ORR improved with the number of cycles (0%, 35%, and 67.57%, respectively). For rPFS, under standard RECIST v1.1, the median rPFS increased with the number of cycles: 2.76 months (95% CI: 2.56–2.86), NE (95% CI: 5.55–NE), and 13.34 months (95% CI: 11.04–NE). Per PCWG3-modified RECIST v1.1, the median rPFS also increased consistently (2.66 months [95% CI: 2.56–2.76], 5.55 months [2.73–NE], and 11.04 months [10.18–14.29], respectively). **Conclusions:** Ga-68-NGUL and Lu-177-DGUL (Pocuvotide Satetraxetan) demonstrates promising survival benefits in mCRPC. The clinical response is particularly robust in patients with lung or lymph node metastases and those completing more treatment cycles. The significant difference in rPFS observed only under PCWG3-modified criteria highlights the importance of using PCWG3-specific assessments in bone-predominant mCRPC. Clinical trial information: NCT05547061. Research Sponsor: CellBion Co., Ltd.; The Korea Drug Development Fund; RS-2025-25454770.

Spatially organized immune niches in high-grade primary prostate cancer. First Author: Aishwarya Atmakuri, Pritzker School of Medicine, The University of Chicago, Chicago, IL

Background: Prostate cancer (PC) has historically been considered immunologically "cold" due to low immune infiltration and a predominantly immunosuppressive tumor microenvironment (TME). However, this understanding is largely based on immune profiling studies of metastatic castration-resistant prostate cancer and may not apply in earlier stages of disease. The composition and organization of the immune TME in primary PC remains poorly defined, especially in relation to Gleason score, the gold standard of pathologic PC grading. We hypothesized that the local PC immune TME is more heterogeneous than previously appreciated, with differences in immune composition and spatial organization between High Gleason (HG) and Low Gleason (LG) PC. **Methods:** We analyzed 29 radical prostatectomy samples (15 LG vs. 14 HG) using a 40-marker multiplex immunofluorescence panel to profile the TME at single-cell resolution. Immune cell phenotypes were defined with respect to the marker panel. Using R, cell composition was computed within tumor, stroma, and tertiary lymphoid structures (TLS, organized aggregates of immune cells that resemble secondary lymphoid organs) and within defined boundary regions at interfaces between each compartment. **Results:** We discovered that HG PC exhibited higher total immune infiltration (p $<$ 0.05) and specifically TLS (p $<$ 0.05) relative to LG PC. Furthermore, advancing Gleason grade was associated with increased T cell infiltration (p $<$ 0.05) and M2-like macrophage density (p $<$ 0.05). Strikingly, TLS were enriched in exhausted (PD1+) CD4 and CD8 T cells, especially near Tregs (p $<$ 0.001) and demonstrated a higher M2-like to M1-like macrophage ratio compared to surrounding tumor (p $<$ 0.001) and stroma (p $<$ 0.05). We observed paradoxically increased proportions of CD4PD1 cells (p $<$ 0.05) and Tregs (p $<$ 0.05) in HG vs. LG samples at the tumor-TLS interface. In HG samples, CD8PD1 cells (p $<$ 0.01), CD4PD1 cells (p $<$ 0.05), and Tregs (p $<$ 0.05) were enriched in tumor-TLS interface relative to TLS-stroma interface. HG tumors also demonstrated a higher ratio of M2-like to M1-like macrophages at the tumor-TLS interface compared to intra-tumoral regions (p $<$ 0.05). **Conclusions:** Our findings challenge the notion that primary PC is uniformly immunologically inert. We show that HG PC has increased levels of immune infiltration. We describe a paradoxical TLS phenotype in HG PC, where TLS harbor high levels of exhausted T cells near Tregs and have an unfavorable macrophage composition. Critically, the tumor-TLS interface emerged as a unique niche of suppression in HG PC, demonstrating multiple features of lymphocytic and myeloid-driven immunosuppression. These immunosuppressive features were not seen in LG PC. The spatial organization of immunosuppressive cells in HG PC provides a rationale for novel immunotherapeutic targeting of the TLS-rich suppressive landscape of HG PC to improve clinical outcomes in the neoadjuvant setting. Neoadjuvant androgen receptor pathway inhibition for patients with high-risk localized prostate cancer: 5-year survival update and PSMA PET correlatives of the randomized NeoPRO trial. First Author: Gabriel Berlingieri Polho, Hospital Sírio-Libanês, São Paulo, Brazil

Background: Patients with high-risk prostate cancer remain at elevated risk of recurrence after local therapy. Ongoing trials are investigating neoadjuvant strategies using androgen deprivation therapy (ADT) combined with androgen receptor pathway inhibitors (ARPI). **Methods:** This phase II trial randomized patients with Gleason $\geq$ 8 and/or cT3N0-1 and/or PSA $\geq$ 20 ng/mL to receive either goserelin (ADT) plus abiraterone acetate and prednisone (AAP arm) or AAP plus apalutamide (A-APA arm) prior to radical prostatectomy. The primary endpoint was the rate of pathological complete response (pCR) or minimal residual disease (tumor $\leq$ 0.5 cm). Here we present updated survival data after a median follow-up of 59 months. Biochemical-free survival (BFS) was defined as the time from randomization to PSA $>$ 0.1 ng/mL, metastasis, or death. Metastasis-free survival (MFS) was defined as the time from randomization to metastasis or death. Kaplan-Meier method and log-rank tests were used for time-to-event analyses. **Results:** Sixty-two patients were randomized (AAP = 31; A-APA = 31). Previous results showed no significant difference in the primary endpoint (Bastos D, et al. ASCO 2022). A total of 35 patients experienced biochemical recurrence. No significant difference was observed between the AAP and A-APA arms in 5-year BFS (48% vs 35%, p = 0.55) or MFS (83% vs 84%, p = 0.88). Achieving complete PSMA response on PSMA PET prior to surgery was a significant prognostic factor for improved 5-year BFS (28% vs 66%, p = 0.003) and MFS (74% vs 100%, p = 0.009). A trend toward higher 5-year overall survival (OS) was also observed among those with complete PSMA response (87% vs 100%, p = 0.09). Residual cancer burden $\leq$ 0.25 cm³ was associated with better 5-year BFS (32% vs 77%, p = 0.008), but not with MFS (79% vs 100%, p = 0.06) or OS (89% vs 100%, p = 0.22). **Conclusions:** No difference in 5-year BFS or MFS was observed between AAP and A-APA. Complete PSMA response on PSMA PET is a promising prognostic marker and may serve as a surrogate for BFS and MFS after neoadjuvant treatment in high-risk prostate cancer. Clinical trial information: NCT02789878. Research Sponsor: Janssen.

A head-to-head comparison of sextant-systematic biopsy versus extended-systematic biopsy for prostate cancer diagnosis in the era of MRI-targeted biopsy: Non-inferiority randomized clinical trial. First Author: Ruiyi Deng, Peking University First Hospital, Beijing, China

Background: In recent years, combined targeted biopsy (TB) and 12-core extended systematic biopsy (SB) (TB+12SB) has been recommended for biopsy-naïve patients with prostate MRI-visible lesions. However, increasing SB cores elevates complication risks and healthcare expenditure. Retrospective data indicated noninferior PCa detection with TB + sextant-SB (TB+6SB) vs TB+12SB. This RCT aims to compare the novel TB+6SB scheme and classical TB+12SB for PCa diagnosis. **Methods:** In this non-inferiority RCT (NCT06684652), 506 biopsy-naïve men with solitary mpMRI lesions (PI-RADS $\geq$3) underwent transperineal cognitive fusion 3-core TB within the predefined mpMRI index lesion (ROI), followed by randomization to 12-core SB or 6-core sextant SB (2 peripheral+1 transitional cores/side). The primary outcome was clinically significant PCa [csPCa, grade group (GG) $\geq$2] detection rate. Non-inferiority was established if the lower 95% CI bound for the rate difference exceeded -15%. **Results:** Baseline characteristics were similar. TB+6SB demonstrated noninferior csPCa detection versus TB+12SB [54.3% (138/254) vs. 54.8% (138/252); rate difference -0.5%, 95%CI -9.2%-8.3%]. Comparable detection was also observed in PCa, high-grade PCa (GG$\geq$3), and clinically insignificant PCa (GG=1). The concordance in GG between biopsy and radical prostatectomy whole-mount specimens was similar for both TB+12SB [52.3% (34/65), κ=0.55] and TB+6SB [51.7% (30/58), κ=0.50] groups (p=0.25). TB+6SB showed superior safety profiles, significantly relieving the procedural discomfort, reducing the post-biopsy pelvic pain, and improving the quality of life ($p<0.05$). The biopsy time of TB+6SB was significantly shorter than that of TB+12SB ($p<0.001$). **Conclusions:** TB+6SB achieves non-inferior diagnostic efficacy to classical TB+12SB with fewer cores and improved safety, positioning it as an effective strategy for PCa diagnosis in biopsy-naïve patients with solitary MRI-suspicious lesions. TB+6SB could improve operational efficiency, providing both clinical safety and cost-effectiveness in histopathological workflows. Clinical trial information: NCT06684652. Long-term oncologic outcomes of PSMA PET–guided salvage radiotherapy for biochemical recurrence after radical prostatectomy: A systematic review and meta-analysis. First Author: Muhammad Moghis, King Edward Medical University, Lahore, Pakistan

Background: Prostate-specific membrane antigen (PSMA) positron emission tomography (PET) imaging has demonstrated superior diagnostic accuracy over conventional imaging in localizing recurrent prostate cancer after radical prostatectomy. Previous meta-analyses have established its value in detection and treatment planning; however, whether PSMA-guided salvage radiotherapy (SRT) translates into improved long-term oncologic outcomes remains uncertain. We conducted a systematic review and meta-analysis to assess the impact of PSMA PET-guided SRT on survival outcomes in patients with biochemical recurrence after radical prostatectomy. **Methods:** A comprehensive search of PubMed, Embase, and Cochrane Library was performed on January 16, 2025. Studies comparing PSMA PET–guided SRT with conventional SRT in post-radical prostatectomy patients with biochemical recurrence were included. Long-term oncologic outcomes including failure-free survival (FFS), biochemical progression-free survival (bPFS) and metastasis-free survival (MFS), were pooled using hazard ratios (HRs). **Results:** Nine studies comprising 4,278 patients met the inclusion criteria, including 1,418 patients treated with PSMA PET–guided salvage radiotherapy and 2,860 who received conventional salvage radiotherapy. Compared with conventional SRT, PSMA PET–guided SRT was associated with significantly improved FFS (HR, 0.46; 95% CI, 0.28–0.75). However, the PSMA PET-guided SRT group had a significantly higher risk of biochemical progression; bPFS (HR, 1.40; 95% CI, 1.16–1.69) and metastasis; MFS (HR, 3.16; 95% CI, 2.08–4.80). **Conclusions:** PSMA PET–guided salvage radiotherapy was associated with reduced early treatment failure, as reflected by improved failure-free survival, but a higher risk of biochemical progression and metastatic events. These findings indicate that while PSMA PET-guided intervention may reduce early treatment failure, its impact on long-term disease control remains uncertain and requires further prospective validation. Evaluation of treatment outcomes in ductal and intraductal prostate cancer: Insights from the National Cancer Database. First Author: Annabel Ricci, St. George's University School of Medicine, True Blue, St. George, Grenada

Background: Ductal and intraductal Prostate carcinoma (DPC) are rare and aggressive histological subtypes of prostate cancer. Based on risk stratification, treatment strategies for localized DPC include radical prostatectomy (RP), radiation with androgen deprivation therapy (RT$\pm$ADT), and observation. However, literature on outcomes across various treatment modalities in DPC is limited. Understanding the impact of these approaches on survival is important for strategizing DPC management. We used the national cancer database to evaluate the survival outcomes with various treatment strategies in DPC. **Methods:** Our study focused on patients diagnosed with localized DPC between 2004 and 2020. Patients were stratified into three arms: RP arm included those who underwent RP with or without adjuvant therapy, RT +/- ADT arm included patients who underwent RT with or without ADT, and observation arm included those who had no treatment. We performed Multivariate Cox regression analysis adjusting for age, race, NCCN risk classification, comorbidities, socioeconomic factors, and facility type. We also conducted Kaplan-Meier analysis to evaluate Overall Survival (OS) across the treatment arms. **Results:** We analyzed 2,650 patients with localized DPC. 1586(59.9%) underwent RP, 785(29.6%) underwent RT$\pm$ADT, and 279(10.5%) were under observation. 2-year OS for RP, RT$\pm$ADT, and observation were 98%, 94% and 78% respectively ($p<0.001$). Similarly, 5-year OS was 92%, 81%, and 54%, respectively ($p<0.001$). Multivariate Cox regression showed that RT+ADT was associated with increased mortality compared to RP (HR: 2.27; $p<0.001$). 2-year OS for patients with PSA $\leq$4 ng/dL and >4 ng/dL was 89.9% and 97.2%, respectively. Similarly, 5-year OS were 75.8% and 88.8%, respectively. Multivariate Cox regression showed that PSA <=4 was associated with an increased risk of mortality compared with PSA >4 (HR: 1.27; $p<0.05$). **Conclusions:** Surgery offers better survival than radiation in localized DPC. The association of low PSA with worse prognosis could be due to dedifferentiation-driven aggressiveness. Therefore, further evaluation of treatment strategies for DPC is warranted. Research Sponsor: None.

Association of cardiovascular outcomes with GnRH agonist and antagonist therapy in non-metastatic prostate cancer. First Author: Abdulraof Ghiblawi, Lahey Hospital and Medical Centre, Burlington, MA

Background: Androgen deprivation therapy (ADT) is known to increase cardiometabolic risk. Randomized trials suggest GnRH antagonists may reduce major adverse cardiovascular events (MACE) compared with agonists, though studies were limited by short follow-up and low event rates. We evaluated the association between ADT mechanism and cardiovascular (CV) outcomes using large-scale real-world data. **Methods:** We conducted a retrospective cohort study using TriNetX database. Adult men with non-metastatic prostate cancer initiating ADT within 1 year of diagnosis were categorized by GnRH agonist or antagonist exposure. Cohorts were balanced using propensity score, matching demographics, CV co-morbidities, CV medications, and socioeconomic risk. Analyses were performed in the overall cohort and stratified by baseline CVD status. CV outcomes were assessed in years 1-10 following ADT initiation. The primary endpoint was MACE, defined as myocardial infarction, heart failure exacerbation, stroke or cardiac death. Secondary outcomes included atrial fibrillation/flutter, thromboembolism, mortality, and healthcare utilization. **Results:** After matching, 2,538 patients were included in both the GnRH antagonist and agonist group, including 785 with prior CVD and 1,460 without. In the overall cohort, GnRH antagonist therapy was associated with lower risk of MACE compared with GnRH agonists (OR 0.80, 95% CI 0.70–0.99; p=0.05) with an absolute risk of 8.0% vs 9.6%. Among patients with established CVD, antagonist use was associated with reduced MACE risk (OR 0.77, 95% CI 0.64–0.93; $p<0.01$) with an absolute risk of 19.6% vs 25.5%. In patients without prior CVD, antagonist use was associated with markedly lower MACE risk (OR 0.30, 95% CI 0.19–0.52; $p<0.01$) with an absolute risk of 1.3% vs 4.2%. For secondary outcomes, antagonist therapy was associated with lower risk of arterial thromboembolism and Emergency visits in the overall cohort, with no significant differences in all other outcomes. Among patients with baseline CVD, antagonist use was associated with lower risk of atrial fibrillation with no significant differences in all other outcomes. Among patients without baseline CVD, antagonist therapy was associated with lower risk of atrial fibrillation, healthcare utilization, and incident type 2 diabetes with no significant difference in all other outcomes. **Conclusions:** GnRH antagonist therapy was associated with lower rates of major adverse cardiovascular events compared with GnRH agonists, regardless of baseline cardiovascular disease status in years 1 through 10 after ADT initiation. Events occurring after the first year are more likely to reflect cumulative treatment-related cardiovascular toxicity, rather than unmasking baseline disease. These findings support further prospective, randomized trials to define the comparative CV safety of different ADT formulations. Research Sponsor: None.

Temporal evolution of prostate cancer incidence and incidence-based mortality from 2000 to 2022: A retrospective analysis by race and age at diagnosis based on USPSTF screening guidelines. First Author: Charles Tobin, Trinity Health Ann Arbor Hospital, Ypsilanti, MI

Background: Prostate-specific antigen (PSA) screening guidelines have evolved substantially since 2000, influencing detection patterns and outcomes. Despite widespread implementation, significant racial disparities persist in prostate cancer incidence and mortality. Understanding temporal trends across guideline eras, stratified by race and age, is critical for optimizing screening strategies and addressing health equity. **Methods:** Using SEER*Stat, we extracted data from the Surveillance, Epidemiology, and End Results (SEER) database (2000–2022). We employed Jointpoint regression to analyze the secular trend in incidence and incidence-based mortality (IBM), which we classified and arranged by race, age at diagnosis, and year of diagnosis. Annual percentage change (APCs) were calculated using weighted least square method. **Results:** A total of 1,259,662 patients met the inclusion criteria for our study. These included diagnosed cases of prostate cancer from 2000-2022. The total age-adjusted incidence rate was 60.7 per 100,000. The APC from 2000-2007 (before 2008 guidelines) was -0.1 ($p < 0.05$), signifying a cumulative annual decrease. The APC was -2.6 ($p < 0.05$) from 2008-2011, 0.1 ($p < 0.05$) from 2012-2017, and 1.5 ($p < 0.05$) from 2018-2022. Based on race, the APC from 2000-2022 was -2.1 for white, -1.7 for blacks, -2.2 for American Indian/Alaska native (AIAN) and -2.7 for asian and pacific islander (API). Based on age at diagnosis, the APC was -1.9 from 55-64 years, -1.7 from 65-74 years, -2.0 from 75- 84 years, and -2.2 at 85 years and above. In terms of incidence based mortality, rate increased from 2.4 (2000) to 37.7 (2022) in white, with APC of 6.3% (95% CI 5.0–7.7), in black, rate increased from 4.8 (2000) to 60.5 (2022), with APC of 5.2% (95% CI 4.0– 6.4), in API, rate increased from 1.8 (2000) to 17.7 (2022) while in AIAN, rate increased from 2.4 (2000) to 21.5 (2022), with APC of 5.0% (95% CI 3.4–6.6). **Conclusions:** Between 2000 and 2022, prostate cancer incidence demonstrated distinct temporal patterns aligned with changes in PSA screening recommendations, with a marked decline from 2008 to 2011, minimal change from 2012 to 2017, and an increase from 2018 to 2022. Across the same period, incidence-based mortality (IBM) increased steadily in all racial groups, despite long-term declines in overall incidence. Incidence-based mortality rates were consistently higher in black patients compared with white patients throughout the study period. These findings demonstrate a difference between incidence and incidence-based mortality over time and highlight persistent racial differences in prostate cancer outcomes across multiple screening eras. Addition of 18F-DCFPyL PSMA PET to MRI to avoid unnecessary biopsy in men on active surveillance: Final results from a phase II diagnostic trial (PROMPT). First Author: Marcelo Bigarella, University of Arkansas, Little Rock, AR

Background: Multiparametric MRI (mpMRI) is used in active surveillance (AS) for prostate cancer (PC) but has limited specificity. This prospective trial evaluated whether combining 18F-DCFPyL PSMA PET with mpMRI improves the detection of clinically significant PC (csPC) in patients on AS and reduces unnecessary biopsies prompted by false-positive mpMRI. **Methods:** In this IRB-approved, single-arm Phase II study, 91 patients on AS underwent PSMA PET and mpMRI on a dedicated PET/MRI scanner followed by systematic and targeted biopsies. PET and mpMRI were interpreted independently. The primary outcome was the diagnostic accuracy of mpMRI versus the combined PSMA PET/MRI for csPC. **Results:** Among 246 targeted lesions, the area under the curve (AUC) for combined PSMA PET/MRI was (0.77) compared to mpMRI alone (0.70) (p=0.2). PSMA PET/MRI showed improved specificity (64.6% vs. 27.5%) with a comparable negative predictive value (89.1% vs. 89.7%). Of 57 csPC lesions, 6 (10.5%) were uniquely identified by the combination. Half of the biopsies for false-positive mpMRI or PET lesions (122/246; 50%) encompassing 17/91 (19%) of patients could have been avoided with combined imaging. Management changed in 9% of patients based on PET/MRI. **Conclusions:** In this first-in-field trial the addition of PSMA PET to mpMRI with dedicated PET/MRI imaging enhances sensitivity in detecting csPC and may reduce the need for unnecessary biopsies in AS patients. Incorporating PSMA PET/MRI into clinical practice could refine surveillance protocols and support biopsy omission in select men with negative imaging. The single health-system nature of the trial may limit the generalizability of our findings. Research Sponsor: the Duane and Dorothy Bluemke Foundation.

Leveraging spatial proteomics to identify epithelial cell subtypes driving poor prognosis in prostate cancer. First Author: William Chen, University of California, San Francisco, San Francisco, CA

Background: Epithelial cell features, such as morphology and cellular organization within the tumor architecture (e.g. Gleason Score), have long been known to be prognostic in prostate cancer. However, the specific epithelial cell subtypes driving clinical outcomes in patients remains unclear. Traditional tumor profiling techniques lack the resolution needed to interrogate complex single-cell biomarkers. Imaging Mass Cytometry (IMC) now enables high-dimensional identification and detailing of epithelial, stromal, and immune cell subtypes within patient tumors. Using a custom IMC panel, we profiled tumor biopsies from a large prospective biopsy cohort with long-term (median >12-year) clinical follow-up to identify potentially targetable epithelial cell populations associated with adverse outcomes in localized prostate cancer. **Methods:** Spatially resolved protein expression profiling was performed on primary prostate cancer tumor biopsies using a custom IMC assay enriched for targetable tumor markers. Cell segmentation and single-cell expression measurement were performed using the published 'steinbock' toolkit. Biochemical progression-free survival (bPFS) and cancer-specific survival (CSS) were pre-specified clinical endpoints. Univariate and multivariable survival analyses stratified by cell abundance tertiles were performed using a Cox proportional hazards model. The Mann-Whitney U test was used to assess for pairwise differences in cell abundance between patient groups. All significance testing was performed using a two-tailed significance level of 0.05. **Results:** Protein co-expression patterns in >3.4 million cells comprising 573 biopsy samples obtained from 385 patients were measured. Single-cell analysis revealed 15 cell clusters representing luminal prostate cancer cells (including PSMA-high, PSMA-intermediate, and PSMA-low), basal epithelial cells, and lymphocytes. Patients with tumors enriched for PSMA-high epithelial cells demonstrated impaired bPFS ($P<0.001$) and CSS ($P=0.016$). PSMA-high epithelial cells were enriched in high-grade (Gleason Score 8+) tumors ($P<0.05$). Multivariable analysis revealed PSMA-high epithelial cell enrichment to be prognostic of bPFS independently of Gleason Score and serum PSA at time of diagnosis ($P<0.05$). Co-expression analysis demonstrated that these prognostic PSMA-high cells also expressed high levels of the cell-surface targets KLK2, B7-H3, and protein. **Conclusions:** We identified an epithelial single-cell biomarker associated with adverse clinical outcomes in localized prostate cancer. If validated through ongoing experiments in an independent cohort, our findings support new potential strategies for treatment intensification using targeted therapies in select high-risk patients. Clinical implications and diagnostic utility of ^{68}Gallium FAPI PET CT in patients with testicular germ cell tumors: The prospective phase Ib FAPI-TEST study. First Author: Maximilian Peter Johannes Karl Brandt, Department of Urology, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany

Background: The fibroblast activation protein (FAP) is overexpressed in tumor tissue by cancer associated fibroblasts and radiopharmaceuticals can bind to this target. Recently, the ^{68}Ga-FAPI PET has emerged as a novel imaging modality for optimized differentiation between benign and malignant lesions. However, data on patients with testicular germ cell tumors (TGCT) are rare. This prospective study aims to investigate the expression, uptake and sensitivity of the ^{68}Ga-FAPI PET in TGCT patients. **Methods:** In this prospective observational phase Ib study, patients with TGCT up to clinical stage III and unfavorable TGCT histology in the testis such as teratomas were included. A ^{68}Ga-FAPI PET was performed in all included patients and analyzed with static (SUVmax/mean). Histology from the testis and whenever available from the metastasis were also stained for FAP and manually categorized into negative, medium and high expression. This study was approved by the local ethics committee (no 2024-17844). **Results:** We included 12 patients with a mean age of 34.5 (SD 8.81). Clinical stage at time of inclusion were CS II (n = 9), CS1 (n = 1) and CS III (n = 1) as well as one extragonadal TGCT. In eight and four cases the ^{68}Ga-FAPI PET was performed before and after completion of curative chemotherapy, respectively. Histology was available in six cases (5 = LNs, 1 = mediastinal tumor). FAP expression in the tumor of the testis was high in 50%, and in metastasis 60%. Stratification for high and low FAP lesions was performed according to mean SUVmax of 7.81 (SD 7,9) for all radiographic and histopathologic true positive metastasis. Sensitivity for ^{68}Ga-FAPI PET was 57% with a specificity 100%. **Conclusions:** This is the first prospective study that evaluates ^{68}Ga-FAPI PET in TGCT patients with the largest cohort so far. Stratification for SUVmax lesions above 7.81 showed excellent specificity, and the 68Ga-FAPI PET might potentially serve as a useful novel imaging modality for primary staging in clinical stages IIA and IIB, as well as post-chemotherapy with residual mass. Research Sponsor: None.

First-in-human PET imaging of ^{68}Ga-FC516, a novel ACP3-targeted radiotracer for prostate cancer. First Author: Kongzhen Hu, Department of Nuclear Medicine, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China

Background: Prostatic acid phosphatase (ACP3) is overexpressed in more than 85% of prostate cancers, and largely absent in normal tissues, resulting in over 100-fold tumor-to-background specificity. ACP3 represents a differentiated imaging biomarker that may complement prostate-specific membrane antigen (PSMA), particularly in PSMA-low or PSMA-treated patients. We developed ^{68}Ga-FC516, a novel ACP3-targeted radiotracer, and evaluated its preclinical characteristics and first-in-human imaging performance. **Methods:** ^{68}Ga-FC516 was studied preclinically using *in vitro* assays (radiochemical stability, enzyme inhibition, cellular uptake, internalization, and efflux) and *in vivo* PET/CT studies, including blocking and biodistribution experiments. A first-in-human exploratory clinical trial was conducted in healthy volunteers and prostate cancer patients. The primary objective was to assess safety and radiation dosimetry; secondary objectives included biodistribution assessment and lesion detection. PET/CT imaging results were compared with PSMA radiotracers or ^{68}Ga-OncoACP3-DOTA when possible. **Results:** ^{68}Ga-FC516 was labeled efficiently with radiochemical purity exceeding 95%. In *in vitro* studies, ^{68}Ga-FC516 demonstrated potent target binding, long cellular retention and high stability. ACP3-specific tumor uptake of ^{68}Ga-FC516 was confirmed via an *in vivo* blocking experiment. The tracer showed low background uptake in liver, kidneys, and salivary glands, with tumor uptake exceeding 16.4% ID/g in a biodistribution study. Gallbladder uptake was markedly lower than that of ^{68}Ga-OncoACP3-DOTA (2.6% vs. 35.0% ID/g) at 1 hour post-injection. In an ongoing clinical trial in metastatic prostate cancer patients, increased uptake of ^{68}Ga-FC516 (SUV_{max} in PET/CT) was observed at 1 to 3 hours across all lesions, with improved tumor-to-kidney ratios over time. The tracer also demonstrated low background uptake, including in salivary glands and kidneys, which was significantly lower than that of PSMA-targeted tracers. Notably, a patient with both prostate and rectal cancers showed strong uptake in the prostate tumor (SUV_{max} 44), but no uptake in the rectal lesion, further establishing the tracer's superior specificity. No adverse events were observed. **Conclusions:** We have shown that ^{68}Ga-FC516 has high ACP3-targeting specificity, low background uptake and excellent imaging performance in preclinical and first-in-human clinical studies. These findings support the potential of ACP3 as a differentiated biomarker for prostate cancer diagnosis and patient stratification, complementing PSMA PET and addressing unmet needs in PSMA-low or PSMA-treated patient populations. The clinical validation study was approved by the Ethics Committee of the First Affiliated Hospital of Jinan University (KY-2025-254). Research Sponsor: FindCure Biosciences Co., Ltd. Clinical trial information: KY-2025-254. Research Sponsor: None.

Explainable machine learning for continuous transcriptomic modeling of metastatic risk in prostate cancer (MET-score). First Author: Sonia Macia, SMED Clinical Research, Alicante, Spain

Background: Metastatic progression is the leading cause of mortality in prostate cancer, yet clinicopathological stratification incompletely identifies primary tumors with latent metastatic potential. Emerging evidence supports metastatic competence as a gradual transcriptional reprogramming, motivating molecular tools that capture continuous risk states. **Methods:** Transcriptomes from primary and metastatic prostate tumors (n = 766; PRIMARY = 507, MET = 259) spanning 16,234 gene features were integrated to train an interpretable XGBoost model. SHapley Additive exPlanations were used to derive a minimal 30-gene signature and define a continuous metastasis-likeness transcriptomic score (MET-score). MET-score was applied to primary tumors to quantify metastasis-likeness and characterize associated biology. External validation was performed in an independent primary prostate cohort profiled with exon microarrays (GSE21034) without model retraining. **Results:** The minimal 30-gene signature captured metastasis-associated signal with high discriminative performance (ROC AUC $\approx$ 0.98). In primary tumors (n = 507), MET-score exhibited a right-skewed continuous distribution (mean 0.0079, SD 0.0640; range 0.0023–0.9953), consistent with heterogeneous degrees of metastasis-like transcriptional activity within primary disease. Using a prespecified high-risk threshold at the 0.85 quantile (cutoff 0.002603), 81/507 (16.0%) primary tumors were classified as HIGH MET-score and 426/507 as LOW, identifying a subset with transcriptomic profiles most closely resembling metastatic disease. MET-score generalized robustly to GSE21034 while preserving its continuous structure and enabling molecular stratification despite platform differences and partial gene loss: 26/30 signature genes were present in the microarray cohort (missing C15orf40, ADIRF, CTC1, NTPCR). However, prognostic validation against clinical endpoints could not be performed because the publicly available metadata did not include clearly annotated time-to-event and event-status variables. **Conclusions:** An explainable 30-gene MET-score was developed to quantify metastasis-likeness as a continuous transcriptomic trait in primary prostate cancer. The score identifies a high-risk primary subset and transfers to an independent external cohort (GSE21034) without model retraining, supporting cross-platform robustness and prioritizing MET-score for clinical outcome validation in RNA-seq–annotated cohorts. Research Sponsor: None.

cfDNA-based signatures of nucleosome organization to enable prostate cancer subtyping. First Author: Weiwei Bian, Dana-Farber Cancer Institute, Boston, MA

Background: Neuroendocrine prostate cancer (NEPC) can arise from prostate adenocarcinoma (PRAD) via therapy-associated lineage plasticity and is characterized by reduced AR signaling and activation of neuroendocrine (NE) regulatory pathways. Nucleosome positioning, inferable from cell-free DNA (cfDNA) fragmentation patterns, reflects lineage-specific gene regulation. Recent studies have shown that active, open chromatin is associated with specific nucleosome spacing patterns, leading to an enrichment of longer cfDNA fragments, including di-nucleosome fragments. We hypothesized that fragmentomic signatures reflecting nucleosome positioning could distinguish PRAD from NEPC, providing a simple means to detect lineage plasticity from cfDNA. **Methods:** We analyzed cfDNA samples from 47 patients (8 with NEPC, 39 with PRAD) with hybrid-capture sequencing. Baits were designed to target adenocarcinoma (AC, 715 sites) and NE-associated regulatory elements (508 sites). For each sample, fragments overlapping each enhancer set were aggregated into 5-bp binned fragment-length distributions (18-500 bp). We quantified di-nucleosome (250-400 bp) and mono-nucleosome (120-180 bp) fragment counts at NE and AC regulatory elements. We calculated the log-ratio of NE versus AC di/mono values: log2 [(di/mono)_NE/(di/mono)_AC]. We also computed a position-free Transcriptional Activation Score (pfTAS) for each enhancer set using a published framework for estimating enhancer activity from cfDNA fragment size distributions, deriving an analogous log-ratio: log2 [pfTAS_NE/pfTAS_AC]. We tested if these ratios could distinguish NEPC versus PRAD, evaluating the area under the receiver operating characteristic curve (AUC) in the full cohort and by leave-one-out cross-validation (LOOCV). **Results:** The enhancer-specific di/mono log-ratio achieved complete separation between PRAD (median: -0.209; range: -0.449 to -0.090) and NEPC (median: 0.030; range: -0.056 to 0.218), yielding an AUC of 1.00 both in-sample and by LOOCV. The pfTAS log-ratio was also discriminative, with an AUC of 0.99 in-sample and an AUC of 0.89 by LOOCV. Overall, nucleosome fragmentation patterns provide a chromatin-based fragmentomic signal that enables accurate discrimination between PRAD and NEPC. **Conclusions:** Leveraging hybrid-capture cfDNA, we identified a biologically grounded chromatin-based signature that robustly discriminates NEPC from PRAD. By reflecting lineage-associated nucleosome positioning, this liquid biopsy-based approach provides a cost-effective and non-invasive molecular metric derived from routinely generated cfDNA sequencing data. It may be particularly useful in clinically challenging settings, including cases with mixed morphology or when a biopsy is difficult to obtain. Research Sponsor: None.

Randomized phase 1 trial of cisplatin-based chemotherapy with or without sodium thiosulfate for men with metastatic germ cell tumor (GCT). First Author: Koral U. Shah, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Cisplatin-induced ototoxicity remains a major survivorship issue in men with metastatic GCT. Sanchez et al., demonstrated that among adult GCT survivors, 78% develop hearing loss, with severity associated with cumulative cisplatin exposure. Sodium thiosulfate (STS; PEDMARK) was FDA-approved in 2022 to reduce the risk of cisplatin-associated ototoxicity in pediatric patients 1 month of age and older with localized, non-metastatic solid tumors. However, prospective data in adults with metastatic GCT receiving curative intent cisplatin-based therapy are lacking. This study aims to address this gap in men with metastatic GCT, and potentially improve long-term quality of life. **Methods:** This open-label, single-center, randomized phase 1 trial evaluates sodium thiosulfate for reducing the incidence of cisplatin-induced ototoxicity in adults with metastatic GCT. Eligible adults have stage II–III GCT and are planned for first- or second-line cisplatin-based chemotherapy; patients receiving second-line therapy require a $\geq$4-week cisplatin washout to establish a new audiometric baseline. Key exclusions include baseline moderate or greater hearing loss, hypersensitivity to sodium thiosulfate or related compounds, chronic systemic corticosteroid use, concurrent non-cisplatin ototoxic medications, and comorbidities requiring sodium restrictions. Participants are randomized 2:1 to receive cisplatin-based chemotherapy with sodium thiosulfate versus chemotherapy alone, with a target enrollment of 39 patients. Sodium thiosulfate is administered intravenously at 20 g/m² over 30 minutes, beginning 6 hours after completion of cisplatin infusion and at least 10 hours before the next cisplatin dose, consistent with FDA-approved multi-day dosing schedules. The primary endpoint is the incidence of clinically meaningful ototoxicity, defined by trial parameters using American Speech-Language-Hearing Association criteria relative to baseline audiometry. Secondary endpoints include incidence of high-frequency ototoxicity, ototoxicity severity, safety per Common Terminology Criteria for Adverse Events (CTCAE) v5.0, and 2-year progression-free survival. Ototoxicity monitoring is performed using serial high-frequency audiometry (testing 250–12,500 Hz) at baseline and 1, 3, and 6 months following completion of cisplatin therapy. Ototoxicity incidence will be compared between arms using a one-sided Fisher's exact test under a modified intention-to-treat framework. Enrollment has begun. Clinical trial information: NCT07218913. Research Sponsor: Fennec Pharmaceuticals Inc.

TPS5132 **Poster Session**

Protocol for ADHERE: A randomised controlled trial evaluating a digital exercise intervention with virtual supervised group exercise sessions compared to standard of care for patients receiving androgen deprivation therapy for prostate cancer. First Author: Emily Curtis, The Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom
Abstract Disclosures

Background: In the UK, supervised exercise is recommended by NICE for prostate cancer patients receiving androgen deprivation therapy (ADT); however, engagement in physical activity remains limited. Although high adherence is observed during supervised exercise, it is unclear whether participants maintain activity after supervision. Barriers include treatment-related side-effects and low motivation. Digital exercise interventions that include education and behaviour change support may address these barriers and promote sustained engagement in physical activity. **Methods:** The primary objective of ADHERE is to determine whether a digital exercise intervention incorporating virtual group exercise sessions improves adherence to physical activity compared with standard of care (SOC). Secondary and exploratory objectives include assessment of health-related quality of life (HRQoL), fatigue, physical function, clinical biomarkers and participant experiences, and evaluation of cost-effectiveness. ADHERE is a single-centre, phase III, two-arm randomised controlled trial. Prostate cancer patients within eight weeks of starting ADT and planned for radiotherapy will be recruited at The Royal Marsden NHS Foundation Trust. Participants will be randomised 1:1, stratified by ADT duration (≤6 months or >6 months), to SOC alone or SOC plus the digital exercise intervention. The intervention includes virtual supervised group exercise sessions delivered weekly over 26 weeks, access to exercise videos, an individualised exercise programme, educational content and "patient buddy" support. Assessments will be conducted at baseline and three, six, and 12-months post-radiotherapy. Primary endpoint is adherence to physical activity guidelines at six months post-radiotherapy, assessed using device-based activity monitor and self-reported exercise diary. Secondary endpoint is HRQoL and will be measured using FACT-P. 160 participants (80 per arm) will be recruited allowing for 20% dropout. ADHERE has ethical and regulatory approval and will be conducted in accordance with Good Clinical Practice. Recruitment for this trial started in December 2025. An interim analysis will be conducted, with final analyses performed following completion of all participant follow-up. Results will be disseminated via peer-reviewed publications and conferences. Clinical trial information: NCT07243834. Research Sponsor: None.

DEPECA-1 (Defeating Penile Cancer 1): A phase II study to evaluate a first-line systemic therapy with enfortumab vedotin plus avelumab for advanced and metastatic penile carcinoma. First Author: Igor Tsaur, Department of Urology, University Hospital Tuebingen, Tuebingen, Germany

Background: Squamous cell carcinoma of the penis (PeCa) is a rare malignancy with unfavorable outcomes in advanced stage. Since the 1990s, platinum-based chemotherapy has been the standard of care for the first-line treatment of metastatic disease. Unfortunately, it is characterized by a response rate of 30-40%, overall survival (OS) of 17 months and progression free survival (PFS) of 6 months at most. Thus, there is a critical medical need to assess novel systemic strategies for PeCa in the first-line setting, given that current regimens are of a limited clinical benefit while exposing patients to considerable chemotherapy-associated toxicities. In this context, the PD-1 inhibitor pembrolizumab yielded a promising activity in squamous cell carcinomas of various origins. Meanwhile, enfortumab vedotin (EV), a Nectin-4 directed antibody-drug-conjugate, in combination with pembrolizumab has been recently approved for the treatment of metastatic urothelial cancer. The incidence of ≥3 grade adverse events with this regimen was > 55%. Notably, a PD-L1 inhibitor avelumab provided a comparable activity as pembrolizumab but a lower overall rate of endocrine adverse events in patients with urothelial carcinoma. Avelumab monotherapy yielded a response rate of 17% and a median duration of response of 16 months in males with a platinum-refractory PeCa or those unfit for platinum chemotherapy in ALPACA trial. Given that approximately 60% of PeCa tissues express both PD-L1 and Nectin-4, the combination of EV with avelumab represents a potentially synergistic therapeutic strategy, leveraging both direct cytotoxicity and immune-mediated anti-tumor activity through complementary mechanisms of action. **Methods:** The DEPECA-1 trial is an investigator-initiated, open label, single-arm, multicenter phase II trial, enrolling 25 males with locally advanced or metastatic PeCa at 10 sites in Germany. Patients must be ineligible for curative surgery and not have received any prior systemic palliative therapy. Participants (ECOG ≤ 2) will receive 1200 mg avelumab on day 1 and EV (1,25 mg/kg) on day 1 and day 8 in a 3-week -cycle for a maximum of 24 months and 32 cycles. Primary endpoint is the objective response rate (ORR) assessed per RECIST 1.1. Secondary endpoints include PFS, OS, duration of response (DOR), disease control rate (DCR) and patient-related outcomes. Exploratory analysis comprises tumor biomarker profiling. DEPECA-1 has received regulatory approval on 29th October 2025. First patient was enrolled on December 16, 2025. Registration IDs: EU CT No. 2025-521644-37-00/NCT07110038. Clinical trial information: NCT07110038. Research Sponsor: Merck Healthcare KGaA; Astellas Pharma GmbH.

TPS5134 **Poster Session**

AcTFirst: A phase 3 trial of ^{225}Ac-PSMA-617 plus ARPI versus standard of care in adults with PSMA-positive metastatic castration-resistant prostate cancer. First Author: Alton Oliver Sartor, LCMC Health, New Orleans, LA

Background: In the VISION and PSMAfore trials, β-emitting radioligand therapy (RLT) with [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) shows superior efficacy and tolerable safety compared with standard of care (SoC) in patients with prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer (mCRPC). [^{225}Ac]Ac-PSMA-617 (^{225}Ac-PSMA-617), an α-emitting agent, may offer an alternative treatment option to SoC in mCRPC because its higher linear energy transfer increases the likelihood of higher cytotoxicity in tumor cells. **Methods:** AcTFirst (NCT06855277) is a phase 3, open-label, multicenter, randomized study to evaluate the efficacy and safety of ^{225}Ac-PSMA-617 plus androgen receptor pathway inhibitor (ARPI) in patients with PSMA-positive mCRPC. Eligible participants are adults with PSMA positron emission tomography-positive mCRPC and progressive disease on androgen deprivation therapy plus one ARPI as their last treatment in the metastatic hormone-sensitive prostate cancer (mHSPC) or earlier setting. ARPI treatment received in the mHSPC setting can be continued until cycle 1. Key exclusion criteria include previous treatment with RLT or systemic anti-cancer therapy for mCRPC. Participants with homologous recombination repair gene-mutated mCRPC who had prior exposure to poly-adenosine diphosphate ribose polymerase inhibitors (PARPi) for HSPC can be included. Participants with inadequate bone marrow, hepatic or renal function are excluded. Participants will be randomized to three treatment arms: 1) a combination of ^{225}Ac-PSMA-617 (up to six cycles) plus ARPI change (enzalutamide or abiraterone); 2) ^{225}Ac-PSMA-617 monotherapy (up to six cycles); or 3) investigator's choice of SoC (ARPI change, taxane chemotherapy or ^{177}Lu-PSMA-617). Efficacy will be assessed using a hierarchical group sequential testing strategy for the primary and key secondary objectives. The primary endpoint is radiographic progression-free survival (rPFS) by conventional imaging for the combination and SoC arms. Key secondary endpoints are overall survival (OS) for the combination and SoC arms, rPFS by conventional imaging for the monotherapy and SoC arms, OS for the monotherapy and SoC arms, and rPFS by PSMA positron emission tomography/computed tomography imaging for the combination and SoC arms. Other outcomes of interest include safety, health-related quality of life and other patient-reported outcomes. As of January 2026, patient enrollment is ongoing. Clinical trial information: NCT06855277. Research Sponsor: Novartis.

TPS5135 **Poster Session**

OMAHA-004: Phase 3 trial of the steroidogenesis inhibitor opevesostat versus androgen receptor pathway inhibitor (ARPI) switch in participants with metastatic castration-resistant prostate cancer (mCRPC) after a prior ARPI. First Author: Donald Charles Vile, Blue Ridge Cancer Care, Roanoke, VA

Background: Opevesostat (MK-5684; ODM-208) is an oral, nonsteroidal inhibitor of cytochrome P450 11A1 (CYP11A1), a catalyst of the first and rate-limiting step of steroid biosynthesis. Opevesostat showed antitumor activity in participants with heavily pretreated mCRPC in the phase 1/2 CYPIDES trial. The randomized, open-label, phase 3 OMAHA-004 trial (NCT06136650) is designed to evaluate the efficacy and safety of opevesostat in participants with mCRPC after a prior ARPI. **Methods:** Eligible participants have mCRPC that progressed during androgen deprivation therapy ≤6 months before screening and on or after 1 ARPI for metastatic or nonmetastatic hormone-sensitive prostate cancer (HSPC) or CRPC for ≥8 weeks (≥14 weeks with bone progression). Prior ARPI plus docetaxel for HSPC is permitted if participants received no more than 6 cycles of docetaxel without radiographic disease progression. Approximately 1314 participants will be randomized 1:1 to opevesostat 5 mg orally twice-daily plus dexamethasone 1.5 mg and fludrocortisone 0.1 mg orally once daily or abiraterone acetate 1000 mg orally once daily plus prednisone 5 mg orally twice daily (if prior enzalutamide, darolutamide, or apalutamide) or enzalutamide 160 mg orally once-daily (if prior abiraterone). Stratification factors are metastatic site (bone only vs liver vs other), androgen receptor ligand binding mutation (AR-LBDm) status (positive vs negative), and prior docetaxel treatment for HSPC (yes vs no). Once the predefined enrollment threshold for participants with either mutation status (AR-LBDm-positive, ~400 participants or AR-LBDm-negative, ~914 participants) is met, no additional participants with that mutation status will be permitted to enroll. The protocol was amended to use radiographic progression-free survival per Prostate Cancer Working Group 3 (PCWG3)-modified RECIST v1.1 by blinded independent central review (BICR), analyzed separately in participants with AR-LBDm–positive and –negative disease, as the primary end point and overall survival as a key secondary end point. Other secondary end points include time to initiation of first subsequent anticancer therapy or death, objective response rate and duration of response per PCWG3-modified RECIST v1.1 by BICR, time to pain progression; time to prostate-specific antigen (PSA) progression, PSA response rate, time to first symptomatic skeletal-related event, and safety and tolerability. Enrollment is ongoing. Clinical trial information: NCT06136650. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; Orion Corporation, who are codeveloping opevesostat.

TPS5136 **Poster Session**

A phase 3 randomized, double-blind, placebo-controlled study of a pasritamig plus best supportive care in metastatic castration-resistant prostate cancer. First Author: Kim N. Chi, BC Cancer Agency, Vancouver, BC, Canada

Background: Metastatic castration-resistant prostate cancer (mCRPC) remains an incurable disease with high morbidity and a median overall survival of 2 years. Human kallikrein 2 (KLK2) is highly and specifically expressed in normal and malignant prostate tissue, including late stage mCRPC. Pasritamig is a humanized, IgG1-based bispecific antibody that targets KLK2-expressing cells via CD3 engagement, inducing T cell-mediated targeted cytotoxicity. In a first-in-human study in participants with mCRPC refractory to standard therapies, pasritamig demonstrated a favorable safety profile ($<$ 5% grade 3 or higher treatment-related adverse events and $<$ 10% cytokine release syndrome, all grade 1) and encouraging efficacy at the recommended phase 2 dose with every 6-week (Q6W) outpatient dosing. **Methods:** KLK2-comPAS is a double-blind, randomized, global phase 3 study to evaluate the safety and efficacy of pasritamig in participants with mCRPC who have previously received all available and suitable life-prolonging therapies including androgen receptor pathway inhibitor, taxane chemotherapy, radioligand therapy (RLT), and poly(ADP-ribose) polymerase inhibitors (for patients with BRCA mutations). Other key inclusion criteria include ECOG performance status 0–2, PSA $\geq$2 ng/mL, adequate organ function, and ongoing androgen deprivation therapy or prior orchiectomy. Key exclusion criteria include visceral metastases, prior KLK2- or CD3-directed therapies, and active autoimmune disease requiring systemic immunosuppression. Approximately 663 patients will be randomized in a 2:1 ratio to receive pasritamig plus best supportive care (BSC) or placebo plus BSC, stratified by prior PSMA-targeted RLT, number of prior taxanes, and ECOG performance status. BSC may include palliative external beam radiation, low dose steroids, pain medications, bone protective agents, and needed palliative procedures. Pasritamig is administered outpatient at a target dose of 300 mg IV Q6W with two step-up doses of 3.5 mg IV on cycle 1 day 1 and 18 mg IV on cycle 1 day 8. Pre-medications (dexamethasone, diphenhydramine, acetaminophen) will be administered for step-up and first target dose. Participants will receive treatment until confirmed radiographic progression or unequivocal clinical progression, intolerable toxicity, withdrawal, or death. The primary endpoint is overall survival. Key secondary endpoints include radiographic progression-free survival (rPFS), PFS (including clinical progression and unconfirmed bone progression), time to symptomatic progression, and time to skeletal-related events. Enrollment commenced in September 2025 and remains ongoing. Clinical trial information: NCT07164443. Research Sponsor: J&J.

TPS5137 **Poster Session**

BNT324-03: Phase 3, randomized, open-label trial of BNT324/DB-1311, a B7H3 ADC, versus docetaxel in patients with taxane-naïve metastatic castration-resistant prostate cancer (mCRPC). First Author: Johann S. De Bono, Royal Marsden Hospital, London, United Kingdom

Background: B7H3 is highly expressed in various human cancers, including mCRPC, and overexpression is associated with a poor patient prognosis. BNT324/DB-1311 is an investigational B7H3 ADC comprised of a topoisomerase-I-inhibitor-based payload with a cleavable linker and a drug-to-antibody ratio of ~6 that received FDA Fast-Track Designation for previously treated CRPC. A phase 1/2 study (DB-1311-O-1001, NCT05914116) is currently enrolling several prostate cancer cohorts: post Lutetium-177 [^{177}Lu]-PSMA-617 radioligand (RLT) (Lu 177-RLT) mCRPC, taxane-naïve mCPRC, and castration-sensitive prostate cancer (CSPC) with suboptimal PSA response, with patients receiving BNT324/DB-1311 alone or with abiraterone or enzalutamide. This study has reported encouraging activity (median radiographic PFS 11.3 months) and a manageable safety profile in heavily pretreated mCRPC (Parsonson A, ASCO 2025 #5015), and in Lu 177-RLT pretreated mCRPC (Stein M, ASCO GU 2026 #176). The treatment landscape of mCRPC has been evolving. As first use of an androgen receptor pathway inhibitor (ARPI) has shifted to the mCSPC setting, more patients will receive docetaxel in early-line mCRPC. The use of Lu 177-RLT in taxane-naïve mCRPC has been increasing; however, outcomes with subsequent docetaxel appear suboptimal. Docetaxel remains the first-line treatment option for symptomatic or rapidly progressive mCRPC, but outcomes are poor. Overall, there is a high unmet need for novel effective and better tolerated treatment options in the post-ARPI and emerging post-RLT settings. **Methods:** BNT324-03 is an open-label, randomized, Phase 3 trial (NCT07365995) designed to determine the efficacy and safety of BNT324 compared with docetaxel in patients ($>$ 18 years, ECOG PS 0–1) with mCRPC previously treated with 1 or 2 prior ARPIs. Patients may have received prior Lu 177-RLT but must not have received prior taxane for mCRPC (allowed in mCSPC if $\geq$6 months since completion without disease progression). Prior treatment with B7H3 targeted therapy is not allowed. Approximately 736 patients will be randomized 1:1 to receive either BNT324 or docetaxel (+ prednisone/prednisolone). Unless there is unacceptable toxicity or withdrawal of consent, BNT324 will be administered until PCWG3-modified RECIST v1.1-defined progressive disease and docetaxel will be administered for up to 10 cycles. Randomization will be stratified by prior Lu 177-RLT, prior taxane use, and site of metastasis. The dual primary endpoints are to assess the efficacy of BNT324 in terms of radiographic PFS and OS when compared with docetaxel. Secondary endpoints include time to first subsequent therapy, ORR and DOR by BICR, time to pain progression, time to first symptomatic skeletal-related event, PSA response and time to PSA progression, and safety. Enrollment is ongoing globally. Clinical trial information: NCT07365995. Research Sponsor: BioNTech SE in collaboration with BioNTech Shanghai Pharmaceutical Co., Ltd and DualityBio Inc.

TPS5138 **Poster Session**

A phase II clinical trial of ivonescimab (VEGFxPD-1 bispecific antibody) in patients with metastatic castration-resistant prostate cancer (mCRPC). First Author: Bilal Ahmed Siddiqui, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with mCRPC achieve limited responses with single-agent immune checkpoint therapies (ICTs), due to tumor microenvironments (TME) characterized by few intratumoral effector T cells and high prevalence of suppressive myeloid cell populations, cytokines, and signaling pathways. In murine models of mCRPC, tyrosine kinase inhibitors (TKIs, i.e. against vascular endothelial growth factor [VEGF] receptor 2, MET, and AXL, among others) inhibited tumor infiltrating myeloid-derived suppressor cells and enhanced responses to ICTs (Lu X et al., *Nature* 2017). Consistent with this, a phase III clinical trial combining TKI and anti-PD-(L)1 demonstrated improved clinical outcomes in a subset of patients with mCRPC (Agarwal N et al., *Lancet Oncol* 2025). Ivonescimab is a first-in-class bispecific antibody simultaneously targeting PD-1 and VEGF-A that has demonstrated clinical activity across multiple tumor types. We hypothesized that ivonescimab will induce anti-tumor responses in a subset of patients with mCRPC. **Methods:** This is an open-label, single-center phase II clinical trial in patients with mCRPC with histologically or cytologically confirmed adenocarcinoma of the prostate without neuroendocrine differentiation or small cell histology. The primary endpoint of the study is objective response rate per Prostate Cancer Working Group 3 (PCWG3) criteria, and secondary endpoints include duration of response (DOR), disease control rate (DCR) greater than 6 months), radiographic progression free survival (rPFS), PSA_{50} responses (defined as confirmed $>$ 50% decline in PSA from baseline) and incidence, severity, and duration of adverse events. Tumor biopsies are collected at baseline and prior to C2D1 for evaluation of biomarkers of response and resistance to therapy. The study is being conducted using a Bayesian optimal phase 2 (BOP2) design. A total of up to 24 patients will be enrolled on study. The study is currently open and enrolling (NCT06567314). Clinical trial information: NCT06567314. Research Sponsor: None.

TPS5139 **Poster Session**

A phase 3 randomized, open-label study of pasritamig (JNJ-78278343), a T-cell engager targeting human kallikrein-2, with docetaxel versus docetaxel for metastatic castration-resistant prostate cancer. First Author: Rana R. McKay, UC San Diego Moores Cancer Center, La Jolla, CA

Background: Metastatic castration-resistant prostate cancer (mCRPC) remains an incurable disease with high morbidity and a median overall survival of approximately two years. Human kallikrein 2 (KLK2) is highly and specifically expressed in normal and malignant prostate tissue, including late stage mCRPC. Pasritamig (PAS) is a first-in-class bispecific T-cell-engager that simultaneously binds KLK2 on prostate cancer cells and CD3 receptor complexes on T cells. In the Phase 1b study (NCT05818683), pasritamig was combined with docetaxel (DOCE) to treat patients with mCRPC. The safety profile of PAS+DOCE was shown to be consistent with previous studies of DOCE and no cytokine release syndrome of any grade was reported (0 of 51 patients). Promising anti-tumor activity was observed in both taxane-naïve and heavily pretreated patients. **Methods:** This global, randomized, open-label, phase 3 study (NCT07225946) evaluates the efficacy and safety of PAS in combination with DOCE versus DOCE alone in adult participants ($\geq$18 years) with mCRPC. Approximately 800 participants will be randomized 1:1. Stratification factors include sites of metastases (on conventional imaging), lactate dehydrogenase, Eastern Cooperative Oncology Group performance status, and prior poly(ADP-ribose) polymerase (PARP) inhibitor use. Key inclusion criteria are histologically or cytologically confirmed adenocarcinoma of the prostate, evidence of metastatic disease, and PSA or radiographic disease progression on 1-2 novel ARPI for any stage of prostate cancer. Key exclusion criteria include prior treatment with T-cell redirecting therapies, chemotherapy, or radiopharmaceutical therapy, uncontrolled central nervous system metastases, or significant comorbidities that could interfere with study participation. PAS is administered in the outpatient setting at a target dose of 300 mg IV Q6W with two step-up doses of 3.5 mg IV on day 1 and 18 mg IV on day 8. Participants in the DOCE alone arm will also receive continuous prednisone per label. The primary endpoint is radiographic progression-free survival assessed by blinded independent central review per Prostate Cancer Working Group 3 and RECIST v1.1 criteria. Key secondary endpoints include overall survival, time to symptomatic progression, time to subsequent therapy, and time to skeletal-related event. Safety, pharmacokinetics, biomarkers, and quality of life assessments will also be evaluated. The study is currently enrolling patients in the North and Latin Americas, European Union and Asia Pacific regions. Clinical trial information: 78278343PCR3003. Research Sponsor: None.

TPS5140 **Poster Session**

Phase 1/2 OMAHA-U01 substudy 01A: Oral steroidogenesis inhibitor opevesostat alone or in combination with other therapies in participants with metastatic castration-resistant prostate cancer (mCRPC). First Author: Arif Hussain, University of Maryland Medical Center, Greenebaum Comprehensive Cancer Center, Baltimore, MD

Background: mCRPC remains an incurable disease and therapeutic agents with novel mechanisms of action are needed for this patient population. Opevesostat (MK-5684; ODM-208), an oral steroidogenesis inhibitor, selectively inhibits cytochrome P450 11A1 (CYP11A1), a catalyst of the first and rate-limiting step of steroid biosynthesis. In the phase 1/2 CYPIDES study, opevesostat showed antitumor activity in participants with heavily pretreated mCRPC. OMAHA-U01 is an adaptive, open-label, rolling-arm, multicenter, phase 1/2 umbrella study designed to evaluate opevesostat-based investigational therapies in participants with prostate cancer. Substudy 01A (NCT06353386) will evaluate the safety and efficacy of opevesostat alone or in combination with other therapies in participants with previously treated mCRPC. **Methods:** Eligible participants have mCRPC that progressed during androgen deprivation therapy ≤6 months before screening, and on or after 1-2 androgen receptor pathway inhibitors for metastatic or nonmetastatic hormone-sensitive prostate cancer and nonmetastatic or mCRPC. Prior treatment with ≤1 taxane-based chemotherapy regimen for mCRPC is allowed. A safety lead-in phase for all opevesostat-based experimental combinations (~10 participants in each arm) will establish the recommended phase 2 dose (RP2D), followed by an efficacy phase (opevesostat alone, ≤100 participants; opevesostat-based combinations, ~40 participants each). Participants will be randomly assigned 1:1:1:1 to receive opevesostat 5 mg PO BID, opevesostat 5 mg PO BID plus olaparib (RP2D), opevesostat 5 mg PO BID plus docetaxel (RP2D), or opevesostat 5 mg PO BID plus cabazitaxel (RP2D). Randomization for the efficacy phase will be stratified according to AR-LBD mutation (AR-LBDm) status (positive or negative). The primary end point for the safety lead-in phase is safety and tolerability. Primary end points for the efficacy phase are safety and prostate-specific antigen response rate per Prostate Cancer Clinical Trials Working Group (PCWG) criteria. Secondary end points include objective response rate and radiographic progression-free survival per PCWG-modified RECIST v1.1 by blinded independent central review (BICR), overall survival, duration of response by BICR, time to first subsequent anticancer therapy, and time to pain progression. The predefined eligibility cap for pts with AR-LBDm-negative status has been reached, and the study is currently only enrolling pts with AR-LBDm-positive status. Clinical trial information: NCT06353386. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA; Orion Corporation, who are codeveloping opevesostat.

TPS5141 **Poster Session**

ProTACT: A first-in-human, phase 1 dose escalation and expansion study evaluating the safety, tolerability, and anti-tumor activity of [^{225}Ac]Ac-FL-020, a PSMA-targeted radioconjugate, in patients with mCRPC. First Author: Robert Dreicer, University of Virginia School of Medicine, Charlottesville, VA

Background: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy is an emerging treatment modality for metastatic castration-resistant prostate cancer (mCRPC). However, many agents targeting PSMA have resulted in quality of life-limiting toxicities, such as xerostomia, due to expression of PSMA in salivary glands and other organs. [^{225}Ac]Ac-FL-020 is a next-generation, PSMA alpha radioconjugate developed using the proprietary UniRDC linker-chelator technology designed to optimize biodistribution. It is intended for the treatment of patients with mCRPC and aims to enhance tumor uptake while sparing radiosensitive organs, such as salivary glands, thus potentially leading to an improved therapeutic window. **Methods:** ProTACT (FL-020-001) is a first-in-human, open-label, multicenter Phase 1 study investigating the safety, tolerability, and preliminary anti-tumor activity of [^{225}Ac]Ac-FL-020 in patients with advanced PSMA-positive mCRPC. This study consists of 2 parts: dose escalation (Part 1) and dose expansion (Part 2). Patients eligible for enrollment must be aged ≥18 years and have: histologically confirmed mCRPC, evidence of disease progression, ≥1 PSMA-positive lesion (uptake higher than liver) on PSMA positron emission tomography/computed tomography imaging, an Eastern Cooperative Oncology Group performance status of 0 to 1, and adequate organ function. Prior treatment with androgen receptor signaling inhibitors or CYP17 inhibitors and ≥1 taxane-based chemotherapy is required, unless declined by the patient. Prior therapy with Lu-177 is allowed. Patients with extensive PSMA-negative disease are excluded. [^{225}Ac]Ac-FL-020 will be administered intravenously at the assigned dose every 6 weeks for up to 6 cycles. Throughout the study, 10 eligible patients will receive 185 ± 20 MBq of [^{111}In]In-FL-020 for dosimetry evaluation ≥8 days prior to their first dose of [^{225}Ac]Ac-FL-020. Part 1 will apply a Bayesian logistic regression model with overdose control to guide dose escalation decisions. Dose cohorts of 1–3 patients (for Cohorts 1 and 2) and 3–6 patients (for Cohorts 3 and beyond) will evaluate ascending dose levels from 1–10 MBq to determine the maximum tolerated dose and/or recommended Phase 2 dose (RP2D). Once the RP2D is established, 18 additional patients will be enrolled in Part 2 to further assess safety and explore early signals of efficacy. Primary endpoints include incidence of dose-limiting toxicities and type, frequency, and severity of adverse events/serious adverse events. Secondary endpoints include overall response rate, disease control rate, radiological progression-free survival, and pharmacokinetic parameters (eg, maximum plasma concentration). The study is active in Australia, the United States, Turkey, and China. Clinical trial information: NCT06492122. Research Sponsor: Full-Life Technologies.

TPS5142 **Poster Session**

TIDAL: A phase II study of the DLL3-directed T-cell engager tarlatamab in DLL3-positive metastatic prostate cancer. First Author: Karen A. Autio, Memorial Sloan Kettering Cancer Center, New York, NY

Background: T-cell engagers directed at canonical prostate adenocarcinoma surface antigens (e.g., STEAP1, KLK2) have demonstrated substantial activity in prostate adenocarcinoma; however, alternative tumor-directed targets are needed for pts whose tumors have undergone lineage plasticity. Delta-like ligand 3 (DLL3) is a surface target variably expressed across the spectrum of neuroendocrine/small cell malignancies. Tarlatamab (Imdelltra, Amgen, Thousand Oaks, CA) is a bispecific T-cell engager targeting DLL3 and CD3, with regulatory approval for small cell lung cancer, and emerging evidence of activity in DLL3-positive prostate cancer. TIDAL is a multi-center, prospective, single arm phase II trial (NCT07111507) evaluating the safety and efficacy of tarlatamab in DLL3-positive advanced prostate cancer. **Methods:** Key eligibility criteria include metastatic prostate cancer with progression on ≥1 prior systemic therapy in the metastatic setting and DLL3-positive disease (IHC ≥50%), irrespective of histologic subtype. Pts without measurable disease by RECIST 1.1 criteria can be enrolled; however, at least 50% of pts enrolled must have measurable disease. Pts will receive tarlatamab in 28-day cycles with a 1 mg priming dose on cycle 1 day 1 (C1D1), followed by a target dose of 10 mg on C1D8, C1D15, and days 1 and 15 of subsequent cycles. All pts are hospitalized for ≥24 hours of monitoring following C1D1 and C1D8 infusions. Mandatory tumor biopsy and circulating tumor DNA (ctDNA) collection are performed at screening and cycle 2, with required ctDNA and optional biopsy at end of treatment (EOT). CT and bone scan are performed every 8 weeks for the first 24 weeks, then every 12 weeks. The primary endpoint is radiographic progression-free survival at 24-weeks. Secondary endpoints include overall response rate (ORR), median duration of response, median rPFS, median composite PFS, median overall survival, and safety. Correlative studies will evaluate associations between tumor DLL3 expression, circulating immune profiles, and clinical outcomes. A subset of pts will be co-enrolled in an imaging biomarker study (NCT04199741) utilizing a novel DLL3 PET tracer (^{89}Zr-DFO-SC16.56). As of January 14, 2026, 4 of the planned 32 pts have been enrolled. Clinical trial information: NCT07111507. Research Sponsor: Amgen.

TPS5143 **Poster Session**

A randomized phase III trial investigating platinum and taxane chemotherapy in metastatic castration-resistant prostate cancer (mCRPC) patients with alterations in DNA damage response (DDR) genes (OPTION-DDR) CCTG-PR-25 NCT06439225. First Author: Michael Ong, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada

Background: Outcomes for patients (pts) with mCRPC after androgen receptor pathway inhibitors (ARPI) remain poor. There are numerous treatment options, including single agent docetaxel, however overall survival (OS) after ARPI is between 12-19 months. Thus, management of mCRPC post-ARPI represents an area of unmet need. 25% of pts have alterations in DDR genes, which may be a biomarker for sensitivity to treatment with platinum agents. Carboplatin has been previously evaluated in smaller trials in pts with mCRPC and shows promise in patients with DDR gene alterations. PR-25 leverages standard of care testing for DDR genes to evaluate in a rigorous manner whether addition of carboplatin to docetaxel improves overall survival (OS) in pts with DDR gene alterations and mCRPC. **Methods:** PR-25 is a phase III randomized controlled trial led by the Canadian Cancer Trials Group comparing docetaxel to docetaxel and carboplatin in pts with DDR alterations. Pts must receive prior ARPI for mCRPC and demonstrate radiographic or PSA progression prior to enrollment. Qualifying DDR gene alterations include: BRCA1, BRCA2, ATM, ATR, BRIP1, BARD1, CDK12, CHEK1, CHEK2, ERCC2, FANCA, FANCC, FANCD2, FANCL, PALB2, RAD51B, RAD51C, RAD51D, RAD54L. The primary endpoint is OS. Secondary endpoints include radiographic progression free survival (PCWG3 and RECIST 1.1), PSA response, time to next systemic therapy, patient reported quality of life and economic evaluation. Statistical design: The target accrual is 236 patients over 3.25 yrs with 2 year follow-up to detect a HR of 0.65 in OS, using a type 1 error rate of 5% (2 sided) and power of 80%. *Conduct to Date:* Study activation – October 2024. First patient enrolled - December 2024. Accrual to date: 10. Clinical trial information: NCT06439225. Research Sponsor: CIHR Grant; NCTN Grant; Canadian Cancer Society Grant.

TPS5144 **Poster Session**

XALience: A phase 3, open-label, multicenter, randomized study of xaluritamig plus abiraterone vs investigator's choice in patients with chemotherapy-naïve metastatic castration-resistant prostate cancer. First Author: Tanya B. Dorff, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: In the first-in-human (FIH) study, xaluritamig, a T-cell engager directed at six-transmembrane epithelial antigen of the prostate 1 (STEAP1), demonstrated potent antitumor activity with a manageable safety profile in patients with metastatic castration-resistant prostate cancer (mCRPC).[1,2] Preliminary data from this FIH study of xaluritamig in combination with abiraterone in chemotherapy-naïve patients with mCRPC[3] supports the initiation of a phase 3 study of xaluritamig plus abiraterone with the aim of improving survival in this population. **Methods:** XALience is a randomized, multicenter, open-label, phase 3 study (NCT07213674) of xaluritamig plus abiraterone vs investigator's choice in patients with chemotherapy-naïve mCRPC. Approximately 750 eligible patients ≥18 years old with histologically confirmed chemotherapy-naïve mCRPC; evidence of disease progression on prior enzalutamide, apalutamide, or darolutamide; ECOG PS of 0-1; and adequate organ function and who may have previously received ≤6 cycles of docetaxel in the metastatic hormone-sensitive prostate cancer (mHSPC) setting will be randomized 1:1 to receive xaluritamig plus abiraterone or investigator's choice of docetaxel, cabazitaxel, or abiraterone. Patients will be stratified by prior docetaxel exposure in mHSPC, presence of liver metastases, prior treatment with prostate-specific membrane antigen radioligand therapy, and planned intention-to-treat with investigator's choice. This study consists of a 28-day screening period, treatment until radiographic progression based on Prostate Cancer Working Group 3 (PCWG3) guidelines, a safety follow-up period, and a long-term follow-up period. To mitigate the risk of cytokine release syndrome, xaluritamig will be initiated at weekly step-up dosing over four doses up to the target dose during cycle 1 followed by target dose administration every 2 weeks from cycle 2 day 1 onwards. The primary endpoint is overall survival, which will be analyzed using a stratified log-rank test at a one-sided 2.5% significance level. Key secondary endpoint is investigator-assessed radiographic progression-free survival per PCWG3. Other secondary endpoints include radiographic and prostate-specific antigen response, safety, tolerability, health-related quality of life, patient-reported outcomes, pharmacokinetics, and immunogenicity. Enrollment is ongoing and 20 patients have been enrolled as of January 19, 2026. References: Kelly WK, Danila DC, Lin CC, et al. *Cancer Discov*. 2024;14:76-89. Kelly WK, Appleman L, Lin C-C, et al. *Ann Oncol*. 2024;35: S963-S964. Data on file, Amgen; 2025. Clinical trial information: NCT07213674. Research Sponsor: Amgen Inc.

TPS5145 **Poster Session**

TALENT: A randomized phase 2 study of talazoparib with or without enzalutamide in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) and homologous recombination repair (HRR) alterations after progression on abiraterone acetate. First Author: Karen A. Autio, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The phase 3 TALAPRO-2 study (NCT03395197) demonstrated superior efficacy with enzalutamide plus talazoparib vs. enzalutamide plus placebo for pts with mCRPC with tumors harboring HRR mutations. Only 8% of HRRm pts enrolled in TALAPRO-2 had prior exposure to abiraterone acetate with prednisone, and none had received an androgen receptor inhibitor. Given the evolving treatment landscape of metastatic hormone sensitive prostate cancer (mHSPC), many patients now receive ADT in combination with abiraterone acetate and prednisone until progression. It is unknown whether the synergistic effects of inhibiting PARP alongside potent AR inhibition will be maintained in those patients with tumors that have demonstrated resistance to an androgen biosynthesis inhibitor such as abiraterone. The TALENT study (NCT06844383) will address this unanswered question by randomizing pts with HRR-mutated mCRPC following progression on abiraterone acetate with prednisone to receive talazoparib in combination with enzalutamide versus talazoparib alone. We hypothesize that synergy between PARP and AR inhibition will be demonstrated in this contemporary patient population. **Methods:** TALENT will enroll approximately 126 pts with mCRPC with prior disease progression while receiving abiraterone acetate for HSPC or locally advanced disease and a confirmed mutation in one of twelve HRR genes. ATM mutations will be limited to 15%. Prior exposure to docetaxel in the mHSPC setting will be included as a stratification factor. Pts will be randomized in a 1:1 fashion to either talazoparib and enzalutamide or talazoparib alone administered along with ADT. Pts will continue treatment until disease progression, unacceptable toxicity, treatment delay > 60 days of talazoparib, protocol violation, withdrawal of consent, physician decision, study termination by the Sponsor, loss to follow-up, or death. Patients will be monitored using RECIST 1.1 and PCWG3 criteria for bone disease. The primary endpoint is investigator-assessed radiographic progression free survival (rPFS). Secondary endpoints include time to PSA50 response, time to PSA progression, overall survival, and patient reported outcomes capturing quality of life. Exploratory analyses will evaluate rPFS by HRR gene (BRCA vs non-BRCA, individual genes, and gene clusters). Pt recruitment is planned at approximately 15 sites in the US. As of January 27, 2026, 0 pts have been enrolled. Clinical trial information: NCT06844383. Research Sponsor: Pfizer Inc.

TPS5146 **Poster Session**

Phase I/II study to evaluate AZD9750, a novel androgen receptor proteolysis-targeting chimera, alone and in combination with other anticancer agents in patients with metastatic prostate cancer (ANDROMEDA). First Author: Neeraj Agarwal, Huntsman Cancer Institute at The University of Utah, Salt Lake City, UT

Background: The androgen receptor (AR) is a key driver of prostate cancer progression. AR pathway inhibitors (ARPIs) are standard of care for metastatic prostate cancer, but acquired resistance is inevitable and often involves reactivation of AR signaling via AR gene alterations such as amplifications or ligand binding domain mutations. The need remains for alternative strategies to target the AR. AZD9750 is a novel oral proteolysis-targeting chimera that potently degrades wild-type, mutant, and amplified forms of the AR. Preclinical data also showed significant antitumor benefit with AZD9750 as monotherapy and combined with the PARP1 selective inhibitor saruparib (AZD5305). ANDROMEDA (NCT07336446) is a first-in-human, phase I/II, open-label, multicenter study investigating the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy of AZD9750 as monotherapy and combined with saruparib in patients (pts) with metastatic castration-resistant prostate cancer. **Methods:** This study follows a modular design in which pts receive AZD9750 as monotherapy (Module 1) or combined with saruparib (Module 2; Table). Each module has 2 parts: monotherapy dose escalation or combination dose finding (Part A) and dose optimization and expansion (Part B). Eligible pts are ≥18 years of age with histologically or cytologically confirmed adenocarcinoma of the prostate and documented metastatic disease with serum testosterone level ≤50 ng/dL, evidence of disease progression, and ECOG performance status of 0 or 1. Pts should have previously received ARPIs and taxane-based chemotherapy, with the exception of no prior taxane-based chemotherapy in Module 1 Part B3. Primary endpoints include occurrence of dose-limiting toxicities (Part A only), incidence of adverse events (AEs) and AEs leading to treatment discontinuation (Parts A and B), and preliminary efficacy (ie, ≥50% decrease in prostate-specific antigen [PSA]; Part B only). Secondary endpoints include preliminary efficacy (ie, ≥50% and ≥90% decrease in PSA, objective response rates and progression-free survival per RECIST v1.1 and PCWG3 criteria, change in target lesion size per RECIST v1.1 criteria, time to PSA response, and time to PSA progression per PCWG3 criteria) and pharmacokinetic parameters (Parts A and B). This study is currently recruiting for monotherapy dose escalation. Clinical trial information: NCT07336446. Research Sponsor: AstraZeneca.

Study part	Module 1: AZD9750 monotherapy	Module 2: AZD9750 plus saruparib
Part A	A1. Dose escalation A2. Backfill cohorts	Combination dose finding[a]
Part B	B1. Dose optimization[a] B2. Dose expansion[b] B3. Dose expansion[b]	Combination dose expansion[c]

[a]Recommended doses determined in Module 1 Part A; [b]To be opened once recommended phase II dose identified in Module 1 Part B1; [c]To be opened once combination dose identified in Module 2 Part A.

TPS5147 **Poster Session**

REINFORCE: A phase III randomized trial of treatment intensification with docetaxel in metastatic hormone-sensitive prostate cancer patients without deep PSA response after initial apalutamide therapy. First Author: Enrique Gonzalez-Billalabeitia, 12 de Octubre University Hospital, Medical Oncology Department, Madrid, Spain

Background: Androgen deprivation therapy (ADT) plus androgen receptor pathway inhibitors (ARPIs) is the standard of care for metastatic hormone-sensitive prostate cancer (mHSPC). However, a substantial proportion of patients fail to achieve a deep prostate-specific antigen (PSA) response, which is consistently associated with worse outcomes. Deep PSA response has emerged as a robust early prognostic marker across multiple phase III trials. Patients lacking this favorable PSA decline represent a poor-risk subgroup with limited treatment personalization. Docetaxel improves survival in high-volume mHSPC and may benefit biologically aggressive disease identified by suboptimal early PSA response. REINFORCE evaluates a PSA-guided strategy of treatment intensification with docetaxel in patients without deep PSA response after apalutamide. **Methods:** REINFORCE is an international, multicenter, open-label, phase III randomized trial. Eligible patients are men ≥18 years with histologically confirmed mHSPC, ECOG performance status ≤1, PSA > 5 ng/ml at diagnosis of metastatic disease, ≤12 weeks of ADT before apalutamide, adequate organ function, who have received apalutamide plus ADT for 24–30 weeks, have not progressed, and have failed to achieve a deep PSA response. Deep PSA response is defined as PSA ≤ 0.2 ng/ml or PSA response ≥ 90% in combination with a PSA ≤4 ng/ml. Approximately 320 patients from 85 sites located in 6 countries will be randomized 1:1 to treatment intensification with docetaxel (75 mg/m² every 3 weeks for 6 cycles) plus continued apalutamide and ADT, or continuation of apalutamide plus ADT alone. Randomization is stratified by metastasis timing (synchronous vs metachronous), presence of visceral metastases, and PSA at study entry (≤4 vs > 4 ng/mL). The primary endpoint is event-free survival (EFS), defined as time from randomization to PSA progression, radiographic progression of soft tissue, visceral or bone lesions, according to PCWG3, or death from any cause. Secondary endpoints include time to castration resistance, radiographic and PSA progression-free survival, overall survival, safety, PSA response rates, and patient-reported outcomes. Preliminary evidence suggests that apalutamide is associated with a ≲ 10% decrease in docetaxel AUC; a dedicated pharmacokinetic sub-study will assess docetaxel drug-drug interaction and bioequivalence when co-administered with apalutamide. An independent data monitoring committee will oversee patient safety, including an early safety review after the first 18 patients included, review a pre-planned interim efficacy analysis, and evaluate pharmacokinetic data, providing recommendations to the sponsor regarding study continuation. Clinical trial information: 2025-524408-30-00. Research Sponsor: Johnson & Johnson Innovative Medicine.

TPS5148 **Poster Session**

An open-label, parallel-cohort, multicenter clinical study of rezvilutamide in combination with androgen deprivation therapy (ADT) with or without docetaxel in the neoadjuvant treatment of oligometastatic prostate cancer. First Author: Qi Lin, Department of Urology, The First Affiliated hospital of Wenzhou Medical University, Wenzhou, China

Background: Oligometastatic hormone-sensitive prostate cancer (omHSPC), defined by ≤5 metastases, represents a distinct disease state with a more favorable prognosis, offering a critical window for treatment intensification aimed at improving long-term outcomes. Cytoreductive radical prostatectomy (cRP) has emerged as a feasible local treatment option for select patients, with phase II data suggesting a survival benefit over systemic therapy alone. The foundation of systemic therapy for metastatic HSPC (mHSPC) is an androgen receptor pathway inhibitor (ARPI) combined with androgen deprivation therapy (ADT). Rezvilutamide, a second-generation ARPI, demonstrated superior efficacy over bicalutamide when combined with ADT in patients with mHSPC. Furthermore, the addition of docetaxel to an ARPI and ADT (triplet therapy) significantly improved survival in mHSPC, including in patients with low metastatic burden. We hypothesize that intensifying neoadjuvant systemic therapy with triplet therapy prior to cRP may maximize tumor cytoreduction and pathologic response in omHSPC. **Methods:** This is a prospective, open-label, parallel-cohort, multicenter phase II study. Patients with newly diagnosed, biopsy-proven omHSPC (≤5 bone or lymph node metastases on conventional imaging, no visceral metastases) who are candidates for and desire cRP are eligible. All patients undergo baseline prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA-PET/CT) prior to ADT initiation. Patients select their neoadjuvant regimen: Cohort A receives ADT plus oral rezvilutamide (240 mg daily) for 24 weeks; Cohort B receives ADT, rezvilutamide (same dose), plus docetaxel (75 mg/m² IV q3w for 6 cycles) for 24 weeks. Upon completion of the 24-week neoadjuvant therapy, metastases are reconfirmed by conventional imaging, and a second PSMA-PET/CT assessment is performed. All patients subsequently undergo cRP with extended pelvic lymph node dissection within 6 weeks. After surgery, patients may opt to continue with ADT or rezvilutamide at their discretion until disease progression. Based on assumed pCR rates of <10% (Cohort A) and 25% (Cohort B) (α=0.05, power=80%), 40 evaluable patients are required per cohort. Accounting for 20% dropout, 100 total patients (50 per cohort) will be enrolled. Key inclusion criteria: ECOG PS 0-1, adequate organ function. Key exclusion criteria: prior systemic therapy for PCa (except ≤4 weeks of ADT), prior second-generation ARPI use, and prostate pathology results indicating neuroendocrine carcinoma. As of January 15, 2026, enrollment is ongoing with 6 patients accrued to date. No data analysis has been performed. Clinical trial information: ChiCTR2400093262. Research Sponsor: the Development Center for Medical Science & Technology National Health Commission Clinical Research Project.

TPS5149 **Poster Session**

TRIPLE-SWITCH (SWOG/CCTG-PR26): A randomized phase III clinical trial for the addition of docetaxel to androgen receptor pathway inhibitors in patients with metastatic castration sensitive prostate cancer (mCSPC) and suboptimal PSA response (NCT06592924). First Author: Michael Ong, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada

Background: Management of patients (pts) with mCSPC remains a challenge due to its incurable nature and heterogeneous response to androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPI). Analyses of phase III ADT + ARPI trials have indicated that pts with mCSPC with suboptimal PSA response (≥0.2ng/ml at 6-12 months) have a short time to castration-resistance (CRPC) and poor median overall survival (OS) of 30-36 months. There is equipoise about the use of docetaxel in mCSPC pts on ARPI because of: 1) an absence of randomized data for docetaxel in this setting; 2) toxicity of docetaxel with impact on quality of life; and 3) selection of docetaxel treatment by disease volume rather than disease biology. **Methods:** PR26 is a joint CCTG-SWOG international, open-label, randomized phase III trial comparing continuing standard ADT + ARPI with the addition of up to 6 cycles of docetaxel to ADT + ARPI in mCSPC pts with suboptimal PSA response(PSA ≥0.2 ng/mL after 6-12 months of ADT and ≥4 months of ARPI). Stratification will be based on PSA levels, ARPI type, presence of liver metastasis, disease recurrence status, and time since ADT initiation. The sample size is 830 pts to detect a targeted 33% improvement in overall survival (hazard ratio 0.75) using a 1-sided 0.025 level test with 85% power. Key eligibility criteria are: ≥18 years, histologically confirmed prostate adenocarcinoma, metastatic disease present and confirmed by conventional imaging (CT and/or bone scan), PSA ≥5.0 ng/mL prior to ADT, receipt of ADT for 6-12 months and ARPI for ≥4 months, PSA ≥0.2 ng/mL within 14 days of enrolment, adequate organ and marrow function, ECOG performance status 0-2, eligible for docetaxel chemotherapy, no evidence of disease or biochemical progression on ADT prior to enrolment. Primary endpoint is OS. Secondary endpoints include PSA response, PSA kinetics, and clinical progression free-survival. Correlative studies will explore the prognostic and predictive value of circulating tumor DNA and the association between molecular signatures and clinical outcomes. Conduct to date: Study activation, January 2025. First patient enrolled, May 2025. Accrual to date: 6. Supported by CIHR grant 39527, NCTN grant #CA180863 and CCS grant #707213. Research Sponsor: None.

TPS5150 **Poster Session**

EORTC GUCG 2238: "Deescalate," a pragmatic trial to revisit intermittent androgen deprivation therapy in metastatic hormone-sensitive prostate cancer in the era of new androgen receptor pathway inhibitors. First Author: Fabio Turco, Oncology Institute of Southern Switzerland (IOSI), Ente Ospedaliero Cantonale (EOC), Bellinzona, Switzerland

Background: The systemic standard of care treatment in patients with metastatic hormone-sensitive prostate cancer (mHSPC) according to international guidelines is combination therapies with androgen deprivation therapy (ADT) + androgen receptor pathway inhibitor (ARPI) +/- docetaxel. These ADT + ARPI combinations (also called maximum androgen blockade, MAB) have been shown in phase 3 randomized clinical trials to reduce the risk of death by 20-40%, delay further treatment, and improve health-related quality of life (HRQoL). Treatment usually continues until biochemical, radiological, or clinical progression, sometimes many years after treatment initiation, exposing patients to chronic side effects affecting their HRQoL. Registration trials included highly selected patients, not representative of the general population, thereby overestimating treatment adherence and effectiveness while underreporting tolerability. Several sub-analyses of the registration trials demonstrated that patients achieving a PSA ≤0.2 ng/ml have prolonged overall survival (OS). In this study, we hypothesized that patients with mHSPC treated with MAB reaching PSA ≤ 0.2 ng/ml may benefit from treatment interruption without compromising OS. **Methods:** The primary goal of this academic-led, open-label, pragmatic, randomized phase III study is to investigate whether intermittent MAB (iMAB) can be safely administered to mHSPC patients who reached a PSA ≤ 0.2 ng/mL at 6 to 12 months after the start of treatment (docetaxel and radiotherapy permitted as part of standard treatment), as compared to continuing MAB (cMAB). Co-primary endpoints are: 1) Feasibility: proportion of patients who do not restart their MAB within one year of interruption. 2) Efficacy: OS assuming the iMAB regimen at three years is non-inferior to continuous treatment. Secondary objectives include toxicity, HRQoL and assessing the impact on treatment resources between iMAB and cMAB. The study will randomize 1600 patients to exclude a 4% OS difference at 3 years while <30% of patients restarted MAB after one year. The study is currently active in Belgium, Croatia, Denmark, Ireland, France and Spain. The activation of the other countries (Portugal, Italy, Romania, Slovenia, Switzerland and Czech Republic) is expected by spring 2026. The study has currently recruited 109 patients (Updated January 26, 2026). Clinical trial information: NCT05974774. Research Sponsor: European Union's HORIZON-MISS-2022-CANCER-01-03; 101104574.

TPS5151 **Poster Session**

AMPLIFY: A phase 3 study of ^{64}Cu-SAR-bisPSMA positron emission tomography in participants with biochemical recurrence of prostate cancer. First Author: Luke Nordquist, XCancer Corporation, Omaha, NE

Background: Prostate cancer (PC) is the second most prevalent cancer in men globally. The need for improved PC imaging is reflected in a biochemical recurrence (BCR) rate of 20 to 40% after initial definitive therapy. Despite advances in technology, many patients will fail to have their recurrence accurately localized by imaging, especially at low PSA levels. Imaging modalities that are widely available and can accurately detect, monitor, and restage residual / recurrent loco-regional and metastatic disease are therefore highly desirable. Prostate-specific membrane antigen (PSMA) is a type II transmembrane glycoprotein that is strongly overexpressed in PC, making it an ideal target for imaging and therapy. ^{64}Cu-SAR-bisPSMA may offer several advantages over the currently approved PSMA positron emission tomography (PET) agents for PC due to the bivalent structure of SAR-bisPSMA and longer half-life of ^{64}Cu ($t_{1/2}$ = 12.7h), compared to the approved monovalent PSMA agents utilizing ^{18}F and ^{68}Ga ($t_{1/2}$ < 2h). Evidence has demonstrated prolonged tumor retention and 2-3x higher tumor uptake with detection of additional PC lesions using ^{64}Cu-SAR-bisPSMA compared to approved PSMA PET agents. **Methods:** AMPLIFY (NCT06970847) is a multi-center, single arm, open-label Phase 3 diagnostic performance study of ^{64}Cu-SAR-bisPSMA PET/CT in participants with a history of prostate adenocarcinoma and rising or detectable PSA after initial definitive treatment. The primary objective is to investigate the ability of ^{64}Cu-SAR-bisPSMA PET/CT to detect recurrence of PC, with co-primary endpoints of participant-level correct detection rate (CDR) and region-level positive predictive value (PPV) assessed independently for Day 1 and Day 2. Key secondary objectives include assessment of safety, participant-level PPV, and participant-level detection rate (DR). A total of 220 patients will be enrolled. All participants are required to have baseline conventional imaging. Eligible patients will receive a single administration of ^{64}Cu-SAR-bisPSMA (200 MBq) followed by a PET/CT scan on Day 1 (1-4h post-dose) and on Day 2 (24±6h post-dose). Participants will then continue into the follow-up period to verify the ^{64}Cu-SAR-bisPSMA PET/CT findings. The Day 1 and Day 2 scans will be interpreted individually by a qualified local reader and 3 independent, blinded, central readers for the presence of abnormal ^{64}Cu-SAR-bisPSMA uptake. ^{64}Cu-SAR-bisPSMA PET/CT results on Day 1 and Day 2 will then be assessed against a composite Reference Standard by a central expert panel. The study is open for recruitment in the United States and Australia. Clinical trial information: NCT06970847. Research Sponsor: Clarity Pharmaceuticals.

TPS5152 **Poster Session**

A phase 2 study of androgen deprivation therapy and the androgen receptor ligand–directed degrader (BMS-986365) prior to radical prostatectomy in patients with high-risk localized prostate cancer. First Author: Kristine Peregrino Lacuna, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Although radical prostatectomy (RP) is a curative approach for patients (pts) with high-risk localized prostate cancer (PC), recurrence rates remain high. Neoadjuvant studies of androgen deprivation therapy (ADT) plus an androgen receptor pathway inhibitor (ARPI) suggest improvement in local disease control at the time of RP and may be associated with better long-term outcomes (McKay et al. PC Prostatic Dis. 2018; McKay et al. ASCO 2023: #5095). An ongoing phase 3 study is evaluating ADT plus apalutamide for 6 months prior to RP in pts with high-risk or locally advanced PC; co-primary endpoints are pathologic complete response (pCR) and metastasis-free survival (NCT03767244). BMS-986365 is an orally administered ligand-directed degrader targeting the androgen receptor (AR) via a first-in-class dual mechanism of 1) AR degradation and 2) AR antagonism. A phase 1 study showed that BMS-986365 was well tolerated with a manageable safety profile, with antitumor activity in pts with metastatic castration-resistant PC (mCRPC) regardless of AR gene alterations (Rathkopf et al. Ann Oncol. 2025), leading to an ongoing phase 3 study in mCRPC (rechARge: NCT06764485). Due to its dual mechanism and promising data in mCRPC, we hypothesize that neoadjuvant treatment with ADT plus BMS-986365 prior to RP will result in robust pathologic response rates. **Methods:** This is a single center, phase 2, single-arm trial testing the combination of ADT plus BMS-986365 for 6 months prior to RP in pts with high-risk localized PC. Eligible pts include those who are candidates for RP and meet $\geq$ 1 high-risk criteria: PSA $\geq$ 20 ng/mL, Gleason $\geq$ 8, or clinical stage $\geq$ cT3a (N1M0 disease allowed). Pts will receive degarelix SC once monthly (first dose 240mg, maintenance dose 80mg) and BMS-986365 at a dose of 300mg PO twice daily (liquid-filled capsule formulation) for 6 months; RP will occur 2 weeks after the last dose of BMS-986365. The dose of BMS-986365 was selected based on the phase 1 data and equivalent doses utilized in the ongoing phase 3 rechARge study. The primary endpoint is the rate of pCR and/or minimal residual disease (MRD, defined as tumor $\leq$ 5mm) at the time of RP. A two-stage design will evaluate if pCR and/or MRD rate exceeds 0.20, which is the rate observed in historical studies of ADT and ARPI prior to RP (McKay et al. J Urol. 2021) 10 pts will be enrolled in Stage 1; if $\geq$ 3/10 pts achieve a pCR and/or MRD, an additional 20 pts will be enrolled in Stage 2. If $\geq$ 10/30 pts achieve a pCR and/or MRD, the treatment will be declared sufficiently active (alpha = 0.05, power 0.80). Secondary endpoints include safety and time to biochemical recurrence. As part of exploratory analyses, cfDNA, pre-/post-treatment (prostatectomy) tissue, and pre-/post-treatment multiparametric MRI will be collected. The study opened to accrual in January 2026. Clinical trial information: NCT07335796. Research Sponsor: Bristol Myers Squibb (BMS); Institutional Funding supported through Philanthropy.

5501 **Oral Abstract Session**

Long-term survival rates and cure modeling with dostarlimab plus chemotherapy in mismatch repair deficient/microsatellite instability-high (dMMR/MSI-H) primary advanced or recurrent endometrial cancer in the ENGOT-EN6-NSGO/GOG-3031/RUBY trial. First Author: Matthew A. Powell, Washington University School of Medicine, Siteman Cancer Center, St. Louis, MO

Background: Dostarlimab + carboplatin-paclitaxel (CP) demonstrated significant progression-free survival (PFS) and clinically meaningful overall survival benefits in patients with dMMR/MSI-H primary advanced or recurrent endometrial cancer (EC) in Part 1 of the phase 3 RUBY trial (NCT03981796). Median PFS was not reached for dostarlimab + CP vs 7.7 months for CP alone in this population. Moreover, plateauing of the PFS Kaplan-Meier (KM) curve suggested that a subset of patients with dMMR/MSI-H EC achieved durable disease control and potential for curative intent with dostarlimab + CP. Mixture cure models (MCMs) complement conventional outcome metrics by quantifying the proportion of patients considered "cured" and by modeling PFS among patients who remain uncured. Here we present an MCM applied to the PFS data from the dMMR/MSI-H population with up to 4.5 years of follow-up treated with dostarlimab + CP. **Methods:** At a median follow-up of 55.6 months (range 49.9–67.7 months), descriptive PFS analyses were conducted in the dMMR/MSI-H population from RUBY Part 1. MCMs were fitted to PFS data to estimate the proportion of patients treated with dostarlimab + CP who had a curative potential. In the MCM, patients with curative potential were assumed to be free of recurrence- and disease-related mortality risks, implying that any additional PFS events would come from death. Mortality risks were assumed to be similar to the background mortality expected in the general population (with matched demographic characteristics). Conversely, the uncured population was considered to be at risk for disease recurrence and death from all causes. **Results:** There was a low rate of progression since PFS was first analyzed, with only 4 new events reported with an additional 2.5 years of follow-up. The 4-year PFS rate was 57.9% (95% CI, 42.3%–70.6%) in the dostarlimab + CP arm vs 15.7% (95% CI, 7.2%–27.0%) in the control arm. The MCM analysis demonstrated that the majority of patients with dMMR/MSI-H EC (54%; 95% CI, 35%–72%) were considered “cured” with dostarlimab + CP. The PFS survival curves estimated from MCMs closely followed the KM curves reported from the RUBY trial data. The model appropriately captured the long-term survival plateau, instilling confidence in the robustness of the model predictions. **Conclusions:** With a minimum of 4 years of follow-up, updated PFS analyses demonstrated that the majority of patients remained alive and progression-free, illustrating durable disease control. Model-based predictions indicated the potential for cure in the dMMR/MSI-H primary advanced or recurrent EC population receiving dostarlimab + CP. These analyses may assist oncologists in understanding long-term survival outcomes and the proportion of patients with a curative potential. Clinical trial information: NCT03981796. Research Sponsor: GSK; N/A.

5502 **Oral Abstract Session**

Updated overall survival analysis and examination of subsequent therapy in endometrial cancer (EC) patients (pts) treated with pembrolizumab plus carboplatin/paclitaxel (CP) as compared to CP plus placebo (PBO) in the NRG-GY018 trial. First Author: Ramez Nassef Eskander, UC San Diego Moores Cancer Center, La Jolla, CA

Background: NRG-GY018, the only phase 3 trial examining dMMR and pMMR EC populations independently, identified a 70% and 46% reduction in the risk of disease progression or death in advanced stage or recurrent dMMR and pMMR EC patients treated with pembrolizumab plus CP. Here we report on updated overall survival and post-study immune checkpoint inhibition (ICI) therapy. **Methods:** 810 pts were randomized 1:1 to pembrolizumab + CP or PBO + CP Q3W for 6 cycles followed by maintenance pembrolizumab or PBO Q6W for up to 24 months. Updated OS analysis data cut off was December 23, 2025, with information fraction of 42% and 78% in the dMMR and pMMR EC cohorts, respectively. Median follow up in the dMMR cohort was 44.6 months (95% CI 42.5 to 46.8) and 40.1 months (95% CI 38.9 to 42.2) in the pMMR cohorts. Study sites were queried to abstract data regarding start and end date of post study ICI use. **Results:** The addition of pembrolizumab resulted in a sustained OS benefit in the dMMR EC cohort. At 48-month landmark assessment, 80% of the pembrolizumab treated dMMR EC patients were alive, versus 60% of those treated with placebo, HR 0.53 (95% CI 0.32 to 0.89). This survival advantage was maintained despite at least 55% (n=62) of dMMR EC patients in the placebo arm receiving post study ICI. In the pMMR EC population, with an information fraction of 78%, the median OS in the pMMR cohort treated with pembrolizumab was 46.9 months versus 35.1 months for those receiving placebo, HR 0.84 (95% CI 0.66 to 1.06). This benefit was maintained despite at least 57% (n=167) pMMR EC patients in the placebo arm receiving post study ICI (most commonly lenvatinib plus pembrolizumab). In the pMMR EC cohort, 70 patients in the pembrolizumab arm and 167 patients in the placebo arm received post study ICI, with the median duration of treatment of 6.2 months in both populations. **Conclusions:** In the NRG GY018 study, with prolonged follow up, the addition of pembrolizumab to CP resulted in a sustained OS benefit despite substantial post study ICI use. In the pMMR population, an 11.8 month OS advantage was observed, despite at least 57% of the placebo patients receiving post study ICI. This data further supports the current US FDA approved indication of this regimen in the treatment of advanced stage or recurrent endometrial cancer irrespective of MMR status. Clinical trial information: NCT03914612. Research Sponsor: National Cancer Institute; U10CA180822; U.S. National Institutes of Health.

5503 **Oral Abstract Session**

Overall survival subgroup analyses for prior taxane use in the phase 3 ROSELLA trial of relacorilant plus nab-paclitaxel versus nab-paclitaxel monotherapy in patients with platinum-resistant ovarian cancer (GOG-3073, ENGOT-ov72, APGOT-Ov10, LACOG-0223, and ANZGOG-2221/2023). First Author: Lucy Gilbert, Division of Gynecologic Oncology, Research Institute, McGill University Health Centre, Gerald Bronfman Department of Oncology, McGill University, Montreal, QC, Canada

Background: Relacorilant is a first-in-class, selective glucocorticoid receptor antagonist that increases tumor sensitivity to chemotherapy-induced apoptosis. The phase 3 ROSELLA trial of relacorilant plus nab-paclitaxel in patients with platinum-resistant ovarian cancer (PROC) recently reported statistically significant results for the dual primary endpoints of progression-free survival (PFS) and overall survival (OS). The relacorilant combination was well tolerated and the safety profile was similar to nab-paclitaxel monotherapy. Here we present final OS subgroup analyses for prior taxane use. **Methods:** Patients (n = 381) were randomized 1:1 to relacorilant (150 mg PO the day before, of, and after nab-paclitaxel) plus nab-paclitaxel (80 mg/m^2 IV on days 1, 8, and 15 of each 28-day cycle) or nab-paclitaxel alone (100 mg/m^2 IV on the same schedule). The final OS analysis was performed after 288 deaths had been reported (76% maturity). The hazard ratio (HR) was estimated with a Cox regression model with treatment group as the main effect and stratification factors at randomization as covariates. Kaplan-Meier methods were used to estimate medians and generate survival curves. **Results:** At a median follow-up of 24.8 months, the addition of relacorilant to nab-paclitaxel resulted in a statistically and clinically significant improvement in OS (HR 0.65; 95% confidence interval [CI], 0.51 to 0.83; P = 0.0004). Median OS in the relacorilant combination arm was extended by 4.1 months compared with the nab-paclitaxel monotherapy arm (16.0 vs 11.9 months). Prior taxane use was almost universal (n = 379/381, 99.5%). A consistent OS benefit was observed irrespective of the taxane-free interval: taxane-free interval $\leq$6 months (n = 55, HR 0.60 [95% CI, 0.31 to 1.15], median difference 5.7 months) and taxane-free interval $>$ 6 months (n = 324, HR 0.66 [95% CI, 0.51 to 0.86], median difference 3.6 months). Moreover, a consistent OS benefit was observed irrespective of whether a taxane was used in the most recent regimen: taxane in the last regimen (n = 73, HR 0.67 [95% CI, 0.38 to 1.19], median difference 3.9 months) and no taxane in the last regimen (n = 308, HR 0.63 [95% CI, 0.48 to 0.82], median difference 4.2 months). Additional safety data will be presented. **Conclusions:** ROSELLA met both dual primary endpoints. Relacorilant plus nab-paclitaxel demonstrated a statistically and clinically significant OS benefit in patients with PROC compared to a weekly taxane, the most efficacious chemotherapy. Subgroup analyses for OS showed a consistent benefit favoring the addition of relacorilant to nab-paclitaxel irrespective of prior taxane use. Clinical trial information: NCT05257408. Research Sponsor: Corcept Therapeutics.

LBA5504 **Oral Abstract Session**

A phase III CHIPRO study of chiauranib plus weekly paclitaxel for platinum-resistant or refractory ovarian cancer. First Author: Xiaohua Wu, Fudan University Shanghai Cancer Center, Shanghai, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

5505 **Oral Abstract Session**

CHRONO: A randomized phase II trial of the chronology of surgery after neoadjuvant chemotherapy for ovarian cancer. First Author: Gwenael Ferron, Institut Claudius Regaud, IUCT-Oncopole and GINECO, Toulouse, France

Background: In patients treated for advanced ovarian cancer not suitable for complete primary surgery, interval surgery after three courses of neoadjuvant chemotherapy (NAC) has been considered standard management since the EORTC randomized trial published in 2010 (NCT00003636, DOI: 10.1056/NEJMoa090880). Delaying surgery after six courses of NAC in highly chemosensitive patients amenable to complete surgery after 3 cycles remains controversial. CHRONO is a multicenter, randomized phase II trial addressing this question (NCT03579394). **Methods:** Patients treated for a stage IIIB-IVA high grade epithelial ovarian cancer by NAC and amenable to complete surgery after 3 cycles were randomized (1:1) to either complete surgery followed by 5 cycles of chemotherapy (control arm: C) or an additional 3 cycles of NAC followed by complete surgery then 2 cycles of chemotherapy (experimental arm: E). Maintenance treatment was administered according to standard of care. Primary endpoint was disease free survival (DFS) defined as the time from randomization until the date of disease progression or second cancer or death from any cause. The study was designed to detect an improvement in median (m) DFS from 10 months to 17 months (HR=0.59) with a 85% power and 2-sided α=0.05. Main secondary endpoints were Pathological complete response (CC0) rate, post operative morbidity and mortality, quality of life (QOL) and overall survival (OS). **Results:** Between 18/10/2018 and 23/04/2024, 209 patients (median age: 69 years) were randomized to arm C (n=103) or E (n=106). Median total number of cycles of NAC was 7 (5-9) and 8 (3-9) in arm C and E .CC0 rate was 83.2% vs 90%. After a median follow up of 40.4 months, mDFS was 20.2 months (95%CI: 18.2-23.6) in arm C vs 23.4 (19.0-30.4) in arm E (Log-rank test p=0.48, HR: 0.88 (95%CI: 0.63-1.24). The longitudinal analysis of QoL found no significant differences between the two arms, however, social functioning, insomnia, and sexuality showed a trend toward further improvement ($\geq$5 points) in arm E. Major postoperative complication rates within 30 days were 5% and 11% in arm C and E, (p=0.11) , with no death within 30 days after surgery. **Conclusions:** CHRONO is the first randomized trial addressing the clinical impact of delayed surgery after 6 courses of NAC in first line treatment of advanced ovarian cancer. No statistically significant difference was shown between the two arms of the study considering DFS, severe morbidity, mortality or QoL. New trials are needed for a better understanding of this alternative to interval surgery in highly chemosensitive advanced ovarian cancer patients. Clinical trial information: NCT03579394. Research Sponsor: This study was fully funded by ARCAGY-GINECO.

5506 **Oral Abstract Session**

A randomized phase II trial of mirvetuximab soravtansine in folate receptor alpha (FRα)–high recurrent ovarian cancer eligible for platinum-based chemotherapy (MIROVA/AGO-OVAR 2.34). First Author: Philipp Harter, Ev. Kliniken Essen-Mitte, Essen, Germany

Background: Mirvetuximab soravtansine (MIRV) has demonstrated single agent activity in patients with platinum-resistant ovarian cancer with FRα high expression. However, its activity and safety in combination with carboplatin has not been defined in platinum eligible patients so far. **Methods:** Randomized phase II trial comparing 6 cycles of carboplatin AUC5+MIRV 6 mg/kg AIBW every 3 weeks followed by MIRV versus 6 cycles of carboplatin combined with either paclitaxel, gemcitabine or pegylated liposomal doxorubicin followed by maintenance PARP inhibitor (PARPi) if applicable. All histologic subtypes were eligible with a platinum-free interval $>$3 months and FRα high expression ($\geq$75% with PS2+ scoring) confirmed by central laboratory. Prior PARPi therapy in BRCAmut patients was mandatory. Strata were BRCA-Status, TFIp and number of prior lines of chemotherapy. The primary endpoint was PFS. **Results:** In total, 145 patients were randomized. Of them, 112/145 (77.2%) patients had received prior bevacizumab and 97/145 (66.9%) had prior PARPi, 15.2% were BRCAmut. In the standard arm, 39.15% received PARPi as maintenance. Median PFS in the standard arm was 9.79 months versus 9.53 months in the experimental arm (p=0.996; HR=1.00; 95% CI: 0.68; 1.46). **Conclusions:** MIROVA/AGO-OVAR 2.34 is the first randomized trial evaluating the activity and safety of the combination of carboplatin with an antibody-drug conjugate in the setting of platinum-eligible relapsed ovarian cancer. The primary endpoint regarding improvement of PFS was not met. Further analysis will be presented. Clinical trial information: NCT04274426. Research Sponsor: ImmunoGen/AbbVie.

Updated efficacy results from the phase I cervical cancer cohort of BAT8008, a TROP-2–directed antibody-drug conjugate, in patients with advanced cervical cancer. First Author: Jianli Zhao, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: BAT8008 is a novel antibody-drug conjugate comprising a TROP-2 antibody and an exatecan payload. Patients with recurrent or metastatic cervical cancer (r/m CC) who have progressed on platinum-based chemotherapy have limited treatment options and poor prognosis. This study reports the safety and efficacy of BAT8008 in a cohort of r/m CC patients from a phase 1 trial. **Methods:** This analysis is part of BAT-8008-001-CR, a multi-center, open-label phase 1 study with dose escalation and expansion cohorts. Patients with r/m CC who had failed prior systemic treatments were enrolled. BAT8008 was administered 2.4 mg/kg or 2.1mg/kg intravenously every two weeks (Q2W) 2.4 mg/kg. **Results:** As of Jan 5, 2026, 68 evaluable patients with r/m CC were enrolled (27 at 2.1 mg/kg, 41 at the 2.4 mg/kg). Patients were heavily pre-treated, with 55.9% having received $\geq$2 prior lines of therapy. 64.7% had prior anti-angiogenic therapy and 38.2% had prior immunotherapy. At the 2.4 mg/kg dose (n=44), the most common TRAEs (any grade/$\geq$G3) were anemia (63.6%/15.9%), WBC decreased (68.2%/25.0%), stomatitis (54.5%/6.8%), and neutrophil count decreased (45.5%/20.5%). No treatment-related deaths occurred. For the RP2D cohort (n=41), the confirmed objective response rate (cORR) was 29.3% and disease control rate (DCR) was 78.0%. The median progression-free survival (mPFS) was 6.7 months (95% CI: 3.5-12.1) and median duration of response (mDoR) was 9.0 months (95% CI: 4.2-12.3). Efficacy was observed across subgroups and was independent of TROP-2 expression level. **Conclusions:** BAT8008 demonstrated promising and durable anti-tumor activity with a manageable safety profile in heavily pre-treated patients with r/m cervical cancer. These findings support the continued development of BAT8008 in this patient population. Clinical trial information: NCT05620017. Research Sponsor: None.

Efficacy Endpoint	2.1 mg/kg (n=27)	2.4 mg/kg (n=41)	Overall (n=68)
cORR, % (95% CI)	22.2 (10.6-40.8)	29.3 (17.6-44.5)	26.5 (17.4-38.0)
DCR, % (95% CI)	81.5 (63.3-91.8)	78.0 (63.3-88.0)	79.4 (68.4-87.3)
mPFS, months (95% CI)	5.3 (3.3-8.3)	6.7 (3.5-12.1)	6.5 (3.5-8.3)
mDoR, months (95% CI)	Not Reached	9.0 (4.2-12.3)	9.0 (5.3-12.3)

5508 **Oral Abstract Session**

A phase 1/2 study of the next-generation nectin-4–targeting antibody-drug conjugate CRB-701 (SYS6002) in patients with recurrent or metastatic cervical cancer. First Author: Tudor-Eliade Ciuleanu, Arensia Research Clinic, Cluj-Napoca, Romania

Background: CRB-701 is a next-generation Nectin-4–targeted monomethyl auristatin E (MMAE)-based antibody–drug conjugate with differentiated safety, efficacy and pharmacokinetics compared with other agents in the same class. As previously reported, CRB-701 demonstrated antitumor responses independent of Nectin-4 expression levels in solid tumors, notably in patients with heavily pretreated head and neck squamous cell carcinoma (HNSCC) and cervical cancer, as well as those with urothelial carcinoma. Here, we provide data from this phase 1/2 trial in patients with cervical cancer enrolled in dose escalation (part A) and dose optimization (part B) (NCT06265727). **Methods:** Patients with recurrent or metastatic (R/M) cervical cancer who had received $\geq$ 1 line of therapy were enrolled. Part A employed a Bayesian Optimal Interval design with four doses (1.8, 2.7, 3.6 and 4.5 mg/kg; each every 3 weeks [Q3W]) to determine the maximum tolerated dose. In part B, the pharmacologically active dose range identified in part A was evaluated using a time-to-event Bayesian optimal phase 2 design. Patients were randomized 1:1 to receive CRB-701 at 2.7 or 3.6 mg/kg Q3W. The primary endpoints for parts A and B were dose-limiting toxicities and objective response rate (ORR), respectively. Safety, tolerability and pharmacokinetics were also assessed. Nectin-4 expression was evaluated retrospectively. **Results:** As of September 2025, 54 patients with cervical cancer had enrolled across parts A and B. At the time of data cut, most patients were awaiting a confirmatory scan. The unconfirmed ORR was 22.2% (4/18 evaluable patients) at the 2.7 mg/kg dose and 37.5% (6/16 evaluable patients) at the 3.6 mg/kg dose. Confirmed partial responses were observed in 1/18 participants at the 2.7 mg/kg dose and 3/16 patients at the 3.6 mg/kg dose. One patient had a confirmed complete response at the 2.7 mg/kg dose. The safety profile of CRB-701 was broadly consistent with earlier findings: keratitis, anemia, alopecia, fatigue and dysgeusia were the most frequently reported treatment-emergent adverse events ($\geq$ 15% of overall solid tumor population [N = 167]). An expanded efficacy analysis reporting an additional 6 months of follow-up, including ORR, duration of response and progression-free survival, will be presented at the congress. Subgroup analyses by treatment history and disease extent will also be presented. **Conclusions:** CRB-701 has shown promising efficacy in patients with R/M cervical cancer, as well as a favorable safety profile compared with other MMAE-based therapies. Ongoing evaluation of CRB-701 will determine its potential as a new treatment option for this patient population. Clinical trial information: NCT06265727. Research Sponsor: None.

5509 Rapid Oral Abstract Session

Phase 1a study results for IMA203CD8, a PRAME-directed T-cell receptor (TCR) T-cell therapy, in ovarian cancer. First Author: Antonia Busse, Charite Medical University Hospital, Berlin, Germany

Background: Pts with advanced ovarian cancer (OC) that progresses after platinum-based chemotherapy and subsequent treatment are lacking therapeutic options for durable clinical benefit. TCR T-cell therapies enable immune recognition of intracellular tumor antigens presented by HLA, expanding the therapeutic landscape beyond targets accessible to conventional immunotherapies. PRAME is a cancer-associated antigen expressed across >50 cancers, including OC. IMA203CD8 is a TCR T-cell therapy that engineers CD8+ and CD4+ T cells to detect and destroy PRAME-expressing tumor cells that evade conventional therapeutic approaches. Results from a phase 1a basket trial (NCT03686124) indicated the potential to target several PRAME+ tumors. Here we present updated dose-escalation results for the subset of pts with OC. **Methods:** Pts were ≥18 y, HLA-A*02:01+, had R/R solid tumors, measurable disease (RECIST 1.1), ECOG PS 0-1, and had exhausted SOC options, including platinum therapy. Following leukapheresis and IMA203CD8 manufacture, pts underwent lymphodepletion (LD) with Cy (500 mg/m^2 × 4 d) and Flu (30 mg/m^2 × 4 d), followed by IMA203CD8 infusion +/- low-dose SUBQ IL-2. Dose escalation is ongoing. **Results:** As of Oct 27, 2025, 16 heavily pretreated pts with OC were infused with IMA203CD8. Most common TEAEs were LD-related cytopenias (100%). Cytokine release syndrome occurred in 100% of pts and was mostly mild to moderate (G1: 44%, G2: 50%, G3: 6%). Immune effector cell–associated neurotoxicity syndrome occurred in 1 pt (G1: 6%). Tolerability in pts with OC was generally consistent with the known IMA203CD8 safety profile. Eleven pts were efficacy evaluable with ≥1 post-baseline scan (median 4 prior lines of therapy) after treatment with IMA203CD8 across escalating dose levels (median: 2.26×10^9 total TCR T cells; range: 1.4-7.1×10^9 TCR T cells). Tumor reduction was observed in 7 pts with maximum reduction of 74%; 3 responses were >6 mo and durable disease control occurred for up to 12 mo. A dose-dependent signal of activity was observed in pts treated at higher doses (n=5; range: 2.3-7.1×10^9 TCR T cells), including 2 confirmed partial responses (PRs) with 1 ongoing metabolic complete response (CRs) at 6 mo, and 1 unconfirmed PR. All responses were observed in pts without post-infusion low-dose IL-2. Updated results from ≥20 efficacy-evaluable pts (including several unconfirmed PRs and CRs after data cutoff) with longer follow-up will be presented. **Conclusions:** In pts with metastatic and/or relapsed OC, IMA203CD8 demonstrated a tolerability profile consistent with prior experience in other solid tumors and encouraging dose-dependent antitumor activity, including durable objective responses according to RECIST. Dose escalation with and without IL-2 at higher doses is currently ongoing to determine RP2D and unlock the full potential of IMA203CD8 in OC. Clinical trial information: NCT03686124. Research Sponsor: Immatics US.

5510 Rapid Oral Abstract Session

The neo-epitope-based vaccine OSE2101 with or without pembrolizumab versus best supportive care as maintenance in platinum-sensitive recurrent ovarian cancer patients with controlled disease after platinum-based chemotherapy: The academic randomized TEDOVA/GINECO-OV244b/ENGOT-ov58 trial. First Author: Alexandra Leary, Gustave-Roussy Cancer Campus, Villejuif, and GINECO, Paris, France

Background: OSE2101 is a neo-epitope vaccine targeting 5 tumor-associated antigens (TP53, MAGE2, MAGE3, CEA and HER2) modified to increase both HLA-A2 and TCR affinity, designed to turn immunogenic 'cold' ovarian cancer (OC) to 'hot' tumors. Patients with platinum sensitive OC (PSOC) relapsing post-PARP inhibitor (PARPi) and bevacizumab (BEV) represent an area of unmet medical need. **Methods:** This international multicenter GINECO-sponsored phase II study randomized PSOC patients in CR, PR, or SD after platinum therapy to best supportive care (BSC, arm A), or maintenance treatment with OSE2101 ((SC, q3w until week 18, then q6w to week 48, then q12w, arm B) or OSE2101+pembrolizumab (IV q6w, Arm C) (1:1:2) for up to 2 years. Eligible pts were HLA-A2 positive and previously treated with, or ineligible for, BEV and a PARPi. Primary endpoint was PFS and randomization was stratified for best response to platinum (CR/PR vs SD). Sample size was calculated to provide 90% power to detect an improved PFS in arm C vs A with HR=0.57. Subsequent hierarchical testing then compared arms C vs B, and arms B vs A. **Results:** 185 pts were randomized to BSC (N=48), OSE2101 (N=46) or OSE+PEMBRO (N=91). Histology was mainly high grade (93%) and serous (93%), 20% harbored a *BRCA1/2* mutation, 51% of pts were in CR/PR and 49% in SD at randomization, 85% and 83% of pts were PARPi and BEV-exposed, respectively. Baseline characteristics were balanced between arms. With a median follow up of 22 months, PFS was significantly improved with OSE2101+Pembro vs BSC (4.1 vs 2.8mo in arms C vs A; HR=0.53, 95%CI, 0.36-0.78; p<0.001), especially among pts in CR/PR to platinum (HR=0.31, 95% CI, 0.17-0.53; p<0.01; test for interaction p=0.02). For OSE2101+Pembro vs OSE2101, HR was 0.72 (p=0.074) and for OSE2101 vs BSC, HR was 0.70 (p=0.099). Treatment emergent AEs were increased in arm C vs B with most common being injection site reaction (57% vs 35%), cytokine release syndrome (CRS, mainly G1/2: 28% vs 9%), arthralgia (21% vs 17%) and >G2 immune related events (18% vs 4%). **Conclusions:** This is the 1st trial demonstrating a significant improvement in PFS with a combination of a neo-epitope vaccine and an anti-PD1 as maintenance after platinum for patients with platinum sensitive relapsed OC progressing post-PARPi and bevacizumab. Clinical trial information: 2024-516096-32-00. Research Sponsor: OSE Immunotherapeutics, SA; ARCAGY-GINECO organization; MSD France.

5511 Rapid Oral Abstract Session

Overall survival for patients with pre-treated platinum-resistant ovarian cancer receiving gotistobart in combination with pembrolizumab. First Author: Joyce N. Barlin, Womens Cancer Care Associates, Albany, NY

Background: Gotistobart, an investigational tumor microenvironment-selective Treg depletion antibody targeting CTLA-4 with a novel mechanism of action, demonstrated anti-tumor activity when combined with prembrolizumab in the PRESERVE-004/GOG-3081 trial in patients (pts) with platinum-resistant ovarian cancer (PROC; Barlin et al., ESMO 2024). Here, we present overall survival (OS) and updated safety data from the Phase 2 trial (NCT05446298). **Methods:** Pts with PROC, tubal, or peritoneal cancer who previously received 1 line of platinum-based therapy and progressed between 3-6 months or received ≥1 line and progressed within 6 months of last dose, were treated with gotistobart (1, 2, 3, or 6 mg/kg, Q3W) and pembrolizumab (200 mg, Q3W). Here we present data from patients that received 1 or 2 mg/kg gotistobart Q3W and pembrolizumab. Primary endpoints included objective response rate (ORR) based on RECIST 1.1 and safety. Secondary endpoints included duration of response (DoR), progression-free survival (PFS) and OS. **Results:** As of November 12, 2025, 83 pts were treated with ≥1 dose of gotistobart in combination with pembrolizumab. Among them, 62 pts (85.5% White with a median age of 65 years and 83.9% with high grade serous OC) had received 1 or 2 mg/kg gotistobart, and 75.8% had received ≥3 lines of prior therapy (median 4, range: 1-10). The median time from randomization to database cutoff was 22.3 months (range 17.8, 27.2). Median OS was 18.9 m (95% CI 3.9, NE) and 8.3 m (95% CI 3.9 – 17.1) with the OS rates at 18 months at 54.3% (95% CI 35.1, 70.0) and 26.9% (95% CI 11.7 - 44.7) in pts that received 1 or 2 mg/kg gotistobart, respectively. Efficacy data are summarized in the table below. Grade ≥3 treatment-related (gotistobart or pembrolizumab) adverse events (TRAEs) were observed in 51.5% and 55.2% pts treated with 1 mg/kg or 2 mg/kg, respectively. Common (≥5%) grade ≥3 TRAEs were colitis (1 mg/kg: 12.1%, 2 mg/kg: 10.3%), hyponatremia (1 mg/kg: 12.1%, 2 mg/kg: 3.4%), increased ALT (1 mg/kg: 9.1%, 2 mg/kg: 3.4%), increased AST (1mg/kg: 9.1%, 2 mg/kg: 3.4%), adrenal insufficiency (1 mg/kg: 9.1%, 2 mg/kg: 3.4%), diarrhea (1 mg/kg: 9.1%, 2 mg/kg: 3.4%), and hypokalemia (1 mg/kg: 0%, 2 mg/kg: 6.9%). **Conclusions:** The chemotherapy-free combination of gotistobart and pembrolizumab demonstrated clinically meaningful ORR, OS and a manageable safety profile in pts with PROC, where the majority were heavily pretreated with no further standard-of-care treatment options. Clinical trial information: NCT05446298. Research Sponsor: Onco C4 Inc.

5512 Rapid Oral Abstract Session

Safety and efficacy of BAT8006 in combination with BAT1308 in patients with advanced endometrial cancer. First Author: Xingtao Long, Chongqing University Cancer Hospital, Chongqing, China

Background: BAT8006 is a folate receptor α (FRα)-targeting antibody-drug conjugate (ADC), while BAT1308 is a recombinant humanized anti-PD-1 monoclonal antibody. Both agents have individually demonstrated acceptable tolerability and promising antitumor activity in solid tumors. Herein, we report a phase Ib/II trial designed to evaluate the safety and efficacy of BAT8006 in combination with BAT1308 for patients with advanced endometrial cancer. **Methods:** Eligible patients included those with pathologically confirmed endometrial cancer who had experienced disease recurrence or progression following at least 1 line of platinum-based chemotherapy or immunotherapy-based regimen, with no more than 3 prior lines of systemic therapy. Enrolled patients received BAT8006 (76 mg/m² or 84 mg/m²) in combination with BAT1308 (fixed dose of 300 mg) every 3 weeks until disease progression, intolerable toxicity, or other protocol-specified reasons. The primary endpoints were safety and ORR as assessed by investigators per RECIST v1.1. **Results:** As of December 25, 2025, a total of 45 patients with advanced endometrial cancer were enrolled in this study. The median age of the cohort was 62 years (range, 27–75 years). Among these patients, 80.0% had ECOG PS of 0, and 80.0% presented with metastatic disease at baseline. All patients had received prior platinum-based chemotherapy; additionally, 48.9% had undergone prior immunotherapy, and 15.6% had received two or more prior lines of systemic therapy. The proportion of patients with FRα positivity (defined as FRα expression ≥1%) was 62.2%. TRAEs were reported in 41 patients (91.1%). Grade ≥3 (G3) TRAEs occurred in 24 patients (53.3%), and SAEs were observed in 17 patients (37.8%). The most common TRAEs (incidence ≥20%) included leukopenia (77.8%), anemia (77.8%), neutropenia (62.2%), nausea (55.6%), thrombocytopenia (53.3%), vomiting (48.9%), lymphopenia (35.6%), pyrexia (26.7%), decreased appetite (26.7%), increased alanine aminotransferase (22.2%), and asthenia (22.2%). No cases of interstitial lung disease were reported. IrAEs occurred in 3 patients (6.7%). TRAEs resulted in dose reduction in 10 patients (22.2%) and treatment discontinuation in 2 patients (4.4%). No treatment-related deaths were recorded. Efficacy was evaluable in 34 patients. The overall ORR was 38.2% (95% CI: 22.2–56.4), and DCR was 70.6% (95% CI: 52.5–84.9). In the BAT8006 (76 mg/m²) + BAT1308 cohort, ORR was 44.4% (95% CI: 21.5–69.2) and DCR was 72.2% (95% CI: 46.5–90.3). In the BAT8006 (84 mg/m²) + BAT1308 cohort, ORR was 31.3% (95% CI: 11.0–58.7) and DCR was 68.8% (95% CI: 41.3–89.0). **Conclusions:** These findings suggest that BAT8006 in combination with BAT1308 may represent an effective therapeutic strategy for advanced endometrial cancer, with a manageable safety profile. Further prospective studies are warranted to validate the efficacy and safety of this combination regimen. Clinical trial information: CTR20242449. Research Sponsor: None.

NAPISTAR 1-01: Results of phase 1 dose escalation of monotherapy with TUB-040, a novel NaPi2b-targeting exatecan ADC, in patients (pts) with platinum-resistant ovarian cancer (PROC). First Author: Toon Van Gorp, BGOG and University Hospital Leuven, Leuven Cancer Institute, Leuven, Belgium

Background: NaPi2b is overexpressed in high-grade serous ovarian cancer and non-small cell lung cancer (NSCLC). TUB-040 is a DAR8 ADC targeting NaPi2b, comprising a humanized Fc-silenced IgG1 mAb conjugated to exatecan via a cleavable, cysteine-selective, stable, solubility-mediating P5 linker providing excellent stability and biophysical ADC properties. In preclinical studies, TUB-040 induces potent antigen-specific cytotoxicity and demonstrates strong by-stander activity. **Methods:** NAPISTAR 1-01 is a phase 1/2a study in biomarker-unselected pts with PROC and NSCLC. TUB-040 was administered Q3W in dose escalation (range 0.5-5.3 mg/kg) to pts with PROC until progression or unacceptable toxicity. **Results:** As of Dec 1, 2025, 67 PROC pts received TUB-040 for a median of 10 cycles (1-25), median duration of exposure was 213 days (21-546), and 42 (63%) pts were ongoing. Median age: 62 years (34-81), ECOG PS 0-1, median prior lines: 4 (1-7), prior treatment included bevacizumab (84%), PARPi (76%), and mirvetuximab soravtansine (13%). Between dose levels 1.67-3.3mg/kg (N=46), the most common all-grade TEAEs were nausea (78%), fatigue (54%), neutropenia (43.5%), anemia (37%), constipation (34%), diarrhea (33%), vomiting (28%), alopecia (28%), and decreased appetite (26%). Gr≥3 heme TEAEs by dose are in Table 1. There were no fatal TEAEs or treatment discontinuations due to TEAEs. Three pts (6.5%) experienced Gr1 pneumonitis, which resolved. Between dose levels 1.67–3.3 mg/kg, 46 pts were evaluated for efficacy. The uORR was 63% [95% CI, 47.5-77.2] and cORR was 60.9% [95% CI, 45.3-75.1] (RECIST; v1.1), including two cCRs. Responses by dose are in Table 1. The majority of responses, 90% (26/29), were ongoing. Disease control rate was 96% [95% CI, 85.2-99.5]. Among CA-125 evaluable pts (N=42), CA-125 response occurred in 81% (34/42) [95% CI, 65.6-91.5]. cORRs were similar across subgroups, including: ≥4 prior lines of therapy (cORR=71%), prior exposures to bevacizumab (62%), mirvetuximab soravtansine (63%) or PARPi (67%). Five pts with stable disease remain on treatment and eligible for response. **Conclusions:** TUB-040 was well tolerated with promising clinical activity at low doses, offering a potential new treatment option with a differentiated, favorable benefit–risk profile and a wide therapeutic window in PROC pts. Dose optimization is currently ongoing. Clinical trial information: NCT06303505. Research Sponsor: Tubulis GmbH.

Phase 1 basket study of telisotuzumab adizutecan (Temab-A, ABBV-400), a c-Met protein–targeting antibody-drug conjugate: Results from patients with platinum-resistant ovarian/primary peritoneal/fallopian tube cancer (PROC). First Author: Gini F. Fleming, University of Chicago Medicine, Chicago, IL

Background: c-Met protein is expressed in several tumor types, including PROC, and is linked with poor clinical outcomes. Temab-A comprises a c-Met protein-targeting antibody conjugated to a topoisomerase 1 inhibitor. Phase 1 studies evaluating Temab-A monotherapy in solid tumors showed antitumor activity and a manageable safety profile (NCT05029882, NCT06084481). Here, we report on the efficacy and safety of Temab-A in PROC. **Methods:** This phase 1, open-label basket study (NCT06084481) enrolled patients (pts) ≥18 years with histologically/cytologically confirmed recurrent PROC, with Eastern Cooperative Oncology Group performance score ≤1. Pts must have had measurable disease per investigator-assessed RECIST v1.1 criteria, have had platinum-resistant disease, and have received ≥1 but ≤5 prior lines of systemic therapy, with ≤2 prior therapies since the development of platinum resistance. Pts received Temab-A at 2.4 mg/kg every 3 weeks. Primary endpoints were safety and efficacy. **Results:** As of Sept. 11, 2025, 41 pts with PROC received Temab-A. Tumor histology included serous carcinoma (n=26), clear cell carcinoma (n=7), and other rare histologies (n=8). The median age was 64 years (range 43–89), and the median number of prior lines of systemic therapy was 3 (range 1–6). Median follow-up was 5.1 months. Objective response rate (ORR) was 37%. Duration of response, progression-free survival, and overall survival were immature at data cutoff. Efficacy data are shown in the Table. The most common treatment-related adverse events (TRAEs) of any Grade (G) included anemia (59%), nausea (59%), and fatigue (39%); G ≥3 TRAEs occurring in ≥10% of pts were anemia (34%), neutrophil count decreased (17%), and white blood cell count decreased (15%). The adjudicated interstitial lung disease/pneumonitis rate was 5% (G1, n=2). TRAEs led to treatment discontinuation in 5%, dose interruption in 39%, and dose reduction in 37% of pts. There were no TRAEs that led to death. Temab-A pharmacokinetics in pts with PROC were consistent with those in other tumor types. Exploratory biomarker analyses are ongoing. **Conclusions:** Temab-A had a manageable safety profile and showed antitumor activity in pts with PROC. Clinical trial information: NCT06084481. Research Sponsor: AbbVie Inc.

5515 Rapid Oral Abstract Session

Updated safety and efficacy of puxitatug samrotecan (Puxi-Sam, AZD8205) in patients (pts) with endometrial cancer (EC) or ovarian cancer (OC): Phase 1/2a BLUESTAR study. First Author: Linda R. Mileshkin, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: B7-H4, a transmembrane glycoprotein that negatively regulates T cells, is highly expressed in EC and OC. Puxi-Sam (AZD8205), a B7-H4–directed topoisomerase I inhibitor antibody–drug conjugate, showed manageable toxicity and promising antitumor activity in BLUESTAR (NCT05123482) dose-escalation. Here, we report updated safety and efficacy results as EC and OC expansion cohorts are fully enrolled. **Methods:** Eligible pts were ≥18 years old with relapsed/metastatic B7-H4–positive (≥25% tumor cell staining by central immunohistochemistry) EC or OC and an ECOG PS ≤1. Pts had progressed on prior standard-of-care therapy including platinum-based chemotherapy. Pts with EC received Puxi-Sam at 2.0 or 2.4 mg/kg IV Q3W and pts with OC received Puxi-Sam at 1.6 or 2.4 mg/kg IV Q3W. The primary objectives were to assess safety and tolerability; secondary objectives included assessment of antitumor activity per RECIST 1.1. **Results:** As of October 30, 2025, 93 pts with EC received Puxi-Sam at 2.0/2.4 mg/kg and 78 with OC at 1.6/2.4 mg/kg. Pts with EC had a median age (min–max) of 63.5 (52–78)/65 (34–81) years, respectively, and median prior lines of therapy (LOT) was 1. Pts with OC had a median age of 58 (28–79)/59 (35–74) years, respectively, and median prior LOT was 2. Treatment-related adverse events (TRAE) occurred in 92.9%/88.2% of pts with EC (2.0/2.4 mg/kg); 42.9%/47.1% had Grade ≥3 TRAEs, most commonly neutropenia (23.8%/31.4%) and anemia (16.7%/27.5%). TRAEs occurred in 87.9%/97.8% of pts with OC (1.6/2.4 mg/kg); 30.3%/75.6% had Grade ≥3 TRAEs, most commonly neutropenia (24.2%/60.0%) and anemia (9.1%/37.8%). One pt (1.1%) with EC and 5 (6.4%) with OC discontinued treatment due to TRAEs. Antitumor activity of Puxi-Sam was most notable in EC at 2.4 mg/kg, with an objective response rate (ORR) of 48% and durable response of 7.1 months; at 2.0 mg/kg in EC, ORR was 34.1%. In OC, ORR was 12.1% at 1.6 mg/kg and 24.4% at 2.4 mg/kg (Table). **Conclusions:** Puxi-Sam showed a favorable safety profile and robust antitumor efficacy, supporting continued development, and is now being investigated in the Phase 3 BLUESTAR-Endometrial01 (NCT07044336) study. Clinical trial information: NCT05123482. Research Sponsor: AstraZeneca.

Updated efficacy, safety, and exploratory biomarker analyses of a phase II trial of abemaciclib plus hormonal therapy in recurrent ovarian (OC) and endometrial cancer (EC). First Author: Jordyn Silverstein, University of California Los Angeles, Los Angeles, CA

Background: We evaluated abemaciclib with hormonal therapy in patients with estrogen receptor positive (ER+) EC, low-grade serous OC (LGSOC), and selected high-grade serous OC (HGSOC) with CDK4/6 molecular activation features in a single-center, phase II study. Preliminary results demonstrated a 24-week progression-free survival (PFS) rate of 53% in ER+ EC and 60% in LGSOC (2025 SGO Abstract 256). Here, we report the final clinical outcomes and present the first exploratory biomarker analyses from this study. **Methods:** Abemaciclib was administered at 150mg twice daily in combination with hormonal therapy. The primary endpoint was 24-week PFS; secondary endpoints were median PFS (mPFS), disease control rate (DCR), objective response rate (ORR) and safety. Exploratory analyses evaluated efficacy by TCGA molecular subgroups and tumor next-generation sequencing–defined alterations. PFS was estimated using Kaplan–Meier and compared using log-rank. **Results:** As of December 2, 2025, 43 patients (21 HR+ EC, 14 LGSOC, 8 HGSOC) were evaluable, with a median follow-up of 29 months (mos). Median age was 64 (range 24-78) and median prior lines of therapy was 3 (range 1-13). Among 21 patients with ER+ EC, the 24-week PFS rate was 56.1% (95% CI 34.5–77.7), mPFS was 9.0 mos (2.4–11.3), DCR was 63%, and ORR was 21%, including one complete response. There were 13 (62%) NSMP, two (10%) MSI-high, two (10%) TP53-abnormal, one (5%) POLE-mutated, and three without molecular data. The NSMP group had 24-week PFS rate and mPFS of 59.8% (32-87.3%) and 10.4 mos (2.4-21.0), compared with 20.0% (0-55.0) and 1.9 mos (1.7-9.3) in the non-NSMP group (p=0.02). Notably, all responses occurred in the NSMP group. The largest difference was observed between patients with CTNNB1mut with a mPFS of 10.4 months (1.9–NR) compared with 5.2 mos (1.7–9.3) in patients with CTNNB1wt (p = 0.22). Among 14 patients with LGSOC, the 24-week PFS rate was 71.4% (47.8-95.1), mPFS was 17.5 mos (3.5-NR), DCR was 79% and ORR was 14%, 5 still on treatment at data cut off. The median time on treatment was 10.5 mos (range 1.7-55.4), 4 patients (28%) were on treatment for more than 3 years, the longest still on treatment after 4.6 years. The most common mutation was KRAS in 7 (50%), with no observed differences by KRAS status (KRASmut 11.9 mos [1.9-NR] mPFS, KRASwt 17.5 mos [3.5-NR] mPFS , p=0.89). Despite the 8 patients with HGSOC having CDK4/6 activating mutations the 24-week PFS rate was 12.5% (0-35.4) and the mPFS was 1.6 mos (0.3-1.9). No new safety signals were observed across all subgroups. **Conclusions:** Abemaciclib demonstrated promising clinical activity in patients with LGSOC regardless of KRASmut status and in ER+ EC, with the greatest activity observed in the NSMP group and potentially CTNNB1-mutated cases; however, these exploratory subgroups need larger validation. Clinical trial information: NCT04469764. Effects of short-term fasting compared to free diet in ovarian cancer patients: Results from a two-arm pilot randomized trial. First Author: Claudia Marchetti, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: Short-term fasting (STF) may enhance chemotherapy efficacy by suppressing insulin-driven pro-survival signaling. Clinical data on the metabolic, oncological, and immunological effects of STF in ovarian cancer (OC) are lacking. **Methods:** In this prospective, pilot randomized trial conducted at our center, women with advanced high-grade serous OC receiving carboplatin/paclitaxel-based neoadjuvant chemotherapy (NACT) were randomized to STF (36h before to 24h after each cycle) or a free diet (FD). Eligibility criteria included body mass index $\geq$ 19 kg/m2. Major exclusions were diabetes mellitus, food allergies, and eating disorders. The primary endpoint was insulin reduction after three NACT cycles. Secondary endpoints included oncological outcomes. Exploratory translational analyses assessed immune profiling. Based on 80% power and a two-sided α of 0.05, 17 patients per arm were required. **Results:** Eighteen patients per arm completed three NACT cycles. Baseline clinical characteristics and insulin levels were comparable between groups. After NACT, insulin increased in FD but decreased in STF (+9.76 vs -1.12 μIU/mL; p=0.01). Patients who did not undergo interval cytoreductive surgery (ICS) after three cycles experienced a greater insulin increase than those who underwent surgery (+11.46 vs +1.35 μIU/mL; p=0.033). At ICS, a chemotherapy response score of 3 was more frequent in STF than in FD (58.8% vs 17.6%; p=0.03). After a median follow-up of 18 months, median progression free survival (PFS) was longer in the STF arm compared with FD (38 vs 24 months; p=0.045). Translational analyses showed that STF limited immunosuppressive subsets correlated with chemotherapy response. **Conclusions:** The primary endpoint was met. STF induced a favourable metabolic shift and was associated with improved pathological response and prolonged PFS, alongside immune modulation. These findings provide a strong rationale for larger randomized trials evaluating STF in OC. Clinical trial information: NCT07039331. Research Sponsor: None.

Population-based prediction of cardiovascular mortality in gynecologic cancer survivors using machine learning (RISKHEART). First Author: Luís Felipe Leite da Silva, Universidade Federal Fluminense, Niterói, Brazil

Background: General-population cardiovascular disease (CVD) risk scores underperform in cancer survivors by failing to capture treatment-related cardiotoxicity. Gynecologic cancer survivors constitute a distinct phenotype defined by older age and heterogeneous therapies. RISKHEART is an oncology-specific, survivorship-oriented model for individualized cardiovascular risk stratification. **Methods:** Women with primary gynecologic malignancies diagnosed between 2000 and 2020 were identified from the SEER program. Predictors included demographics (age, race, marital status) and SEER-available treatment variables (surgery, radiation, and chemotherapy [yes/no]). Model performance was evaluated using AUC, and explainability was assessed via SHAP. **Results:** The study included 104,384 women with gynecologic cancer. CVD-specific death occurred in 4,962 patients, with cumulative incidence rates of 2.44% at 5 years and 4.75% at 10 years. Affected patients were significantly older at diagnosis than those without CVD death (mean age, 75.0 vs 62.5 years; $P < .001$). CVD mortality differed by marital status and race (both $P < .001$), with widowed patients accounting for a higher proportion of CVD deaths (37.3% vs 17.7%). Endometrial cancer accounted for most CVD deaths (58.2%), whereas ovarian cancer was underrepresented among CVDs deaths relative to its prevalence in the overall cohort (15.1% vs 27.8%). In the independent testing cohort, the RISKHEART model demonstrated good discrimination for 10-year cardiovascular mortality (AUC, 0.786). For 5-year cardiovascular mortality, discrimination was slightly higher (AUC, 0.796), with sensitivity of 0.73 and specificity of 0.74. For the 5-year cardiovascular mortality model, discrimination remained elevated across 2000-2009 (AUC, 0.805) and 2010-2020 (AUC, 0.784). Explainability analyses identified age at diagnosis as the dominant predictor of cardiovascular death, with treatment-related variables contributing more prominently to short-term risk and sociodemographic factors increasing in relative importance over longer follow-up. **Conclusions:** In this large population-based cohort of gynecologic cancer survivors, the RISKHEART ML model demonstrated clinically meaningful discrimination for predicting CVD-specific mortality. This approach may support individualized CVD risk stratification and inform survivorship care. Research Sponsor: None.

Feasibility and concordance of a large language model (ChatGPT-5) as a clinical decision support tool in gynecologic oncology tumor boards: A blinded, multi-observer study. First Author: Hatice Asoglu, Cukurova University Department of Medical Oncology, Adana, Turkey

Background: The integration of artificial intelligence (AI) into oncology practice is accelerating; however, the reliability of Large Language Models (LLMs) in complex clinical decision-making remains insufficiently validated. This study evaluated the concordance of ChatGPT-5 with multidisciplinary tumor board (MDT) decisions in gynecologic oncology, assessing accuracy, reproducibility across repeated queries, and specific domains of discordance. **Methods:** We analyzed 97 gynecologic cancer cases requiring multimodal treatment planning, evaluated at the Cukurova University Faculty of Medicine Gynecologic Oncology MDT between 2024-2025. Cases included ovarian (n=34), endometrial (n=41), cervical (n=16), and rare tumors (n=6). Standardized clinical summaries (staging, pathology, molecular markers, comorbidities, patient preferences) were input using a structured prompt template. Each case was queried independently at three time points within the same day to assess reproducibility. Recommendations were evaluated by two blinded medical oncologists using a 5-point Likert scale (1=completely inappropriate, 5=completely appropriate). A composite performance score was calculated as [(mean Likert score)/5]$\times$100. Inter-rater reliability and concordance were analyzed using Cohen's kappa (κ). **Results:** Inter-rater reliability was high for both MDT (κ=0.748, $p<0.001$) and AI evaluations (κ=0.802, $p<0.001$). Concordance between MDT and ChatGPT-5 recommendations was fair (Rater 1: κ=0.267; Rater 2: κ=0.341), indicating frequent disagreement in specific clinical nuances despite similar overall quality scores. Mean performance scores were significantly higher for MDT versus AI (Rater 1: 94.2%$\pm$4.8 vs. 89.8%$\pm$6.3, $p<0.001$; Rater 2: 93.8%$\pm$5.1 vs. 90.1%$\pm$5.9, $p<0.001$). Crucially, ChatGPT-5 demonstrated full consistency across three queries in only 38% of cases (37/97), with a mean reproducibility score of 4.10$\pm$0.83. Subgroup analysis revealed superior AI performance in early-stage (I–II) versus advanced-stage (III–IV) disease (p=0.024). However, AI performance was significantly inferior in cases requiring genetic testing recommendations (p=0.019), fertility-sparing approaches (p=0.045), and novel therapeutics integration (p=0.012). **Conclusions:** ChatGPT-5 demonstrates potential as a clinical decision support tool but currently lacks sufficient reliability for independent use in complex gynecologic malignancies. Key limitations include inconsistent reproducibility (62% variability across queries), suboptimal performance in advanced-stage disease, and deficiencies in precision oncology domains. Human expertise remains essential to mitigate risks associated with AI-generated inaccuracies, particularly for novel therapeutic integration. Research Sponsor: None.

Quantitative pathology biomarkers for platinum resistance in ovarian cancer. First Author: Durga Vahini Sritharan, Yale School of Medicine, Department of Therapeutic Radiology, New Haven, CT

Background: Despite serving as the first-line systemic treatment for high-grade serous ovarian cancer, roughly 20% of patients fail to respond to platinum-based chemotherapy. However, there is a paucity of biomarkers which correlate to platinum resistance. Effective biomarkers would allow for individualized risk profiling and early identification of patients who may benefit from treatment escalation. Quantitative pathologic biomarkers have shown prognostic utility in several cancers and offer a potential low-cost approach to address challenges in assessing platinum resistance. We examined the utility of machine learning (ML)-derived pathologic biomarkers in identifying platinum-resistant ovarian cancer. **Methods:** Our multi-institutional dataset included 158 whole-slide images (WSIs) obtained from resection of primary ovarian cancer, with 86 (54%) in the training cohort and 72 (46%) in the validation cohort. Our dataset included 112 (71%) platinum-sensitive and 46 (29%) platinum-resistant WSIs. The CLAM deep learning framework and CONCH visual-language foundation model were utilized to segment tissue, generate 256 x 256 image patches, and extract 512-dimensional features from each patch. Non-linear dimensionality reduction, employing Uniform Manifold Approximation and Projection (UMAP), was applied to cluster training samples, and validation samples were projected onto the learned low-dimensional space. Samples were stratified into predicted-sensitive and predicted-resistant cohorts based on similarity to training-derived clusters, and clinical characteristics were compared using a two-tailed t-test and chi-square tests. **Results:** UMAP analysis identified distinct phenotypes associated with platinum sensitivity and resistance. At the image level, UMAP-defined phenotypes exhibited high predictive ability. Of the predicted-sensitive images in the validation cohort, 79% showed platinum sensitivity. UMAP-defined phenotypes demonstrated moderate patch-level accuracy in identifying platinum-sensitive samples (training accuracy 69%, validation accuracy 65%). Additionally, clinical correlates to pathology-based predictions were investigated. Predicted-resistant patients were significantly older (median age, 69 years [IQR 59.5–76.26] vs. 62 years [IQR 55–68], p = .021) and more frequently higher-staged (IIIC/IV 89% vs. 77%, p = .087) compared to predicted-sensitive patients. **Conclusions:** ML-derived pathologic biomarkers can aid in the identification of platinum-resistant ovarian cancer. Our future work will evaluate the relationship between quantitative biomarkers and known clinical predictors of platinum resistance, such as CA-125 and the extent of residual disease at cytoreduction. Integrating multimodal biomarkers in clinical decision-making practices will allow for improved risk stratification and individualized treatment for patients. Research Sponsor: None.

Income inequality and cervical cancer: A comparative analysis of demographics and healthcare burden of women in the lowest and highest income quartiles. First Author: Dhruvi Dipakkumar Pathak, Government Medical College, Surat, India

Background: Cervical cancer disproportionately affects women of lower socioeconomic status, yet comprehensive data comparing the demographic profiles and comorbidity burden across income strata remain limited. This study examines differences in patient characteristics, comorbidities, and healthcare utilization between women in the lowest and highest income quartiles hospitalized with cervical cancer in the United States. **Methods:** We identified women hospitalized with cervical cancer in the United States between 2016 and 2022 using ICD-10 codes C53.x in the National Inpatient Sample. Patients were classified into the lowest (0–25th percentile) and highest (76th–100th percentile) income quartiles based on median household income for their residential ZIP code. We compared demographic characteristics including age, race, socioeconomic distribution, and clinically relevant comorbidities across the two groups. Healthcare utilization was evaluated by analyzing length of stay and inflation-adjusted mean hospital charges. **Results:** We identified 88,240 women hospitalized with cervical cancer; 69.7% were in the lowest income quartile and 30.3% in the highest. Women in the highest income quartile were older (mean age 55.45 vs. 52.62 years, $p<0.001$) and incurred higher inflation-adjusted hospital charges ($88,955 vs. $76,121, $p<0.001$), though length of stay was comparable (5.64 vs. 5.82 days, p=0.134). Significant racial disparities were evident: the highest income quartile had more White patients (63.2% vs. 46.2%) while the lowest quartile had more Black (29.1% vs. 11.1%) and Hispanic (19.0% vs. 12.2%) patients ($p<0.001$). Women in the lowest income quartile had significantly higher prevalence of smoking (40.2% vs. 31.0%), diabetes (19.8% vs. 13.8%), chronic kidney disease (16.6% vs. 14.0%), obesity (14.4% vs. 11.5%), HIV (2.1% vs. 0.9%), depression (12.1% vs. 10.9%), opioid use disorder (3.1% vs. 1.9%), drug abuse (7.7% vs. 3.5%), and alcohol abuse (2.0% vs. 1.4%) (all $p<0.05$). Conversely, the highest income quartile had higher rates of metastatic cancer (41.8% vs. 38.7%, $p<0.001$). No significant differences were observed in dyslipidemia (17.6% vs. 16.7%, p=0.165), cachexia (4.3% vs. 4.6%, p=0.396), or palliative care utilization (13.0% vs. 13.5%, p=0.413). **Conclusions:** Women in the lowest income quartile comprise the majority of cervical cancer hospitalizations and face disproportionately higher rates of modifiable risk factors and comorbidities. Targeted interventions addressing screening access, preventive care, and comorbidity management in low-income populations are essential to reduce health disparities in cervical cancer. Research Sponsor: None.

Treatment patterns and PD-L1 testing among persistent, recurrent, or metastatic cervical cancer patients in the United States community oncology setting. First Author: Elizabeth A. Szamreta, Merck & Co., Inc., Rahway, NJ

Background: Pembrolizumab was approved for persistent, recurrent, or metastatic cervical cancer (PRM-CC) among patients (pts) with PD-L1 expression in October 2021. This followed its June 2018 approval for PD-L1-positive recurrent, metastatic pts who progressed after chemotherapy. This real-world study aimed to describe treatment patterns and PD-L1 testing patterns among pts with PRM-CC between 2018-2024. **Methods:** Electronic medical record data from The US Oncology Network identified adult PRM-CC pts diagnosed between July 2018 and July 2022 and followed through June 2024. Persistent disease was defined as either absence of a complete response or provider-documented progression within 90 days following the completion of initial CC-related treatment. **Results:** There were 216 PRM-CC pts eligible for the study. Overall, median age was 55 years and median duration of follow-up was 12.8 months. Overall, 56% (n = 121) of PRM-CC pts had documented PD-L1 testing during the study observation period, of which 78% (n = 94) had a positive result and 7% (n = 8) had undocumented result. Among PD-L1 positive pts without metastatic disease at initial diagnosis (n = 121), 41% were tested after PRM-CC diagnosis date and had a median time from diagnosis to PD-L1 testing of 1.4 months, and 11% were tested prior to PRM-CC diagnosis date. PD-L1 testing increased from 54% to 69% after October 2021, yet 43% of PD-L1+ patients did not receive pembrolizumab after 2021. 12% (8/69) of pts who received pembrolizumab did not have documented PD-L1 testing. Pembrolizumab was received by 27 pts in 1L (pre-2021: 16, post-2021: 11) and 26 patients in 2L pre-2021: 17, post-2021: 9). Most patients had metastatic disease (74%, n = 159), of which 60% (n = 95) presented with metastatic disease at initial diagnosis. Concurrent chemoradiation prior to metastatic disease was received by 38% (n = 81) of pts. The majority of pts with metastatic disease received first line (1L) treatment (n = 86%, n = 137) and 28% (N = 45) of pts initiated 2L treatment. During the first regimen of 1L, 96 pts received a platinum+taxane-containing regimen (+bevacizumab, n = 72). **Conclusions:** Between 2018-2024, many PRM-CC pts were not tested for PD-L1 although biomarker-driven treatments were available. Among those tested, almost half of PD-L1 positive patients did not receive standard-of-care therapy. The current treatment landscape provides a valuable opportunity to standardize and enhance PD-L1 testing in order to optimize treatment selection and support personalized care in this population. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc.

Radiotherapy use among locally advanced cervical cancer patients (LACC) in the United States community oncology setting. First Author: Elizabeth A. Szamreta, Merck & Co., Inc., Rahway, NJ

Background: Brachytherapy with concurrent chemoradiation +/- pembrolizumab is the current standard of care for LACC. American Society for Radiation Oncology (ASTRO) recommends external beam radiation therapy (EBRT)+brachytherapy, and since 2020 has recommended intensity modulated radiation therapy (IMRT) over other forms of EBRT due to reduced toxicity risk. However, real-world evidence is needed to characterize patient outcomes based on the type of radiation received. **Methods:** Electronic medical record (EMR) data from The US Oncology Network identified adult LACC (FIGO 2018 Stage IB3-IVA) patients (pts) diagnosed between July 2018 – July 2022 and followed through June 2024. Pts were stratified by receipt of IMRT or Volumetric Modulated Arc Therapy (VMAT) and brachytherapy during the observation period. Patient characteristics and provider-documented progression were assessed descriptively. **Results:** This study included 250 LACC pts; 73 (29%) pts received IMRT or VMAT, 177 (71%) pts received other forms of EBRT; and 189 (76%) pts received brachytherapy. Overall, 61 pts (24%) received both IMRT or VMAT and brachytherapy. Among the 148 pts who were diagnosed in 2020 or later, 28% received IMRT or VMAT. Disease progression occurred among 14% of IMRT or VMAT pts and 63% of non IMRT or VMAT patients; progression was similar across brachytherapy and non-brachytherapy patients. **Conclusions:** Advanced radiation techniques such as IMRT or VMAT and brachytherapy are associated with improved outcomes for patients with LACC, yet their combined use only occurs among 1 in 4 LACC patients, which is notably less than clinical trials. These findings present an opportunity to broaden adoption of evidence-based radiation strategies, supporting optimal treatment delivery and improved patient outcomes. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc.

Targeting stromal FAK signaling to address chemotherapy and immunotherapy resistance in gastric-type endocervical adenocarcinoma. First Author: Ting Peng, Department of Obstetrics and Gynecology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China

Background: Gastric-type endocervical adenocarcinoma (GAC) is a rare, HPV-independent cervical cancer subtype with profound resistance to standard chemotherapy and radiotherapy and an exceptionally poor prognosis. Unlike HPV-associated cervical cancers, GAC lacks established molecular targets and effective treatment strategies. Whether patients with GAC can benefit from immunotherapy remains unclear, and the biological mechanisms underlying its intrinsic resistance to both cytotoxic and immune-based therapies are poorly understood. **Methods:** We established an integrated translational platform incorporating patient-derived GAC cell lines, organoids, and matched primary cancer-associated fibroblasts (CAFs). These models were integrated with multi-omics profiling of clinical specimens, including single-cell RNA sequencing of 58 cervical lesions across disease states, together with molecular and functional validation assays, to systematically characterize tumor–stroma interactions and identify actionable therapeutic vulnerabilities. **Results:** Multi-omics analyses revealed that GAC converges on a pancreatic ductal adenocarcinoma–like transcriptional and microenvironmental program characterized by stromal dominance and therapeutic refractoriness. Mechanistically, GAC tumor cells reprogram the tumor microenvironment through secretion of LAMA3, activating a CD44/ITGB1-dependent FAK signaling axis in CAFs. Stromal FAK activation drives extracellular matrix remodeling and endothelial dysfunction, establishing a profoundly immunosuppressive niche marked by impaired antigen presentation and enrichment of tissue-resident $CD8^+$ T cells ($CD8^+ITGA1^+$). This stromal program mechanistically underlies resistance to both chemotherapy and immunotherapy. In patient-derived GAC organoid-based models, FAK inhibition enhanced responses to chemotherapy and immunotherapy in vitro, supporting a translational rationale for FAK-targeted combination strategies. Based on these findings, we initiated a multicenter, phase II clinical trial evaluating the FAK inhibitor IN10018 in combination with nab-paclitaxel and cadonilimab in patients with metastatic, recurrent, or persistent GAC (NCT06654011). **Conclusions:** Gastric-type endocervical adenocarcinoma is a stroma-driven malignancy in which aberrant stromal FAK signaling is a central mediator of resistance to both chemotherapy and immunotherapy. Targeting this stromal dependency provides a compelling therapeutic strategy and directly informs an ongoing phase II clinical trial addressing a critical unmet need in this aggressive disease. Retrospective study of guideline concordance in cervical cancer screening surveillance by age, race, and ethnicity. First Author: Maeve Fitzgerald Givens, Weill Cornell Medical College, New York, NY

Background: Nearly one in five new cervical cancer cases occur in individuals aged ≥ 65, with higher incidence among Black women compared to White women. Despite these disparities, evidence guiding screening and surveillance in older women is limited. This study evaluates guideline concordance for follow-up after abnormal cervical cancer screening and examines variation by age, race, and ethnicity. **Methods:** This retrospective cohort study assessed 1,861,906 cervical cancer screening results (2009-2024) from the TrinetX database. Included patients were female, ≥ 21 years old, and had an HPV test or pap smear. Guideline concordance (i.e., colposcopy within one year of high-risk cervical cancer screenings result) was assessed by running logistic regression models by age group, race, and ethnicity. Logistic regression assessed odds of concordant follow-up by age, race, and ethnicity, using women aged 30–39 and non-Hispanic White women as reference groups, respectively. **Results:** Guideline-concordant follow-up varied by age: 56.87% aged 21-29, 58.84% aged 30-39, 56.36% aged 40-49, 53.93% aged 50-65, and 45.80% aged 65+. Compared with women aged 30-39, both younger and older women were significantly less likely to receive guideline concordant follow-up. Women 65+ had 44% lower odds of concordant follow-up (OR= 0.56, 95% CI 0.53 to 0.60, p<.001). Guideline-concordant care also varied by race and ethnicity: 51.11% of non-Hispanic Black, 56.65% of non-Hispanic Asian, 60.36% of non-Hispanic White, 58.43% of non-Hispanic Other, and 51.71% of Hispanic patients. Compared to non-Hispanic White women, all other groups had significantly lower odds of follow-up, with non-Hispanic Black women having 30% lower odds (OR = 0.70, 95% CI 0.68 to 0.72, p<.001) and Hispanic women having 28% lower odds (OR= 0.72, 95% CI 0.71 to 0.74, p<.001) of concordant follow-up. **Conclusions:** Overall, the rate of guideline concordant follow-up after high-risk cervical cancer screening results was low (57.83%) and declined with age, with lowest rates among women ≥ 65 (45.80%). All other age groups had significantly lower odds of concordance than those 30-39, with those 65+ having the lowest odds of concordance. Significant disparities were also observed by race and ethnicity, particularly among non-Hispanic Black and Hispanic women. Further research is needed to assess the decreased surveillance rates after high-risk cervical cancer screening results at the population level and specific attention should be focused on groups who have been under-surveilled. Research Sponsor: None.

Efficacy and safety of cadonilimab (CD) in combination with disitamab vedotin (RC48) or nab-paclitaxel (NP) in the treatment of recurrent or metastatic cervical cancer (r/mCC): A prospective, double-cohort, multi-center, open-label, phase II clinical study. First Author: Min Zheng, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: The prognosis for patients(pts) with r/mCC is poor. The available second-line treatment regimens are limited, highlighting the need for more effective therapies. CD is a dual-target immune checkpoint inhibitor targeting PD-1 and CTLA-4 and RC48 is an antibody-drug conjugate targeting HER2. Here, we report updated results from a phase II study of CD plus RC48 or NP in r/mCC. **Methods:** This is a prospective, multicenter, open-label, phase II trial with two parallel cohorts(AK001). Eligible patients had r/mCC with progression after 1-3 prior lines of chemotherapy. Patients were assigned by HER2 immunohistochemistry (IHC): cohort I (HER2 IHC 1+ - 3+) received CD (6mg/kg) plus RC48 (2.5mg/kg) biweekly; cohort II (HER2 IHC 0) received CD (10mg/kg) plus NP (260mg/m^2) triweekly. The primary endpoint of the study was objective response rate (ORR). Key secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS) and safety. A Simon's two-stage design was applied, with the ORR from the innovaTV 204 study as a historical control, which was 24%. Assuming the ORR for cohort I is 50% and for cohort II is 40%, with a power of 0.8 and a one-sided α of 0.05, and considering a dropout rate of 10%, the total sample size calculated was 32 for cohort I and 42 for cohort II. **Results:** As of the data cutoff (January 15, 2026), 62 pts were enrolled, including 53 evaluable pts (26 in cohort I and 27 in cohort II) across 5 large academic centers in China. Median follow-up was 12.03 months (range, 1.87 - 26.57). For cohort I, the ORR was 57.7% (95% CI, 36.9% - 76.6%) and median DOR was not reached (95% CI, 3.97 - NR). Median PFS was 8.23 (95% CI, 3.41 - 13.06) months and 12-month PFS rate was 45%. For cohort II, the ORR was 55.6% (95% CI, 35.3% - 74.5%) and median DOR was 4.57 (95% CI, 2.30 - 6.83) months. Median PFS was 5.87 (95% CI, 4.55 - 7.19) months and 12-month PFS rate was 38%. Toxicity was tolerable in both cohorts. Grade 3-4 treatment-related adverse events occurred in 15.4% of pts in cohort I and 21.4% of pts in cohort II. **Conclusions:** Our current results support a potential HER2 expression-guided option for second-line treatment of r/mCC. CD plus RC48 demonstrated favorable efficacy and a manageable safety profile, and may emerge as a novel effective combination for the treatment of HER2 positive cervical cancer. Long-term benefits and further analysis of the role of this combination therapy in r/mCC will be critical to advancing treatment strategies. Clinical trial information: ChiCTR2300076740. Impact of adjuvant sequential chemoradiotherapy on long-term overall survival in early-stage cervical cancer: Final analysis of the STARS phase III randomized trial. First Author: He Huang, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: The STARS trial (NCT00806117) previously demonstrated that adjuvant sequential chemoradiotherapy (SCRT) significantly improved disease-free survival (DFS) compared with radiotherapy (RT) or concurrent chemoradiotherapy (CCRT) in early-stage cervical cancer patients with pathological risk factors. This pre-specified analysis reports the mature overall survival (OS) results. **Methods:** In this open-label, phase III trial, 1,048 cervical cancer patients with FIGO stage IB1–IIA2 and postoperative pathological risk factors were randomized (1:1:1) to receive RT alone, CCRT (RT with weekly cisplatin), or SCRT (paclitaxel-cisplatin chemotherapy before and after RT). The second endpoint was OS, analyzed by intention-to-treat. Subgroup analyses were performed based on risk stratification: intermediate-risk (deep stromal invasion or lymphovascular space invasion) and high-risk (node-positive or parametrial involvement). **Results:** With a median follow-up of 90 months, SCRT significantly improved OS compared to both RT (10-year OS 89.0% vs 81.0%; HR 0.54, 95% CI 0.35-0.83; P=0.005) and CCRT (89.0% vs 83.0%; HR 0.64, 0.41-0.98; P=0.040) in intention to treat population. No significant difference was observed in OS between CCRT and RT (HR 0.85, 0.58-1.24; P=0.404). The survival benefit of SCRT was consistent across key subgroups: it was most pronounced in intermediate-risk patients (HR 0.54 vs RT, 95% CI 0.31-0.93; P=0.027) and showed a clinically meaningful trend in high-risk patients (HR 0.61, 95% CI 0.30-1.24). However, CCRT showed no overall benefit in these risk-based populations but was markedly effective in the subgroup with deep stromal invasion without lymphovascular invasion (HR 0.20 vs RT, 95% CI 0.05-0.85; P=0.029) in per-protocol population. SCRT achieved higher protocol completion than CCRT (73.4% vs 62.3%) and was an independent favorable prognostic factor for OS (HR 0.54) in multivariable analysis, along with lymph node metastasis and adenocarcinoma histology. **Conclusions:** The long-term STARS trial update confirms adjuvant SCRT as the optimal strategy, demonstrating both DFS and OS superiority in early-stage cervical cancer with postoperative risk factors. The significant 10-year survival benefit strongly supports adopting SCRT where radiotherapy access is limited. Clinical trial information: NCT00806117. Research Sponsor: Sun Yat-sen University Clinical Research 5010 Program (Number 2007041).

Impact of para-aortic lymphadenectomy on prognosis and quality of life in preoperative IB2-IIA2 cervical cancer: A multi-center cohort study. First Author: Xinqu Qu, Obstetrics and Gynecology Hospital of Fudan University, Shanghai, China

Background: The indication of para-aortic lymphadenectomy (PALD) in preoperative IB2-IIA2 (FIGO 2018) cervical cancer remains unclear. We aimed to access the impact of PALD on the prognosis and life quality in preoperative IB2-IIA2 cervical cancer patients. **Methods:** This cohort study, a target trial emulation, was conducted at the Obstetrics and Gynecology Hospital of Fudan University, including cervical cancer patients with a preoperative stage of IB2-IIA2 from 2019 to 2023 (clinical trial ChiCTR2400092255). Propensity score matching at a 1:1 ratio (PALD versus non-PALD) was applied to balance baseline characteristics. Primary outcomes were progression-free survival (PFS), overall survival (OS), and cancer-specific survival (CSS). Secondary outcomes included perioperative complications and adverse events (AEs). Kaplan-Meier and subgroup analyses were conducted, and Cox proportional hazard models were established. External validation was performed at another three tertiary hospitals in China. **Results:** Of the 2609 patients included, 683 (26.2%) underwent PALD during radical surgery. Propensity score matching yielded a cohort of 1250 patients with balanced covariates. Patients who underwent PALD demonstrated similar PFS (hazard ratio 1.27; 95% CI, 0.89-1.80; P=0.188), OS (hazard ratio 1.17; 95% CI, 0.71-1.93; P=0.544), and CSS (hazard ratio 1.20; 95% CI, 0.70-2.06; P=0.512) as those who did not. Additionally, no significant differences were detected in survival associated with receiving PALD among subgroups defined by lymph node status based on preoperative imaging, the para-aortic lymph node (PALN) metastasis prediction model, and other postoperative pathological risk factors. External validation drew consistent conclusions regarding the effect of PALD on survival. Moreover, the PALD group compared with non-PALD group showed more intraoperative hemorrhage (P=0.005), longer operation time (P=0.004), and a higher tendency for chylous fistula (P=0.077). **Conclusions:** PALD, compared with non-PALD, was not associated with survival benefits for IB2-IIA2 cervical cancer patients yet was associated with increased surgical complications. Research Sponsor: None.

Azenosertib plus paclitaxel for platinum-resistant ovarian cancer: Results from a phase 1b study. First Author: Meena Okera, Cancer Research SA, Adelaide, SA, Australia

Background: Most patients (pts) with ovarian cancer develop platinum-resistant disease following surgery and platinum-based chemotherapy and have a poor prognosis. Paclitaxel (PAC) monotherapy is the most efficacious chemotherapy for platinum-resistant ovarian cancer (PROC) but clinical benefits require further improvement. Azenosertib (Azeno) is a potentially best-in-class, novel, selective and orally bioavailable small molecule inhibitor of the WEE1 tyrosine kinase. Herein we report results from a Phase 1b study of Azeno plus PAC for PROC. **Methods:** MUIR (NCT04516447) is an open-label Phase 1b study evaluating the safety, efficacy and preliminary clinical activity of Azeno plus chemotherapy (Part 1 dose escalation) for PROC. Eligible pts were aged ≥18 years, had ECOG PS score ≤2, histologically/cytologically confirmed high-grade serous epithelial ovarian, fallopian tube, or peritoneal carcinoma, and measurable disease per RECIST v1.1; pts had received 1–4 prior lines of systemic therapy and had platinum-resistant disease. Pts were assigned to 1 of 4 cohorts: carboplatin, gemcitabine, pegylated liposomal doxorubicin, or PAC (80 mg/m^2 IV on Days 1, 8 and 15 of 28-day cycles). Azeno plus PAC is the focus of this analysis where Azeno was orally administered 200 mg (continuously) or 200, 250 and 300 mg (intermittently 5 days on, 2 days off [5:2]) for 28-day cycles. Primary objectives were safety and tolerability. Clinical activity was a key secondary objective assessed by objective response rate (ORR) and duration of response (DOR) per RECIST v1.1, and progression-free survival. Exploratory objectives included analysis of baseline tumor and plasma biomarkers with optional biopsies/blood plasma. **Results:** As of December 1, 2025, 46 pts received Azeno (continuously 200 mg, n=7 and intermittently 5:2: 200 mg, n=15; 250 mg, n=12; 300 mg, n=12) plus PAC. Median age was 66 years (range 45–83), median number of prior lines of therapy was 2 (range, 1–4), and all pts received prior PAC. Most common treatment related adverse events (TRAEs) were fatigue (61%), anemia (59%), nausea (52%), and neutropenia (50%); most frequent grade ≥3 TRAEs were neutropenia (30%) and anemia (20%). Serious TRAEs occurred in 20% of pts. Overall, confirmed ORR was 39.1% (95% CI, 25.1–54.6) with a median DOR of 5.6 months (95% CI, 5.6–9.2) (Table). **Conclusions:** Azeno plus PAC showed promising clinical activity and tolerability in pts with PROC. ORR and median DOR were improved when compared historically with PAC monotherapy supporting the continued evaluation of this regimen in PROC and other indications. Clinical trial information: NCT04516447. Research Sponsor: Zentalis.

Global disparities in current clinical trials in cervical cancer. First Author: Sneha Ahuja, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cervical cancer is one of the most disproportionately distributed cancers worldwide, with highest incidence and mortality rates occurring in low- and middle-income countries (LMICs). Although clinical trials provide the crucial foundation for the development of standards of care, oncology research is disproportionately concentrated in high-income settings. **Methods:** We assessed the current global landscape of cervical cancer clinical trials to determine whether trial activity aligns with disease burden and to characterize various disparities in trial representation. Interventional phase II and III cervical cancer clinical trials registered on ClinicalTrials.gov between January 1, 2014, and December 31, 2025, were identified. Trials were further categorized by intervention class, patient population, funding source, and location. Representation of trials in relation to disease burden for cervical cancer was determined using trial-to-age-standardized incidence rate (ASIR) from Global Cancer Observatory estimates. Countries were classified by World Bank Income Level and disease burden, where high burden countries had an ASIR above the global ASIR of 14.1. Non-parametric statistical tests were used to compare trial-to-ASIR ratios across groups. **Results:** A total of 269 eligible trials were included. Most studies were phase II (62.5%) and evaluated systemic or combination therapies (83.6%). The majority of trials were institutionally funded (55.0%), with industry sponsorship accounting for 33.5% of studies. Clinical trial activity was concentrated in a small number of countries, with single-country trials conducted predominantly in China (60.2%) and the United States (13.0%), while multinational trials were largely conducted in high-income countries. When adjusted for disease burden, most high-burden countries had few or no trials relative to incidence, resulting in significantly lower trials per ASIR compared with non–high-burden countries ($P < .001$). Significant disparities were also observed across income groups, with high-income countries demonstrating substantially higher trial-to-ASIR ratios than lower-income countries ($P < .001$). **Conclusions:** The global distribution of cervical cancer clinical trials remains misaligned with disease burden, with high-burden and lower-income countries underrepresented in research participation. Funding patterns and trial sponsorship may further influence where trials are conducted. Addressing these disparities will be essential to ensure equitable evidence generation and improve global cervical cancer care. Research Sponsor: None.

Genomic landscape and patient demographics in endocervical adenocarcinoma: Insights from the AACR Project GENIE. First Author: Rechuma Hafter, Hunter College CUNY, New York, NY

Background: Endocervical Adenocarcinoma (EA) makes up 20-25% of cases of cervical cancer, and has an 80-90% association with HPV infection.Treatment outcomes of EA have significant disparities: cases of EA arising from HPV have a much higher survival rate than survival rate for non-HPV-related EA. While survival outcomes with modern treatments such as radical hysterectomy are positive for HPV associated cases, increasing frequency of diagnosis and treatment heterogeneity, along with variability in diagnostic timing emphasize the need to define molecular drivers for targeted therapies. Using the AACR GENIE database, this study characterizes EA's mutational landscape to identify genetic markers and therapeutic targets. **Methods:** The American Association for Cancer Research Project Genomics Evidence Neoplasia Information Exchange database was accessed using cBioPortal (v18.0-public) on November 29, 2025 to identify all patients with EA. The most common somatic point mutations, demographic correlations, and mutual exclusivities were analyzed using a two-sided T-test and non-parametric tests, with Benjamini-Hochberg false discovery rate correction. **Results:** This study included 257 samples from 245 patients. The patient cohort was 61.2% non-Hispanic and 13.9% Hispanic. The cohort was 10.2% Asian, 61.2% White, 4.1% Black, and 12.2% unknown/other patients. A majority of the samples used were obtained from primary tumors (60.3%), while 80 (31.1%) were from metastatic tumors. The most common mutations were identified in PIK3CA (n=68; 26.4%), TP53 (n=51; 19.8%), KRAS (n=41; 15.9%), SMAD4 (n=37; 14.4%), ERBB2 (n=35; 13.6%), ARID1A (n=32; 12.4%), KMT2D (n=26; 10.1%), GNAS (n = 26; 10.1%), ERBB3 (n = 23; 8.9%), KMT2C (n = 21; 8.1%), STK11 (n = 20; 7.8%), MED12 (n = 18; 7.0%), and ATM (n = 17; 6.6%). Several mutations were uniquely observed in Black patients, HFE,RAD54B, ADAMTS20, ADGRB3, and BCL3, with n = 1 for each observed mutation. Among exclusively primary tumor samples, the HSD3B2 mutation was identified (n = 1). RXRA ($p < 0.05$), TBX3, and TET1 ($p > 0.05$) mutations with n = 3 each were exclusively observed in the metastatic samples. Frequencies of recurrent alterations in key genes such as KRAS (15.2%) and PRKDC (7.5%), showed substantial overlap and no significant differences between the groups. No significant mutual exclusivity patterns were identified among profiled genes. **Conclusions:** To the best of our knowledge, this is the first GENIE database analysis of EA, addressing a significant knowledge gap regarding its genomic landscape. These findings suggest PIK3CA and TP53 as targets for targeted inhibitors or immunomodulators. Further research is warranted to validate these genomic associations and translate them into precision medicine therapeutics for patients with endocervical adenocarcinoma. Research Sponsor: None.

GT101 autologous TIL therapy in patients with recurrent and metastatic cervical cancer: A phase 1 study. First Author: Pin Wang, University of Southern California, Los Angeles, CA

Background: Adoptive cell therapy with autologous TILs has shown durable clinical benefit in selected advanced solid tumors after progression on standard therapies. We report results from a phase I, open-label, single-arm, multicenter trial (NCT05430373) evaluating GT101 in patients with recurrent or metastatic cervical cancer. Primary objectives were safety; second objectives included preliminary efficacy and PK. **Methods:** Eleven patients with recurrent or metastatic cervical cancer received a lymphodepletion regimen followed by GT101 infusion and high-dose IL-2. The primary endpoint was safety, including treatment-emergent adverse events (TEAEs), serious adverse events (SAEs) and adverse events (AEs), graded per CTCAE v5.0. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), duration of response (DoR), and overall survival (OS), assessed by RECIST v1.1. Flow cytometry of immune cells and T cell receptor (TCR) sequencing were performed on peripheral blood samples collected from patients before and after treatment. **Results:** As of September, 2025, 11 patients were treated (median age was 48 years; median two prior lines of therapy). Following FC lymphodepletion, patients received GT101 at doses ≥5×10^9 viable cells (median 4.1×10^{10}), followed by high-dose IL-2 (600,000 IU/kg, up to 6 doses). Most AEs were Grade 1-2. Grade ≥3 AEs were primarily related to lymphodepletion and IL-2, and included lymphopenia, leukopenia, neutropenia, anemia, pyrexia, and thrombocytopenia; most resolved or improved to Grade ≤2 within 14 days. The ORR was 45.5% (5/11), with DCR of 90.9% (10/11). Median DoR was 6.4 month. Four patients (36.4%) achieved confirmed PR, one patient (9.1%) achieved a CR, and five patients (45.5%) had stable disease (SD). Median PFS was 4.83 months; OS follow-up is ongoing. One patient with stage IIIC2 cervical squamous cell carcinoma achieved a confirmed CR lasting 14.5 months, with tumor burden reduced from a baseline sum of diameters of 71.57 mm to complete resolution by Week 12. Pharmacokinetics and Correlation Analyses: Peripheral blood analyses demonstrated peak circulating T cells 5-7 days post-infusion, followed by contraction to near-baseline by two weeks. Responders exhibited lower proportions of $CD39^+PD\text{-}1^+$ T cells. TIL infusion increased T-cell clonal diversity in all patients, with greater expansion observed in non-responders who has lower baseline diversity; persistence of TIL-derived clones did not differ consistently between groups. **Conclusions:** GT101 demonstrated a manageable safety profile with no treatment-related SAEs or dose-limiting toxicities and showed clinically meaningful and durable antitumor activity in recurrent or metastatic cervical cancer. These findings support further clinical development, and a pivotal phase II study is ongoing. Clinical trial information: NCT05430373. Research Sponsor: None.

Neoadjuvant chemotherapy and individualized de-escalation surgery for fertility preservation in stage IB1-IIA2 cervical cancer: A multicenter prospective study (FIND study). First Author: Yanling Feng, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China

Background: Radical trachelectomy (RT) has long been the standard fertility-sparing surgery (FSS) for early-stage cervical cancer (most validated for tumor<2cm), produced satisfied oncologic outcomes but adverse pregnancy outcomes. Neoadjuvant chemotherapy (NACT) offers a potential pathway for tumor downstaging, which may further expand the population eligible for FSS. Based on this, this study aimed to evaluate the oncologic and reproductive outcomes of an individualized, NACT-based fertility-preserving strategy in patients with early-stage cervical cancer (FIGO 2018 IB1–IIA2) (CSEM009, NCT02624531). **Methods:** This prospective, non-randomized clinical study enrolled patients aged 18–40 years with pathologically confirmed stage IB1–IIA2 squamous, adenocarcinoma, or adenosquamous carcinoma and a strong desire for fertility preservation. All patients underwent pretreatment pelvic MRI. Patients with a baseline tumor diameter <1 cm proceeded directly to simple trachelectomy (ST). Those with tumors ≥1 cm received 2–3 cycles of platinum-based NACT. Individualized surgery was performed based on Post-NACT MRI: cervical conization (CON) for complete response, ST for residual disease ≤2 cm, and RT for residual disease 2–4 cm. Lymph node assessment involved sentinel lymph node biopsy (SLNB) or systematic lymphadenectomy. Primary endpoints were 5-year overall survival (OS), 5-year progression free survival (PFS), and reproductive outcomes. **Results:** From June 2015 to June 2023, 99 eligible patients were enrolled. Among them, 84 received NACT, and 80 ultimately underwent FSS. Median follow-up duration was 67 months (range: 7–122). For the entire cohort of 99 patients, 5-year PFS and OS were 88.9% and 93.9%, respectively. In the FSS group (n=80), 5-year PFS and OS were 91.3% and 96.3%. In FSS patients, univariate analysis identified lymphovascular space invasion (LVSI) as significantly associated with recurrence and mortality ($p<0.05$). Patients with initial tumors ≤2 cm (n=42), 2–4 cm (n=29), and ≥4 cm (n=9) had 5-year PFS rates of 95.2%, 86.2%, and 88.9%, and 5-year OS rates of 97.6%, 93.1%, and 100%, respectively. Nineteen patients failed to undergo FSS with 5-year PFS 78.9% and 5-year OS 84.2%. Of 40 FSS patients attempting pregnancy, 19 (47.5%) achieved at least one pregnancy, resulting in 17 cumulative deliveries: 3 after conization and 14 after ST. No successful pregnancies occurred after RT. **Conclusions:** This prospective study demonstrates that fertility-sparing strategy involving NACT and individual less radical FSS provides favorable long-term oncologic safety and meaningful reproductive potential in patients with FIGO 2018 IB1-IIA2 cervical cancer. Clinical trial information: NCT02624531. Research Sponsor: None.

Quality of life outcomes following hypofractionated radiotherapy in locally advanced cervical cancer. First Author: David Francisco Cantu De Leon, Instituto Nacional de Cancerología, Mexico, DF, Mexico

Background: Cervical cancer remains a significant global health burden, particularly in low- and middle-income countries where access to radiotherapy is often limited. While concurrent chemoradiotherapy is the standard of care, hypofractionated radiotherapy has emerged as a potential strategy to improve treatment efficiency without compromising outcomes. Our purpose was to assess the impact of hypofractionated radiotherapy on quality of life in comparison with conventional fractionation in patients with locally advanced cervical cancer. **Methods:** Health-related quality of life was evaluated using EORTC QLQ-C30 and QLQ-CX24 questionnaires in patients with FIGO stage IB3–IIIC1 cervical cancer enrolled in a phase II randomized trial. All patients received concurrent chemotherapy and were assigned to either standard external-beam radiotherapy (50 Gy in 25 fractions) or hypofractionated radiotherapy (37.5 Gy in 15 fractions), followed by radical hysterectomy with bilateral pelvic lymphadenectomy. QoL scores were calculated using standard EORTC methodology. Higher scores indicate better functioning or greater symptom burden, and changes were interpreted based on established thresholds for clinical relevance. Outcomes were compared between groups across predefined time points using ANOVA. Statistical significance was defined as $p < 0.05$. **Results:** A total of 91 patients were included (49 standard fractionation, 42 hypofractionation). No significant differences in global QoL were observed between treatment groups. However, QoL varied significantly over time, with the greatest deterioration occurring between completion of concomitant chemoradiotherapy and surgery. Quality-of-life scores recovered to baseline levels by three months after treatment completion in both groups. **Conclusions:** Hypofractionated radiotherapy was not associated with worse quality-of-life outcomes compared with conventional fractionation. These findings support hypofractionation as a feasible alternative for locally advanced cervical cancer, particularly in resource-limited settings. Further studies with larger cohorts and longer follow-up are warranted to confirm these results. Clinical trial information: NCT03750539. Research Sponsor: None.

Trends in rural-urban disparities in U.S. cervical cancer mortality before and after the HPV vaccine introduction: A CDC analysis, 1999-2023. First Author: Jasvindar Kumar, Bassett Medical Center/Bassett Healthcare Network, Cooperstown, NY

Background: Cervical cancer mortality has declined in the United States following the introduction of HPV vaccination. However, disparities by urbanization, geography, and race may persist. Rural women remain up to 40% more likely to die from cervical cancer. Understanding rural–urban trends is essential to guiding equitable prevention strategies. **Methods:** CDC WONDER mortality data for females ≥15years with cervical cancer (ICD-10 C53) were analyzed. Age-adjusted mortality rates (AAMR) per 100,000 population were analyzed. Urbanization data were available till 2020 and were used for urban–rural stratification (NCHS classification). Temporal trends were assessed using joint point regression to determine average annual percent change (AAPC). **Results:** Between 1999 and 2023, 102,205 cervical cancer deaths were identified. The overall AAMR declined from 1.52 to 1.28 during the pre-vaccine era (1999–2005; AAPC = −2.95%, 95% CI −4.0 to −1.8) and further to 1.09 during the post-vaccine era (2006–2023; AAPC = −0.86%, 95% CI −1.0 to −0.7). Rural-urban mortality (AAMR) ratio increased in post-vaccine era from 1.13 vs 1.15 with 1.47% increase in disparity. By urbanization, declines were greatest in central metropolitan areas (AAMR 1.72 to 1.48 pre-vaccine; 1.14 post-vaccine; AAPC = −1.40%, 95% CI −1.6 to −1.2), while small metro (1.36 to 1.29 pre-vaccine; 1.11 post-vaccine; AAPC = −0.93%, 95% CI −1.2 to −0.6) and micropolitan areas (1.70 to 1.44 pre-vaccine; 1.32 post-vaccine; AAPC = −0.34%, 95% CI −1.3 to 0.6) showed slower improvement which widened mortality gap. Subgroup analyses showed the steepest mortality declines among women aged ≥75 years (AAPC = −3.66%), among Black women (AAPC = −2.81%), and in the Northeast region (AAPC = −2.16%). **Conclusions:** U.S. cervical cancer mortality declined after the HPV vaccine introduction; however, rural–urban, racial, and regional disparities persisted. Declines were slower in small metropolitan and nonmetropolitan areas and highest among Black individuals, underscoring the need for targeted vaccination, screening efforts and access-to-care. HPV-stratified tissue factor expression and multi-omic correlates of overall survival after tisotumab vedotin in cervical cancer. First Author: Shaina Bruce, Penn State Health, Hershey, PA

Background: Cervical cancer (CxC) is heterogeneous, and the impact of HPV status on outcomes with tisotumab vedotin (TV; tissue factor [TF/F3]–targeted ADC) remains incompletely defined. We evaluated HPV-stratified associations between TF expression and real-world overall survival (OS) after TV and explored molecular correlates of long vs short survival. **Methods:** 274 CxC patients who received TV (HPV+, n=106; HPV-, n=45) underwent DNA and RNA sequencing. HPV16/18/31/33/45 status was determined from whole exome sequencing (WES). Real-world OS was calculated from first TV claim to death/last contact. Hazard ratio (HR) was estimated by Cox proportional hazards, with p-value using log-rank test. TFH was defined as TF (F3) expression (RNA-seq normalized expression) ≥ the cohort-specific median (median split) among TV-treated cases with available data. For transcriptomic comparisons, LS (long survival) and SS (short survival) were defined as above-median vs below-median OS after TV within each HPV stratum, respectively. **Results:** Among TV-treated patients with available TF/OS data, TFH vs TFL showed no statistically significant OS difference in the overall cohort (n=195; TFH n=98 vs TFL n=97; median OS 11.73 vs 9.79 months; HR 0.765; log-rank p=0.142) or in the HPV+ cohort (n=69; TFH n=35 vs TFL n=34; median OS 10.22 vs 10.35 months; HR 0.602; log-rank p=0.138). In contrast, in the HPV− cohort (n=27; TFH n=14 vs TFL n=13), TFH was associated with improved OS (median OS 21.81 vs 9.79 months; HR 0.251, 95% CI 0.065–0.977; log-rank p=0.032). Transcriptomic profiling suggested HPV-dependent survival: in HPV− patients, LS was enriched for cell-cycle/DDR, and energy metabolism pathways (e.g., p53 pathway NES 1.86; FDR-adjusted $p<0.0001$), whereas in HPV+ patients, SS was enriched for inflammatory pathways (e.g., interferon-γ response NES −2.25; FDR-adjusted $p<0.0001$; TNF–NFκB) and LS for tumor-intrinsic metabolic/drug-handling and coagulation-related pathways (e.g., Xenobiotic metabolism, NES 2.13, FDR-adjusted p=0.0021; Coagulation). In the HPV+ cohort, exploratory genomic correlates of survival included enrichment of ARID1A pathogenic mutations (3/18, 16.7% LS vs 0/41, 0% SS; p=0.0073) and AKT2 amplifications (2/17, 11.8% LS vs 0/39, 0% SS; p=0.0292), consistent with tumor-intrinsic pathway alterations in LS. **Conclusions:** TF expression and HPV status may interact in TV-treated cervical cancer. While TFH was not associated with OS in the overall or HPV+ cohorts, TFH was associated with improved OS in HPV− disease. HPV-stratified transcriptomic analyses further suggest distinct biological contexts of benefit and lack thereof, supporting the need to HPV-stratified biomarker analyses for evaluating TV benefit in CxC, potentially extending to other ADCs, and motivating validation in independent datasets. The impact of re-adoption of open radical hysterectomy on postoperative outcomes in the United States: An interrupted time series analysis. First Author: Alex Ede Rosenthal Powers, Massachusetts General Hospital, Boston, MA

Background: The Laparoscopic Approach to Cervical Cancer (LACC) trial, published in 2018, demonstrated inferior disease-free and overall survival outcomes with minimally invasive radical hysterectomy compared to open surgery for cervical cancer, establishing open radical hysterectomy (ORH) as the standard of care. This study evaluates the impact of the rapid adoption of ORH after publication of the LACC trial on postoperative outcomes. **Methods:** We categorized 2013-2017 as the *pre*-LACC period, 2019-2022 as the *post*-LACC period, and 2018 as the washout period. We included patients who underwent radical hysterectomy for cervical cancer in a Commission on Cancer-accredited program with the highest utilization of ORH (top quartile, $>$ 83%) in the post-LACC period. We fit linear probability models with cluster-robust standard errors to estimate the causal association between ORH adoption, postoperative length of stay, 30-day readmission rates, and 90-day mortality, using pre-LACC trends to estimate a counterfactual outcome for 2019 and comparing these with outcomes from the post-LACC period. **Results:** 2,982 patients were treated in the 107 rapid adopter hospitals. Mean age was 46.5 (SD 12). Most patients were white (67%), followed by Hispanic (14%), and Black (11%). Most patients had grade 1 or 2 (60%) tumors with squamous cell (52%) or adenocarcinoma (40%) histology. Thirty-two percent of patients had positive LVSI and 12% of patients had positive lymph nodes. The proportion or ORH was 45% vs 94% in the pre- vs post-period and ORH utilization was 65 percentage points (p.p.) higher than the estimated 2019 counterfactual ORH utilization. In the pre-period, MIS use increased significantly over time (4.1 p.p. per year, 95% CI 1.9-6.3, $p < 0.001$) while mean length of postoperative stay declined (0.3 days per year, 95% CI 0.1-0.5, $p = 0.003$). Rapid adoption of ORH in 2019 (+65.1 p.p., 95% CI 53.4-76.8, $p < 0.001$) was associated with a 1.7 day (95% CI 1.0-2.5, $p < 0.001$) increase in the duration of postoperative hospitalization, from 1.5 to 3.3 days. There was no significant association with a change in 30-day readmission rates (3.6% pre vs 1.9% post, 1.7 p.p. decrease, 95% CI -5.3 to +1.8, $p = 0.35$). Only 13 patients (0.4%) died within 90 days of surgery over the entire study period, precluding analysis of postoperative mortality. **Conclusions:** Rapid adoption of ORH following the LACC trial was associated with a moderate increase in postoperative length of stay, but no change in 30-day readmission rate. Research Sponsor: None.

Optimal adjuvant therapy for early-stage cervical cancer (ESCC) with intermediate-risk factors: A target trial emulation of GOG-0263 based on the NCDB. First Author: Ifeyinwa Ejisoby-Nwosu, Emory University, Atlanta, GA

Background: Optimal adjuvant therapy for early-stage cervical cancer (ESCC) patients with intermediate-risk factors remains uncertain, specifically whether the addition of concurrent chemotherapy (CRT) to radiation therapy (RT) confers a survival benefit. The GOG-0263 randomized phase III trial compared adjuvant RT vs CRT in patients with FIGO Stage I-IIA cervical cancer who had undergone radical hysterectomy. We sought to emulate this trial using real-world data from the National Cancer Database (NCDB) to evaluate the benefit of CRT versus RT on overall survival (OS) in intermediate risk ESCC. **Methods:** Using the NCDB, we conducted a target trial emulation of GOG-0263 for patients diagnosed from 2004-2020 with pathologic T1-T2a2 N0 M0 cervical cancer who underwent radical hysterectomy. Eligible patients had intermediate risk factors, defined as tumor size $\geq$ 2 cm with lymph-vascular invasion (LVI) or tumor size $\geq$ 4 cm. OS, defined from the date of definitive surgery, was compared between patients who received adjuvant RT alone versus adjuvant CRT. Kaplan-Meier methods and Cox proportional hazards models, along with an inverse probability treatment weighting (IPTW) schema, were implemented to assess the treatment effect. Subgroup and sensitivity analyses were conducted to identify specific disease characteristics that maximize the benefit of CRT and to evaluate the impact of potential immortal time bias. **Results:** Among 1,171 eligible patients, 537 (45.9%) received CRT and 634 (54.1%) received RT alone, with median ages of 44 years (IQR: 36-55) and 46 years (IQR: 39-57) and median follow-up times of 7.5 years (IQR: 4.8-10.5) and 6.6 years (IQR: 4.2-9.9), respectively. There was no significant difference in OS between CRT and RT in unadjusted (HR 0.94; 95% CI, 0.71–1.25), adjusted (HR 0.89; 95% CI, 0.67–1.18), or weighted analyses (HR 0.88; 95% CI, 0.66–1.17). Five-year OS was similar between groups (86.4% vs. 86.6%). No subgroup demonstrated a significant survival benefit from CRT. **Conclusions:** In this real-world emulation of GOG-0263, addition of concurrent chemotherapy to adjuvant RT was not associated with improved OS for intermediate-risk ESCC. These findings support emerging trial evidence and supplement the conclusion of the GOG-0263 trial. The indication of this study suggests that chemotherapy may be safely omitted in this population under a doctor's careful discretion, thereby potentially reducing treatment-related toxicity and preserving patients' quality of life without compromising survival. These findings highlight the need for improved risk stratification and patient selection to identify those most likely to benefit from treatment intensification with concurrent chemotherapy in addition to adjuvant RT. Evaluation of imiquimod treatment outcomes in vulvar melanoma. First Author: Alyssa Osheim, (UT Health Houston) McGovern Medical School, Houston, TX

Background: Vulvar and vaginal melanomas account for approximately 10% of vulvar malignancies and less than 1% of all melanomas. Compared to cutaneous melanoma at other sites, vulvovaginal melanoma is associated with significantly worse outcomes. Wide local excision is the standard treatment for vulvar melanoma, but anatomical challenges and the "field effect" complicate complete resection. The field effect refers to a margin of pre-cancerous intraepithelial cells extending beyond the visible tumor and is thought to contribute to local recurrence. Imiquimod, an immune-modifying cream indicated for genital warts and some types of early keratinocyte carcinomas, is used off-label as an adjunct therapy to prevent marginal recurrence of vulvar melanoma in situ. Its benefit in this setting remains unclear due to limited outcome data, and it is associated with significant side effects. More research is needed to clarify the role of imiquimod and explore alternative therapies. This case series aims to evaluate recurrence and survival outcomes following imiquimod treatment and inform clinical management in this understudied cancer subtype. **Methods:** Patients were identified by two criteria: (1) confirmed vulvar melanoma and (2) treatment with imiquimod. Cases were drawn from a previously published institutional cohort focused on adjuvant radiation therapy in vulvovaginal melanoma and from MD Anderson's electronic medical records. Regional progression-free survival and overall survival were defined as study endpoints. Data included demographics, clinical characteristics, and recurrence and mortality outcomes. Kaplan–Meier analysis compared progression-free and overall survival between patients treated with imiquimod and those who were not. **Results:** Among 124 patients, 19 received imiquimod. The imiquimod group showed a modest improvement in regional progression-free survival, but no significant difference in overall survival (p = 0.1753 and p = 0.2775, respectively). Imiquimod was associated with notable side effects, including burning, itching, and blistering. **Conclusions:** This case series highlights the limited evidence supporting imiquimod as an effective adjunct therapy for vulvar melanoma. Although there was a trend toward delayed regional progression, differences were not statistically significant, and side effects raise concerns about patient quality of life. These findings underscore the need for more effective and tolerable strategies. A systematic review is underway, and multi-institutional efforts aim to expand the dataset. Greater evidence is essential to guide treatment decisions, optimize outcomes, and ensure survivor-centered care in this rare and understudied cancer. Research Sponsor: National Institutes of Health, National Cancer Institute; R25 CA056452.

Association of steroid exposure with overall survival and hypersensitivity reaction risk in paclitaxel-treated patients with gynecologic cancers. First Author: Mohammad Harris Jalili, Zuckerberg Cancer Center, Northwell Health, Lake Success, NY

Background: Paclitaxel remains a first-line agent in chemotherapy regimens for gynecologic cancers but is associated with hypersensitivity reactions (HSRs) in up to 40% of patients. Though this risk is largely mitigated by dexamethasone-based premedications, preclinical studies suggest that dexamethasone can induce treatment resistance through enhanced DNA repair capacity, immune suppression, or inhibition of apoptosis, raising concern that pretreatment could compromise paclitaxel efficacy. Furthermore, the effect of cumulative steroid exposure on survival outcomes remains unknown. This study evaluates the impact of cumulative steroid exposure on overall survival (OS) and explores factors associated with HSRs among paclitaxel-treated patients with gynecologic cancers. **Methods:** This IRB-approved retrospective cohort study included patients with gynecologic malignancies treated with paclitaxel-based chemotherapy at the R.J. Zuckerberg Cancer Center, Northwell Health Cancer Institute, New York, between May 2023 and December 2024. Treatment characteristics and outcomes data were analyzed using univariable and multivariable zero-inflated Poisson regression models for HSRs and Cox regression models for OS. **Results:** A total of 163 patients who completed at least three cycles of paclitaxel-based chemotherapy were included. The median age (range, 38-87) was 66 years. Patients were 49% White, 18% Asian, 17% Black, 6% Hispanic, and 11% other or unknown. Cancer types included endometrial cancer (53%), ovarian/peritoneal (42%), cervical (4%), and vaginal (1%). At initial diagnosis, 30% of patients had AJCC stage I disease, 31% stage II-III, 9% stage IV, and 30% had insufficient staging data. Most patients (85%) were newly diagnosed. Twenty one percent of patients developed at least one HSR. Body surface area, race, and prior exposure to paclitaxel were not independently associated with HSRs. In contrast, stage IV disease at diagnosis was associated with a higher rate of HSR compared with stage I disease, with a rate ratio of 2.83 (95% CI 1.01-7.93; p=0.048) after adjustment for key confounders. Cumulative dexamethasone exposure did not impact OS in either univariable or multivariable analyses. **Conclusions:** HSRs occurred in 21% of paclitaxel-treated patients and were independently more common among those with stage IV disease. This suggests that greater disease burden may reflect differences in immune responsiveness that predispose to HSRs. While dexamethasone is commonly used to improve treatment tolerability and reduce the risk of HSRs, cumulative exposure did not impact OS. Further studies are needed to clarify the mechanisms underlying paclitaxel-associated HSR and to define the optimal role of steroid premedication. Research Sponsor: None.

Association of post-treatment vaginal structural changes with psychosexual dysfunction in young cervical cancer survivors: Evidence from a low- and middle-income country. First Author: Suriana Sultana, National Institute of Cancer and Research Hospital, Dhaka, Bangladesh

Background: Vaginal stenosis is a known late side effect of pelvic radiotherapy for cervical cancer. In low- and middle-income countries (LMICs), the extent of vaginal changes and their effects on sexual and emotional health are poorly studied due to cultural stigma and limited counseling. This study examined objective vaginal changes and their association with psychosexual distress among young cervical cancer survivors. **Methods:** This cross-sectional mixed-method study included 300 women aged ≤45 years who completed pelvic radiotherapy, with or without surgery and/or brachytherapy, 6–24 months earlier at Delta Hospital and collaborating centers. Participants completed a bilingual interviewer-administered questionnaire on counseling, intimacy, psychosocial distress, and perceived barriers. A standardized clinical examination was used to assess vaginal changes, including vaginal length, elasticity, adhesions, dryness, and dyspareunia, graded using LENT-SOMA and CTCAE v5.0 criteria. Outcomes were compared between women treated with definitive chemoradiation and those who underwent surgery followed by adjuvant radiotherapy ± brachytherapy. **Results:** The mean post-treatment vaginal length was 4.1 ± 1.2 cm. Reduced vaginal elasticity and adhesions were found in 68% of participants. Severe vaginal shortening (≤2 cm) or blind-ending occurred more often in women who received surgery followed by adjuvant radiotherapy and brachytherapy (approximately 40%) compared with those treated with definitive chemoradiation ($p<0.05$). The psychosexual impact was marked: 80% of women reported no return to penetrative intimacy or regular vaginal dilation, and 85% reported loss of sexual interest. The most common barriers were fear of injury or cancer recurrence (72%), pain during intercourse (65%), sociocultural stigma (48%), and partner separation or dysfunction (36%). Although 52% recalled receiving some counseling, only 15% actively discussed sexual health concerns, and fewer than 10% accessed specialized psychosexual care. **Conclusions:** Objective vaginal shortening and fibrosis are strongly linked to psychosexual distress and avoidance of intimacy among young cervical cancer survivors, especially after multimodality treatment. In low- and middle-income countries, unstructured counseling alone is not sufficient. Survivorship care should include regular vaginal assessment and culturally sensitive, partner-inclusive psychosexual counseling. Research Sponsor: None.

Real-world outcomes comparing the use of GLP-1 receptor agonists in patients with endometrial cancer and comorbid obesity: A propensity score matched analysis from a global federated health research network. First Author: Yajur Arya, Mayo Clinic Florida, Jacksonville, FL

Background: Glucagon-like peptide-1 (GLP-1) receptor agonists are widely used for the treatment of type 2 diabetes and obesity. Emerging evidence suggests that these agents may have potential anti-tumor activity as GLP-1 signaling may influence pathways involved in cell proliferation and inflammation. Endometrial cancer is the most common gynecologic malignancy, and obesity represents a well-established, modifiable risk factor that may adversely affect oncologic outcomes through chronic inflammation and metabolic dysregulation. Our study aims to evaluate the impact of GLP-1 receptor agonists on outcomes among patients with endometrial cancer and comorbid obesity. **Methods:** A retrospective cohort study was conducted using the TriNetX Global Collaborative Network, covering January 2000 to December 2025, encompassing data from 168 global healthcare organizations. Patients aged 18 and above with endometrial cancer and comorbid obesity were identified and then stratified into two groups based on treatment with GLP1 agonists or not. The two groups were then propensity-matched based on age, ethnicity, medical comorbidities, and stage of cancer. Outcomes were assessed for five years from treatment initiation and included overall mortality, myocardial infarction (MI), ischemic stroke; development of peritoneal, lymph node, and visceral metastases; sepsis, pancreatitis, and ED visits. Time-to-event analyses were performed using Kaplan-Meier methods and Cox proportional hazards models. **Results:** After propensity matching, 6352 patients were included in each cohort with balanced baseline characteristics. Our analysis found that patients with endometrial cancer and comorbid obesity who received GLP-1 agonists had a significantly lower risk of overall mortality (Hazard Ratio [HR]: 0.45, 95% CI: 0.39-0.51, p-value <0.001), development of peritoneal metastases (Risk Difference [RD]: -2.16%, 95% CI: -2.74% to -1.58%, p-value <0.001), nodal metastases (RD: -0.41%, 95% CI: -0.72% to -0.09%, p-value =0.01), visceral metastases (RD: -3.76%, 95% CI: -4.60% to -2.93%, p-value =0.01), and sepsis with and without shock (RD: -1.42%, 95% CI: -2.14% to -0.70%, p-value <0.001) compared to patients who did not receive GLP-1 agonists. There was no statistically significant difference in the rates of MI, ischemic stroke, ED visits, and pancreatitis between the two cohorts. **Conclusions:** In this large real-world analysis, patients with endometrial cancer and comorbid obesity who received GLP-1 agonists had lower rates of overall mortality; peritoneal, lymph node, and visceral metastases, and sepsis with or without shock. Additional longitudinal cohort studies are imperative to explore the associations between these agents and inform clinical practice guidelines in this patient population. Research Sponsor: None.

A phase 1 dose-escalation and -expansion study of AFN0328, a novel mRNA-based immunotherapy, in patients with HPV16/18-associated high-grade squamous intraepithelial lesions. First Author: Yunxia Cao, First Affiliated Hospital of Anhui Medical University, Hefei, China

Background: Persistent infection with high-risk human papillomavirus (HPV), particularly HPV16 and HPV18, drives the development of high-grade squamous intraepithelial lesions (HSIL), an obligate precancerous condition. The standard care of cervical HSIL requires either surgical excision (LEEP or cold-knife conization), or in some circumstance, watchful waiting. AFN0328 is a novel mRNA-based immunotherapy encoding HPV16/18-related antigens, designed to elicit antigen-specific immune responses and interrupt viral antigen-driven disease progression. **Methods:** Safety, tolerability and preliminary efficacy of AFN0328 were assessed in patients with HPV16- and/or HPV18-associated HSIL (CIN2/3) in an ongoing, multicenter, open-label Phase 1 trial. The study comprised two sequential parts: Part 1 employed a classic 3+3 dose-escalation design to assess safety and determine the maximum tolerated dose (MTD); Part 2 is a dose-expansion cohort at selected doses (150 μg and 300 μg) to further characterize safety, tolerability, and preliminary efficacy. AFN0328 was administered intramuscularly at 0, 4, and 12 weeks. The primary endpoints included safety and tolerability (dose-limiting toxicities within 28 days post-first dose, adverse events graded per CTCAE v5.0). For Part 2, the efficacy endpoints included viral clearance rate at Week 24 and Week 36, and histopathological regression at Week 36. Secondary endpoints included pharmacokinetic parameters, HPV16/18-specific IgG antibody titers, and pharmacodynamic markers (cellular immune responses and serum cytokines). **Results:** As of December 29, 2025, 23 patients had received at least one dose of AFN0328. No DLTs, serious adverse events, or grade ≥3 treatment-related adverse events (TRAE) were observed. PK analyses of first and last doses showed that circulating mRNA encoding HPV-related antigens peaked within 48 hours and declined gradually, with detectable levels persisting for up to at least 4 weeks across dose levels. All evaluable patients developed specific IgG responses and viral clearance was observed in evaluable patients during follow-up. **Conclusions:** AFN0328 demonstrated favorable safety and tolerability with robust immune responses in HPV16/18-associated HSIL, supporting further clinical development as an immunotherapy for HPV-driven precancerous disease. Clinical trial information: CTR20244013. Research Sponsor: None.

Summary of safety and immunogenicity outcomes.

Outcome	Result
Patients treated	23
Dose-limiting toxicities	0
Grade ≥3 treatment-related AEs	0
Most common TRAEs	Injection-site reactions, fever
Specific IgG response rate	100%*
Observed viral clearance	Yes*

*Observed in evaluable patients during interim follow-up.

Limb compression therapy and chemotherapy-induced peripheral neuropathy in women with gynecologic cancers: A prospective self-controlled study (NEURO-GLOVE Trial)—Updated long-term analysis. First Author: Kadriye Başkurt, Etlik City Hospital, Department of Medical Oncology, Ankara, Turkey

Background: No established strategy prevents taxane-induced CIPN. We evaluated if dual-site mechanical compression reduces CIPN severity at 3 and 6 months post-treatment. **Methods:** In this prospective, self-controlled study (Dec 2023–Dec 2024), 76 women receiving carboplatin–paclitaxel were enrolled. During infusions, compression was applied to the non-dominant hand (two surgical gloves) and ipsilateral foot (Class II stocking); contralateral limbs served as controls. The primary endpoint was the incidence of Grade ≥2 sensory/motor neuropathy (CTCAE v5.0) at End-of-Treatment (EOT), 3 months, and 6 months. **Results:** Among 76 patients (median age 61), Grade ≥2 CIPN was lower in compression vs control limbs at Cycle 3 (27/76 [35.5%] vs 41/76 [53.9%]; P=.001) and EOT (45/76 [59.2%] vs 53/76 [69.7%]; P=.021). Benefits persisted at 3 months (22/76 [28.9%] vs 40/76 [52.6%]; P=.015) and 6 months (15/74 [20.3%] vs 25/74 [33.8%]; P=.002). Longitudinal analysis showed significant time-by-limb interactions for hand sensory (P=.003), foot sensory (P=.018), and motor domains (P=.041). EORTC QLQ-CIPN20 sensory scores showed high accuracy (AUC 0.92 at Cycle 3; 0.97 at EOT). **Conclusions:** Compression significantly reduces acute and persistent CIPN. Sustained benefits at 3 and 6 months suggest prevention of irreversible damage, supporting compression as an effective neuroprotective strategy. Clinical trial information: NCT07105553. Research Sponsor: None.

Limb-specific incidence of moderate-to-severe chemotherapy-induced peripheral neuropathy by EORTC QLQ–CIPN20 across time.

Systemic inflammation and tumor immune microenvironment biomarkers (FOXP3, CD68, CD163) stratified by BRCA/HRD status in high-grade serous ovarian carcinoma: Associations with PFS and OS. First Author: Carolina Ibañez Caceres, Pontificia Universidad Catolica de Chile, Santiago, Región Metropolitana, Chile

Background: Outcomes in high-grade serous ovarian carcinoma (HGSOC) may be influenced by systemic inflammation and the tumor immune microenvironment. We evaluated the prognostic impact of systemic inflammatory markers and intratumoral immune biomarkers, including FOXP3⁺ regulatory T cells and tumor-associated macrophages (CD68 and CD163), in the context of BRCA/HRD status. **Methods:** We conducted a retrospective cohort study of patients with HGSOC with available baseline systemic inflammatory markers and tumor immunohistochemistry. Systemic inflammation was assessed using neutrophil-to-lymphocyte ratio (NLR >3.5) and lactate dehydrogenase (LDH >220). Intratumoral FOXP3, CD68, and CD163 expression was evaluated by immunohistochemistry. BRCA/HRD status was coded as positive versus negative. Progression-free survival (PFS) and overall survival (OS) were analyzed using multivariable Cox proportional hazards models. **Results:** Twenty-nine patients were included, with 27 PFS events and 25 OS events. In multivariable analysis for PFS, elevated systemic inflammation was independently associated with worse outcomes: NLR >3.5 (HR 5.88, 95% CI 1.35–25.54; p=0.018) and LDH >220 (HR 6.70, 95% CI 1.33–33.74; p=0.021). Within the tumor microenvironment, higher intratumoral CD68 was associated with inferior PFS (HR 1.10, 95% CI 1.04–1.17; p=0.001), whereas higher CD163 was associated with improved PFS (HR 0.92, 95% CI 0.87–0.97; p=0.002). BRCA/HRD positivity was not independently associated with PFS. For OS, BRCA/HRD positivity was strongly protective (HR 0.14, 95% CI 0.03–0.60; p=0.008), while NLR >3.5 remained independently associated with worse OS (HR 4.27, 95% CI 1.17–15.68; p=0.028). High FOXP3 expression was associated with improved OS (HR 0.06; p=0.032). CD68 and CD163 showed borderline associations with OS. **Conclusions:** In this HGSOC cohort, baseline systemic inflammation was associated with inferior PFS, and elevated NLR predicted worse OS. Intratumoral immune biomarkers showed distinct prognostic patterns, suggesting that the balance and functional state of myeloid and regulatory immune compartments influence outcomes. BRCA/HRD positivity remained strongly favorable for OS. These findings support further investigation of integrated systemic and tumor immune profiling in larger, prospectively annotated cohorts. Genomic signature–based risk score for PARP inhibitor response in *BRCA*-mutated ovarian cancer: A whole-exome sequencing analysis. First Author: Junhwan Kim, Center for Gynecologic Cancer, National Cancer Center, Goyang-Si, South Korea

Background: To identify whole-exome sequencing (WES)–based genomic signatures associated with response to poly(ADP-ribose) polymerase (PARP) inhibitors and develop a prediction model for PARP inhibitor effectiveness in *BRCA*-mutated advanced ovarian cancer, given the heterogeneous real-world treatment outcomes. **Methods:** This retrospective cohort study included patients with advanced ovarian cancer harboring *BRCA*1/2 mutations who received olaparib or niraparib as first-line maintenance therapy between 2020 and 2022 at the National Cancer Center, South Korea. Among them, patients with at least one year of follow-up from the reference date (August 1, 2024) and sufficient additional tumor samples for WES were identified. Baseline characteristics were collected, and progression-free survival (PFS) and overall survival (OS) from the initiation date of PARP inhibitors were extracted from electronic medical records. Formalin-fixed, paraffin-embedded tumor samples of eligible patients underwent DNA extraction and WES. Prognostic modeling incorporated clinical and genetic variables using Cox proportional hazards regression with the least absolute shrinkage and selection operator (Lasso) method with leave-one-out cross-validation. Model performance was assessed using time-dependent area under the curve (AUC(t)). **Results:** Fifty-five patients were included. The median patient age was 57 years (range, 39–72). High-grade serous carcinoma comprised 96.4%. Neoadjuvant chemotherapy (NACT) was performed in 40.0%. Complete remission after adjuvant chemotherapy occurred in 87.3%. Olaparib was administered in 76.4% and niraparib in 23.6%. NACT-exposed samples had lower Mutant-Allele Tumor Heterogeneity (MATH) scores than non-NACT-exposed samples, indicating reduced intratumor heterogeneity ($P < 0.001$). Recurrence during PARPi maintenance occurred in 11 patients (20.0%) (olaparib: 5/42 [11.9%]; niraparib: 6/13 [46.2%]). No deaths were observed. The median PFS was 37.9 months (range, 4.2–54.5), and the median OS was 43.3 months (range, 20.2–60.1). Mutations significantly associated with progression-free survival included *POLN* (HR, 2.02; 95% CI, 1.12–3.67), *ABCC10* (HR, 4.57; 95% CI, 1.13–18.5), *GTPBP6* (HR, 2.07; 95% CI, 1.04–4.12), and *TCTEX1D1* (HR, 0.19; 95% CI, 0.05–0.82). A genomic risk score model incorporating these mutations stratified patients ino low- and high-risk groups with strong prognostic discrimination for progression-free survival (HR, 4.44; 95% CI, 2.26–8.68; log-rank $P < 0.001$; AUC(t), 0.87). **Conclusions:** The genomic signature-based risk score model independently predicted PARP inhibitor effectiveness. External validation is warranted. Research Sponsor: National Cancer Center, Republic of Korea; NCC2510290-2.

ErbB family members as mediators of acquired resistance to immunotherapy in high-grade serous ovarian cancer. First Author: Mengyao Xu, Massa-Massachusetts General Hospital Cancer Center, Boston, MA

Background: Efforts to improve immunotherapy for ovarian cancer (OC) have focused on optimizing T-cell effector-based strategies such as immune checkpoint inhibitors (ICIs), bispecific T-cell engagers (BiTEs), or chimeric antigen receptor (CAR)-T cells, or combining them with other therapeutic modalities. Relatively little is known about how adaptive resistance occurs or how to improve the intrinsic susceptibility of ovarian cancer cells to T cell-mediated cytolysis. **Methods:** An OC organoid derived from a patient who relapsed on immunotherapy (MGH538) was generated. OVCAR3 immune-edited cell line (OVCAR3^{IE}) was generated by treating OVCAR3 wild-type (OVCAR3) tumor-bearing mice with activated T-cells, anti-PD-1, and anti-CTLA4 antibodies. Peritoneal tumors were then harvested and cultured *in vitro*. BiTEs-resistant cell line (OVCAR3^{R}) was generated by treating OVCAR3 cells with anti-MUC16 BiTEs *in vitro* until the cells were resistant. Comparative RNA sequencing analysis was performed on OVCAR3, OVCAR3^{IE}, and OVCAR3^{R}. Protein expression was assessed by Western blot analysis. To evaluate cytotoxicity, OVCAR3, OVCAR3^{IE}, and OVCAR3^{R} were co-cultured with MUC16-specific CAR-T cells and MUC16-directed BiTEs, alone or in combination with pharmacologic inhibitors targeting EGFR, RAS, and Bcl-xL, including a Bcl-xL degrader DT2216. **Results:** MGH538, OVCAR3^{IE} and OVCAR3^{R} were confirmed to be resistant to T-cell directed cytolysis compared to OVCAR3. RNA sequencing analysis revealed significant differences in the transcriptome profiles of immune-naive and immunotherapy-exposed OC cells. In particular, significant changes in the RNA expression levels of three out of four ErbB family members (EGFR (ErbB1), ErbB2 and 3) were detected. In Western blot analysis, this finding was paralleled by significant changes in the ratio of phospho-ERK to ERK, an important component of ErbB downstream signaling. In functional assays, EGFR inhibition with gefitinib significantly enhanced CAR-T cell-mediated killing in OVCAR3, OVCAR3^{IE} and OVCAR3^{R} cells. Furthermore, blocking downstream EGFR signaling with a Ras inhibitor also restored sensitivity to immunotherapy. Finally, blocking anti-apoptotic signaling with Bcl-family inhibitor navitoclax, or the Bcl-xL inhibitor DT2216 restored susceptibility to both CAR-T cell and BiTEs-mediated killing. **Conclusions:** Adaptive resistance to T-cell mediated cytotoxicity appears to be mediated, at least in part, by upregulation of ErbB family members and consequent downstream Ras signaling and resistance to apoptosis. While further functional *in vitro* and therapeutic *in vivo* studies are warranted to investigate the translational potential of our findings, EGFR signaling may represent a promising target for clinical combination strategies. Development of payload-resistant human ovarian cancer cell lines to better understand antibody-drug conjugate sequencing and resistance mechanisms. First Author: Janina Pearce, Program in Women's Oncology, Department of Obstetrics and Gynecology, Women and Infants Hospital, Brown University, Providence, RI

Background: Within gynecologic oncology, limited data exist regarding mechanisms of resistance to antibody-drug-conjugates (ADC) or the impact on response to future ADC treatment. The purpose of this study was to develop and characterize payload-resistant human ovarian cancer cell lines, and to determine the effect of payload resistance on subsequent ADC exposure. **Methods:** Three commercially available human high grade serous ovarian cancer cell lines (PEA1, PEA2, and OVCAR8) were each exposed separately to three commercially available payloads with corresponding, clinically approved ADCs (deruextecan/trastuzumab deruxetecan, SN38/sacituzumab govitecan, and DM4/mirvetuximab soravtansine). Cell viability assays were performed to confirm and quantify resistance after completion of treatment for payload-resistant cell lines, and western blot analyses performed to evaluate changes in HER2, TROP2, and FOLR1 expression between payload-resistant cells and their controls. Lastly, paired payload-resistant and -sensitive cell lines were then exposed to ADCs with different payloads for 48 hours, and cell viability assays were performed. **Results:** The development of payload-resistant cell lines demonstrates notable variability in timelines for attaining resistance, both across the three cell lines and within individual cell lines across different payload exposures. Compared to payload-sensitive controls, payload-resistant cells displayed similar morphologic changes including increased surface area; however, demonstrated variable differences in HER2, TROP2, and FOLR1 protein expression. Additionally, different payload-resistant cell lines responded differently to subsequent ADC exposure. As a specific example, DM4-resistant PEA1 cells were more sensitive to subsequent exposure to sacituzumab govetecan compared to DM4-senstive controls at various doses ($p < 0.0001$, see Table). **Conclusions:** This study illustrates challenges in developing payload-resistant cell lines, and highlights variability in molecular changes with payload resistance. The data demonstrate subsequent ADC susceptibility in some payload-resistant cell lines, highlighting the complexities of changes that occur with drug treatment. Our data suggests that HGSOC patients that received mirvetuximab soravtansine may be more susceptible to future treatment with sacituzumab govitecan. Future work is underway to expand these findings to determine ideal sequencing of these different ADCs, and to determine other off-target effects that may influence non-ADC treatment response. Research Sponsor: None.

Viability of DM4-resistant versus sensitive PEA1 human ovarian cancer cells after exposure to sacituzumab govitecan (SG).

	DM4 resistant		Control		
	Average % viability	SEM	Average % viability	SEM	p value

Geographical heterogeneity in modeled CA-125 KELIM values: Insights from more than 50,000 real-world calculations on the Biomarker Kinetics platform. First Author: Benoit You, Centre Hospitalier Lyon Sud, and GINECO, Pierre-Benite, France

Background: The modeled CA-125 KELIM is a pragmatic indicator of primary tumor chemosensitivity during neoadjuvant (NACT) or adjuvant chemotherapy (post-primary cytoreductive surgery: ADJUVANT) in ovarian cancer. In a recent GCIG meta-analysis, Japanese patients with stage III–IV high-grade serous carcinoma had higher median KELIM values than Western populations (Corbaux.et.al., Proc ESGO 2025). To further assess potential geographical variations in chemosensitivity, we analyzed KELIM values calculated via the free online platform *www.biomarker-kinetics.org*, which performs approximately 30,000 calculations annually worldwide. **Methods:** All CA-125 KELIM calculations performed on the BK platform between April 2024 and January 2026 were extracted. Median KELIM values were compared separately for NACT and adjuvant settings across continents and countries. **Results:** During the 21-month study period, 50,055 KELIM calculations were recorded worldwide (NACT 59%; ADJUVANT 41%), originating from Asia (n=27,280; 55%), Europe (n=16,461; 33%), North America (n=3,690; 7%), South America (n=1,363; 3%), and rest of globe. Marked geographical variations in KELIM distribution were observed. In the NACT setting, median KELIM values (standardized by the classical cutoff) were significantly higher in patients from Asia (median 1.06, 95%CI [1.05–1.07]), Middle-East (median 0.96 [0.89–1.0.6]), and North America (median 0.91 [0.89–0.94]) compared to those from Europe (median 0.85 [0.84–0.86]) ($P < 0.0001$). Within Asia, KELIM values were similarly elevated in China (n=10,617; median 1.07 [1.06–1.08]) and Japan (n=3,092; median 1.05 [1.03–1.07]) (P=NS). Similar results were noted in the ADJUVANT setting (Asia median 0.91, North America 0.80, vs Europe 0.75; all $P<0.0001$). Weighted median ($\tau = 0.5$) quantile regression confirmed significantly higher standardized KELIM values in Asia (+0.21), Middle East (+0.12), and North America (+0.06) compared with Europe in the NACT setting. Similar outcomes were found in ADJUVANT setting : Asia (+0.16), Middle East (+0.28), and North America (+0.04) compared to Europe. **Conclusions:** Consistent with the GCIG meta-analysis, this global extraction of >50,000 KELIM calculations in the last 2 years confirms substantial geographic variability in tumor chemosensitivity, with higher median standardized KELIM values observed in patients from Asia and, to a lesser extent, the Middle East, while those from Europe exhibited the lowest values. These findings suggest potential important worldwide differences in primary tumor sensitivity to 1st-line carboplatin-paclitaxel chemotherapy and support the need for further biological and clinical investigations across diverse geographic and ethnic populations. YL205, a novel anti-Napi2b antibody drug conjugate (ADC), in patients with ovarian cancer: Preliminary result from a first-in-human trial. First Author: Xiaohua Wu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Sodium-dependent phosphate transport protein 2b (NaPi2b) is a rapidly internalizing sodium-phosphate transporter which is highly overexpressed in ovarian cancer (OC). The prognosis of patients (pts) with heavily pretreated ovarian cancer remains poor, highlighting a significant unmet need. YL205 is a unique antibody-drug conjugate comprising a NaPi2b-directed antibody conjugated to a potent topoisomerase 1 inhibitor payload developed with TMALIN platform. The preliminary safety and efficacy of YL205 monotherapy in ovarian cancer from a multi-center, open-label, phase I/II trial are presented. **Methods:** Pts with advanced solid tumors, mainly OC, who had failed standard therapy or no available standard therapy were enrolled in the trial YL205-CN-101-01. It consists of dose-escalation (BF-BOIN design), followed by dose-expansion. Pts received YL205 IV at 1.0~3.0 mg/kg once every 3 weeks. Primary objectives were to assess safety and tolerability. **Results:** As of the data cut-off on Dec. 12, 2025, 48 OC pts were dosed with YL205 monotherapy in China and United States with median follow up time of 5.5 months (range 0.2-17.2). Pts had median age of 54.2 yo (range 32-70), 68.8% with ECOG PS 1, 37.5% with $\geq$ 4 prior lines of therapy. Previous therapies included bezacizumab (89.6%), PARP inhibitors (43.8%), and mirvetuximab soravtansine (2.1%). No maximum tolerated dose (MTD) was defined. Grade 3 TRAEs occurred in 27.1% of pts. 14.6% of pts developed SAEs related to tx. The most common TRAEs were neutropenia (60.4%; G≥3: 12.5%), anaemia (60.4%, G≥3: 4.2%), nausea (47.9%, G≥3: 0), vomiting (33.3%, G≥3: 0), decreased appetite (27.1%, G≥3: 0) and thrombocytopenia (25.0%, G≥3: 6.3%) across all dose levels. Among 43 efficacy evaluable pts, confirmed ORR was 46.5% (95% CI: 31.2 – 62.3), and DCR was 95.3% (95% CI: 84.2 – 99.4). At the date cutoff, the median progression-free survival (PFS) data was immature, 62.5% (15/24) of patients with a response remain on treatment. NaPi2b expression as evaluated by H-score was found to be low (0-100) in 1 pt, medium (101-201) in 11 pts (101-200) and high (201-300) in 35 pts whose tumor tissues available at baseline. No correlation trend was observed between NaPi2b expression and response. **Conclusions:** YL205 demonstrated a manageable safety profile in heavily pretreated ovarian cancer patients, with preliminary efficacy observed irrespective of NaPi2b expression intensity. The promising clinical data supports further investigation of this ADC in OC. Clinical trial information: NCT06459973. Research Sponsor: None.

A first-of-its-kind multi-omic assay using lipids and proteins to identify early-stage ovarian cancer in symptomatic individuals. First Author: Abigail McElhinny, AOA Dx, Denver, CO

Background: Ovarian cancer (OC) is often diagnosed at advanced stages, leading to one of the highest mortality rates for gynecologic malignancies. While 85% of patients are symptomatic even at early stages, symptoms are vague and overlap with benign conditions. Existing diagnostic tools such as CA125 and HE4 lack sufficient sensitivity and specificity to detect early-stage disease, even in symptomatic individuals. As a result, there is a critical unmet need for a highly sensitive diagnostic tool designed for patients presenting with vague abdominal symptoms. **Methods:** Here, we report the first large-scale, prospective U.S. clinical trial evaluating a targeted multi-omic assay of symptomatic women, its intended-use population. Assay performance was assessed in a subset of an independent, prospectively recruited, multi-site study enrolled across the United States, supplemented with samples from a commercial vendor (N=346). The cohort comprised patients diagnosed with OC across stages and subtypes (N=116: 50 early-stage I/II, 66 late-stage III/IV) and a symptomatic control group (N=230), comprising individuals with benign adnexal masses (BAN; N=116) and symptomatic individuals with vague abdominal symptoms who were followed longitudinally for 12 months to confirm absence of malignancy (symptomatic normal; N=114). Serum lipids including selected phospholipids, sphingolipids, and ceramides were quantified by mass spectrometry. Proteins were measured using clinically validated immunoassays. An ensemble machine learning modeling approach was applied using targeted feature subsets from a refined panel of 23 lipid and 5 protein markers, with outputs weighted to reflect anticipated disease prevalence in the intended-use population. **Results:** The assay demonstrates consistently high diagnostic performance, achieving 96.5% sensitivity with 80.6% specificity for OC vs. symptomatic control, and 92% sensitivity for early-stage OC in the same comparison. Integrating lipid and protein biomarkers into a targeted multi-omic model therefore results in a substantial improvement in OC detection, especially early-stage, over current standard-of-care biomarkers. **Conclusions:** In a large, prospectively collected cohort reflecting real-world symptomatic patients, this first-of-its-kind, targeted multi-omic assay accurately distinguishes OC from non-malignant conditions in symptomatic women with dramatic improvement in early-stage detection. These findings support the feasibility and clinical utility of a multi-omic assay in addressing a longstanding diagnostic gap for symptomatic women, clearing a path to earlier triage and diagnosis. Preoperative assessment of peritoneal carcinomatosis with [^{68}Ga]Ga-FAPI-46 PET/CT. First Author: Ayca Arcay Ozturk, Department of Nuclear Medicine, Institut Jules Bordet, Hôpital Universitaire de Bruxelles, Université Libre de Bruxelles, Brussels,, Belgium

Background: Accurate preoperative mapping of peritoneal carcinomatosis (PC) is essential for selecting patients for cytoreductive surgery (CRS) and guiding treatment planning. Conventional imaging including [^{18}F]FDG PET/CT may underestimate PC tumour burden. This study evaluated [^{68}Ga]Ga-FAPI-46 PET/CT for preoperative PC assessment using a surgico-pathological reference standard and compared its performance with MRI and [^{18}F]FDG PET/CT. **Methods:** In this prospective phase II study (FAPeCa, NCT06061874), patients with colorectal or ovarian cancer with known or suspected PC underwent [^{68}Ga]Ga-FAPI-46 PET/CT, [^{18}F]FDG PET/CT (FDG PET), and MRI within 4 weeks before diagnostic laparoscopy and/or CRS. PC extent was quantified using a 10-segment adaptation of the Peritoneal Cancer Index (PCI). Reference standard was intraoperative PCI with histopathological confirmation, with pathology adjudicating discordant findings. Agreement between imaging-derived total PCI and the reference-standard PCI was assessed using intraclass correlation coefficient (ICC, two-way mixed, absolute agreement). Segment-level diagnostic performance was evaluated after dichotomisation (PCI 0 vs ≥1). Subgroup analyses were performed according to recent chemotherapy (<3 months). **Results:** Sixty-one patients were enrolled. Median (IQR) total PCI values were 11 (18.5) for the reference standard, 12 (15.5) for FAPI PET, 6 (15.5) for MRI, and 4 (6.5) for FDG PET; FAPI-PCI was higher than MRI-PCI and FDG-PCI (Wilcoxon signed-rank, $p<0.001$). Agreement with the reference standard was highest for FAPI PET (ICC 0.81; BCa 95% CI 0.67–0.89), followed by MRI (ICC 0.76; BCa 95% CI 0.63–0.85) and FDG PET (ICC 0.54; BCa 95% CI 0.29–0.74). In the recent chemotherapy subgroup, FAPI PET maintained good agreement with the reference standard (ICC 0.75, BCa 95% CI 0.56–0.86), whereas agreement declined to moderate for MRI (ICC 0.65, BCa 95% CI 0.41–0.82) and was lower for FDG PET (ICC 0.46, BCa 95% CI 0.17–0.75). Segment-level sensitivity, specificity, and accuracy were 77.6%, 71.2%, and 74.8% for FAPI PET; 67.0%, 84.4%, and 74.7% for MRI; and 47.5%, 91.8%, and 67.2% for FDG PET . Overall segment-level sensitivities and specificities differed across the three modalities (Cochran's Q, $p<0.001$). **Conclusions:** [^{68}Ga]Ga-FAPI-46 PET/CT demonstrated the strongest agreement with surgico-pathological PCI and maintained good agreement after recent chemotherapy. It showed higher detectability than MRI and [^{18}F]FDG PET/CT, albeit at the expense of lower specificity. These findings support[^{68}Ga]Ga-FAPI-46 PET/CT as a promising modality for preoperative PC mapping. Clinical trial information: NCT06061874. Research Sponsor: None.

Trastuzumab deruxtecan (T-DXd) + bevacizumab (BEV) as first-line (1L) maintenance therapy in patients (pts) with human epidermal growth factor receptor 2 (HER2)–expressing ovarian cancer (OC): Results from the DESTINY-Ovarian01 (DO-01/ENGOT-ov89/GOG-3112/APGOT-OV13) safety run-in (SRI). First Author: Antonio Gonzalez Martin, GEICO and Cancer Center Clinica Universidad de Navarra, Madrid, Spain

Background: HER2 immunohistochemistry (IHC) expression scores of 3+, 2+, or 1+ occur in up to ~6%, ~28%, and ~21% of OC cases, respectively. In DESTINY-PanTumor02, T-DXd, a HER2-directed antibody–drug conjugate, showed clinically meaningful antitumor activity in pts with heavily pretreated HER2-expressing OC, establishing HER2 as a targetable biomarker. BEV + chemotherapy, followed by maintenance BEV ± poly (ADP-ribose) polymerase inhibitors (PARPi), is a recommended 1L treatment; however, an unmet need remains for PARPi-ineligible pts with HER2-expressing OC. We report the SRI results from DO-01 (NCT06819007), a randomized, open-label, phase 3 trial evaluating T-DXd + BEV vs BEV alone as 1L maintenance therapy in pts with HER2-expressing OC. **Methods:** Pts with newly diagnosed, advanced, high-grade, locally or centrally determined HER2-expressing (IHC 3+/2+/1+) epithelial OC, with no disease progression after 1L chemotherapy + BEV, and ineligible for PARPi, were enrolled and received T-DXd 5.4 mg/kg + BEV 15 mg/kg intravenously every 3 weeks. Pts were treated for ≥2 cycles. Preliminary safety of T-DXd + BEV was assessed by dose-limiting toxicity (DLT; ~30% maximum acceptable rate) and the frequencies of treatment-emergent adverse events (TEAEs) and TEAEs of special interest. **Results:** At data cutoff (DCO; October 23, 2025), 21 pts received a median of 4 cycles (range, 2-8) of T-DXd + BEV; no pt withdrew before cycle 2. Median age was 57 years (range, 22-71) and 19 pts (90.5%) were Asian; 7 (33.3%) and 14 pts (66.7%) had FIGO stages III and IV at baseline, respectively. Median treatment duration was 3.0 mo (range, 1.4-5.5). At DCO, 20 pts (95.2%) completed DLT evaluation and remained on treatment; 1 withdrew after the DLT evaluation period. DLTs occurred in 2 pts (10.0%). TEAEs are shown in the Table. Grade ≥3 drug-related TEAEs occurred in 9 pts (42.9%). Drug-related TEAEs led to dose reduction in 5 pts (23.8%) and dose delay in 6 pts (28.6%). No drug-related TEAEs led to discontinuation or death. Most common drug-related TEAEs (>50%) were nausea (76.2%), leukopenia (52.4%), and neutropenia (52.4%). No cases of adjudicated drug-related interstitial lung disease or left ventricular dysfunction were reported. **Conclusions:** The preliminary safety profile of T-DXd + BEV was consistent with the known safety profiles of the individual agents, and no new safety signals were identified, supporting continued investigation of T-DXd + BEV in DO-01. Clinical trial information: NCT06819007. Research Sponsor: Daiichi Sankyo, Inc.

Pts with events, n (%)	T-DXd + BEV N = 21
Drug-related TEAEs	21 (100)
Drug-related grade ≥3 TEAEs	9 (42.9)
Drug-related TEAEs leading to discontinuation	0
Drug-related TEAEs leading to dose reduction	5 (23.8)
Drug-related TEAEs leading to dose delay	6 (28.6)
TEAEs with outcome of death	0

Integrating a small extracellular vesicle protein–based ovarian cancer score with O-RADS Ultrasound to improve preoperative risk stratification of adnexal masses. First Author: Qunxian Rao, Department of Gynecologic Oncology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: Accurate preoperative differentiation of adnexal masses remains a major clinical challenge. Although the Ovarian-Adnexal Reporting and Data System (O-RADS) standardizes ultrasound-based risk assessment, approximately 30-35% of adnexal masses are classified as indeterminate (O-RADS 3/4), often resulting in diagnostic uncertainty, unnecessary surgery, or delayed referral to gynecologic oncologists. Conventional serum biomarkers such as CA125 are limited by poor specificity and biological heterogeneity. The small Extracellular vesicle (sEV)-associated biomarkers have emerged as a promising approach to improve diagnostic accuracy by more closely reflecting tumor-related molecular signals. This study evaluated whether a serum sEV-based Ovarian Cancer Score (OCS) provides independent and incremental diagnostic value when integrated with O-RADS ultrasound. **Methods:** This retrospective diagnostic study included 250 consecutive patients with adnexal masses treated at Sun Yat-sen Memorial Hospital. All patients underwent standardized transvaginal ultrasound with O-RADS classification and serum CA125 testing. OCS was assessed using a chemiluminescent immunoassay based on serum sEV-derived CA125, HE4, and C5a. Final histopathology served as the reference standard. Diagnostic performance was evaluated overall and stratified by O-RADS category. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of malignancy. **Results:** Overall, OCS demonstrated significantly higher diagnostic accuracy for malignancy than serum CA125 alone. In masses with clearly benign or malignant imaging features (O-RADS 2 and 5), OCS maintained an accuracy of approximately 90% (87.5% and 94.6%). Within the clinically challenging O-RADS 3/4 subgroup (n = 115), OCS achieved a diagnostic accuracy of 86.1%, substantially outperforming serum CA125 (69.6%). Multivariate analysis identified OCS positivity as the strongest independent predictor of malignancy (OR 106.08, 95% CI 15.37-732.15, $p < 0.001$), exceeding individual high-risk ultrasound features such as ascites or mixed cystic-solid components. Diagnostic performance was further enhanced when OCS was combined with selected ultrasound characteristics. **Conclusions:** A serum sEV-based OCS provides robust and independent diagnostic information that complements O-RADS ultrasound in the preoperative evaluation of adnexal masses. By addressing the diagnostic gray zone of O-RADS 3/4, this integrated approach extends beyond conventional serum biomarkers and may support improved risk stratification and triage decisions. Clinical trial information: NCT06366997. Research Sponsor: None.

Neoadjuvant disitamab vedotin plus carboplatin in HER2-expressing advanced ovarian cancer: A prospective, single-arm, phase II trial. First Author: Yifan Meng, Department of Gynecologic Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Standard neoadjuvant paclitaxel-carboplatin for advanced ovarian cancer causes significant neurotoxicity impacting quality of life. Disitamab vedotin (RC48), an anti-HER2 antibody-drug conjugate, demonstrated efficacy and favorable tolerability in HER2-expressing solid tumors. We evaluated RC48 plus carboplatin as neoadjuvant therapy in HER2-expressing advanced ovarian cancer. **Methods:** This single-arm phase II trial (NCT06574763) enrolled patients with newly diagnosed FIGO stage III-IV high-grade serous ovarian, fallopian tube, or primary peritoneal cancer expressing HER2 (IHC 1+ or ERBB2 amplification) who were ineligible for primary cytoreductive surgery. Treatment comprised carboplatin (AUC 5, day 1, Q3W) alone in cycle 1, then RC48 (2.5 mg/kg, day 1, Q3W) plus carboplatin for cycles 2-4. A 6-patient safety run-in determined optimal RC48 dosing. Interval debulking surgery (IDS) was performed 14-28 days after cycle 4. Primary endpoint: complete resection rate (CRR, defined as no macroscopic residual disease at IDS). Secondary endpoints: pathological complete response (pCR), objective response rate (ORR per RECIST v1.1), progression-free survival, overall survival, and safety (CTCAE v5.0). **Results:** From October1st, 2024 to December 31st, 2025, 33 patients were enrolled.; 25 completed neoadjuvant therapy and underwent IDS. Among 24 evaluable patients (1 excluded for mixed histology meeting exclusion criteria), median age was 57 years (range 42-71); all had stage IIIC (n=18, 75%) or IVB (n=6, 25%) disease. The regimen achieved exceptional surgical outcomes: CRR 91.6% (22/24), with 2 patients having minimal residual disease <1 cm. ORR was 87.5% (21/24). pCR rate was 4.2% (1/24). Robust tumor regression was observed: median residual viable tumor in primary lesions 22% (range 0-80%), in omental implants 44% (range 0-80%). With median follow-up of 5.0 months (range 2.3-10.6), no disease recurrence occurred. Grade ≥3 treatment-related adverse events occurred in 29.2% of patients, primarily hematological toxicities (neutropenia, thrombocytopenia) that resolved to ≤grade 2 within one week with supportive care. Critically, no patient (0/27, 0%) experienced peripheral neuropathy of any grade. **Conclusions:** Neoadjuvant disitamab vedotin plus carboplatin demonstrated exceptional surgical outcomes with 91.6% complete resection rate and complete elimination of neurotoxicity in HER2-expressing advanced ovarian cancer. The regimen induced substantial pathological regression with a favorable safety profile. These results support RC48-carboplatin as a promising neurotoxicity-sparing alternative to standard paclitaxel-based therapy. Updated survival data will be presented. Clinical trial information: NCT06574763. Research Sponsor: Remegen.

Understanding palliative care gaps in young adult ovarian cancer: A population-based study of 37,880 hospitalizations. First Author: Rigved Virendra Jeurkar, Byramjee Jeejeebhoy Government Medical College, Pune, Mumbai, India

Background: Palliative care (PalC) improves both quality of life and survival compared to usual care. Despite this, significant implementation gaps persist due to delayed or absent utilization. This study examines the determinants, trends, clinical profiles, and outcomes of PalC among young women hospitalized with ovarian cancer. **Methods:** We identified ovarian cancer patients among young adults aged 18-45 years using the National Inpatient Sample (NIS) from 2016-2022. We first estimated the prevalence of PalC utilization and then developed a multivariable logistic regression model to estimate the association of demographic, clinical, and hospital-level variables with PalC use. The in-hospital mortality burden associated with PalC receipt was also estimated. **Results:** We found 37,880 ovarian cancer young adults with 8.78% using PalC. Several variables were associated with PalC utilization. Clinical comorbidities demonstrated the strongest associations: metastatic cancer(aOR 4.123, 95% CI: 3.385-5.023, $p<0.001$), frailty (aOR 3.407, 95% CI: 2.803-4.142, $p<0.001$), and cachexia (aOR 3.817, 95% CI: 2.460-5.922, $p<0.001$). Depression was also significantly associated with PalC utilization (aOR 1.360, 95% CI: 1.056-1.751, p=0.017). Temporal trends revealed increasing PalC utilization in more recent years compared to 2016, with significantly higher odds in 2020 (aOR 1.412, 95% CI: 1.005-1.985, p=0.047) and 2021 (aOR 1.565, 95% CI: 1.122-2.184, p=0.008). Weekend admissions were associated with 38.2% higher odds of PalC receipt (aOR 1.382, 95% CI: 1.107-1.727, p=0.004), and each additional year of age increased odds by 1.5% (aOR 1.015, 95% CI: 1.001-1.029, p=0.034). Insurance status significantly influenced PalC receipt. Compared to Medicare beneficiaries, patients with private insurance had 36.6% lower odds of receiving PalC (aOR 0.634, 95% CI: 0.452-0.890, p=0.008), while self-pay patients had 51.1% lower odds (aOR 0.489, 95% CI: 0.293-0.816, p=0.006). Additionally, patients from the highest income quartile had 25.7% lower odds of PalC compared to those in the lowest income quartile (aOR 0.743, 95% CI: 0.555-0.996, p=0.047). Race, hospital location/teaching status, hospital region, and hospital bed size were not significantly associated with PalC receipt. The overall in-hospital mortality rate was 3.0%, with stark differences by PalC receipt: 21.5% among those receiving PalC versus 1.22% among those not receiving PalC (aOR 16.532, 95% CI: 11.205-24.389, $p<0.001$). **Conclusions:** Among hospitalized young adults with ovarian cancer, fewer than 1 in 10 received PalC. Services concentrated among patients with metastasis, frailty, and cachexia, suggesting late rather than early integration. Significant disparities by insurance and income highlight access barriers requiring intervention for equitable PalC integration into comprehensive cancer care. Research Sponsor: None.

Ocular toxicity and safety profile of mirvetuximab soravtansine in ovarian cancer: A systematic review and meta-analysis of clinical trials and real-world studies. First Author: Priyanka Nagdev, UNC HBR, Morganton, NC

Background: Mirvetuximab soravtansine (MIRV) is a folate receptor alpha (FRα)–targeting antibody–drug conjugate approved for FRα-positive, platinum-resistant ovarian cancer. Ocular adverse events are a characteristic toxicity of MIRV; however, the incidence and severity of ocular and selected non-ocular toxicities across clinical trials and real-world studies have not been comprehensively synthesized. **Methods:** This systematic review and meta-analysis study was conducted according to PRISMA guidelines and registered in PROSPERO (CRD420251270297). MEDLINE/PubMed, Embase, Scopus, and CENTRAL were searched from inception through December 2025 for prospective phase I–III trials and real-world observational studies evaluating MIRV in epithelial ovarian, fallopian tube, or primary peritoneal cancer. Two reviewers independently screened studies and extracted data. Primary outcomes included any-grade and grade $\geq$3 ocular adverse events, as well as ocular toxicity–related dose reductions and treatment discontinuations. Secondary outcomes included grade $\geq$3 pneumonitis and thrombocytopenia. Clinical trial and real-world data were analyzed separately. Random-effects meta-analyses of proportions were performed using logit transformation, with heterogeneity assessed using the I^2 statistic. Analyses were conducted in R version 4.5.2. **Results:** Fourteen studies comprising approximately 750 patients were included. In pooled analyses of clinical trials, any-grade ocular adverse events were common (56.2%; 95% CI, 5.2–96.8) with substantial heterogeneity contributing to wide confidence intervals, whereas grade $\geq$3 ocular adverse events were rare (1.41%; 95% CI, 0.47–4.13) with no observed heterogeneity. Dose reduction due to ocular toxicity occurred in 31.2% (95% CI, 18.0–48.4) of patients, while treatment discontinuation due to ocular adverse events was less frequent (9.98%; 95% CI, 0.70–63.58). Severe non-ocular toxicities were uncommon, with pooled incidences of 1.41% (95% CI, 0.47–4.13) for grade $\geq$3 pneumonitis and 1.44% (95% CI, 0.09–19.44) for grade $\geq$3 thrombocytopenia. Across three real-world studies involving 289 patients, treatment discontinuation due to ocular adverse events was rare (0.35%; 95% CI, 0.00–20.54), with safety findings consistent with those from clinical trials. **Conclusions:** MIRV is associated with frequent, but predominantly low-grade, ocular adverse events, which are commonly managed with dose modification, while severe ocular and non-ocular toxicities are rare. Real-world evidence supports the tolerability profile observed in clinical trials, highlighting the importance of proactive ocular monitoring to optimize treatment continuity. Research Sponsor: None.

Updated efficacy of dalpiciclib and nonsteroidal aromatase inhibitors (NSAIs) in estrogen receptor–positive (ER+) recurrent/metastatic (R/M) ovarian cancer and uterine neoplasms. First Author: Huijuan Yang, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Initial results from our trial showed the anti-tumor activity and good tolerance of CDK4/6 inhibitor dalpiciclib combined with NSAIs in patients (pts) with ER+ R/M ovarian cancer and uterine neoplasms (SGO, 2024, #S283; IGCS, 2025, #397). Here, we report updated results. **Methods:** This single-center, single-arm, open label, phase 2 trial enrolled pts with ER+, R/M ovarian cancer and uterine neoplasms which met the following criteria: pretreated low-grade serous ovarian carcinoma (LGSOC), pretreated uterine endometrioid carcinoma (EC), uterine leiomyosarcoma (LMS), or untreated low-grade endometrial stromal sarcoma (LGESS). Pts received dalpiciclib (150mg po d1-21 q28d) and NSAIs (mainly letrozole 2.5mg po qd) until disease progression, unacceptable toxicity or consent withdrawn. The primary endpoint was 12-week progression-free survival (12wPFS) rate. A Simon's two-stage design was used (one-sided α=0.05, power=80%), and the null hypothesis (P0=0.2) would be rejected if totally $>$10 of 33 pts achieved primary endpoints. **Results:** As the data cutoff (Jan 5, 2026), 35 pts with a median of one prior therapy for R/M disease were enrolled, including 11 with LGSOC, 15 with EC, 8 with LGESS and 1 with LMS. With a median follow-up of 11.4 months (range, 0.1-52.2), 22 of 29 efficacy-evaluable pts had reached the primary endpoint, with a 12wPFS rate of 75.9% (95% CI 56.5-89.7), suggesting the value of further investigation. Detailed efficacy results are shown in Table 1. Grade 3-4 treatment-related adverse events (TRAEs) occurred in 82.9% (29/35) of pts, mostly neutrophil count decreased (71.4%), white blood cell count decreased (45.7%) and platelet count decreased (14.3%). Sixteen pts had dose reduction of dalpiciclib, mostly due to hematologic toxicities. No serious adverse events or treatment-related deaths occurred. Twelve pts were still on-treatment, with 3 pts treated for $>$4 years. **Conclusions:** The trial achieved its positive primary endpoint, showing meaningful efficacy of dalpiciclib + NSAIs in ER+ R/M ovarian cancer and uterine neoplasms. No new safety signals were observed. Clinical trial information: ChiCTR2000040597. Research Sponsor: None.

Phase II study of sintilimab combined with nab-paclitaxel in the treatment of platinum-resistant recurrent ovarian cancer. First Author: Nan Zhang, Peking University Cancer Hospital and Institute, Beijing, China

Background: Platinum-resistant recurrent ovarian cancer (PROC) remains a major therapeutic challenge with limited effective treatment options. This single-arm phase II trial aimed to evaluate the efficacy, safety, and tolerability of sintilimab combined with nab-paclitaxel in patients with platinum-resistant recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer. **Methods:** A total of 28 patients were enrolled and received intravenous sintilimab (200 mg, day 1) plus nab-paclitaxel (260 mg/m², day 1) every 3 weeks. The primary endpoint was objective response rate (ORR); secondary endpoints included progression-free survival (PFS), disease control rate (DCR), overall survival (OS), and safety. **Results:** The median age was 57 years (range: 37–74 years), with 96.4% having high-grade serous histology, 67.9% being BRCA wild-type, 57.1% with prior bevacizumab exposure, and 50% with a PD-L1 combined positive score (CPS) $\geq$1. After a median follow-up of 11.8 months, the ORR was 35.7% (10 partial responses), DCR was 64.3%, median PFS was 4.28 months, and median OS was 15.83 months. Patients with CPS $\geq$1 had a higher ORR (42.9% vs. 28.6%) and DCR (71.4% vs. 57.1%) than those with CPS $<$1, but no significant difference in PFS (3.83 vs. 4.13 months, p = 0.18). Similar trends were observed for CPS $\geq$5 and CPS $\geq$10, with ORRs of 44.4% and 50.0%, respectively, but no significant PFS differences (all p $>$ 0.05).Notably, patients with tumor-infiltrating lymphocytes (TILs) $\geq$10% exhibited a significantly higher ORR (72.7% vs. 12.5%, p = 0.005) and longer median PFS (15.57 months vs. 3.4 months, p = 0.005). Treatment-related adverse events (TRAEs) were mainly leukopenia (28.6%), neutropenia (25.0%), anemia (46.4%), and peripheral neuritis (28.6%), with rare grade 3–4 toxicities. **Conclusions:** Sintilimab combined with nab-paclitaxel shows promising efficacy and acceptable safety in PROC, with TILs $\geq$10% and a high $CD8^+/CD4^+$ ratio emerge as potential predictive biomarkers, while PD-L1 CPS shows limited utility. This regimen represents a potential new therapeutic option for this difficult-to-treat population and warrants further investigation in randomized controlled trials. Clinical trial information: 2000031890. Research Sponsor: Xisike-CSPC Tumor Research Fund; Y-SY201902-0010.

Treatment duration with avutometinib/defactinib in recurrent low-grade serous ovarian carcinoma by KRAS mutation status. First Author: Anna Shvygin, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Low grade serous ovarian carcinoma (LGSOC) is characterized by MAPK pathway alterations (most commonly *KRAS*, which occurs in 1/3 of tumors) and poor chemosensitivity. Avutometinib (MEK/RAF clamp) in combination with defactinib (FAK inhibitor) has shown durable responses in patients with recurrent LGSOC harboring a *KRAS* mutation and was recently FDA approved for this indication. However, data is lacking regarding the activity of avutometinib + defactinib (A+D) vs single agent MEK inhibitors for treatment of women with recurrent LGSOC. Here we examine patients who were treated with A+D. We also examine the duration of treatment in patients who received a single agent MEK inhibitor followed by A+D. **Methods:** In this single-institution retrospective cohort study, patients with recurrent LGSOC treated with A+D between 2021 – 2025 were included and stratified by tumor *KRAS* mutation status. The primary outcome was median duration of treatment on A+D, compared using Wilcoxon-Rank sum test. Pair-wise comparison of treatment duration in patients who were treated with single agent MEK inhibitors and A+D was performed. **Results:** 26 patients were included in the final analysis. Median age at diagnosis was 49 years (range 20-85). Patients had a median of 4 (range 1-9) prior lines of therapy, including hormonal (92%, n=24), bevacizumab (38%, n=10), and MEK inhibitors trametinib and binimetinib (35%, n=8). Eight (31%) patients harbored a tumor *KRAS* mutation. Among these 26 patients, median duration of treatment with A+D was 16.8 months in the *KRAS*-mutant and 5.5 months in the *KRAS*-wild type cohorts, respectively (p=0.037). Nine patients were treated with both A+D and a MEK inhibitor, three of whom had *KRAS*-mutant tumors. All nine patients received the single agent MEK inhibitor prior to treatment with A+D, with a median of 7 (range 4-8) prior lines of therapy before treatment with A+D. Among the three patients with *KRAS*-mutant tumors, median duration of treatment with single agent MEK inhibitor was 4.4 months (range 0.4-24.2) while with A+D, it was 17.6 months (range 6.1-23.4). **Conclusions:** In this single-institution retrospective cohort, treatment with A+D was associated with a significantly longer median duration of therapy in patients with *KRAS*-mutant recurrent LGSOC compared with *KRAS*-wild type disease. Among patients who received both regimens, A+D appeared to provide longer treatment duration than prior single agent MEK inhibitors in the *KRAS*-mutant subset, though this is limited by small sample size. These findings support improved activity of A+D in *KRAS*-mutant LGSOC and warrant confirmation in larger prospective studies. Research Sponsor: None.

Circulating tumor DNA to add prognostic stratification beyond CA-125 in epithelial ovarian cancer. First Author: Grace Gorecki, Allegheny Health Network, Pittsburgh, PA

Background: Ovarian cancer has a high risk of recurrence, particularly in patients with advanced-stage disease. CA-125 is routinely used to assess disease burden and recurrence risk but has limited prognostic accuracy. Circulating tumor DNA (ctDNA) has emerged as a potential biomarker that may better reflect tumor biology and enable earlier identification of recurrence. **Methods:** Patients with epithelial ovarian cancer and available plasma ctDNA and CA-125 measurements collected in association with surgical debulking were included. CA-125 was stratified using a standard clinical cutoff of 35 U/mL. Average cfDNA yield (ng/mL) was stratified into high and low ctDNA groups based on the cohort median. Associations were assessed using correlation and categorical analyses. Overall survival (OS) was evaluated using Kaplan–Meier methods and Cox proportional hazards models, including multivariable analyses. **Results:** Among 89 patients, ctDNA concentration was positively associated with CA-125 (Spearman ρ = 0.25; p = 0.017). Patients with high CA-125 had higher ctDNA levels than those with low CA-125 (mean 21.2 vs 7.6; p = 0.0044). High ctDNA concentration was associated with worse OS compared with low ctDNA (log-rank p = 0.0036; HR 3.48, 95% CI 1.50–8.06), with median OS (mOS) of 1386 days versus not reached. Patients with both high CA-125 and high ctDNA experienced markedly worse mOS than patients with low ctDNA (log-rank p = 0.0045; HR 3.48, 95% CI 1.47–8.21), with a mOS of 827 days versus not reached respectively. This added stratification by ctDNA persisted across multiple sensitivity analyses, including stratification by timing of sample collection relative to surgery, with consistent prognostic associations observed in pre-surgery samples (mOS 953 days; log-rank p = 0.031) and post-surgery samples (mOS 569 days; log-rank p = 0.045), as well as in analyses of high-grade serous ovarian cancer, advanced-stage disease, and neoadjuvant therapy. In multivariable Cox regression adjusting for CA-125, disease stage, surgical status, and neoadjuvant therapy, ctDNA remained independently associated with OS (HR 1.012, 95% CI 1.003–1.019). **Conclusions:** ctDNA consistently added prognostic value beyond CA-125 despite treatment-related heterogeneity, suggesting that ctDNA concentration captures biologic features of tumor behavior not reflected by CA-125 alone. Importantly, ctDNA remained predictive regardless of the timing of sample collection. These findings support ctDNA as a complementary biomarker for baseline prognostic stratification. The HER2 paradox in ovarian clear cell carcinoma: Expression and intrinsic resistance to trastuzumab deruxtecan (T-DXd). First Author: Junsik Park, Department of Obstetrics and Gynecology, Soonchunhyang University Bucheon Hospital, Bucheon, South Korea

Background: Trastuzumab deruxtecan (T-DXd) shows potent activity in HER2-expressing ovarian cancer (OC). However, efficacy across histologic subtypes remains under-characterized. Specifically, data on T-DXd response in ovarian clear cell carcinoma (OCCC), a distinct chemo-resistant entity, are lacking. This study aimed to evaluate T-DXd efficacy in recurrent OC across different histologic subtypes. **Methods:** We retrospectively analyzed 59 patients with recurrent OC who received T-DXd treatment between 2020 and 2025 at Yonsei Cancer Center. HER2 status (IHC), objective response rate (ORR), progression-free survival (PFS), duration of response, and safety were assessed by histology. **Results:** Patients included HGSC (n=38), Mucinous (n=9), OCCC (n=10), and Endometrioid (n=2). Median age was 55; median prior lines of therapy was 3. Notably, 100% of OCCC, mucinous, and endometrioid tumors were HER2 2+/3+, vs. 89.5% in HGSC. Despite high HER2 expression, outcomes diverged. ORR was 55.3% (26/47) for HGSC/Mucinous vs. 0% (0/12) for OCCC/Endometrioid ($P<0.001$). Specifically, HGSC achieved 57.9% ORR (2 CRs) vs. 0% in OCCC. PFS was significantly shorter in the OCCC/Endometrioid group (median 1.2 vs 6.9 months; HR 18.3; $P<0.0001$). OCCC patients showed rapid progression. Regarding safety, among 54 evaluable patients, 36 (66.7%) experienced Grade 3-4 adverse events, and 5 cases (9.3%) of ILD occurred; however, no new safety signals or treatment-related deaths were reported. **Conclusions:** T-DXd showed robust efficacy in recurrent HGSC and mucinous OC but no response in OCCC and endometrioid OC. Thus, HER2 expression alone does not guarantee T-DXd response in OCCC, possibly due to its chemo-refractory nature. Mechanisms of T-DXd resistance in OCCC warrant investigation. Research Sponsor: None.

A small extracellular vesicle protein-based model for ovarian cancer relapse detection and monitoring. First Author: Zheng Feng, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Recurrence surveillance of epithelial ovarian cancer (EOC) is a major clinical challenge, given the suboptimal performance of serum CA125 levels and limitations of radiological assessments. Serum small extracellular vesicle (sEV)-based liquid biopsy provides tumor-enriched and stable biomarkers, with potential to improve the precision of recurrence monitoring and support post-treatment surveillance. This study aimed to develop and preliminarily validate a serum sEV protein-based model to enhance recurrence monitoring in ovarian cancer. **Methods:** The study was designed with two stages (model development and validation) and plans to prospectively enroll 200 patients with EOC (NCT06925126). This analysis reports preliminary stage I data, and patients were categorized into relapse and non-relapse groups based on imaging-confirmed recurrence status. All relapsed patients were platinum-sensitive with low tumor burden. Quantitative assessment was performed on biomarkers derived from sEVs (specifically, E-CA125, E-HE4, and E-C5a) as well as corresponding serum markers measured in routine clinical practice (namely, H-CA125 and H-HE4), utilizing peripheral blood samples. Biomarker distributions were compared between groups, and predictive performance for recurrence detection was evaluated using receiver operating characteristic (ROC) analysis, including area under the curve (AUC), accuracy, sensitivity, and specificity. **Results:** A total of 113 patients were analyzed (42 non-relapsed, 71 relapsed), with a median age of 57 years. The majority (95/113) of patients had high-grade serous ovarian cancer, while other histological types were also included. Levels of E-CA125, E-HE4, H-CA125, and H-HE4 were significantly higher in relapsed patients compared with non-relapsed patients (all $p < 0.01$), while E-C5a showed no discriminative value between the two groups. Among individual sEV biomarkers evaluated, E-CA125 demonstrated the highest performance for recurrence detection (AUC = 0.877), followed by E-HE4 (AUC = 0.689) and E-C5a (AUC = 0.528). Moreover, the sEV protein-based model achieved an accuracy of 77.9% with a sensitivity of 71.8% and a specificity of 90.9%. This performance surpassed that of the conventional serum CA125, which exhibited an accuracy of 50.0%, a sensitivity of 26.8%, and a specificity of 100.0%. These results indicate that the sEV protein-based model may provide added clinical value when serum CA125 monitoring is unreliable after prior therapy. **Conclusions:** The sEV-derived CA125 and the sEV model demonstrate promising performance for recurrence detection in EOC. These findings support the feasibility of a serum sEV-based surveillance strategy that may improve the reliability of post-treatment monitoring. Prospective validation is ongoing to determine its potential role in guiding clinical surveillance and intervention. Clinical trial information: NCT06925126. Research Sponsor: None.

Efficacy prediction for progression-free survival (PFS) and overall survival (OS) by genomic instability score (GIS) cutoffs in patients (pts) with advanced ovarian cancer (aOC): Post hoc results from the phase 3 PRIMA/ENGOT-OV26/GOG-3012 trial. First Author: Bradley J. Monk, GOG Foundation, Philadelphia, PA, and Florida Cancer Specialists and Research Institute, West Palm Beach, FL

Background: GIS is a key component of a companion diagnostic assay for determining homologous recombination deficiency (HRD) status to identify pts with aOC who may benefit from maintenance therapy. While the standard GIS cutoff to classify tumors as homologous recombination-deficient (HRd) is ≥42, this study analyzed PRIMA final analysis data to see if a lower cutoff of ≥33 based on the VELIA/GOG-3005 trial could identify additional pts who experienced a PFS benefit with niraparib (nir) first-line maintenance (1LM) vs placebo (PBO). **Methods:** Pts with aOC were randomized 2:1 to nir or PBO 1LM. Tumor HRD status and GIS were assessed using the myChoice HRD test (Myriad Genetics). In pts with GIS data, tumor GIS distribution was assessed in the overall population and by HRD/*BRCA* status. Investigator-assessed PFS at GIS cutoffs <33 vs ≥33 and <42 vs ≥42 was evaluated using Kaplan-Meier methods with Cox proportional hazards modeling (cutoff, 08Apr2024). Two statistical utility tests were performed for each cutoff: 1) to evaluate each cutoff's potential to add incremental value to the explanation of pt response on top of treatment, and 2), in nir-treated pts, to assess each cutoff's ability to predict long-term PFS (≥3 y). OS was assessed by increasing GIS cutoffs. **Results:** In the overall population (n=568), GIS ranged from 0 to 95, and 64.3% of pts had GIS ≥33 (GIS groups: 0 to <33, n=203; ≥33 to <42, n=67; ≥42, n=298). Of pts with *BRCA* mutation, 9.4% (21/223) of pts had GIS <42. Nir 1LM produced a significant PFS benefit vs PBO across all GIS cutoffs, with greater benefit observed in higher GIS groups (Table). The GIS ≥33 cutoff improved the Cox model fit vs the ≥42 (ie, explaining more PFS variability and showing more powerful association with PFS after treatment adjustment). In nir-treated pts with GIS data (n=387), the ≥33 cutoff increased sensitivity (0.8936 > 0.7872), identifying 10.6% more patients with PFS ≥3 y, but lowered specificity (0.4369 < 0.5734) vs the ≥42 cutoff. Higher GIS cutoffs were also associated with more favorable nir 1LM on OS effects (lower hazard ratios). **Conclusions:** In PRIMA, GIS existed along a spectrum, and nir 1LM resulted in a PFS benefit vs PBO across all GIS cutoffs. Pts with higher GIS experienced greater PFS benefit than pts with lower GIS. The GIS ≥33 cutoff identified more long-term PFS responders than the GIS ≥42 cutoff. Results suggest that GIS cutoffs of ≥33 used for HRd status determination may optimize identification of pts with aOC who may benefit from nir 1LM. Clinical trial information: NCT02655016. Research Sponsor: GSK; N/A.

Platinum re-challenge in platinum-resistant ovarian cancer: Real-world patterns and outcomes. First Author: Prakirthi Yerram, Flatiron Health, New York, NY

Background: Platinum-resistant ovarian cancer (PROC), defined as recurrence within 6 months of completing platinum-based chemotherapy, has limited treatment options and poor outcomes. Although guidelines recommend non-platinum therapy, platinum rechallenge still occurs in real-world practice, despite limited evidence. This study examines real-world patterns and outcomes of platinum rechallenge versus non-platinum therapy at first PROC occurrence overall and by biomarker status, prior therapy, and time to PROC. **Methods:** Using the US-based, EHR-derived deidentified Flatiron Health Research Database, ovarian cancer patients diagnosed after January 1, 2017 (data cutoff August 31, 2025) were selected. Patients with PROC, defined as progressing ≤ 6 months after platinum, that received subsequent therapy were included; primary platinum refractory patients (< 3 months) were excluded. Patients were grouped by first PROC therapy (platinum rechallenge vs non-platinum therapy), and rwPFS and rwOS were assessed overall and by BRCA/HRD status, use of prior first-line maintenance (1LM), number of prior platinum lines, and time to PROC. Associations were assessed using Kaplan-Meier estimates and IPTW-adjusted Cox models accounting for demographics, ECOG PS, practice type, insurance, index year, biomarkers, and prior 1LM and platinum exposure. **Results:** Among 29,194 patients with ovarian cancer, 2,907 had PROC. Of these, 528 received platinum rechallenge and 2,379 received non-platinum therapy (71% received chemotherapy ± bevacizumab) as subsequent treatment. Baseline characteristics in both groups were similar; the platinum rechallenge group had fewer patients with BRCA mutations (BRCAm) (9.3% vs 12%) and no residual disease (36% vs 40%) but more with only one prior platinum line (56% vs 48%). Median rwPFS was 5.8 mo with platinum rechallenge vs 3.9 mo with non-platinum therapy (adjusted HR 0.72, 95% CI, 0.64 to 0.81; $P < .001$), and median rwOS was 13 vs 11 mo (adjusted HR 0.81, 95% CI, 0.72 to 0.92; $P = .001$). In adjusted analyses, rwPFS advantage of platinum rechallenge was consistent across major subgroups, including biomarker-defined populations (BRCA-wild type and HRD-positive non-BRCAm), prior 1LM and platinum exposure, and time to PROC. rwOS benefit was more limited, confined to patients with BRCAm, earlier recurrence, and more heavily pretreated disease, with limited events in several subgroups. **Conclusions:** In this large real-world cohort, platinum rechallenge improved rwPFS and rwOS vs non-platinum therapy in PROC. Consistent rwPFS benefits across most subgroups and selective rwOS advantages, particularly in BRCAm, highlight heterogeneity within PROC populations and support individualized decisions for platinum rechallenge beyond a strict 6-month platinum-free interval. Prospective studies are required to identify patients most likely to benefit from platinum rechallenge. Research Sponsor: Flatiron Health, Inc.

Circulating tumor DNA to enhance detection of high-risk minimal residual disease in ovarian cancer relative to second look laparoscopy. First Author: Helen D. Clark, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Minimal residual disease (MRD) following frontline treatment of ovarian cancer has been established as a predictor of recurrence and survival. Historically, second look laparoscopy (SLL) has served as the gold-standard method to assess MRD; however the need for surgical evaluation limits widespread adoption and clinical applicability. Circulating tumor DNA (ctDNA) offers a non-invasive alternative for MRD detection and enables longitudinal monitoring with the potential for early identification of recurrence. Presently, the concordance between ctDNA-based detection and surgical assessment remains incompletely characterized. In this retrospective cohort study, we compare the predictive performance of ctDNA versus SLL for detecting clinically significant MRD after frontline treatment for high-grade ovarian cancer. **Methods:** This retrospective, single-institution study included patients with high-grade epithelial ovarian cancer who completed frontline chemotherapy and surgery. All patients underwent SLL to determine surgical MRD status. At the time of SLL, plasma was collected and profiled using NeXT Personal. Using whole-genome sequencing, this ultrasensitive, tumor-informed assay tracks up to 1,800 tumor-specific variants to detect ctDNA at levels down to ~1 part per million. Statistical analyses were conducted using RStudio (version 2026.01.0.392). **Results:** The cohort consisted of 72 patients (median follow up 38.9 months) with high-grade epithelial ovarian cancer, of whom 69 patients (95.8%) were in clinical remission by Ca-125 and imaging. Despite this, 30 patients (41.7%) were positive for MRD by ctDNA and 33 patients (45.8%) were positive for MRD by SLL. On multivariable analysis, ctDNA positivity independently predicted worse PFS (HR 4.35, 95% CI 2.17-8.72, p<0.001). The results of MRD and SLL were concordant in 53 (73.6%) of cases. There were 8 cases in which ctDNA was positive and SLL was negative. To date, 6/8 patients (75%) have recurred. There were 11 cases in which SLL was positive and ctDNA was negative. To date, 6/11 (54.5%) have recurred. Among these discordant cases, individuals with positive ctDNA but negative SLL had significantly worse PFS than cases with concordant negative results (HR 3.03, 95% CI 1.13-8.14, p=0.03). Whereas among cases with positive SLL and negative ctDNA, there was not a significant difference compared with concordant negative cases (HR 1.54, 95% CI 0.58-4.12, p=0.39). **Conclusions:** In this cohort where nearly all patients were in clinical remission, ctDNA was an independent predictor of PFS after frontline therapy in high-grade ovarian cancer. Although discordance occurs between ctDNA and SLL, these data suggest that ctDNA may detect clinically meaningful MRD not captured by SLL and could represent a more clinically relevant prognostic tool in this setting. Dose-dense weekly versus standard three-weekly paclitaxel in combination with carboplatin for resectable stage II-IV epithelial ovarian carcinoma: A retrospective cohort study. First Author: Sehrish Sarwar Baloch, Aga Khan University Hospital, Karachi, Pakistan

Background: Dose-dense weekly paclitaxel combined with carboplatin has demonstrated variable efficacy in first-line treatment of resectable epithelial ovarian cancer across different populations. While Japanese and selected real-world studies suggest improved outcomes, large Western trials have failed to confirm a survival advantage. Data from South Asian populations remains limited. This study compared progression-free survival (PFS), overall survival (OS), and toxicity profiles of dose-dense versus standard three-weekly paclitaxel plus carboplatin in a real-world, resource-constrained setting. **Methods:** This single-center retrospective cohort study included women aged ≥20 years with resectable, FIGO stage II–IV epithelial ovarian, fallopian tube, or primary peritoneal carcinoma treated between January 2015 and December 2018. Patients received first-line carboplatin at an AUC of 5 (Area Under Curve 5) with either dose-dense weekly paclitaxel (80 mg/m² on days 1, 8, and 15) or standard three-weekly paclitaxel (175 mg/m²). Kaplan–Meier methods were used to estimate PFS and OS, and comparisons were performed using the log-rank test. Cox proportional hazards models were applied for univariate and multivariate analyses. **Results:** Seventy-two patients were included, 36 in each arm. The majority presented with stage III disease (63.9% in the dose-dense arm vs. 52.8% in the standard arm). High-grade serous carcinoma was the predominant histology in both groups (83% vs. 75%). The distribution of primary versus interval debulking surgery and rates of residual disease were similar between the two arms. The dose-dense regimen was associated with significantly improved PFS compared with the standard schedule (mean PFS 25 vs. 18 months; 95% CI: 23.1-28.4; log-rank p = 0.01); median PFS was 32 months in the dose-dense arm, whereas it could not be estimated in the standard arm. OS favoured the dose-dense group (mean OS of 56 vs. 50 months), although this difference was not statistically significant (p = 0.27). In the multivariate analysis of the dose-dense cohort, elevated baseline Ca-125 (HR = 6.80; 95% CI: 1.38–34.20; p = 0.01) and cytoreduction type (HR = 13.30; 95% CI: 1.90–90.20; p = 0.008) were independent predictors of PFS but not for OS. Rates of grade ≥3 treatment-related adverse events were comparable between arms, while sensory neuropathy occurred more frequently with dose-dense therapy (39% vs. 28%). **Conclusions:** This real-world analysis supports the use of dose-dense weekly paclitaxel combined with carboplatin for improved PFS, findings consistent with some regional studies. While OS data showed a non-significant trend favouring the dose-dense regimen with some risk of neuropathy, they highlight the need for larger prospective regional studies to better define patient populations most likely to benefit. Research Sponsor: None.

Everolimus and aromatase inhibitors for advanced and recurrent low-grade serous ovarian carcinoma. First Author: Halle Goodwin, Atrium Health Levine Cancer Wake Forest University, Charlotte, NC

Background: Treatment options for advanced and recurrent low grade serous ovarian carcinoma (LGSOC) are limited. Mutations in the PI3K/AKT/mTOR pathway have been described in LGSOC, but the use of everolimus and aromatase inhibitors (AI) has not been studied. Our primary objective was to determine the disease control rate (DCR) of everolimus (used off-label) and an AI in patients with LGSOC. Secondary objectives included progression free survival (PFS) and overall survival (OS). **Methods:** Diagnosis codes and medication lists were used to identify all patients with LGSOC from a single tertiary-care institution who were treated with everolimus and an AI between 2000-2025. Data were extracted from the electronic medical record including demographics, staging, treatment, CA-125, imaging studies, reported side effects, recurrence, and survival data. Response was defined with RECIST 1.1 when measurable disease was present, otherwise clinical response was used. CA-125 was used independently as an additional measure of response. **Results:** A total of eight patients were identified, six with stage IIIC disease and two with stage IVB disease. Patients had between 0 and 4 debulking surgeries. Prior to treatment with everolimus and an AI, patients had 1-6 prior lines of therapy. All patients had received prior endocrine therapy, and five received chemotherapy. All patients were treated with everolimus 10mg and an AI (6 with letrozole and 2 with anastrozole). Patients remained on this regimen between 2 and 20 months (median = 15 months). One patient continues treatment today after 21 months of treatment. By RECIST criteria, two patients had a partial response, and four patients had stable disease. One patient has had clinically stable disease (soft tissue thickening and a stable CA-125) for 21 months and continues treatment. When comparing initial CA-125 to nadir while on treatment, CA-125 was stable in three patients and decreased 29%-64% (median = 50.5%) in four patients. One patient did not have CA-125 available in the EMR. Overall, the DCR was 87.5% (7 of 8 patients). Median PFS was 16.8 months, and median OS was 26 months. Of the seven patients who discontinued treatment, reasons for discontinuation included progression (n=3), death from disease (n=2), and inability to tolerate (n=2, one with grade 3 pneumonitis). **Conclusions:** In a group of eight patients with advanced LGSOC, everolimus and an AI demonstrated a DCR of 87.5%, a median PFS of 16.8 months, and a median OS of 26 months. While larger retrospective studies or prospective studies are needed, this regimen should be considered for advanced, recurrent LGSOC. Research Sponsor: None.

Exposure–response (E–R) analyses of efficacy and safety with raludotatug deruxtecan (R-DXd), a CDH6-directed antibod-drug conjugate (ADC), to inform dose selection for phase (Ph) 3 development in platinum-resistant ovarian cancer (PROC). First Author: Felipe K. Hurtado, Daiichi Sankyo, Inc., Basking Ridge, NJ

Background: R-DXd, an ADC, comprises a humanized cadherin 6 (CDH6) IgG1 monoclonal antibody attached to a topoisomerase I inhibitor payload (DXd) via a tumor-selective cleavable linker. R-DXd monotherapy demonstrated promising antitumor activity and a manageable safety profile at doses up to 6.4 mg/kg IV Q3W in patients (pts) with heavily pretreated ovarian cancer (OC) in a Ph 1 study and in pts with PROC in an ongoing Ph 2/3 study. We report findings from E–R analyses of key efficacy and safety endpoints that supported R-DXd dose selection for Ph 3 clinical investigation in patients with PROC. **Methods:** Data were included from (i) the first-in-human Ph 1 study in pts with advanced OC (N=156) or renal cell carcinoma (RCC; N=23) evaluating R-DXd 1.6–9.6 mg/kg Q3W (NCT04707248), and (ii) the dose-optimization part of the Ph 2/3 REJOICE-Ovarian01 study in pts with PROC (N=107) (NCT06161025), in which pts were randomized 1:1:1 to receive R-DXd 4.8, 5.6, or 6.4 mg/kg Q3W. E–R analysis for efficacy was conducted based on pooled data from 241 pts with PROC using BICR-assessed endpoints: ORR (primary endpoint in the Ph 2 part of REJOICE-Ovarian01), best change in target lesion size, DOR, and PFS. Further, E–R analysis for safety was performed for 11 AEs of clinical interest using data from 286 pts treated with R-DXd across tumor types (OC, RCC). ORR and all safety endpoints, except interstitial lung disease (ILD), were analyzed by logistic regression; DOR, PFS, and ILD were analyzed using the Kaplan–Meier method. Numerous patient-specific covariates were evaluated. **Results:** E–R analyses demonstrated positive dose–response relationships for both efficacy and safety. Higher R-DXd exposure was associated with increased probability of achieving objective response, greater reduction in target lesion size from baseline, longer PFS, and longer DOR. Covariate analysis identified that baseline CDH6 expression was positively associated with ORR and tumor response. Higher R-DXd or DXd payload exposure was associated with an increase in drug-related TEAEs, including Grade $\geq$3 (G3+) AEs, any-grade ILD, G2+ gastrointestinal AEs (nausea/vomiting), G3+ cytopenias (anemia, neutropenia, thrombocytopenia), and AEs leading to dose reduction. While higher doses of R-DXd are predicted to maximize efficacy based on the E–R analysis, the 5.6 mg/kg dose provides an overall optimal balance of safety, tolerability, and efficacy compared to 6.4 mg/kg and 4.8 mg/kg. **Conclusions:** Integrated E–R analyses, combined with the totality of data from 286 pts, support selection of 5.6 mg/kg Q3W as the optimal R-DXd monotherapy dose for the Ph 2 extension and Ph 3 parts of REJOICE-Ovarian01, in accordance with the principle of benefit/risk for oncology dose optimization and guidelines from the FDA's Project Optimus. Research Sponsor: Daiichi Sankyo; Merck.

Population pharmacokinetic analysis of raludotatug deruxtecan (R-DXd), a cadherin 6 (CDH6)–directed antibody–drug conjugate (ADC), in patients (pts) with advanced ovarian cancer (OC) or renal cell carcinoma (RCC). First Author: Felipe K. Hurtado, Daiichi Sankyo, Inc., Basking Ridge, NJ

Background: R-DXd is a CDH6–directed ADC under clinical investigation for the treatment of pts with advanced or metastatic solid tumors, including platinum-resistant OC (PROC). This analysis was done to characterize the population pharmacokinetics (PopPK) of R-DXd and its small-molecule payload, DXd, in pts with OC or RCC. The analysis used data from two clinical studies of R-DXd: the first-in-human Ph 1 study in pts with OC or RCC (DS6000-A-U101; U101) and an ongoing global, randomized Ph 2/3 study in pts with PROC (REJOICE-Ovarian01). **Methods:** A joint PopPK model was developed for R-DXd and DXd, based on pooled data from the dose-escalation and -expansion parts of U101 (156 pts with OC and 23 with RCC; 1.6–9.6 mg/kg IV Q3W) and the dose-optimization primary analysis of REJOICE-Ovarian01 (107 pts with OC; 4.8, 5,6, or 6.4 mg/kg IV Q3W). The analysis was performed using nonlinear mixed-effects modeling in NONMEM (version 7.5.1). The effect of key intrinsic/extrinsic factors on the PK of R-DXd was explored through preliminary covariate analysis. **Results:** The PK of R-DXd and unconjugated DXd were adequately captured by the PopPK model. R-DXd displayed time-varying clearance, resulting in an elimination half-life of approximately 8 days after the first dose and 14 days at steady state. The overall PK profile supports a Q3W dosing interval. Consistent with findings from other mAbs and DXd-based ADCs, covariate analysis identified body weight (BW) as an influential covariate affecting R-DXd and DXd exposure, with the largest effect seen at the extremes of the BW distribution; pts with high BW (101 kg; 95th percentile) showed 26% and 66% higher R-DXd and DXd steady state area under the concentration–time curve (AUC), respectively, relative to a reference pt (61 kg; median BW). Post-hoc estimates of R-DXd and DXd AUC by BW quartiles showed that exposure in pts in the highest BW quartile ($>$75 kg) trended higher yet remained within the range of pts with average BW (53–74 kg; 25th–75th percentile). Other baseline covariates did not have a clinically important effect on R-DXd or DXd AUC, with effects falling within the predefined range of 80–125% vs reference. These covariates were CDH6 expression (total % membrane staining at any intensity); R-DXd formulation; hepatic function (mild impairment vs normal); renal function (mild-to-moderate impairment vs normal); tumor size; albumin level; number of prior lines of therapy (1 vs 2–3 vs $\geq$4); tumor type (RCC vs OC); Asian vs non-Asian race. **Conclusions:** R-DXd 5.6 mg/kg IV Q3W, the recommended Ph 3 dose, does not appear to warrant adjustment for any of the patient-specific covariates and clinical characteristics investigated. These findings support the adequacy of this dose for the global population of pts with PROC being recruited in the Ph 3 part of REJOICE-Ovarian01. Research Sponsor: Daiichi Sankyo; Merck.

Multi-modal liquid biopsy integrating cfDNA fragmentomics and serum biomarkers for the differential diagnosis of ovarian tumors. First Author: Zhoumei Liu, Peking University Cancer Hospital Yunnan, Yunnan Cancer Hospital, The Third Affiliated Hospital Kunming Medical University, Kunming, Yunnan, China

Background: Ovarian cancer (OC) remains the leading cause of mortality among gynecological malignancies, primarily due to delayed diagnosis. Current diagnostic modalities, including imaging and serum biomarkers, exhibit suboptimal specificity, leading to unnecessary surgical interventions for benign adnexal masses. This study explores the clinical utility of cell-free DNA (cfDNA) fragmentomics, a high-dimensional genomic feature reflecting chromatin accessibility, in distinguishing malignant from benign ovarian tumors. **Methods:** This multi-center study enrolled 595 participants across three cohorts: a training set (n=236) and an internal validation set (n=172) from Yunnan Cancer Hospital, and an independent external validation set (n=136) from Beijing Obstetrics and Gynecology Hospital. Additionally, a prediction cohort included borderline ovarian tumors (BOT, n=51). Using whole-genome sequencing (WGS), we characterized cfDNA via four fragmentomic dimensions: copy number variations (CNVs), fragment size profiles (FSPs), nucleosome footprints (NFs), and genomic element perturbations (ARTEMIS). An ensemble model was trained to classify malignant ovarian cancer versus benign disease, and a generalized linear model was constructed by integrating fragmentomic scores with CA125 and HE4 levels to further improve the performance. **Results:** The cfDNA-only model demonstrated robust performance with Area Under the Curve (AUC) values of 0.937, 0.930, and 0.932 in the training, internal, and external cohorts, respectively. At 90% sensitivity in training (internal: 88.4%; external: 89.2%), specificities remained stable at 77.12%, 77.91%, and 78.87%. The model exhibited exceptional sensitivity for High-Grade Serous Ovarian Cancer (HGSOC) ($>$90%) with sensitivity increased with stages; early-stage (I–II) sensitivities were maintained $\geq$77%. Integrating the cfDNA fragmentomic score with CA125 and HE4 significantly enhanced AUCs to 0.961 (training), 0.964 (internal) and 0.964 (external). While maintaining high sensitivity (~90%), the combined model substantially increased specificity to 90.1% (training). Among 37 surgically treated stage I–III patients, higher preoperative predictive scores were significantly associated with shorter disease-free survival (DFS) ($p < 0.05$), independent of age, stage, and histology. In BOT patients, 39.2% were classified as higher malignant-risk, consistent with an intermediate phenotype. **Conclusions:** The integration of cfDNA fragmentomics with traditional biomarkers provides a highly sensitive and specific non-invasive tool for the differential diagnosis of ovarian masses. This multi-modal approach significantly outperforms current clinical standards, offering a promising strategy for early detection and clinical risk stratification in ovarian cancer management. Real-world outcomes of olaparib with versus without bevacizumab in bevacizumab-naïve BRCA1/2-mutated ovarian cancer. First Author: Love Kumar, Charleston Area Medical Center (CAMC), Charleston, WV

Background: For patients with BRCA1/2-mutated epithelial ovarian, fallopian tube, or primary peritoneal cancer who complete primary platinum-based therapy, maintenance strategies differ based on prior bevacizumab (Bev) exposure. Patients who received Bev during frontline platinum therapy may receive Bev plus olaparib, whereas those without prior Bev exposure are generally treated with olaparib alone. No real-world evidence has evaluated outcomes of adding Bev to olaparib in patients who did not receive Bev during initial treatment. Using a large multi-institutional electronic health record dataset, we compared survival outcomes between olaparib monotherapy and olaparib–Bev combination therapy in this population. **Methods:** Adult patients from 2015-2024 with a diagnosis of ovarian, fallopian tube, or peritoneal cancer who received platinum chemotherapy followed by olaparib were first identified. Patients were then categorized based on bevacizumab exposure around the time of olaparib initiation (-1 to +3 months). This group was compared to patients who did not received Bev at any time. The index date was defined as 3 months after olaparib initiation to align treatment timing and minimize immortal time bias and propensity score matching was performed on age, race, metastatic sites, comorbidities, and prior treatments. Follow-up was then truncated at 3-years. **Results:** Before matching, 111 patients received Bev around the time of olaparib and 1,461 did not. After matching, 110 patients remained in each group with balanced characteristics. Three-year overall survival was significantly lower in the Bev group compared with the no-Bev group (52% vs 73%; HR 2.28, 95% CI 1.4–3.8; p=0.001). Treatment switching also occurred more often in the Bev group (54% vs 22%, $p < 0.0001$), with a median time to switching of 16.7 months; the no-Bev group did not reach median time. **Conclusions:** In real-world clinical practice, the addition of bevacizumab to olaparib in patients without prior bevacizumab exposure was associated with worse survival outcomes and earlier treatment switching. These findings may reflect the selection of patients with more aggressive or treatment-resistant disease for combination therapy, or they may suggest that intensifying therapy in this setting does not confer added benefit. Prospective, controlled studies are needed to clarify the underlying reasons for these observations and to better define which patients, if any, derive benefit from this treatment approach. A phase II evaluation of sacituzumab govitecan in platinum-resistant ovarian cancer (NCT06028932). First Author: Alessandro Santin, Yale School of Medicine, Division of Gynecologic Oncology, New Haven, CT

Background: Patients with platinum-resistant ovarian cancer (PROC) have few therapeutic options. More than 60% of high-grade serous ovarian cancers overexpress ($\geq$ 2+ by immunohistochemistry) Trop2, a key regulator of growth pathways and marker of aggressive disease. Sacituzumab govitecan (SG) is an antibody-drug conjugate consisting of a Trop-2–specific antibody conjugated with SN-38, an active metabolite of irinotecan. **Methods:** NCT06028932 is a single-institution open-label phase II study. Patients received SG at 10 mg/kg intravenously days 1 and 8 of a 21-day cycle until prohibitive toxicity or progression. The primary endpoint was objective response rate (ORR) by RECIST 1.1. Secondary endpoints included progression-free (PFS) and overall (OS) survival, as well as safety. **Results:** Twenty patients were enrolled. Median age was 67 years (range: 45-84). Most participants (85%, n=17) were White. The median number of prior lines prior to enrollment was 3 (range: 1-8). ECOG performance status was 0 (n=16) or 1 (n=4). Most patients had a poorly differentiated tumor (90%, n=18) with advanced disease (stage III/IV) at initial diagnosis (85%, n=17). Serous histology predominated (75%, n=15), followed by clear cell (15%, n=3), endometrioid (5%, n=1), and carcinosarcoma (5%, n=1). Across a median follow-up of 9.9 months, there were 15 progressions and 4 deaths. ORR was 35% (7/20); there were no complete responses, and stable disease was achieved in 40% (8/20). Median PFS was 8.0 months (95% CI: 3.8-14.8); median OS was not yet reached. No new safety signals were observed. The most common grade 3-4 treatment-emergent adverse events were neutropenia (n=15), hypokalemia (n=3), and anemia (n=2). The most frequent grade 1-2 events included diarrhea (n=59), fatigue (n=27), abdominal pain (n=20), nausea (n=20), alopecia (n=16), anorexia (n=14), and vomiting (n=13). **Conclusions:** SG exhibits encouraging efficacy for PROC with manageable toxicities. Future studies are warranted. Clinical trial information: NCT06028932. Research Sponsor: None.

Preliminary efficacy and safety of first-line anlotinib plus carboplatin/paclitaxel induction therapy followed by anlotinib maintenance in advanced ovarian cancer: Results from the ALTER-GO-010 phase II multicenter trial. First Author: Wenjun Cheng, Jiangsu Provincial Hospital, Nanjing, China

Background: Several studies have shown that antiangiogenic drugs combined with chemotherapy as first-line treatment, followed by maintenance therapy with anti-angiogenic agents, significantly improve outcomes for ovarian cancer patients. Anlotinib, a highly effective multi-target tyrosine kinase inhibitor targeting VEGFRs, FGFRs, PDGFRs, and c-Kit, has been approved for multiple tumor types in China. The ALTER-GO-010 study is a single-arm, multicenter phase II trial designed to assess the efficacy and safety of anlotinib in combination with carboplatin/paclitaxel as first-line induction therapy, followed by anlotinib maintenance, in patients with newly diagnosed advanced ovarian cancer. **Methods:** Eligible patients with newly diagnosed FIGO stage III–IV primary epithelial ovarian, fallopian tube, or primary peritoneal cancer (ECOG PS 0–1) who have undergone primary or interval debulking surgery will receive 6-8 cycles of chemotherapy (paclitaxel 175 mg/m² + carboplatin AUC 5 every 3 weeks) combined with anlotinib (12 mg orally once daily on days 1–14, 21-day cycle; omitted during the first cycle to prevent delayed wound healing). Following chemotherapy completion, anlotinib will be continued as maintenance monotherapy until disease progression, unacceptable toxicity, or death. Exclusion criteria include prior anti-angiogenic therapy or major surgery within 28 days before anlotinib initiation. The primary endpoint is progression-free survival (PFS). Key secondary endpoints include overall survival, and safety profile. **Results:** As of the data cutoff date (November 30, 2025), 54 patients had received at least one dose of the study drug and were included in the analysis. The median age was 56 years, 98.11% had high-grade serous carcinoma and 1.89% had endometrioid carcinoma. 96.23% had FIGO stage III and 3.77% had stage IV. The data maturity for PFS analysis was 40.7%. The median PFS was 20.76 months (95% CI: 11.58-29.95). Patients without prior history of neoadjuvant therapy had longer mPFS than those with prior therapy. The median OS was not reached. The most common all-grade treatment emergent adverse events (TEAEs) were white blood cell deceased, anemia, neutrophil count decreased, platelet count decreased and lymphocyte count decreased. Grade $\geq$3 TEAEs occurred in 75.5% of patients during the chemotherapy phase and 22.7% during maintenance. No treatment-related deaths were reported. **Conclusions:** The preliminary efficacy and safety data suggest that anlotinib plus carboplatin/paclitaxel induction therapy, followed by anlotinib maintenance, is a promising regimen for newly diagnosed advanced ovarian cancer, with a median PFS of 20.76 months and a favorable safety profile. Clinical trial information: NCT04807166. Research Sponsor: None.

A novel prognostic index for survival prediction in ovarian cancer: Beyond FIGO staging. First Author: Arya Prathap, AIIMS Bhubaneswar, Bhubaneswar, India

Background: Prognostication in ovarian cancer is traditionally based on FIGO stage, although survival is influenced by additional patient- and treatment-related factors. We developed a new scoring system integrating age, comorbidities, and disease burden to improve survival prediction. **Methods:** Patients with ovarian malignancies treated with curative intent between June 2016 and November 2024 were identified from a prospectively maintained database. Cox proportional hazards regression was performed for 4-year overall survival (OS). Regression coefficients of significant variables were used to construct a new index. Survival outcomes were assessed using Kaplan–Meier analysis. Predictive performance of new index was compared with FIGO staging using receiver operating characteristic (ROC) analysis. **Results:** Of 221 consecutive patients, 167 treated with curative intent were analyzed. Median age of the cohort was 52 years (IQR 22–78), and FIGO stage IIIC was most common (45.7%). Optimal cytoreduction was achieved in 80.8%, and 71.3% received adjuvant therapy. At a median follow-up of 38.3 months, recurrence and mortality rates were 32.9% and 26.2%, respectively. The new score incorporated age, total surgical PCI, hypothyroidism, diabetes mellitus, and hypertension with regression-derived coefficients of 0.044, 0.114, 0.329, 0.146, and 0.313 respectively. For each patient, a prognostic index (PI) was calculated as the weighted sum of regression coefficients corresponding to that patient's covariate profile, using formula, where PI (Prognostic index)= $\sum (\beta_{1\,x}$ age) + (β_2 x PCI) + (β_3 x C_1) + (β_4 x C_2)+....(β_k x C_k), C_1...C_k = individual comorbidities (eg., diabetes, hypertension, etc), if present = 1, absent = 0). Based on the prognostic index, patients were classified into low- (33.75%), intermediate- (31.3%), and high-risk (31.3%) groups. Compared with the low-risk group, OS was worse in the intermediate-risk group (HR 2.37; 95% CI, 0.95–5.91; p = 0.06) and significantly inferior in the high-risk group (HR 7.89; 95% CI, 3.37–18.49; $p < 0.001$). Disease free survival (DFS) also showed a similar trend. The prognostic index demonstrated superior discrimination compared with FIGO staging (C-index 0.73 vs 0.68; AUC 0.71 vs 0.65) and remained robust on bootstrap internal validation. A prespecified subgroup analysis restricted to FIGO stage III patients was performed and demonstrated superior discrimination for overall survival compared with FIGO staging alone (AUC 0.71 vs 0.61), highlighting prognostic heterogeneity beyond anatomic staging. **Conclusions:** The prognostic index demonstrated improved discrimination compared with FIGO staging by integrating patient age, comorbidities, and disease burden. This practical, clinically applicable index may facilitate improved risk stratification beyond anatomic staging and may support individualized management strategies in ovarian cancer. Beyond survival: Understanding unmet needs among a diverse cohort of ovarian cancer survivors. First Author: Caroline P. Shermoen, University of Pennsylvania, Philadelphia, PA

Background: Improvements in therapy have resulted in a growing population of ovarian cancer survivors, with both incidence and survivorship increasing among non-White racial and ethnic groups. Despite increasing survivors, supportive care for ovarian cancer survivors has been reported as insufficient. Existing instruments to address survivorship needs were developed in homogenous populations, predominantly consisting of White patients. The purpose of this study was to gain a deeper understanding of the needs and experiences in a diverse cohort of ovarian cancer survivors. **Methods:** Structured focus groups of ovarian cancer survivors were conducted at a single academic NCI-designated cancer center. During focus groups, participants were guided in discussion about their experience, perspective, and unmet needs as an ovarian cancer survivor. The topics were developed in consultation by providers involved in direct ovarian cancer research and patient care. Thematic analysis was used to systematically code and analyze focus group transcripts, allowing for identification of recurrent patterns and themes within the data. **Results:** Three focus groups of 20 patients were conducted. 12 (60%) patients identified as White, 4 (20%) as Asian, 3 (15%) as Black, and 1(5%) as Hispanic; additional patient characteristics are in Table 1. Participants generally reported their care during treatment was efficient and streamlined; however, gaps in survivorship care emerged. Key themes included poor care coordination with non-oncologic providers, feelings of abandonment after active treatment, limited communication about long-term expectations after surgery and/or chemotherapy, lack of individualized care plans, and uncertainty about where to find reliable resources. Suggested improvements included centralized access to survivorship resources, expanded peer support opportunities, and more tailored, patient-specific communication. **Conclusions:** The study highlights specific gaps in ovarian cancer survivorship among a diverse patient population. Deficits in care coordination, individualized communication, and access to tailored resources may contribute to feelings of abandonment and uncertainty following treatment. Targeted survivorship interventions addressing these areas may help to improve quality of life among an increasingly diverse population of ovarian cancer survivors. Phase II study of utidelone plus fruquintinib for the treatment of platinum-resistant recurrent ovarian cancer (FRUTD trial). First Author: Hao Wen, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Patients (pts) with platinum-resistant ovarian cancer (PROC) have a poor prognosis, and traditional cytotoxic drugs have limitations in efficacy and safety. Therefore, we are exploring the combination of utidelone capsule (UTD2), a novel oral microtubule inhibitor, with fruquintinib capsule (F), a tyrosine kinase inhibitor targeting VEGFR 1,2,3, for the treatment of platinum-resistant recurrent ovarian cancer. **Methods:** This study is an open-label and Simon two-stage phase II clinical trial, aiming to enroll 35 pts with platinum-resistant recurrent epithelial ovarian cancer, fallopian tube cancer, or primary peritoneal cancer. All pts were high-grade serous ovarian cancer, with prior 1-5 lines of systemic therapy, and no more than 3 lines of subsequent therapy after platinum-resistant recurrence. Subjects received F in combination with UTD2 in 21-day cycles. The dose of F was 5 mg once daily, taken orally from day 1 to day 14 of each cycle. The dose of UTD2 was 60 mg/m²/day once daily, taken orally from day 1 to day 5 of each cycle. Primary endpoint was objective response rate (ORR) per RECIST v1.1. In Stage 1, 14 pts received per protocol treatment, and the study would proceed to Stage 2 (enrolling additional 21 patients) if ≥2 objective responses (CR/PR) were observed in Stage 1. Secondary endpoints included investigator-assessed progression-free survival (PFS), disease control rate (DCR), duration of response (DoR), overall survival (OS) and Safety. **Results:** From March 18, 2025 to December 22, 2025, 19 pts were enrolled. Median age was 59 years (range, 44-68) with an ECOG PS score of 1. Median prior lines systemic therapy was 3 (range, 1-5) with 1, 2, 3, 4 and 5 lines for 4 pts (21.1%), 2 pts (10.5%), 6 pts (31.6%), 5 pts (26.3%), and 2 pts (10.5%), respectively. Median number of chemotherapy lines after platinum resistance was 1 (range, 0-3), with 0, 1, 2, or 3 lines of chemotherapy for 6 pts (31.6%), 6 pts (31.6%), 5 pts (26.3%), and 2 pts (10.5%), respectively. 14 pts were evaluated for efficacy with an outcome of 1 complete response, 8 partial responses and 5 stable diseases. ORR was 64.3% (95% CI: 38.8-83.7) and DCR was 100%. Median PFS was 7 months (95% CI: 2.8-7.2) and median OS has not reached. The Grade 3 treatment-related AE (TRAE) included neutropenia (n=2), mucositis oral (n=1), palmar-plantar erythrodysesthesia syndrome (n=1), skin ulceration (n=1), diarrhea (n=1), pain (n=1) and neurotoxicity (n=1). There were no ≥Grade 4 TRAE. 1 patient discontinued UTD2+F due to TRAEs. **Conclusions:** Utidelone plus Fruquintinib demonstrated encouraging efficacy for the treatment of PROC with a tolerable safety profile. This study is still actively ongoing, and further data will be provided at time of presentation. Clinical trial information: NCT06973421. Research Sponsor: Beijing Biostar Pharmaceuticals Co., Ltd.

Phase I, multicenter, first-in-human (FIH) global study of SIM0505, an anti-CDH6 (CDH6) antibody-drug conjugate (ADC) in patients with advanced solid tumors. First Author: Xiaohua Wu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Cadherin 6 is a transmembrane glycoprotein overexpressed in multiple cancers, including ovarian cancer (OC) and uterine serous cancer (USC). SIM0505 is an ADC comprised of an anti-CDH6 humanized IgG1 monoclonal antibody, a stable linker cleaved within tumor cells, and a novel topoisomerase I inhibitor, CPT116. Here, we report initial results from a global FIH study of SIM0505 (NCT06792552). **Methods:** This is a Phase 1 study to evaluate the safety, tolerability, pharmacokinetics, and preliminary anti-tumor activity of SIM0505 in patients (pts) with advanced solid tumors. SIM0505 was administered IV every 21 days from 1.6 mg/kg to 9.6 mg/kg. Dose levels from 3.2-8.0 mg/kg were backfilled. **Results:** As of 26 Dec 2025, 38 pts were enrolled without preselection for CDH6 expression (29 OC, 4 USC, 2 endometrioid endometrial cancer, 3 renal cell cancer) from 1.6 mg/kg to 9.6 mg/kg in the dose-escalation part. The median age was 57.0 years (range 42-78). The median number of prior therapy regimens was 5 (range 1-11). Of the 29 OC pts, 27 (93.1%) were high grade serous and 23 (79.3%) were platinum resistant. 22 (75.9%), 20 (69.0%) and 2 (6.9%) had received bevacizumab, PARPi and mirvetuximab soravtansine (MIRV), respectively. The median treatment duration was 10.6 weeks (range 3.0-33.6). Any-grade and Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 37 (97.4%) and 21 (55.3%) pts, respectively. Any-grade and Grade ≥3 treatment-related adverse events (TRAEs) occurred in 35 (92.1%) and 17 (44.7%) pts, respectively. The most common (≥10%) Grade ≥3 TRAEs were thrombocytopenia (23.7%), neutropenia (21.1%), and white blood cell count decreased (18.4%). One pt at 9.6 mg/kg had dose-limiting toxicity of Grade 4 febrile neutropenia and thrombocytopenia and discontinued treatment. Another patient discontinued treatment due to Grade 2 interstitial lung disease. Serious TRAEs were observed in 6 (15.8%) pts. No TEAEs led to death. MTD was not reached. Among 30 evaluable pts, 11 partial responses (PR, 9 OC and 2 USC) and 13 stable disease were observed. 8 PRs occurred among 14 evaluable OC pts at potential therapeutic dose range of 4.8-8 mg/kg. 9 of 21 Gynecological Cancer Intergroup (GCIG) evaluable pts had CA-125 response. The exposure of SIM0505 was proportional to dose in general, with a half-life of about 8 days. The PK profile was similar to that of total antibody, indicating good stability of the ADC in the circulation. **Conclusions:** SIM0505, a first in class CDH6 CPT116 payload ADC showed manageable safety and tolerability, including at higher dose levels with encouraging efficacy in OC and USC, with a favorable PK profile. These data support initiating the dose optimization portion of the study in gynecological cancers. Clinical trial information: NCT06792552. Research Sponsor: None.

Impact of organ-adjacent extracellular vesicle proteomics from uterine lavage on accurate detection and discrimination of ovarian cancer. First Author: John A. Martignetti, MDDx, Inc, Tarrytown, NY

Background: Survival in ovarian cancer (OvCA) exceeds 90% when disease is localized, yet most cases present at advanced stage and effective early detection remains elusive. Blood-based liquid biopsies may be limited by low tumor signal in early disease. We evaluated whether organ-adjacent sampling via uterine lavage extracellular vesicle (EV) proteomics combined with machine-learning (ML) classification could enable accurate detection of OvCA and clinically relevant discrimination from endometrial cancer (EndoCA). **Methods:** Uterine lavage samples were collected under IRB-approved protocols from women undergoing gynecologic evaluation for abnormal uterine bleeding and/or abnormal pelvic imaging. EVs were isolated using an affinity-based capture method and analyzed by liquid chromatography-tandem mass spectrometry. Protein features meeting predefined quality thresholds were analyzed using a novel ML pipeline incorporating entropy-based marker scoring and correlation filtering. Classifier performance was assessed using repeated random two-fold validation and receiver operating characteristic analysis. **Results:** Among 807 participants, diagnoses included OvCA (n=85), benign conditions (n=488), and EndoCA (n=234). An OvCA-versus-benign classifier derived from a 91-protein panel demonstrated strong discrimination (AUC >0.9). Across 100 validation splits, 83 of 85 OvCA cases were correctly classified, including all stage I cases (27/27). A separate 21-protein classifier distinguished OvCA from EndoCA with a sensitivity of 0.94 and specificity of 0.92. **Conclusions:** EV proteomic analysis of uterine lavage specimens enables accurate detection of ovarian cancer, including stage I disease, and reliably distinguishes OvCA from EndoCA in women undergoing gynecologic evaluation. These findings support further prospective clinical validation of organ-adjacent EV proteomics as a translational diagnostic strategy for earlier and more precise classification of gynecologic malignancies. Research Sponsor: None.

Fluorescence-guided surgery with 5-aminolevulinic acid (5-ALA) in ovarian, fallopian tube, and primary peritoneal cancers: Efficacy and safety results from the GINGA study. First Author: Takashi Motohashi, Tokyo Women's Medical University Hospital, Shinjukuku, Tokyo, Japan

Background: Administration of 5-aminolevulinic acid (5-ALA) results in tumor-selective accumulation of protoporphyrin IX, enabling visualization of malignant lesions as red fluorescence under blue light illumination. Although 5-ALA–based photodynamic diagnosis (ALA-PDD) is well established for non-muscle invasive bladder cancer, its role in gynecologic malignancies remains insufficiently characterized. We conducted an investigator-initiated clinical study to evaluate the efficacy and safety of ALA-PDD in ovarian, fallopian tube, and primary peritoneal cancers. **Methods:** From October 2024 to May 2025, patients scheduled for cytoreductive surgery or exploratory laparotomy were enrolled. After exclusion of one patient due to a change in treatment strategy, 22 patients received oral 5-ALA hydrochloride (20 mg/kg) 3–8 hours prior to surgery. Diagnostic performance for detecting peritoneal dissemination under blue light (BL) was compared with that under conventional white light (WL), assessing sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). Statistical tests were performed using McNemar's-test (sensitivity and specificity) or Chi-square test (PPV and NPV). Safety was evaluated based on the incidence and severity of adverse events. **Results:** Overall sensitivity was comparable between BL and WL (88.8% vs 80.9%), whereas BL demonstrated significantly higher specificity (67.3% vs 51.9%, p = 0.0229), indicating fewer false-positive findings. Notably, in patients undergoing interval debulking surgery (IDS; n = 9), BL significantly outperformed WL across all diagnostic metrics, including sensitivity, specificity, PPV, and NPV (all $p < 0.05$). These findings suggest that ALA-PDD enables more accurate intraoperative discrimination between malignant and non-malignant lesions following neoadjuvant chemotherapy. All patients experienced adverse events, predominantly Grade ≤2. One case of postoperative ileus was reported; however, no causal relationship with 5-ALA was identified, and no clinically relevant safety signals emerged. **Conclusions:** ALA-PDD appears to enhance intraoperative diagnostic accuracy compared with conventional white light inspection and demonstrates an acceptable safety profile in ovarian, fallopian tube, and primary peritoneal cancers. In IDS patients, ALA-PDD may serve as a clinically meaningful adjunct to achieve precise cytoreduction and support surgical decision-making in the neoadjuvant chemotherapy setting. Clinical trial information: jRCTs031240345. Research Sponsor: None.

Differential impact of *TP53* and *KRAS* pathogenic variants on overall survival in advanced ovarian carcinoma. First Author: Shreyas Kudrimoti, Kaiser Permanente Santa Clara Medical Center, Santa Clara, CA

Background: Advanced epithelial ovarian carcinoma, including high grade serous ovarian carcinoma (HGSOC), clear cell ovarian carcinoma (CCOC), endometrioid ovarian carcinoma (EOC) and mucinous ovarian carcinoma (MOC), frequently presents in advanced stages and is associated with poor outcomes. In addition to common germline mutations in *BRCA1/2*, many patients also harbor *TP53* and *KRAS* pathogenic variants (PVs) in their tumors. However, the role of these genomic alterations in advanced epithelial ovarian cancer remains unclear. **Methods:** Our study examined a large cohort of patients (n = 1060) with advanced epithelial ovarian cancer with genomic profiling performed using next-generation sequencing (StrataNGS). Cox regression modeling was used to examine the associations between *TP53* and *KRAS* PVs and overall survival (OS), adjusting for covariates including age, race/ethnicity, performance status, Charlson Comorbidity Index, and other genomic alterations. **Results:** Our cohort included HGSOC (n = 924), CCOC (n = 66), EOC (n = 42), and MOC (n = 28). Median OS was 33.4, 33.8, 25.1 and 66.8 months for HGSOC, CCOC, MOC and EOC, respectively. In the CCOC group, *TP53* PVs were associated with worse OS (hazard ratio [HR] = 3.23, [95% confidence interval [CI], 1.05-9.89]), while *KRAS* PVs were associated with better OS (HR = 0.29, [95% CI ,0.09-0.89]). In patients with HGSOC 71.3% had *TP53* PVs, whereas 8.0% had *KRAS* PVs. *KRAS* PVs were associated with better OS (HR = 0.72, [95% CI, 0.50-1.02]) in HGSOC. *TP53* PVs were associated with worse OS only within the sub-cohort that also harbored *KRAS* PVs (HR = 3.42, [95% CI, 1.13-10.33]. *TP53* PVs were not associated with OS in the *KRAS* wild-type sub-cohort (HR = 0.95, [95% CI, 0.72-1.25]). Our finding that *TP53* PVs were associated with worse OS in *KRAS* PVs sub-cohort was confirmed by interaction analysis (HR = 2.06, [95% CI, 0.98-4.35]). There was no OS difference between TP53 gain-of-function versus non-gain-of-function PVs in HGSOC patients. **Conclusions:** In our large study cohort of patients with advanced epithelial ovarian carcinoma, we found that *TP53* and *KRAS* PVs were differentially associated with OS. Surprisingly, *KRAS* PVs were associated with higher OS in HGSOC while *TP53* PVs were associated with worse OS only in conjunction with *KRAS* PVs, highlighting the need to deepen our understanding of the oncogenic role *KRAS* plays in ovarian epithelial carcinoma. Further mechanistic studies to understand the roles of these common mutations in ovarian cancers could provide deeper insights. Research Sponsor: None.

Incidence and genomic characteristics of a low homologous recombination deficiency score subgroup in *BRCA*-mutant ovarian cancer. First Author: Caiyan Liu, Department of Gynecological Oncology, Tianjin Central Hospital of Gynecology Obstetrics, Tianjin, China

Background: Homologous recombination deficiency (HRD) is a pivotal molecular phenotype in ovarian cancer (OC) and serves as a key biomarker for guiding PARP inhibitor (PARPi) therapy. Current clinical algorithms assess HRD status by integrating pathogenic BRCA1/2 mutations and genomic scar scores. Nevertheless, a paradoxical phenotype exists: BRCA mutations with a low HRD score. The incidence and genomic characteristics of this subgroup remain poorly understood. **Methods:** We retrospectively analyzed a cohort of OC patients tested at a centralized laboratory (2024-2025). A composite genomic instability score was calculated as the sum of three biomarkers: loss of heterozygosity (LOH), telomeric allelic imbalance (TAI), and large-scale state transitions (LST). HRD positivity was defined as the presence of a BRCA1/2 pathogenic/likely pathogenic variant and/or a HRD score (LOH+TAI+LST) $\geq$ 42. **Results:** Among 441 ovarian cancer samples, 151 of 310 (34.24%, 151/441) BRCA wild-type patients had an HRD score $\geq$ 42, primarily driven by other homologous recombination repair (HRR) gene alterations. Conversely, among 131 BRCA-mutant patients, 30 (6.80%, 30/441) had an HRD score $<$ 42. Notably, 13 patients (2.95%, 13/441) with pathogenic BRCA variants exhibited remarkably low HRD scores ($<$ 10). This subgroup comprised 10 BRCA1 and 3 BRCA2 alterations, including: 4 somatic truncating mutations [Exon11 S1389* (VAF=4.41%; HRD=0), Exon11 D1868Vfs*5 (VAF=4.80%; HRD=4), Exon10 E597* (VAF=17.37%; HRD=3), Exon10 K339Rfs*2 (VAF=30.65%; HRD=6)]; 6 germline truncating mutations [Exon21 Q1785* (VAF=50.29%; HRD=9), Exon13 G1492* (VAF=47.61%; HRD=7), Exon10 L1086* (VAF=46.52%; HRD=2), Exon11 S1882* (VAF=50.83%; HRD=0), Exon10 Q1200* (VAF=49.37%; HRD=0), Exon11 L1908Rfs*2 (VAF=44.44%; HRD=0)]; and 3 germline copy number deletions (HRD=2, 2, 0). We hypothesize potential mechanisms for this discordance: 1) Monoallelic inactivation: Single-allele inactivation (first hit) without a complete loss-of-function second hit, leading to partial HR function retention. 2) Subclonal variants: Low VAF suggests BRCA mutations may reside in tumor subclones, not dominating the pan-tumor HRD phenotype, with signals diluted by HR-proficient cells. 3) Time-dependency: BRCA inactivation might occur late in tumor evolution, insufficient for accrual of HRD-associated genomic scars at testing. **Conclusions:** This study quantifies a rare subgroup (~3%) of OC with pathogenic BRCA mutations but low HRD scores. This suggests monoallelic BRCA mutation alone may be insufficient to induce high genomic instability, potentially contributing to primary resistance to PARPis, though validation with clinical outcome data is required. Future studies integrating multi-omics data are needed to precisely evaluate HR pathway status and guide individualized treatment decisions. Research Sponsor: None.

Virtual multiplex immunofluorescence characterization of spatial immune architectures and tertiary lymphoid structures in high-grade serous ovarian cancer. First Author: Junhwan Kim, Center for Gynecologic Cancer, National Cancer Center, Goyang-Si, South Korea

Background: GigaTIME (*Cell*, 2026) is a deep learning–based virtual multiplex immunofluorescence (mIF) model that has been validated using TCGA datasets and enables spatial tumor immune microenvironment (TIME) profiling directly from H&E whole-slide images (WSIs). This study aims to evaluate the feasibility of GigaTIME for characterizing the spatial TIME of high-grade serous ovarian cancer (HGSOC) using public datasets. **Methods:** We analyzed UBC-OCEAN and CPTAC-OV HGSOC H&E WSIs using GigaTIME to generate virtual 21-channel (e.g., DAPI, CK, CD3, CD8, CD20, and Ki67) mIF pixel-level inferred probability maps. Exploratory analyses of 5$\times$5 stitched regions of interest (ROI, 2560$\times$2560 pixels $\approx$ 1.28$\times$1.28 mm) were performed to detect tertiary lymphoid structures (TLS) via density-based spatial clustering of applications with noise (DBSCAN), identified as CD20$^+$ clusters (major axis $\geq$100 μm) adjacent to CD3$^+$ zones, with maturity defined by intra-cluster Ki67$^+$ proliferation. Tumor-immune interaction metrics were analyzed in ROIs using Group Degree Centrality (GDC, fraction of tumor cells contacting immune cells) and Cluster Co-occurrence Ratio (CCR, observed/expected contacts). CPTAC-OV HGSOC H&E WSI–derived virtual mIF features were correlated with bulk proteomics using Spearman's rank correlation. Integrated K-means clustering was performed on the combined cohorts after Z-score normalization. **Results:** The UBC-OCEAN cohort (N=195) exhibited an immune-inflamed phenotype with high tumor-immune engagement (mean GDC [mGDC] 0.25) and structural aggregation (mean CCR [mCCR] 1.41), whereas CPTAC-OV (N=222) displayed an immune-excluded phenotype with minimal contact (mGDC 0.05) and near-random distribution (mCCR 1.03). While total TLS density was comparable (UBC-OCEAN 3.92 vs. CPTAC-OV 3.60), UBC-OCEAN exhibited a twofold higher density of mature TLS compared to CPTAC-OV (1.83 vs. 0.77). Integrated clustering (k=2, silhouette=0.71) revealed that High-TLS (N=39) tumors paradoxically exhibited significantly lower mGDC (p=0.016) and mCCR (p=0.001) despite higher TLS density, indicating a spatially segregated and organized immune architecture. In CPTAC-OV validation, virtual CD3 intensity showed a significant positive correlation with bulk proteomics (N=17, ρ=0.547, p=0.023), supporting the biological validity of the T-cell-based spatial metrics. **Conclusions:** GigaTIME is feasible for evaluating comprehensive spatial TIME including TLS and demonstrates the heterogeneous immune landscape of HGSOC, providing spatial insights that are not captured by bulk proteomics alone. This warrants the utility of virtual mIF-based profiling as a scalable tool to identify distinct immune phenotypes for personalized immunotherapy at minimal cost. Research Sponsor: None.

Surufatinib combined with toripalimab for the treatment of recurrent ovarian clear cell carcinoma: Update of a prospective single center, single-arm phase II clinical trial. First Author: Huijuan Yang, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Ovarian clear cell carcinoma (OCCC) is a histologically aggressive subtype of epithelial ovarian cancer with limited effective treatment options, particularly for recurrent disease. This study aims to evaluate the efficacy and safety of surufatinib (a kinase inhibitor targeting VEGFR 1, 2, 3, FGFR 1, and CSF-1R) in combination with toripalimab (an anti PD-1 antibody) for recurrent OCCC. Here, we present the latest efficacy and safety data. **Methods:** 23 patients aged 18-75 with histologically confirmed recurrent OCCC, ECOG performance status of 0-2, and failed first or subsequent-line therapy was enrolled (If the patient only had first line chemotherapy, platinum-free interval should be less than 12 months or disease progression occurred during chemotherapy). Patients received orally surufatinib 250 mg once daily in combination with toripalimab 240 mg on day 1 every 3 weeks until disease progression or unacceptable toxicity. Primary endpoint is progression-free survival (PFS), and secondary endpoints include objective response rate (ORR), overall survival (OS), and safety. **Results:** From Jul. 2023 to Dec. 2025, 19 patients (median age 51) were enrolled, with 52.6% (10/19) had an ECOG PS of 0, 73.7% (14/19) were classified as clinical stage of I-II. 57.9% (11/19) had received prior first-line treatment, while the remaining 8 patients had received twice or more. Eight patients had previously received bevacizumab. Among the 19 patients, 10 were platinum-resistant while 9 were platinum-sensitive. The primary metastatic sites were lymph nodes (8/19, 42.1%), lungs (6/19, 31.6%), pelvic cavity (6/19, 31.6%) and peritoneum (5/19, 26.3%). With a median follow-up of 7.1 months, the median PFS was 4.4 months (95% CI: 2.6-8.8). Tumor response was evaluable in 19 patients, with 1 complete response, 4 partial response and 11 had stable disease, resulting in an ORR of 26.3% (95% CI: 9.2-51.2%), and a disease control rate of 84.2% (95% CI: 60.4-96.6%). The most common ($\geq$20%) treatment related adverse events (TRAEs) were hyperthyroidism (42.1%), proteinuria (36.8%), hypertension (36.8%), diarrhea (36.8%), anaemia (31.6%), rash (31.6%), increased TSH (26.3%), hypoalbuminaemia (21.1%), increased AST (21.1%) and increased ALT (21.1%). Grade 3 TRAEs ($\geq$10%) were mainly hypertension (15.8%), increased AST (15.8%), increased ALT (10.5%). All of AEs were effectively controlled after temporarily discontinuing surufatinib or toripalimab, or reducing the dose of surufatinib, or receiving symptomatic treatment. There were no cases with fatal outcome. **Conclusions:** The combination of surufatinib and toripalimab exhibited potential clinical activity and tolerable toxicity in patients with recurrent OCCC. Clinical trial information: ChiCTR2400083672. Research Sponsor: None.

IGNITE-Cerala: A phase II signal-seeking trial of ceralasertib targeting recurrent high-grade serous ovarian cancer with cyclin E1 overexpression with and without gene amplification. First Author: George Au-Yeung, Department of Medical Oncology and the Sir Peter MacCallum Department of Oncology, Peter MacCallum Cancer Centre and the University of Melbourne, Melbourne, VIC, Australia

Background: Cyclin E1 (*CCNE1*) gene amplification and protein over-expression is a marker of platinum resistance in high grade serous ovarian, fallopian tube or primary peritoneal cancer (HGSC). Preclinical studies in breast and HGSC models have identified cyclin E1 amplification or over-expression as a potential predictive biomarker for improved sensitivity to ATR inhibition. We aimed to assess the efficacy of ceralasertib, an ATR inhibitor, in HGSC with cyclin E1 over-expression. **Methods:** IGNITE is a multicentre, Phase 2 trial enrolling women with recurrent platinum resistant HGSC. Tumors were assessed for Cyclin E1 protein expression by IHC and *CCNE1* copy number by FISH. Patients with evaluable disease by RECIST v1.1 or GCIG CA-125 criteria were included. Ceralasertib 160mg PO was given twice daily on days 1-14 of a 28-day cycle. The primary endpoint was investigator assessed overall response rate (ORR), defined as partial response (PR) or complete response (CR) at 16 weeks by RECIST v1.1 among patients with measurable disease, or by GCIG CA-125 criteria for patients with non-measurable disease. Here we present the 16-week response data for all patients treated with ceralasertib with a data cut-off of July 2025. **Results:** Between Feb-2024 and Apr-2025, 32 patients were accrued to IGNITE-Cerala. One patient was deemed ineligible after registration and was excluded. Median age was 64 years (range 40-76) and 74% had received ≥2 prior lines of chemotherapy. Median cyclin E1 IHC H-score was 190 (range 60 – 260). Twenty-seven patients (87%) had measurable disease by RECIST. Median number of cycles commenced was 3 (range 1-18). The ORR at 16 weeks was 10% (0 CR and 3 PR). The 6 month progression free survival estimate was 26% (range 12-42%). Treatment related adverse events (TRAE) were mostly grade 1-2 with the most common being gastrointestinal or hematologic. Six patients (19%) had Grade 3 TRAE, and one patient had Grade 4 TRAE. Six patients (19%) required a dose reduction, and no patients discontinued study drug due to toxicity. **Conclusions:** Ceralasertib was a well tolerated treatment, however responses did not appear to be enriched in a biomarker selected population and therefore future studies should consider rationale combinations with ceralasertib. Cyclin E1 over-expression and amplification remains an important biomarker in HGSC, with other strategies such as CDK2 or PK-MYT1 inhibitors under active investigation. Clinical trial information: ACTRN12619001185156. Research Sponsor: AstraZeneca.

Response at 16 weeks	Response evaluable patients (n=31)	RECIST measurable patients (n=27)

Budget impact analysis of heated intraperitoneal chemotherapy at interval cytoreductive surgery for stage III high grade serous carcinoma of tubo-ovarian origin. First Author: Tal Milman, University of British Columbia, Vancouver General Hospital, Vancouver, BC, Canada

Background: Heated Intraperitoneal Chemotherapy (HIPEC) at interval cytoreductive surgery (ICS) for high grade serous carcinoma of tubo-ovarian origin (HGSOC) improves overall survival (OS) by 11.6 months and increases platinum sensitivity at recurrence. Our aim was to estimate the payer budget impact of adopting HIPEC in BRCA wild-type patients at a quaternary Canadian center. **Methods:** A retrospective review was conducted of patients undergoing surgery for metastatic HGSOC at Vancouver General Hospital, Vancouver, Canada between January 1 and December 31, 2024. A payer-perspective Markov model was constructed with monthly cycles and a five-year horizon. Six cycles of carboplatin and paclitaxel were costed in the initial episode. Health states were progression-free (PF), first platinum-sensitive recurrence (PS1), second platinum-sensitive recurrence (PS2), platinum-resistant recurrence (PR), and death. PF progression hazards were derived from median PFS reported in randomized clinical trials. Post-progression mortality hazards were calibrated to match OVHIPEC-1 median overall survival. Direct medical costs were estimated in 2025 Canadian dollars using publicly available provincial drug pricing data in British Columbia and institution-specific costs for surgery, HIPEC, and inpatient care. **Results:** Annual volume of ICS patients was 98, of whom 25 were eligible for HIPEC and wtBRCA. Over 5 years, with 25 new patients entering annually, total costs were $9.05M without HIPEC versus $11.07M with HIPEC, yielding an incremental budget impact of $2.02M ($16,186 per patient). Incremental cost was driven by the surgical episode (+$1.90M), longer duration of maintenance niraparib (+$0.26M), and treatment of platinum-sensitive recurrence (+$0.15M) with carboplatin doublets. Incremental cost was partially offset by an estimated 11 fewer platinum-resistant recurrences within the 5-year horizon, resulting in cost savings of −$0.28M from reduced platinum-resistant treatment. **Conclusions:** Adding HIPEC at ICS to patients with stage III wtBRCA HGSOC increases 5-year payer spending by $2M for a 25 patient per year program. Additional cost is driven by provision of HIPEC surgery and postoperative care and is partially offset by near-term savings on platinum-resistant recurrence. Research Sponsor: None.

Treatment cost across a 5-year horizon for 25 patients treated annually (n = 125).

Category	No HIPEC	HIPEC	Incremental Cost	Incremental Cost Per Patient
Surgery +/- HIPEC	$2,085,500	$3,983,250	$1,897,750	$15,182
Initial chemotherapy	$1,829,348	$1,829,348	$0.00	$0.00
Niraparib Maintenance	$2,376,117	$2,638,599	$262,482	$2,100
Platinum Sensitive Recurrence	$1,243,222	$1,389,325	$146,103	$1,169
Platinum Resistant Recurrence	$1,515,639	$1,232,611	-$283,027	-$2,264
Total	**$9,049,824**	**$11,073,132**	**$2,023,308**	**$16,186**

Enhanced predictive value of KELIM for surgical resectability in HRD-positive high-grade serous ovarian cancer. First Author: Mayerly Castrillón Sánchez, McGill University Health Centre, Montréal, QC, Canada

Background: Neoadjuvant chemotherapy followed by interval debulking surgery is commonly used in the management of advanced ovarian cancer. However, there is currently no reliable tool to predict the likelihood of achieving complete cytoreduction after 3–4 cycles of chemotherapy. Surgical outcomes are classified as R0 (no residual disease), R1 (residual lesions <1 cm), or R2 (residual disease ≥1 cm). The KELIM index, calculated from CA-125 kinetics during chemotherapy, has emerged as a potential biomarker of tumor regression and chemosensitivity in advanced ovarian cancer. We aim to study the performance of KELIM score as predictor of complete cytoreduction. **Methods:** This single-center, retrospective study included 69 patients with advanced high-grade serous ovarian cancer (Stage III/IV) who underwent interval cytoreductive surgery following neoadjuvant chemotherapy between January 2020 and December 2025. Kelim index values were calculated using Biomarker-Kinetics and categorized as favorable (≥1) or unfavorable (<1) as per literature. Further, ROC curve analysis was performed to identify the optimal KELIM cutoff for predicting complete cytoreduction. Correlations with degree of cytoreduction (R0, R1, R2) were analyzed using comparative statistics. Associations with molecular markers (BRCA, HRD) were also explored. **Results:** The median age of patients was 62 years [IQR 57–70]. The median KELIM score was 0.85 [IQR 0.69-1.00]. KELIM demonstrated statistically significant predictive performance for R0, with an area under the curve (AUC) of 0.69 (95% CI, 0.56–0.82; p = 0.004). The AUC optimal cutoff was KELIM = 0.995, yielding a sensitivity of 53.9% and specificity of 92.6%. Notably, this value closely aligns with the cutoff reported in the literature (KELIM = 1.0), which in our cohort corresponded to a sensitivity of 51.3% and specificity of 96.3% (Youden index = 0.47). Additional analyses were conducted using the literature-defined cutoff of KELIM = 1.0. Patients were categorized into two groups: Group A (22 patients) with favorable (≥1) and Group B (47 patients) with unfavorable (<1) KELIM scores. Patients with a favorable KELIM were significantly more likely to achieve complete cytoreduction compared with those with an unfavorable KELIM (R0: 95.2% vs 41.3%, p < 0.001). The discriminative performance of KELIM was numerically higher in HRD-positive patients AUC 0.706 (95% CI, 0.28-1) compared with HRP patients AUC 0.563 (95% CI, 0-1). KELIM was associated with degree of cytoreduction: Median 1 [0.71-1.20] for R0, 0.79 [0.70-0.88] for R1, and 0.64 [0.48-0.70] for R2, p=0.019. **Conclusions:** KELIM is a good predictor of complete resectability in high grade serous ovarian cancer. The differential predictive performance among the HRD status should be further explored. Research Sponsor: None.

Impact of niraparib maintenance on progression-free survival and overall survival: An updated meta-analysis. First Author: Roshan Mustafa Pathan, Government Siddhartha Medical College, Vijayawada, India

Background: Niraparib is an oral poly(ADP-ribose) polymerase (PARP) inhibitor used as maintenance therapy in advanced ovarian cancer after platinum response. Mature OS data were lacking, so we performed an updated meta-analysis. **Methods:** PubMed, Embase, and CENTRAL were searched from January 2023 to January 2026 for randomized controlled trials (RCTs) of niraparib maintenance in advanced ovarian cancer. Hazard ratios with 95% confidence intervals were pooled using random-effects models for TFST, OS, overall PFS, and subgroup PFS by BRCA, HRD status, and newly diagnosed patients. The study is registered in PROSPERO with ID CRD420261294461. **Results:** Four RCTs (PRIMA, NOVA, NORA, and PRIME) including 1935 patients were analysed, of whom 1,291 received niraparib, and 644 received placebo. Niraparib significantly prolonged the TFST (HR 0.54, 95% CI 0.42-0.69; I^2=77.6%; p<0.0001). No statistically significant improvement in OS was observed (HR 0.94, 95% CI 0.82-1.08; I^2=10.0%; p=0.398). Niraparib significantly improved overall PFS (HR 0.42, 95% CI 0.31-0.58; I^2=83.8%). PFS in BRCA-mutated patients (HR 0.33, 95% CI 0.24-0.45; I^2=46.0%), HRD-positive patients (HR 0.41, 95% CI 0.30-0.56; I^2=58.6%) (all p<0.0001). HRD-negative patients (HR 0.56, 95% CI 0.35-0.89; I^2=52.4%), and newly diagnosed (HR 0.55 95% CI 0.39-0.80, I^2=79.1%) (all p≤0.015). **Conclusions:** Niraparib provides durable disease-control benefits across molecular subgroups and significantly delays the need for subsequent therapy, however, mature data does not demonstrate a corresponding overall survival advantage. These findings refine patient selection and highlight the need for strategies that translate PFS gains into survival benefit. Research Sponsor: None.

Updated meta-analysis of niraparib efficacy outcomes in advanced ovarian cancer.

Post-treatment ctDNA monitoring using a tumor-informed whole-genome sequencing-based assay in homologous recombination–proficient ovarian cancer. First Author: Sophie Blakey-Cheung, AdventHealth Cancer Center, Orlando, FL

Background: Ovarian cancer (OC) has high mortality due to advanced stage at diagnosis and frequent, incurable recurrences. Homologous recombination–proficient (HRP) disease comprises approximately half of high-grade serous OC and is associated with limited benefit from platinum chemotherapy and PARP inhibitors, leading to poorer outcomes. Circulating tumor DNA (ctDNA) is a validated biomarker for molecular residual disease and early relapse; this study evaluates it's ability to stratify HRP patients (pts) into clinically meaningful risk groups. **Methods:** We performed a retrospective analysis of clinically annotated residual samples from commercial ctDNA testing in pts diagnosed with OC. Signatera Genome assays (Natera, Inc.) were designed from the respective pts' matched tumor and normal whole genome sequencing (WGS) data to detect and quantify ctDNA in serially collected post-operative plasma. Adjuvant chemotherapy (ACT) decisions and cadence of testing were at the provider's discretion. HR status was determined using available clinical records and/or genomic data. Descriptive statistics were used to compare association of ctDNA across stages and at various timepoints post-surgery. Correlation between ctDNA status and progression-free survival (PFS) was assessed using Cox regression analysis. **Results:** Study cohort comprised 164 Stage I-IV OC pts, with 1,256 plasma samples for ctDNA testing (median: 7 tests/ pt, range 1–24). The median age at diagnosis was 66 (range 19–89) years. A total of 157 cases were HRP; among these, clinical outcome data was available for 44 pts with corresponding ctDNA timepoints for analysis. ctDNA-positivity within two weeks post-debulking surgery (before starting ACT) was associated with significantly worse PFS compared to ctDNA-negativity (N=20; HR: 14.01, 95%CI: 0.6–308.16; p=0.01). Furthermore, ctDNA-positivity post-ACT was also associated with worse PFS (N=26; HR: 6.6, 95%CI: 1.7–25.3; p=0.002) compared to ctDNA-negativity. Among ctDNA-positive pts, 50% (5/10) had progression $<$6 months post-ACT, whereas no events were observed $<$12 months post-ACT in ctDNA-negative pts (N=12). Clinical follow-up and additional analyses are ongoing. **Conclusions:** Tumor-informed ctDNA monitoring identifies pts with HRP OC who are at high risk for recurrence post-surgery including treatment refractory/resistant cases. Post-operative and post-adjuvant ctDNA positivity was strongly associated with inferior PFS. These findings support the use of ctDNA as a clinically important biomarker to inform post-surgical/treatment risk stratification, and consideration of alternative or escalated therapeutic strategies in this high-risk population. These results showcase the utility of ctDNA to further risk stratify HRP OC pts, which supports it's integration into prospective clinical trials and clinical care. Research Sponsor: None.

Spatial distribution and functional heterogeneity of CD56bright and CD56dim natural killer cells and the effects on the immune microenvironment in ovarian cancer. First Author: Guo Huiming, The First Affiliated Hospital of Kunming Medical University, Kunming, China

Background: Natural killer (NK) cells are key components of antitumor immunity, yet their functional heterogeneity and spatial distribution within the tumor microenvironment (TME) remain incompletely understood in ovarian cancer. CD56bright and CD56dim NK cell subsets exhibit distinct immunologic functions, but their relative infiltration patterns and associations with other immune cell populations have not been systematically characterized. **Methods:** A total of 157 ovarian cancer specimens were analyzed using multiplex immunofluorescence staining. NK cells were classified as CD56bright and CD56dim subsets, and their densities were quantified separately in tumor parenchyma and stroma. The associations between NK cell infiltration patterns and the densities of multiple immune cell populations. **Results:** Overall, ovarian cancer exhibited a CD56dim NK cell–dominant infiltration pattern. In tumor parenchyma, the mean density of CD56bright NK cells was 149 cells/mm², whereas CD56dim NK cells reached 406 cells/mm². In tumor stroma, CD56bright and CD56dim NK cell densities were 108 cells/mm² and 277 cells/mm², respectively. Patients with higher overall NK cell infiltration showed significantly increased densities of multiple immune cell populations in both tumor parenchyma and stroma, including $CD8^+$ T cells (P=0.0091, 0.0167), M1 macrophages (P=0.0002, 0.0001), M2 macrophages (P=0.0011, 0.0008), $PD\text{-}L1^+$ macrophages (P=0.0164, 0.0006), $CD20^+$ B cells (P=0.0001, 0.0193), $CD4^+$ T cells (P=0.0001, 0.0001), and $CD4^+FOXP3^+$ regulatory T cells (P=0.0001, 0.0001). When comparing NK cell subset dominance, patients with lower CD56dim than CD56bright NK cell infiltration in tumor parenchyma exhibited significantly higher M1 macrophage density (342 vs 180 cells/mm², P=0.0344) and lower stromal M2 macrophage infiltration (P=0.0356). In tumor stroma, lower CD56dim-dominant cases showed significantly increased infiltration of M1 macrophages (435 vs 242 cells/mm², P=0.0336), M2 macrophages (171 vs 48 cells/mm², P=0.0053), $CD8^+PD\text{-}1^+$ T cells (34 vs 10 cells/mm², P=0.0299), $CD4^+$ T cells (140 vs 25 cells/mm², P=0.0119), and $CD4^+FOXP3^+$ T cells (73 vs 4 cells/mm², P=0.0016). **Conclusions:** Ovarian cancer is characterized by predominant infiltration of CD56dim NK cells; however, the balance between CD56bright and CD56dim NK cell subsets is closely associated with distinct immune microenvironment patterns. These findings highlight the functional heterogeneity of NK cell subsets and provide a potential mechanistic explanation for the variable prognostic and therapeutic relevance of NK cells across tumor types and immunotherapy contexts. Spatially resolved profiling of NK cell subsets may offer valuable insights for immunotherapy stratification in ovarian cancer. Research Sponsor: None.

Comprehensive profiling of antibody-drug conjugate target expression in epithelial ovarian cancer with pre- and post-ADC longitudinal assessment. First Author: Yong jae Lee, Department of Obstetrics and Gynecology, Yonsei University College of Medicine, Seoul, South Korea

Background: Antibody–drug conjugates (ADCs) are increasingly used in ovarian cancer, yet target expression may evolve over time and under treatment pressure. We characterized key ADC targets across disease timepoints and assessed paired changes after ADC exposure. **Methods:** We retrospectively analyzed epithelial ovarian cancer treated at Yonsei Cancer Center (n=158). Serial specimens obtained at diagnosis, interval debulking surgery, and relapse underwent immunohistochemistry for TROP2, HER2, FOLR1, CLDN6, B7H4, B7H3, and CDH6. Targets were scored 0/1+/2+/3+; overexpression was defined as 2+ or 3+. Longitudinal transitions were summarized using Sankey plots, including pre-/post-ADC comparisons. **Results:** We analyzed 158 epithelial ovarian cancer patients (HGSC n=120; non-HGSC n=38). In HGSC, the most frequent overexpressed targets (2+/3+) were TROP2 (100%) and FOLR1 (91.5%) at diagnosis, remaining high at relapse (TROP2 93.2%, FOLR1 82.2%), while HER2 overexpression was uncommon (20.3% at diagnosis; 6.9% at relapse). In non-HGSC subtypes, TROP2 was most frequently overexpressed in endometrioid (3+ in 100%) and clear cell tumors (2+/3+ in 100%), whereas mucinous tumors showed predominant HER2 overexpression (2+/3+ in 70%). In ADC-exposed paired pre-/post-ADC specimens, expression of the cognate ADC target generally decreased after exposure, including reduced FOLR1 after MIRV/MORAb-202, reduced HER2 after T-DXd, and reduced CDH6 after R-DXd. **Conclusions:** TROP2 and FOLR1 are broadly and consistently expressed across timepoints. Non-HGSC exhibits distinct histology-specific patterns, with particularly high HER2 expression in mucinous tumors. ADC treatment resulted in a reduced expression profile of its cognate target protein, which may contribute to the development of ADC resistance; however, further investigation is required to elucidate additional underlying mechanisms. Primary analysis of pembrolizumab combined with chemotherapy in platinum-sensitive recurrent low-grade serous ovarian cancer: The NOGGO PERCEPTION phase II study. First Author: Jacek P. Grabowski, North-Eastern German Society of Gynaecological Oncology (NOGGO) and Department of Gynecology with Center for Oncological Surgery, Charité-University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany

Background: Low-grade serous ovarian cancer (LGSOC), a rare ovarian malignancy, exhibits a very limited responsiveness to chemotherapy. There is a pressing need for new therapeutic combinations with modern agents to enhance response rates and prognosis in this patient subgroup. Immune checkpoint inhibitors offer a promising pathway, having shown effectiveness in various malignant diseases, including selected cases of ovarian cancer. If our trial should show pembrolizumab effectivity in LGSOC, it would be a signal and impulse for future clinical studies in this rare disease. **Methods:** This multicenter, single-arm phase II study evaluates pembrolizumab in combination with platinum-based chemotherapy (carboplatin plus pegylated liposomal doxorubicin [PLD] or carboplatin plus gemcitabine) and as maintenance therapy in recurrent LGSOC. Eligible patients include those with disease progression or recurrence $\geq$6 months post prior platinum-based therapy and ECOG performance status 0-1. The primary endpoint is the 12-month progression-free survival (PFS) rate. Secondary endpoints include response rate (RR), PFS and ORR based on Ki67 expression. Using Simon's two-stage design, 33 patients were enrolled. Success is defined as $\geq$11 patients achieving 12-month PFS. Assuming a true PFS rate of 40%, the study has 5% type I error and 80% power. **Results:** Data from 33 patients were evaluated. At data cut-off, 12 patients were progression free at 12-months (median PFS 15.5 months) while 19 patients progressed or died within 12 months (median PFS 5.6 months). Overall PFS median was 8.4 months. Comparing the subgroups of pre-treatment Ki67 expression $<$3.6% vs. $\geq$ 3.6%, the median PFS was 5.1 vs. 8.8 months. Four patients remain on pembrolizumab treatment; two of these have not yet reached the 12-month PFS endpoint. Median patient age was 52 years (range: 37-81), with ECOG performance status 0 in 30 patients (90.9%). Most patients had one prior chemotherapy line (61.1%; range: 1-5). Chemotherapy regimens included carboplatin + PLD (75.8%) and carboplatin + gemcitabine (24.2%). SAEs were reported in 22 patients (66.7%), with 11 (33.3%) considered treatment-related. **Conclusions:** The study achieved its primary objective in terms of the 12-months PFS and thus suggests efficacy of pembrolizumab in patients with platinum-sensitive recurrent LGSOC. Clinical trial information: 2023-508155-40-00. Research Sponsor: MSD Sharp & Dohme GmbH.

Update of the EORTC QLQ-Ovarian Cancer Module (EORTC-QLQ-OV28) phase I and II. First Author: Vesna Bjelic-Radisic, Breast Unit, Helios University Clinic, University Witten-Herdecke, Wuppertal, Germany

Background: Ovarian cancer is the eighth most common cancer in women worldwide. The 5-year survival rate is 90.0% for early-stage disease and 30.2% for advanced disease. The introduction of new treatment options, such as PARP inhibitors, immunotherapy and bevacizumab, has led to improved recurrence-free intervals and an increased number of long-term survivors. However, new therapies have also brought new side effects that are not sufficiently covered by the EORTC QLQ OV-28, which was developed in 1997. There is therefore a strong clinical and research need to update the questionnaire to reflect contemporary treatments and their impact on QoL. This work presents the results of Phases 1 and 2 of the EORTC module development study updating the EORTC QLQ-OV28. **Methods:** The EORTC QLQ-OV28 module was adapted in accordance with the EORTC QLG guidelines for methodology for updating modules focused on identifying QoL issues relevant to ovarian cancer patients. This involved a systematic literature search, a review of questionnaires , investigator brochures, focus groups, and research group meetings (Phase 1).An issue was added to the list if it had a patient and/or HCP relevance rating of at least 2 (on a scale of 1 to 4) and a priority rating of at least 30%. The relevant issues were then translated into items, resulting in a preliminary questionnaire (Phase 2). **Results:** The mixed methods approach identified 57 issues related to QoL in ovarian cancer patients. An issue list was created and used for interviews with 58 patients and 31 HCPs, who rated each issue according to its relevance using a four-point response format: 'not at all', 'a little', 'quite a bit', 'very much' and priority (yes/no). Of the initial 57 issues, 20 (as rated by patients) and 34 (as rated by HCPs) met both inclusion criteria. Sixteen of these were covered by the existing EORTC QLQ-OV28, and five new issues were identified: weight loss, numbness in the hands and feet, anxiety, concerns about acceptance of their condition, and impaired sexuality. Twelve issues from the existing questionnaire did not fulfil all the inclusion criteria.In Phase II, these issues were translated into items and used to create a preliminary 39-item questionnaire to assess QoL in ovarian cancer patients. **Conclusions:** The results of Phases I and II indicate that the current EORTC QLQ-OV28 module does not adequately address all the relevant QoL issues for patients with ovarian cancer. Five new issues are not addressed by the existing module, and twelve existing issues did not fulfil all the inclusion criteria. Therefore, the EORTC QLQ-OV28 module should be updated. A preliminary questionnaire will be tested in Phase III of the EORTC module development process. Note: This document represents preliminary findings of the module development and is subject to revision; subsequent modifications of the module in the next stages may reflect significant changes. Research Sponsor: EORTC QLQ.

Vididencel, an active immunotherapy in high-grade serous ovarian carcinoma patients: Analysis of tumor-directed immune responses post-primary treatment. First Author: Annegé Vledder, University Medical Centre Groningen, Groningen, Netherlands

Background: Ovarian cancer (OC) remains the most common cause of mortality in gynecologic cancers, with advanced-stage high-grade serous carcinoma (HGSOC) accounting for most cases. PARP inhibitors have provided significant benefits and notable progression-free survival for patients with BRCAmut and HRD+, but survival benefits following primary treatment remains a major clinical challenge. We have conducted a phase 1 trial (NCT04739527) assessing the role of an active immunotherapy, vididencel, in patients with HGSOC post-primary treatment. Vididencel expresses multiple tumor-associated antigens (TAA), including WT1 and PRAME, which are frequently upregulated in HGSOC. **Methods:** Following primary treatment, patients received 8 doses of vididencel intradermally administered every 14 days, followed by 2 booster injections at week 14 and 18. Peripheral blood mononuclear cells (PBMC) were obtained at week 0, 4, 10, 14, 18 and 22. Disease status was evaluated at week 22 using clinical assessment and CA125 levels. Patients were followed for disease status for 2 years. IFNγ ELISpot was performed on PBMC for WT1, PRAME, MAGEA3/4 and NY-ESO1. Vididencel induced T-cell responses were calculated as $\geq$2-fold increase of the mock-corrected baseline response. **Results:** All 17 patients completed treatment phase (up to week 22 or end of treatment). Patient demographics are outlined in table I. 11 out of 17 patients completed predefined 2-year follow-up. With median follow-up of 26.4 months 8 out of 11 patients remain alive. 12 out of 17 patients (71%) showed improved tumor-directed vididencel-induced immune responses (VIR) and are associated with improved progression-free survival. 5 of 12 patients (42%) with VIR still had stable disease, with 2 patients beyond 3.5 years of follow-up. **Conclusions:** Long-term follow-up of HGSOC patients treated with vididencel confirms safety, tolerability and feasibility resulting in strong T cell response against TAA. The improved tumor-directed responses were associated with better progression-free survival. These data confirm that vididencel is a safe immunotherapy and provides strong basis for novel combination treatments for ovarian cancer patients. Clinical trial information: NCT04739527. Association of AI-based quantitative B7-H3 evaluation in the tumor microenvironment with molecular subtypes in high-grade serous ovarian carcinoma. First Author: Ryusuke Murakami, Department of Gynecology and Obstetrics, Graduate School of Medicine and Faculty of Medicine, Kyoto University, Kyoto, Japan

Background: High-grade serous ovarian carcinoma (HGSC) exhibits heterogeneous tumor microenvironments (TME) that correlate with clinical outcomes. We previously reported four molecular histopathological subtypes of HGSC based on gene expression profiles reflecting TME characteristics: Immune Reactive (IR), Mesenchymal (MT), Solid/Proliferative (SP), and Papillary/Glandular (PG). The IR subtype, characterized by tumor-infiltrating lymphocytes, demonstrates favorable prognosis (PMID:26993207, 30853361). We also identified lower B7-H3 expression in IR compared to non-IR subtypes (PMID: 34799346). Here, we developed an AI-based B7-H3 IHC quantification method across TME compartments and investigated its association with molecular subtypes. **Methods:** Forty-five HGSC patients who underwent primary debulking surgery were enrolled. Molecular histopathological subtyping categorized cases into IR (n=16), MT (n=20), and Other (SP/PG, n=9). B7-H3 immunohistochemistry-stained whole slide images were analyzed using DeepPathFinder, an AI-based pathological image analysis tool that performs automated tissue segmentation and IHC marker quantification. B7-H3 expression was quantified across three tumor-associated compartments: tumor, peritumor (within 1000 μm of the tumor border), and necrosis. An integrated B7-H3 score was calculated as the mean density across these compartments. Survival analyses were performed using the Kaplan-Meier method and Cox proportional hazards regression. **Results:** The integrated B7-H3 score showed a stepwise increase across subtypes: IR (0.148) $<$ MT (0.219) $<$ Other (0.252) (Kruskal-Wallis p=0.091), and was significantly lower in IR compared to non-IR subtypes (0.148 vs 0.229, p=0.034). B7-H3 expression was consistently lower in IR across all compartments: tumor (IR: 0.171, MT: 0.205, Other: 0.257), peritumor (IR: 0.100, MT: 0.154, Other: 0.164), and necrosis (IR: 0.171, MT: 0.298, Other: 0.336; p=0.025). Survival analysis revealed significant prognostic differences among subtypes. Compared to IR, MT showed significantly worse outcomes (PFS: HR=8.35, 95% CI 3.00–23.24, p$<$0.0001; OS: HR=15.35, 95% CI 3.50–67.31, p=0.0003). The Other subtype also demonstrated inferior OS (HR=6.38, 95% CI 1.17–34.95, p=0.033). Both MT and Other (SP/PG) subtypes, which exhibited higher B7-H3 expression, were associated with worse prognosis. **Conclusions:** AI-based quantitative B7-H3 evaluation revealed subtype-specific expression patterns in the HGSC tumor microenvironment. B7-H3 expression was lowest in IR and higher in non-IR subtypes across all tumor-associated compartments. These findings suggest that patients with higher B7-H3-expressing subtypes may benefit from B7-H3-targeted therapy. Research Sponsor: None.

Vaccine-induced immune responses, HLA genotyping, and molecular profiling in patients with metastatic ovarian cancer (the PESCO trial). First Author: Ana Veneziani, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: PESCO, a phase 1/2 trial of Maveropepimut-S (MVP-S) in combination with Pembrolizumab and metronomic cyclophosphamide, showed safety and efficacy signals in metastatic ovarian cancer (OC). MVP-S uses the lipid-based DPX delivery platform to stimulate T cell immune response to survivin epitopes restricted by 5 HLA class I haplotypes (A1, A2, A3, A24, B7). Survivin is highly expressed in OC. We report exploratory correlative analysis including immune responses, HLA typing and molecular profiling. **Methods:** The study included a phase 1 dose escalation and expansion cohorts: A (platinum-sensitive high-grade serous [HGS]), B (platinum-resistant HGS), and C (rare OC histologies). Survivin-specific T-cell responses were assessed by flow cytometric detection of IFNγ following ex vivo PBMC re-stimulation with pooled survivin epitopes at on-treatment timepoints. A positive immune response was predefined as $>$0.1% IFNγ^+ CD8$^+$ T cells. HLA genotyping was mapped to MVP-S–restricted alleles. Molecular profiling was performed using next-generation sequencing (NGS) and/or whole-genome transcriptomic sequencing (WGTS). **Results:** Across 44 patients (pts), 37 (84%) carried $\geq$1 vaccine-relevant HLA allele and 23 (52%) carried $\geq$2. The most frequent alleles were A24 (16/44; 36%), A02 (15/44; 34%), A03 (12/44; 27%), B07 (11/44; 25%), and A01 (8/44; 18%). Survivin-specific immune responses were detected in 15/24 (62%) immune-evaluable pts and were strongly enriched among pts with clinical benefit: CR 1/1 (100%), PR 7/7 (100%), SD 6/10 (60%), versus PD 1/6 (16%); overall, 14/15 (93%) immune responders had clinical benefit. The longest survivin-specific response persisted for 195 weeks in a pt with MMR deficient tumor who had CR for 3 years. Exploratory HLA-outcome analysis suggested enrichment of A24 in pts with clinical benefit but absent in PD. NGS was performed in 44 pts and WGTS in 36. NGS identified at least one SNV/indel in 43/44 (97.7%) pts. In Phase 1 and Cohorts A/B (n=34, 68% HGS), TP53 was dominant (76.5%, 86% in HGS), followed by MYC (17.6%), NF1 (14.7%), and BRCA1/2 (each 8.8%). In Cohort C (n=10, 8 clear cell), ARID1A (70%) and PIK3CA (60%) were frequent. In platinum resistant pts (n=24), alterations included TP53 (67%), BRCA1/2 (21%), CCNE1(17%). Tumors with cell cycle/replication stress alterations were enriched among pts with PD (29% vs 8% in non-PD; P = 0.099) and immune non-responders (37.5% vs 6.7% in IFN responders; P = 0.103). Tumor mutation burden was low in all 26 pts tested. **Conclusions:** Survivin-specific immune responses were strongly enriched among pts with clinical benefit, supporting survivin as an active target in OC. HLA typing demonstrated broad coverage of MVP-S epitopes across pts. Molecular subtype may have influenced immune responses in this study. Our findings support biomarker-integrated studies to optimize immunotherapy combinations in OC. Clinical trial information: NCT03029403. Research Sponsor: None.

Addressing barriers to FRα-directed therapy integration in platinum-resistant ovarian cancer: A multi-phase, community-informed initiative. First Author: Kia Jones, Medlive - A PlatformQ Health Brand, Needham, MA

Background: Antibody–drug conjugates (ADCs) targeting folate receptor alpha (FRα) represent an important therapeutic advancement in ovarian cancer, introducing a new standard of care (SOC) for patients with FRα–positive platinum-resistant ovarian cancer (PROC). Despite this progress, real-world integration of FRα biomarker testing and FRα-directed therapies into clinical practice remains variable, particularly in community settings where most patients receive care. This multi-phase initiative was designed to assess real-world practice patterns and barriers related to FRα-directed care and to evaluate outcomes from an educational intervention addressing these gaps. **Methods:** Phase 1 formative research included a national claims data analysis, a community-based practice pattern analysis survey (n=100), and a clinician case crowdsourcing survey (n=100) examining biomarker testing practices, treatment sequencing, and perceived challenges in PROC care. Findings from Phase 1 informed development of a 60-minute, on-demand CME activity (Phase 2) targeting oncologists, gynecologic oncologists and pathologists, and APPs. Educational outcomes were assessed using pre-/post-activity knowledge and confidence measures, polling, and post-activity evaluations. Interim Phase 2 outcomes are reported. **Results:** Phase 1 analyses demonstrated variable use of FRα biomarker testing across the patient journey, with testing more frequently performed at initial diagnosis. Clinicians cited barriers including testing access and turnaround time, tissue adequacy, uncertainty around eligibility thresholds for FRα-directed therapy, and challenges in sequencing FRα-directed agents relative to other targeted options. Claims data showed continued predominance of cytotoxic regimens at first PROC progression. As of 2.5 months post-launch, over 5,100 clinicians have engaged with the education. Pre- to post-activity assessments demonstrated the largest gains in knowledge related to limitations of the current SOC in PROC and in understanding the role of FRα biomarker testing in informing treatment decisions. Confidence in appropriately incorporating FRα-directed therapies into treatment plans remained low at post-test. Intended practice changes included increased use of comprehensive biomarker testing (36%), reassessment of the role of PFI in treatment selection (41%), and routine FRα testing at recurrence (37%). **Conclusions:** This multi-phase initiative identified persistent gaps in FRα biomarker testing and therapeutic integration in PROC and demonstrated early educational gains in knowledge, with ongoing needs related to clinical application and confidence. These findings highlight the value of outcomes-driven education in addressing real-world barriers and supporting informed integration of FRα-directed therapies into PROC care. Research Sponsor: Genmab US, Inc.

Prognostic effect of neoadjuvant chemotherapy in gBRCA-mutated compared to gBRCA wild-type patients with advanced HGSOC treated with first-line PARP inhibitor maintenance: A large series propensity score–matching analysis. First Author: Ilary Ruscito, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: Recent results from the TRUST trial (ENGOTov33/AGO-OVAR OP.7) have renewed interest in the prognostic role of primary debulking surgery (PDS) versus interval debulking surgery (IDS) in advanced high-grade serous ovarian cancer (HGSOC). This study evaluated the prognostic impact of neoadjuvant chemotherapy (NACT) according to germline BRCA (gBRCA) status in advanced HGSOC patients receiving first-line PARP inhibitor (PARPi) maintenance, and its influence on outcomes at recurrence. **Methods:** We retrospectively identified patients with advanced HGSOC, treated between 2019 and 2024 at our gynecologic oncology referral center, who underwent upfront surgery and platinum-based chemotherapy followed by PARPi monotherapy. gBRCA status, surgical approach(PDS vs NACT+IDS), and survival outcomes, were collected. Patients were stratified by gBRCA status (gBRCAmut vs gBRCAwt). Propensity score matching (PSM) was performed based on age, ECOG-PS, FIGO stage, tumor histotype, surgical approach, and residual disease after first cytoreduction. Progression-free survival (PFS), overall survival(OS), post-recurrence PFS(PFS2), and post-recurrence OS(OS2) were analyzed. **Results:** After PSM, 406 patients were included (203 gBRCAmut and 203 gBRCAwt). In the gBRCAmut cohort, 58.6% underwent PDS and 41.4% received NACT+IDS, while 42.9% and 57.1% of gBRCAwt underwent PDS and NACT+IDS, respectively. All gBRCAmut patients received olaparib maintenance; among gBRCAwt, those with somatic BRCA mutations received olaparib (45/203) and the remainder niraparib (158/203). Complete cytoreduction was achieved in 92.1% of cases, with no differences between groups. Among gBRCAwt patients, median PFS was 43 months with PDS versus 19 months with NACT+IDS (p=0.008). Among gBRCAmut, median PFS was not reached with PDS and was 28 months with NACT+IDS ($p<0.001$). Median OS was not reached in either surgical group for gBRCAwt patients, whereas in gBRCAmut patients median OS was not reached with PDS and was 60 months following NACT+IDS ($p<0.001$). At recurrence, PFS2 did not differ by upfront treatment. However, NACT+IDS was associated with inferior OS2 in both gBRCAwt (p=0.019) and gBRCAmut (p=0.048) patients, with shorter median OS2 observed in gBRCAmut (15 vs 18 months). **Conclusions:** NACT was associated with inferior survival outcomes in advanced HGSOC patients receiving first-line PARPi, with a more pronounced detrimental effect observed in gBRCAmut patients. This suggests that BRCA-mutated tumors, despite their intrinsic sensitivity to PARP inhibition, may be particularly vulnerable to the negative consequences of delayed cytoreduction, with potential implications for treatment sequencing and surgical decision-making. Research Sponsor: None.

Onsite serial monitoring of high grade serous ovarian cancer (HGSOC) mutations in circulating tumor DNA (ctDNA) via droplet digital PCR. First Author: John Nakayama, Allegheny Health Network, Pittsburgh, PA

Background: Comprehensive Genomic Profiling (CGP) of tumor and blood samples is increasingly employed for ovarian cancer diagnosis. We used diagnostic CGP sequencing results (523 genes) to identify mutations in HGSOC patients for surveillance of tumor treatment response by an onsite ddPCR assay (Bio-Rad, Hercules, CA). We compared ctDNA mutations to imaging (computed tomography & MRI) and CA125 values across a cohort of HGSOC patients undergoing surgery followed by platinum-based therapy with diverse outcomes. **Methods:** CGP mutations from matched index tumor, plasma and buffy coat cell samples (TSO-500, Illumina) were used to identify tumor- and patient-specific, coding mutations for interrogation of serial blood samples. Concordance was high for tumor and blood (MED = 97.1%, Q1: 93.3%, Q3: 98.8%) and 15 patients with inclusive longitudinal samples were selected for retrospective analysis of ctDNA samples versus CA-125, imaging and outcomes. Mutation variant allele frequency (VAF) suitable for primer construction ranged in variant allele frequency (VAF) from 0.5 to 24.4% (MED = 2.5%, Q1: 1.2; Q3: 3.8%) in cfDNA. A lower limit of detection (LLOD) of 1 to 2 copies/nanogram cell free DNA (cfDNA) was established using synthetic gene Block targets and FFPE tumor dilutions. **Results:** There was a significant correlation (r^2= 0.85, $p<0.0001$) of initial target cfDNA VAF and numbers of mutation copies detected per nanogram cfDNA. There was no significant correlation of mutation copies with index or serial CA125 values (r^2=0.11, p=0.38) over the wide range of CA125 values across the patient cohort. However, all patients displayed parallel dynamic changes in multiplex ctDNA mutations and CA125 values with variations in disease status and outcome over 1-3 years. Platinum-sensitive patients with a sustained response to therapy (n=3) based on imaging and CA 125 values displayed rapid elimination of tumor mutations via ddPCR prior to stabilization of "normal" CA125 values. Absence of mutations was further validated by interrogating 5X concentrated patient cfDNA aliqouts. Three patients (platinum-resistant) that initially responded to treatment by imaging and declining CA 125 values never achieved ctDNA mutation levels below the LLOD. These patients subsequently displayed tumor escalation with correlative increases in ctDNA mutation levels and CA125 values. **Conclusions:** Patient mutation monitoring via ddPCR of blood samples collected and processed onsite, provided rapid, iterative and quantitative results consistent with radiographic imaging and CA 125 assays. In addition, durable remission cases were characterized by rapid loss of mutations detected by ctDNA ddPCR assays prior to imaging and diminution of CA125 values. Low levels of ctDNA mutations above LLOD persisted in responders who otherwise achieved normal CA125 values but later developed disease progression. Research Sponsor: None.

The use of circulating tumor DNA to stratify the risk of recurrence after surgical debulking in epithelial ovarian cancer. First Author: Muhammad Anees, Allegheny Health Network Cancer Institute, Allegheny Health Network, Pittsburgh, PA

Background: Accurate risk stratification after debulking surgery in ovarian cancer remains challenging. Although surgical debulking status (SDS) and CA125 are standard prognostic markers, patients remain at high risk of recurrence despite optimal debulking and normalization of CA125. Circulating tumor DNA (ctDNA) has emerged as a sensitive biomarker for detecting molecular residual disease (MRD). We evaluated the prognostic value of post-surgical ctDNA compared with SDS and post-surgical CA125 in predicting recurrence. **Methods:** In a prospectively collected cohort of ovarian cancer patients undergoing standard-of-care treatment, we evaluated 37 patients with a reportable post-surgical MRD before initiation of adjuvant chemotherapy. Tumor-informed, patient-specific panels created from whole genome sequencing of matched tumors and normal samples were used to assess MRD (Precise MRD, Myriad Genetics). Postoperative CA-125 was stratified using a standard clinical cutoff of 35 U/mL. Median follow-up was 30 months (IQR 21.9). **Results:** Post-operative ctDNA was detected in 75.7% (28/37) of patients with 24.3% (9/37) detected at ultra-low levels ≤100 PPM. Among ctDNA-positive patients, 85.7% (24/28) recurred, compared with no recurrences among ctDNA-negative group (median PFS: 7.6 [3.0-23.2] months vs. not reached; $p<0.001$). Post-operative CA125 showed a similar trend with elevated-CA125 patients having a shorter median PFS (7.5 [2.8-21.1] vs. 25.1 [9.7-58.0]; $p<0.05$). Optimal SDS showed a trend toward longer median PFS (Optimal: 22.0 [4.1-58.0] vs. suboptimal: 10.8 [2.8-19.9], p=0.075). Notably, all patients with suboptimal SDS and detectable ctDNA experienced recurrence (4/4). Among patients achieving no gross residual disease (NGR; n=25), ctDNA strongly stratified outcomes: 82.4% (14/17) of ctDNA-positive patients recurred, whereas there we no recurrences in ctDNA-negative patients (median PFS: 4.6 [2.9-38.9] vs. not reached; $p<0.001$). The median tumor fraction (TF) within this cohort for positive cases was 432.0 PPM (IQR: 49.4–2510.0), where 29.4% (5/17) were detected below 100 PPM. Similarly, within the NGR group, normal-CA125 patients demonstrated a trend toward improved PFS (38.9 [6.9-58.0] vs. 4.6 [2.7-23.2]; p=0.11). Importantly, among patients with normal-CA125 (n=15), ctDNA further discriminated risk: 90% (9/10) of ctDNA-positive patients recurred with a median PFS of 20.3 (4.1-38.9) months, while no recurrences occurred in ctDNA-negative patients ($p<0.05$). Within this subgroup, the median TF was 235.0 PPM (IQR: 71.4–2640.0), where 26.7% (4/15) were below 100 PPM. **Conclusions:** Post-operative ctDNA after surgical debulking predicts early recurrence in ovarian cancer, including patients with NGR, supporting its role as a biomarker of MRD and postoperative risk stratification along with CA125. Precision histopathologic classification of epithelial ovarian cancer subtypes using a computationally efficient multilayer perceptron framework with global validation. First Author: Elangovan Krishnan, AIM DOCTOR, Thiruverkadu, India

Background: Epithelial ovarian cancer is the leading cause of gynecologic cancer mortality, with treatment and prognosis strongly dependent on accurate histopathologic subtype classification. The five major epithelial subtypes—high-grade serous, low-grade serous, endometrioid, mucinous, and clear cell carcinoma—exhibit distinct clinical behaviors, yet conventional interpretation is limited by subjectivity and interobserver variability. Although deep learning has advanced digital pathology, most high-performing models require substantial computational resources, limiting clinical scalability. We evaluated whether a lightweight multilayer perceptron (MLP) combined with structured dimensionality reduction could enable accurate and globally deployable ovarian cancer subtyping. **Methods:** We analyzed 9,521 anonymized histopathology image patches representing five epithelial ovarian cancer subtypes from publicly available datasets with expert pathologist consensus ground truth. Images underwent Gaussian random projection followed by principal component analysis to preserve discriminative morphologic features. A feedforward MLP (2,048→1,024→512→5 neurons) with batch normalization and dropout (p=0.3) was trained using AdamW optimization with cosine annealing over 50 epochs on 80% of the data. External validation was performed on independent datasets. Performance metrics included accuracy, sensitivity, specificity, F1 score, and AUROC. The model was deployed on a cross-platform digital pathology system and evaluated by pathologists across six continents. **Results:** The MLP achieved 97.4% test accuracy with balanced subtype performance. Sensitivity ranged from 94.2% to 99.3%, with a macro-averaged F1 score of 0.993 and AUROC $>$0.99 for all classes. External validation accuracy ranged from 91% to 93% across heterogeneous staining protocols. Sensitivity for low-grade serous carcinoma (92.1%) exceeded reported interobserver agreement (52–73%). Inference time averaged 0.33 seconds per image on standard CPU hardware. Pathologists rated the system clinically useful in $>$90% of evaluations. The model contained 2.8 million parameters, representing an 89% reduction compared with conventional convolutional architectures. **Conclusions:** A computationally efficient MLP enables accurate and reproducible epithelial ovarian cancer subtype classification while substantially reducing computational complexity. This approach mitigates interobserver variability and supports scalable AI-assisted pathology deployment. Prospective multicenter studies are warranted to assess integration into routine diagnostic workflows and impact on treatment stratification. Research Sponsor: None.

High-dimensional multiplex immunofluorescence to reveal immune microenvironment remodeling in matched primary and recurrent serous ovarian cancer. First Author: Yookyung Lee, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea

Background: Recurrent serous ovarian cancer is associated with treatment resistance and poor prognosis, and changes in the tumor immune microenvironment (TIME) during recurrence have been suggested to contribute to these clinical features. However, spatial studies that quantitatively compare immune cell composition between primary and recurrent tumors at the single-cell level within the same patients remain limited. This study aimed to compare the TIME of primary and recurrent serous ovarian cancer using high-dimensional multiplex immunofluorescence. **Methods:** Tissue microarray (TMA) were constructed from formalin-fixed, paraffin-embedded (FFPE) tumor samples obtained from patients with primary and recurrent serous ovarian cancer. High-dimensional multiplex immunofluorescence staining was performed using the Akoya IO60 panel. Single-cell image analysis was conducted to segment cells and classify them into 19 distinct cell types. Differences in cell proportions were evaluated using unpaired analyses across all cores and paired analyses using matched primary-recurrent samples from the same patients (n=35). For paired analyses, cell proportions were compared using paired t-tests. **Results:** The 19 cell types included tumor epithelial cells, immune cell populations, and stromal cell populations. In unpaired analyses, recurrent tumors showed differences in immune cell composition compared with primary tumors, with relatively higher proportions of T cell-macrophage-associated populations and B cells. In paired analyses of matched samples (n=35), the proportion of T cell-macrophage-associated populations was significantly increased in recurrent tumors compared with primary tumors (p=0.0042). The proportion of B cells was also higher in recurrent tumors (p=0.0463). No statistically significant differences were observed in other cell types. **Conclusions:** Using high-dimensional multiplex immunofluorescence–based spatial analysis, we compared the tumor immune microenvironment of primary and recurrent serous ovarian cancer at the patient-matched level. Paired analyses demonstrated increased proportions of T cell-macrophage-associated populations and B cells in recurrent tumors, suggesting selective remodeling of the immune microenvironment during disease recurrence. Bevacizumab rechallenge in platinum-resistant ovarian cancer: Evidence from a propensity score–matched analysis. First Author: Celso Silva Sousa Filho, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: Bevacizumab is approved for the treatment of ovarian carcinoma across multiple disease settings, from first-line therapy to late platinum-resistant recurrences (PROC). The greatest relative benefit of bevacizumab has been observed in the platinum-resistant setting. While evidence supports bevacizumab rechallenge in the first platinum-sensitive recurrence, no randomized trial has demonstrated a benefit of bevacizumab rechallenge in PROC. **Methods:** We conducted a retrospective cohort study including patients with PROC treated with chemotherapy with or without bevacizumab. Patients were matched using propensity score matching based on histology (HGSC vs others), chemotherapy backbone, line of platinum-resistant treatment, age, BRCA pathogenic variant status, and prior bevacizumab exposure. Nearest-neighbor matching with a 1:2 ratio (bevacizumab:non-bevacizumab) and a caliper of 0.2 was applied. Balance between groups was assessed using standardized mean differences. Progression-free survival (PFS) and overall survival (OS) were estimated using Kaplan–Meier methods and compared using log-rank tests. Hazard ratios (HRs) were estimated using Cox proportional hazards models with robust variance accounting for matching. Subgroup analyses were performed according to prior bevacizumab exposure, and treatment–exposure interaction was formally tested. **Results:** A total of 149 patients with PROC were included. Baseline clinicopathologic characteristics were well balanced between treatment groups. In the overall matched cohort, bevacizumab use was associated with significantly improved PFS compared with chemotherapy alone (median PFS 7.79 vs 4.37 months; HR 0.49, 95% CI 0.36–0.68; p$<$0.001), as well as improved OS (median OS 23.06 vs 10.45 months; HR 0.47, 95% CI 0.34–0.66; p$<$0.001). In bevacizumab-naïve patients, bevacizumab remained significantly associated with longer PFS (median 7.79 vs 4.04 months; HR 0.47, 95% CI 0.33–0.68; p$<$0.001) and OS (median 23.06 vs 10.05 months; HR 0.46, 95% CI 0.32–0.67; p$<$0.001). Among patients previously exposed to bevacizumab, re-exposure was associated with numerically longer PFS (median 8.49 vs 4.89 months; HR 0.61, 95% CI 0.31–1.20; p=0.15) and OS (median 21.29 vs 10.45 months; HR 0.54, 95% CI 0.26–1.11; p=0.09), although these differences did not reach statistical significance. There was no statistically significant interaction between prior bevacizumab exposure and treatment effect for PFS (p for interaction = 0.60). **Conclusions:** The addition of bevacizumab to chemotherapy is associated with significant benefit in bevacizumab-naïve patients with PROC. In patients previously exposed to bevacizumab, re-exposure was not associated with a statistically significant improvement in outcomes, underscoring ongoing uncertainty regarding the role of bevacizumab rechallenge in this setting. Research Sponsor: Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP); 2024/13952-4.

AI-driven multi-scale histopathologic classification of epithelial ovarian cancer to support precision oncology. First Author: Yashwanth Kancharla, Harnett Health GME, Dunn, NC

Background: Epithelial ovarian cancer (EOC) comprises five histologically distinct subtypes associated with divergent molecular profiles, therapeutic responsiveness, and prognostic outcomes. Accurate histologic classification is essential for precision oncology but remains limited by morphologic overlap and interobserver variability. Deep learning architectures capable of multi-scale spatial feature extraction may enable objective and reproducible subtype discrimination. We evaluated the performance of a multi-scale factorized convolutional neural network (InceptionV3) for automated EOC subtype classification. **Methods:** Digitized hematoxylin–eosin–stained histopathology images were obtained from the University of British Columbia Ovarian Cancer Subtype Classification and Outlier Detection (UBC-OCEAN) dataset, including high-grade serous, low-grade serous, endometrioid, clear cell, and mucinous carcinomas. An ImageNet-pretrained InceptionV3 architecture was fine-tuned using a five-class classification head. The model leverages parallel convolutional branches with factorized asymmetric kernels to simultaneously capture fine cellular features and global tissue architecture. Images were normalized and augmented. Training was performed using 299$\times$299 inputs, Adam optimizer (learning rate 1×10^{-4}), cross-entropy loss, and six epochs. Performance was assessed using accuracy, precision, recall, F1-score, and macro-averaged AUROC. External clinical validation was conducted by 57 board-certified gynecologic pathologists and oncologists across 14 geographic regions. **Results:** The model achieved an overall accuracy of 95.0% (491/517 test images). Subtype-specific F1-scores were 0.96 for high-grade serous carcinoma, 0.94 for endometrioid, 0.93 for clear cell, 0.92 for mucinous, and 0.88 for low-grade serous carcinoma. Macro-averaged AUROC was 0.957 (95% CI, 0.948–0.966). Computational efficiency was preserved with 23.9 million parameters and 11.6 billion FLOPs. Independent clinician validation demonstrated strong concordance with AI predictions, with mean inter-rater agreement of 95.3% (κ=0.936; 95% CI, 0.923–0.949), consistent across institutional practice settings. **Conclusions:** Multi-scale factorized convolutional modeling enables near-expert performance for automated EOC subtype classification by integrating cellular- and tissue-level morphologic features. High inter-rater concordance with an international specialist cohort supports translational reliability. This framework represents a scalable decision-support tool with potential to improve diagnostic standardization and precision therapeutic stratification. Prospective multi-center validation is warranted. Research Sponsor: None.

The role of combined T cell and NK cell activity in immune checkpoint inhibitor (ICI) therapy in endometrial cancer (EC). First Author: Danielle Greenberg, UC Irvine Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, Orange, CA

Background: The efficacy of ICI in EC has largely been attributed to high microsatellite instability (MSI-H) causing increased tumor mutational burden (TMB) and T-cell mediated immunity. However, a subset of patients with microsatellite-stable (MSS) tumors also derive clinical benefit, indicating that MSI status alone is insufficient for patient selection and contributing to the 2024 Food and Drug Administration approval of chemotherapy plus ICI for all patients with EC. We evaluated established biomarkers of a T-cell–inflamed tumor microenvironment alongside alternative immune pathways, notably natural killer (NK) cell activity, to define determinants of overall survival (OS) benefit in EC patients treated with ICI. **Methods:** Patients with EC treated with pembrolizumab or dostarlimab were identified from the Caris Life Sciences database with paired whole exome and transcriptome sequencing (WES/WTS). OS was defined from ICI initiation to death or last contact via insurance claims. Patients were grouped as long vs short survivors (LS/SS) by median post-ICI OS (mOS). Associations between OS and expression of pre-annotated T- and NK-cell-related genes were analyzed with Kaplan–Meier and multivariable Cox models adjusting for clinicopathologic factors. **Results:** Of 6,354 patients, 25% were MSI-H and 71% MSS. Immune deconvolution of WTS showed higher levels of $CD8^+$ T cells (p=0.034) and regulatory T cells (p=0.026) in LS vs SS. In multivariable analyses of the MSS subset, 63 T- and NK-cell–related genes were associated with improved OS, including FASLG (mOS 19.7 months vs 14.7 months in LS vs SS, HR=0.77, CI 0.70–0.85), IFNG (mOS 18.9 months vs 15.5 months in LS vs SS, HR=0.78, CI 0.71-0.86) and SIRPG (mOS 18.8 months vs 15.6 in LS vs SS, HR=0.79, CI 0.71-0.87) (all $p<0.0001$). The IFN Tumor Inflammation Signature (TIS) was not associated with OS in MSS EC, whereas T-cell, NK-cell, and combined T/NK gene signatures were (Table 1). **Conclusions:** Improved OS after ICI in MSS EC is associated with both T-cell and NK-cell activity. NK-cell–related and combined T/NK signatures were associated with improved survival, suggesting NK-cell activation contributes to ICI efficacy. These findings warrant validation in independent cohorts prior to use as a potential biomarker for ICI use in MSS EC. Research Sponsor: None.

T/NK signature scores are associated with improved OS in MSS EC.

Label	HR (95% CI)	*P* value
Gene set		
NK (high vs low)	0.82 (0.74–0.90)	<0.001
T + NK (high vs low)	0.84 (0.77–0.93)	0.001
T (high vs low)	0.84 (0.77–0.93)	0.001
Covariate		
p53: mutant vs wildtype	1.54 (1.38–1.73)	<0.001
TMB: high vs low	0.66 (0.49–0.90)	0.008
Chemotherapy: yes vs no	1.13 (0.98–1.31)	0.101
Biopsy site: metastasis vs primary	0.92 (0.83–1.02)	0.124
Lenvatinib: yes vs no	0.95 (0.86–1.05)	0.293

Multivariable Cox models adjusted for p53 status, TMB, site, chemotherapy and lenvatinib use.

Sequencing of fallopian tube p53 signature found concurrently with p53 mutant uterine cancers and their somatic mutation profiles. First Author: Erika Joelle Lampert, UPMC Magee, Pittsburgh, PA

Background: The tumor protein 53 gene (p53) encodes a protein that suppresses replication of DNA-damaged cells. Mutations resulting in protein dysfunction are common in many cancers. A p53 signature is an aberrant immunohistochemical expression in 12 or more consecutive epithelial cells in the fallopian tube (FT) and is thought to be an early precursor lesion in a spectrum to high grade serous ovarian carcinoma (HGSOC). P53 mutations have also been described in endometrial cancer (EC), specifically high grade histologies such as uterine papillary serous carcinoma (UPSC). NextGen Sequencing of UPSC tumors and concurrent FT lesions has identified overlapping p53 mutations, raising the possibility that these could represent a precursor lesion. The objective of this study was to delineate the clonal relationship between p53-mutation harboring epithelial lesions in the FT and other histologic subtypes of EC, which could have implications for risk stratification, counseling, and treatment. **Methods:** We identified 7 patients with EC and a concurrent p53 FT signature. DNA extraction (Qiagen) from FFPE samples was performed and sent for whole genome sequencing (Novogene) on the paired FT and endometrial tissues to identify the specific p53 mutations. Using a position-wise comparison, we evaluated the clonal relationship between the specific p53 mutations identified in each pair. **Results:** In this cohort, 4 patients had endometrioid adenocarcinoma, 1 had mixed endometrioid and carcinosarcoma, 1 had high grade endometrial stromal sarcoma (ESS), and 1 had UPSC. All 7 patients had a p53 signature identified in the FT. Four patients had p53 overexpression while 3 had heterogenous p53 expression in the endometrium on IHC. Among the 7 patients, sequencing revealed 5 pairs with at least 1 shared somatic mutation identified in both the endometrium and FT. A shared mutation was identified in patients with carcinosarcoma, high grade ESS, UPSC, and two endometrioid adenocarcinomas. As of 9/2025 or last follow-up, no patients had developed a primary peritoneal malignancy, but 2 patients had disease recurrence. Both patients who had disease recurrence were among those with a shared somatic mutation identified. **Conclusions:** To our knowledge, this is the first study evaluating the relationship between concurrent FT p53 signatures and uterine cancer beyond serous. We identified 5 patients with at least 1 shared somatic p53 mutation. While these specific mutations have not been described as known pathogenic driver mutations in the literature to date, further exploration into these alleles is needed. A clonal relationship between FT lesions and endometrial cancer could have important implications on clinical counseling and management, thus further research into the specific p53 mutations identified and validation within a larger cohort is warranted. Research Sponsor: None.

Ultra-sensitive circulating tumor DNA (ctDNA) detection as predictor of survival outcomes in endometrial cancer patients undergoing frontline treatment. First Author: Jeffrey Andrew How, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: For endometrial cancer (EC), clinicopathologic and molecular characterization add to the risk stratification complexity, but remain limited to predict risk of recurrence. Precise biomarkers are needed to guide treatment. This study seeks to investigate the value of circulating tumor DNA (ctDNA) in EC patients. **Methods:** In an ongoing, single-institution prospective study of EC patients undergoing primary surgical management, serial plasma samples were collected at multiple timepoints: pre-(pre-op)/post-operatively (post-op), post-definitive treatment (dTx), and surveillance. If patients did not have adjuvant therapy, the post-op time point was considered the dTx timepoint. ctDNA analysis was performed on banked samples at the non-surveillance timepoints using NeXT Personal, a personalized whole genome sequencing-based tumor-informed assay tracking up to 1800 mutations, (Personalis, Fremont, CA). Primary endpoint was ctDNA detection rate. Secondary endpoints included correlation with survival outcomes (recurrence free survival [RFS] and overall survival [OS]). Multivariable analysis was performed for RFS adjusting for dTX ctDNA detection, stage, and TP53 mutation status. Given the limited number of deaths, multivariable analysis was not performed for OS. **Results:** 99 patients and 254 samples were included for ctDNA analysis. Median age at surgery was 65.1 (range 42-85) years. After a median follow-up of 24.1 (range 3.4 – 67) months, there were 25 recurrences and 10 deaths. Majority had stage I (68.7%), grade 3 (73.7%) tumors, non-endometrioid histologic tumor components (63.7%), and received adjuvant therapy (79.8%; therapy declined in 4 [4%] patients). Adjuvant radiation and chemotherapy was given in 67 (67.7%) and 53 (53.5%) patients, respectively. ctDNA was detected in 83.3% (75/90) of pre-op, 19.5% (17/87) of post-op, and 14.1% (9/64) of dTx samples. Although pre-op ctDNA was not associated with survival, post-op ctDNA detection was associated with worse RFS (HR 6.3, 95% CI 2.6-15.5; $p<0.001$) and OS (HR 24.6, 95% CI 3-205; p=0.003). Post-op detection in the ultrasensitive range (<100 PPM) were also significantly prognostic of worse RFS (HR: 5.1, 95% CI 1.3-19.5, P=0.02). Similarly, dTx detection was associated with worse RFS (HR 27.7, 95% CI 8.9-86.6; $p<0.001$) and OS (HR 7.5, 95% CI 1.7-33.7; p=0.01). On multivariable analysis, dTx detection was independently associated with worse RFS (HR 27.7, 95% CI: 8.9-86.6; $p<0.001$). **Conclusions:** In a predominantly early-stage, high-risk cohort of EC patients, post-op and dTx ctDNA detection is associated with inferior survival. ctDNA detection in the ultrasensitive range may hold promise to identify EC patients at risk for recurrence which may not be identified in conventional assays. These results support ctDNA as a promising biomarker for clinical decision-making in EC. Research Sponsor: None.

Pembrolizumab–lenvatinib beyond immunotherapy progression in endometrial cancer: A real-world analysis. First Author: Alberto Farolfi, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: The integration of immune checkpoint inhibitors (ICIs) into frontline therapy for advanced or recurrent endometrial cancer (aEC) has transformed treatment paradigms. However, the management of patients who experience disease progression after ICI-based therapy remains challenging. In the absence of prospective guidance, ICI rechallenge and ICI-based combinations beyond progression are already being used in clinical practice. In this real- world study, we aimed to evaluate the effectiveness of pembrolizumab-lenvatinib (PL) beyond ICI progression in patients with aEC. **Methods:** A retrospective study was conducted using the TriNetX database, defining two cohorts of aEC patients: 527 patients who received PL and 2,582 patients who did not receive PL but were treated with either paclitaxel or doxorubicin (chemotherapy, CHT cohort). Both cohorts had received an ICI-based regimen within the previous three years. Patients with any other malignancy were excluded. Propensity score matching (PSM) was used to balance cohorts for age, race, body mass index (BMI), major comorbidities, mismatch repair (MMR) status and prior olaparib exposure. The primary endpoint was overall survival (OS); secondary endpoints were treatment-related toxicities, including hypothyroidism and heart failure. OS was estimated using Kaplan–Meier methods, with hazard ratio (HR) used to compare OS and odds ratio (OR) used to compare toxicities. **Results:** After PSM, 521 matched pairs of patients (mean age +/- standard deviation: 66,4 +/- 9,6 years) were included in the PL and CHT cohorts, respectively, with well-balanced baseline characteristics. Asian patients were similarly represented in the two groups (7.3% vs 7.4%), most patients were obese (BMI ≥30: 59,3% vs 57,8%), only a small proportion had known MMR-deficient disease (2.1% and 1.9%), and just few of them were previously treated with olaparib (1.9%). After a median follow-up of 8.6 months (interquartile range, IQR 14.3) in the PL cohort and 11.5 months (IQR 16.7) in the CHT cohort; median OS was 27,4 months with PL and was not reached with CHT (HR = 2.25, 95% CI 1.76–2.89; $p<0.001$). **Conclusions:** The rise of ICIs in frontline therapy for aEC marks a paradigm shift and raises the question on how to manage patients who progress after prior immunotherapy. This is the first large, real-world cohort analysis to evaluate PL beyond immunotherapy progression in aEC. In this study, PL did not improve OS compared with CHT in patients previously exposed to ICIs. These findings suggest that PL may not be the optimal choice in this setting, and further work is needed to clarify the best post-ICI sequencing strategies and to develop approaches to overcome resistance. Circulating tumor DNA (ctDNA) from a phase II study of adjuvant dostarlimab with pelvic radiation in locally advanced, mismatch repair–deficient (MMR-D) endometrial cancer (D-RT study). First Author: Gabriela Sotolongo, Gynecologic Oncology Service, New York, NY

Background: Although ctDNA is a promising, non-invasive tool for cancer evaluation and monitoring, it's use in endometrial cancer (EC) is currently limited. We sought to evaluate ctDNA dynamics and associations with clinical outcomes as part of a novel study of adjuvant immune checkpoint blockade (ICB) with radiation (RT) in locally advanced MMR-D EC. **Methods:** The D-RT study was an investigator-initiated, single-arm, phase II trial evaluating the safety and efficacy of 5 cycles of dostarlimab given concurrently with standard pelvic intensity modulated RT (IMRT), NCT04774419. The study included patients with newly diagnosed clinical stage III/IVA MMR-D EC. Primary endpoint was progression-free survival (PFS) at 2 years defined by RECIST V1.1 compared with historical control. All patients consented to MSK-IMPACT tumor-normal genetic testing. We performed MSK-ACCESS targeted ctDNA sequencing in a subset of patients with at least 3 timepoints (baseline post-surgery, on-treatment, post-treatment/follow-up) and correlated with baseline tumor genomics and clinical outcomes. **Results:** We previously reported the primary endpoint in 31 evaluable patients with 2-year PFS of 80.6% (95% 1-sided CI 65.3-100%), meeting pre-specified threshold for a positive study (data cutoff 8/1/2025). Here, we report ctDNA results from a subset of 15 patients with 58 total samples. Median age was 62 years (range 51-89 years) with 1 stage IB (i+), 3 stage IIIA, 9 stage IIIC1, and 2 stage IIIC2 MMR-D ECs (FIGO 2009). Histology included 8 endometrioid grade I/II, 5 endometrioid grade III, and 2 dedifferentiated carcinomas. Six patients (40%) had detectable baseline ctDNA post-surgery, with 5/6 (84%) having visible/residual disease at baseline. Of these, 3/6 (50%) had eventual disease recurrence post adjuvant treatment. In 8 patients with visible disease post-surgery, only 2 did not have detectable baseline ctDNA. ctDNA cleared post-treatment in all but 2 patients who had aggressive, dedifferentiated carcinomas. Among the 5 patients with recurrence (4 distant, 1 local), ctDNA detection preceded or coincided with radiographic detection of disease in the 4 patients (80%) with distant disease. One patient had a biopsy-proven, vaginal cuff recurrence only and never had detectable ctDNA. In the 10 patients without disease recurrence, none had detectable ctDNA post-treatment. **Conclusions:** In patients with locally advanced MMR-D EC, ctDNA detection after surgery correlated with visible disease. ctDNA levels declined during dostarlimab and RT treatment for most patients, and ctDNA detection was correlated with disease recurrence in distant but not local disease, suggesting its potential as a non-invasive marker of disease. Future studies should explore the utility of ctDNA as a disease monitoring tool to guide therapy decisions. Clinical trial information: NCT04774419. Research Sponsor: Federal; GSK.

Forecasting global disparities in cervix and corpus uteri cancers: GLOBOCAN 2022–2040 projections. First Author: Sonia Babu, Mercy Catholic Medical Center, Darby, PA

Background: Uterine cancers, including cervix uteri (C53) and corpus uteri (C54), are a major burden on global healthcare with marked geographic and socioeconomic disparities. Key risk factors including persistent high-risk HPV infection for cervical cancers), limited screening access, and modifiable factors like obesity and exogenous hormone exposure (e.g., oral contraceptive use), which vary across settings and could influence future burden. Predicting epidemiological trends is essential to guide prevention, screening, and treatment modalities. This study compares predicted changes in incidence and mortality for C53 and C54 across countries, WHO regions, income groups, and HDI categories from 2022 to 2040. **Methods:** Incidence and mortality data for 2022 and predictions for 2040 were extracted from GLOBOCAN database for 185 countries. Countries were classified by WHO region, World Bank income level, and HDI categories. Percentage changes in incidence and mortality were calculated for both cancer types across all categories. **Results:** Globally, C53 incidence is forecasted to rise from 1.32 million to 5.94 million cases (+348.4%), with mortality increasing from 697,418 to 3.41 million deaths (+389.5%). C54 shows a modest increase in incidence (840,256 to 899,224; +7.0%) but substantial increase in mortality (195,310 to 899,224; +360.5%). Across WHO regions, the largest increases in C53 incidence and mortality occur in AFRO and EMRO (+1043%, +1066% and +918%, +1029%, respectively). C54 incidence advances most in AFRO (+279%) and EMRO (+254%) and least in EURO (+97.8%). Mortality growth is highest in EMRO (+1205%) and AFRO (+1106%). Income-level patterns show increasing disparities: low-income countries have the highest increases for C53 incidence (+1062%) and mortality (+1073%), with high-income regions showing the lowest (+693%, +781%). Similar trends are observed for C54, with incidence rising most in low-income settings (+302%) and least in high-income regions (+139%), while mortality increases range from +1096% (low-income) to +872% (high-income). HDI patterns are similar to income trends: Low-HDI countries reveal the highest increases for C53 (+1062% incidence, +1073% mortality) and C54 (+302%, +1096%), while Very-High-HDI regions show the lowest rises for both cancers. **Conclusions:** Burden of uterine cancer is predicted to rise steeply by 2040, with greatest increases in low-income, low-HDI, AFRO, and EMRO regions. The disproportionate escalation in mortality (especially for corpus uteri cancers) highlight the importance of prevention, screening, early detection, and equal access to treatment to prevent expanding global disparities, including improved availability of HPV vaccination, targeted public education efforts, and engagement of primary care physicians and OB/GYNs to ensure that patients are vaccinated and screened appropriately. Research Sponsor: None.

A phase II trial of lenvatinib plus pembrolizumab in patients (pts) with endometrial or ovarian carcinosarcoma. First Author: Sminu Bose, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Carcinosarcoma is a rare and aggressive histology of gynecologic carcinomas that has limited treatment options and is often excluded from larger therapeutic clinical trials. In KN775, treatment with multikinase inhibitor lenvatinib plus PD-1 inhibitor pembrolizumab led to significantly longer progression-free survival (PFS) and overall survival (OS) than chemotherapy among patients with previously treated advanced non-carcinosarcoma endometrial carcinomas. We report results from a phase 2 trial of lenvatinib + pembrolizumab in pts with endometrial or ovarian carcinosarcoma. **Methods:** In this open label, single institution, investigator initiated, phase 2 study, pts had confirmed recurrent/persistent endometrial or ovarian carcinosarcoma with progression after at least 1 prior platinum chemotherapy but no more than 3 prior lines, measurable disease, and ECOG performance status $\leq$1. Pts received oral lenvatinib 20 mg/day plus pembrolizumab 200 mg intravenously every 3 weeks. The primary endpoints were objective response rate (ORR) per RECIST v1.1 and PFS rate at 27 weeks (PFR27). Secondary endpoints included median duration of response (mDOR), clinical-benefit rate (CBR: complete response (CR) + partial response (PR) + stable disease (SD) at 27 weeks), median overall survival (mOS), and safety. Next generation sequencing, MSK-IMPACT, was performed on tumors from all 27 patients for exploratory analysis. **Results:** As of data cutoff on 12/15/2025, 27 pts enrolled; median age was 63 years (range: 51−79); and at least 26.4% pts were non-white. Primary tumor site was 63% (17/27) endometrial and 37% (10/27) ovarian; tumors were 19% (5/27) dMMR and 81% (22/27) pMMR. Confirmed ORR was 18.5% (5/27; 0 CRs, 3 PRs in endometrial, 2 PRs in ovarian), meeting the interim analysis primary endpoint. Of the 5 confirmed responses, 4 occurred in pts with pMMR tumors, and 1 in a pt with dMMR tumor. There are 2 additional unconfirmed PRs. Responses in pts with ovarian tumors included 1 platinum-sensitive and 1 platinum-resistant. PFR27 was 35.7% (90% CI: 24 - 100), mDOR was 26.5 months (80% CI: 3.8 - NE), CBR was 37% (80% CI: 24.4 - 51.2), and mOS was 15.3 months (95% CI: 7.1 – 24.4). Two pts remain on treatment and were censored for time to event analyses. All pts had at least one treatment-emergent adverse event (TEAE). The most common TEAEs were fatigue (74%), hypertension (56%), diarrhea (52%), anorexia (48%), and weight loss (48%). Grade 3 and 4 TEAEs occurred in 44% and 7.4% patients, respectively. There were no grade 5 TEAEs. 5 Pts (19%) discontinued study treatment due to TEAEs. Further genomic analyses are underway. **Conclusions:** Encouraging efficacy and durable responses were observed in endometrial and ovarian carcinosarcoma pts treated with lenvatinib + pembrolizumab, regardless of MMR status or primary site. The study met its predefined interim analysis endpoint. No new safety signals were identified. Clinical trial information: NCT02501096. Research Sponsor: None.

Antibody-drug conjugate (ADC) biomarker targets in endometrial cancer (EC): Molecular characterization and implications for therapeutic decision-making. First Author: Britt Kristina Erickson, University of Minnesota, Masonic Cancer Center, Minneapolis, MN

Background: Given the evolving landscape of ADCs, we evaluated expression of emerging ADC targets in EC and compared expression patterns across molecular subgroups (POLE mutated [POLEm], MSI-high [MSI-H], TP53-mutated [TP53m] or No Specific Molecular Profile [NSMP]) defined by the Proactive Molecular Risk Classifier for Endometrial Cancer. **Methods:** Tumors were analyzed by DNA and RNA sequencing and immunohistochemistry (IHC) for select proteins (Caris Life Sciences, Phx, AZ). ER+ defined as % staining $\geq$ 1%. Statistics were calculated by Mann-Whitney U test and adjusted for multiple comparisons ($q < 0.05$). Expression was split into top quartile (^{H}) and bottom quartile (^{L}). Overall survival (OS) was obtained from insurance claims data and calculated from first treatment to last contact. Hazard ratios (HR) were calculated by Cox proportional hazards with p-values by log-rank tests. **Results:** Of 13,731 EC samples, 2.4% (n=335) were POLEm, 21.6% (n=2,961) MSI-H, 46.8% (n=6,420) TP53m and 29.2% (n=4,015) NSMP. HER2+ by IHC was highest in TP53m tumors compared to POLEm, MSI-H, and NSMP (15.9% vs 1.2% vs 0.8% vs 4.0%; $p<0.05$). TP53m tumors had the highest RNA expression of CDH6, B7-H4, CLDN6, ERBB3, ERBB2, FOLR1, NECTIN2, NECTIN3, and TF; NSMP tumors had the highest expression of TROP2 and NECTIN4 relative to other subtypes (Table 1). Compared to all solid tumors, TP53m EC had the highest median RNA expression of B7-H4 and second highest of CLDN6 and FOLR1. Assessing the prognostic effect of ADC targets by subtype, POLEm CLDN6^{H} tumors had improved OS compared to CLDN6^{L} (HR 0.39, p=0.003). In MSI-H tumors, TROP2^{H}, CDH6^{H}, B7-H4^{H}, CLDN6^{H}, ERBB3^{H}, ERBB2^{H}, FOLR1^{H} and NECTIN2-4^{H} was associated with improved OS (HR 0.57-0.84, $p<0.05$). In TP53m tumors, TROP2^{H}, B7-H4^{H}, FOLR1^{H}, HER3^{H}, and NECTIN4^{H} was associated with improved OS (HR: 0.75-0.80, $p<0.05$) and NECTIN1^{H} and B7-H3^{H} with worse OS (HR: 1.26, $p<0.001$). In ER- NSMP tumors (n=804), B7-H4^{H}, ERBB3^{H}, ERBB2^{H} and NECTIN4^{H} had improved OS (HR: 0.62-0.74, $p<0.05$) and B7-H3^{H} and NECTIN1^{H} had worse OS (HR: 1.40, p=0.01). In ER+ NSMP tumors (n=2,896), TROP2^{H} and TF^{H} had improved OS (HR: 0.73-0.82, $p<0.05$) and ERBB2^{H} and CDH6^{H} had worse OS (HR: 1.24-1.29, $p<0.05$). **Conclusions:** Expression of ADC targets differs by molecular subtype with varying associations with OS in EC patients. Focusing future clinical trials on EC subsets with high biomarker expression will be critical to efficiently developing novel targeted therapeutics. Research Sponsor: None.

Accumulation of cholesterol, cortisol, and glutathione in mitochondria as a marker of metabolic adaptation in serous and clear cell endometrial carcinoma. First Author: Anna Petrovna Menshenina, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: Aggressive endometrial carcinoma subtypes, such as serous (USC) and clear cell (CCC) carcinomas, are characterized by distinct cellular metabolism and dysregulation. Altered homeostasis of metabolites and hormones within mitochondria serves as a molecular driver of metabolic reprogramming in cancer cells. Excess mitochondrial cholesterol can induce oxidative stress, whereas glutathione provides antioxidant defense. Cortisol levels are capable of modulating organelle function. The aim of this study was to evaluate the levels of cholesterol, cortisol, and glutathione in mitochondria isolated from serous and clear cell endometrial carcinomas to characterize the metabolic profile of tumor cells. **Methods:** The study was conducted on mitochondria isolated from tumor tissue of 41 patients with USC (n=21) and CCC (n=20), stage III–IV, histological grade G3; the mean patient age was 59.6±6.7 years. Mitochondria isolated from normal endometrium (n=20) obtained during hysterectomies for uterine leiomyoma (mean age 57.8±8.2 years) served as controls. Cortisol, cholesterol, and glutathione concentrations in the mitochondrial fraction were determined by enzyme-linked immunosorbent assay (ELISA). Statistical analysis was performed using parametric and nonparametric tests with adjustments for multiple comparisons. **Results:** A significant increase in cholesterol levels was observed in mitochondria from these rare endometrial carcinoma subtypes: 2.1-fold in USC and 1.9-fold in CCC compared with normal endometrium. Cortisol content was elevated by 2.1- and 2.5-fold, respectively. Mitochondrial glutathione concentration was also increased: 2.4-fold in USC and 1.9-fold in CCC. **Conclusions:** The data reveal a universal mechanism of metabolic adaptation in serous and clear cell endometrial carcinomas, characterized by a unified mitochondrial metabolic profile featuring co-accumulation of cholesterol, cortisol, and glutathione. Elevated cholesterol generates a pro-apoptotic signal, which is counterbalanced by increased glutathione levels to maintain redox homeostasis. The concurrent rise in cortisol indicates the engagement of mitochondrial stress-response pathways. This constellation of alterations reflects fundamental reprogramming of cellular homeostasis in aggressive endometrial cancers and may be considered a potential target for mitochondrial-directed therapy. p53 R248Q upregulation of VTCN1 via dual mechanisms as a driver of immune evasion and adaptive resistance to CDK4/6 inhibitors: Rationale for combination immunotherapy in endometrial cancer. First Author: Yan Ding, Tongji University, Shanghai, China

Background: TP53-mutated endometrial cancer (EC) is a heterogeneous disease with variable responses to immunotherapy. While generic p53 mutation status is a standard biomarker, the distinct clinical impact of specific hotspot mutants remains underappreciated. Our bioinformatics analysis of TCGA data suggested that the R248Q hotspot—but not others—is specifically linked to an "immune-desert" phenotype. We aimed to mechanistically define this subtype and validate its diagnostic value as a predictor for immune exclusion and CDK4/6 inhibitor sensitivity. **Methods:** We performed a comprehensive bioinformatic analysis of the TCGA-UCEC cohort to correlate specific p53 hotspot mutations with immune landscapes. To elucidate the underlying mechanism, we engineered a panel of isogenic EC cell lines (p53-null, R248Q, R175H, R248W, R273H/C) and assessed VTCN1 (B7-H4) regulation via biochemical assays. To validate these findings clinically, we established an independent cohort of 254 EC patients with tissue microarrays (TMA); whole-exome sequencing (WES) is currently underway to pinpoint hotspot mutations and correlate them with VTCN1 expression and immune infiltration. **Results:** Discovery of Diagnostic Target: In the TCGA cohort, stratifying p53 mutants revealed that R248Q carriers exhibited the most profound "cold" tumor microenvironment compared to other hotspots, suggesting it as a potential negative predictive biomarker. Mechanistic Validation: Using our isogenic models, we observed that R248Q specifically drives high VTCN1 expression. Mechanistically, R248Q appears to promote VTCN1 via a dual pathway: transcriptional upregulation and, uniquely, protein stabilization by inhibiting proteasomal degradation. This indicates VTCN1 as a potential surrogate marker for the R248Q subtype. Therapeutic Implications: In preclinical models, abemaciclib treatment paradoxically upregulated VTCN1 in R248Q cells, suggesting adaptive resistance. However, this induced vulnerability was associated with enhanced sensitivity to combined CDK4/6 inhibition and immunotherapy (anti-VTCN1), which elicited superior tumor regression compared to monotherapy. **Conclusions:** Our study suggests the potential value of refining p53 diagnostics from binary (mutant/WT) to hotspot-specific resolution. Current data indicate that p53 R248Q may function as a distinct driver that contributes to an immunosuppressive "cold" TME in EC, likely through synergistic transcriptional and post-translational upregulation of VTCN1. Furthermore, abemaciclib-induced VTCN1 elevation points to a possible mechanism of monotherapy resistance. These findings provide a strong preclinical rationale to explore combining CDK4/6 inhibitors with immunotherapy, specifically for patients with the high-risk p53 R248Q subtype. Preoperative endocrine treatment response in primary postmenopausal endometrial cancer. First Author: Fabian Trillsch, LMU University Hospital, LMU Munich, Munich, Germany

Background: While preoperative endocrine therapy with letrozole has become an established approach for treatment decisions in estrogen receptor (ER) positive breast cancer, this concept has not been transferred to endometrial cancer so far. We hypothesized that preoperative endocrine treatment response to letrozole, assessed by changes in Ki67 expression between baseline and surgery as a marker for cellular proliferation, can be evaluated in primary endometrial cancer as a predictive, patient-specific biomarker. **Methods:** Postmenopausal patients with first diagnosis of endometrial cancer planned to undergo definitive surgical management with hysterectomy were prospectively included in this single-arm biomarker analysis. Letrozole was administered orally at a daily dose of 2.5mg for a period of 2 to 4 weeks until surgery. Eligibility criteria included all molecular subtypes and histologies and no prior treatment for endometrial cancer was allowed. Ki67 expression was assessed immunohistochemically by two independent pathologists as the percentage of positive tumour nuclei. Relative change in Ki67 (%) from pre-treatment biopsy to post-treatment specimen was assessed using the Wilcoxon signed-rank test, substantial response was defined as relative reduction of Ki67 expression ≥50%. **Results:** A total of 23 patients were prospectively enrolled with median age of 70 years (range 52-88) and median BMI of 32 kg/m² (range 20-48). 22 patients had endometrioid histology (22/23, 95.7%), of those 86.4% (19/22) low-grade and three high-grade (13.6%). One patient had a high-grade serous tumor. 17 of the 23 patients (73.9%) were classified as NSMP (no specific molecular profile), 14 of them ER positive (82.3%). 5 of 23 patients were classified as dMMR (mismatch repair deficient, 21.7%) and one as p53mut (p53 mutant). Median pre-treatment Ki67 expression was 50% (range 10-85) compared to 15% (range 1-80) post-treatment ($p<0.0002$). Following preoperative letrozole treatment, 16 of 23 patients (69.6%) had a relative reduction of more than 50% in Ki67 expression, 13 of these (81.3%) were of NSMP, three (18.8%) of dMMR molecular subtype. Regarding ER expression in these responders, all dMMR and 11/13 NSMP tumors (84.6%) were ER positive. Two NSMP tumors (14.5%) showed a response to endocrine treatment despite being ER negative. **Conclusions:** Short-term preoperative letrozole treatment enables identification of patients with substantial endocrine treatment response in primary endometrial cancer. Using this preoperative window-of-opportunity, dynamic Ki67 evaluation might serve as an easily accessible predictive biomarker to tailor patient-specific treatment decisions. Racial disparities in endometrial cancer (EC) survival after molecular classification (MC). First Author: Jill Roberts, Sylvester Comprehensive Cancer Center/University of Miami, Miami, FL

Background: Black (BAA) patients with EC have double the mortality rate compared to White patients. It is unclear if these survival differences persist after MC. Here, we examine racial disparities in this context and seek to identify molecular differences by race. **Methods:** EC samples (n = 10,162: BAA n=2,410, White n=7,752) were analyzed by NGS (NextSeq/NovaSeq) and RNA (NovaSeq) (Caris Life Sciences, Phx, AZ). Four well-described EC groups were created: POLE ultramutated (POLE-mt), MSI-H, TP53-mt, or No Specific Molecular Profile (NSMP; TP53-wt). Overall survival (OS) was obtained from insurance claims and calculated from tissue collection to last contact for MC cohorts. Hazard ratio (HR) was calculated by Cox proportional hazards, with p-value calculated by log-rank test. Race was self-reported. **Results:** There was a higher prevalence of BAA patients in the TP53-mt subtype (69.1% vs. 43%), compared with POLE-mt (1% vs. 2.26%) and NSMP (16.4% vs. 31%) ($p<0.001$). Across EC, BAA patients had shorter OS (29.8 vs 39.7 months (m); HR: 1.30 (1.22-1.39), $p<0.001$). BAA patients had worse OS in the NSMP cohort (36.8 vs 49.5m; HR 1.35 (1.15-1.59), $p<0.001$) and TP53-mt cohort (26.1 vs 29.6 m; HR 1.13 (1.05-1.22), p=0.002). Race was not associated with differences in OS in POLE-mt (NR vs was 51.4 m) and MSI-H (44.4 vs 45.9 m). There were molecular differences between race when stratified by MC ($q<0.05$) (Table 1). Gene set enrichment analysis showed downregulation of immune-related pathways in BAA. In NSMP tumors, BAA patients had lower IFNγ signature (0.72-fc) and worse post-pembrolizumab survival (16.9 vs 24.6 m; HR 1.46 (1.09-1.95), p=0.011). **Conclusions:** Previous studies demonstrated that racial disparities in endometrial cancer persist even when controlling for histology. This study demonstrates that these disparities persist even after controlling for MC, as defined by the ProMisE classification. BAA patients were more likely to develop TP53-mt tumors, but the survival disparity was largest in the NSMP group. Furthermore, Black and White patients exhibit differential expression of known prognostic mutations even within the same MC group. Research Sponsor: None.

Aspirin use and survival outcomes in endometrial cancer. First Author: Zachary Gentry, The Ohio State University, Columbus, OH

Background: Given the worsening survival trends of endometrial cancer in the United States, further improvement in adjuvant treatment of this cancer is needed. Aspirin use has been shown to reduce cancer risk in multiple cancer types. A randomized controlled trial recently showed that aspirin therapy significantly improved overall survival in patients with colorectal cancer with PIK3CA mutations, a mutation that is seen in up to 50% of endometrial cancers. We therefore hypothesized that aspirin use may similarly improve survival in patients with endometrial cancer. **Methods:** We conducted a retrospective review of all patients with endometrial cancer treated at a single academic institution between 2014-2017. Demographics, clinicopathologic data, surgical and adjuvant treatment, and aspirin use were collected from the medical record. Proportional variables were compared using Fisher's exact and Chi-square tests. Continuous variables were compared using t-tests and Mann-Whitney U-tests. Disease-specific survival (DSS, time from diagnosis to death due to cancer) was estimated using Kaplan-Meier plots, with log-rank and Cox proportional hazards analysis used to compare groups. **Results:** A total of 765 patients were included in the study. Most patients were white (92%), had Stage I disease (79.9%), had endometrioid histology (87.1%), and were mismatch repair (MMR) proficient (74.6%). Of the 765 patients, 243 (31.8%) were taking ASA at the time of their endometrial cancer diagnosis, while 522 (68.2%) were not. Patients taking aspirin at the time of diagnosis were significantly older than those who were not (66.2 vs 59.8, $p<0.0001$). Otherwise, there was no significant difference in BMI, stage, grade, histology, MMR status, or adjuvant treatment between the two groups. On multivariate analysis, aspirin use at diagnosis was significantly associated with improved DSS (HR 0.27 [0.10-0.64], p=0.0020) after adjusting for age, stage, grade, histology, MMR status, and adjuvant treatment. **Conclusions:** Aspirin use at the time of endometrial cancer diagnosis was associated with a significant improvement in DSS in our cohort. While retrospective, this data is promising as a potential improvement in therapy for patients with endometrial cancer. Additionally, this intervention would be inexpensive and easily accessible for all patients. Prospective data is needed to further evaluate the effect of aspirin on endometrial cancer outcomes. Research Sponsor: None.

MicroRNAs as surrogate biomarkers of future endometrial malignancy in women with endometrial hyperplasia without atypia and an open-label randomized trial of metformin, weight control, and exercise intervention. First Author: Chyong-Huey Lai, Gynecologic Cancer Research Center, Taoyuan City, Taiwan

Background: Endometrial hyperplasia (EH) is regarded as an endometrial cancer (EC) precursor. The severity of atypia reflects risk of future EC. According to Kurman et al., the risk of progression to EC was $<$ 1% in simple hyperplasia (SH) and 3% in complex hyperplasia (CH) without atypia (non-A). Our group previously identified 4 MicroRNAs (MiRs) and PTEN by immunohistochemistry stain are significant risk biomarkers of future endometrial malignancy. **Methods:** This prospective open-label randomized controlled study enrolled a total of 60 patients SH/CH non-A. All participants were randomized 1:1 to with or without metformin intervention and received education for exercise and weight control. A stratification of body mass index was performed, but not for HbA1C. PTEN immunohistochemistry stain and MiR profiles of the endometrial tissue were analyzed. **Results:** 57 participants were eligible for analysis. After all the participants had been followed up for 3 years, an analysis was performed in which 3 with progression to atypical hyperplasia and 6 with recurrent SH/CH non-A were observed. Exercise intensity was inversely correlated with use of metformin or not (p = 0.028). The predicting progression/recurrence by any of the 4 miRs (miR30a-3p, miR141, miR-200a, and miR200b) were all significant ($p < 0.05$). PTEN expression, metformin, exercise, or body weight control intervention did not alter the risk of EH recurrence/EC progression. Metformin group has a trend of decreased risk of progression/recurrence yet not significant (p = 0.291). The decreased impact of metformin may be partly related to their lower intensity of exercise as compared to no-metformin group. Impact of interventions may need longer observation. **Conclusions:** Presence of any of the 4 miRs (miR30a-3p, miR141, miR-200a, and miR200b) seem related to risk of recurrence/progression of SH/CH non-A, while PTEN expression, metformin, exercise, and weight control are not, in our prospective cohort. Clinical trial information: NCT05292573. Research Sponsor: National Science and Technology Council, Taiwan; 2018-2021 MOST-107-2314-B-182-040 -MY3.

Whole-genome sequencing–based ctDNA testing for post-surgical monitoring and early detection of recurrence or progression in uterine cancer. First Author: Abigail Barger, St. Luke's University Health Network, Bethlehem, PA

Background: Reliance on clinicopathologic risk factors to guide adjuvant therapy in early-stage uterine cancer (UC) has not improved survival, underscoring the need for biomarkers for post-treatment monitoring. In this study, we evaluate ctDNA as a prognostic biomarker using a whole-genome sequencing (WGS)–based assay in the post-surgical UC setting. **Methods:** We performed a retrospective analysis of clinically annotated residual samples from commercial ctDNA testing in 118 patients diagnosed with UC. Signatera Genome assays (Natera, Inc.) were designed from the WGS data of matched tumor tissue and normal blood samples to detect and quantify ctDNA in serially collected post-operative plasma. Descriptive statistics were used to compare association of ctDNA across stages and timepoints. **Results:** Among 118 UC patients, 20/118 were metastatic and excluded from analysis. Of the remaining 98 patients, 77 had stage I and 21 had stage II-III disease. Median clinical follow-up was 11.2 months (range: 0.8–33.2) with 13% (13/98) of patients having recurrence/progression within a median of 8.5 (range: 3.9-25.1) months from surgery. ctDNA analysis was performed across 1004 total tests with a median of 8 tests per patient (range: 2–16) and a median testing cadence of 2.9 (range: 0-12.7) months. Post-surgical ctDNA assessment (2–8 weeks post-operatively) was available for 35 stage I patients with a ctDNA detection rate of 9% (3/35). Focusing on the 32 patients with $>$12 months of postoperative clinical follow-up, one patient was ctDNA-positive postoperatively and recurred 7.2 months after surgery. Among the ctDNA-negative patients (N=31), 84% (26/31) remained serially negative with no evidence of recurrence at a median clinical follow-up of 26.3 (range: 13.5-38.7) months post-surgery. The remaining ctDNA-negative patients (N=5) converted to positive during longitudinal monitoring, all subsequently experiencing recurrence/death. Longitudinal ctDNA detection rate during surveillance was 32.1% (25/78) in stage I and 47.6% (10/21) in stage II-III. Of the stage I patients with recurrence (N=8), 100% were ctDNA-positive prior to or at the time of the clinical finding, with a median lead time of 5.2 (range: 1.2–15.8) months. Similarly, in stage II-III patients with recurrence/progression (N=5), 100% were ctDNA-positive prior to the clinical finding with a median lead-time of 6.07 (range: 4.1-23.7) months. **Conclusions:** ctDNA positivity postoperatively identifies UC patients at increased risk of recurrence/progression, often preceding clinical relapse by several months. Serial ctDNA negativity using a tumor-informed, WGS-based ctDNA assay correlated with absence of recurrence. Postoperative longitudinal ctDNA monitoring shows promise as a clinically actionable biomarker to guide adjuvant treatment decisions and improve post-operative surveillance. Research Sponsor: None.

Development of an endometrial cancer test from a vaginal swab. First Author: Bridget Z. Gagrat, Exact Sciences Corporation, Madison, WI

Background: Endometrial cancer (EC) is the most common gynecologic cancer and abnormal uterine bleeding (AUB) is the predominant presenting symptom. While $<$10% of AUB represents underlying EC, endometrial sampling is currently required to rule out EC. To develop an alternative, non-invasive rule-out strategy, we aimed to refine a previously reported EC-associated methylated DNA marker (MDM) panel in vaginal swabs. **Methods:** Patients $\geq$18 years old with AUB who met ACOG recommendations for endometrial sampling and those undergoing a hysterectomy for biopsy-proven EC or atypical hyperplasia (AH) were prospectively enrolled in a multicenter cohort study. A vaginal fluid specimen was collected via swab by a provider during a speculum exam. DNA was extracted from samples and bisulfite treated, followed by a target and signal amplification method to detect 8 previously identified MDMs. The cross-validated EC classification model used the mean of standardized MDMs. Clinical classification of benign endometrium (BE), EC, and AH was based on central pathology review. EC diagnoses were based on hysterectomy specimens. Endometrioid and mucinous constituted type 1 EC; serous, carcinosarcoma, clear cell, and mixed histology ECs were collectively analyzed as type 2. **Results:** Of 693 participants enrolled, 670 were evaluable with valid results: 524 in the AUB cohort and 146 in the suspected EC cohort. Within the AUB cohort, 16 had EC or AH. The final analysis cohort included 508 BE, 156 EC, and 6 AH. Of the evaluable participants 20% identified as Black, 3% Asian or Pacific Islander, 75% White, and 3% Other; 7% reported Hispanic ethnicity. Median age was 66 and 50 years for EC and BE AUB, respectively; 80% of those with EC and 43% with benign AUB reported being postmenopausal. Among participants with EC, 102 (65%), 17 (11%), 30 (19%), 6 (4%) were stage I, II, III, and IV, respectively; one EC was unstaged. Type 2 EC accounted for 42 (27%) of all EC cases. A 4-MDM panel yielded an AUC of 0.97 (0.96-0.99, 95% CI) for EC; models with 5-8 MDMs gave identical performance. All-stage EC sensitivity was 97, 97, 96, 95, and 92% at specificities ranging from 75, 80, 85, 90, and 95%, respectively. At the 85% (82-88%) specificity threshold, sensitivities across EC stage, type, and age were consistently high (Table). Sensitivity for AH was 33% (10-70%). **Conclusions:** An MDM panel demonstrated high sensitivity for EC across stage and EC type, supporting the potential for a non-invasive vaginal swab-based test to rule out EC. Future studies are necessary to finalize the panel and algorithm, prior to validating the test. Clinical trial information: NCT06294886. Research Sponsor: Exact Sciences Corporation.

EC	Sensitivity (%, 95% CI) at 85% Specificity
All Stages (n=156)*	96 (92-98)
Stage I (n=102)	94 (88 - 97)

GLP-1 receptor expression in a molecularly characterized cohort of endometrial carcinoma: Results from the GEICO 163-T/SPECTRUM study. First Author: Carlos González-Merino, Medical Oncology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: The glucagon-like peptide-1 receptor (GLP-1R) plays a central role in metabolic, and hormonal signaling and has gained increasing clinical relevance due to the widespread use of GLP-1R agonists. Given the strong link between obesity and endometrial carcinoma (EC), data on GLP-1R expression in EC are of clinical interest. We aimed to evaluate GLP-1R expression in a large, molecularly classified EC cohort and analyze its association with clinicopathological and molecular features. **Methods:** GLP-1R immunohistochemistry was performed on tissue microarrays from 192 ECs included in the SPECTRUM cohort. This cohort included 111 low grade endometrioid and 81 high grade ECs. 187 tumors were successfully classified according to WHO 2020 criteria, including 3% POLE-mutated (POLEmut), 25% mismatch repair–deficient (dMMR), 43% no specific molecular profile (NSMP), and 29% p53 abnormal (p53abn) carcinomas. Additionally, *CTNNB1* mutation status was available in 168 tumors (16% mutated). GLP-1R expression was evaluated using the Allred scoring system (range 0–8). GLP-1R positivity was defined as Allred $\geq$6 according to previously published criteria (Kanda et al. 2018). Associations were evaluated using univariable analyses and multivariable logistic regression, reporting ORs with 95% confidence intervals; $p<0.05$ was considered statistically significant. **Results:** GLP-1R expression was evaluated in 172 EC. GLP-1R positivity was observed in 32.0% of the overall cohort and differed across molecular subtypes: 41.9% in NSMP, 40.0% in POLEmut, 28.9% in p53abn and 20.5% in dMMR tumors (p=0.099). Progesterone receptor (PR) levels were significantly higher in GLP-1R–positive compared with GLP-1R–negative tumors (median 55% vs 20%, p=0.015), whereas a non-significant trend toward higher estrogen receptor (ER) expression was observed (median 50% vs 25%, p=0.18). GLP-1R positivity was more frequent in *CTNNB1* mutated tumors (50.0% vs 28.9%; p=0.041). In multivariable logistic regression including PR (continuous), *CTNNB1* mutation status and molecular classification, only PR levels remained independently associated with GLP-1R positivity (OR per 10% increase 1.15, 95% CI 1.02–1.30; p = 0.019). **Conclusions:** GLP-1R is frequently expressed in EC, particularly in PR positive tumors and within the NSMP molecular subtype, suggesting that the underlying pathway of carcinogenesis may influence GLP-1R expression. These findings may inform the design of future translational and clinical studies exploring GLP-1R–targeted strategies in endometrial carcinoma. Research Sponsor: None.

Examining the relationship between social support and inflammatory markers among patients with gynecologic cancer. First Author: Oluwafemifola Oyedeji, North Knoxville Medical Center, Powell, TN

Background: Social support has been associated with improved health outcomes. Little research on the association between social support and inflammatory markers has been done among patients with gynecological cancer. The aim of this study is to examine whether there is an association between social support and inflammatory markers in patients currently receiving treatment for gynecologic cancer. **Methods:** These data were collected from a prospective cohort study designed to investigate the potential associations between cardiometabolic health and cancer treatment among women with gynecological cancer. As a secondary outcome, social support was assessed using the social provision scale (SPS), with higher scores indicating greater perceived social support. Fasting venous blood was collected for inflammatory marker analysis (Interleukin-6: IL-6, Tumor Necrosis Factor-alpha: TNF-α, C-reactive protein: CRP). Descriptive statistics included means for continuous variables and frequencies for categorical variables. Correlation analyses were used to assess the degree of relationship between variables. Partial correlations were used to adjust for potential confounders. Study protocol was approved by IRB at the University of Tennessee Graduate School of Medicine. **Results:** A total of 43 women with gynecological cancer (primary site: uterus = 16, ovary = 24, cervix = 1, vulva/vagina = 2) completed study measures. The mean age was 63.5 years (SD=10.5). Regarding participants characteristics, 91% identified as White, 99% identified as non-Hispanic, 35% reported being high school graduate or GED, 45% were unemployed, 66% were married, 51.2% had newly diagnosed cancer, 49% had metastatic disease, 74% received chemotherapy only, 14% immunotherapy, 12% combination of both immunotherapy and chemotherapy. SPS scores were negatively correlated with IL-6 ($\rho = -0.362$, p = 0.038), indicating that higher perceived social support was associated with lower IL-6 levels. SPS scores were not significantly correlated with CRP ($\rho = -0.09$, p = 0.62) and TNF-α ($\rho = -0.295$, p = 0.096). After adjusting for BMI, SPS score showed significant associations with IL-6 ($\rho = -0.406$, p = 0.021) and TNF-α ($\rho = -0.360$, p = 0.043), but its relationship with CRP ($\rho = -0.029$, p = 0.874) remained non-significant. **Conclusions:** The results of this study suggest a negative association between social support and inflammation among patients with gynecologic cancer. Future research may consider exploring the pathways to explain this relationship and identify possible interventions focused on social support to decrease inflammatory processes among patients with gynecologic cancer. Research Sponsor: University of Tennessee Medical Center Cancer Institute.

A phase 2 study evaluating SSGJ-707 (PF-08634404), a PD-1/VEGF bispecific antibody, + chemotherapy (chemo) in patients (pts) with first-line (1L) advanced/recurrent endometrial cancer (EC). First Author: Qi Zhou, Cancer Hospital Affiliated to Chongqing University, Chongqing, China

Background: SSGJ-707 is a fully human immunoglobulin G4 bispecific antibody targeting programmed death 1 (PD-1) and vascular endothelial growth factor (VEGF). SSGJ-707 has demonstrated promising efficacy and manageable safety alone and in combination with chemo in phase 2 studies in solid tumors. We report results from the phase 2 SSGJ-707-ST-II-02 study (NCT06522828) of 1L SSGJ-707 + chemo in advanced/recurrent EC. **Methods:** Pts with newly diagnosed stage III/IV or recurrent EC with low potential for cure by radiation therapy (tx) or surgery and systemic tx-naive were enrolled. Pts received SSGJ-707 5 mg/kg or 10 mg/kg Q3W + chemo (carboplatin AUC 5 + paclitaxel 175 mg/m^2) Q3W for 6 cycles, followed by SSGJ-707 maintenance tx until loss of clinical benefit or intolerable toxicity for up to 2 years. Primary endpoints were safety and ORR (RECIST 1.1). Secondary endpoints include duration of response (DOR), PFS, OS, PK, and biomarkers. **Results:** At data cutoff (Nov 28, 2025), 32 pts with EC (26 mismatch repair proficient [pMMR], 6 MMR deficient [dMMR]) received 5 mg/kg (n=16) or 10 mg/kg (n=16) SSGJ-707 + chemo. Median SSGJ-707 tx duration was 5.6 mo (range, 0.2-13.6); 8 pts (25.0%) discontinued tx. In the evaluable population, confirmed ORR was 85.7% (12/14 pts) for the 5 mg/kg dose and 80.0% (12/15) for the 10 mg/kg dose. Results for pMMR and dMMR groups are in the Table. Median PFS, OS, and DOR were not reached for either dose. Any-grade tx-related adverse events (TRAEs) were reported in 30/32 pts (93.8%) and grade $\geq$3 TRAEs in 22/32 pts (68.8%). The most common TRAEs ($\geq$40%) included neutrophil count decreased (59.4%), white blood cell count decreased (59.4%), anemia (56.3%), and platelet count decreased (56.3%). No TRAEs led to death. TRAEs led to discontinuation of SSGJ-707 in 2 pts (6.3%). Immune-related AEs occurred in 6 pts (18.8%): hypothyroidism (n=4), hyperthyroidism (n=3), and rash (n=2). VEGF-related AEs occurred in 13 pts (40.6%): blood pressure elevation (n=6), proteinuria (n=6), hemorrhage (urinary occult blood positive; n=2), perforation and fistula (n=2), and venous thrombosis (n=1). **Conclusions:** SSGJ-707 + chemo demonstrated promising efficacy with a manageable safety profile in pts with tx-naive advanced/recurrent EC, supporting further investigation of SSGJ-707 in these pts. Clinical trial information: NCT06522828. Research Sponsor: This study was originally sponsored by 3SBio; SSGJ-707 was licensed to Pfizer in July 2025. Medical writing support was provided by Akshaya Srinivasan, PhD, and Eleanor Porteous, MSc, of Nucleus Global, an Inizio Company, and was funded by Pfizer.

TroFuse-036/GOG-3123/ENGOT-cx22: A 2-part, phase 3, randomized study of sacituzumab tirumotecan (sac-TMT) + pembrolizumab (pembro) ± bevacizumab (bev) vs standard of care (SoC) as first-line maintenance therapy for PD-L1–positive cervical cancer. First Author: Brian M. Slomovitz, GOG Foundation and Mount Sinai Medical Center, Miami Beach, FL

Background: First-line pembro + platinum-doublet chemo ± bev is the preferred SoC for PD-L1-positive stage IVB, persistent, or recurrent cervical cancer. However, ~50% of patients experience progressive disease (PD) within 1 y, highlighting the need for first-line maintenance therapies that can extend clinical benefit. Sac-TMT is a TROP2-directed antibody-drug conjugate with a unique, bifunctional linker that maximizes payload delivery to tumor cells. In a prior phase 2 basket study, sac-TMT + pembro demonstrated promising antitumor activity (ORR, 58% [22/38]) with a manageable safety profile in participants (pts) with recurrent or metastatic cervical cancer that progressed on or after platinum-doublet chemo. TroFuse-036/GOG-3123/ENGOT-cx22 (NCT07216703) is evaluating first-line maintenance therapy with sac-TMT + pembro ± bev vs SoC in pts with cervical cancer. **Methods:** This 2-part, phase 3, randomized, open-label study is enrolling pts aged $\geq$18 y with persistent, recurrent, or newly diagnosed stage IVB squamous cell carcinoma, adenosquamous carcinoma, or adenocarcinoma of the cervix that is not amenable to curative treatment (surgery/radiation), ECOG PS of 0 or 1, and PD-L1 combined positive score $\geq$1. In part 1 (safety run-in), ~20 eligible pts who complete 6 cycles of induction therapy with pembro 200 mg Q3W + paclitaxel 175 mg/m^2 Q3W + cisplatin 50 mg/m^2 (or carboplatin AUC 5 mg/mL/min Q3W) + bev 15 mg/kg Q3W without PD per investigator will receive maintenance therapy with sac-TMT 4 mg/kg Q2W + pembro 400 mg Q6W for $\leq$14 6-wk cycles + bev 15 mg/kg Q3W until treatment discontinuation criteria are met. Enrollment in part 2 will start after enrollment in part 1 is complete. In part 2, ~1003 eligible pts will receive 6 cycles of induction therapy (same doses as in part 1) with pembro + platinum-doublet chemo ± bev at investigator discretion. For randomization to maintenance therapy, pts must complete induction therapy and have CR, PR, or SD per RECIST v1.1 by investigator as assessed by an evaluable tumor scan at week 18; evaluable TROP2 expression; and resolution of any AEs to grade $\leq$1. After part 1 safety data review is complete, ~802 eligible pts in part 2 maintenance part will be randomized 1:1 to receive sac-TMT 4 mg/kg Q2W + pembro 400 mg Q6W for $\leq$14 6-wk cycles ± bev 15 mg/kg Q3W or SoC with pembro 400 mg Q6W for $\leq$14 6-wk cycles ± bev 15 mg/kg Q3W; bev use is at investigator discretion and continues until treatment discontinuation criteria are met. The primary endpoint is safety in part 1 and PFS per RECIST v1.1 by blinded independent central review and OS with maintenance therapy in part 2. Secondary endpoints associated with maintenance therapy in part 2 are PFS2 per investigator, safety, and patient-reported outcomes. Enrollment began in Dec 2025. Clinical trial information: NCT07216703. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Iparomlimab and tuvonralimab combined with paclitaxel and cisplatin as neoadjuvant therapy for cervical cancer: A phase II umbrella trial. First Author: Junjun Qiu Sr., Obstetrics and Gynecology Hospital of Fudan University, Shanghai, China

Background: There is an urgent need to improve neoadjuvant therapy for locally advanced cervical cancer (LACC) and fertility-preserving neoadjuvant therapy for early-stage cervical cancer patients. However, there is no study evaluating the efficacy and safety of PD-1 and CTLA-4 dual blockade-based therapy for above clinical scenarios. The present study aims to assess QL1706 combined with paclitaxel and cisplatin as neoadjuvant therapy for LACC and early-stage cervical cancer patients for fertility-preservation respectively. **Methods:** Trial design: For Arm 1 (LACC), patients aged 18-75 years, with FIGO 2018 stages IB3, IIA2, IIB, or IIICr (lesion ≥4 cm, confirmed by MRI), histologically confirmed as cervical squamous cell carcinoma, cervical adenocarcinoma, or cervical adenosquamous carcinoma will be included. For Arm 2 (fertility preservation), patients aged 18-45 years old, who have a strong desire to preserve fertility, with FIGO 2018 stages IB2, IB3 (lesion ≤6 cm), IIA1, or IIA2 (lesion ≤6 cm) and histologically confirmed as cervical squamous cell carcinoma, cervical adenocarcinoma, or cervical adenosquamous carcinoma, will be included. All participants will be given 3 cycles of neoadjuvant treatment with QL1706 (5 mg/kg), paclitaxel (135-175 mg/m^2) and cisplatin (75-80 mg/m^2) per 21 days. Patients in Arm 1 (LACC) who achieve CR/PR will undergo radical hysterectomy plus lymphadenectomy after 3 cycles of neoadjuvant therapy whereas patients in Arm 2 (fertility preservation) who achieve CR/PR will undergo fertility-preserving surgery. For IB1/IB2 patients, conization or simple trachelectomy plus lymphadenectomy will be performed. For IIA1/IIA2 patients, radical trachelectomy plus lymphadenectomy will be performed. Patients achieve PD/SD will be given standard treatment according to the current NCCN guideline. The primary endpoints consist of objective response rate (ORR), pathological complete response (pCR) and changes in tumor-related biomarkers (ctDNA, etc). Secondary endpoints include 2-year overall survival (OS), 2-year disease-free survival (DFS) and adverse events. Other endpoints are 2-year pregnancy rate and infant survival rate for Arm 2. Sample size is 20 for Arm 1 and 15 for Arm 2. Clinical trial identification: NCT06878222. Clinical trial information: NCT06878222. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

TPS5630 **Poster Session**

A phase II trial of a FAK inhibitor combined with albumin-bound paclitaxel and an anti–PD-1/CTLA-4 bispecific antibody for metastatic, recurrent, or persistent gastric-type endocervical adenocarcinoma (GIFT Study). First Author: Yingchao Zhao, Hubei Key Laboratory of Precision Radiation Oncology, Wuhan, Hubei, China

Background: Gastric-type endocervical adenocarcinoma (GAC) is a rare, HPV-independent subtype of cervical cancer with an aggressive clinical course and an exceptionally poor prognosis. Current clinical guidelines offer largely non-specific treatment recommendations, and conventional chemotherapy-based regimens, even when combined with immunotherapy, frequently demonstrate limited efficacy and early resistance in patients with advanced, recurrent, or metastatic disease. Preclinical studies demonstrate that FAK inhibition can remodel the tumor microenvironment and enhance sensitivity to both cytotoxic chemotherapy and immunotherapy. This study aims to evaluate the efficacy and safety of the FAK inhibitor IN10018 in combination with immunotherapy and chemotherapy in patients with GAC. **Methods:** The GIFT study is a multicenter, open-label, single-arm, prospective phase II trial designed to evaluate the combination of the FAK inhibitor IN10018 with nab-paclitaxel and cadonilimab (a PD-1/CTLA-4 bispecific antibody) in patients with metastatic, recurrent, or persistent gastric-type endocervical adenocarcinoma. A total of 25 eligible patients will receive oral IN10018 (100 mg once daily) in combination with intravenous nab-paclitaxel (260 mg/m²) and cadonilimab (10 mg/kg) on day 1 of each 21-day cycle. Tumor response will be assessed every 6 weeks by imaging according to RECIST v1.1. Patients will receive up to six cycles of combination chemotherapy, followed by maintenance therapy with IN10018 and cadonilimab until disease progression or unacceptable toxicity. The primary endpoint is objective response rate. Secondary endpoints include progression-free survival, disease control rate, and safety. An additional exploratory objective is to longitudinally evaluate alterations in peripheral circulating cell-free DNA and the tumor microenvironment and to examine their association with therapeutic response. The study is currently active and enrolling patients. As of the data cutoff, 14 of the planned 25 patients have been enrolled. The trial is registered at ClinicalTrials.gov (NCT06654011). Clinical trial information: NCT06654011. Research Sponsor: Noncommunicable Chronic Diseases-National Science and Technology Major Project; 2025ZD0544103; National Natural Science Foundation of China; 82372929.

TPS5631 **Poster Session**

Neoadjuvant chemoimmunotherapy before chemoradiation vs chemoradiation alone for stage IIB-IIIC1 carcinoma of the cervix: A phase II open-label randomized controlled trial (NeoCHIMERA). First Author: Praveen Kumar Marimuthu, Christian Medical College, Vellore, Tamil Nadu, India

Background: Locally advanced cervical cancer (FIGO 2018 stages IIB–IIIC1) remains a major cause of cancer-related mortality in low- and middle-income countries. Concurrent chemoradiation (CCRT) with brachytherapy is the current standard of care; however, rates of persistent disease and distant failure remain substantial, particularly in patients with bulky tumors or nodal involvement. Although advances in radiotherapy have improved outcomes, survival in resource-constrained settings continues to lag behind that in high-income countries. Recent randomised trials have demonstrated improved outcomes with two distinct strategies: delivery of dose-dense induction chemotherapy followed by timely initiation of chemoradiation, and the addition of immunotherapy with pembrolizumab to concurrent chemoradiation followed by maintenance therapy for up to one year. Despite these advances, concerns about radiotherapy dose and technique in induction chemotherapy trials, and the feasibility of prolonged maintenance immunotherapy in resource-limited settings, have limited widespread adoption. The optimal dose, timing, and duration of immunotherapy in locally advanced cervical cancer remain undefined. This study was designed to evaluate whether short-course neoadjuvant chemo-immunotherapy administered prior to standard CCRT can improve early tumor response with an acceptable safety profile while preserving treatment feasibility across diverse healthcare settings. **Methods:** The NeoCHIMERA trial is a multicenter, open-label, randomized phase II study designed to evaluate this hypothesis. Eligible patients include those with biopsy-proven FIGO 2018 stage IIB–IIIC1 cervical carcinoma (squamous, adeno, or adenosquamous histology) who are treatment-naïve and suitable for CCRT. Participants will be randomized 1:1 to the experimental or control arm, stratified based on stage and histology. The experimental arm will receive six weeks of neoadjuvant carboplatin (AUC 2) and paclitaxel (60 mg/m²) weekly, combined with low-dose nivolumab (40 mg IV every three weeks for two cycles), followed by standard CCRT (cisplatin 40 mg/m² weekly with external beam radiation and brachytherapy). The control arm will receive CCRT alone. The primary endpoint is complete clinical response at 3 months after completion of chemoradiation. Secondary endpoints include safety, treatment completion rates, event-free survival, quality of life, and cost-effectiveness from a societal perspective. A total of 154 patients (77 per arm) will be accrued. One interim safety analysis is planned after 40 patients with predefined stopping rules for excess toxicity. Thirty-three of the planned 154 participants have been recruited. This study is registered with the Clinical Trials Registry of India (CTRI/2025/04/085540). Clinical trial information: CTRI/2025/04/085540. Research Sponsor: Christian Medical College, Vellore.

TPS5632 **Poster Session**

NRG-GY037: A phase III randomized trial of induction chemotherapy and pembrolizumab followed by chemoradiation and pembrolizumab maintenance versus standard chemoradiation and pembrolizumab maintenance in high-risk locally advanced cervical cancer. First Author: Jyoti Mayadev, University of California, San Diego Medical Center, La Jolla, CA

Background: Concurrent chemoradiation therapy (CCRT) is the standard of care for locally advanced cervical cancer (LACC); however, outcomes remain suboptimal in patients with high-risk disease. Recent studies suggest that integration of immunotherapy (IO) with definitive chemoradiation, or induction chemotherapy prior to CCRT improves outcomes. Whether treatment intensification with induction systemic therapy and IO prior to CCRT and IO further improves disease control remains unknown. Induction chemotherapy may reduce tumor burden, eradicate micrometastatic disease, and improve tumor immunogenicity prior to definitive CCRT. Preclinical and clinical data support synergy between systemic therapy or radiotherapy and immune checkpoint blockade, providing the rationale for evaluating an induction strategy incorporating chemotherapy and immunotherapy before standard CCRT with immunotherapy, followed by maintenance immunotherapy. Optional tumor tissue and blood samples will be collected for exploratory correlative analyses, including immune and molecular biomarkers associated with response, resistance, and patterns of failure. **Methods:** NRG-GY037 is a prospective, multi-institutional phase III randomized trial conducted through NRG Oncology. A total of 336 patients will be enrolled (168 per arm). Patients will be stratified by FIGO stage (III vs. IVA) and presence or absence of para-aortic lymph nodes (N2). The primary endpoint is progression free survival (PFS). The study has 90% power to detect PFS hazard ratio of 0.65 in the experimental arm. Treatment: Patients with previously untreated, high-risk LACC are randomized to receive either induction chemotherapy with pembrolizumab for 6 weeks followed by CCRT with pembrolizumab and pembrolizumab maintenance, or standard CCRT with pembrolizumab followed by pembrolizumab maintenance. Major Eligibility Criteria: Eligible patients have histologically confirmed cervical carcinoma (squamous, adenocarcinoma, or adenosquamous), TNM T3 and T4 disease, N0-2, ECOG performance status 0–1, and no prior definitive therapy for cervical cancer. Current Enrollment Status: The trial is actively accruing patients. No efficacy or safety data are available at the time of submission. Clinical Trial Registration: ClinicalTrials.gov identifier: NCT07061977. Clinical trial information: NCT07061977. Research Sponsor: National Cancer Institute.

TPS5633 **Poster Session**

A single-arm, phase 2 study of neoadjuvant mirvetuximab soravtansine and carboplatin for FRα-expressing advanced-stage serous epithelial ovarian, fallopian tube, or primary peritoneal cancer (M25-231; NCT06890338; GOG-3115). First Author: Rebecca Arend, University of Alabama at Birmingham, O'Neal Comprehensive Cancer Center, Birmingham, AL

Background: Folate receptor alpha (FRα) has limited expression on normal tissues but is highly expressed in most high-grade serous epithelial ovarian cancers (EOC), making it an attractive therapeutic target. Mirvetuximab soravtansine (MIRV), an antibody-drug conjugate targeting FRα, has demonstrated efficacy and manageable safety in recurrent, FRα-expressing EOC when used as monotherapy. Additionally, a phase 1b/2 study (IMGN853-0402) of MIRV + carboplatin showed promising clinical activity in patients with platinum-sensitive ovarian cancer who had tumor recurrence after platinum-based chemotherapy. The safety and efficacy of neoadjuvant MIRV + carboplatin in newly diagnosed, advanced-stage FRα-expressing high-grade serous ovarian cancer (HGSOC) remains unknown. **Methods:** This single-arm phase 2 trial will evaluate the safety and efficacy of MIRV + carboplatin in newly diagnosed patients with advanced-stage (Stage III/IV), FRα-expressing (≥75% tumor cells with ≥2+ membrane intensity per the VENTANA FOLR1 (FOLR1-2.1) RxDx Assay [Roche Diagnostics]) HGSOC. Approximately 140 patients (aged ≥18 years) will be enrolled; 5 patients were enrolled as of January 23, 2026. Patients will receive ≤6 cycles of MIRV (6 mg/kg adjusted ideal body weight) and carboplatin (AUC 5) intravenously every three weeks before interval debulking surgery (IDS), with a total of ≤9 cycles pre- and post-IDS. IDS suitability will be evaluated radiologically, and all eligible patients, including those with progressive disease (PD), will undergo IDS after Cycle 3 Day 1. IDS-ineligible patients may receive ≤3 additional cycles and undergo repeat imaging to assess IDS suitability. Patients with complete response (CR), partial response (PR), or stable disease will resume MIRV + carboplatin 3–6 weeks post-IDS following radiologic assessment. At the treating physician's discretion, bevacizumab may be added post-IDS and standard-of-care maintenance therapy may begin ≥21 days after MIRV + carboplatin ± bevacizumab completion. Imaging will occur every 9 weeks after IDS (for those who undergo IDS) or last radiologic tumor assessment (for those who do not) until 1 year from the first dose of study treatment and then every 12 weeks until PD, death, or withdrawal of consent. The primary endpoint is objective response (OR), defined as best overall response of radiographic CR or PR assessed by Independent Central Review (ICR) per Response Evaluation Criteria in Solid Tumors v1.1 prior to initiation of subsequent anticancer therapy (including IDS). Secondary endpoints include OR by investigator (INV), disease control by ICR and INV, IDS, extent of cytoreduction at the time of IDS, cancer antigen 125 response, progression-free survival by INV, and patient-reported outcomes (NFOSI-18). Clinical trial information: NCT06890338. Research Sponsor: AbbVie Inc.

TPS5634 **Poster Session**

NRG-GY036: A phase III trial of one vs. two years of maintenance olaparib, with or without bevacizumab, in patients with *BRCA1/2*-mutated or homologous recombination deficient (HRD+) ovarian cancer following response to first line platinum-based chemotherapy. First Author: Ying L. Liu, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The profound progression-free survival (PFS) benefit shown in the SOLO-1 and PAOLA-1 randomized clinical trials set the standard of 2 years of PARP inhibitor (PARPi) maintenance with olaparib, with or without bevacizumab, in patients with *BRCA1/2*-mutated and homologous recombination deficient (HRD+) ovarian carcinoma after response to frontline platinum-based chemotherapy, and this was approved by the FDA in December 2018. However, newer studies have elucidated the long-term toxicity risk of prolonged PARPi use, specifically treatment-related myeloid neoplasms (TMN), along with detrimental effects on subsequent platinum-based chemotherapy and overall survival. Given this, we seek to test de-escalation of PARPi maintenance therapy, evaluating if 1 year is non-inferior to 2 years, using a pragmatic and streamlined study design. **Methods:** NRG GY036 is a phase III, randomized, non-inferiority study of 1 versus 2 years of olaparib maintenance, with our without bevacizumab, in those with *BRCA1/2*-associated and HRD+ ovarian cancer, after response to frontline platinum-based chemotherapy (NCT06580314). Key eligibility criteria include a deleterious *BRCA1/2* mutation, germline or somatic, or HRD+ tumor using any CLIA-certified test. Patients must have undergone cytoreductive surgery and had a clinical response after a minimum of 4 cycles of platinum-based chemotherapy. The primary endpoint is investigator assessed PFS using RECIST v1.1 criteria for 1 vs. 2 years in a modified intention to treat (mITT) population, where time at risk starts 360 days after randomization to account for the time where both arms receive the same treatment. Secondary endpoints include overall survival (OS), PFS2, PFS in the ITT and as-treated populations, and toxicity including rates of TMN. The statistical design is based on a hazard ratio non-inferiority margin of 1.36 (1-sided alpha 0.05, power 0.9). The null hypothesis will be rejected if HR <1.15, giving 90% certainty that the true median PFS loss is not more than 10 months based on historical controls from SOLO1 and the HRD+ subgroup of PAOLA-1. We anticipate enrolling 880 patients to have at least 735 patients in the mITT population. This IND-exempt study pragmatically mimics real-world clinical practice by using commercially available drug, implementing broad eligibility criteria, allowing physician's choice bevacizumab, and incorporating individual physician and institution's standard practices. It also employs a streamlined approach with minimal data collection forms and abbreviated adverse event reporting. NRG GY036 was activated on 1/16/2025. The first patient enrolled on 3/12/2025. As of 1/16/2026, there are 676 participating sites and 152/880 (17%) patients enrolled. Clinical trial information: NCT06580314. Research Sponsor: NRG Oncology and NIH/NCI/CTEP.

TPS5635 **Poster Session**

A phase I, open-label, dose-finding, safety, tolerability, and exploratory trial of intraperitoneal THEO-260 in patients with high-grade serous or endometrioid ovarian cancer. First Author: Helen D. Clark, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Ovarian cancers are immunologically cold at baseline and typically characterized by a rich stromal component with a high proportion of cancer-associated fibroblasts (CAF). These features limit efficacy of immunotherapy and virotherapy due to the immunosuppressive effects of abundant CAFs. THEO-260 is an oncolytic adenovirus that exhibits selective replication, lysis, and killing of cancer cells and CAFs. This unique mechanism-of-action positions THEO-260 as a potential efficacious treatment option for patients with platinum-resistant ovarian cancer. Intraperitoneal (IP) delivery may further enhance efficacy by enabling high locoregional dose with lower systemic exposure. **Methods:** This phase I, open-label, single-institution study (NCT07211659) evaluates IP THEO-260 in patients with platinum-resistant or refractory high grade serous (HGS) or endometrioid ovarian, peritoneal, or fallopian tube cancer. The primary objectives are to evaluate the safety and tolerability of THEO-260 when administered intraperitoneally and to establish the recommended phase 2 dose (RP2D) using a Bayesian Optimal Interval design with 4 dose levels in cohorts of 3. Patients receive up to 6 doses of THEO-260 over 15 days: 2 desensitization doses followed by 4 target-dose administrations. Secondary objectives include PK, viral shedding, systemic cytokine release, and preliminary efficacy assessment. Response assessments will be conducted every 8 weeks starting on day 29 through week 52 and thereafter every 12 weeks until progression, death, or end of trial. Eligibility includes histologically confirmed, platinum-resistant or refractory HGS, endometrioid cancer of the ovary, peritoneum, or fallopian tube, measurable peritoneal disease per RECIST v1.1, ECOG 0-1, adequate organ function, life expectancy of ≥6 months, and feasibility of intraperitoneal catheter placement. Prior treatments must include optimal surgical debulking, bevacizumab, or PARP inhibitor therapy as indicated. Key exclusions include serosal disease >3cm, bowel obstruction history or symptoms, uncontrolled pleural or pericardial effusions, and prior pneumonitis or interstitial lung disease. Enrollment began in November 2025. Clinical trial information: NCT07211659. Research Sponsor: Theolytics.

TPS5636 **Poster Session**

TroFuse-022/ENGOT-ov84/GOG-3103 part 2: A phase 3 study of maintenance therapy with sacituzumab tirumotecan ± bevacizumab vs standard of care following second-line platinum-based doublet chemotherapy for platinum-sensitive recurrent ovarian cancer. First Author: Antonio Gonzalez Martin, GEICO and Cancer Center Clinica Universidad de Navarra, Madrid, Spain

Background: There is an unmet clinical need for novel therapies for patients with platinum-sensitive recurrent ovarian cancer (PSROC). Trophoblast cell-surface antigen 2 (TROP2) is highly expressed in multiple tumor types, including ovarian cancer. Sacituzumab tirumotecan (sac-TMT) is a TROP2-directed antibody-drug conjugate with a unique, bifunctional linker that maximizes delivery of a belotecan-derived topoisomerase 1 inhibitor payload to tumor cells. The current TroFuse-022/ENGOT-ov84/GOG-3103 study (NCT06824467) is evaluating maintenance therapy with sac-TMT ± bevacizumab (bev) vs standard of care (SoC) following second-line (2L) platinum-based doublet chemotherapy (chemo) in participants (pts) with PSROC. The study includes a safety run-in part (part 1) and a phase 3 part (part 2). We present the trial design for part 2 of this study. **Methods:** Part 2 is enrolling ~750 pts aged ≥18 y with histologically confirmed epithelial ovarian, fallopian tube, or primary peritoneal carcinoma with PSROC (radiographic evidence of PD >180 d after the last dose of first-line [1L] platinum-based doublet chemo ± bev); pts with *BRCA* mutation or homologous recombination deficiency-positive status with no evidence of disease (NED), CR, or PR after 1L chemo must have received a PARP inhibitor as 1L maintenance therapy. All pts must have received 6 cycles of 2L carboplatin-based doublet chemo ± bev and achieved NED, CR, PR, or SD per investigator assessment; pts with SD must have received bev in combination with 2L chemo and be eligible to continue treatment with bev. Other inclusion criteria are an ECOG PS of 0 or 1 and an available tumor sample for central testing of TROP2 and *BRCA* status. Candidates for curative-intent surgery or radiotherapy at enrollment are not eligible. Pts are randomized 1:1 to receive maintenance therapy with sac-TMT 4 mg/kg IV Q2W ± bev 15 mg/kg IV Q3W (arm 1) or SoC treatment with observation ± bev 15 mg/kg IV Q3W (arm 2). Use of bev is at the investigator's discretion and can only be given to eligible pts who received ≥2 doses of bev 15 mg/kg Q3W or equivalent dose (with no dose reductions) in combination with 2L chemo; pts with SD after 2L chemo must receive bev (pts with SD not receiving bev are ineligible). Treatment with sac-TMT (arm 1) and bev (if elected, arms 1 and 2) continues until PD, unacceptable toxicity, or other protocol-defined reason for discontinuation. Pts in arm 2 are not permitted to cross over to arm 1. The primary endpoint is PFS per RECIST version 1.1 as assessed by blinded independent central review. Secondary endpoints include OS, safety and tolerability, and patient-reported outcomes. PFS and OS will be assessed in pts with medium/high TROP2 expression tumors and all pts. The study is ongoing, and enrollment in part 2 is open. Clinical trial information: NCT06824467; EU CT, 2023-508015-23; UTN, U1111-1297-4489. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS5637 **Poster Session**

REJOICE-Ovarian01: Phase 3 part of a phase 2/3 study evaluating raludotatug deruxtecan (R-DXd) versus treatment of physician's choice in patients with platinum-resistant ovarian cancer. First Author: Debra L. Richardson, Stephenson Cancer Center, University of Oklahoma Health Campus, Oklahoma City, OK

Background: Platinum-resistant ovarian cancer (PROC) is associated with poor outcomes. Standard-of-care single-agent non-platinum therapies, with or without bevacizumab, have demonstrated only modest activity in PROC, while targeted therapies remain limited to specific biomarker-defined patient populations. Cadherin-6 (CDH6), a mediator of cell–cell adhesion, is aberrantly expressed in up to 94% of epithelial ovarian cancer tumors. R-DXd is an antibody–drug conjugate comprising a humanized CDH6 antibody covalently linked to a topoisomerase I inhibitor payload (DXd) via a tumor-selective cleavable linker. REJOICE-Ovarian01 is a Phase 2/3 study of R-DXd monotherapy in patients with PROC. Among patients who had completed ≥18 weeks of follow-up or discontinued treatment in the Phase 2 dose-optimization part, the objective response rate (ORR) by blinded independent central review (BICR) was 44.4% (16/36) at 4.8 mg/kg, 50.0% (18/36) at 5.6 mg/kg, and 57.1% (20/35) at 6.4 mg/kg, including three complete responses overall. Clinically meaningful tumor responses were observed irrespective of tumor CDH6 expression, and the safety profile of R-DXd was manageable. R-DXd 5.6 mg/kg was identified as the optimal dose for further evaluation in the Phase 3 part of REJOICE-Ovarian01, which is described here. **Methods:** The Phase 3 part of REJOICE-Ovarian01 (NCT06161025) is a global, randomized, open-label study of R-DXd in patients with platinum-resistant, high-grade serous or high-grade endometroid ovarian, primary peritoneal, or fallopian tube cancer. Patients must have received 1–4 prior lines of therapy (LOT), including bevacizumab (unless ineligible) and mirvetuximab soravtansine for folate receptor α–positive disease (unless not available locally). Patients are not selected based on tumor CDH6 expression. Approximately 600 patients will be randomized 1:1 to receive either R-DXd 5.6 mg/kg intravenously every 3 weeks until disease progression per Response Evaluation Criteria in Solid Tumours version 1.1 (RECIST 1.1), lost to follow-up, death, or other reason per protocol, or treatment of physician's choice (TPC; weekly paclitaxel, pegylated liposomal doxorubicin, or topotecan) per local guidelines. Randomization will be stratified by number of prior LOT, tumor CDH6 expression, and by TPC. The primary endpoint is progression-free survival (PFS) by BICR per RECIST 1.1. Key secondary endpoints include overall survival (OS) and quality of life. Stratified log-rank tests will be used to compare PFS and OS between treatment groups. Stratified Cox regression models will be fitted to estimate the hazard ratios for PFS and OS. Enrollment in Phase 3 began in December 2025. Clinical trial information: NCT06161025. Research Sponsor: Daiichi Sankyo, Inc.; Merck.

TPS5638 **Poster Session**

A phase 1/2 study of ubamatamab (REGN4018), a MUC16×CD3 bispecific antibody, administered alone or in combination with cemiplimab in a low-grade serous ovarian cancer cohort: Trial in progress. First Author: Els Van Nieuwenhuysen, Leuven Kankerinstituut, Leuven, Belgium

Background: Low grade serous ovarian cancer (LGSOC) typically has a poor response to chemotherapy, presenting an unmet need for efficacious novel therapies that remain tolerable. Mucin 16 (MUC16) is a cell surface glycoprotein that is highly expressed in ovarian cancers, including LGSOC, and has been identified as a potential therapeutic target. Ubamatamab, a MUC16 × cluster of differentiation 3 bispecific antibody, bridges MUC16+ tumor cells and T cells through a major histocompatibility complex-independent mechanism, promoting cytotoxicity. In a first-in-human study (NCT03564340), ubamatamab demonstrated an acceptable safety profile and durable clinical activity in recurrent ovarian cancer, including LGSOC, which has particularly high MUC16 expression on tumor cells. Here, we describe an LGSOC-specific expansion cohort. **Methods:** In the LGSOC-specific cohort, patients who have received prior platinum-containing therapy (no maximum number of prior therapies) and whose disease has relapsed or progressed after the most recent line of therapy will receive ubamatamab 800 mg intravenously (IV) once every 3 weeks (Q3W). Prior to Q3W dosing of ubamatamab, patients will receive once-weekly step-up dosing to mitigate the risk of cytokine release syndrome, as well as sarilumab 350 mg IV prophylaxis on Day 1. Utilizing a Simon two-stage design, 20 patients will initially be enrolled in this cohort, expanding to 50 if there are ≥3 objective responses. The cohort may be further expanded to 100 patients if ≥14 objective responses (28%) are observed in the first 50 patients. The primary endpoint is objective response rate per Response Evaluation Criteria in Solid Tumors version 1.1. Secondary endpoints include safety, pharmacokinetics, patient-reported outcomes and further efficacy assessments. As of January 5, 2026, 6 patients with LGSOC have initiated ubamatamab treatment. Findings from this study will clarify the therapeutic potential of targeting MUC16 in LGSOC. Clinical trial information: NCT03564340. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS5639 **Poster Session**

A phase 1/2 study of REGN5668, a MUC16×CD28 costimulatory bispecific antibody, in combination with other targeted therapies, in patients with recurrent ovarian or endometrial cancer: Trial in progress update. First Author: Roisin Eilish O'Cearbhaill, Department of Medicine, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY

Background: REGN5668 and ubamatamab are immunoglobulin G4-based bispecific antibodies that bridge mucin 16 (MUC16)+ tumor cells to T-cell–expressed cluster of differentiation (CD)28 and CD3, respectively, to stimulate T-cell cytotoxicity. Cemiplimab (anti–programmed cell death-1 [PD-1]) and fianlimab (anti-lymphocyte activation gene 3 [LAG-3]) are monoclonal antibodies that target inhibitory T-cell immune checkpoints. This first-in-human, multicenter, Phase 1/2 trial (NCT04590326) will assess safety, tolerability, pharmacokinetics (PK), and antitumor activity of REGN5668 + cemiplimab ± fianlimab (Module 1) or ubamatamab (Module 2) in patients with platinum-resistant recurrent ovarian cancer (OC) or endometrial cancer (EC). In Module 1, REGN5668 dose escalation is complete (n=58), demonstrating early clinical activity and only 1 dose-limiting toxicity, a treatment delay of >7 days due to Grade 1 dry eye. Here we present details of additional dose escalation and expansion modules currently enrolling patients. **Methods:** Module 1 dose expansion will evaluate REGN5668 + cemiplimab ± fianlimab in OC and EC cohorts. In the OC cohort, patients will receive REGN5668 + cemiplimab + fianlimab, with an initial 12-patient safety lead-in. In the EC cohort, patients will receive REGN5668 + cemiplimab; an additional EC cohort may be added to evaluate REGN5668 + cemiplimab + fianlimab. Each cohort will follow a Simon two-stage design. In stage 1, 20 patients will be enrolled; if there are ≥3 objective responses, stage 2 will proceed with enrollment of ≤50 patients. In Module 2, dose escalation will evaluate patients with OC receiving escalating doses of REGN5668 + ubamatamab using a Bayesian optimal interval design. Patients may also receive sarilumab to mitigate the risk of cytokine release syndrome. Key OC cohort eligibility criteria include histologically confirmed diagnosis of advanced epithelial OC (except carcinosarcoma), ≥1 prior line of platinum-based systemic therapy, and disease relapse or progression during most recent therapy. Key EC cohort eligibility criteria include histologically confirmed diagnosis of EC with disease recurrence or progression after anti–PD-1 therapy and platinum-based chemotherapy, ≤4 prior lines of systemic therapy, ≥30 days since anti–PD-1 therapy administration, and ≥25% of tumor cells that are MUC16+. Primary endpoints are safety and PK in dose escalation, and objective response rate (ORR) in dose expansion. Secondary endpoints include ORR (Module 2 dose escalation), safety and PK (Module 1 dose expansion), further efficacy outcomes, and immunogenicity (all cohorts). Module 1 dose expansion has opened, with the first two patients enrolled. In Module 2, dose escalation of REGN5668 has progressed through multiple dose levels; enrollment is ongoing. Clinical trial information: NCT04590326. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS5640 **Poster Session**

RegeNovar: A phase I/II study of ubamatamab plus carboplatin, paclitaxel, and bevacizumab as salvage therapy in ovarian cancer with poor response to first-line chemotherapy. First Author: Benoit You, Centre Hospitalier Lyon Sud, and GINECO, Pierre-Benite, France

Background: Patients with advanced epithelial ovarian cancer (EOC) treated with neoadjuvant platinum-based chemotherapy who are not amenable to complete interval cytoreductive surgery (ICS) due to poor chemosensitivity—defined by a CA-125 KELIM score <1.0—have a particularly poor prognosis, with approximately 20% 5-year overall survival. Ubamatamab is a human IgG4-based bispecific antibody targeting MUC16 (CA-125–expressing ovarian cancer cells) and CD3+ T cells and has demonstrated clinical activity in platinum-resistant recurrent ovarian cancer (Lee et al, Proc ESMO 2025). We hypothesize that adding ubamatamab to standard carboplatin–paclitaxel–bevacizumab may enhance tumor response and improve surgical resectability in patients with advanced high-grade EOC with poor chemosensitivity and disease not amenable to complete ICS after initial neoadjuvant chemotherapy. **Methods:** RegeNovar (EuCT 2025-524232-20-00) is an academic, multicenter phase I–II trial enrolling patients with stage III–IV high-grade EOC who, after 3–4 cycles of standard neoadjuvant carboplatin–paclitaxel administered every 3 weeks, present two poor prognostic features: (1) unfavorable standardized KELIM score <1.0, and (2) disease considered not amenable to complete ICS. The trial includes two sequential parts: (i) a phase I safety run-in to evaluate the safety of ubamatamab in combination with carboplatin–paclitaxel–bevacizumab and confirm the recommended phase II dose (RP2D); and (ii) a phase II efficacy part assessing the antitumor activity of this combination. Patients receive carboplatin AUC5 ; paclitaxel 175 mg/m²; and bevacizumab 15 mg/kg Q3 weeks for three cycles. Ubamatamab is administered with weekly step-up dosing during cycle 1, followed by a fixed dose of 800 mg Q3 weeks during cycles 2 and 3. Feasibility of complete late cytoreductive surgery is evaluated after three cycles of the study regimen. Subsequent maintenance treatment consists of olaparib plus bevacizumab for patients with BRCA-mutated or HRD-positive tumors, or ubamatamab plus bevacizumab for up to 15 months in patients with HRD-negative tumors. The primary endpoint of phase I is safety, including treatment-related adverse events (NCI CTCAE v6.0), DLT within the first 4 weeks, and RP2D determination using a BOIN design targeting a DLT probability ≤28%. The primary endpoint of phase II is the objective response rate (ORR) after three cycles per RECIST 1.1 (H0 5%, H1 30%, one-sided α=5%, power=80%). Total 31 to 43 patients are required, depending on potential need for dose de-escalation. Secondary endpoints include ORR, duration of response, disease control rate, rate of late cytoreductive surgery, PFS, OS, and progression-free survival during subsequent therapy. The trial is sponsored by ARCAGY-GINECO, conducted in 12 French centers, and funded by Regeneron. Clinical trial information: EuCT 2025-524232-20-00. Research Sponsor: Regeneron.

TPS5641 **Poster Session**

RAINFOL-04 (ENGOT-OV96/GOG-3134): A phase 3, open-label, randomized study of rinatabart sesutecan (Rina-S) plus standard of care (SOC) vs SOC as maintenance treatment after second-line platinum-based chemotherapy in patients with recurrent platinum-sensitive ovarian cancer. First Author: Toon Van Gorp, Division of Gynaecological Oncology, University Hospital Leuven, Leuven Cancer Institute, Leuven, Belgium; and BGOG, Leuven, Belgium

Background: Ovarian cancer (OC) is the eighth leading cause of cancer-related death in women globally. In patients with advanced OC, 70%-80% develop recurrent platinum-sensitive OC (PSOC) within 3 years after initial therapy. Standard treatment for recurrent PSOC includes platinum-based chemotherapy ± bevacizumab (BEV), but in most patients, disease progression occurs within a year. Rina-S is an antibody-drug conjugate targeting folate receptor alpha (FRα) with a novel hydrophilic protease-cleavable linker and a topoisomerase I inhibitor, exatecan, payload. In cohort B1 of the phase 1/2 RAINFOL-01 study (NCT05579366), Rina-S showed encouraging antitumor activity and was tolerated in patients with heavily pretreated advanced OC. We report the design of ENGOT-OV96/GOG-3134 (RAINFOL-04), a phase 3, randomized study of Rina-S + standard of care (SOC) vs SOC as maintenance treatment for patients with recurrent PSOC (NCT07225270). **Methods:** This phase 3 open-label study will enroll ~528 patients with platinum-sensitive high-grade serous or endometrioid epithelial OC, primary peritoneal cancer, or fallopian tube cancer regardless of their FRα expression. Patients must have disease progression >6 months after the last dose of first-line platinum chemotherapy and have achieved at least stable disease following completion of second-line platinum-based chemotherapy ± BEV. Patients will be randomized 1:1 to receive Rina-S 120 mg/m^2 intravenously every 3 weeks plus SOC or SOC (BEV or observation) until disease progression, unacceptable toxicity, or discontinuation. The primary endpoint is progression-free survival (PFS) per RECIST v1.1 by investigator assessment. The key secondary endpoint is overall survival. Additional secondary endpoints include PFS per RECIST v1.1 by blinded independent central review, PFS2 (time from randomization to the second progression or death), safety, and patient-reported outcomes. The trial is currently recruiting. Clinical trial information: NCT07225270. Research Sponsor: Genmab.

TPS5642 **Poster Session**

A phase 3, randomized, open-label study of INCB123667 versus investigator's choice of chemotherapy in patients with platinum-resistant ovarian cancer with cyclin E1 overexpression (MAESTRA 2, ENGOT-OV95, GOG-3137). First Author: Rebecca Kristeleit, Guy's and St Thomas' NHS Foundation Trust, Great Maze Pond, London, United Kingdom

Background: Epithelial ovarian cancer (EOC) accounts for ~90% of ovarian cancers, with high-grade serous ovarian cancer (HGSOC) the most common histology. Despite high initial response rates to platinum-based therapy, ~70% of patients (pts) with advanced EOC relapse and nearly all recurrent disease ultimately becomes platinum resistant. Platinum-resistant ovarian cancer (PROC) remains a major therapeutic challenge with poor prognosis and limited treatment options. Standard therapies include single-agent, non-platinum chemotherapy with or without bevacizumab (bev), and mirvetuximab soravtansine (mirv) for pts with folate receptor alpha (FRα)-positive HGSOC. Approximately 50% of ovarian cancers overexpress cyclin E1. Cyclin E1 overexpression and increased cyclin-dependent kinase 2 (CDK2) activity are associated with poor outcomes and treatment resistance in ovarian cancer. A synthetic lethal relationship between CDK2 inhibition and cyclin E1 overexpression provides a strong biological rationale for selective CDK2 inhibition in this molecularly defined population. INCB123667 is a potent, selective, oral, small-molecule CDK2 inhibitor. In an ongoing phase 1 study, INCB123667 demonstrated manageable safety and objective response rates >30% in heavily pretreated pts with PROC and cyclin E1 overexpression [Damian S, et al. *J Clin Oncol.* 2025;43(16 suppl):5514; Simonelli M, et al. *Ann Oncol.* 2024;35(suppl 2):S495]. **Methods:** MAESTRA 2 (NCT07214779) is a global, multicenter, randomized, open-label phase 3 study evaluating the efficacy and safety of INCB123667 vs investigator's choice chemotherapy (ICC) in ~466 female pts with platinum-resistant, high-grade serous epithelial ovarian, fallopian tube, or primary peritoneal cancer with tumor cyclin E1 overexpression by immunohistochemistry (IHC; ≥75% of tumor cells with IHC score ≥1+). Eligible pts must have received 1-4 prior lines of systemic therapy, for whom single-agent chemotherapy is an appropriate next treatment. Pts should have received prior bev, and pts with FRα-positive disease should have received prior mirv. Pts are randomized 1:1 to INCB123667 50 mg twice daily or ICC (weekly paclitaxel, pegylated liposomal doxorubicin, gemcitabine, or topotecan). Randomization is stratified by primary platinum-free interval, ICC, and number of prior lines of systemic therapy. Dual primary endpoints are progression-free survival (PFS) by blinded independent central review (BICR) per RECIST v1.1 and overall survival. A key secondary endpoint is objective response by BICR per RECIST v1.1. Additional secondary endpoints include safety and tolerability, duration of response, PFS and objective response by investigator assessment, and health-related quality of life. The first pt was enrolled in Dec 2025. Clinical trial information: NCT07214779. Research Sponsor: Incyte Corporation.

TPS5643 **Poster Session**

Rationale and study design of the KOV-HIPEC-04: A phase III randomized controlled trial in primary stage three and four ovarian cancer after interval cytoreductive surgery (FOCUS). First Author: Myong Cheol Lim, Center for Gynecologic Cancer, National Cancer Center, Goyang, South Korea

Background: The addition of hyperthermic intraperitoneal chemotherapy (HIPEC) during interval cytoreductive surgery increases progression-free and overall survival for patients with stage III ovarian cancer in two randomized controlled trials (OV-HIPEC-01 and KOV-HIPEC-01). This trial aims to identify the survival benefit of HIPEC in stage III & IV ovarian cancer in the era of maintenance therapy of bevacizumab and/or PARP inhibitors. **Methods:** Ovarian cancer patients will be randomized at the time of interval cytoreductive surgery with achieving complete cytoreduction or cytoreduction with no more than 2.5mm size of residual disease to receive HIPEC (41.5 cisplatin 75mg/m^2, 90 minutes) or not (Control arm). After recovery from surgery, patients will receive postoperative platinum-based adjuvant chemotherapy followed by maintenance therapy with PARP inhibitor or bevacizumab. The primary objective of the trial is to evaluate OS in two groups. Secondary objectives are PFS, cancer-specific survival, time to first subsequent therapy (TFST), safety, CA-125 KELIM, and quality of life. Assuming that the enrollment period is 5 years and the follow-up period is 3 years, the total number of events required is 263. Based on the log-rank test, the total number of subjects required to prove HR 0.67 with a two-sided alpha of 0.05 and 90% power is 494. Considering 5% drop-out, 520 patients are finally studied. Clinical trial information: NCT05827523. Research Sponsor: National Cancer Center Korea (NCC2110790, NCC2110770).

TPS5644 **Poster Session**

FRAmework-01: A two-part phase 3 study of sofetabart mipitecan versus chemotherapy or mirvetuximab soravtansine in platinum-resistant ovarian cancer (PROC), and sofetabart mipitecan plus bevacizumab versus platinum-based chemotherapy plus bevacizumab in platinum-sensitive ovarian cancer (PSOC). First Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard, University Claude Bernard, Lyon, France

Background: Folate receptor alpha (FRα) is overexpressed in ovarian cancer and is a validated therapeutic target. Mirvetuximab soravtansine (MIRV), an antibody drug conjugate (ADC) targeting FRα, is approved for the treatment of patients with PROC and high FRα expression (≥75% tumor cells with 2+ and/or 3+ staining intensity). Given MIRV's limited indication and its association with specific side effects, including ocular adverse events and peripheral neuropathy, there remains a significant medical need to improve outcomes for a broader population of patients with ovarian cancer. Sofetabart mipitecan is an FRα-targeting ADC composed of an Fc-silenced, humanized IgG1 antibody, a novel polysarcosine hydrophobicity masking agent with a dipeptide cleavable linker, and the topoisomerase I inhibitor payload exatecan at a drug-antibody ratio of 8. Data from the Phase 1 study indicate that sofetabart mipitecan monotherapy demonstrates promising and durable clinical activity, with high objective response rates and a tolerable safety profile, in heavily pretreated patients with PROC. Responses were observed across all FRα levels, including in patients who received prior MIRV treatment, and there were no reports of keratopathy or significant peripheral neuropathies. Sofetabart mipitecan was recently granted Breakthrough Therapy Designation by the FDA. **Methods:** In Part A, 530 participants with PROC who received ≤3 prior lines of systemic cytotoxic therapy (or ≤4 lines if MIRV was included), will be randomized in a 1:1 ratio to receive either sofetabart mipitecan, or the investigator's choice (IC) of chemotherapy (paclitaxel, pegylated liposomal doxorubicin [PLD], gemcitabine, or topotecan) or MIRV (if eligible per local label). In Part B, 550 participants with PSOC who received ≤2 prior lines of systemic cytotoxic therapy and had disease progression either during or within six months of completing treatment with a poly (ADP-ribose) polymerase inhibitor (PARPi), will be randomized in a 1:1 ratio to receive either sofetabart mipitecan plus bevacizumab (bev), or the IC of carboplatin-based chemotherapy (paclitaxel, PLD, or gemcitabine) plus bev. Study Parts A and B will enroll participants irrespective of their tumor's FRα expression level. Each part has progression-free survival as its primary endpoint, while overall survival is a key secondary endpoint. Study parts will be conducted separately, and statistical analyses will be performed independently. Trial Status: The study is actively enrolling participants in Part A and B. Clinical trial information: NCT07213804. Research Sponsor: Eli Lilly and Company.

TPS5645 **Poster Session**

Fern-EC-01 (BNT323-01): A phase 3 trial of trastuzumab pamirtecan (HER2 ADC) versus investigator's choice of chemotherapy in patients with previously treated, HER2-expressing, recurrent endometrial cancer (EC). First Author: Floor Jenniskens Backes, Division of Gynecologic Oncology, Ohio State University Wexner Medical Center, Columbus, OH

Background: Despite advancements in frontline therapies for EC, treatment options for recurrent/refractory disease remain limited. HER2 overexpression in EC is associated with rapid disease progression, tumor invasiveness, a high risk of recurrence, and poor prognosis. Trastuzumab pamirtecan (T-Pam; BNT323/DB-1303) is an investigational HER2-targeting antibody-drug conjugate (ADC) with a DNA topoisomerase I inhibitor payload and a drug-to-antibody ratio of ~8. In a phase 1/2a trial (NCT05150691), T-Pam demonstrated encouraging clinical benefit in patients with HER2-expressing EC, efficacy was observed across all HER2 expression levels and patient subgroups with a manageable safety profile. **Methods:** Following a protocol amendment, this open-label, randomized, multi-site, phase 3 trial (Fern-EC-01; BNT323-01) is enrolling patients with recurrent, HER2 expressing EC (assessed by central laboratory testing using IHC) who have measurable disease defined by RECIST v1.1, an ECOG PS of 0-2, and have received ≥1 prior line of platinum-based therapy (in any setting) and prior immune-checkpoint inhibitor treatment. Up to three lines of prior therapy are permitted. Prior hormonal therapy and radiation are allowed but do not count as prior lines of therapy. Prior exatecan-containing treatment is not allowed. All patients will receive treatment until RECIST v1.1 defined progressive disease, unacceptable toxicity, withdrawal of consent, or other discontinuation criteria are met. The trial is enrolling two cohorts. In Cohort 1, ≈420 patients with HER2-expressing (IHC 1+ or 2+) EC will be randomized 2:1 to evaluate the efficacy and safety of T-Pam vs investigator's choice of chemotherapy (doxorubicin, paclitaxel, or docetaxel in case of contraindication to paclitaxel and availability at the site). Stratification is based on HER2 expression (IHC 1+; 2+) and prior lines of therapy (1; 2+). The primary endpoint for Cohort 1 is progression-free survival (PFS) by blinded independent central review (BICR); overall survival is a key secondary endpoint. In Cohort 2, ≈60 patients with HER2 IHC 3+ EC will receive T-Pam; the primary endpoint for this cohort is objective response rate by BICR. Enrollment is ongoing globally. Clinical trial information: NCT06340568. Research Sponsor: BioNTech SE in collaboration with Duality Biologics.

TPS5646 **Poster Session**

RAINFOL-03 (ENGOT-EN-31/GOG-3128): A global, phase 3, open-label, randomized study of rinatabart sesutecan (Rina-S) vs investigator's choice of chemotherapy in patients with endometrial cancer after platinum-based chemotherapy and programmed death-ligand 1 inhibition. First Author: Antonio Gonzalez Martin, Department of Medical Oncology, Cancer Center Clínica Universidad de Navarra, Madrid, Spain

Background: Patients with recurrent endometrial cancer (EC) whose disease progresses after platinum-based chemotherapy (PBC) and programmed death (ligand) 1 [PD-(L)1] inhibition have a poor prognosis and limited, ineffective treatment options. Single-agent chemotherapy in this setting has been associated with low objective response rates (ORRs; ~15%) and median progression-free survival (PFS) of ~3-4 months. Rina-S is an investigational antibody-drug conjugate targeting folate receptor alpha (FRα) with a novel hydrophilic protease-cleavable linker and topoisomerase I inhibitor, exatecan, payload. In the phase 1/2 RAINFOL-01 trial (NCT05579366), Rina-S 100 mg/m^2 showed encouraging antitumor activity, with a 50% confirmed ORR, including 2 complete responses, and a manageable safety profile in patients with heavily pretreated EC after progression on PBC and a PD-(L)1 inhibitor (Winer IS, et al. *J Clin Oncol*. 2025:43[16 suppl]:3039). We report the design of RAINFOL-03, a global, open-label, randomized phase 3 study of Rina-S vs investigator's choice (IC) therapy in patients with EC who have progressed on PBC and a PD(L)-1 inhibitor (NCT07166094). **Methods:** This phase 3 open-label study will enroll ~544 patients with recurrent or progressive EC (any subtype excluding neuroendocrine tumors, carcinosarcoma, or endometrial sarcoma), measurable per RECIST v1.1, who have received 1-3 prior lines of therapy, including PBC and a PD(L)-1 inhibitor. Patients will be randomized 1:1 to receive Rina-S 100 mg/m^2 intravenously every 3 weeks or IC therapy (paclitaxel or doxorubicin) until disease progression or unacceptable toxicity. Patients will be enrolled regardless of FRα expression level; however, FRα expression levels will be required for stratification at randomization. Dual primary endpoints are PFS per RECIST v1.1 by investigator assessment and overall survival. The key secondary endpoint is ORR per RECIST v1.1 by investigator assessment. Additional secondary endpoints include PFS and ORR per RECIST v1.1 by blinded independent central review (BICR), duration of objective response per RECIST v1.1 by investigator assessment and BICR, safety, and quality of life outcomes. The trial is currently recruiting. Clinical trial information: NCT07166094. Research Sponsor: Genmab A/S.

Puxitatug samrotecan (AZD8205) vs chemotherapy in patients with B7-H4–selected advanced/metastatic endometrial cancer: The phase 3 randomized Bluestar-Endometrial01 (BE01)/GOG-3110/ENGOT-EN28 trial. First Author: Stephanie Gaillard, Johns Hopkins Sidney Kimmel Cancer Center, Baltimore, MD

Background: The transmembrane glycoprotein B7-H4 is highly expressed in endometrial cancer (EC), with limited expression in normal tissue; therefore, B7-H4 is an attractive antibody–drug conjugate (ADC) target in the treatment of advanced/recurrent EC. Puxitatug samrotecan (Puxi-Sam), a novel B7-H4-directed topoisomerase I inhibitor ADC, was assessed as monotherapy in the first-in-human, Phase 1/2a BLUESTAR trial in several B7-H4-expressing tumors, and showed manageable toxicity and promising efficacy during dose escalation in heavily pre-treated patients (pts).[1] In pts with advanced/recurrent EC, who progressed after available standard of care therapy (including chemotherapy and/or a programmed death [PD]-ligand [L] 1 inhibitor), objective response rates (ORRs) were 34.6% and 38.5% with 2.0 and 2.4 mg/kg Puxi-Sam, respectively, after ≥13 weeks of follow-up.[2] The safety profile of Puxi-Sam was favorable, with manageable hematologic and gastrointestinal toxicities, no adverse events (AEs) leading to discontinuation, and low dose reduction rates due to treatment-related AEs.[2] Following these encouraging results, Bluestar Endometrial01, a global Phase 3 trial, will investigate Puxi-Sam monotherapy versus physician's choice of chemotherapy in pts with B7-H4-selected EC whose disease has progressed following prior platinum-based chemotherapy and immunotherapy. **Methods:** This Phase 3, randomized, open-label, multicenter study includes pts with B7-H4-selected advanced/metastatic EC that progressed following platinum-based chemotherapy and anti-PD-1/anti-PD-L1 therapy. Approximately 700 pts will be randomized 1:1 to either Arm A: Puxi-Sam (2.4 mg/kg; intravenous [IV] on Day 1 every 3 weeks [q3w]) or Arm B: either doxorubicin (60 mg/m^2 IV on Day 1 q3w) or paclitaxel (80 mg/m^2 IV on Days 1, 8, and 15 in 28-day cycles). The primary outcomes are progression-free survival (PFS) and overall survival (OS). Secondary outcomes include ORR, duration of response (DoR), second PFS, time until first subsequent anticancer therapy (TFST) and second subsequent anticancer therapy (TSST) after discontinuation of the randomized treatment, or death, and time until discontinuation of treatment (TDT) for any reason, or death. All outcomes are to be assessed for Arm A versus Arm B. Safety will be assessed throughout. Clinical trial information: NCT07044336. First Patient In date: Aug 1, 2025. 1. Meric-Bernstam F, et al. *Ann Oncol*. 2024;35:S485–S486. 2. Gaillard S, et al. *Gynecol Oncol*. 2025;200:347–348. Adjuvant radiotherapy versus observation following curative surgery for early-stage oral squamous cell carcinoma (AREST; CTRI/2017/07/009114). First Author: Sudhir Vasudevan Nair, Tata Memorial Center, Mumbai, India

Background: The role of adjuvant radiotherapy (RT) in early-stage, node-negative oral squamous cell carcinoma (OSCC) with one or more intermediate risk factors - such as depth of invasion (DOI) ≥5 to ≤10mm, perineural invasion (PNI), lymphovascular emboli (LVE), or poor differentiation - remains debatable and is largely based on retrospective data. This multicenter, open-label, phase III randomized controlled trial was designed to assess the impact of post-operative adjuvant RT in this setting. **Methods:** Patients with early-stage (pT1-T2), node-negative (pN0) OSCC undergoing adequate surgery (defined as clear margins ≥5mm and at least ipsilateral level I-III neck dissection with ≥16 nodes) with presence of one or more intermediate risk factors were screened. Eligible patients underwent stratified randomization (oral cavity subsite, PNI/LVE, and differentiation) in 1:1 ratio to either observation or adjuvant RT (60Gy in 30 fractions over 6-weeks) to the resected tumor-bed and at-risk neck nodal region after written informed consent. Primary endpoint was loco-regional recurrence-free survival (LRFS) measured from randomization to first documented event of local and/or regional recurrence from index cancer. All time-to-event outcomes were computed using Kaplan-Meier (KM) method with log-rank test for comparison and expressed as 3-year point estimates with 95% confidence intervals (CI). The planned sample size (N=392) provided 80% power at an α of 0.05 to detect a Hazard Ratio (HR) of 0.6256, assuming 3-year LRFS of 70% in the observation arm. **Results:** Following curative surgery, a total of 392 patients were randomized (191 to adjuvant RT; 201 to observation). Baseline characteristics were balanced between the two arms. At a median follow-up of 47.2 months (inter-quartile range=30-59.4 months), 3-year KM estimate of LRFS was 89.2% in adjuvant RT arm vs 80.9% in observation arm (HR=0.52, 95% CI=0.30-0.91; p=0.02) in the intention-to-treat (ITT) population and 91.1% vs 80.9% (HR=0.43, 95%CI=0.23-0.80; p=0.01) on per-protocol (PP) analyses. Cumulative incidence of loco-regional failure with death as competing event was 10.6% (95%CI=6.1%-15.1%) with adjuvant RT and 18.9% (95%CI=13.3%-24.6%) with observation (HR=0.52, 95% CI=0.30-0.91; p=0.021) in the ITT population and 8.7% (95%CI=4.3%-13.1%) vs 18.9% (95% CI=13.3%-24.6%) (HR=0.43, 95%CI=0.23-0.79; p=0.007) on PP analyses. Disease-free and overall survival were not significantly different between the two arms. Subgroup analysis identified oral tongue deriving higher benefit of adjuvant RT compared to buccal mucosa. **Conclusions:** Adjuvant RT significantly reduces risk of loco-regional recurrence for early-stage, node-negative adequately resected OSCC, particularly oral tongue. However, such reduction in loco-regional failure does not translate into significant survival benefit. Clinical trial information: CTRI/2017/07/009114. Research Sponsor: NATIONAL CANCER GRID; NCG Project No.2019/01.

Impact of lymph node dissection extent on disease-free survival with postoperative nivolumab plus concurrent chemoradiotherapy in head and neck squamous cell carcinoma: A post-hoc analysis of the NIVOPOSTOP trial. First Author: Ariane Lapierre, Hospices Civils de Lyon, Pierre Benite, France

Background: Postoperative nivolumab added to concurrent Chemo-Radiotherapy (CRT) after surgery has been shown to improve disease-free survival (DFS) in patients with resected head and neck squamous cell carcinoma (HNSCC) at high risk of relapse. However, extensive nodal dissection has long be suspected to hinder response to immunotherapy but prospective data remains scarce. **Methods:** We analyzed the surgical procedures of the patients included in the primary analysis of the NIVOPOSTOP study regarding neck lymph node dissection (LND). Patients were classified with either uni- or bilateral LND. The number of nodes in the pathological report was also studied. The extent of the LND on DFS was analyzed in univariate and multivariate analysis. **Results:** Surgical information was available for all 666 patients. Four patients did not undergo any LND. Of the 662 patients who underwent nodal surgery, 239 (36%) underwent unilateral LND and 423 (64%) bilateral LND. The proportion of patients with bilateral / unilateral LND was similar in both treatment. Patients who underwent bilateral LND had statistically higher stage tumors versus unilateral LND (76% vs 61% stage IV) and a significantly higher proportion of laryngeal and hypopharyngeal tumors (17% vs 3% and 16% vs 7% respectively). The median numbers of nodes removed were 39 overall, 25 on the right side of the neck, and 24 on the left. As compared to unilateral LND, bilateral LND was associated with worse DFS in univariate analysis (HR 1.56 (95%CI 1.18; 2.05)). After adjusting for performance status, tumor site and p16 status, clinical stage, pathological risk factors of relapse (nodal extracapsular extension, margin status, perineural invasion, ≥ 4 involved nodes), the association was no longer statistically significant: HR 1.26 (95%CI 0.92; 1.71), Wald test p-value 0.15. There was no interaction between the type of LND (unilateral or bilateral) and the type of treatment (without or with nivolumab) on DFS. The benefit of adding Nivolumab to CRT was similar for unilateral LND (HR 0.79 (95%CI 0.50; 1.26)) and bilateral LND (HR 0.77 (95%CI 0.57; 1.03)) in Cox model stratified for p16 status. Regarding the extent of LND, the benefit of adding Nivolumab to CRT in the 330 patients who underwent removal of more than 39 neck lymph nodes, on one or both sides, was similar to that of the whole population (HR 0.75 (95%CI 0.54; 1.05)). **Conclusions:** The DFS benefit of adding nivolumab to standard postoperative therapy (cisplatin-RT) was not changed by whether the LND was bilateral or unilateral and persisted in patients in whom more than 39 cervical lymph nodes were removed, on one or both sides. As such, no evidence supports reducing the extent of neck LND when immunotherapy is incorporated into the management of high risk resected HNSCC. Clinical trial information: NCT03576417. Metronomic adjuvant chemotherapy (MACE) in locally advanced oral cavity squamous cell carcinoma post-surgery and adjuvant treatment (MACE postop): A phase III randomized controlled trial. First Author: Pankaj Chaturvedi, ACTREC, Tata Memorial Centre, Homi Bhabha National Institute, Mumbai, India

Background: The role of maintenance systemic therapy following definitive surgery and adjuvant treatment in locally advanced oral cavity squamous cell carcinoma (OCSCC) remains undefined. This phase III trial evaluated whether oral metronomic adjuvant chemotherapy (MACE) improves survival compared with observation. **Methods:** This multicenter, open-label, phase III superiority trial conducted in India enrolled patients with stage II–IV OCSCC (AJCC 7th edition) who were clinico-radiologically disease-free 1–2 months after completion of definitive surgery with adjuvant treatment. Patients were randomly assigned (1:1) to observation (OBS) or oral MACE for up to 18 cycles. MACE comprised methotrexate 15 mg/m² once weekly (four doses per 28-day cycle) plus celecoxib 200 mg twice daily. Adherence to MACE was monitored at 3-monthly follow-up visits using patient-reported medication logs, supplemented by objective verification through review of returned empty drug containers. The primary endpoint was 2-year overall survival (OS). The planned sample size was 712; accrual was stopped early following emerging external evidence, with ethics committee approval. **Results:** Between February 2017 and April 2025, 410 patients were enrolled (OBS, n=208; MACE, n=202); approximately three-quarters had stage IV disease in both arms. The median number of MACE cycles delivered was 15; 92 patients discontinued treatment, most commonly because of noncompliance (n=55) or disease progression (n=27). At a median follow-up of 42.5 months, 129 deaths were observed (70 in OBS and 59 in MACE). Two-year OS was 70.2% (95% CI, 63.0–76.2) in the OBS arm and 79.2% (95% CI, 72.5–84.4) in the MACE arm (hazard ratio [HR], 0.76; p=0.13). Two-year progression-free survival was 68.0% (95% CI, 61.0–74.1) with OBS and 77.0% (95% CI, 70.2–82.4) with MACE (HR, 0.72; p=0.044). Distant recurrences occurred in 30 patients (14.4%) in the OBS arm and 17 patients (8.4%) in the MACE arm, while second primary malignancies were observed in 8 (3.8%) and 3 (1.5%) patients, respectively. Grade 3–4 toxicity with MACE was observed in 6.9%. Exploratory subgroup analyses suggested greater benefit in patients with extranodal extension and stage IV disease. The average cost of MACE per cycle, including toxicity management, was approximately USD 10. **Conclusions:** MACE following definitive local therapy did not significantly improve overall survival in locally advanced OCSCC. However, a statistically significant improvement in progression-free survival was observed, driven by a reduction in distant metastases and second primary malignancies. These findings suggest that selected high-risk subgroups—particularly patients with extranodal extension and advanced-stage disease—may derive benefit from this low-cost and well-tolerated strategy. Clinical trial information: CTRI/2017/02/007777. Research Sponsor: None.

6003 **Oral Abstract Session**

Two-cycle versus three-cycle induction chemotherapy followed by concurrent chemoradiotherapy in locoregionally advanced nasopharyngeal carcinoma: A phase III randomized noninferiority trial. First Author: Hu Liang, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China

Background: Although two- and three-cycle induction chemotherapy are both widely utilized and confer significant survival benefits in locoregionally advanced nasopharyngeal carcinoma, direct comparative evidence remains lacking. Furthermore, given the cumulative treatment-related toxicity, economic burden, and potential delays in the initiation of radiotherapy, the optimal number of induction chemotherapy cycles remains undefined. **Methods:** We conducted a phase 3, open-label, multicenter, randomized controlled noninferiority trial in an endemic area. Patients with previously untreated, stage III-IVB (except T3-4N0, AJCC 8th edition) nasopharyngeal carcinoma, aged 18-70 years without severe comorbidities were enrolled. Eligible patients were randomly assigned to receive two cycles or three cycles induction chemotherapy followed by concurrent chemoradiotherapy in a 1:1 ratio. The primary endpoint was failure-free survival (FFS) and the noninferiority margin was defined as an 8% absolute between-group difference, with an 80% statistical power and a one-sided α of 0.025. The secondary endpoints included overall survival, distant metastasis-free survival, locoregional relapse-free survival, and toxicity, , among others. **Results:** Among 654 eligible patients, 327 were allocated to each group (two-cycle vs three-cycle). Two groups were well-balanced in all prognostic factors. After a median follow-up of 34.3 months, intention-to-treat analysis showed that estimated 3-year FFS was 85.4% (95% CI 80.9-89.9) in the two-cycle group and 86.7% (95% CI 82.4-91.0) in the three-cycle group, with a difference of -1.3% (95% CI, -7.54% to 4.94%; hazard ratio 1.11, 95% CI 0.72-1.71; P = 0.0031 for noninferiority). Similar result was found in the per-protocol analysis: estimated 3-year FFS for two-cycle group and three-cycle group was 86.5% (95% CI 82.0-91.0) and 87.0% (95% CI 82.7-91.3), respectively, with a difference of -0.5% (95% CI, -6.74% to 5.74%; hazard ratio 1.10, 95% CI 0.69-1.75; P = 0.0014 for noninferiority). No differences were observed between groups in terms of overall survival and the cumulative incidences of locoregional relapse and distant metastasis. Patients in the three-cycle group developed significantly more grade 3-4 adverse events such as neutropenia (three-cycle group 34.3% vs two-cycle group 24.8%), leukopenia (32.7% vs 24.5%) and vomiting (15.9% vs 10.4%). No patients died from treatment-related causes. **Conclusions:** Two-cycle induction chemotherapy followed by concurrent chemoradiotherapy provides comparable disease control and survival, with less toxicity, compared to three-cycle counterpart in locoregionally advanced nasopharyngeal carcinoma. Clinical trial information: ChiCTR1800018417. Research Sponsor: None.

6004 **Oral Abstract Session**

Carboplatin-based versus cisplatin-based induction-concurrent chemoradiotherapy with locoregionally advanced nasopharyngeal carcinoma: A multicenter, parallel-group, non-inferiority, randomized, phase 3 trial. First Author: Xiaoqing Wang, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Cisplatin-based chemoradiotherapy has been the standard of care in locoregionally advanced nasopharyngeal carcinoma (LA-NPC). However, the cisplatin-based chemotherapy is known to the severe side-effects and poor compliance. Carboplatin is the second-generation platinum drug with similar anti-cancer efficacy but less side-effects. The purpose of this study is to investigate whether the carboplatin-based induction-concurrent chemoradiotherapy was non-inferior to the cisplatin-based induction-concurrent chemoradiotherapy in LA-NPC. **Methods:** We performed a multicentre, parallel-group, non-inferiority, randomized, phase 3 trial at six institutions in China. Patients initially diagonosed with non-keratinizing NPC and stage III-IVa were randomly assigned to carboplatin group or cisplatin group. Patients in the carboplatin or cisplatin group received two cycles carboplatin-based or cisplatin-based induction chemotherapy, followed by concurrent chemoradiotherapy with carboplatin or cisplatin for two or three cycles. Allocation was done by a central randomization system using sequentially numbered, opaque, sealed envelopes. The primary endpoint was 3-year failure-free survival (FFS). Secondary endpoints are overall survival (OS), distant metastasis-free survival (DMFS), loco-regional failure-free survival (LRFFS), and toxic effects. If the upper limit of the 95% CI for the difference in 3-year failure-free survival between the carboplatin-based and cisplatin-based groups did not exceed 10%, non-inferiority was met. This trial is registered with ClinicalTrials.gov, NCT03919552. **Results:** From Apr 16, 2018 to Aug 7, 2024, a total of 482 patients were enrolled and randomly assigned to carboplatin group (n=241) or cisplatin group (n=241). With a median follow-up of 40.0 months (IQR 21.0-57.0), the 3-year FFS was 85.7% (95%CI 80.4-91.0) in carboplatin group and 87.6% (83.1-92.1) in the cisplatin group (stratified hazard ratio [HR]1.234, 95% CI: 0.744-2.045, p=0.414), with a difference of 1.9% (95% CI −8.9 to 5.1; p non-inferiority=0.0112). Patients in the cisplatin group had a higher frequency of grade 3 or 4 neutropenia (31.6% vs 22.5%, $p < 0.001$), and anorexia (16.9% vs 3.6%, $p < 0.001$). A significantly higher frequency of any grade nausea (4.8% vs 3.6%, $p < 0.001$), vomiting (2.6% vs 0.5%, $p < 0.001$), and nephrotoxicity (1.3% vs 0%, $p < 0.001$). No patients died from treatment-related causes. **Conclusions:** The primary results indicated that carboplatin-based induction-concurrent chemoradiotherapy represents an alternative doublet treatment strategy to cisplatin-based induction-concurrent chemoradiotherapy for patients with LA-NPC. A longer follow-up is needed to confirm the promising regimen. Clinical trial information: NCT03919552. 6006 **Oral Abstract Session**

A phase 2 study of ipatasertib in combination with pembrolizumab for first-line treatment of recurrent or metastatic squamous cell cancer of the head and neck. First Author: Jacob Stephen Thomas, Division of Medical Oncology, Department of Medicine, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Single agent pembrolizumab in relapsed/metastatic head and neck squamous cell carcinoma (R/M HNSCC) has limited activity. The immunosuppressive tumor microenvironment (TME) includes regulatory T cells (Treg)s and myeloid-derived suppressor cells (MDSC)s, which may contribute to the low responses to anti-PD-1 therapy. Preclinical studies demonstrate that anti-PD-1 antibodies induce Treg activation through the AKT pathway. AKT blockade selectively inhibits the proliferation of human Tregs compared to conventional T cells. Furthermore, inhibiting the AKT pathway limits MDSC infiltration and differentiation while boosting effector T cell function within tumors. Ipatasertib is an oral highly selective small-molecule inhibitor of all three isoforms of AKT. This phase II trial compares the efficacy of combination ipatasertib plus pembrolizumab (I+P) versus pembrolizumab (P) monotherapy in R/M HNSCC. **Methods:** This is a prospective, two-arm, phase II, multicenter trial for 1st line treatment of R/M HNSCC. Patients were randomized 1:1 to either Arm 1 - P 200mg on day 1 with I 400mg daily on days 1-14 of 21-day cycles, or Arm 2 – P monotherapy. PD-L1 CPS score $\geq$1 was required. The primary objective is to compare the PFS between the two arms. Secondary objectives included safety and ORR per RECIST 1.1. **Results:** As of 1/21/2026, 52 patients were randomized, with 27 enrolled in the I+P arm. The median age was 67 and 77% were male. The primary tumor sites were 46% oral cavity, 38% oropharynx, and 15% larynx. Among pts with oropharynx primary, 75% were p16 positive. PD-L1 CPS score was $\geq$20 in 60%. In the I+P arm the most common G1-3 treatment-related adverse events (TRAEs) occurring in $\geq$10% were diarrhea (70.4%), fatigue (44.4%), Nausea (40.7%), AST increase (18.5%), ALT increase (14.8%), and maculopapular rash (14.8%). Only 1 pt had grade 3 diarrhea. In P arm the most common G3 TRAEs were maculopapular rash (29.2%), AST increase (16.7%), and diarrhea (12.5%). There were no G4 or G5 TRAEs. Four patients required dose reduction of ipatasertib, primarily for diarrhea. Ten pts in the I+P arm and 6 pts in P arm required dose interruptions. One patient in each arm discontinued due to adverse events. At the data cutoff 4 pts remain on treatment in I+P arm and 2 remain on P arm. The ORR in I+P arm and P arm was 41% and 17% respectively. The CR rate was 15% in I+P arm and 4.2% in P arm. The DCR (CR+PR+SD) was 70% in I+P arm and 42% in P arm. With a median follow up of 7.0 months, the PFS in I+P arm is 8.1 months (95% CI: 4 – NA) and in P arm is 6.2 months (95% CI 1.9 – 13.5). **Conclusions:** I+P demonstrated an acceptable safety profile and shows promising clinical activity in R/M HNSCC. Clinical trial information: NCT05172258. Research Sponsor: National Cancer Institute.

Amivantamab in HPV-unrelated recurrent/metastatic head and neck squamous cell cancer after disease progression on immune checkpoint inhibitor and chemotherapy: Pivotal results from the phase 1b/2 OrigAMI-4 study. First Author: Barbara Burtness, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: Prognosis is poor for patients with HPV-unrelated recurrent/metastatic (R/M) head and neck squamous cell cancer (HNSCC) after disease progression on immune checkpoint inhibitor (ICI) and chemotherapy, with participants (pts) who received cetuximab showing an objective response rate (ORR) of 24% and median progression-free survival (PFS) of 3.8 months (Fayette *Clin Cancer Res* 2025). In addition to EGFR, MET expression is also elevated in R/M HNSCC. Therefore, we evaluated amivantamab, an EGFR-MET bispecific antibody with immune cell–directing activity, as monotherapy in HPV-unrelated R/M HNSCC after progression on platinum-based chemotherapy and a PD-(L)1 inhibitor. **Methods:** Cohort 1 of OrigAMI-4 (NCT06385080) evaluated subcutaneous (SC) amivantamab at a dose of 1600 mg (≥80 kg, 2240 mg) on Cycle 1 Day 1, then 2400 mg (≥80 kg, 3360 mg) on Cycle 1 Day 8 and Day 15, and then every 3 weeks. Pts with R/M HNSCC who had disease progression on a PD-(L)1 inhibitor and platinum-based chemotherapy were enrolled. Prior anti-EGFR therapy was exclusionary. The primary endpoint was ORR per RECIST v1.1. The sample size provided >99% power to reject the null hypothesis (ORR ≤10%) assuming an ORR of 30% with a 2-sided alpha of 5%. Secondary endpoints included duration of response (DoR), PFS, and safety. **Results:** As of 6 Jan 2026 (median follow-up: 9.0 months), the cohort was fully enrolled with 102 pts having received ≥1 dose of SC amivantamab. The median age was 63 years (range, 30–81), 77% were male, and 67% had an ECOG performance status of 1. All pts had received prior PD-(L)1 inhibitor and platinum-based chemotherapy. The confirmed ORR was 47% (48/102; 95% CI, 37–57), with 4 complete responses, 44 partial responses, and 39 pts with stable disease. A majority (79%) experienced shrinkage of target lesions. Among confirmed responders, the median DoR was 7.2 months (95% CI, 5.8–not estimable [NE]). Responses were rapid, with a median time to initial response of 6.6 weeks (range, 5.6–43.4). Median PFS was 6.8 months (95% CI, 5.2–8.2). Treatment-emergent adverse events (AEs) were mainly EGFR/MET-related, with the most common (>25%) being hypoalbuminemia, rash, dermatitis acneiform, paronychia, stomatitis, and fatigue. Administration-related reactions were seen in 13% of pts (all grade 1–2). In total, 6 (6%) pts discontinued due to treatment-related AEs. Longer follow-up, subgroup, and biomarker analyses will be presented at the meeting. **Conclusions:** SC amivantamab monotherapy demonstrated an ORR of 47%, with rapid and durable responses in pts with HPV-unrelated, R/M HNSCC after disease progression on an ICI and chemotherapy. The safety profile and tolerability are consistent with prior reports. Clinical trial information: NCT06385080. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

Clinical activity of REM-422, a MYB mRNA degrader, in recurrent/metastatic adenoid cystic carcinoma: Final results from the phase 1/2 dose-escalation cohort. First Author: Renata Ferrarotto, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Adenoid cystic carcinoma (ACC) is a malignant neoplasm characterized by dysregulation of MYB, with the majority of tumors containing a hallmark t(6:9) rearrangement resulting in a MYB:NFIB fusion oncogene, or aberrant MYB overexpression. There are no FDA approved systemic therapies for the treatment of ACC. REM-422 is a first-in-class, potent, selective, oral small molecule mRNA degrader of MYB. **Methods:** This Phase 1/2 study aims to determine the safety, PK/PD and efficacy of REM-422 in patients (pts) with recurrent or metastatic (R/M) ACC. During Phase 1 Dose Escalation and Optimization, patients received oral REM-422 once daily (3-48mg) in 28-day cycles. Enrollment was biomarker-agnostic; MYB mRNA transcripts targetable by REM-422 (biomarker positive) were retrospectively assessed in tumor specimens. **Results:** In the Phase 1 study, 69 pts were enrolled (median age 57 [range 20-82]); 75% received ≥1 prior line of systemic therapy. Fifty-nine pts were efficacy evaluable: 32 biomarker positive, 24 biomarker negative, and 3 unknown. Fifteen patients received REM-422 at the recommended phase 2 dose (RP2D) of 24 mg. REM-422 was generally well-tolerated. No dose-limiting toxicities were observed. The most common treatment-related adverse events at the RP2D included epistaxis (60%), fatigue (60%) and anemia (40%), all of which were grade 1 or 2. Pharmacodynamic analysis in peripheral blood and on-treatment tumor biopsy confirmed robust target engagement including reduction in MYB mRNA and protein at efficacious exposures. In the biomarker positive population, tumor regression was observed at doses ≥12mg, with 21/30 pts (70%) experiencing reduction in target lesions and 14/30 (47%) achieving at least ≥20% shrinkage. Clinical activity was seen across both molecular subtypes (ACC-I and II) and in pts previously treated with antibody-drug conjugates. At the RP2D of 24 mg, 3 PRs were observed among 7 biomarker positive pts (ORR 42%). Time to response ranged from 4-8 months with durations up to 12 months and ongoing at the data cutoff (07 January 2026). **Conclusions:** REM-422 is the first small molecule MYB mRNA degrader to demonstrate clinical activity in R/M ACC and is generally well-tolerated. These findings support further evaluation of REM-422 in a biomarker-selected population. Accrual to the Phase 2 Confirmatory Cohort is ongoing. Clinical trial information: NCT06118086. Research Sponsor: Remix Therapeutics.

Emiltatug ledadotin (Emi-Le), a B7-H4–directed antibody-drug conjugate (ADC), in patients with aggressive adenoid cystic carcinoma (ACC): Phase 1 interim analysis. First Author: Glenn J. Hanna, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: ACC is a rare cancer that typically arises in the salivary glands but can affect various organs. About 40% of patients (pts) have an aggressive form of ACC (referred to as ACC-I; Ferrarotto et al., *Clin Cancer Res* 2021) characterized by solid/basaloid or high-grade transformation histology and poor prognosis with median progression-free survival (PFS) of 2–3 months and median overall survival (OS) of approximately 3 years. There are no approved systemic therapies for recurrent or metastatic ACC. B7-H4 is an immune checkpoint protein with elevated expression in ACC and other cancers. Emi-Le (XMT-1660) is a B7-H4-directed ADC with an auristatin F-HPA microtubule inhibitor payload. Here we report antitumor activity results from the Phase 1 ACC-specific dose escalation/backfill cohort, along with safety data for all enrolled pts (NCT05377996). **Methods:** Adult pts with select advanced or metastatic solid tumors, including aggressive ACC, were enrolled. Eligibility criteria for ACC pts required features consistent with aggressive disease that included 1 of the following: 1) clinically aggressive phenotype, defined as < 3 years to recurrence/progression or de novo metastatic disease with atypical metastatic sites and solid tumor morphology, and/or 2) molecular features consistent with poor prognosis (activating *NOTCH1–4* mutations or c-Myc positive or p63 negative/low per IHC). Across dose escalation and backfill, eligible pts received Emi-Le at doses of 7.2–115 mg/m^2 IV per Q3W or Q4W cycle. Pts with ACC received Emi-Le at doses of 57.4–89 mg/m^2 IV per Q3W or Q4W cycle. Primary objectives included safety and preliminary antitumor activity. **Results:** As of October 1, 2025, 221 pts were dosed. Of these, 35 pts had ACC, with a median of 1 prior line of therapy (range 0–3), median age 58 years, and 57% were female. For the safety set of 221 pts, Emi-Le was well tolerated with no new safety signals identified. The most common treatment-related adverse events (TRAEs) were proteinuria (49.8%), transient AST increase (49.3%), and fatigue (41.2%). The only Grade 3 TRAEs in ≥10% of pts were transient AST increase (17.6%) and proteinuria (17.6%). TRAEs leading to treatment discontinuation occurred in 3.6% of pts. No treatment-related deaths were reported. Among 25 evaluable (≥1 post-baseline scan) pts with ACC, objective response rate was 40% (9/25 confirmed, 1/25 unconfirmed ongoing and on treatment) and disease control rate was 76% (19/25). At data cut-off, median PFS (95% CI: 13.0 weeks, not reached [NR]) and OS (95% CI: 26.6 weeks, NR) have not been reached. **Conclusions:** Based on these data, Emi-Le appears to demonstrate favorable tolerability and promising antitumor activity in pts with aggressive ACC who have no available treatments and a poor prognosis. Further clinical development is ongoing. Clinical trial information: NCT05377996. Research Sponsor: Day One Biopharmaceuticals.

6011 **Clinical Science Symposium**

Trastuzumab deruxtecan in patients with HER2-low recurrent/metastatic salivary gland carcinoma: Results from the phase II MYTHOS trial. First Author: Ichiro Kinoshita, Department of Medical Oncology, Hokkaido University Hospital, Sapporo, Hokkaido, Japan

Background: Trastuzumab deruxtecan (T-DXd) is a HER2-directed antibody–drug conjugate with established efficacy across multiple HER2-expressing malignancies. Salivary gland carcinoma (SGC) is a rare disease with limited treatment options, particularly for tumors with HER2-low expression. The MYTHOS trial is a multicenter, investigator-initiated phase II study evaluating T-DXd efficacy in recurrent or metastatic (RM) SGC patients with HER2 overexpression or HER2-low expression. Here, we report the efficacy and safety results of the HER2-low cohort (Cohort 2). **Methods:** Eligible patients had histologically confirmed RM SGC with HER2-low expression (IHC 1+ or IHC 2+/ISH−), as determined by central assessment according to the ASCO/CAP 2018 breast cancer guidelines, and no indication for curative treatment. Patients received T-DXd at 5.4 mg/kg intravenously every 3 weeks. The primary endpoint was confirmed objective response rate (ORR) assessed by independent central review (ICR) according to RECIST v1.1. Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. The required sample size for Cohort 2 was 33 patients, based on a threshold ORR of 25%, an expected ORR of 50%, 83% power, and a two-sided alpha of 0.05 using an exact binomial test. The primary efficacy decision was based on the prespecified Simon's two-stage minimax design in the first 33 patients; efficacy in the full analysis set (FAS) was summarized descriptively. **Results:** A total of 36 patients were included in the FAS, including 30 with salivary duct carcinoma (SDC). HER2-low status comprised IHC 2+/ISH− in 14 and IHC 1+ in 22; 25 had received prior systemic therapy for RM disease. Median follow-up was 25.1 months. The ORR by ICR was 38.9% (14/36; 95% CI, 23.1–56.5%), and the DCR was 94.4% (95% CI, 81.3–99.3%). Median PFS was 8.7 months (95% CI, 6.5–13.3), and median OS was 24.8 months (95% CI, 18.7–NE). In a prespecified subgroup analysis by histology, the ORR by ICR was 46.7% (14/30; 95% CI, 28.3–65.7%) in SDC and 0% (0/6; 95% CI, 0–45.9%) in other SGC subtypes. Common grade ≥3 adverse events (>10%) were neutrophil count decreased (36.1%), lymphocyte count decreased (19.4%), white blood cell count decreased (11.1%), and decreased appetite (11.1%). Drug-related interstitial lung disease (ILD)/pneumonitis occurred in 9 (25.0%; grade 1/2 in 7, grade 3 in 1, and grade 5 in 1). There was one drug-related death due to ILD/pneumonitis. **Conclusions:** Although the prespecified primary efficacy endpoint was not met, T-DXd demonstrated clinically meaningful antitumor activity in patients with HER2-low RM SGC, particularly in those with SDC. The safety profile was generally consistent with the known profile of T-DXd in the Japanese population, with ILD/pneumonitis remaining an important identified risk requiring careful monitoring. Clinical trial information: jRCT2011210017. Research Sponsor: Daiichi Sankyo Company, Limited.

6012 Clinical Science Symposium

A phase 2 study of darolutamide plus leuprolide acetate in hormone therapy–naïve recurrent and/or metastatic androgen receptor (AR)–positive salivary gland cancer (ETCTN 10553). First Author: Alan Loh Ho, Solid Tumor Oncology Division, Head and Neck Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: A subset of salivary gland cancers (SGCs) express the androgen receptor (AR). A prior AR+ SGC trial with the anti-androgen enzalutamide alone failed to meet its primary endpoint. This is a multicenter, phase II study evaluating the efficacy and safety of the anti-androgen darolutamide (Bayer) in combination with androgen-deprivation therapy (ADT; leuprolide acetate) in hormone-therapy naïve patients with AR+ SGCs. **Methods:** Patients with locally advanced/unresectable or recurrent/metastatic AR+ SGCs were enrolled. AR status was determined locally by immunohistochemistry (IHC). Prior AR-targeted therapy was not allowed, unless administered in the neoadjuvant and/or adjuvant setting >6 months before disease recurrence. Darolutamide 600 mg orally twice daily was given with leuprolide acetate intramuscular injections (1 cycle= 28 days). The primary endpoint was best overall response (BOR) rate according to RECIST v1.1 within 1 year of initiating treatment. Secondary endpoints were progression-free survival (PFS), overall survival (OS), and toxicity. Exploratory endpoints were evaluating biomarkers in serially obtained research biopsies and exploring efficacy among patients who had not received prior systemic therapy. A two-stage minimax design was used to detect a 50% BOR rate (vs. 25%) (alpha = 9%; beta = 83%). ≥3 responses in the first 9 patients would trigger accrual to 20; ≥8 responses would be considered promising. **Results:** Study accrual of 20 patients (pts) with AR+ SGCs was completed on 10/30/25. 15 males, 5 females with a median age of 70.5 years were enrolled. Among the 9 pts in the first stage, 6 confirmed partial responses (PRs) were observed, allowing for full study accrual. With a data cutoff of 1/21/26, the best RECIST v1.1 responses among 20 pts were 8 (40% [19.1% 63.9%]) PRs (7 confirmed, 1 unconfirmed with pt still on treatment), 10 (50% [27.2%, 72.8%]) stable disease (SD), 1 (5% [1%, 24.9%]) progression of disease; 1 pt on treatment has not had radiographic assessments yet. 6 (30% [11.9%, 54.3%]) pts came off trial for disease progression, 1 (5% [1%, 24.9%]) withdrew consent after 6 cycles, and 13 (65%, [40.8%, 84.6%]) remain on treatment. Among 5 female pts, best responses were 1 (5% [1%, 24.9%]) PR, 3 (15% [3.2%, 37.9%]) SD, 1 (5% [1%, 24.9%]) PD. With additional follow-up, PFS, OS, and biomarker data (AR IHC %, HER2 status) will be presented. **Conclusions:** In this molecularly selected cohort of patients with SGC, darolutamide plus ADT possesses significant clinical activity, validating AR as a relevant therapeutic target in a subset of SGCs. Analysis of serial research biopsies will be performed to identify biomarker and/or drug combination strategies to enhance the efficacy of AR-targeting. Clinical trial information: NCT05669664. Research Sponsor: U.S. National Institutes of Health; Bayer.

6013 Rapid Oral Abstract Session

Induction chemotherapy with nab-paclitaxel and cisplatin versus docetaxel, cisplatin, and fluorouracil followed by chemoradiotherapy in patients with stage III–IVA nasopharyngeal carcinoma: An open-label, noninferiority, randomized, controlled, phase 3 trial. First Author: Xing Lyu, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: The docetaxel, cisplatin, and 5-fluorouracil (TPF) regimen is the standard induction therapy regimen for locoregionally advanced nasopharyngeal carcinoma (LANPC). However, it is associated with poor patient compliance and notable side effects. This phase 3 trial aimed to compare the efficacy and safety of induction chemotherapy with nab-paclitaxel plus cisplatin (nab-TP) with those of the TPF regimen in patients with LANPC. **Methods:** In this multicenter, noninferiority, open-label, randomized controlled trial, treatment-naive patients with LANPC were recruited from 5 hospitals in China and were randomly assigned to receive two cycles of nab-TP (nab-paclitaxel 260 mg/m², cisplatin 80 mg/m²) or TPF (docetaxel 60 mg/m², cisplatin 60 mg/m², 5-FU 3 g/m²), followed by concurrent chemoradiotherapy. The primary endpoint was the 3-year failure-free survival (FFS) rate (non-inferiority margin 10%) in the intention-to-treat population. Secondary endpoints included overall survival, treatment response, safety, and patient-reported outcomes. This trial is registered with chictr.org.cn (ChiCTR1800019922) and is now completed. Based on previous studies, we hypothesized that the 3-year FFS (approximately 80%) is the same between the TPF regimen and the nab-TP regimen for patients with LANPC. We specify a clinically acceptable noninferiority margin of 10%. The dropout rate in both arms was set at 4% per year. Accordingly, a minimum of 506 participants was needed to achieve 80% statistical power with a one-sided type I error of 2·5%. **Results:** Between January 22, 2019 and March 24, 2023, 515 patients (71·8% male; median age: 45 years (IQR 37–51)) were randomized: 259 to the nab-TP group and 256 to the TPF group. Compared with the TPF group, the nab-TP group had significantly better treatment compliance. With a median follow-up of 55·2 months, the 3-year FFS rate in the intention-to-treat population was 86·7% (95% confidence interval (CI): 82·6–90·9) in the nab-TP group and 88·2% (95% CI: 84·2–92·1) in the TPF group. The difference in the 3-year FFS between groups was -1·4% (95% CI: -7·2 to 4·3)($P_{non\text{-}inferiority}$ = 0·0018). Compared with the TPF group, the nab-TP group had significantly lower incidences of grade 1+ leucopenia (34·0% vs. 62·6%, P < 0·0001), neutropenia (20·3% vs. 48·8%, P < 0·0001), electrolyte disturbances (86·3% vs. 96·5%, P < 0·0001), and diarrhea (28·5% vs. 39·0%, P = 0·012), whereas the nab-TP group had a higher incidence of nausea (91·0% vs. 85·4%, P =0·047). No treatment-related death was documented. **Conclusions:** In LANPC, nab-TP was non-inferior to TPF in terms of 3-year FFS rate and was associated with a significantly better safety and tolerability profile, supporting its use as a viable therapeutic alternative. Clinical trial information: ChiCTR1800019922. Research Sponsor: National Natural Science Foundation of China; No. 82172863; Natural Science Foundation of Guangdong Province.

6014 Rapid Oral Abstract Session

Neoadjuvant ivonescimab (AK112, a PD-1/VEGF bispecific antibody) combined with nab-paclitaxel and cisplatin (AP) for resectable locally advanced head and neck squamous cell carcinoma (LA-HNSCC): An exploratory phase II study. First Author: Kunyu Yang, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Previously, neoadjuvant PD-1 plus AP followed by surgery and radiotherapy showed promising disease control and laryngeal preservation in resectable LA-HNSCC. Ivonescimab, a PD-1/VEGF bispecific antibody, potentially exerts synergistic anti-tumor activity by normalizing tumor vasculature and enhancing immune infiltration. This study evaluates the efficacy and safety of neoadjuvant Ivonescimab plus AP in resectable LA-HNSCC. **Methods:** This single-center phase II trial enrolled patients (18-70 yrs) with resectable stage III-IVa LA-HNSCC (oral cavity, oropharynx, hypopharynx, or larynx). Neoadjuvant therapy: 3 cycles of Ivonescimab (20mg/kg Q3W) plus AP, followed by surgery. Postoperative treatment included radiotherapy ± chemotherapy and maintenance Ivonescimab (10mg/kg Q3W) for 14 cycles. Primary endpoints: pCR and 2-year EFS. MRD and PD-L1 CPS were also investigated. **Results:** By November 2025, 36 patients were enrolled (median age 58; 75% Stage IV). Primary tumor sites were hypopharynx (50.0%), larynx (25.0%) and oral cavity (19.4%). Radiological assessment performed prior to Cycle 3 demonstrated an exceptional objective response rate (ORR) of 100% among 34 evaluable patients. Notably, a remarkably deep radiological response was achieved, with a complete response (CR) rate of 50.0% (17/34) and a partial response (PR) rate of 50.0% (17/34). Deep tumor shrinkage was observed in all cases. 30 patients underwent surgery with a 100% R0 resection rate. The overall pCR rate was 50.0% (15/30). Specifically, pCR was achieved in 70.0% (21/30) of primary lesions and 64.3% (18/28) of lymph nodes. While robust pathological responses were observed in the hypopharynx (64.3%), tongue (57.1%), and oropharynx (50.0%), the pCR rate in the larynx was markedly lower at 12.5%. Crucially, the profound tumor downsizing induced by Ivonescimab enabled volume-reduced resections, achieving 100% successful laryngeal and pharyngeal preservation while maintaining negative margins. High PD-L1 predicted efficacy; median CPS was 30.0 in pCR vs. 10.0 in non-pCR (p=0.18). Notably, 100% of pts with CPS > 30 achieved pCR. Pre-op MRD specificity for pathological conversion was 91.7% (sensitivity 37.5%). Safety: The most common Grade≥3 AEs were pharyngeal fistula (surgical-related) and transient transaminase elevation. Most drug-related AEs were manageable and consistent with the known profiles of PD-1 and VEGF inhibitors. **Conclusions:** Neoadjuvant Ivonescimab plus chemotherapy demonstrated unprecedented radiological response depth and pathological remission rates in LA-HNSCC. This novel PD-1/VEGF-based dual blockade may redefine neoadjuvant standards for head and neck cancer. High CPS and MRD negativity are robust predictors of deep pathological response. Clinical trial information: NCT06537011. Research Sponsor: None.

6015 Rapid Oral Abstract Session

Timing of postoperative chemoradiotherapy and survival outcomes in high-risk locally advanced head and neck squamous cell carcinoma: A supplementary analysis of JCOG1008. First Author: Yoshinori Imamura, Kobe University Hospital, Kobe, Japan

Background: For patients with post-operative high-risk locally advanced head and neck squamous cell carcinoma (LA-HNSCC), initiation of chemoradiotherapy (CRT) within 6 weeks after surgical resection is recommended based on previous reports. However, the guideline-defined 6-week threshold for initiating post-operative radiotherapy (PORT) is derived mainly from data in patients treated with PORT alone. Therefore, its relevance in patients receiving post-operative CRT remains uncertain. **Methods:** This supplementary analysis used data from the JCOG1008 trial (jRCTs031180135), which compared post-operative CRT with weekly cisplatin versus 3-weekly cisplatin. Associations between the surgical-to-PORT interval (S-PORT) and locoregional relapse-free survival (LRFS), overall survival (OS), and relapse-free survival (RFS) were evaluated using restricted cubic spline analyses, Kaplan–Meier methods, and Cox proportional hazards models. Treatment package time (TPT), defined as the sum of S-PORT and radiotherapy duration, was also assessed. **Results:** Among 261 enrolled patients, 251 were eligible for this analysis (median age, 62 years; 16.3% female; 45.8% with oral cavity primaries). The median S-PORT and TPT were 7.0 weeks (range, 2.9–10.0) and 13.9 weeks (range, 7.6–16.9), respectively. Restricted cubic spline analyses demonstrated minimal variation in risk across the observed S-PORT range, with hazard ratios (HRs) remaining close to 1 for LRFS, OS, and RFS. Kaplan–Meier analyses using the guideline-defined 6-week cutoff showed similar 5-year LRFS between patients with S-PORT ≤6 weeks and >6 weeks (64.0% vs 64.9%; HR 0.91, 95% CI 0.60–1.37; Table), with no significant differences in OS or RFS. In multivariable Cox models adjusting for clinical covariates, S-PORT was not independently associated with outcomes. Findings for TPT closely paralleled those for S-PORT, with no significant associations observed between TPT and treatment. **Conclusions:** In this supplementary analysis of JCOG1008, no prognostic disadvantage was observed when PORT was initiated within the range observed in this trial (6–10 weeks after surgery) among patients receiving post-operative CRT. These findings support individualized S-PORT timing rather than rigid cutoff-based decision-making in contemporary standardized CRT. Clinical trial information: jRCTs031180135. Research Sponsor: Japan Agency for Medical Research and Development (AMED); Grant-in- Aid for Clinical Cancer Research from the Ministry of Health, Labor and Welfare of Japan; National Cancer Center Research and Development Funds.

Kaplan–Meier analyses according to guideline-defined 6-week surgical-to-postoperative radiotherapy interval (S-PORT) cutoff.

	S-PORT ≤ 6 weeks	S-PORT > 6 weeks
5y LRFS (95% CI)	64.0% (52.1%–73.7%)	64.9% (57.3%–71.5%)
HR (95% CI), p-value	1	0.91 (0.60–1.37), 0.65
5y OS (95% CI)	65.3% (53.4%–74.9%)	66.6% (59.1%–73.1%)
HR (95% CI), p-value	1	0.88 (0.58–1.34), 0.54
5y RFS (95% CI)	60.0% (48.0%–70.1%)	60.2% (52.6%–67.0%)

6016 Rapid Oral Abstract Session

Phase II randomized trial of radiotherapy with pembrolizumab vs. cisplatin for unfavorable-risk p16+ head and neck squamous cell carcinoma (KEYCHAIN). First Author: Loren K. Mell, UC San Diego Moores Cancer Center, La Jolla, CA

Background: Standard chemoradiation (CRT) for unfavorable risk p16+ head and neck squamous cell carcinoma (HNSCC) is associated with high rates of toxicity and treatment failure. We hypothesized that concurrent and adjuvant pembrolizumab (pembro) could achieve superior PFS with acceptable toxicity compared to CRT in this population. **Methods:** KEYCHAIN was an open-label randomized phase II trial conducted at 6 US academic centers. Eligible patients had newly diagnosed unresected p16+ HNSCC with unfavorable risk (AJCC 8th edition stage II-III oropharynx or stage III-IVB non-oropharynx HNSCC). Patients were randomized 1:1 to RT (70 Gy in 35 fractions) plus pembro (200 mg, 2 weeks prior to RT then every 3 weeks starting day 1 of RT up to 20 total cycles) or RT plus concurrent cisplatin (cis) (100 mg/m^2 every 3 weeks). Age, ECOG status, and oropharynx site were stratification factors. The primary endpoint was PFS, defined as time from randomization to first progression or death from any cause. Primary analysis was in the modified intent-to-treat population, including all patients having $\geq$ 1 dose of study medication and $\geq$ 1 efficacy evaluation after baseline. The study design had 80% power with 1-sided α = 0.15 (log-rank test) and planned sample size of 50 analyzable subjects per arm. The study is registered with clinicaltrials.gov (NCT03383094). **Results:** Between Feb 2019 and Aug 2025, 108 patients were randomized (53 pembro, 55 cis), with 102 analyzable (50 pembro, 52 cis). Median follow-up was 26.5 months. 79% had minimum follow-up of 2 years. At 2 years, there were 7 PFS events and 1 death in the pembro arm, and 14 PFS events and 7 deaths in the cis arm. Two-year PFS was 84% (95% CI: 74-96%) vs. 70% (95% CI: 58-85%) in the pembro vs cis arm (HR 0.57, 95% CI: 0.25-1.31; 1-sided p = 0.09) (see Table). Two-year OS was 98% (95% CI: 94-100%) vs. 85% (95% CI: 76-96%) for pembro vs. cis (HR 0.33, 95% CI: 0.09-1.28; 1-sided p = 0.048). HRs adjusted for T3-4 and N2-3 category were 0.68 (PFS) and 0.31 (OS). As of the latest follow-up, there were 24 total PFS events and 12 deaths. Grade $\geq$ 3 adverse events definitely or probably related to treatment were 36% vs. 46% in the pembro vs. cis arm. The median number of cycles received in the pembro arm was 18. In the cis arm, 94% completed $\geq$ 2 cycles. Results by CPS status will be reported when available. **Conclusions:** Pembro plus RT met the pre-specified significance criterion for improvement in PFS compared to cisplatin plus RT in this phase II trial. A phase III trial of RT with pembrolizumab for unfavorable risk p16+ HNSCC is warranted. Clinical trial information: NCT03383094. Research Sponsor: Merck.

6017 Rapid Oral Abstract Session

Final analysis of the investigator-initiated randomized study of anti–PD-L1 durvalumab (durva) with radiation versus chemoradiation (CRT) for intermediate-risk HPV-positive (HPV+) locally advanced oropharyngeal squamous cell carcinoma (LA-OPSCC): Canadian Cancer Trials Group (CCTG) HN.9 (EORTC 1740-HNCG). First Author: Anna Spreafico, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: Primary immunotherapy (IO) with radiotherapy remains an investigational approach in HPV+ LA-OPSCC. The CCTG-led international phase II, randomized, non-comparative, HN.9 (NCT03410615) trial evaluated the efficacy of the of durva+RT as a chemo-sparing approach in patients (pts) with intermediate-risk, HPV+, LA-OPSCC. **Methods:** Pts with newly diagnosed, PDL1-unselected, pathologically proven, treatment-naïve HPV+ LA-OPSCC (UICC/AJCC 8th Edition T1-2N1 or T3N0-1 smokers [$\geq$10 pack years] or T1-3 N2 with any smoking history) eligible for definitive CRT were randomized (1:2) to Arm A (CRT: 70Gy/35F + cisplatin 100 mg/m2 Q3W on days 1,22,43 of RT) vs Arm B (durva IV 1500 mg, days -7, 22 of RT, followed by adjuvant durva for 6 doses). Primary objective was 3-year EFS in Arm B (efficacy if one-sided 90% CI lower bound [LB] $>$83%). Secondary objectives: QoL (MDADI, FACT-HN at baseline, end of RT, 3,6,12,24 and 36 mo), OS, safety, distant metastasis-free survival (DMFS) and locoregional control (LRC). Safety was assessed per CTCAE v5. The trial closed early based on emerging external efficacy data of IO in HN LA setting, enrolling 129 pts overall (80 of the planned 120 in Arm B) with approximately 80% power retained for the primary analysis. **Results:** 129 pts were randomized across 21 Canadian and European sites. Baseline characteristics were well balanced between arms. At the data cutoff (Sep 19, 2025), median follow-up time was 55.7 mo. In both arms, all pts received the planned RT schedule. In Arm A, the median number of cisplatin cycles was 2 (21% received $<$200m/m^2 and 79%$\geq$ 200 mg/m^2). In arm B, all pts (100%) received durva concurrent to RT. 126 pts were eligible for efficacy analysis. The estimated 3-year EFS in Arm B was 80% (one-sided 90% CI: LB 73%); the prespecified efficacy criterion (LB $>$83%) was not met. The 3-year EFS in Arm A was 89%. The estimated 3-year OS rates were 92% in both arms. At 3 years, LRC were 97 and 91% in Arms A and B respectively. DMFS was 89% in Arm A and 86% in Arm B. Grade $\geq$ 3 adverse events any time during trial were similar between Arm B (69%) and Arm A (63%). QoL completion was 96% at baseline and 80%+ throughout; acute worsening during RT followed by gradual recovery (slower in arm B during adjuvant durva), with longer-term persistence of isolated issues (hearing loss, dry mouth) was similar to published experience for drug+RT regimens. **Conclusions:** Durva+RT did not improve 3-year EFS in the overall patient population of intermediate-risk HPV+ OPSCC. No new safety signal was observed. Specific toxicities varied by arm, but overall QoL experience, including swallowing, was similar between arms and with prior trials. Subgroup analysis, blood, tissue and microbiome-based correlates are ongoing. Clinical trial information: NCT03410615. Research Sponsor: Canadian Cancer Society; 707213; AstraZeneca.

6018 Rapid Oral Abstract Session

Randomized phase I/II trial adjuvant CD40.HVAC, an immunotherapy engaging dendritic cells (DC), in patients with HPV16+ oropharyngeal carcinoma (OPC). First Author: Caroline Even, Head and Neck Department, Gustave Roussy, Villejuif, France

Background: Up to 70% of OPCs are HPV-mediated predominantly by HPV16. E6/E7 oncoproteins, constitutively expressed in malignant cells, represent optimal immunotherapeutic targets. We evaluated CD40.HVac, a new DC engager combining a humanized IgG4 monoclonal antibody fused to HPV16 E6/E7, designed to target the CD40 receptor on DCs. **Methods:** This trial enrolled OPC HPV16$^+$ patients (pts) in complete remission 16–22weeks (W) post curative treatment. In cohorts 1 (n=11) and 2 (n=11), pts were randomized (5:1) to receive subcutaneously, Hiltonol (1mg) adjuvanted CD40.HVac, 1 and 3 mg, respectively, or placebo, at W0, 4, 24. Dose-limiting toxicity (DLT) was assessed from W0–W6. Blood E6/E7-specific T cells were assessed 2W post-injection using stimulation of PBMCs with vaccine E6/E7 pools of peptides. CD8+T cells were characterized by expression of Activation Induced Markers (AIM). Immune response was defined as a $\geq$3-fold increase in HPV specific T cell responses over unstimulated controls after in vitro restimulation, or a net increase of $\geq$ 0.03% reaching at least 0.05% AIM$^+$ T cells compared to baseline. **Results:** Median age was 58 years (IQR 51; 65), 68% were male, 68% were stage I or II, 32% stage III. At entry, 21 pts were lymphopenic (3 grade 3). All pts received the 3 planned injections. Four pts were randomized to placebo, 18 to CD40.HVac. No DLTs nor grade 3-5 adverse events (AEs) were reported. From W0 to W32, all pts treated with CD40.HVac experienced at least 1 vaccine related AE; 5 (28%) experienced at least 1 grade 2 AE while the 13 others experienced only grade 1 AEs. At W6, 77% of pts treated with CD40.HVac in the both 1 mg and 3 mg cohorts exhibited a 27-fold and 42-fold increase from baseline, respectively, in CD4$^+$ T cells producing IL-2, IFNγ and/or TNF. By W26, responses were observed in 100% of pts treated with CD40.HVac in both cohorts, with 35-fold (1 mg) and 83-fold (3 mg) increases from baseline. AIM assays confirmed the induction of HPV specific CD4$^+$ and CD8$^+$ T cell responses. HPV specific CD8$^+$ T cell responses were detected in 50% and 44% of pts treated with CD40.HVac at W6 in the 1 mg and 3 mg cohorts, respectively, and in 71% and 44% at W26. HPV specific CD8$^+$ T cells displayed a polyfunctional cytotoxic phenotype, expressing IFNγ, TNF, granzyme B and CD107a, along with PD-1, consistent with an activated state. Both CD4$^+$ and CD8$^+$ T cell responses were durable and persisted up to1 year post-prime vaccination. Only minimal or no increases in HPV specific responses were observed in pts treated with placebo. After a median follow-up of 1 year, no pt presented disease relapse. HPVct DNA monitoring will be presented at the meeting. **Conclusions:** The safety and immunogenicity of CD40.HVac support further clinical development of this strategy in pts with HPV16+ OPC. Clinical trial information: NCT06007092. Research Sponsor: EnnoDC.

6019 Rapid Oral Abstract Session

Phase II study of izalontamab (SI-B001) in combination with paclitaxel or docetaxel in patients with recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). First Author: Ye Guo, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China

Background: Izalontamab is a bispecific antibody targeting EGFR and HER3. Here we present safety and efficacy results from a phase II study on izalontamab in combination with paclitaxel/docetaxel in patients with R/M HNSCC. **Methods:** Patients with R/M HNSCC who had progressed on prior anti-PD-(L)1 therapy, with or without platinum-based chemotherapy, and received no more than two prior lines of treatment were enrolled. Izalontamab was administered at 12mg/kg QW in combination with paclitaxel (80mg/m^2 IV QW) (for patients without prior exposure to paclitaxel) or docetaxel (35mg/m^2 IV D1D8D15 Q4W) (for patients with prior exposure to paclitaxel). Primary endpoint was investigator-assessed ORR. Secondary endpoints included PFS, OS, DCR, and DoR. **Results:** As of Nov 7, 2025, a total of 45 patients (44 HNSCC and 1 sinnonasal) were enrolled, of whom 35 (77.8%) received one prior line of therapy and 10 (22.2%) received two prior lines of therapy. HNSCC patients who received at least one dose of study drug were included in the analysis. Median follow-up was 15.0 months. Overall, ORR was 43.2%, confirmed ORR was 31.8%, median PFS was 4.0 months, and median OS was 10.0 months. In patients treated with izalontamab combo with paclitaxel (n = 34), ORR was 52.9%, confirmed ORR was 41.2%, median PFS was 5.4 months, and median OS was 11.2 months. Grade$\geq$3 TRAEs occurred in 57.8% of patients. The most common grade$\geq$3 TRAE was leukopenia (20.0%), followed by neutropenia (15.6%), rash (13.3%), and anemia (8.9%). One (2.1%) patient discontinued study treatment due to TRAE. No treatment-related death was observed. **Conclusions:** Izalontamab in combination with paclitaxel showed encouraging antitumor activity and a manageable safety profile in patients with R/M HNSCC who were previously treated with anti-PD-(L)1 therapy. Clinical trial information: NCT05054439. Research Sponsor: Sichuan Baili Pharmaceutical Co., Ltd.

6020 Rapid Oral Abstract Session

FID-007 in combination with cetuximab in recurrent or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC). First Author: Guilherme Rabinowits, Moffitt Cancer Center, Tampa, FL

Background: Paclitaxel is commonly used to treat HNSCC but is associated with infusion-related reactions and peripheral neuropathy (PN). Historically, the median progression-free survival (PFS) of standard of care, second line therapy for metastatic HNSCC is 2-3 months (mo). FID-007 is a novel nanoencapsulated paclitaxel utilizing a proprietary poly(2-ethyl-2-oxazoline) polymer excipient. This formulation overcomes the limited water solubility and pharmacodynamics of paclitaxel, enhancing both tumor penetration and retention. **Methods:** FID-007-003 is an ongoing phase 2, randomized, multicenter, open-label study. Patients must have progressed after anti-PD1/PD-L1 therapy and have not received >1 line of prior therapy for R/M HNSCC. Prior cetuximab or taxane in the R/M setting were not allowed. Patients were stratified by p16 status and prior taxane exposure, and randomized 1:1 to one of two doses of FID-007 (Arm A: 75 mg/m^2; Arm B: 125 mg/m^2) IV on days 1, 8, and 15 in combination with cetuximab 500 mg/m^2 IV on days 1 and 15 every 28 days starting with Cycle 2. The primary endpoint was investigator-assessed objective response rate (ORR) by RECIST 1.1. **Results:** As of the preliminary data cut-off date of 20DEC2025, 45 patients were randomized and received ≥ 1 dose of FID-007; 42 patients were efficacy-evaluable (19 in Arm A, 23 in Arm B). Median age was 65 years (range 45-81), 62% (28/45) received prior platinum-based therapy and 67% (30/45) received 1 prior systemic therapy for R/M disease. The median cumulative dose of FID-007 was 825 mg/m^2 in Arm A and 1,450 mg/m^2 in Arm B. The median duration of treatment was 4 mo in Arm A and 4.3 mo in Arm B, with a median follow-up of 4.2 mo. The ORR/complete response (CR) rate was 60%/17% (58%/11% in Arm A, 61%/22% in Arm B), and the median PFS was 7.2 mo [6.7 mo in Arm A (2.0-12.8), and 7.2 mo in Arm B (4.0-NR)]. The median duration of response was 7.4 mo (7.4 mo in Arm A, NR in Arm B) with 56% (14/25) of responders continuing to respond at the time of data cut-off. The overall survival data are immature at present. Treatment-related adverse events (TRAEs) were mostly of grade 1-2. Grade 3-4 TRAEs occurring in ≥ 2 patients included neutropenia (3 in Arm A, 5 in Arm B), anemia (2 in Arm A, 4 in Arm B), leukopenia (3 in Arm B), acneiform dermatitis (2 in Arm A), maculo-papular rash and other rash (2 in Arm B). There was 1 Grade 5 TRAE: pneumonia (Arm B). **Conclusions:** FID-007, administered in combination with cetuximab, demonstrated clinically encouraging and durable anticancer activity at both doses tested in this population of pre-treated R/M HNSCC. Notably, the absence of infusion-related reactions and the lack of grade ≥ 3 PN, along with a tolerable safety profile potentially compares favorably with other taxanes, which may ultimately enable a longer treatment duration and lead to improved therapeutic outcomes. Clinical trial information: NCT06332092. Research Sponsor: Fulgent Pharma.

Nivolumab plus lenvatinib for unresectable anaplastic thyroid cancer: Results of the phase 2 NAVIGATION study. First Author: Makoto Tahara, National Cancer Center Hospital East, Kashiwa, Japan

Background: Anaplastic thyroid cancer (ATC) is one of the most aggressive and lethal malignancies, characterized by limited treatment options and a dismal prognosis. Although lenvatinib has shown some efficacy, its impact remains modest, and no standard systemic therapy has been established for unresectable ATC—particularly for BRAF wild-type (BRAF-negative) disease. **Methods:** The NAVIGATION study (NCT05696548) is an open-label, multicenter, phase 2 trial evaluating the combination of nivolumab and lenvatinib in patients with unresectable ATC. As primary endpoints, Step 1 assessed dose-limiting toxicities (DLTs), while Step 2 evaluated the objective response rate (ORR) by independent radiological central review (IRCR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), best overall response, disease control rate, clinical benefit rate, safety, and quality of life. Eligible patients had histologically confirmed unresectable ATC, measurable disease per RECIST v1.1, adequate organ function, an ECOG performance status of 0–1, and a life expectancy of over 90 days. Lenvatinib was administered orally at 24 mg once daily, and nivolumab intravenously at 240 mg every two weeks, continued until disease progression or unacceptable toxicity. The Step 2 sample size of 48 patients was determined based on a historical ORR of 23.5% and an expected ORR of 44%, providing 80% power with a two-sided α of 0.05, accounting for a 20% dropout rate. ORR was evaluated in the full analysis set of patients with ATC confirmed by independent pathological central review (IPCR). **Results:** Between December 2019 and February 2024, 51 patients were enrolled across 10 sites in Japan (Step 1: n=3; Step 2: n=48). No DLTs were observed in Step 1. In Step 2, the median age was 69.5 years (range, 43-89); 46 patients had metastatic disease, 40 had prior history of surgery, and 42 were pathologically confirmed as ATC by IPCR. The ORR by IRCR was 47.6% (95% CI: 33.4-62.3), meeting the primary endpoint. At a median follow-up of 11.6 months, the median duration of response was 12.9 months (95% CI: 6.28 -27.6), median PFS was 5.6 months (95% CI: 5.5-9.1), and median OS was 14.7 months (95% CI: 10.1-29.2). The 1-year OS rate was 56.9%. In Step 2, grade 3 or 4 treatment-related adverse events (TRAEs) occurred in 38/48 patients (79.2%), serious TRAEs in 20 (41.7%), and there was one treatment-related death (2.1%). **Conclusions:** Nivolumab plus lenvatinib demonstrated a clinically meaningful ORR, meeting the primary endpoint. The combination also achieved favorable PFS and OS with manageable toxicity under appropriate supportive care, suggesting that this regimen may represent a new treatment option for patients with unresectable ATC. Clinical trial information: NCT05696548. Research Sponsor: None.

Whole slide imaging–based prediction of immunohistochemistry markers and surgical pathological features. First Author: Yusuf Sadek, The Ohio State University, Columbus, OH

Background: Immunohistochemistry (IHC) marker testing and identification of pathological features are essential tasks in surgical pathology following resection of head and neck cancers. However, IHC testing is time-consuming, and identifying pathologic features typically requires examination of multiple slides. We hypothesized that imaging features from a single H&E-stained whole slide image (WSI) could predict this information using machine learning. **Methods:** We utilized data from the publicly available HANCOCK dataset for machine learning model development and testing. All patients had undergone surgical resection for locoregional head and neck cancer. Image features (embeddings extracted by TITAN, a pretrained vision-language pathology foundation model) from each primary tumor's H&E-stained WSI served as model inputs. Four machine learning algorithms (XGBoost, support vector machine, multilayer perceptron, and random forest) were trained to predict seven IHC markers (CD3, CD8, CD56, CD68, CD163, MHC-I, PD-L1) and three surgical pathological features (tumor grading, lymphovascular invasion, and perineural invasion). IHC marker positivity was determined using DeepLIIF-derived percent-positive staining, with non-PD-L1 markers binarized by median split and PD-L1 positivity defined using a 10% threshold. Surgical pathological features were binary except for tumor grade, which included four classes. All models underwent nested stratified five-fold cross-validation with hyperparameter tuning. Performance was assessed using AUC and F1 score for binary tasks (IHC markers, lymphovascular invasion, perineural invasion), and balanced accuracy and macro-F1 score and for tumor grading. **Results:** Between 685 and 699 cases were available for model development depending on the prediction task. Support vector machine (SVM) was the best-performing model for five tasks, followed by XGBoost (XGB) for three tasks and random forest (RF) for two tasks. Performance metrics for the best-performing models are detailed in the table. **Conclusions:** Our findings demonstrate that IHC markers and surgical pathological features can be predicted with reasonable accuracy from image features extracted from a single H&E-stained WSI. Future work will focus on external validation of these models in independent cohorts and exploration of advanced foundational models to further improve prediction performance. Research Sponsor: None.

Development and multicenter validation of a machine learning framework for predicting severe myelosuppression in nasopharyngeal carcinoma: Evidence from large-scale real-world data and prospective clinical trials. First Author: Tingxi Tang, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China

Background: Severe treatment-related myelosuppression (Tr-MS) in nasopharyngeal carcinoma (NPC) necessitates dose reductions, compromising survival. Current static models rely on baseline "snapshots," failing to capture dynamic bone marrow fluctuations. We developed a dynamic deep learning system using longitudinal real-world data to predict cycle-specific Tr-MS risk. **Methods:** We analyzed 103,919 longitudinal records from 12,065 NPC patients (Nanfang/SYSUCC). A rolling-window strategy incorporated dynamic pre-dose labs, prior-cycle nadirs, and cumulative exposure to predict Grade ≥3 Tr-MS (CTCAE v6.0). Models (Logistic/XGBoost/LightGBM/TabPFN) were trained (6:3:1 split) and validated in two independent external cohorts (n=197) and three prospective trials (NCT03919552, NCT06767488, NCT06017895; n=173). The model was deployed as an EHR-integrated tool for automated real-time risk stratification. **Results:** Dynamic models demonstrated robust discrimination across all validation hierarchies (Table). In internal validation, AUCs ranged from 0.84 to 0.96. Performance remained stable in external cohorts (AUC 0.75-0.87) and prospective trials (AUC 0.79-0.86). SHAP analysis identified cumulative chemotherapy dosage and prior-cycle nadirs as dominant risk factors. Notably, the HIS-integrated tool successfully automated data retrieval, eliminating manual entry burden. **Conclusions:** This first EHR-integrated, cycle-specific dynamic system for Tr-MS in NPC captures longitudinal marrow exhaustion, enabling a shift from reactive rescue to precise, proactive prevention. AI-powered assessment of tertiary lymphoid structures (TLS) from H&E whole-slide images as a prognostic tool in HNSCC. First Author: Jiyoon Lim, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Tertiary lymphoid structures (TLS) are recognized prognostic markers in Head and Neck Squamous Cell Carcinoma (HNSCC), yet manual assessment from H&E whole-slide images (WSI) remains subjective and labor-intensive, limiting clinical utility. This highlights the need for a reproducible and objective AI-based approach to TLS assessment using routine H&E slides. **Methods:** We conducted an integrative analysis by combining transcriptomic and histopathologic data. TCGA HNSCC mRNA expression data (n = 566) were analyzed using xCell to compute enrichment scores for B cells, T cells (CD4+ and CD8+), and dendritic cells. A TLS enrichment score was calculated by averaging the z-standardized aggregate scores of these lineages. Patients in the top and bottom quartiles were labeled 'TLS enriched' and 'non-enriched,' respectively; these labels were used to train a foundation model-based AI using Imagene's OI Suite powered by CanvOI with a 3:1 train–test split. Survival analyses were performed at the patient level in 443 evaluable patients with high-quality H&E whole-slide images and definitive AI-predicted TLS enrichment status. Univariable and multivariable Cox regression evaluated AI-predicted TLS enrichment as an independent predictor of overall survival. **Results:** The AI model demonstrated robust performance for TLS assessment, achieving an AUC of 0.77 in the training set (n = 332, 75%) and AUC of 0.85 in the test set (n = 111, 25%). Kaplan–Meier analysis showed that among 443 patients, the AI-predicted TLS-enriched (TLS+) group (n = 146, 33%) demonstrated improved overall survival compared with the TLS-non-enriched (TLS-) group (n = 297, 67%), with median OS 57.9 vs 35.4 months (HR 0.72; 95% CI 0.53–0.98; log-rank P = 0.039). After adjustment for age, sex, and stage, AI-predicted TLS enrichment remained independently associated with improved overall survival (HR, 0.73; 95% CI, 0.54–1.00; P = 0.0499). These findings suggest that the AI model successfully translates molecular TLS signatures into histological predictors, capturing critical tumor microenvironment (TME) features that refine risk stratification beyond standard clinicopathologic factors. **Conclusions:** AI-based H&E WSI analysis helps identify TLS enrichment as a potential predictor of overall survival in HNSCC. This unbiased computational approach provides a reproducible and objective methodology using H&E slides alone, without the need for additional molecular or immunohistochemical assays, thereby supporting immune risk stratification for precision immunotherapy, particularly in resource-limited settings. Volrustomig monotherapy for recurrent/metastatic HNSCC: Substudy 2 of the eVOLVE-02 phase 2 study. First Author: Ye Guo, Department of Oncology, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China

Background: Inhibition of PD-1 is an important part of standard of care treatment options for patients (pts) with recurrent/metastatic (R/M) HNSCC, but prognosis remains poor and there is a need for novel regimens to improve outcomes. Dual PD-(L)1 and CTLA-4 inhibition has shown a trend towards improved survival vs the EXTREME regimen as first-line (1L) therapy in PD-L1-expressing R/M HNSCC. Volrustomig, a monovalent, bispecific, humanized IgG1 monoclonal antibody, inhibits PD-1 and CTLA-4, with increased CTLA-4 blockade on PD-1-positive activated T cells compared to PD-1-negative resting peripheral T cells. We report safety and efficacy from the planned interim analysis of substudy 2 of the phase 2 eVOLVE-02 (NCT06535607) study, investigating volrustomig monotherapy in pts with R/M HNSCC. **Methods:** Eligible pts had histologically or cytologically confirmed R/M HNSCC of the hypopharynx, oral cavity, larynx, or oropharynx (HP, OC, LX, OP), had ECOG performance status (PS) 0/1, and were either treatment-naïve in the 1L setting with confirmed PD-L1 positivity or had disease progression (PD) on/after a 1L platinum-containing regimen. Pts received IV volrustomig until PD (RECIST v1.1)/discontinuation criteria were met. Primary endpoints: safety and confirmed objective response rate (cORR). Secondary endpoints include progression-free survival (PFS) and overall survival. Data cutoff (DCO): August 15, 2025. **Results:** 23 pts with recurrent (n=12) or metastatic (n=11) HNSCC (7 HP, 8 OC, 4 LX, 4 OP) received volrustomig as 1L (n=12) or 2L (n=11) treatment. Median age was 61 years; 16 pts (69.6%) had PS 1; 19 (82.6%) had a PD-L1 combined positive score (CPS) ≥1. Median duration of exposure was 2.1 months (range 0.7–6.4). Treatment-emergent adverse events (TEAEs) were reported in 91.3% of pts (30.4% grade 3/4, 34.8% serious TEAEs); treatment-related AEs per investigator were reported in 82.6% (8.7% grade 3/4, 4.3% serious AEs). No pts discontinued treatment due to AEs. Grade 5 AEs were reported in 13.0% of pts (none considered related to treatment). At DCO, median follow-up was 5.4 months. In pts with CPS ≥1: 5 had partial responses (3 LX, 1 HP, 1 OC); cORR was 26.3%; disease control rate was 52.6%. Median time to response was 2.6 months (IQR 1.4–2.8); responses were ongoing in 60% of responders at DCO. Blood RNA seq showed increased CTLA-4-associated immune proliferation/activation (Ki67/ICOS gene expression) with volrustomig on cycle 1, day 8 vs at baseline. **Conclusions:** Volrustomig monotherapy showed an acceptable safety profile and encouraging activity in pts with R/M HNSCC, warranting further clinical development. Volrustomig is under investigation in combination with chemotherapy as 1L treatment for R/M HNSCC in the phase 2 eVOLVE-02 substudy 3, and as consolidation monotherapy in locally advanced HNSCC after concurrent chemoradiotherapy in the phase 3 eVOLVE-HNSCC (NCT06129864) study. Clinical trial information: NCT06535607. Research Sponsor: AstraZeneca.

6026 **Poster Session**

An open-label, randomized phase 2 trial of ramucirumab and pembrolizumab versus pembrolizumab as first-line therapy for PD-L1–positive, recurrent or metastatic head and neck squamous cell carcinoma (RM-HNSCC). First Author: Christine Auberle, Washington University in St. Louis, St. Louis, MO

Background: Vascular endothelial growth factor (VEGF) is commonly overexpressed in head and neck squamous cell carcinoma (HNSCC). Combination therapies inhibiting VEGF and PD-(L)1 have improved efficacy outcomes compared to PD-(L)1 inhibitors alone in pre-clinical models and in other cancer types. The hypothesis of this randomized phase 2 trial in RM-HNSCC was the objective response rate (ORR) with ramucirumab (a VEGF-2 inhibitor) and pembrolizumab would be higher than pembrolizumab alone. **Methods:** Eligible patients had untreated RM-HNSCC with PD-L1 CPS >1, an ECOG performance status of 0 or 1, and adequate organ function. RM disease within 6 months of curative-intent systemic therapy was permitted. Patients were randomized (stratification factors: HPV status [+ or -] and PD-L1 CPS [1-19 or ≥20]) 2:1 to ramucirumab 10mg/kg and pembrolizumab 200mg (Arm 1) or pembrolizumab (Arm 2) given on Day 1 of each 3-week cycle. The primary endpoint was tumor response as assessed with RECIST v1.1 by BICR. A two-stage group sequential design was used with an O'Brien-Fleming stopping rule to accept the null hypothesis at a one-sided alternative hypothesis. We hypothesized an ORR of ≥50% in Arm 1 and ≤19% in Arm 2. The required sample sizes for stage 1 and stage 2 to obtain 80% power at the type I error of 5% were 36 and 72, respectively. At the end of stage 1, if the standardized Z test statistic was ≥0.453, the study could proceed to stage 2. Otherwise, the study was to be stopped, and the null hypothesis accepted. Secondary endpoints include duration of response (DoR), progression free survival (PFS), overall survival (OS) and adverse events. Here, the results of the interim analysis are reported per protocol. **Results:** Thirty-seven patients were enrolled and treated in stage 1. Median age was 65 years (IQR 60-70), 76% were male, and tumor characteristics (including status of HPV and PD-L1 CPS and prior systemic therapy within 6 months) were balanced between the two arms. The ORR was 28% (7 of 25 patients, 95% CI: 12.1-49.4%) in Arm 1 and 33.3% (4 of 12 patients, 95% CI: 9.9-65.1%) in Arm 2 [z= -0.327]. The null hypothesis was accepted, and the trial did not proceed to stage 2. **Conclusions:** Among patients with previously untreated PD-L1 positive, RM-HNSCC, ramucirumab and pembrolizumab did not result in a higher ORR than pembrolizumab. Clinical trial information: NCT05980000. Research Sponsor: Joseph Sanchez Foundation; Eli Lilly.

Phase 1 basket study of telisotuzumab adizutecan (Temab-A, ABBV-400), a c-Met protein–targeting antibody-drug conjugate: Results from patients with head and neck squamous cell carcinoma (HNSCC). First Author: Victoria Meucci Villaflor, University of California, Irvine Health Chao Family Comprehensive Cancer Center, Orange, CA

Background: c-Met protein is expressed in several tumor types, including HNSCC, and is associated with a poor prognosis. Temab-A comprises a c-Met protein-targeting antibody conjugated to a topoisomerase 1 inhibitor. Phase 1 studies evaluating Temab-A monotherapy in solid tumors showed antitumor activity and a manageable safety profile (NCT05029882, NCT06084481). Here, we report on the efficacy and safety of Temab-A in HNSCC. **Methods:** This phase 1, open-label basket study (NCT06084481) enrolled patients (pts) ≥18 years with histologically/cytologically confirmed locally advanced or recurrent/metastatic, unresectable HNSCC, with Eastern Cooperative Oncology Group performance score ≤1. Pts must have had measurable disease per RECIST v1.1 criteria, and disease progression following ≥1 line of systemic therapy in the advanced/metastatic setting. Pts were platinum-resistant or deemed ineligible/unfit for platinum-based therapy per investigator. Prior checkpoint inhibitor treatment was required, unless contraindicated. Pts received 2.4 or 3.0 mg/kg Temab-A every 3 weeks. Primary objectives were safety and efficacy. **Results:** As of Sept. 11, 2025, 43 pts with HNSCC received Temab-A. The median age was 64 years (range 20–85). Median number of prior lines of systemic therapy was 3 (range 1–12), and median follow-up was 12 months. Objective response rate (ORR) was 21%; duration of response and overall survival were immature at data cutoff. Efficacy data are shown in the Table. The most common treatment-related adverse events (TRAEs) of any Grade (G) included fatigue (51%), anemia (49%), and nausea (40%). TRAEs G ≥3 occurred in 47% of pts. G ≥3 TRAE occurring in ≥10% of pts was anemia (33%). The adjudicated interstitial lung disease/pneumonitis rate was 9.3% (G1, n=2; G2, n=1; G3, n=1). TRAEs led to treatment discontinuation in 12%, dose interruption in 30%, and dose reduction in 26% of pts. There was 1 TRAE that led to death. Exploratory biomarker analyses are ongoing. Pharmacokinetics of Temab-A in HNSCC were consistent with other tumor types. The half-life of the conjugate and payload was 4 and 13 days, respectively. **Conclusions:** Temab-A had a manageable safety profile and showed encouraging antitumor activity in advanced HNSCC. Clinical trial information: NCT06084481. Research Sponsor: AbbVie Inc.

Efficacy and safety of pralsetinib in advanced or metastatic *RET*-altered thyroid cancer (TC): Final analysis of the phase 1/2 ARROW study. First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center and Sarah Cannon Research Institute, Houston, TX

Background: *RET* alterations are targetable oncogenic drivers in multiple solid tumors and TCs. Pralsetinib is an oral, potent, selective RET inhibitor granted accelerated approval by the FDA for adults and children aged ≥12 y with advanced/metastatic *RET* fusion-positive TC who require systemic therapy and are radioactive iodine-refractory, based on ARROW trial (NCT03037385) results. Accelerated approval for medullary TC (MTC) was withdrawn by the sponsor in 2023 due to recruitment challenges in the confirmatory trial. We report final efficacy and safety in ARROW patients with *RET*-altered TC and MTC. **Methods:** Phase 2 ARROW patients were enrolled from 84 sites in 13 countries. Primary end points were overall response rate (ORR; per RECIST v1.1) and safety. Progression-free survival (PFS), overall survival (OS), and safety were assessed in patients with advanced/metastatic TC and MTC who received ≥1 dose of pralsetinib (Efficacy Population [EP]). ORR and duration of response (DOR) were assessed in the Measurable Disease Population (MDP). **Results:** At the May 20, 2024, data lock, 28 patients with *RET*-altered TC and prior systemic treatment and 145 patients with *RET*-altered MTC received pralsetinib 400 mg/d (median treatment duration: 24.7 mo [TC]; and 35.4 mo [MTC]). In the TC and MTC groups, median age was 58 and 57 y; 39% and 64% were male; median (range) prior lines of treatment was 2 (1, 9) and 1 (1, 6). 53.8% of MTC patients had prior systemic treatment. In TC and MTC patients, ORRs (95% CI) were 91.7% (73.0, 99.0) and 68.2% (59.5, 76.0) (Table). Treatment-related adverse events (TRAEs) occurred in 27 (96%) TC and 142 (98%) MTC patients; 68% and 67% had grade ≥3. TRAEs in ≥35% of TC and MTC patients were increased AST (50% and 38%) and ALT (43% and 30%), decreased white blood cell count (39% and 30%), and anemia (39% each). Death due to a TRAE occurred in 1 TC patient (liver injury) and 1 MTC patient (pneumonia). Safety was consistent with prior reports. **Conclusions:** The final analysis of ARROW confirms that pralsetinib yields clinically meaningful and durable responses in patients with *RET*-altered TC and MTC with a manageable safety profile consistent with prior reports. Clinical trial information: NCT03037385. Research Sponsor: Rigel Pharmaceuticals, Inc.

Penpulimab (AK105) combined with cetuximab as first-line treatment in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC): A phase II clinical trial. First Author: Shu Tian, Eye & ENT Hospital of Fudan University, Shanghai, Shanghai, China

Background: Combination therapy with PD-1 and EGFR inhibitors has shown promising efficacy in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). This open-label, single-arm, multicenter phase II study aimed to evaluate the efficacy and safety of penpulimab (an anti-PD-1 monoclonal antibody) plus cetuximab as first-line treatment in this patient population (NCT05260671). **Methods:** Eligible patients had R/M HNSCC with no prior immunotherapy or EGFR inhibitor exposure. Participants were either treatment-naïve for systemic therapy or had received platinum-based neoadjuvant/adjuvant or chemoradiotherapy more than 6 months before enrollment. All patients received cetuximab 500 mg/m² intravenously as a lead-in dose on day −14, followed by cetuximab 500 mg/m² plus penpulimab 200 mg intravenously on days 1 and 15 of each 28-day cycle. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between March 15, 2022, and January 19, 2026, 31 patients were enrolled. The median follow-up was 20.13 months (95% CI: 15.6–NA). Of these, 29 patients were evaluable for efficacy. The ORR was 44.8% (13/29), and the DCR was 82.8% (24/29). Four patients (13.8%) achieved a complete response (CR). The median DOR was 12.1 months (95% CI: 6.13–NA). For the entire cohort, median PFS was 6.0 months (95% CI: 4.3–18.3), with a 12-month PFS rate of 35.6%. Median OS was 29.1 months (95% CI: 18.2–NA), and the 12-month OS rate was 72.4%. Treatment-related adverse events (TRAEs) occurred in 29 patients (93.5%). Grade ≥3 TRAEs were observed in 4 patients (12.9%), including acneiform rash (6.5%), anemia (3.2%), and oral mucositis (3.2%). No fatal TRAEs were reported. **Conclusions:** The combination of penpulimab and cetuximab demonstrated favorable clinical efficacy and a manageable safety profile in patients with R/M HNSCC, supporting its potential as a first-line treatment option. Trial Registration: NCT05260671. Ethics Approval: This study was approved by the Ethics Committee for Drug Clinical Trials of the Eye & ENT Hospital of Fudan University (Approval No. [20211141-1], 2022). All participants provided written informed consent prior to enrollment. Clinical trial information: NCT05260671. Research Sponsor: Bethune Foundation Colorectal Cancer and Head & Neck Cancer Medical Seed Research Grant.

Real-world efficacy and safety of photoimmunotherapy for recurrent nasopharyngeal carcinoma: A nationwide multicenter study in Japan. First Author: Hideki Tanaka, Department of Otolaryngology, Head and Neck Surgery, Tokyo Medical University, Tokyo, Japan

Background: Treatment options for locally recurrent or residual nasopharyngeal carcinoma (NPC) after definitive radiotherapy remain limited. Salvage surgery is often challenging due to anatomical constraints, while re-irradiation and systemic therapies provide modest efficacy with substantial toxicity. Photoimmunotherapy (PIT) is a light-activated anticancer treatment targeting epidermal growth factor receptor (EGFR) that has been approved in Japan since September 2020 for unresectable locally advanced or locally recurrent head and neck cancers. However, real-world clinical data on PIT for recurrent NPC are limited. We conducted the NPC-PIT Study, a nationwide observational study evaluating the real-world efficacy and safety of PIT in patients with recurrent NPC. **Methods:** Patients with recurrent or residual NPC treated with PIT were enrolled from 26 institutions. Patients with at least 3 months of follow-up after initial PIT were evaluated. Clinical characteristics, prior treatments, PIT illumination techniques, treatment response, overall survival, EBV-DNA levels, and treatment-related adverse events were analyzed. **Results:** As of November 2025, 46 patients were enrolled. The four cases with follow-up <2 months were excluded from the evaluation. The median follow-up duration was 18.6 months. Seventeen patients received one PIT cycle, 14 received two, 6 received three, and 5 received four sessions. Among the 42 evaluable patients, 29 (69.0%) achieved a complete response (CR) lasting ≥2 months. Twenty patients remain alive with no evidence of disease. Disease-related deaths occurred in 3 patients, and 2 patients died from carotid artery rupture after treatment. Grade ≥3 adverse events were observed in 9 patients (21.4%). The 1-year overall survival rate was 89.7%. Among cases where pre-treatment blood samples were collected, 80% (4/5) showed elevated EBV-DNA levels on Cycle 1 Day 7, suggesting that EBV-DNA levels may reflect biological changes associated with PIT treatment. **Conclusions:** In this nationwide real-world cohort, PIT provided meaningful and long-lasting local control with a manageable safety profile for recurrent NPC. These findings support PIT as a clinically meaningful local treatment option for recurrent NPC and warrant further optimization of patient selection and risk mitigation strategies. Research Sponsor: Rakuten Medical Inc.

***Bacteroides sp. DH3716P* and mediation of immunotherapy response in oligometastatic nasopharyngeal carcinoma via the gut–nasopharyngeal axis.** First Author: Zhenhua Zhou, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: Predictors of benefit from gemcitabine/cisplatin (GP) plus PD-1 blockade in oligometastatic nasopharyngeal carcinoma (OM-NPC) remain limited. We investigated whether baseline gut microbiome features are linked to response through a gut–nasopharyngeal axis. **Methods:** We performed metagenomic sequencing on baseline fecal samples from 69 OM-NPC patients receiving GP chemotherapy combined with PD-1 blockade. β-diversity analyses (PCA, PCoA, NMDS) characterized microbiota compositional differences. LEfSe analysis identified differentially abundant taxa between responders (R) and non-responders (NR). Functional enrichment analyses (KEGG, KO, MetaCyc) determined pathway differences. Co-occurrence network analysis assessed microbiota stability. Single-cell RNA sequencing from 7 tumor specimens was analyzed using SAHMI algorithm to determine bacterial-immune cell interactions. Machine learning models built on microbiota, clinical parameters, and serum biomarkers predicted treatment response. **Results:** Microbiota composition differed significantly between R and NR groups. R group showed significant enrichment of *Enterococcus*, *Megasphaera*, and *Streptococcus*. Functional analysis revealed R group possessed enhanced short-chain fatty acid (SCFA) synthesis, glycolysis, and lipid metabolism pathways. Network analysis demonstrated R group had denser ecological networks with superior stability and functional redundancy compared to NR. At species level, *Bacteroides sp. DH3716P* abundance associated with response and prolonged progression-free survival (PFS). This strain highly expressed SusD/RagB family outer membrane proteins and glycoside hydrolase activities, suggesting xylan degradation pathway activation leading to host glycolysis stimulation and SCFA-mediated immune regulation. scRNA-seq analysis revealed *Bacteroides* predominantly infected CD8+ cells in tumor microenvironment. *Bacteroides+* CD8+ T cells demonstrated enhanced IL-15 pathway activity, activated multiple immune response pathways, and increased sensitivity to ICIs. Cell-cell communication analysis indicated *Bacteroides+* CD8+ T cells recruited proliferative T cell subsets through CCL5-CCR5 axis, promoting sustained CD8+ T-mediated anti-tumor immunity. Integrated machine learning models achieved high accuracy in predicting treatment response (AUC: 0.996, 95% CI: 0.989-1.000). **Conclusions:** *Bacteroides sp. DH3716P* sustains immunotherapy response in OM-NPC through enhanced SCFA production and IL-15-CCL5/CCR5 axis-mediated CD8+ T cell activation and proliferative T cell recruitment in the tumor microenvironment. Our microbiota-derived predictive model (AUC 0.996) establishes a clinically feasible strategy for microbiome-assisted personalized immunotherapy in OM-NPC. Research Sponsor: None.

Stereotactic body radiotherapy combined with chemotherapy and PD-1 inhibitor in oligometastatic nasopharyngeal carcinoma (STOMP): A prospective phase II clinical trial. First Author: Jingjing Miao, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center, Guangzhou, China

Background: To evaluate the efficacy and safety of stereotactic body radiation therapy (SBRT) combined with gemcitibine plus cisplatin (GP) chemotherapy and PD-1 inhibitor in patients with oligometastatic nasopharyngeal carcinoma (NPC), registered on clincialtrials.gov (NCT05524168). **Methods:** Main eligibility criteria included diagnosed as oligometastasis NPC (≤5 lesions), and have ≥1 measurable lesion meeting the RECIST 1.1 criteria. Patients firstly receive SBRT for oligometastatic lesions (6-8Gy/fraction × 3-5 fractions), then receive GP+PD-1 inhibitor for 4-6 cycles followed by PD-1 inhibitor maintenance for 1 year. For patients with primary metastasis, the primary lesion and regional metastatic lymph nodes are given radiotherapy (RT) after completing 4-6 cycles of GP+PD-1 inhibitor. The primary endpoint was the 1-year progression-free survival (PFS) rate. **Results:** Between Nov 2022 to Jun 2025, 41 oligometastasis NPC patients were recruited (Table 1). 23 patients were primary metastases, and 17 had distant metastasis (DM) after receiving chemo-radiotherapy, and 1 had regional relapse and DM. All patients finished SBRT for metastatic lesions followed by GP+PD-1, and 23 patients with primary metastasis also received RT for primary lesions after 6 cycles of GP+PD-1. Then 17 received ≥1 year PD-1 maintenance, 3 discontinued for PD, 1 requested to withdraw, and 20 still under PD-1 maintenance. With the median follow-up time of 17.3 (IQR, 12.9-21.8) months, all these metastatic lesions receiving SBRT controlled well; 7 patients had disease progression, including 1 regional relapse, 4 DM, and 2 loco-regional relapse and DM, and all these lesions were newly developed metastatic lesions except one regional relapse which didn't receive SBRT. The primary endpoint 1-year PFS rate was 92.2% (95%CI, 77.6-97.4%), and the secondary survival endpoints 1-year OS, DMFS and LRRFS rate were 100.0% (95%CI, 100-100%), 92.2% (95%CI, 77.6-97.4%), and 97.5% (95%CI, 83.5-99.6%), respectively. The best objective response rate (ORR) and disease control rate (DCR) before starting PD-1 maintenance were 92.7% and 100%, with 27 got complete response, 11 got partial response and 3 got stable disease. The median value of EBV DNA copies pretreatment was 743 (IQR, 151.5-5331.0) copies/ml, then decreased to 0 (IQR, 0-0) copies/ml post 6 cycles of GP+PD-1. No grade 5 therapeutic toxicity was observed in this trial. **Conclusions:** Patients with oligometastatic NPC who receive SBRT for metastatic lesions combined with GP and PD-1 inhibitor could achieve good therapeutic effects with acceptable toxicities. Clinical trial information: NCT05524168. Research Sponsor: Young Talents Program of Sun Yat-sen University Cancer Center; Sun Yat-sen University Cancer Center 308 Program.

Cadonilimab in combination with chemotherapy versus chemotherapy alone in patients with immunotherapy-refractory recurrent or metastatic nasopharyngeal carcinoma: A multicenter, randomized, phase III trial the CONQUEST trial). First Author: Shuiqing He, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Chemotherapy combined with immune checkpoint inhibitors (ICIs) is the standard first-line treatment for recurrent or metastatic nasopharyngeal carcinoma (R/M NPC); however, resistance is common. In the post-ICI setting, prospective trials have demonstrated limited efficacy, with objective response rates (ORRs) ranging from 4.2% to 34.3%. A prior phase II study of nab-paclitaxel, cisplatin, and capecitabine (TPC) plus cadonilimab demonstrated a promising ORR of 68% in ICI-refractory patients, providing the rationale for this phase III trial comparing TPC plus cadonilimab versus TPC alone in this population. **Methods:** In this randomized, multicenter, phase III trial, patients were assigned (1:1) to receive TPC plus cadonilimab or TPC alone. TPC consisted of nab-paclitaxel 200 mg/m² d1, cisplatin 60 mg/m² d1, and capecitabine 1000 mg/m² BID d1–14 (Q3W). In the experimental arm, cadonilimab (10 mg/kg d1) was added. Maintenance with capecitabine plus cadonilimab (experimental) or capecitabine alone (control) continued until disease progression, unacceptable toxicity, or 2 years. The primary endpoint was progression-free survival (PFS), defined as the time from randomization to disease progression or death from any cause. Secondary endpoints included overall survival (OS), ORR (defined as the best overall response), and safety. **Results:** A total of 84 patients were randomized (n=42/arm) at three hospitals. Baseline prior therapies were balanced (*P*=0.533): 35 (83.3%) patients in the experimental arm and 37 (88.1%) in the control arm had received 1-3 prior lines of therapy, while 7 (16.7%) and 5 (11.9%) had received >3 prior lines, respectively. After a median follow-up of 10.2 months, PFS was significantly prolonged in the experimental arm versus the control arm (8.9 months [95% CI 6.3-11.4] vs. 5.1 months [95% CI 3.2-6.9]; HR 0.47, 95% CI 0.28-0.80; *P*=0.004). The ORR was 61.9% in the experimental arm versus 52.4% in the control arm, showing no statistically significant difference (*P*=0.378). Median OS was not reached. All patients experienced adverse events (AEs). Grade 3-4 AEs occurred in 19 (45.2%) patients in the experimental arm versus 23 (54.8%) in the control arm (*P*=0.383). The most common Grade 3-4 AEs were anemia (31.0% vs. 21.4%), neutropenia (21.4% vs. 21.4%), and leukopenia (16.7% vs. 14.3%). Immune-related AEs (irAEs) were more frequent in the experimental arm (34 [82.9%] vs. 25 [58.1%]; *P*=0.013); however, no Grade 3-4 irAEs were observed in either arm. **Conclusions:** TPC chemotherapy combined with cadonilimab demonstrated a statistically significant improvement in PFS compared with TPC alone in heavily pretreated, ICI-refractory R/M NPC patients, with a manageable safety profile (NCT06664983). Clinical trial information: NCT06664983. Research Sponsor: None.

6034 Poster Session

Reirradiation with NBTXR3/SBRT in combination with nivolumab or pembrolizumab for the treatment of patients with recurrent or metastatic head & neck squamous cell carcinoma (HNSCC) in the phase I trial study 1100. First Author: Colette Shen, Department of Radiation Oncology, School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: HNSCC reirradiation with stereotactic body radiation therapy (SBRT) has emerged as a potential option for the management of locoregionally recurrent (R) or metastatic (M) HNSCC, however treatment toxicity remains a limiting factor. NBTXR3 is a novel intratumoral radioenhancer composed of functionalized hafnium oxide nanoparticles which locally amplifies radiation therapy (RT). In pre-clinical models, NBTXR3/RT has demonstrated an ability to generate cell killing effects at low RT doses as well as trigger local and systemic immune responses. Here we report outcomes in pts with R or R+M HNSCC who were treated with reirradiation with NBTXR3/SBRT followed by immune checkpoint inhibitors (ICIs). **Methods:** A phase I dose escalation/expansion trial [NCT03589339] evaluating NBTXR3/SBRT followed by ICI (nivolumab or pembrolizumab) included a subgroup with R or R+M HNSCC that were either naïve or resistant to prior ICI. Pts received an intra-tumoral NBTXR3 injection at dose of 22% or 33% of gross tumor volume (GTV), SBRT (35 Gy in 5 fractions), and ICI. Primary objective was safety and establishing RP2D of NBTXR3/SBRT/anti-PD-1 combination. The expansion part tested the RP2D (33% of GTV). Secondary objectives include efficacy. **Results:** From June 2019 to February 2025, 30 pts were treated: 16 ICI naïve, 14 ICI resistant with median age of 67 years, 90% ECOG 0-1, and 55% HPV negative. 20 pts (66.7%) had R disease, 10 (33.3%) pts had R+M disease. All injected lesions were in a previously irradiated H&N field. Median time from end of prior radiotherapy to NBTXR3 injection was 21.3 [5-229] months. Median GTV was 16.1 [3-110] mL. 4 pts (13.3%) experienced G≥3 injection-related AEs, 8 (26.7%) G≥3 RT-related AEs, and 6 (20%) G≥3 NBTXR3-related AEs. Carotid injury was not observed. Most frequent injection or NBTXR3-related AEs were injection site pain (10%), oropharyngeal pain (6.7%), tumor pain (6.7%), dysphagia (6.7%), and soft tissue necrosis (6.7%). 27 pts (90%) were evaluable for efficacy. For all disease (i.e. injected and non-injected), the objective response rate (ORR) was 48.1% (13/27) and disease control rate (DCR) was 77.8% (21/27). In R pts, ORR was 64.7% (11/17) and DCR was 88.2% (15/17). In R+M pts, ORR was 20% (2/10) and DCR was 60% (6/10). Survival outcomes in reirradiation pts with R and R+M HNSCC will be presented. **Conclusions:** Reirradiation with NBTXR3 with SBRT and anti-PD1 was feasible in R or R+M HNSCC with an adverse effect profile expected for this clinical setting. Encouraging preliminary efficacy outcomes have been observed, thus warranting further investigation. Clinical trial information: NCT03589339. Research Sponsor: None.

Trends in end-of-life immunotherapy use in metastatic head and neck squamous cell carcinoma: A National Cancer Database analysis. First Author: Ronit Sethi, Department of Medical Education, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Aggressive systemic cancer treatment near the end of life (EOL) rarely benefits patients and is an established marker of low-quality healthcare. While EOL chemotherapy use has substantially declined over time, EOL immunotherapy administration has increased in the era of immune checkpoint inhibitors (ICIs). For metastatic head and neck squamous cell carcinoma (mHNSCC), a high-burden disease with rapidly expanding approvals, ICIs have emerged as a compelling mainstay of treatment. However, these expansions may have increased nonbeneficial ICI use among end-stage patients, contributing to quality impacts like decreased hospice enrollment and high financial burden. Given recent evolutions in head and neck cancer care, we conducted a retrospective cohort study to examine temporal trends and factors associated with EOL immunotherapy initiation in mHNSCC. **Methods:** Patients diagnosed with mHNSCC who received first-course immunotherapy between 2016-2022 were identified in the National Cancer Database. EOL-initiated immunotherapy was defined as initiation within 1 month of death. Two-sample t- or χ^2 testing was used for comparison of means and proportions, respectively, between EOL and non-EOL immunotherapy initiation groups. Multivariable logistic regression with *a priori* covariate selection was used to identify factors associated with EOL immunotherapy initiation. Sensitivity analyses were conducted with 2 and 3-month EOL thresholds. **Results:** Among 8806 included patients, 29.3% received immunotherapy, rising from 17.7% in 2016 to 40.9% in 2022 following first-line FDA ICI approvals. By 2021, EOL-initiated immunotherapy occurred among 6.7%, 13.0%, and 16.4% of treated patients at 1-, 2-, and 3-month EOL thresholds, with possible upward trends after 2019 (2021 vs 2019, 1-month EOL, p=0.114; 2-month EOL, $p<0.05$, χ^2 test). In regression analysis, predictors of one-month EOL initiation included female sex (odds ratio [OR]=2.09, 95% CI=1.33–3.27), disadvantaged insurance status (Medicaid/other governmental OR=2.27, 95% CI=1.18–4.35; uninsured/unknown OR=5.09, 95% CI=2.33–11.12), high metastatic burden (≥3 sites OR=8.77, 95% CI=2.94–26.12), and surgical treatment (OR=2.12, 95% CI=1.19–3.79). Protective factors included academic setting (OR=0.60, 95% CI=0.40–0.90), oropharyngeal primary site (OR=0.54, 95% CI=0.32–0.92), and concurrent radiotherapy (OR=0.53, 95% CI=0.35–0.79) or chemotherapy (OR=0.48, 95% CI=0.31–0.73). **Conclusions:** EOL-initiated immunotherapy occurs among a small but notable proportion of mHNSCC patients and is associated with various indicators of clinical and demographic vulnerability. As ICI use expands, our findings underscore the importance of optimizing patient selection, EOL treatment guidelines, and system-level practices to ensure judicious use of immunotherapy in terminal settings. Research Sponsor: U.S. National Institutes of Health; 5R25CA281789-03.

6036 Poster Session

Penpulimab plus oral anlotinib and capecitabine as first-line treatment for recurrent or metastatic nasopharyngeal carcinoma (R/M NPC): A multicenter, single-arm, phase 2 clinical trial. First Author: Jun Ma, Department of Radiation Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: Patients (pts) with NPC progressing after intensive radical treatment often have limited treatment tolerance and poor prognosis. Incorporation of oral agents into triple therapy combining chemotherapy, immunotherapy, and targeted therapy may improve efficacy while reducing toxicity. **Methods:** This multicenter, single-arm, phase 2 trial evaluated first-line penpulimab (a PD-1 blockade) plus oral anlotinib (a tyrosine kinase inhibitor) and capecitabine in pts with R/M NPC previously treated with radical chemo/radiotherapy for non-metastatic disease. Pts from 4 academic hospitals in China received 4–6 cycles of penpulimab 200 mg IV d1, anlotinib 10 mg PO qd d1–14, and capecitabine 650 mg/m^2 PO bid d1–21 q3w, followed by penpulimab-capecitabine maintenance until disease progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival (OS), safety, and quality-of-life (QoL; assessed by the EORTC and FACT surveys). This trial was to be considered positive if the median PFS significantly reached an expected value of 11 mo than a historical threshold of 7 mo, with a 1-sided α of 2.5% and 80% power. This trial was registered with ClinicalTrials.gov (NCT05807880) and is now ongoing. **Results:** Between Sept. 2023 and July 2025, 59 eligible pts (median [IQR] age, 50 [40–58] yrs; 33.9% women) were included, of which 23 (38.9%) and 41 (69.5%) pts had recurrent and metastatic diseases, respectively. Overall, 74.6% (44/59) of pts completed at least the required 4 cycles of the triple therapy. After a median follow-up of 10 mo (data cutoff: Nov. 14, 2025), the median PFS was 13.5 mo (95% CI, 13.1–not reached [NR]) and the 12-mo PFS was 64.4% (95% CI, 50.3–78.5%). The median OS was NR, and the 12-mo OS was 87.8% (95% CI, 78.4–97.2%). The ORR was 71.4% in 56 pts with available assessments, including complete and partial responses in 5 (8.9%) and 35 (62.5%) pts, respectively. Pts with baseline EBV DNA $\leq$ 4000 copies/mL had higher median PFS (NR *vs* 6.0 mo) and 12-mo PFS rate (71.3% *vs*41.7%) than those with EBV DNA $>$ 4000 copies/mL (p = 0.024). Twelve (20.3%) pts had grade 3–4 acute treatment-related adverse events (trAEs), with the most frequent trAE of palmar–plantar erythrodysesthesia (5.1%). Fifty-seven (96.6%) pts had all-grade trAEs, mainly including palmar–plantar erythrodysesthesia (39.0%), hypothyroidism (37.3%), stomatitis (33.9%), sore throat (32.2%), anemia (27.1%), and leukopenia (23.7%). Two treatment-related deaths were observed. Twenty-nine of 37 QoL domains (78.4%) remained stable or showed clinically meaningful improvement. **Conclusions:** First-line therapy of penpulimab plus oral anlotinib and capecitabine provides promising antitumor efficacy, low toxicity, and favorable QoL for pts with R/M NPC. Clinical trial information: NCT05807880. Research Sponsor: Chia Tai Tian Qing Pharmaceutical Group Co., Ltd.

6037 Poster Session

Safety and efficacy of dostarlimab monotherapy as first-line treatment in programmed cell death-ligand 1–positive recurrent/metastatic head and neck squamous cell carcinoma: Results from a phase 2 trial. First Author: Robert I. Haddad, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: The use of immune checkpoint inhibitors (ICIs) in recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC) has improved patient outcomes and showed benefit in the perioperative setting. The GALAXIES H&N-202 study (NCT06062420) evaluated novel immunotherapy combinations versus dostarlimab monotherapy in patients with R/M programmed cell death-ligand 1 (PD-L1)-positive HNSCC. Here, we present updated safety and efficacy results for patients who received dostarlimab monotherapy. **Methods:** GALAXIES H&N-202 is a multicenter, open-label, randomized, Phase 2 study assessing immunotherapy as monotherapy or in combination as first-line treatment (1L) in adults with R/M PD-L1-positive (combined positive score [CPS] $\geq$1) HNSCC. The dostarlimab monotherapy arm comprised patients randomized to receive dostarlimab 500 mg every 3 weeks until progression, unacceptable toxicity, death, or withdrawal. Investigator-confirmed objective response rate (ORR) per Response Evaluation Criteria in Solid Tumours (RECIST) version 1.1 was the primary endpoint, and safety was a secondary endpoint. Outcomes were analyzed descriptively. **Results:** At data cutoff (July 14, 2025), 66 patients were enrolled in the dostarlimab monotherapy arm. All patients had $\geq$4.5 months of follow-up from first dose. The mean patient age was 64.7 years, 80% were male, and 53% had lung metastases. After a median treatment duration of 19.0 weeks (range: 3.0–69.0), ORR was 27.3% (95% confidence interval [CI]: 17.0, 39.6) overall and 42.4% (25.5, 60.8) for those with a CPS $\geq$20 (Table), and median PFS (95% CI) was 4.2 (2.7, 5.8) and 7.8 (3.0, NE) months, respectively. Treatment-emergent adverse events (TEAEs) occurred in 59 (91%) patients and treatment-related adverse events (TRAEs) in 33 (51%) patients. Three (5%) patients discontinued treatment due to TEAEs. Grade $\geq$3 TEAEs were reported in 21 (32%) patients and Grade $\geq$3 TRAEs in 3 (5%) patients. Seventeen (26%) patients experienced serious adverse events (SAEs) and 3 (5%) experienced treatment-related SAEs. Fatal SAEs were reported in 7 (11%) patients; none were treatment related. **Conclusions:** Dostarlimab monotherapy showed encouraging antitumor activity, particularly in patients with a CPS $\geq$20, and a consistent safety profile in 1L R/M HNSCC that is comparable to other ICIs in HNSCC. Clinical trial information: NCT06062420. Research Sponsor: This study (NCT06062420; GSK Study 219885) was funded by GSK.

Real-world treatment patterns and overall survival in recurrent/metastatic head and neck squamous cell carcinoma following treatment with immune checkpoint inhibitor and platinum-based chemotherapy. First Author: Ari Joseph Rosenberg, Department of Medicine, Section of Hematology and Oncology, University of Chicago, Chicago, IL

Background: Treatments for recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) include immune checkpoint inhibitors (ICI) and/or platinum-based chemotherapy, yet most patients (pts) will experience disease progression, with poor survival and limited therapeutic options in later-line settings. Real-world evidence in R/M HNSCC after ICI and platinum-based chemotherapy is limited. We characterize real-world treatments and survival outcomes in pts with heavily pretreated R/M HNSCC. **Methods:** This retrospective analysis used electronic medical records from the US Flatiron Health Advanced EDM (71% community centers, 22% academic centers, 7% both). Study period was 1 Jan 2015 to 31 Mar 2025 (date of data cutoff). All identified pts had R/M HNSCC and had received prior PD-1 inhibitor and platinum-based chemotherapy. Demographics, baseline disease characteristics, and treatment patterns were analyzed descriptively. Kaplan-Meier method was used to evaluate real-world overall survival (rwOS), defined as time from index date (first date of treatment after PD-1 inhibitor and platinum-based chemotherapy) until date of recorded death. Subgroups by HPV-unrelated (oral cavity, larynx, hypopharynx, HPV-negative oropharyngeal) and HPV-related (HPV-positive oropharyngeal) HNSCC were evaluated. **Results:** In total, 2105 pts with R/M HNSCC were identified from the Flatiron database as previously treated with PD-1 inhibitor and platinum-based chemotherapy. There were 1271 pts who did not receive any subsequent treatment, while 834 pts received an index line of therapy after PD-1 inhibitor and platinum-based chemotherapy and were eligible for analysis. Among those eligible, primary tumor site distribution was 55% oropharynx (81% HPV-positive / 19% HPV-negative), 21% larynx, 18% oral cavity, and 6% hypopharynx. Most pts had an ECOG score of 0 or 1 (77%). Most common regimens in the index line of therapy included chemotherapy, anti-EGFR, and/or PD-(L)1 agents. Among the 834 pts identified, rwOS was 7.8 months (95% CI, 7.0–8.4). There were 373 and 461 pts identified with HPV-related and HPV-unrelated disease, respectively. Median rwOS was significantly longer for the HPV-related vs HPV-unrelated group (9.3 months [95% CI, 8.2–10.9] vs 6.8 months [95% CI, 6.1–7.3]; HR, 0.85 [95% CI, 0.73–0.99]; P=0.036). The 6-month rwOS rate was 65% vs 55%, respectively. Of note, a substantial portion of pts died prior to receiving another line of therapy (39% for HPV-related and 49% for HPV-unrelated). **Conclusions:** Median rwOS is poor in R/M HNSCC following treatment with PD-1 inhibitor and platinum-based chemotherapy, and particularly poor for HPV-unrelated disease, with nearly half dying by 6 months. These results highlight the pressing need for innovative treatments to improve survival in R/M HNSCC. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

Defining the role of locoregional radiotherapy for de novo metastatic nasopharyngeal carcinoma in the immunotherapy era: A systematic review and meta-analysis. First Author: Kunpeng Wu, Heyuan People's Hospital, Heyuan, China

Background: In the pre-immunotherapy era, a phase 3 randomized controlled trial (NCT02111460) confirmed locoregional radiotherapy (LRRT) combined with palliative chemotherapy improved overall survival (OS) and progression-free survival (PFS) in de novo metastatic nasopharyngeal carcinoma (dmNPC). Consequently, this strategy has been adopted by major clinical practice guidelines, including NCCN, CSCO, and ESMO. However, with immunotherapy now integrated into first-line treatment, the contemporary role of LRRT and the definition of patients most likely to benefit from it are uncertain and necessitate further exploration. **Methods:** This meta-analysis was conducted in accordance with PRISMA guidelines. A comprehensive search was conducted in electronic databases including PubMed, Cochrane Library, and Web of Science from their inception to December 31, 2025, to identify eligible studies comparing immunochemotherapy with or without LRRT in dmNPC. The primary outcomes were PFS and OS. Meta-analysis was performed using OnlineMeta V1.1. **Results:** A total of six clinical trials were rated as high-quality and included in this meta-analysis. Our meta-analysis results showed that the palliative immunochemotherapy (PICT) plus LRRT group achieved significantly longer PFS (HRs: 0.560, 95%CIs: 0.431-0.727) and OS (HRs: 0.502, 95%CIs: 0.289-0.869) than the PICT alone group. Additionally, single-arm meta-analysis results demonstrated that the 1-year, 2-year, and 3-year PFS rates (with 95% CIs) in the PICT plus LRRT group were 80.5% (76.3%-84.2%), 56.3% (53.7%-58.9%), and 37.6% (28.6%-47.5%), compared with 62.7% (56.2%-68.8%), 26.3% (16.8%-38.7%), and 7.6% (2.4%-21.6%) in the PICT group. Regarding OS, the 1-year, 2-year, and 3-year rates (with 95% CIs) were 97.1% (95.3%-98.2%), 84.2% (72.3%-91.6%), and 76.0% (47.4%-91.7%) in the PICT plus LRRT group, whereas those in the PICT group were 76.9% (33.5%-95.7%), 55.8% (13.7%-90.9%), and 39.7% (1.7%-88.4%). Sensitivity analysis confirmed the stability of the results, and no significant publication bias was detected. Subgroup analyses indicated that dmNPC patients achieved greater PFS benefit from LRRT when they had partial or complete response to PICT (HRs: 0.509, 95%CIs: 0.368-0.704), undetectable post-treatment EBV DNA (HRs: 0.541, 95%CIs: 0.378-0.774), or oligometastatic disease (HRs: 0.349, 95%CIs: 0.193-0.634). **Conclusions:** In the immunotherapy era, LRRT combined with PICT confers significant and durable survival benefits for dmNPC patients, with pronounced efficacy among those achieving PR/CR to PICT, harboring undetectable post-treatment EBV DNA, or presenting with oligometastatic disease. Research Sponsor: None.

6040 Poster Session

Depth and durability of response with TGF-β trapping in recurrent or metastatic (R/M) HPV-negative head and neck squamous cell carcinoma (HNSCC): Long-term results from two expansion cohorts of a phase 1/1b study of ficerafusp alfa plus pembrolizumab. First Author: Deborah J.L. Wong, University of California, Los Angeles, Los Angeles, CA

Background: In HPV-negative HNSCC, TGF-β overexpression creates fibrotic barriers within the tumor microenvironment that limit tumor penetration and drive resistance to anti-EGFR and anti-PD1 therapy. Ficerafusp alfa is the first and only bifunctional EGFR-directed antibody designed to trap TGF-β, enabling tumor penetration of immune cells and driving deep and durable responses for potential overall survival (OS) benefit. **Methods:** Two dose-expansion cohorts of an ongoing phase 1/1b study (NCT04429542) enrolled adults with 1L R/M HNSCC with PD-L1 CPS ≥1. Patients received ficerafusp alfa 750 or 1500 mg IV on D1, 8, and 15 plus pembrolizumab (pembro) 200 mg IV Q3W. Assessments included objective response rate (ORR), duration of response (DOR), and progression free survival (PFS) per RECIST v1.1; OS; safety; and pharmacodynamic (PD) and pharmacokinetic analyses. This is the first report of long-term efficacy follow-up across two cohorts of ficerafusp alfa. **Results:** As of December 16, 2025, 61 HPV-neg pts were treated in two cohorts (750 mg, n=31; 1500 mg, n=30); 58 pts were efficacy evaluable. Exposure increased in an approximately dose-proportional manner with manageable safety observed in both cohorts. A higher proportion of pts had exposure levels associated with meaningful efficacy with 1500 mg vs 750 mg dosing. Improved outcomes were observed in the 1500 mg vs 750 mg cohort, including deep responses (≥80% tumor shrinkage in 80% vs 47% of responders) and mPFS (9.9 mo vs 6.9 mo), along with increased markers of TGF-β inhibition and tumor penetration in paired biopsies, and increased pro-inflammatory cytokines in blood (Table). **Conclusions:** Deeper and more durable tumor responses were observed with ficerafusp alfa 1500 mg vs 750 mg. Exposure and PD markers of TGF-β inhibition demonstrated dose-related trends consistent with mechanism of action. Together, these data suggest that TGF-β inhibition with ficerafusp alfa facilitates T-cell infiltration, enhancing immunologic activity, contributing to deep and durable responses for patients with HPV-neg HNSCC. These findings support the rationale for FORTIFI-HN01, an ongoing phase 2/3 trial evaluating this combination in 1L PD-L1 pos, HPV-neg, R/M HNSCC (NCT06788990). Clinical trial information: NCT04429542. Research Sponsor: Study funded by Bicara Therapeutics Inc. with access to pembrolizumab in collaboration with Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA (NCT04429542).

First-in-class Trop2-targeted PET imaging with ^{68}Ga-MY6349 for diagnostic accuracy and altered management in recurrent/metastatic thyroid cancer compared to standard ^{18}F-FDG PET/CT. First Author: Haojun Chen, The First Affiliated Hospital of Xiamen University, Xiamen, Fujian, China

Background: Accurate, non-invasive detection of recurrent and metastatic thyroid cancer remains an unmet clinical need due to the limitations of conventional imaging and biopsy. Trop2 is a tumor-associated antigen that frequently overexpressed in thyroid cancer, it represents a promising molecular target for imaging. This study aimed to evaluate the diagnostic accuracy of Trop2-targeted PET/CT using the novel nanobody tracer, ^{68}Ga-MY6349, the results were compared with those of ^{18}F-FDG PET/CT. **Methods:** In this prospective, single-center, single-arm trial conducted at the First Affiliated Hospital of Xiamen University (Xiamen, China), adults with suspected or confirmed recurrent or metastatic thyroid cancer were enrolled between January and December 2024. Each participant underwent both ^{68}Ga-MY6349 and ^{18}F-FDG PET/CT scans within one week. Three independent, blinded readers assessed the PET/CT images. The primary endpoints were patient-based sensitivity and specificity, using histopathology or clinical follow-up as the reference standard. The full analysis set included patients with evaluable PET/CT imaging and a confirmed final diagnosis. The trial is registered with ClinicalTrials.gov, NCT06465017 and is closed to enrollment. **Results:** Of 161 screened participants, 143 were finally included in the primary analysis. Papillary thyroid cancer (PTC) was the most common pathological subtype (115/143, 80%). The median clinical follow-up duration was 19 months (IQR: 14-22 months). In the overall cohort, the sensitivity and specificity of ^{68}Ga-MY6349 PET/CT was 90% (95% CI 83-94) and 91% (95% CI 76-97), respectively. Among participants with PTC, its sensitivity and specificity were 94% (95% CI, 87–98) and 96% (95% CI, 79–100), respectively. Additionally, ^{68}Ga-MY6349 PET/CT demonstrated superior diagnostic accuracy in participants with thyroglobulin-elevated negative iodine scintigraphy (TENIS), with sensitivity of 92% (95% CI 82-97) and accuracy of 93% (95% CI 84-97), respectively. Further details are presenting in the Table. No grade 2 or higher adverse event was observed during study. **Conclusions:** ^{68}Ga-MY6349 PET/CT is a safe and highly accurate imaging modality for detecting recurrent and metastatic thyroid cancer, particularly in PTC and patients with TENIS. These findings suggest it could significantly influence clinical practice and may become a standard imaging option in this setting. Further multicenter studies are warranted to validate its diagnostic accuracy and assess its long-term impact on patient management and outcomes. Clinical trial information: NCT06465017. Research Sponsor: None.

First-line HLX07 vs placebo combined with serplulimab and chemotherapy for nasopharyngeal carcinoma: A randomized, double-blind, multicenter phase 2 study. First Author: Wenfeng Fang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Programmed cell death protein 1 (PD-1) blockade with chemotherapy confers significant survival benefit compared to chemotherapy alone and is the standard first-line therapy for recurrent or metastatic nasopharyngeal carcinoma (R/M-NPC). Epidermal growth factor receptor (EGFR) is overexpressed in approximately 85% of all NPCs and associated with poor outcomes, suggesting a potential target for improved efficacies. This study explores the efficacy of HLX07 (a novel humanized anti-EGFR antibody) versus placebo, in combination with serplulimab (PD-1 inhibitor) and chemotherapy as first-line treatment for R/M-NPC. **Methods:** This is a randomized, double-blind, multicenter phase 2 study. Patients with histopathologically confirmed, unresectable, R/M NPC that is not amenable to local or radical treatment and had no prior systemic therapy were randomized 2:1 to receive either HLX07 at 1000 mg (HLX07 group) or placebo (placebo group), along with serplulimab (300 mg) and chemotherapy (gemcitabine and cisplatin) Q3W intravenously. Primary endpoint was blinded independent central review (BICR)-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included other efficacy endpoints, safety, pharmacokinetics and biomarker explorations. **Results:** As of December 24, 2025, 75 patients were randomized to the HLX07 group (n=50) or placebo group (n=25). Efficacy results are reported for the per-protocol set (n = 72), which excluded two patients who violated the enrolment criteria and one with no post-baseline tumor assessment in the HLX07 group. With 26.0 months of follow-up, BICR-assessed confirmed ORR was 74.5% vs. 72.0% for the two groups. Overall, a trend of an improved median progression-free survival (PFS) was observed with HLX07 (17.3 months vs. 9.4 months, stratified hazard ratio [HR] 0.79, 95% CI 0.40–1.56). Median overall survival was not reached vs. 27.9 months (stratified HR 0.40, 95% CI 0.16–0.99) for the respective groups. Subgroup analysis revealed a trend of improved PFS in the HLX07 group compared to the placebo group for patients with PD-L1 CPS <10 (median PFS, 8.1 vs. 6.8 months, HR 0.54, 95% CI 0.19–1.56) as well as for patients with EGFR H-score ≥200 (median PFS, not reached vs. 7.8 months, HR 0.30, 95% CI 0.08–1.15). 74 (98.7%) patients experienced treatment-emergent adverse events (TEAEs), with grade ≥3 TEAEs reported in 60 (80.0%) patients. TEAEs led to treatment discontinuation occurred in 14 (18.7%) patients. Deaths due to TEAEs were reported in 5 (6.7%) patients, with 1 (1.3%) in the HLX07 group that was treatment related. **Conclusions:** The addition of HLX07 to serplulimab and chemotherapy showed encouraging efficacy along with a manageable safety profile in patients with treatment-naïve R/M-NPC. Further investigation of this treatment regimen is warranted. Clinical trial information: NCT05513573. Research Sponsor: Shanghai Henlius Biotech, Inc.

Expansion of circulating NKG7$^+$ cytotoxic CD4$^+$ T cells as a predictor of response to PD-1 blockade in recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC): A prospective phase II study with translational analysis. First Author: Chang Gon Kim, Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Nivolumab has demonstrated meaningful survival benefit in patients with refractory R/M HNSCC. Nevertheless, reliable predictive biomarkers remain scarce—particularly those capable of identifying long-term survivors—underscoring the need for translational studies to uncover immune correlates of durable response. In this prospective phase II study (NCT04603248), we sought to define dynamic circulating immune cell–based biomarkers predicting durable clinical outcomes with nivolumab in patients with R/M HNSCC. **Methods:** Patients with R/M HNSCC who had prior failure of or intolerance to platinum-based chemotherapy were treated with nivolumab (3 mg/kg) intravenously every 2 weeks until disease progression or unacceptable toxicity occurred. Clinical outcomes were correlated with single-cell transcriptomic profiles of circulating immune cells at baseline (cycle 1 day 1) and on-treatment (cycle 2 day 1). To validate the transcriptomic findings at the protein level, mass cytometry by time-of-flight (CyTOF) analysis was additionally performed. **Results:** A total of 48 patients were enrolled. The objective response rate was 22.9%, and the disease control rate was 62.5%. The median progression-free survival (PFS) and overall survival (OS) were 4.4 and 13.3 months, respectively. Single-cell transcriptomic analysis revealed a significant expansion of circulating NKG7$^+$ cytotoxic CD4$^+$ T cells in long-term responders (PFS > 48 months; n=6) compared with early progressors (PFS < 2 months; n=6) at cycle 2 day 1. T cell receptor analysis further demonstrated that nivolumab induced marked clonal expansion of these NKG7$^+$ cytotoxic CD4$^+$ T cells, particularly in long-term responders. Their sustained presence was confirmed in blood samples collected one year after treatment initiation in long-term responders. CyTOF analysis (n=37) revealed that expansion of NKG7$^+$ cytotoxic CD4$^+$ T cells at cycle 2 day 1 was significantly associated with both PFS and OS, supporting their potential role as predictive biomarkers of response to PD-1 blockade. **Conclusions:** Expansion and clonal amplification of circulating NKG7$^+$ cytotoxic CD4$^+$ T cells represent a key immune correlate of favorable outcomes with nivolumab in refractory R/M HNSCC. These findings highlight their potential as predictive biomarkers of durable response to PD-1 blockade in R/M HNSCC and implicate this immune subset as a promising target for future immunotherapeutic strategies. Clinical trial information: NCT04603248. Research Sponsor: None.

Cytokine dynamics in a phase II trial of metronomic carboplatin/paclitaxel combined with cemiplimab in recurrent/metastatic head and neck squamous cell carcinoma. First Author: Marcelo Raul Bonomi, The Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, The Ohio State University, Columbus, OH

Background: Standard-dose chemotherapy combined with immunotherapy improves response rates in recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC), but its use is often constrained by significant toxicity. Metronomic chemotherapy (MCT) offers a potentially better-tolerated alternative while preserving immunemodulatory properties. We evaluated cytokine profiles and their longitudinal dynamics to investigate the relationship between immune-mediated mechanisms and clinical outcomes in patients treated with MCT plus cemiplimab. **Methods:** Single- arm phase II trial (NCT04862650). R/M HNSCC pts received first-line cemiplimab 350 mg IV Q3W ($\leq$35 cycles) plus weekly carboplatin (AUC1) and paclitaxel (25 mg/m²) for 24 weeks. Primary endpoint was overall response rate (ORR) per RECIST v1.1 at week 12. Forty immunemodulatory cytokines were assessed at baseline, week 3, and week 6 using the Luminex xMAP platform. **Results:** From Nov 2021 to Dec 2024, 40 evaluable patients were enrolled (median age was 66 years, 82.5% were male; 35% were HPV-positive). Median follow-up was 10 months (range 1–28). ORR was 42.5% (15% CR) and Median OS was 14.8 months (95% CI, 10.3–23.9). Responders had significantly higher IFN-β at all timepoints (P=.008–.04). Elevated IL-4, IL-5, and IL-10 at baseline were associated with improved ORR. Overall, LIGHT, FasL and TGF-α decreased while PD-L1 increased over time (all $q<0.001$). Compared to baseline, on week 6, responders showed decreased VEGF-A, TSLP, FasL, and IL-4 ($P < .03$), while non-responders exhibited increased IFN-γ, PD-L1, and IL-6Rα ($P < .04$). Changes in IFN-γ (HR 3.23, P=.006) and IL-4Rα (HR 3.06, P=.008) from baseline to week 3 were associated with worse overall survival. **Conclusions:** MCT combined with cemiplimab demonstrated clinically meaningful antitumor activity. Alterations in plasma concentrations of select cytokines were associated with therapeutic response and overall survival. These results are hypothesis-generating and support the need for prospective validation. Clinical trial information: NCT04862650. Research Sponsor: Regeneron Pharmaceuticals; Internal founds from The Ohio State University.

Updated results of benmelstobart combined with anlotinib and chemotherapy as neoadjuvant therapy for locally advanced head and neck squamous cell carcinoma: A single-arm, open-label phase II clinical trial. First Author: Yiqian Liu, Department of Oncology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Locally advanced head and neck squamous cell carcinoma (HNSCC) is characterized by high risks of local recurrence and distant metastasis, resulting in poor prognosis. Neoadjuvant therapy has the potential to improve survival outcomes in these patients. This study aimed to evaluate the safety and efficacy of benmelstobart in combination with anlotinib and chemotherapy as neoadjuvant therapy for resectable locally advanced HNSCC. Preliminary results were presented at the 2025 ESMO Congress (Abstract 1454eP), and updated consecutive results are reported herein. **Methods:** This single-center, phase II clinical trial enrolled patients with stage III/IVA HNSCC who met predefined eligibility criteria. Patients underwent neoadjuvant therapy with benmelstobart (1200mg), anlotinib (10mg), cisplatin (60mg/m²), and nab-paclitaxel (125mg/m², d1, d8) for three 21-day cycles. Surgical resection was performed within two weeks after neoadjuvant therapy completion, with tumor specimens collected for pathological evaluation. The primary endpoint was major pathological response (MPR) rate. Postoperative adjuvant therapy was administered based on risk assessment. Secondary endpoints included objective response rate (ORR), pathological complete response (pCR) rate, 2-year disease-free survival (DFS), 2-year locoregional recurrence-free survival (LRFS), 2-year distant metastasis-free survival (DMFS), 2-year overall survival (OS), and safety assessment. **Results:** As of Jan 9, 2026, a total of 36 patients who met the inclusion and exclusion criteria were enrolled. The median age was 61 years (range: 38-77), with males accounted for 91.7%. ECOG performance status 0 was observed in 80.5% of patients, and hypopharyngeal carcinoma was the most common primary tumor site (50.0%). Stage III and IVA disease accounted for 25.0% and 75.0% of patients, respectively. At the data cut-off date, 32 patients completed neoadjuvant therapy, achieving an ORR of 96.9% and a disease control rate (DCR) of 100%. Among them, 27 patients underwent surgery and completed histopathological assessment. MPR was achieved in 23 cases (including 20 with pCR), resulting in an MPR rate of 85.2% (95%CI: 66.3%-95.8%). The incidence of all grade treatment-emergent adverse events (TEAEs) was 86.1% (31/36). The incidence of grade$\geq$3 TEAEs was 8.3% (3/36), most commonly myelosuppression (5.6%) and renal impairment (2.8%). **Conclusions:** The combination of benmelstobart, anlotinib, and chemotherapy demonstrated promising efficacy as neoadjuvant therapy for resectable HNSCC, with high ORR and MPR rates, along with an acceptable safety profile. These updated results support further evaluation of this combination in randomized controlled trials. Clinical trial information: NCT0669949. Research Sponsor: None.

6046 **Poster Session**

Second-line cetuximab plus immune checkpoint inhibitor (ICI) versus cetuximab plus carboplatin and paclitaxel following ICI-containing regimen in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). First Author: Jennifer Dorcas Hwang, The Ohio State University Comprehensive Cancer Center - The James Cancer Hospital and Solove Research Institute, Columbus, OH

Background: ICI-containing regimens are the standard first-line therapies for R/M HNSCC. However, the optimal therapeutic regimen after progression on ICI-containing therapies remains uncertain. This study compares outcomes among patients (pts) who received either second-line cetuximab plus ICI (CICI) or cetuximab plus weekly carboplatin and paclitaxel (CPT). **Methods:** We performed a retrospective analysis of R/M HNSCC pts treated at our institution between 2018 and 2025 who received cetuximab combination therapy after progressing on first-line ICI alone or ICI with chemotherapy. Pts with ECOG 0-2 were included. All pts received cetuximab 400 mg/m^2 followed by 250 mg/m^2 weekly as tolerated, concurrently with either pembrolizumab (200 mg every 3 weeks) or chemotherapy (carboplatin AUC 1.5 and paclitaxel 45 mg/m^2 weekly). The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall survival (OS), disease control rate (DCR; SD+PR+CR), objective response rate (ORR; CR+PR), and rate of treatment modification. Time-to-event outcomes were estimated using the Kaplan-Meier method and compared using log-rank tests and Cox proportional hazards models. Fisher's exact test was used to compare binary outcomes. Results were deemed significant when $p<0.05$. Subgroup analyses were considered exploratory. **Results:** Out of 100 pts included, 31 received CICI, and 69 received CPT. Median age at the start of cetuximab was 65 years (range 34-93), 79% were male, 95% were Caucasian, and 38% had HPV-related disease. Primary tumor sites included oropharynx (47%), oral cavity (26%), and larynx (19%). 9% had CPS 0, 30% had CPS 1-19, and 43% had CPS $\geq$ 20. For first-line treatment, 41% had received an ICI alone, and 59% had received an ICI with chemotherapy. Median follow-up was 7.6 months (range 3.8-13.4) with CICI and 38.8 months (range 4.3-71.5) with CPT. DCR was 77.4% with CICI and 60.6% with CPT (p=0.12). ORR was 51.6% versus 34.8%, respectively (p=0.13). Median PFS was 7.6 months (95% CI 4.1-NR) with CICI and 2.7 months (95% CI 2.0-4.4) with CPT (HR 0.48, 95% CI 0.29-0.82, $p<0.01$). Median OS was 11.3 months (95% CI 9.1-NA) with CICI and 9.4 months (95% CI 8.2-10.5) with CPT (HR 0.78, p=0.10). Subgroup analyses showed favorable PFS with CICI in select groups: age $\leq$ 65 (p=0.037), male sex (p=0.009), ECOG 0-1 (p=0.024), and prior ICI plus chemotherapy ($p<0.001$). No clear differences were found within subgroups with CPS 1-19 or CPS $\geq$ 20. There was no difference in the rates of treatment modification (p=1.00). **Conclusions:** In this retrospective cohort of R/M HNSCC pts, CICI was associated with a longer PFS than CPT. This effect remained significant in pts who previously received first-line ICI plus chemotherapy. A longer follow-up is planned to evaluate for differences in OS. Research Sponsor: None.

6047 **Poster Session**

An open-label, single-center phase II trial of mitoxantrone hydrochloride liposome combined with programmed death-1 (PD-1) inhibitors for pretreated recurrent or metastatic nasopharyngeal carcinoma. First Author: You Rui, Nasopharyngeal Cancer Center, the Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, Guangdong, China

Background: Liposomal mitoxantrone (Lipo-MIT) in combination with programmed death-1 (PD-1) inhibitors exhibits potential synergistic antitumor effects. This study aimed to evaluate the efficacy and safety of this regimen in patients with pretreated recurrent/metastatic nasopharyngeal carcinoma (R/M NPC). **Methods:** This was a single-arm, Simon two-stage clinical study enrolling patients with R/M NPC who were refractory to platinum-based chemotherapy and PD-1 inhibitors. Patients received intravenous infusion of Lipo-MIT (20 mg/m²) combined with a PD-1 inhibitor on Day 1 of each 21-day treatment cycle, for a maximum of 6 cycles. Subsequent maintenance therapy with PD-1 inhibitors alone was administered until disease progression, occurrence of intolerable toxicity, or completion of 2-year treatment. The primary endpoint was objective response rate (ORR). Key secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety profile. **Results:** A total of 32 patients were enrolled between February 3, 2024, and July 21, 2025, all of whom were included in the efficacy and safety analysis sets. The ORR was 40.6% (95% confidence interval [CI], 24.2–59.2), and the DCR was 78.1% (95% CI, 59.6–90.1). With a median follow-up duration of 8.1 months (range, 4.7–17.2 months), the median OS was not reached and the median PFS was 7.4 months (95% CI, 6.0–not reached [NR]). Grade 3 or higher treatment-related adverse events (TRAEs) were observed in 18 patients (56.3%), and the most common TRAEs were leukopenia (25.0%), anemia (21.9%), neutropenia (18.8%), pneumonia (15.6%), and thrombocytopenia (12.5%). No treatment-related deaths were observed. **Conclusions:** Lipo-MIT combined with PD-1 inhibitors demonstrates promising antitumor activity with manageable toxicities in patients with pretreated R/M NPC. Long-term survival data are pending as follow-up is still ongoing. Clinical trial information: NCT06472713. Research Sponsor: None.

6048 **Poster Session**

A prospective, single-arm, phase II exploratory clinical study on the efficacy and safety of neoadjuvant adebrelimab combined with cisplatin and docetaxel in patients with clinical stage IVB oral squamous cell carcinoma. First Author: Zi-Li Yu, School and Hospital of Stomatology, Wuhan University, Wuhan, Hubei, China

Background: Oral squamous cell carcinoma (OSCC) is one of the most common malignant tumors of the head and neck. Stage IVB OSCC had long been considered unresectable with extremely poor prognosis, and mainstream guidelines encourage exploring new therapies via clinical trials. This study aimed to evaluate the efficacy and safety of adebrelimab plus cisplatin/docetaxel as neoadjuvant therapy for stage IVB OSCC (NCT06277791). **Methods:** IVB OSCC patients aged 18–75 years were enrolled and received 2 cycles of neoadjuvant immunochemotherapy (adebrelimab 1200 mg + cisplatin 75 mg/m²/docetaxel 75 mg/m², q3w). Three weeks after neoadjuvant treatment, patients underwent extended primary tumor resection and radical neck dissection, followed by adjuvant radiotherapy/chemoradiotherapy. The primary endpoint was pathological response rate (pCR+MPR); secondary endpoints included radiographic response, R0 resection rate, and safety. **Results:** 28 patients were enrolled between June 2023 and January 2026. The mean age was 47.8 years, with a male predominance (25, 89.3%). Primary tumors were mainly located in the buccal mucosa (14, 50.0%) and tongue (10, 35.7%). Smoking, alcohol consumption, and betel nut chewing histories were noted in 75.0%, 42.9%, and 64.3% of patients, respectively. Most had an ECOG performance status of 1 (75.0%). 8 cases (28.6%) were classified as cT4b and 20 cases (71.4%) as cN3b at baseline. Three patients (10.7%) were excluded from efficacy analysis due to insufficient data. In the evaluable population (n=25), no complete response (CR) was observed; 8 (28.6%) achieved partial response (PR), 14 (50.0%) stable disease (SD), and 3 (10.7%) progressive disease (PD), with an overall objective response rate (ORR) of 32.0% (8/25). Subgroup ORRs were 33.3% (2/6) for cT4b and 31.6% (6/19) for cN3b. Pathological assessment was available for 25 patients: based on the combined pathological assessment of the primary tumor and lymph nodes, 15 (60.0%) achieved MPR, 1 (4.0%) pCR, resulting in a 64.0% pathological response rate. For subgroups, the pathological response rate was 50.0% in 6 evaluable cT4b (2 MPR, 1 pCR) and 68.4% in 19 evaluable cN3b (13 MPR, no pCR). The R0 resection rate was 100% among 25 surgical patients. Treatment-related adverse events (TRAEs) were mostly grade 1–2. Grade 3 TRAEs occurred in 2 cases (7.2%), with no grade 4/5 events. At data cutoff (median follow-up: 12.0 months), 3 deaths occurred. The estimated 1-year OS rate was 87.9%, with subgroup rates of 89.1% for cN3b (median follow-up: 12.0 months) and 87.5% for cT4b (median follow-up: 19.4 months). **Conclusions:** Neoadjuvant adebrelimab combined with chemotherapy achieves a high pathological response rate in stage IVB OSCC, with manageable adverse events and favorable safety. Clinical trial information: NCT06277791. Research Sponsor: None.

Evaluation of autologous tumor-infiltrating lymphocytes (GT201) plus toripalimab in recurrent or metastatic head and neck cancer. First Author: Pin Wang, University of Southern California, Los Angeles, CA

Background: Immune checkpoint inhibitors (ICIs) are the standard treatment for recurrent and/or metastatic (R/M) squamous cell carcinoma of the head and neck (HNC) after failure of platinum-based chemotherapy; however, the clinical benefit remains limited, with reported overall response rate (ORR) of approximately 13% and median progression-free survival (PFS) of about 2 months in the second line setting. GT201 is an autologous TIL therapy engineered to express membrane-bound IL-15 (mbIL-15), which may enhance immune activation in the tumor microenvironment and promote durable response. We report preliminary safety and efficacy results from an open-label, single-arm study evaluating GT201 in combination with the PD-1 inhibitor toripalimab in patients with R/M HNC (NCT06190275). **Methods:** The primary endpoint was safety, including treatment-emergent adverse events (TEAEs) graded per CTCAE v5.0. Secondary endpoints included ORR, disease control rate (DCR), PFS, duration of response (DOR), and overall survival (OS), assessed per RECIST v1.1. **Results:** As of November 30, 2025, 6 patients with R/M HNC were treated (median age of 57 years; median 1 prior line of therapy). Histology indicated 5 squamous cell carcinoma and 1 lymphoepithelial carcinoma. All patients received 1–2 cycles of bridge therapy, followed by lymphodepletion (low-dose in 5 patients; intermediated-dose in 1 patient), GT201 infusion (5×10^9-5×10^{10} viable cells), and high-dose IL-2 (600,000 IU/Kg; 4-6 doses). Five patients subsequently received toripalimab; one patient progressed prior to PD-1 inhibitor treatment. Maximum follow-up was 15.5 months. Most of AEs were Grade 1-2. Grade $\geq$ 3 AEs were primarily related to lymphodepletion and IL-2, and included cytopenia, neutropenia, lymphocytopenia, monocytopenia, hypokalemia, rash, and increased bilirubin; all resolved or improved to Grade $\leq$ 2 within 14 days. The ORR was 66.7% (4/6), including 2 complete response (CR) and 2 partial response(PR); DCR was 83.3% (5/6). One patient with CR remains progress-free exceeding 12 months. Median PFS and OS have not yet been reached. GT201 cells expanded robustly and persisted in peripheral blood for at least 6 months post-infusion. **Conclusions:** GT201 combined with toripalimab demonstrated a manageable safety profile and encouraging antitumor activity in heavily pretreated R/M HNC, supporting further clinical development of this combination. Clinical trial information: NCT06190275. Research Sponsor: Grit Biotechnology. Research Sponsor: None.

Defining a long-term benefit phenotype to PD-1 inhibitors in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC): A multicentre retrospective study. First Author: Justin Panasci, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: Limited data exists on predictors of durable benefit to PD-1 inhibitors in R/M HNSCC. We aimed to identify clinical characteristics associated with long-term benefit from anti-PD-1 therapy in R/M HNSCC. **Methods:** We reviewed clinical data from patients with R/M HNSCC treated with PD-1 inhibitors between December 2018 and August 2025, at Princess Margaret Cancer Centre (an academic hospital) or within the William Osler Healthy System (a community hospital). Eligible patients received pembrolizumab or nivolumab, either alone or with chemotherapy (for pembrolizumab), and had available tissue for planned biomarker studies. Patients were grouped by progression-free survival (PFS): (A) PFS $\geq$ 24 months (m), (B) PFS 12-24 m and (C) best response of progressive disease (PD). Best response was determined from treating physician documentation based on clinical and radiographic assessment. PFS was estimated with the Kaplan-Meier method. Univariate analysis used Kruskal-Wallis test for continuous variables and Fisher's exact or Chi-square tests for categorical variables. **Results:** A total of 150 patients were included: 31 in group A (PFS $\geq$ 24 months), 28 in group B (PFS 12-24 months) and 91 in group C (PD as best response). We observed significantly more immune-related adverse events (irAEs) (61% vs 16%, OR 8.0, 95% CI 3.2-19.9, $p<0.001$) and corticosteroid use (32% vs 8.8%, OR 4.9, 95% CI 1.7-14.1, p= 0.002) in group A compared to group C. There was a trend toward a higher proportion of patients with lung-only metastases in group A compared to C (39% vs 21%, OR 2.4, 95% CI 1.0-5.8, p= 0.052). Similar associations were found for irAEs ($p<0.001$), corticosteroid use (p= 0.011) and lung-only metastases (p= 0.054) in group B compared with group C. Additionally, we found more active smokers (p=0.010) and ex-smokers (p= 0.036) in group B compared to group C, as well as more active smokers in group B compared to group A (p= 0.042), whereas smoking rates were similar in groups A and C. Interestingly, there was no significant difference in Charlson Comorbidity Index (CCI) scores, albumin levels or neutrophil-to-lymphocyte ratios (NLR) between the three groups. The mean CCI scores were 7.3, 7.3 and 7.1; albumin levels 39.1, 40.1 and 39.7 and NLR 6.8, 6.5 and 8.7 for groups A, B and C respectively. P16 status and PD-L1 CPS were distributed similarly between the groups, although PD-L1 testing was not available in 25% of patients. **Conclusions:** IrAEs, corticosteroids and lung-only metastases are associated with PFS $\geq$ 12 m in patients with R/M HNSCC treated with anti-PD-1 agents. Smoking is associated with PFS 12-24 m but not with PFS $\geq$ 24 m, suggesting a potential role in acquired resistance. Further molecular analysis in this population is underway to identify biomarkers of long-term benefit. Research Sponsor: Canadian Association of Medical Oncologists (J.P.); Princess Margaret Cancer Centre Drug Development Fellowship Program (J.P.).

Preliminary efficacy and safety of intratumoral long-acting cisplatin-SRGel (TumoCure) in refractory locally advanced head and neck squamous cell carcinoma: Phase Ib CLPR-001. First Author: Arnon Aharon, IntraGel Therapeutics, Nazareth, Israel

Background: Refractory LA-HNSCC progressing despite standard therapies is associated substantial locoregional disease driven morbidity and limited effective salvage therapies that achieve modest response rates and are poorly tolerated. Intratumoral (IT) therapies enabling high and durable drug exposure at the site of disease with minimal systemic toxicity may address this unmet need. TumoCure is a long acting injectable IT cisplatin formulation (100mg/mL) incorporated in SRGel, a solvent free biodegradable matrix designed to provide IT cisplatin release for up to 2 months, aiming to maximize locoregional cisplatin exposure with minimal systemic exposure. **Methods:** CLPR-001 is an open-label, multicenter Phase I/Ib study evaluating IT TumoCure in patients with chemo and/or radio resistant LA-HNSCC with no available curative or effective standard treatment options. TumoCure is administered as a single IT injection; individualized based on tumor dimensions to optimize IT dispersion. The primary endpoint is safety and tolerability. Secondary endpoints include locoregional response by RECIST v1.1, PK and QoL assessment. **Results:** Eight patients received IT TumoCure (5 males and 3 females) with a mean age of 66y. Patients were in average 7y from diagnosis and were heavily pretreated: 7/8 (87.5%) had prior surgery and 7/8 (87.5%) were platinum-resistant or refractory. The mean number of prior systemic treatment lines (including RT and IO) was 3. Target lesions reflected substantial locoregional tumor burden (longest diameter 30-98 mm). Administration was feasible across tumor sizes, with injection volumes of 0.4-1.0 mL. Treatment was generally well tolerated. Procedure related AEs were uncommon and limited to injection site pain. No systemic cisplatin related AEs were reported. Early clinical activity was observed, with 3 months best response of 45% and 37% reductions in tumor diameter and corresponding volumetric reductions of 75% and 36% respectively. Patients also experienced clinically meaningful improvement in tumor bulk related manifestations. Preliminary PK analyses demonstrated systemic platinum exposure at least one order of magnitude lower than historical systemic cisplatin exposure. **Conclusions:** In heavily pretreated, platinum-resistant/refractory patients, TumoCure treatment was safe and well tolerated. Early signals of tumor regression and improvement in tumor bulk-related symptoms were observed, supported by markedly reduced systemic platinum exposure. These findings support continued development of TumoCure as treatment for refractory LA-HNSCC. A subsequent study is planned to evaluate TumoCure + IMRT in cisplatin ineligible patients, addressing an unmet need where current chemoradiation regimens remain suboptimal, with the goal of improving outcome while minimizing toxicity. Clinical trial information: NCT05200650. Research Sponsor: None.

First-line lenvatinib versus dabrafenib plus trametinib (D+T) in *BRAF*-mutated differentiated thyroid cancer (DTC): Insights from real-world data. First Author: Wilson Ngai, Eisai Inc., Nutley, NJ

Background: *BRAF* mutations are present in approximately 40%–60% of patients with DTC. Lenvatinib is the NCCN Category 1 preferred first-line (1L) systemic therapy for progressive radioiodine-refractory (RAI-R) DTC—including *BRAF*-mutated disease. For patients with *BRAF* V600E–positive, RAI-R DTC, *BRAF*-targeted therapy is recommended for those unsuitable for lenvatinib or as a 2L agent for patients after disease progression or intolerance to one or more prior multikinase inhibitors. This analysis compares real-world effectiveness of 1L treatment with lenvatinib versus D+T in patients with *BRAF*-mutated tumors. **Methods:** Patients with DTC who initiated lenvatinib monotherapy (n=319; Dec 2014–Jul 2025) or D+T (n=131; June 2016–Sept 2025) were identified from the Tempus multimodal real-world database. Among them, 88 patients were treated with lenvatinib and 54 patients were treated with D+T as 1L therapy for DTC harboring *BRAF* V600E and/or K601E mutations. Retrospective analyses in this patient cohort (n=142) were performed to compare real-world progression-free survival (rwPFS) and overall survival (exploratory; rwOS) between patients treated with 1L lenvatinib and those treated with 1L D+T in *BRAF*-mutated DTC. **Results:** Of the 142 patients in the study cohort who were treated with lenvatinib or D+T, the median age was 66 years (interquartile range: 57–74); 45% of patients were female and 55% were male. The majority (75%) of patients were White, 5.7% were Asian, 3.4% were African American, and 16% had their race categorized as "Other." Papillary, follicular, and Hürthle histology accounted for 92%, 0.7%, and 1.4% of patients, respectively, while the remaining 6% had uncommon or unspecified histology. Demographics and clinical characteristics were balanced between patients treated with 1L lenvatinib or D+T. At median follow-up of 33.6 months, median rwPFS indexed from treatment initiation dates was 17.0 months (95% confidence interval [CI], 12.2–27.8) in patients treated with lenvatinib and 6.2 months (95% CI, 4.9–8.7) in patients treated with D+T (hazard ratio [HR] for lenvatinib vs D+T, 0.44 [95% CI, 0.28–0.69]. Median rwOS was 70.7 months (95% CI, 51.8 – 90.8) in patients treated with lenvatinib, and 37.8 months (95% CI, 16.4–66.4) in patients treated with D+T (HR for lenvatinib vs D+T, 0.34 [95% CI, 0.18–0.62]). Sensitivity analyses showed that rwPFS and rwOS benefits associated with lenvatinib were maintained irrespective of age, sex, or race. **Conclusions:** In this retrospective study of real-world data, 1L therapy with lenvatinib demonstrated longer rwPFS and rwOS compared with 1L D+T in patients with DTC harboring *BRAF* mutations. While recognizing the inherent limitations of real-world data, this study has implications regarding the sequencing of agents used to treat patients with *BRAF*-mutated RAI-R DTC. Research Sponsor: Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

The association of nutritional factors on disease control and survival in patients with recurrent/metastatic head and neck squamous cell carcinoma (R/M-HNSCC) treated with anti–PD-1 monoclonal antibody. First Author: Jessica Zheng, University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: Anti-PD-1 mAb therapy is standard of care for systemic treatment for R/M-HNSCC. These patients (pts) also face significant issues with malnutrition. Therefore, we evaluated whether there was any association between outcomes with anti-PD-1 treatment and nutritional markers including BMI, prognostic nutritional index (PNI), and serum albumin. **Methods:** We collected baseline serum albumin, PNI [(10 $\times$ serum albumin (g/dL)) + (0.005 $\times$ total lymphocyte count)], BMI, and initial BMI trend (baseline to 3 months), on pts with R/M-HNSCC treated with anti-PD-1 at our institution and evaluated association with disease control (CR/PR/SD vs. PD), PFS, and OS. Baseline BMI was analyzed as a continuous variable and binarily [$<$18.5 vs. $\geq$18.5, and median split (23.85)]. Associations of explanatory variables with disease control were evaluated using multivariable logistic regression, reported as odds ratios (ORs) and 95% confidence intervals (CIs) and with PFS and OS using Cox proportional hazards regression, reported as hazard ratios (HRs) and 95% CIs. All analyses were conducted using R version 4.5.2. **Results:** In our retrospective cohort (n = 124), the median age was 68 and primary sites included oral cavity (39%), larynx (16%), hypopharynx (5%), oropharynx (34%; 64% p16+), and other (6%). 43% of patients received anti-PD-1 for platinum failure and 57% for frontline. On univariate analysis, higher PNI was significantly associated with increased disease control (OR = 1.11; 95% CI: 1.04–1.21; p = 0.007), PFS (HR = 0.96; 95% CI: 0.94-0.98; p $<$ 0.001), and OS (HR = 0.97; 95% CI: 0.95–0.99; p = 0.002). Higher albumin was significantly associated with increased PFS (HR = 0.45; 95% CI: 0.24-0.85; p = 0.014) and OS (HR = 0.25; 95% CI: 0.13-0.48; p $<$ 0.001). Evaluation of baseline characteristics showed platinum failure was significantly associated with worse efficacy and therefore multivariate analysis was conducted, adjusting for platinum failure status. PNI was still significantly associated with increased disease control (OR = 1.09; 95% CI: 1.03–1.18; p = 0.016) and PFS (HR = 0.97; 95% CI: 0.95–0.99; p $<$0.001). Higher serum albumin was only significantly associated with increased OS (HR = 0.29; 95% CI: 0.14–0.57; p $<$0.001). Neither baseline nor trend in BMI was associated with efficacy. **Conclusions:** In our cohort of anti-PD-1 treated R/M-HNSCC pts, higher baseline albumin was associated with increased OS while higher baseline prognostic nutritional index was associated with increased disease control and PFS, including in multivariate analysis. While BMI has been associated with efficacy of anti-PD-1 in other solid tumors, it was not in our cohort. Our data suggests that markers that factor in nutritional and immune status may be more relevant in R/M-HNSCC. Further study is warranted. Research Sponsor: None.

Four-year landmark survival analysis of low-dose nivolumab added to metronomic chemotherapy in advanced head and neck squamous cell carcinoma: A phase III randomized trial. First Author: Mehak Trikha, Tata Memorial Hospital, Mumbai, India

Background: In advanced head and neck squamous cell carcinoma (HNSCC), the addition of low-dose nivolumab to triple metronomic chemotherapy (TMC-I) previously demonstrated an overall survival (OS) benefit versus triple metronomic chemotherapy (TMC) alone. We report extended follow-up with a 4-year landmark survival analysis to assess the durability of benefit. **Methods:** This was an open-label, randomised, phase III superiority trial enrolling 151 adult patients ($\geq$18 years) with relapsed–recurrent or newly diagnosed advanced HNSCC with ECOG performance status 0–1, and adequate organ function. Patients were randomized 1:1 to receive oral TMC comprising of Methotrexate 9 mg/m² weekly, Celecoxib 200 mg twice daily and Erlotinib 150 mg daily, with (TMC-I) or without (TMC) nivolumab 20 mg intravenously every 3 weeks. Treatment was continued until disease progression or unacceptable toxicity. The primary endpoint was OS. Survival outcomes were analyzed using Kaplan–Meier methods, log-rank tests, and Cox proportional hazards models. A 4-year landmark analysis was performed. **Results:** At a median follow-up of 55.6 months (95% CI, 45.0–66.2), the median OS was 6.60 months (95% CI, 5.74–7.47) in the TMC arm and 9.33 months (95% CI, 8.00–10.66) in the TMC-I arm (p = 0.045). Treatment with TMC-I was associated with a 29% reduction in the risk of death [hazard ratio (HR), 0.709; 95% CI, 0.506–0.994; p = 0.046]. At 3 years, OS was 5.1% (95% CI, 1.7–12.3) with TMC versus 13.6% (95% CI, 9.7–26.3) with TMC-I [HR 0.686; 95% CI, 0.485–0.971; p = 0.033]. On 4-year landmark analysis, overall survival curve separation was maintained, with OS remaining superior in the TMC-I arm. The median PFS was 4.50 months (95% CI, 3.89–5.12) with TMC and 6.47 months (95% CI, 4.02–8.93) with TMC-I (p = 0.007). The OS benefit with TMC-I was consistent across prespecified subgroups including age, gender, ECOG performance status, disease site, prior platinum exposure, and tumour programmed death ligand (PD-L1) expression. **Conclusions:** With extended follow-up exceeding 4.5 years, the addition of low dose nivolumab to triple metronomic chemotherapy demonstrates a clinically meaningful, durable and statistically significant survival advantage at a 4-year landmark in a predominantly relapsed/refractory advanced HNSCC population compared with TMC alone, confirming the long-term clinical benefit of this strategy in the palliative setting. Clinical trial information: CTRI/2020/11/028953. Research Sponsor: None.

Second-line cetuximab monotherapy following PD-1 inhibitor treatments in patients with recurrent/metastatic head and neck carcinoma. First Author: Mercedes Porosnicu, Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC

Background: PD-1 inhibitors, alone or in combination with chemotherapy, are standard first-line therapy for recurrent/metastatic head and neck squamous cell cancer (R/M HNSCC). No established second-line standard exists for majority of patients who progress on immunotherapy. Cetuximab, the only approved targeted biologic agent in HNSCC, has historically shown modest activity as monotherapy, with a 13% response rate. We hypothesized that cetuximab administered after PD-1 inhibitors may demonstrate enhanced efficacy due to potentially synergistic, immunomodulatory effects. **Methods:** This non-randomized single-institution study included patients with R/M HNSCC who experienced disease progression or intolerance to PD-1 inhibitor therapy, with or without chemotherapy, and were subsequently treated with cetuximab monotherapy. Imaging was performed every 6 weeks, and response was assessed per RECIST v1.1. Outcomes included best overall response (BOR), progression-free survival (PFS), overall survival (OS), and toxicity. Survival outcomes were estimated using Kaplan–Meier methods. **Results:** Twenty-seven patients (8 female, 19 male) were included; 5 were HPV-positive. All HPV-positives had metastatic disease, while all HPV-negatives had recurrent disease. Two patients experienced anaphylaxis with the first cetuximab infusion, and two died from tumor-related complications prior to first restaging; all were included in outcome analyses. Nine patients (33.3%) achieved a partial response (PR), while 18 (66.7%) were non-responders, including 10 (37.0%) with stable disease (SD), 4 (14.8%) with progressive disease (PD), and 4 (14.8%) non-evaluable. Median follow-up was 32.4 mos, with 21 deaths observed. Median OS was 11.6 mos (95% CI, 8.0–21.0) in all patients, 15.5 mos (95% CI, 4.2–24.9) in responders and 11.4 mos (95% CI, 5.3–25.0) in non-responders, with 18.0 mos (95% CI, 4.4–32.0) in patients with SD. Median PFS was 4.4 mos overall, 5.3 mos (2.7 to 11.5) in responders, and 4.4 mos (2.6 to 6.2) in non-responders, with 5.9 mos (2.5 to 7.0) in patients with SD. Median OS was 32.0 mos (11.7 to NE) in HPV-positive patients and 10.8 mos (5.3 to 18.0) in HPV-negatives. Two patients experienced anaphylactic reaction with the initial cetuximab administration. All treated patients developed acneiform skin rash, with 17 (68%) experiencing grade 3, necessitating oral antibiotics. **Conclusions:** Cetuximab monotherapy following PD-1 inhibitor therapy demonstrated encouraging clinical activity in patients with R/M HNSCC, with improved outcomes compared with historical cetuximab monotherapy. These findings suggest that sequential targeting of immune-mediated pathways may provide clinical benefit after an immunotherapy failure. Larger prospective studies are warranted to validate these results and to better define response patterns in the immunotherapy setting. Clinical trial information: NCT04375384. Research Sponsor: None.

Evaluation of the impact of regional lymph node depletion on response to immune checkpoint blockade in recurrent and metastatic head and neck squamous cell carcinoma. First Author: Joshua D. Smith, Department of Otolaryngology-Head and Neck Surgery, University of Pittsburgh, Pittsburgh, PA

Background: Lymphadenectomy remains a central component of definitive treatment for head and neck squamous cell carcinoma (HNSCC). However, lymphadenectomy disrupts the draining regional lymph node basin where anti-tumor immune cell priming can occur. We hypothesized that history of regional lymph node depletion may be associated with decreased efficacy of immune checkpoint blockade (ICB) in patients who suffer recurrent or metastatic (R/M) HNSCC. **Methods:** This was a single-institution retrospective cohort study including all patients treated with ICB (anti-PD-1 mAb) for R/M HNSCC from 2015 - 2025. Patients with distant metastatic disease at presentation were excluded. Demographic, clinicopathologic, and treatment history prior to ICB were collated and summarized for each patient. We defined regional lymph node depletion (LN depletion) as history (at any time prior to ICB initiation) of bilateral lymphadenectomy, $>$ 4 levels dissected, or $\geq$18 lymph nodes excised. We then examined history of LN depletion as a predictor of ICB disease control rate (DCR: SD, PR, or CR) and progression-free survival (PFS) after ICB with Kaplan-Meier method and Cox models alone and controlling for tumor HPV status. **Results:** Our cohort was comprised of 100 patients (median age 72 years, 71% male). Primary tumor sites included oral cavity (n=38) p16+ oropharynx (n=23), larynx (n=21), p16- oropharynx (n=13) and sinonasal (n = 5). Forty-six were treated with first-line ICB, while 54 were treated after platinum chemotherapy failure. Sixty had a history of lymphadenectomy prior to ICB. Of these 60 patients, 51 (85%) had a history of radiation prior to ICB. History of regional LN depletion was significantly associated with lower DCR with ICB when considering bilateral lymphadenectomy (25.9% vs 54.8%, p = 0.03), $>$ 4 levels dissected (25.0% vs. 54.8%, p = 0.02), or $\geq$18 lymph nodes excised (25.0% vs. 84.6%, $p < 0.0001$) analyzed alone and on bivariate analysis controlling for HPV status. In patients meeting all three criteria for LN depletion (n = 24), DCR was the lowest at 16% compared to 75% for patients meeting none of the criteria. On bivariate analyses controlling for HPV status, history of bilateral lymphadenectomy (HR: 2.04 [95% CI 1.1 – 3.8] p = 0.02), $>$ 4 levels dissected (HR: 1.82 [95% CI: 1.0 – 3.3] p = 0.05, and $\geq$18 lymph nodes excised (HR: 3.35 [95% CI: 1.4 – 8.1] $p < 0.01$) were independently associated with poorer PFS after ICB. **Conclusions:** In patients with R/M HNSCC, prior regional LN depletion was associated with lower DCR and PFS after ICB. This suggests that greater surgical disruption of draining regional lymph node basins prior to ICB may affect immune response. Research Sponsor: None.

6057 Poster Session

Neoadjuvant and adjuvant pembrolizumab (pembro) plus standard of care (SOC) for resectable locally advanced head and neck squamous cell carcinoma (LA HNSCC): Efficacy by surgical outcomes in the phase 3 KEYNOTE-689 trial. First Author: Douglas Adkins, Siteman Cancer Center, Washington University, St. Louis, MO

Background: In the phase 3 KEYNOTE-689 trial (NCT03765918), neoadjuvant and adjuvant pembro plus SOC (surgery and postoperative [chemo]radiotherapy) significantly improved EFS versus SOC in participants (pts) with resectable LA HNSCC. We present results from an exploratory analysis of EFS by surgical outcomes in KEYNOTE-689. **Methods:** Adults with newly diagnosed resectable LA HNSCC were randomly assigned to receive 2 cycles neoadjuvant pembro 200 mg followed by surgery and 15 cycles adjuvant pembro starting concurrently with postoperative (chemo)radiotherapy (pembro arm) versus surgery and postoperative (chemo)radiotherapy only (control arm). This exploratory analysis evaluated EFS in pts with R0 resection (negative [$\geq$5mm] or close [1-5mm] margin) by local assessment, and postoperative presence or absence of extranodal extension (ENE) or positive ($<$1mm) surgical margins by BIPR in the PD-L1 CPS $\geq$1 and total populations of the study. Median study follow-up (data cutoff date: July 25, 2024) was 38.3 months (range, 9.0-66.5). **Results:** Of 714 total pts, 630 underwent surgery (n = 322, pembro arm; n = 308, control arm). Among 630 who underwent surgery, 307 in the pembro arm and 294 in the control arm had tumors with PD-L1 CPS $\geq$1. EFS in subgroups by surgical outcome is shown in the table. **Conclusions:** In this exploratory analysis of the KEYNOTE-689 study, EFS benefit with neoadjuvant and adjuvant pembro added to surgery and postoperative (chemo) radiotherapy occurred in all subgroups by surgical outcome, consistent with the primary analysis population. Fewer pts in the pembro arm had ENE or positive margins post-surgery indicating downstaging due to neoadjuvant pembro. ENE presence or positive margins were associated with a poorer EFS prognosis; however, EFS was better in the pembro arm vs control in pts with or without these high-risk pathological features. Results further support the addition of neoadjuvant and adjuvant pembro to SOC for resectable LA HNSCC. Clinical trial information: NCT03765918. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

The impact of depth of response on long-term clinical outcomes: Exploratory analyses from multiple expansion cohorts of a phase 1/1b study of ficerafusp alfa plus pembrolizumab in first-line recurrent/metastatic (R/M) HPV-negative head and neck carcinoma (HNSCC). First Author: John M. Kaczmar, Hollings Cancer Center, The Medical University of South Carolina, Charleston, SC

Background: Ficerafusp alfa is the first and only bifunctional EGFR-directed antibody designed to trap TGF-β, enabling tumor penetration of immune cells and driving deep and durable responses. Depth of response has been shown to correlate with prolonged progression free survival (PFS) and overall survival (OS) in several solid tumors. However, such data are limited in R/M HPV-negative HNSCC. Here we performed exploratory analyses to evaluate whether depth of response achieved with ficerafusp alfa and pembrolizumab is associated with prolonged duration of response (DOR), PFS and OS. **Methods:** Three cohorts of a phase 1/1b study (NCT04429542) in 1L, R/M HNSCC, with PD-L1 CPS $\geq$1 evaluated ficerafusp alfa (750mg QW,1500 mg QW, or 2000 mg Q2W) IV combined with pembrolizumab IV. Objective response rate (ORR) per RECIST v1.1, DOR, PFS, and OS were assessed. In the pooled efficacy evaluable set from the three cohorts, we explored if the magnitude of tumor regression, comparing tumor regression $\geq$80% regression (defined as a deep response) vs. tumor regression 0 to $<$80%, is predictive of longer-term clinical outcomes (DOR, PFS, OS). **Results:** As of December 16, 2025, 85 patients with HPV-negative disease were efficacy evaluable across three cohorts (n=30, n=28, and n=27 at 750mg, 1500mg, and 2000mg doses of ficerafusp alfa, respectively). Among these, the confirmed ORRs were 57%, 54%, and 48%, respectively, including 47%, 80%, and 77% of responders achieving a deep response. In the pooled efficacy evaluable set the percentage of patients with a deep response was 36%, with tumor regression 0 to $<$80% was 46%, and no tumor regression was 18%. mDOR was longer for patients with a deep response compared to patients with tumor regression 0 to $<$80% (21.9 mo vs 8.2 mo, HR 0.27). mPFS was also longer in patients with a deep response compared to patients with tumor regression 0 to $<$80% (26.4 mo vs 6.5 mo, HR 0.19). mOS was not reached (NR) in patients with deep response and 14.9 mo in patients with tumor regression 0 to $<$80% (NR vs 14.9 mo, HR 0.17). **Conclusions:** Ficerafusp alfa plus pembrolizumab demonstrated deep responses across multiple dose levels. Deep responses were associated with improved long-term efficacy outcomes, including DOR, PFS, and OS. This suggests that depth of response may represent a clinically meaningful surrogate for understanding long-term efficacy outcomes in HPV-negative HNSCC. Clinical trial information: NCT04429542. Research Sponsor: Study funded by Bicara Therapeutics Inc. with access to pembrolizumab in collaboration with Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA (NCT04429542).

Outcomes of PD-(L)1 inhibitor continuation or rechallenge after first-line progression in recurrent or metastatic head and neck squamous cell carcinoma. First Author: Jong Chul Park, Mass General Brigham, Harvard Medical School, Boston, MA

Background: PD-(L)1 inhibitors are a standard first-line (1L) backbone for recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC). However, many patients progress after 1L PD-(L)1–based therapy, and optimal post-progression strategies remain undefined. In particular, the benefit of continuing or rechallenging PD-(L)1 inhibitors beyond progression is unclear. **Methods:** In this multicenter retrospective study, we included patients diagnosed with R/M HNSCC (oral cavity, oropharynx, larynx, and hypopharynx) between 2016 and May 2025 at Samsung Medical Center and Mass General Brigham. Eligible patients received 1L PD-(L)1–containing regimen, experienced disease progression, and underwent subsequent second-line systemic therapy. Patients were categorized by post-progression strategy: continuation or rechallenge with PD-(L)1 inhibitors versus non–PD-(L)1–based therapy. Overall survival (OS) was defined as the time from initiation of 1L therapy to death from any cause. **Results:** A total of 252 patients with R/M HNSCC met eligibility criteria. Median age was 64; 191 (76%) were male; 68 (27.0%) were HPV-positive; and 217 (86%) were PD-L1 positive (CPS $\geq$1). Twenty-six patients (10.3%) received anti-PD-(L)1 monotherapy, and 84 (33%) remained on 1L therapy for $\geq$6 months. Median OS for the entire cohort was 18 months (95% CI, 15.9-20.1). Median OS was 21.1 months among patients who continued or were rechallenged with PD-(L)1 inhibitor (n = 112) versus 14.4 months in those who were not (n = 140) ($p < 0.001$). On multivariable analysis including post-progression PD-(L)1 continuation/rechallenge, HPV status, PD-L1 expression, age, sex, ECOG performance status, and duration of 1L PD-(L)1 therapy, continuation or rechallenge with PD-(L)1 inhibitors (HR 0.583, p=0.003) and 1L PD-(L)1 duration $\geq$6 months (HR 0.487, p$<$0.001) were independently associated with improved OS. **Conclusions:** In this study, continuation or rechallenge with PD-(L)1 inhibitors after progression on 1L therapy was associated with improved OS in patients with R/M HNSCC, independent of PD-L1 expression or HPV status. Prolonged benefit from 1L PD-(L)1 therapy was also independently associated with favorable survival. These findings suggest that selected patients may derive continued clinical benefit from anti-PD-(L)1–based strategies beyond progression and support prospective studies to refine patient selection and optimize post-progression treatment strategies. Research Sponsor: None.

6060 Poster Session

Efficacy and safety of HLX43 (an anti–PD-L1 ADC) in previously treated recurrent/metastatic nasopharyngeal carcinoma: A multicenter, randomized phase 2 study. First Author: Jun Ma, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: Treatment options are limited and clinical outcomes remain unsatisfactory for patients with recurrent/metastatic nasopharyngeal carcinoma (r/m NPC) in the later-line setting. HLX43 is a novel anti-programmed cell death-ligand 1 (PD-L1) antibody-drug conjugate with promising antitumor activity in advanced tumors. Here we present results from a phase 2 study evaluating HLX43 in previously treated r/m NPC. **Methods:** This randomized, multicenter trial enrolled patients with histologically or cytologically confirmed r/m NPC who had received at least second-line chemotherapy (including one prior line of platinum-based chemotherapy) and progressed on or were intolerant to programmed death (ligand) 1 (PD-[L]1) inhibitor. Patients were randomized 1:1:1 to receive 2 mg/kg, 2.5 mg/kg, or 3 mg/kg of intravenous HLX43 every 3 weeks. The primary endpoints were objective response rate (ORR) and progression-free survival (PFS) per investigator's assessments. **Results:** As of September 18, 2025, 30 patients were randomized to the 2, 2.5, or 3 mg/kg group (n = 10 for each group). The median follow-up duration was 2.8 months (range 2.1–5.6). Twenty-six patients (86.7%) had performance status 1; 27 (90.0%) had prior radiotherapy. The median line of prior systemic therapy was 3 (range 2–8). ORR was 36.7%, with partial responses (PRs) in 11 patients. ORR in the three dose groups was 20.0%, 20.0% and 70.0% (all confirmed by December 2025), respectively; disease control rate (DCR) was 50.0%, 50.0% and 80.0%. PFS data were immature. Overall, treatment-emergent adverse events (TEAEs) occurred in 29 patients (96.7%; grade ≥3, 50.0%). TEAE incidence was 90.0%, 100% and 100% in the three dose groups, respectively. TEAE leading to dose reduction was reported in 3 patients (30.0%) in the 3 mg/kg group only. TEAE leading to treatment discontinuation occurred in 1 (10.0%) each in the 2.5 mg/kg and 3 mg/kg groups. There was no death due to TEAE. The efficacy and safety findings are detailed in Table 1. **Conclusions:** HLX43 showed promising efficacy with a manageable safety profile in r/m NPC patients who had progressed after second-line or later chemotherapy and PD-(L)1 inhibitors. Further investigation is warranted. Clinical trial information: NCT06839066. Research Sponsor: Shanghai Henlius Biotech, Inc.

A prospective phase II clinical study of different time-delivered drugs combined with intensity-modulated radiotherapy for locally advanced nasopharyngeal carcinoma. First Author: Feng Jin, Afiliated Hospital of Guizhou Medical University, Guizhou, China

Background: To compare the effects of combining intensity-modulated radiotherapy administered at different times on the toxic side effects, quality of life (QoL) and long-term survival of patients with locally advanced nasopharyngeal carcinoma (LA-NPC). **Methods:** A total of 160 patients with LA- NPC were randomized into the experimental group and the control group of 80 patients each, both groups received 2 cycles of TPF (docetaxel, cisplatin, and 5- fluorouracil) induced chemotherapy sequential synchronous radiochemotherapy, the experimental group received chrono- chemotherapy, while the control group received conventional chemotherapy. Primary study endpoints included Grade ≥ 3 acute adverse reactions, Secondary study endpoints included quality of life and 8- year overall survival (OS), progression- free survival (PFS), distant metastasis-free survival (DMFS), and local recurrence- free survival (LRFS). **Results:** As of October 10, 2024, the incidence rates of grade ≥ 3 acute vomiting, oral mucositis, leukopenia, and neutropenia in the experimental group were 3.75%, 6.25%, 27.5%, and 35.0%, while those in the control group were 15.0%, 16.25%, 47.5%, and 52.5%, and the differences were statistically significant ($P < 0.05$). In the experimental group, the incidence rates of Grade 1- 2 xenosomia and hearing impairment were 63.2% and 23.5%, respectively, compared to 80% and 48.6% in the control group, with a statistically significant difference ($P < 0.05$), and no Grade 3- 4 late toxicities were reported in either group. The experimental group demonstrated significantly higher overall QoL scores compared to the conventional group, with statistically significant differences in vomiting, general health status, and quality of life scores between the two groups ($P < 0.05$). However, no statistically significant differences were observed in 8-year OS, PFS, DMFS, or LRFS between the groups ($P > 0.05$). **Conclusions:** The integration of chronotherapy with IMRT significantly reduced adverse reactions and improved quality of life with LA-NPC, without compromising long-term survival outcomes. Clinical trial information: NCT02937519. Research Sponsor: None.

A phase 1/2 study of the next-generation nectin-4–targeting antibody-drug conjugate CRB-701 (SYS6002) in patients with recurrent or metastatic head and neck squamous cell carcinoma. First Author: Charlene Mantia, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: CRB-701 is a next-generation Nectin-4–targeted monomethyl auristatin E (MMAE)-based antibody–drug conjugate with differentiated safety, efficacy and pharmacokinetics compared with other agents in the same class. As previously reported, CRB-701 demonstrated antitumor responses independent of Nectin-4 expression levels in solid tumors, notably in patients with heavily pretreated head and neck squamous cell carcinoma (HNSCC) and cervical cancer, as well as urothelial carcinoma. Here, we provide data from this phase 1/2 trial in patients with recurrent or metastatic (R/M) HNSCC enrolled in dose escalation (part A) and dose optimization (part B) (NCT06265727). **Methods:** Patients with R/M HNSCC who had received ≥ 1 line of therapy were enrolled. Part A employed a Bayesian Optimal Interval design with four doses (1.8, 2.7, 3.6 and 4.5 mg/kg; each every 3 weeks [Q3W]) to determine the maximum tolerated dose. In part B, the pharmacologically active dose range identified in part A was evaluated using a time-to-event Bayesian optimal phase 2 design. Patients were randomized 1:1 to receive CRB-701 at 2.7 or 3.6 mg/kg Q3W. The primary endpoints for parts A and B were dose-limiting toxicities and objective response rate (ORR), respectively. A scan ≥ 4 weeks after the initial response was required to confirm partial and complete responses. Safety, tolerability and pharmacokinetics were also assessed. Nectin-4 expression and human papilloma virus (HPV)/p16 status were evaluated retrospectively. **Results:** As of September 2025, 60 patients with HNSCC were enrolled across parts A and B. The median (range) number of previous therapies was 3.0 (1–9) in the 2.7 mg/kg group and 3.0 (1–8) in the 3.6 mg/kg group; 85% of patients were refractory to immunotherapy and platinum-based regimens. The confirmed ORR was 33.3% (4/12 patients; unconfirmed ORR also 33.3%) at the 2.7 mg/kg dose, and 33.3% (7/21 patients; unconfirmed ORR, 47.6% [10/21 patients]) at the 3.6 mg/kg dose. Responses were observed regardless of HPV/p16 status. The safety profile of CRB-701 was broadly consistent with earlier findings: keratitis, fatigue, alopecia, dysgeusia and anemia were the most frequently reported treatment-emergent adverse events (≥ 15% of overall solid tumor population [N = 167]). An expanded efficacy analysis reporting an additional 6 months of follow-up, including ORR, duration of response and progression-free survival will be presented at the congress. Subgroup analyses by HPV status, treatment history and disease extent will also be presented. **Conclusions:** CRB-701 has shown promising efficacy in patients with heavily pretreated R/M HNSCC, along with a favorable safety profile compared with other MMAE-based therapies. Further investigation of CRB-701 is warranted in this difficult-to-treat patient population. Clinical trial information: NCT06265727. Research Sponsor: Corbus Pharmaceuticals, Inc.

6063 Poster Session

PD-L1 CPS ≥10 population subgroup analysis of KEYNOTE-412: Pembrolizumab plus chemoradiotherapy versus placebo plus chemoradiotherapy for unresected locally advanced head and neck squamous cell carcinoma. First Author: Barbara Burtness, Yale University School of Medicine, New Haven, CT

Background: At the end-of-trial analysis of the randomized, double-blind, phase 3 KEYNOTE-412 trial (NCT03040999) in participants with unresected locally advanced (LA) head and neck squamous cell carcinoma (HNSCC), pembrolizumab plus chemoradiotherapy (CRT) was associated with a clinically meaningful event-free survival (EFS) benefit over placebo plus CRT (HR 0.79; 95% CI, 0.65-0.96) in the total population, and in participants whose tumors expressed PD-L1 CPS ≥1 (HR 0.80; 95% CI 0.64-0.98) and CPS ≥20 (HR 0.70; 95% CI, 0.49-1.00). We conducted a post hoc analysis of outcomes in the PD-L1 CPS ≥10 population. **Methods:** Adults with high-risk unresected LA HNSCC (T3-4 N0-3 or T1-4 N2a-3 laryngeal/hypopharyngeal/oral cavity/p16-negative oropharyngeal SCC, or T4 or N3 p16-positive oropharyngeal SCC) were randomly assigned to receive definitive CRT plus 17 cycles of pembrolizumab 200 mg or placebo intravenously every 3 weeks concurrently and after CRT. This exploratory analysis evaluated EFS and overall survival (OS) in the PD-L1 CPS ≥10 population. **Results:** Of 804 total participants, 382 had tumors expressing PD-L1 CPS ≥10 (n = 194, pembrolizumab group; n = 188, placebo group). As of data cutoff date (August 21, 2024), median study follow-up in the PD-L1 CPS ≥10 population was 74.1 months (range, 63.8-88.1). Median EFS was not reached (NR) in the pembrolizumab group and 61.4 months in the placebo group (HR 0.71; 95% CI, 0.53-0.97). The 60-month EFS rates were 62.4% and 50.3%, respectively. Median OS was not reached in either the pembrolizumab or the placebo group; the 60-month OS rates were 70.7% and 60.9%, respectively (HR 0.75 [95% CI, 0.53-1.04]). **Conclusions:** Results from this post hoc analysis of the KEYNOTE-412 trial with over 2 years of additional follow-up were consistent with those of the end-of-trial analysis in the overall population. For participants whose tumors expressed PD-L1 with a CPS ≥10, we observed a clinically meaningful EFS and OS benefit for pembrolizumab plus CRT over placebo plus CRT, with a numerically lower HR than reported for the overall population. Clinical trial information: NCT03040999. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Clonal hematopoiesis in head and neck carcinomas receiving immunotherapy. First Author: Niki Gavrielatou, Attikon University Hospital, Athens, Greece

Background: Clonal hematopoiesis (CH) is an age-related accumulation of somatic genetic alterations in hematopoietic stem cells. It is implicated in the evolution of myeloid neoplasms and has been associated with poor prognosis in patients with solid tumors. Immunotherapy (ITx) has become the standard of care in the treatment of recurrent/metastatic head and neck cancer (R/M HNSCC), however, response rate corresponds to 20% of total population and relies in a robust innate host immunity. This study aims to identify the presence of CH among ITx-treated R/M HNSCC patients and its potential association with treatment outcomes. **Methods:** Matched pre-treatment peripheral blood (PB) and tumor tissue samples of 32 ITx-treated R/M HNSCC patients were used for DNA extraction. The ten most commonly mutated CH genes were sequenced using a custom NGS Qiagen panel with unique molecular identifiers. Low confidence and synonymous variants were excluded. Pathogenic, likely pathogenic and conflicting with moderate or high annotation impact variants based on the ClinVar database were investigated for associations with progression-free (PFS) and overall survival (OS) as well as for differences in expression between blood and tissue. The same gene alterations and their correlation with survival in HNSCC were also explored in three public datasets (TCGA, GENIE, MSKCC) as an external validation of our findings. **Results:** A total of 2,088 variants were detected with 1,222 silent variants. After filtering,105 pathogenic, likely pathogenic and conflicting interpretation variants were retained. Mutations in CH related genes were identified in 18 out of 32 PB samples (56%). In tissue samples, (excluding *TP53*) mutations were identified in 12 out of 32 samples (37%). *TP53*mutations were significantly higher in tissue samples versus PB (*P*=0.028). *PPM1D* mutations in PB were correlated with shorter PFS (*P*=0.003) and OS (*P*=0.0116), while *TP53* mutations in tissue showed a trend for decreased OS (*P* =0.097). TCGA and MSKCC analysis confirmed a negative association of *TP53* mutations in tissue with OS (*P*=0.0020, *P*=0.0001, respectively). **Conclusions:** CH was frequently detected in PB and tumor tissue of R/M HNSCC patients. CH-related *PPM1D* mutations in PB and *TP53* in tumor tissue, were associated with shorter PFS and OS to ITx, suggesting a potential association between both peripheral and intratumoral immune contexture and clinical outcomes. Prognostic impact of tumor suppressor and DNA damage repair gene mutations in oral cavity squamous cell carcinoma: A clinico-genomic analysis from a real-world database. First Author: Parisa Abedi, Smilow Cancer Center, Yale School of Medicine, New Haven, CT

Background: Oral cavity squamous cell carcinoma (OCSCC) has unique genomic features, yet molecular biomarkers predicting prognosis remain poorly defined. Prior surgical series and TCGA analyses demonstrated TP53 and TERT promoter mutations associate with worse outcomes, while DDR pathways may influence immunotherapy response. However, no study has systematically evaluated these mutations with linked treatment and survival data. This is the first real-world clinico-genomic analysis addressing this gap in OCSCC. **Methods:** Using a pre-specified protocol with IRB approval, we analyzed 381 OCSCC patients from the Flatiron Health-Foundation Medicine Clinico-Genomic Database. Inclusion required confirmed OCSCC, genomic profiling (~300 genes), and survival data. We evaluated tumor suppressors (TP53, CDKN2A), TERT promoter, PIK3CA, and DDR genes (BRCA1/BRCA2/PRKDC). IPTW adjusted for age, sex, stage, smoking, advanced disease, and TMB. A 90-day landmark eliminated immortal time bias. Complete case analysis handled missing data. IO cohort (n=213, 56%) received checkpoint inhibitors. Primary endpoint: OS from diagnosis; secondary: OS from IO initiation. **Results:** Stage IV was the strongest clinical prognostic factor (HR 1.64, 95%CI 1.29-2.08, p$<$0.0001). In IO-treated patients, TMB-high showed improved survival (HR 0.54, p=0.035). DDR pathway mutations were associated with markedly inferior outcomes from IO initiation (HR 2.34, 95%CI 1.00-5.49, p=0.049; median OS 5.7 vs 13.8 months; 12-month OS 17.4% vs 50.4%). TP53+CDKN2A co-mutation showed a trend toward worse survival versus TP53 alone (HR 1.50, 95%CI 0.99-2.27, p=0.056; median OS 9.8 vs 12.8 months; 12-month OS 34.7% vs 51.5%). **Conclusions:** In this first real-world clinico-genomic analysis of OCSCC, TP53 mutation was associated with worse OS, and TP53+CDKN2A co-mutation identified an even higher-risk subset with nearly halved median survival (20.9 vs 44.5 months) compared to wild-type. CDKN2A co-occurred with TP53 in 95% of cases. TERT promoter mutations confirmed their adverse prognostic role. Notably, PIK3CA mutation showed favorable prognosis (HR 0.59), potentially relevant for targeted therapeutics. DDR pathway mutations predicted particularly poor outcomes following immunotherapy. These findings provide a molecular framework for risk stratification in OCSCC and warrant prospective validation. Research Sponsor: None.

Prognostic impact of gene mutations on overall survival in oral cavity cancer.

Genes	HR (95%CI)	p-value	Median OS (MT vs WT)	12-mo OS (from diagnosis)
TP53+CDKN2A co-mutation	1.83 (1.23-2.72)	0.003	20.9 vs 44.5 mo	76.5% vs 83.9%
TP53	1.72 (1.20-2.47)	0.003	26.0 vs 44.5 mo	80.6% vs 85.1%
CDKN2A	1.34 (1.04-1.73)	0.024	20.9 vs 34.2 mo	77.3% vs 83.6%
TERT promoter	1.35 (1.01-1.80)	0.041	24.4 vs 38.0 mo	77.6% vs 88.8%
PIK3CA	0.59 (0.42-0.85)	0.004	51.3 vs 25.7 mo	83.5% vs 81.0%

Clinical validation of ultra-sensitive WGS-based MRD detection in head and neck squamous cell carcinoma: Results from MONSTAR-SCREEN-3. First Author: Naoki Akisada, Head and Neck Surgery, National Cancer Center Hospital East, Kashiwa, Japan

Background: Circulating tumor DNA (ctDNA)-based molecular residual disease (MRD) detection has shown promise across various malignancies, yet limited data exist for Head and Neck Squamous Cell Carcinoma (HNSCC). The prospective, multicenter MONSTAR-SCREEN-3 study evaluates an ultra-sensitive whole-genome sequencing (WGS)-based MRD assay in patients with resectable solid tumors undergoing curative-intent therapy. Here, we report preliminary results from patients with resectable HNSCC enrolled in the definitive cohort (target n=1,100). **Methods:** Personalized ctDNA panels were generated using a WGS-based tumor-informed platform (Myriad Genetics), incorporating up to 1,000 tumor-specific variants identified through WGS of matched tumor tissue. Serial plasma samples were collected at baseline, 1 month post-surgery, quarterly during the first year, and biannually thereafter for up to two years. **Results:** As of November 2025, 44 patients with resectable HNSCC were enrolled; MRD results were available for 139 samples from 34 patients. Median age was 65 years (range: 39-87), with male predominance (65.7%). Clinical staging included Stage III (15.6%), IVA (75.0%), and IVB (9.4%). All patients underwent upfront radical surgery. Personalized panel creation succeeded in 100% of patients (34/34), identifying a median of 6,119 highly confident tumor-specific alterations per patient (range: 1,288-15,418) and yielding bespoke panels containing 717-1,000 alterations. Customized panels were created with 97.7% SNVs and 2.3% indels. The assay demonstrated 100% baseline ctDNA detection (34/34), with 5.9% detected at ultra-sensitive levels (tumor fraction $<$100 parts per million [ppm]; minimum detection: 83.3 ppm). MRD positivity at 1 month, 3 months, and 6 months was at ultrasensitive levels in 10/14 (71.4%), 6/16 (37.5%), and 4/5 (80%) patients, respectively. Among 10 patients who developed radiological recurrence, median lead time was 2.7 months (range: 0-4.6 months). MRD-positive patients at 1 month after surgery had poorer disease-free survival than MRD-negative patients (HR 18.9, 95% CI 2.4–148.9; log-rank P$<$0.0001). Nine of the 13 patients who were ctDNA-positive at 1 month experienced recurrence, whereas only 1 of the 20 ctDNA-negative patients recurred. **Conclusions:** The WGS-based personalized ctDNA assay achieved high technical feasibility in HNSCC, with comprehensive customized variant panels highlighting the critical importance of ultra-sensitive platforms. These results suggest potential clinical utility for recurrence surveillance in HNSCC. Updated results will be presented. Clinical trial information: UMIN000053975. Research Sponsor: None.

Integrated proteogenomic profiling to reveal prognostic subtypes and actionable targets in adenoid cystic carcinoma. First Author: Jiawei Zhou, Clinical Trial Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Adenoid cystic carcinoma (ACC) is a rare head and neck malignancy characterized by highly variable clinical outcomes and a lack of validated biomarkers to guide risk stratification or therapeutic decision-making. Despite a generally low tumor mutational burden, patients frequently experience late recurrence and distant metastasis, underscoring the need for biologically informed prognostic models. Existing genomic and transcriptomic classifiers have failed to adequately explain this heterogeneity. We therefore performed integrated multi-omic profiling to define biologically grounded prognostic subtypes and clinically actionable biomarkers in ACC. **Methods:** We established a multi-omics cohort of 55 surgically resected ACC tumors, including salivary gland–derived and pulmonary ACC, with matched adjacent normal tissues. Whole-exome sequencing, RNA sequencing, quantitative proteomics, and phosphoproteomics were performed. Cross-omics concordance and driver-anchored pathway effects were assessed. Transcriptomic and proteomic data were integrated using Similarity Network Fusion (SNF) to derive molecular subtypes. Prognostic proteins were evaluated using Cox regression. Targeted quantitative mass spectrometry was applied for orthogonal validation and for quantifying antibody–drug conjugate (ADC) targets and pathway stoichiometry. **Results:** ACC exhibited a low-mutational genomic landscape but profound proteomic and phosphoproteomic remodeling, with systematic activation of replication, cell-cycle, chromatin remodeling, and receptor tyrosine kinase–adhesion pathways, accompanied by suppression of immune-associated signaling. Driver effects were more consistently captured at the protein level than at the RNA level, indicating a proteome-driven tumor biology. SNF-based multi-omic integration identified three molecular subtypes with significantly different disease-free survival (DFS; log-rank P=0.0064), outperforming the conventional ACC-I/II classifier. These subtypes formed a biological continuum defined by metabolic robustness and cell-cycle competence. A compact three-protein signature independently stratified DFS. Quantitative profiling demonstrated broad and functionally relevant expression of ADC targets, including TROP2 and B7-H3, and identified ratio-based functional indices (e.g., IGF2/IGF1R and TP63/NOTCH1) associated with risk groups. **Conclusions:** ACC is a proteome-driven malignancy in which post-transcriptional regulation and signaling stoichiometry dominate clinical behavior. Integrated multi-omic analysis redefines ACC prognostic architecture and yields quantitative, translatable biomarkers that may inform precision risk stratification and therapeutic strategies in this rare head and neck cancer. Baseline spatial tumor microenvironment states to define response and primary resistance to immune checkpoint inhibition in recurrent/metastatic head and neck squamous cell carcinoma. First Author: Armando Di Bello, Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario "A Gemelli"-IRCCS, Rome, Italy

Background: Despite the clinical impact of immune checkpoint inhibitors (ICIs) in recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC), durable benefit is limited to a minority of patients and robust predictive biomarkers are lacking. PD-L1 combined positive score incompletely captures response heterogeneity, likely due to the spatial complexity of the tumor microenvironment (TME). We used spatial transcriptomics to identify baseline TME architectures associated with ICI response. **Methods:** Pre-treatment primary tumor samples from 12 patients with R/M HNSCC treated with ICIs were profiled using high-resolution spatial transcriptomics (Xenium In Situ, 10x Genomics; 380-gene immuno-oncology panel). Exceptional responders (ER) were defined by progression-free survival (PFS) $\geq$20 months, while poor responders (PR) had PFS $\leq$3 months. Differential gene expression and Gene Ontology (GO) enrichment were integrated with cell-type–resolved analyses to map transcriptional programs to cellular compartments. **Results:** Distinct baseline TME architectures separated ER and PR. ER tumors showed coordinated upregulation of interferon-related and immune activation genes (STAT1, MX1, CD274) together with cell-cycle-associated genes (MKI67, CDK1). Functional enrichment highlighted immune signaling, chemokine-mediated recruitment, and vascular remodeling, consistent with an immune-inflamed and spatially permissive microenvironment. In contrast, PR tumors exhibited dominant fibroblast-driven extracellular matrix and inflammatory programs, with enrichment of FN1, SPARC, LUM, VCAN and IGFBP7. GO enrichment in PR highlighted integrin-mediated processes, PDGFR-centered signaling, TGF-β–related pathways, and platelet-related signaling programs. Cell-type–resolved spatial mapping showed that fibroblast/ECM programs in PR were predominantly localized to fibroblast-enriched stromal compartments, whereas interferon-response programs in ER were distributed across both tumor and immune compartments. **Conclusions:** Baseline spatially organized TME states are associated with ICI outcomes in R/M HNSCC. ER exhibit an interferon-enriched, immune-permissive architecture, whereas primary resistance is linked to a fibroblast-dominated, ECM-rich and immune-restrictive niche. Proteomic validation of key spatial signals is ongoing to prioritize candidate predictive biomarkers for evaluation in a larger cohort. Enrichment of integrin-mediated processes and PDGFR-centered signaling in PR highlights actionable stromal vulnerabilities warranting translational investigation. Circulating HPV DNA for early detection of minimal residual disease after definitive therapy in oropharyngeal cancer: A phase II biomarker-driven study. First Author: Luana Guimaraes de Sousa, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Persistent detection of circulating HPV DNA (cfHPVDNA) in plasma following definitive therapy for HPV-positive oropharyngeal squamous cell carcinoma (HPV+OPSCC) is strongly associated with inferior outcomes, including increased risk of relapse and distant metastasis, and defines a high-risk patient population. Immune checkpoint blockade targeting the PD-1 pathway has demonstrated clinically meaningful activity in both curative and palliative settings. We hypothesize that balstilimab, an anti–PD-1 antibody, can induce cfHPVDNA clearance in patients (pts) with persistent ctHPVDNA after definitive treatment and improve long-term disease control. **Methods:** Eligible pts had HPV+OPSCC, stage I–III per AJCC 8th edition (excluding T1–2N0 and T1–2N1 with lymph nodes $<$3 cm), and baseline ctHPVDNA ($>$20 copies/ml) per our institution digital droplet PCR assay. After completion of definitive standard-of-care therapy, ctHPVDNA was assessed at 3- and 6-months. Pts with positive ctHPVDNA test in the absence of radiographic evidence of disease were eligible to receive balstilimab (AGEN2034) at 3 mg/kg intravenously every 2 weeks for 6 months. The primary endpoint was cfHPVDNA clearance rate. Secondary endpoints included time to cfHPV DNA clearance, recurrence-free survival, overall survival, and safety. The study was designed to enroll up to 20 pts using a Bayesian optimal phase II design considering an expected clearance rate of 30%. In order to treat 20 pts, 140 pts would needed to be pre-screened with a baseline positive ctHPVDNA (15% of expected minimal residual disease). **Results:** A total of 168 pts were pre-screened, of whom 139 were eligible to proceed; disease stage was I, II, and III in 46% (N=64), 28% (N=39), and 26% (N=36) of pts, respectively. The median baseline ctHPVDNA level was 614 copies/mL (range, 26–239,111). A total of 130 of 139 pts had the 3-month ctHPVDNA assessment, as nine have been excluded (loss of follow-up or withdraw consent). Five had a positive ctHPVDNA result, all of whom had radiographic evidence of disease recurrence (3 local, 1 distant, and 1 both local and distant). Among the remaining 125 pts, 100 have completed the 6-month ctHPVDNA assessment. One pt had a positive ctHPVDNA result with radiographic evidence of local recurrence. One patient had a qualitative positive test ($<$20 copies/ml) without evidence of disease, but the following test prior to trial enrollment was negative. To date, no pts has been allocated to receive balstilimab. **Conclusions:** Persistent ctHPV DNA positivity without radiographic evidence of disease has not been observed following definitive therapy. These findings suggest that cfHPVDNA surveillance may have limited utility for early detection of minimal residual disease in this setting, thereby challenging the feasibility of ctHPVDNA–guided post-definitive intervention strategies. Clinical trial information: NCT05363709. Research Sponsor: Charles and Daneen Stiefel MD Anderson Oropharyngeal Cancer Fund; Agenus Inc; Cancer Moonshot NCI.

Identification of tumor repopulating–like epithelial cells and a repair-dominant niche in pathological responders after neoadjuvant chemo-immunotherapy for HNSCC. First Author: Yongchao Yu, Department of Head and Neck Surgery, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: Neoadjuvant PD-1 blockade plus chemotherapy can induce deep pathologic responses in HNSCC. However, pCR is an imperfect surrogate for OS, and the prior study showed that $>$50% of patients achieving CR after neoadjuvant chemo-immunotherapy relapse rapidly without local therapy, suggesting post-treatment ecosystems may retain programs supporting residual cell persistence and relapse. **Methods:** We profiled tumors from treatment-naïve patients and from patients receiving neoadjuvant taxane/platinum (TP) plus PD-1 blockade with partial response or pCR using scRNA-seq and Xenium spatial transcriptomics. Integrated computational analyses mapped residual epithelial/microenvironmental programs and spatial organization, with validation by immunoblotting, flow cytometry, and mIHC. Translational strategies were evaluated in a 4NQO-induced murine model and a PD-1–resistant murine tongue cancer line. **Results:** We identified a KRT15+IL1R2+ stem-like epithelial population enriched after therapy, most prominent in pCR (61/78 patients), localized to post-treatment regression beds but not discernible on H&E. They were viable and quiescent, lacking DNA damage and cell-death activation; CytoTRACE indicated high differentiation potential, suggesting tumor-repopulating cells. Concerning the microenvironment, across the response continuum from treatment-naïve to partial pathologic response to pCR, scRNA-seq revealed stepwise enrichment of infiltrating non-exhausted cytotoxic CD8 effector T cells, consistent with progressively strengthened tumoricidal immunity. In contrast, deep responders displayed a shift toward a repair-dominant niche: macrophages progressively transitioned from CXCL9+ inflammatory monocytes to SPP1+ macrophages with reduced antigen-presentation programs and enhanced tissue-remodeling features, accompanied by enrichment of multiple repair-associated fibroblast states. Xenium further supported spatial proximity and putative interactions among IL1R2+ epithelium, macrophages, and fibroblasts, which may limited T cell–tumor contact. IL1R2 upregulation was also observed in a PD-1–resistant murine tongue cancer line. In vivo, IL-1β co-administration with PD-1 blockade attenuated treatment efficacy, whereas anti–IL-1β antibody combined with PD-1 blockade enhanced efficacy. **Conclusions:** Deep responses to neoadjuvant chemo-immunotherapy are coupled with a paradoxical repair program and enrichment of IL1R2+ stem-like epithelium that may permit residual persistence and recurrence. The IL-1β–IL1R2 axis is a translationally actionable lever to improve durability and mitigate relapse. Given residual risk even after pCR, de-escalation of local therapy (such as reducing surgical extent or altering definitive treatment strategies) warrants caution. Research Sponsor: National Natural Science Foundation of China; 82303881; 82573603.

Inferring optimal detection of homozygous loss (homozygous deletion) in head and neck cancer: Associations with HPV status, primary disease site, and clinical outcomes. First Author: Jessica Lyn Geiger, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH

Background: Validated detection of homozygous loss is becoming increasingly important in clinical practice. Examples include targeting the AKT pathway in breast cancer with *PTEN* loss and ongoing multi-tumor trials of PRMT5 and MAT2A inhibitors, with *MTAP* loss serving as a key biomarker. Homozygous losses are challenging to detect and require intentional next-generation sequencing assay design and validation. We evaluated the prevalence of the most common homozygous losses in advanced head and neck squamous cell carcinoma (HNSCC) and their associations with HPV status, primary site, and clinical outcomes on standard first-line (1L) therapies. **Methods:** This study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine head and neck cancer clinico-genomic database (FH-FMI CGDB), originating from approximately 280 US cancer clinics (~800 sites of care). Patients with advanced HNSCC who underwent tissue-based genomic profiling with FoundationOneCDx were included. First-line therapy included chemotherapy alone or in combination with cetuximab or immune checkpoint inhibitors (ICIs). Logistic regression assessed the associations of prior treatment, HPV status, and primary disease site with homozygous losses. Clinical outcomes were evaluated with Cox proportional hazards models. **Results:** Among 969 HNSCC specimens, homozygous losses were most frequent in *CDKN2A* (22.1%), *CDKN2B* (17.8%), *MTAP* (9.4%), and *PTEN* (5.3%). *CDKN2A, CDKN2B and MTAP* losses were enriched in tumors arising from the larynx and hypopharynx compared with the oral cavity and oropharynx and were largely mutually exclusive with HPV positivity. *PTEN* loss was most common in the oropharynx and was enriched in HPV-positive tumors and in metastatic liver biopsies. In univariable analysis, homozygous losses were not associated with outcomes after 1L therapy. In multivariable analysis, HPV negativity and higher ECOG scoring, but not PD-L1 status, were independently associated with worse overall survival. **Conclusions:** Using an assay that is FDA-approved to detect and report copy-number (CN) losses, homozygous losses of *CDKN2A*, *CDKN2B*, *MTAP*, and *PTEN* were frequently observed in HNSCC. These alterations were not directly associated with outcomes following 1L therapy. Similar to *CDKN2A/B* loss, *MTAP* loss was enriched in HPV-negative tumors and defines a clinically relevant subset of HNSCC (~10%) potentially eligible for emerging MTAP-targeted therapies. Comprehensive genomic profiling of adenoid cystic carcinoma using the AACR Genie Database. First Author: Madeline Patrick, Santa Clara University, Santa Clara, CA

Background: Adenoid cystic carcinoma (ACC) is a rare neoplasm of the secretory glands, comprising <1% of head and neck tumors. While most commonly arising in salivary glands, ACC has also been reported in the skin, breasts, prostate, and female genital tract. Despite multimodal treatment, no standardized therapeutic approach exists, and prognosis remains poor, with a 5-year survival rate of 50-60%. This study utilizes the American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) database to characterize the genomic landscape of ACC and identify prognostic biomarkers and therapeutic targets. **Methods:** The AACR GENIE database was accessed via cBioPortal (v18.0-public) on December 12, 2025, to identify ACC cases. Frequently mutated genes, demographic associations, and patterns of mutual exclusivity were evaluated using two-sided t-tests and non-parametric analyses with Benjamini-Hochberg false discovery rate correction. **Results:** A total of 540 samples from 500 patients were analyzed, of whom 229 (45.8%) were male, and 266 (53.2%) were female. The cohort included 334 (66.8%) non-Hispanic patients and 39 (7.8%) Hispanic patients. By race, 334 (66.8%) were White, 46 (9.2%) Asian, and 42 (8.4%) Black. Most tumor samples were metastatic (293, 54.3%), followed by primary tumors (217, 40.2%). The most frequently mutated genes were *NOTCH1* (n=152; 28.1%), *KDM6A* (n=59; 10.9%), *ARID1A* (n=54; 10.0%), *BCOR* (n=52; 9.6%), *KMT2C* (n=44; 8.1%), and *KMT2D* (n=42; 7.7%). Sex-stratified analysis demonstrated *FH* mutations occurring exclusively in females (n=4, $p<0.001$), and a higher prevalence of *KMT2C* in female patients (n=25 vs n=8, $p<0.001$). *TET2* alterations were more frequent in males (n=8 vs n=1). Race-based analysis identified *GATA3* mutations exclusively in Asian patients (n=2; p=0.002) and a higher frequency of *FGFR3* alterations in Asians compared with non-Asian patients (n=2 vs n=1; p=0.0447). Co-occurrence was observed between *NOTCH1* and *ARID1A* (n=21/106; $p<0.001$), *CREBBP* (n=17/98; $p<0.001$), and *KDM6A* (n=22/117; p=0.003). Additional co-occurrence was noted between *KDM6A* and *ARID1A* (n=14/80; $p<0.001$), and *CREBBP* with *PIK3CA* (n=8/50; p=0.001). Mutations in *APC* (n=6; $p<0.001$), *CDK12* (n=4; p=0.05), *ELF3* (n=4; $p<0.05$), *MDM2* (n=4; $p<0.05$), and *JAK2* (n=4; $p<0.05$) were observed exclusively in primary tumors. **Conclusions:** To our knowledge, this is the first comprehensive analysis of ACC using the GENIE database. Our findings corroborate prior reports implicating *CREBBP*, *NOTCH1*, and *KDM6A* in ACC while identifying a novel demographic association with GATA3 mutations exclusive to Asian patients. These findings highlight *CREBBP*, *NOTCH1*, *KDM6A,* and *GATA3* as potential targets for future therapeutic development. Research Sponsor: None.

Environmental exposure and prevalence of papillary thyroid cancer in West Virginia: An ecological analysis of per and polyfluoroalkyl substances (PFAS)—impacted regions. First Author: Sanjana Nethagani, West Virginia University Cancer Institute, Morgantown, WV

Background: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental contaminants with widespread exposure through contaminated surface water, groundwater, and drinking water systems. In West Virginia, PFAS contamination has been documented across counties within the Ohio River basin and inland regions affected by industrial activity, waste disposal, and groundwater contamination. This project aimed to study the prevalence of papillary thyroid cancer at a county-level to assess geographic clustering in relation to PFAS-impacted regions and compare statewide incidence with national benchmarks. **Methods:** We conducted a statewide, county-level ecological analysis using Epic electronic health record-driven data to identify papillary thyroid cancer cases diagnosed between 2015 and 2025. County specific prevalence rates were calculated using averaged county population denominators. Relative risks (RR) with 95% confidence intervals were calculated for each county relative to the statewide thyroid cancer prevalence using Poisson-based methods. Spatial patterns were evaluated in relation to counties within the Ohio River basin, including the Monongahela and Kanawha sub-basins, as well as counties with documented or suspected PFAS-related groundwater contamination. Statewide thyroid cancer incidence was contextualized using U.S. Cancer Statistics (1999-2022). **Results:** Papillary thyroid cancer prevalence demonstrated marked geographic heterogeneity across WV, with spatial clustering observed in multiple PFAS-impacted counties. Counties with elevated prevalence demonstrated RRs ranging from approximately 1.75 to 2.75, with the highest RR observed in Harrison (RR 2.75 CI 2.35-3.22), Marion (RR 2.33 CI 1.94-2.79), Braxton (RR 2.30 CI 1.58-3.33), Barbour (RR 2.13 CI 1.50-3.00) and Webster (RR 1.98 CI 1.21-3.24) counties. All associations were statistically significant ($p<0.05$). Many counties outside PFAS-impacted regions demonstrated RR approximating or below 1.0. At the population level, WV demonstrated a higher thyroid cancer incidence than the U.S. overall (20.5 vs 17.4 per 100,000, age-adjusted). **Conclusions:** Papillary thyroid cancer in West Virginia has a spatial clustering pattern in PFAS-impacted counties and a higher statewide incidence compared with national benchmarks. Experimental evidence provides biologic plausibility, as perfluorooctanoic acid disrupts thyroid-stimulating hormone receptor signaling, impairs N-glycosylation, and promotes pro-tumorigenic cellular pathways. Although causal inference is limited by the ecologic design, the convergence of geographic clustering and elevated statewide incidence warrants further investigation of PFAS-related papillary thyroid cancer risk using exposure-resolved individual-level analytic approaches. Discovery of gene set–based biomarkers and therapeutic targets for papillary thyroid cancer based on circulating DNA and tissue RNA. First Author: Hsih-Te Yang, Department of Biostatistics and Data Sciences, Atrium Health Levine Cancer, Charlotte, NC

Background: Mutations in pathways known to promote oncogenesis in Papillary Thyroid Carcinoma (PTC) have been demonstrated in cell-free DNA (cfDNA) samples from patients with PTC, and at higher levels in patients with advanced and dedifferentiated disease such as anaplastic thyroid cancer (ATC). In our study, the most frequent cfDNA mutations were associated with activation of *BRAF*-independent pathways and epigenetic regulation, suggesting a prominent role as drivers of disease in some patients. Also observed were mutations more frequently associated with dedifferentiated thyroid cancer, such as *TP53* at 10% (5/49) in cfDNA vs 2% (1/47) in tissue samples. We hypothesized that nucleosome pattern analysis on cfDNA samples from a *BRAF*-independent subgroup would reveal evidence of heightened epigenetic signaling. **Methods:** We classified PTC into two subtypes based on cfDNA mutation profiles: *BRAF*-independent pathway (BI, 35% of patients with ≥1 mutation in *KMT2A*, *ATM*, or *TP53*) and *BRAF*/alternate-mediated pathway (B/a, 65% with *ARID1A*, *BRAF*, or others). These two gene groups were mutually exclusive by co-mutation and protein interaction networks. Chromatin structure was inferred from cfDNA fragment patterns using LIQUORICE. Gene signatures and pathway scores were then analyzed via GSEA and GSVA on the tissue RNA-seq data. **Results:** Significantly higher H3K4me1 signal (p = 0.047) was detected in cfDNA from the BI subgroup, indicating active epigenetic enhancer states. Additional gene expression analysis on tumor tissue revealed a unique six-gene signature (FDR = 0.089) enriched in the maternal-to-zygotic transition (MZT) pathway, with GSVA scores differing markedly between BI and B/a groups (p = 0.004). Cross-referencing these patients with the PTC cohort data from The Cancer Genome Atlas (TCGA) showed worse disease-free survival in the BI group (p = 0.008) but no difference in overall survival (p = 0.580) between the two groups, possibly due to early-stage diagnosis. **Conclusions:** Mutations in *TP53*/*ATM*/*KMT2A*, associated with *BRAF*-independent pathways, correlate with active epigenetic states in PTC. This supports the hypothesis that epigenetic mechanisms are important drivers of progression in PTC. This study also supports a therapeutic strategy which targets these pathways, such as HDAC inhibitors previously validated in ATC cell lines and PDX models. Finally, six MZT-related genes may serve as biomarkers and regulators of epigenetic and transcriptional reprogramming important to the evolution of cancer in PTC patients. Intrapatient comparative analysis of tumor-informed ctDNA and ctHPV-DNA in patients with HPV-driven OPSCC. First Author: Evgeny Izumchenko, University of Chicago, Department of Hematology/Oncology, Chicago, IL

Background: The rising incidence of oropharyngeal squamous cell carcinoma (OPSCC) is largely attributable to human papillomavirus associated (HPV+) disease, which accounts for ~70% of OPSCC cases. Circulating tumor (ct)DNA has the potential to enable more accurate treatment response assessment, guide response-adaptive management, and detect minimal residual disease to indicate persistence or recurrence. Both mutation-based tumor-informed ctDNA and ctHPV-DNA testing have demonstrated utility in HPV+ disease, but prospective intrapatient evaluations remain limited. A direct comparison of these approaches is essential to determine redundancy versus complementarity and to guide optimal integration into OPSCC patient management. **Methods:** In an ongoing prospective study, serial plasma samples were obtained from patients with stages I-IV OPSCC undergoing curative intent treatment. Up to 50 patient specific somatic variants were selected based on tumor whole exome sequencing to develop a personalized tumor-informed next generation sequencing (NGS) ctDNA assay (Haystack MRD) for plasma analysis. In patients with HPV+ disease (determined via ISH, IHC, and/or NGS), plasma was also analyzed using an NGS-based assay interrogating 13 high-risk HPV strains (Haystack HPV). Paired intrapatient samples were analyzed using percent agreement with 95% confidence intervals and Cohen's kappa; concordance of dynamic changes was assessed using Spearman's correlation. **Results:** As of January 2026, ctDNA results were available for 111 serial timepoints from 26 patients. The median number of timepoints per patient was 4 (range 1-9). Seventeen patients (65%) had HPV+, and 9 (35%) had HPV− disease. In HPV+ patients, across 85 longitudinal samples collected during multimodal treatment and post-treatment surveillance, mutation-based ctDNA and ctHPV demonstrated high concordance (91%; 95% CI, 82.5–95.2; κ=0.80). Of 30 ctDNA+ samples, 28 were ctHPV+ (93%; 95% CI, 78.7–98.2%), while 49 of 55 ctDNA- samples were ctHPV- (89%; 95% CI, 78.2–94.9%). Discordance was infrequent (8/85, 9.4%), predominantly ctHPV+/ctDNA- (6/85, 7.1%). All ctHPV+/ctDNA- cases occurred during neoadjuvant treatment monitoring and reflected earlier clearance of ctDNA, with ctHPV clearance lagging by several weeks to months. Two low-level (<100 parts per million) ctDNA+/ctHPV- cases were observed in the adjuvant setting. When both analytes were present, dynamic changes in ctDNA and ctHPV levels were highly concordant (Spearman's ρ=0.94), although ctHPV was consistently detected at higher absolute levels. **Conclusions:** In HPV-driven OPSCC, tumor-informed ctDNA and ctHPV show high longitudinal concordance and distinct clearance kinetics, with earlier ctDNA clearance. Ongoing analyses will define how these assays can be optimally integrated into response assessment, treatment adaptation, and surveillance strategies. Biologic and clinical implications of HPV genome state variation in oropharyngeal cancers. First Author: Vikram Vasan, University of Pennsylvania, Philadelphia, PA

Background: HPV integration enhances carcinogenesis by ensuring viral DNA retention and increasing E6/E7 expression. Though HPV usually integrates in cervical cancer, DNA episomes persist in ~50% of HPV+ oropharyngeal cancers (OPCs), and prior studies relating integration to clinical outcomes are contradictory. Defining molecular traits and clinical behavior of episomal vs. integrated OPCs is impeded by the complexity of HPV genome states, which defy classification by any one assay. Here we classified HPV states based on concordance between HPV-host fusion mRNA detection (suggesting integration) and E6/E7 levels. Gene expression and clinical outcomes were compared among groups to seek biomarkers allowing therapeutic personalization. **Methods:** Samples were curated from 851 therapy-naïve HPV+ OPCs receiving robotic surgery at a single institution (2007-2020). RNA sequencing was performed on 50 HPV+ OPCs that later recurred (cases) and 50 that were cured (controls). Groups were matched for stage, smoking, and adjuvant therapy. OPCs were deemed likely episomal if absence of HPV-host fusion mRNA was accompanied by E6/E7 levels in the bottom tertile and likely integrated if fusion mRNA presence coincided with E6/E7 in the top tertile. These two OPC subsets were defined as E6/E7-concordant and the rest as E6/E7-discordant. Molecular traits were analyzed as previously (Sannigrahi MK et.al, *JNCI* 2025 117:7) using GSEA of Hallmark pathways and by two scores derived by GSVA of host mRNAs that potently stratified recurrence risk across multiple HPV+ OPC cohorts: (1) an immune suppression score (ISS) measuring reduced anti-tumor immunity and (2) a *t*umor progression score (*TPS*) capturing aggressive tumor cell-intrinsic traits. **Results:** In the overall cohort (n=100), the fusion (+) OPCs (n=49) had increased risk of recurrence (OR 2.90, 95% CI=1.27-6.64, p=.01). Whereas E6/E7 levels alone did not stratify recurrence risk, combining it with fusion status optimized prediction: the likely integrated OPCs (n=23) had high recurrence risk vs. likely episomal OPCs (n=24) (OR=3.81, 95% CI=1.13-12.82, p=.03) despite similar clinical characteristics in both groups. Time to recurrence was also shorter in likely integrated vs. episomal subsets (p=.02). By contrast, fusion read status did not stratify recurrence risk in the E6/E7-disconcordant OPCs (n=53). Adverse gene expression features were upregulated in likely integrated vs. likely episomal OPCs, as reflected in increased TPS (p=.04) and ISS (p=.04). These differences were absent in fusion (+) tumors of the E6/E7-discordant group. **Conclusions:** Our findings offer the most compelling evidence to date supporting independent association of HPV integration with adverse tumor biology and recurrence risk in OPCs. Jointly considering HPV-host fusion mRNAs and E6/E7 levels may guide the molecular biomarker development needed to personalize therapy based on HPV genome state. Validation of Immunoscore for prognostic stratification in HPV-associated oropharyngeal cancer: An international multicenter study. First Author: Dac Hung Nguyen, Université de Paris Cité, AP-HP, Hôpital Européen Georges Pompidou, Department of Otorhinolaryngology; INSERM UMRS 1138, Integrative Cancer Immunology; PARCC UMRS 970, INSERM, Paris, France

Background: Treatment optimization in HPV-associated oropharyngeal cancer (OPSCC) remains challenging due to the limited results of de-escalation trials. Existing patient selection criteria, mainly based on smoking history and TNM classification are insufficient and highlight the urgent need for standardized prognostic biomarkers. Herein, we present the first validation of the Immunoscore (IS) as a prognostic stratification tool in HPV-associated OPSCC. **Methods:** A cohort of 191 HPV-associated ($p16^+$ and HPV DNA/RNA^+) OPSCC patients treated between 2015–2024 was analyzed, including a French training cohort (N = 48) and three independent validation cohorts: a French retrospective monocentric (N = 48), a French prospective multicenter (N = 50) and a US retrospective multicenter cohort (N = 45). IS, an IHC-based standardized clinical digital pathology assay, quantifies $CD3^+$ and $CD8^+$ cell densities in tumor cores and invasive margins of FFPE sections. IS cut-offs were defined using the 25^{th} percentile of immune cell density in the training cohort and subsequently validated across all cohorts. Associations with disease-free survival (DFS), time to recurrence (TTR), and overall survival (OS) were assessed, along with immune profiling by 3′RNA-seq and sequential immunofluorescence. **Results:** Median age 65; 80% male; 74% smokers; 66% T1-2; 82% N0-1 (AJCC 8^{th}). Treatments included surgery only (9%), radiotherapy ± chemotherapy (27%) and surgery + radiotherapy ± chemotherapy (64%). 52.4% were IS-High (N = 100) and 47.6% IS-Low (N = 91). IS-High patients showed significantly improved DFS, consistently across the training and validation cohorts 1-3 (log-rank P = 0.0004, 0.003, 0.006, and 0.001, respectively). Multivariable analysis identified IS-Low as the strongest independent risk factor for DFS (HR 9.27; 95% CI: 4.14-20.76; $P < 0.001$), outperforming smoking status, T/N stage, and treatment modality. The model combining IS with clinical factors showed higher predictive accuracy for DFS (C-index 0.82) than clinical variables alone (0.70; $P < 0.0001$). Similar strong prognostic value of IS was observed for TTR (HR 7.64; 95% CI: 3.37-17.33; $P < 0.001$) and OS (HR 7.26; 95% CI: 2.77-18.99; $P < 0.001$). IS-High tumors showed enrichment of lymphoid and myeloid immune cell populations, contrasting with immune-poor signatures in IS-Low tumors (all $P < 0.05$). **Conclusions:** IS is a robust biomarker that outperforms standard clinical variables in both prognostic and predictive accuracy. The enriched cytotoxic immune infiltrate in IS-High tumors explains favorable outcomes and supports their potential suitability for treatment de-escalation. Prospective validation in future trials is warranted. Research Sponsor: None.

6078 Poster Session

Prognostic value and role in guiding individualized treatment of imaging extranodal extension (iENE) in nasopharyngeal carcinoma. First Author: Chuanrun Zhang, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Imaging extranodal extension (iENE) is a critical prognostic factor in nasopharyngeal carcinoma (NPC). While international consensus has standardized iENE grading, its prognostic value in NPC remains to be validated. Furthermore, evidence is lacking regarding the utility of iENE-based risk stratification in guiding individualized treatment, particularly for identifying candidates benefiting from adjuvant chemotherapy (AC). **Methods:** A total of 694 non-metastatic NPC patients with cervical lymph node metastasis who received intensity-modulated radiotherapy (IMRT) at Sun Yat-sen University Cancer Center from 2016 to 2017 were included. iENE was graded based on international group consensus by two radiologists through a consensus reading protocol: G0 (no extranodal extension), G1 (infiltration of perinodal fat), G2 (matted nodes), and G3 (invasion of adjacent structures including muscles and neurovascular bundles). Progression-free survival and overall survival were analyzed using the Kaplan–Meier method and log-rank test. Multivariable Cox proportional hazards models were applied to adjust for confounders. Time-dependent receiver operating characteristic (TD-ROC) curve analysis was used to evaluate the predictive performance of clinical variables. Stratified analysis for prognosis was performed based on treatment strategies including concurrent chemoradiotherapy(CCRT), induction chemotherapy plus CCRT(IC+CCRT), and IC+CCRT followed by adjuvant chemotherapy (IC+CCRT+AC). **Results:** The cohort included 257 (37.0%) G0, 117 (16.9%) G1, 216 (31.1%) G2, and 104 (15.0%) G3 patients. Survival analysis for OS, PFS, DMFS, and LRRFS revealed that G1 patients showed a comparable prognosis to G0 patients(5-year PFS: 82.1% vs. 89.1%, P > 0.05), whereas G2 and G3 patients exhibited significantly worse outcomes; therefore, G0 and G1 were combined into a low-risk subgroup. Multivariable analysis adjusting for T stage, N stage, volume of maximal lymph node, clinical stage, and treatment regimens confirmed that the refined iENE grading was an independent prognostic factor for PFS (G2 vs. G0/1: HR 1.77, 95% CI 1.25–2.51, P = 0.001; G3 vs. G0/1: HR 1.90, 95% CI 1.08–3.36, P = 0.027). TD-ROC curve demonstrated that the predictive performance of iENE for 1-, 3-, and 5-year PFS and OS was superior to that of T stage and pre-treatment EBV DNA. Most importantly, subgroup analysis indicated that the addition of AC significantly improved PFS outcomes in the G2/G3 subgroup (P = 0.006 and P = 0.009, respectively), whereas no survival benefit was observed in the low-risk G0/G1 subgroup (P = 0.133). **Conclusions:** The refined iENE grading system provides robust risk stratification for NPC. This system outperforms traditional biomarkers like EBV DNA, better distinguishing prognostic outcomes in patients and effectively guiding the application of intensified treatment. Research Sponsor: None.

Prognostic significance of imaging-detected extranodal extension (iENE) in pathological ENE-negative head and neck squamous cell carcinoma. First Author: Ryo Kuboki, Department of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Advances in perioperative systemic therapy for head and neck squamous cell carcinoma (HNSCC) (e.g., KEYNOTE-689) have increased the need to tailor postoperative management, balancing oncologic benefit against toxicity and resource constraints. Imaging-detected extranodal extension (iENE) has been incorporated as a potential prognostic factor in the UICC TNM 9th edition. However, the prognostic impact of iENE among patients without pathological extranodal extension (pENE) remains unclear. We evaluated the association between iENE status and clinical outcomes in pENE-negative HNSCC. **Methods:** We retrospectively reviewed patients with HNSCC of the oral cavity, oropharynx, hypopharynx, or larynx, radiologically suspected lymph node metastasis, and underwent primary surgery with neck dissection without adjuvant therapy, between 2012 and 2021. Eligible patients had pathologically confirmed lymph node metastasis, negative surgical margins, and no evidence of pENE. Preoperative iENE status was assessed by board-certified radiologists. Survival endpoints included event-free survival (EFS) and overall survival (OS). Patients were stratified into low-risk (non-candidates for adjuvant therapy) and intermediate-risk (candidates for postoperative radiotherapy alone) groups according to NCCN guidelines. **Results:** Of 3,771 screened patients, 133 met the eligibility criteria (low-risk: 20, intermediate-risk: 113), of whom 41 (30.8%) were iENE-positive. At a median follow-up of 60.6 months, iENE-positive patients demonstrated poorer outcomes than iENE-negative patients, including shorter EFS (5-year: 33.1% vs 55.4%; hazard ratio [HR], 1.69; p=0.029). The association between iENE positivity and inferior EFS was observed consistently across both risk strata. Overall survival also favored iENE-negative patients (5-year: 80.4% vs. 68.7%). On multivariate analysis, iENE positivity, ECOG Performance Status ≥1, and lower baseline serum albumin were independently associated with poorer EFS. Patients meeting none of the three factors had excellent outcomes despite omission of adjuvant therapy (5-year EFS: 69.8%, 5-year OS: 88.0%). **Conclusions:** iENE may help identify an unfavorable-prognosis subset among pENE-negative HNSCC patients. The study cohort predates the routine use of perioperative immunotherapy, and the generalizability of these findings in contemporary treatment settings requires prospective validation. Research Sponsor: None.

Five-year EFS by iENE status: Overall and by risk group.

Group	iENE status	5y-EFS	HR (95% CI)	P-value
ALL (n = 133)	Positive	33.1%	1.69 (1.05-2.71)	0.029
	Negative	55.4%	Ref.	
Intermediate risk (n = 113)	Positive	34.2%	1.57 (0.94-2.63)	0.08
	Negative	51.9%	Ref.	
Low risk (n = 20)	Positive	28.6%	3.57 (0.85-15.04)	0.06
	Negative	76.9%	Ref.

A phase 3, randomized, double-arm, open-label, controlled study of ASP-1929 photoimmunotherapy (PIT) versus physician's choice standard of care (SOC) for patients with locoregional, recurrent head and neck squamous cell carcinoma (HNSCC). First Author: Anastasios Maniakas, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Locoregional recurrence is the main cause of morbidity and mortality in HNSCC, yet therapeutic choices are limited by sequelae of previous treatment and the potential for significant loss of function. ASP-1929 PIT is a novel cancer-targeted technology, utilizing an anti-EGFR monoclonal antibody conjugated to the dye IR700, that is activated by 690 nm light to induce rapid selective tumor cell destruction and trigger immune response. **Methods:** This global phase 3 study was conducted at 40 study centers located in the US, Taiwan, Japan, India, and Ukraine. Patients with locoregionally recurrent HNSCC who had failed or progressed on or after at least 2 lines of therapy were randomized 2:1 to the PIT arm or SOC. The planned sample size was 275. In the PIT arm, each cycle consisted of ASP-1929 infusion (640 mg/m^2) on Day 1, followed 24 $\pm$ 4 hours later by illumination (50 J/cm^2 superficial and/or 100 J/cm interstitial). Retreatment occurred $\geq$4 weeks apart, based on tumor response, for up to 8 cycles. In the control arm, patients received the physician's choice of standard of care (docetaxel, cetuximab, methotrexate, or paclitaxel) until disease progression, intolerable adverse effects, or discontinuation of study treatment. Safety and efficacy outcomes were evaluated, with a data cutoff of 30 April 2025. **Results:** Active patient enrollment was discontinued due to challenges in patient recruitment and changes in the SOC landscape. As of 17 December 2024, 135 patients had been enrolled, with 68 patients experiencing progression or death and 36 patients in the ongoing long-term survival follow-up phase of the study. Median age was 62.0 years; 80.7% were male. In PIT and SOC arms, 64.0% and 63.0% of patients had received $\geq$ 3 prior therapy lines. Despite similar progression-free survival (HR 0.91; 95% CI 0.24 - 3.45), median overall survival was 15.7 months in the PIT arm compared to 9.6 months in the SOC arm (HR 0.83; 95% CI 0.50 - 1.36). Objective response rate was 25.8% in the PIT arm and 15.2% in the SOC arm, and disease control rate was 68.5% and 43.5%, respectively. Grade $\geq$3 treatment-emergent adverse events (TEAEs) occurred in 58.3% of patients in the PIT arm and 36.4% of patients in SOC; however, fewer TEAEs led to dose modification, delay, or interruption in the PIT arm (15.5% vs 30.3%). **Conclusions:** Considering the limitations of the study data, these results support ASP-1929 PIT as a tolerable and clinically active treatment option for locoregional, recurrent HNSCC and its ongoing evaluation in the current randomized global Phase 3 ASP-1929-381 study. Clinical trial information: NCT03769506. Research Sponsor: Rakuten Medical Inc.

Efficacy of neoadjuvant immunochemotherapy followed by surgery in locally advanced buccal squamous cell carcinoma: A single-center real-world study. First Author: Haolei Tan, Head and Neck Surgery Department, Hunan Cancer Hospital and The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China

Background: The 5-year overall survival (OS) rate for locally advanced (stage III–IV) buccal squamous cell carcinoma (LA BSCC) is under 50%. In stage IV disease, the 2-year OS rate is under 45%, and the 5-year OS rate is under 30% (29.3% for the anterior buccal and only 18.7% for the posterior buccal). Evidence is limited regarding whether betel nut chewing and tumor subsites influence the efficacy of neoadjuvant immunochemotherapy. **Methods:** Retrospective analysis of 115 patients with LA BSCC received neoadjuvant therapy at Hunan Cancer Hospital between August 2021 and October 2024. Treatment regimen: Neoadjuvant albumin-bound paclitaxel plus cisplatin or carboplatin combined with a PD-1 inhibitor, followed by definitive surgery. Postoperative adjuvant radiotherapy or chemoradiotherapy was administered based on pathological findings. Primary endpoint: Pathological complete response and major pathological response (pCR/MPR) rate; Secondary endpoints: Overall survival (OS) and disease free survival (DFS) at 1 and 2 years; Subgroup analyses: Outcomes were evaluated by betel nut chewing history, tumor subsite, and TNM stage. **Results:** Of 113 evaluable patients, 16% had stage III and 84% had stage IV disease. A history of betel nut chewing was present in 71.9%. The objective response rate to neoadjuvant therapy was 83.5%, including a 28.3% clinical complete response rate. 98 patients proceeded to surgery; the pCR/MPR rate was 27.6%, and the partial pathological response (pPR) rate was 52.0%. With a median follow-up of 29 months (15-53 months), 1-year OS and DFS rates were 80.5% and 74.3%, respectively; 2-year OS and DFS rates were 70.0% and 67.5%, respectively. 2-year OS did not differ significantly by betel nut chewing (P=0.8578) or by tumor subsite (anterior vs posterior buccal; P=0.5568). More advanced TNM stage was associated with poorer survival (P=0.0352). Patients achieving pCR or MPR had significantly better 2-year OS and DFS than those who did not (P=0.0386 and P=0.0102, respectively). Grade$\geq$3 adverse events occurred in 18% of patients and no treatment-related deaths were observed. **Conclusions:** Neoadjuvant immunochemotherapy increased the 2-year OS rate of LA BSCC to 70%, with the 27.6% pCR/MPR rate. Treatment efficacy did not differ by betel nut chewing or by tumor subsite, whereas TNM stage remained an independent prognostic factor. Deep pathological response (pCR/MPR) was associated with superior long-term outcomes. Research Sponsor: None.

Phase II randomised controlled trial on postoperative radiotherapy, in high-risk, resected, non-medullary, non-anaplastic thyroid cancers (THYRO-RT). First Author: Gouri Pantvaidya, Tata Memorial Centre, Mumbai, Maharashtra, India

Background: Locally advanced thyroid cancers have high rates of locoregional recurrence after standard treatment with surgery and radioactive iodine (RAI). Repeated surgery and RAI in recurrent disease contributes to significant morbidity. Retrospective studies have shown that the addition of adjuvant external beam radiotherapy (EBRT) may improve locoregional control in selected high-risk patients. This randomized phase II trial evaluated the role of adjuvant EBRT in reducing locoregional recurrence (LRR) in high-risk resected thyroid cancer. **Methods:** This was a phase II randomized controlled trial comparing surgery with RAI versus surgery with RAI plus EBRT in high-risk resected thyroid cancers. Patients with resected non-medullary, non-anaplastic thyroid cancer and predefined high-risk features were randomized (1:1) between July 2013 and April 2021. Patients randomized to EBRT received 6-MV IMRT with daily IGRT to a dose of 60 Gy in 30 fractions over six weeks. The primary endpoint was locoregional recurrence. Secondary endpoints included acute and late toxicity (LENT-SOMA scale) and quality of life. **Results:** Seventy-two patients were randomized, with 36 assigned to each arm; five patients withdrew consent. Overall, 86.6% had pathological T4a disease and 89.6% had pathological N1a/b disease. Further, 71.6% demonstrated extracapsular nodal extension and R1/R2 resection was seen in 49.3% of the patients. With a median follow-up of 102 months, on an intention to treat analysis, LRR occurred in 19.4% of patients in the surgery + RAI arm (OR 1.376, 95% CI 0.852-2.222), and 9.7% in the Surgery+RAI+EBRT arm (OR 0.611, 95% CI 0.299-1.632). This difference was not statistically significant (p = 0.263). Logistic regression analysis did not identify any factor significantly associated with LRR. There was no significant difference in 10 year-locoregional recurrence free survival between the two arms. Grade 3 acute radiation induced toxicity was observed in two patients. At last follow up, there was one death in the entire cohort, which was non-cancer related. **Conclusions:** In this very high-risk, resected thyroid cancer cohort, the addition of adjuvant EBRT to surgery and RAI did not significantly decrease locoregional recurrence. The overall acute toxicity was low and if adjuvant EBRT is indicated, it can be delivered with acceptable toxicity. Clinical trial information: NCT03669432. Research Sponsor: Department of Atomic Energy- Clinical Trials Unit, Government of India.

C-POST study of adjuvant cemiplimab for high-risk cutaneous squamous cell carcinoma (CSCC): Disease-free survival (DFS) analyses per high-risk criteria and per start time after radiotherapy. First Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: C-POST, a phase 3 trial (NCT03969004) in patients (pts) with high risk CSCC after surgery and radiotherapy (RT), demonstrated superior disease-free survival (DFS) for adjuvant cemiplimab (cemi) vs placebo (pbo) (HR, 0.32; $P<0.0001$); treatment discontinuation due to adverse events occurred in 9.8% vs 1.5% of pts (Rischin, et al. *N Engl J Med*. 2025). With approximately 6 months of additional follow-up, we present exploratory analyses of DFS per high-risk criteria and per the interval between completion of prior RT and study randomization (2-6 wk vs $>$6 wk). These additional analyses provide key data to understand the importance of risk factors and the impact of time post RT. **Methods:** Pts were randomized 1:1 (N=415) to adjuvant cemi or pbo (350 mg cemi or pbo Q3W for 12 wk, then 700 mg cemi or pbo Q6W for 36 wk). All pts had nodal high-risk disease (with extracapsular extension [ECE] and $\geq$1 node $\geq$20 mm, or $\geq$3 nodes regardless of ECE) and/or non-nodal high-risk disease (in-transit metastases, perineural invasion, T4 lesions, or recurrent CSCC with $\geq$1 other feature). Tumors could meet $\geq$1 high-risk criteria. Randomization occurred within 2-11 wk after completion of RT. Data cutoff was April 7, 2025. **Results:** Among 415 pts (209/206 cemi/pbo) randomized, the DFS HR was 0.35 (95% CI, 0.23-0.55) at a median follow-up of 30 months. The most common high-risk criterion was nodal ECE, present in 48.4% of pts (201/415). DFS was improved with cemi vs pbo across all high-risk features, including both nodal and non-nodal criteria (Table 1). A consistent benefit was observed regardless of whether the interval between prior RT completion and study randomization was 2-6 wk (DFS events, 17/117 [14.5%] vs 37/112 [33.0%]; HR, 0.39; 95% CI, 0.22-0.70) or $>$6 wk (DFS events, 12/91 [13.2%] vs 31/93 [33.3%]; HR, 0.36; 95% CI, 0.19-0.71). **Conclusions:** In this phase 3 study, adjuvant cemi demonstrated a DFS benefit vs pbo across all high-risk features and regardless of the interval between prior RT completion and randomization. Clinical trial information: NCT03969004. Research Sponsor: Regeneron Pharmaceuticals Inc. and Sanofi.

DFS with cemi vs pbo: Analyses per high-risk criteria.

Criteria[a]	Met high risk criteria, n/N (%)	DFS events in cemi arm, n/N (%)	DFS events in pbo arm, n/N (%)	DFS HR (95% CI)
Nodal high risk				
ECE with ≥1 node ≥20 mm	201/415 (48.4)	14/105 (13.3)	27/96 (28.1)	0.44 (0.23-0.84)
≥3 nodes	71/415 (17.1)	7/34 (20.6)	18/37 (48.6)	0.34 (0.13-0.92)
Non-nodal high risk				
In-transit metastases	41/415 (9.9)	2/20 (10.0)	9/21 (42.9)	0.07 (0.01-0.58)
T4 lesion	33/415 (8.0)	6/17 (35.3)	5/16 (31.3)	0.58 (0.16-2.11)
Perineural invasion	64/415 (15.4)	3/32 (9.4)	8/32 (25.0)	0.27 (0.07-1.04)
Recurrent CSCC with ≥1 additional high-risk criteria	105/415 (25.3)	9/55 (16.4)	22/50 (44.0)	0.19 (0.08-0.45)

[a]Tumors could meet $\geq$1 high-risk criteria.

Evaluation of a tissue-free genome-wide methylome enrichment assay for detecting molecular residual disease (MRD) in patients with head and neck squamous cell carcinoma (HNSCC). First Author: Geoffrey Liu, Princess Margaret Cancer Centre, University Health Network and Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada

Background: Squamous cell carcinomas comprise ~90% of head and neck cancers (HNCs). Although ~80% of patients with HNSCC are eligible for curative therapy, an estimated 20% to 35% will develop recurrence, typically within 2 years. Recurrence is associated with poor survival, but early detection may enable salvage therapy. We previously reported clinical validation of a tissue-free, genome-wide methylome enrichment MRD assay for recurrence detection in HNC. Here we present performance of an updated classifier in a subset of patients with HNSCC. **Methods:** Test performance was evaluated using blood samples collected at ~3 (landmark), 12, and 24 mo after curative-intent treatment from patients with stage I-IVb HNSCC. MRD testing was performed using an assay based on cell-free methylated DNA immunoprecipitation and high throughput sequencing (cfMeDIP-seq) as previously described (Liu et al. *Ann Oncol*. 2025;36(1):108-117). To improve test performance and clinical actionability, we evaluated the effect of defining an *indeterminate* test category near the classifier threshold. An updated classifier defining 5% of training samples as *indeterminate* was analyzed in a training set, followed by a pre-specified clinical validation analysis. The primary endpoint was recurrence-free survival (RFS), comparing patients with MRD detected vs not detected. RFS was estimated using the Kaplan-Meier method, with differences assessed by the 2-sided log-rank test. Hazard ratios (HR) were estimated using the Cox proportional hazards model. **Results:** Among 117 patients in the validation set, median follow-up was 65.3 mo. MRD detection during surveillance was strongly associated with inferior RFS (HR, 54.5 [95% CI, 18.4-161.2]), an improvement over the previously reported HR of 35.7. Lead time between MRD detection and clinical recurrence was up to 10.8 mo (mean, 3.3 mo). MRD detection was also prognostic for OS (HR, 89.3 [11.8-676.4]). The updated classifier showed improved performance, with a sensitivity of 86.7% (26/30) and a specificity of 97.7% (85/87) for recurrence detection. Positive predictive value was 92.9% (26/28); negative predictive value was 95.5% (85/89). Performance was similar (P=0.24) among patients with HPV-positive oropharyngeal carcinoma (n=52) vs HPV-negative disease (n=65), patients with stage I-II (n=72) vs stage III-IVb (n=45) disease (P=0.20), and patients with surgery (n=34) vs non-surgical (n=83) definitive treatment (P=0.37). **Conclusions:** This study demonstrates that tissue-free, blood-based MRD testing using a genome-wide methylome enrichment platform is prognostic for recurrence in patients with HNSCC treated with curative intent, regardless of stage, HPV status, or treatment modality. The platform offers a robust, sensitive approach for early detection of recurrence in a broad patient population. Research Sponsor: Adela, Inc.

Neoadjuvant chemotherapy with/without PD-1i in locally advanced laryngeal/hypopharyngeal cancer: A multicentered retrospective study. First Author: Xiaomin Ou, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The efficacy of adding programmed death-1 (PD-1) inhibitors to neoadjuvant chemotherapy (NACT) for improving survival in locally advanced laryngeal/hypopharyngeal carcinoma remains unclear. This study aimed to compare progression-free survival (PFS) between patients receiving NACT with or without a PD-1 inhibitor (NACT+PD-1i). **Methods:** This multicenter retrospective study enrolled 267 patients with T2-4N0-3M0 laryngeal/hypopharyngeal squamous cell carcinoma who received NACT with (n=165) or without (n=102) a PD-1 inhibitor, followed by definitive radiotherapy, between 2019 and 2024, from Fudan University Shanghai Cancer Center, Fujian Cancer Hospital and Sun Yat-sen University Cancer Center. The primary endpoint was PFS. Inverse probability of treatment weighting (IPTW) was used to adjust for baseline imbalances. **Results:** The NACT+PD-1i group demonstrated significantly improved PFS versus NACT alone (median PFS: not reached vs. 33.0 months; hazard ratio [HR]=0.61, 95% confidence interval [CI]: 0.41–0.90; p=0.012). The 2-year PFS rates were 70.2% and 56.5%, respectively. This PFS benefit persisted after IPTW (p=0.012). PD-1 inhibition was an independent favorable factor for PFS in multivariable analysis (unadjusted, HR=0.54, p=0.005; IPTW-adjusted, HR= 0.63, p=0.040). Notably, the NACT+PD-1i group showed superior regional recurrence-free survival (RRFS) (2-year RRFS: 92.1% vs. 81.0%; HR=0.31, p=0.001) and higher objective response rate (ORR) (93.9% vs. 85.9%, p=0.027), particularly for cervical lymph nodes (94.2% vs. 81.6%, p=0.002). Achieving an ORR after neoadjuvant therapy was a strong predictor for improved outcome, either in unadjusted PFS (HR=0.40, p=0.0005) or in IPTW-adjusted PFS (HR=0.49, p=0.0005). **Conclusions:** In this real-world analysis, adding a PD-1 inhibitor to NACT significantly improved ORR and PFS in locally advanced laryngeal/hypopharyngeal carcinoma, supporting its further evaluation in neoadjuvant strategies. Induction toripalimab and chemotherapy for organ preservation in locally advanced laryngeal and hypopharyngeal cancer: 3-year follow-up of the INSIGHT study. First Author: Xiaomin Ou, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: This phase II study evaluated the efficacy and larynx-preservation potential of induction chemotherapy combined with the toripalimab in patients with locally advanced laryngeal and hypopharyngeal squamous cell carcinoma (LA-L/HPSCC). Primary and 1-year survival outcomes were previously reported; here we present the 3-year follow-up results. **Methods:** This is a single-arm phase II study. Patients with histopathologic confirmed, resectable LA-L/HPSCC and ECOG PS 0-1 were eligible. Three cycles of induction chemotherapy (paclitaxel 175mg/m^2 d1, cisplatin 25mg/m^2 d1-3) combined with toripalimab (240mg d0) were administered. Response assessment was performed after induction chemoimmunotherapy using RECIST 1.1 criteria. Patients with CR/PR of primary tumor received concurrent chemoradiation, followed by maintenance therapy of toripalimab. Otherwise, patients were referred to surgery, followed by adjuvant (chemo)radiation, and maintenance therapy of toripalimab. The primary endpoint is larynx-preservation rate at three months post-radiation. Secondary endpoints included overall survival (OS), progression-free survival (PFS), larynx preservation rate, and larynx-preservation survival (LPS), etc. **Results:** Twenty-seven patients were enrolled. Most cases exhibited stage IV disease (81.5%), with T4 representing 37.0%. Five patients underwent pretreatment tracheostomy. The date of data cut-off was Jan 23, 2026. With a median follow-up of 36.4 [95%CI: 33.4-39.4] months, 3-year OS rate, PFS rate, larynx preservation rate and LPS rate was 73.5%, 61.1%, 84.3% and 73.6%, respectively. Excluding patients with pretreatment tracheostomy, these rates improved to 86.4%, 70.8%, 90.2% and 81.1%. The 3-year larynx preservation rate for T2/3 and T4 disease was 92.9% and 70.0%, respectively (p=0.081). All patients with preserved larynx at last follow-up maintained functional laryngeal status, free from tracheostomy or feeding tube dependence. **Conclusions:** Induction toripalimab combined with chemotherapy provided promising and durable larynx preservation rate in this cohort of extensively LA-L/HPSCC. Clinical trial information: NCT04995120. Research Sponsor: National Natural Science Foundation of China; 82072951; Chinese Society of Clinical Oncology Foundation; Y-Young2021-0127.

Comparison of patients enrollment and survival among pivotal clinical trials.

Study	Phase	Clinical Stage	Larynx preservation rate at 3 year	Progression-free rate at 3 year
GORTEC 2000-01	III	Stage III, IV Hypopharynx 54.0%, larynx 46.0%	70.1% for TPF and 57.5% for PF	58% for TPF and 44% for PF
Subgroup analysis of TAX324	II	Stage III 26.5% Stage IV 73.5%, Hypopharynx 46.4%, larynx I 64.5%	Not available	43% for TPF and 29% for PF
This study	II	Stage III 18.5% Stage IVa 33.3% Stage IVb 48.1% Hypopharynx 66.7%, larynx 33.3%	84.3% for whole cohort and 90.2% when excluding patients with pre-treatment tracheostomy	61.1% for whole cohort and 70.8% when excluding patients with pre-treatment tracheostomy

A prospective trial of single-dose neoadjuvant PD-1 blockade with or without a CD40 agonist in HPV-negative HNSCC. First Author: Lova Sun, University of Pennsylvania, Philadelphia, PA

Background: Neoadjuvant PD-1 blockade is approved for resectable locally advanced HPV-negative HNSCC, but major pathologic response rates are $<$10%, underscoring the need for effective combination strategies. Agonists of the TNF receptor superfamily member CD40 can reverse dendritic cell dysfunction, a key mediator of immune resistance, and may combine with PD-1 blockade to enhance anti-tumor T cell recruitment. We investigated the safety and immunologic effects of combination neoadjuvant PD-1 blockade with CD40 agonism. **Methods:** We enrolled 20 patients with resectable HPV-negative HNSCC; 10 received a single intravenous dose of PD-1 inhibitor (LVGN3616, 300mg), and 10 received a PD-1 inhibitor (LVGN3616, 300mg) in combination with a CD40 agonist (LVGN7409, 1mg/kg), administered prior to surgical resection (window, 4-28 days). Pre-treatment biopsies, post-treatment surgical specimens, and peripheral blood samples were collected. The primary endpoint was safety, with secondary endpoints including pharmacodynamic immune changes and pathologic responses. **Results:** Median age was 65 years (range, 39-79); 16 (80%) were male; 16 (80%) were White; 18 (90%) had oral cavity cancer (2 larynx); and 17 (85%) had PD-L1 CPS $\geq$1. Baseline demographics and PD-L1 were well-balanced between arms. Neoadjuvant immunotherapy was administered a median of 9 days (range, 5-19) before surgery, with no surgical delays observed. Treatment was well tolerated; grade 3/4 events occurred in 12/20 patients, nearly all attributable to post-surgical complications and unrelated to study drug. The only treatment-related grade 3/4 events were transient elevations in liver enzymes seen in two patients in the PD-1+CD40 arm. With a minimum of 6 months' follow-up, 3/20 patients (1 in PD1 arm, 2 in PD1+CD40 arm) had progressed. Serum analyses revealed that combined PD-1 and CD40 agonist therapy induced significant increases in multiple cytokines including IL-15 (p=0.0084), IP-10 (p=0.0379), MCP-1 (p=0.0002), MDC (p$<$0.0001), and MIG (p=0.0178) at 24 hours, indicating enhanced immune activation. A biomarker-driven inflammatory score based on baseline LCN2 and SAA levels predicted pathological response with 85% accuracy, 71.4% sensitivity, and 92.3% specificity (Fisher's exact p=0.0072). Pathologic tumor response (pTR) was observed in 3/10 patients in the PD-1 arm (pTR1, 10-49%) and 4/10 patients in the PD-1+CD40 arm (including one pTR2 with 85% regression. Multiplex IHC was performed on tissue samples using CD3, Ki67, PD-L1, CD8, FOXP3, CD68, and panCK markers; quantitative spatial analyses are ongoing and results will be presented. **Conclusions:** Single-dose neoadjuvant PD-1 blockade combined with a CD40 agonist for HPV-negative HNSCC was safe, did not delay surgery, and produced modestly improved pathologic regressions that correlated with a cytokine-based baseline inflammatory score. Clinical trial information: NCT06159621. Research Sponsor: Conquer Cancer, the ASCO Foundation; Abramson Cancer Center.

Baseline skeletal muscle index as an independent prognostic factor in locally advanced head and neck squamous cell carcinoma: A post hoc analysis of the REACH trial. First Author: Florian Clatot, Institute of Research Onco-Normand (IRON), Rouen University Hospital and Centre Henri Becquerel, Rouen, France

Background: The prognosis for locally advanced squamous cell carcinoma of the head and neck (LAHNSCC) is heterogeneous. A low skeletal muscle mass index (SMI) assessed by computed tomography reflects sarcopenia and is associated with a poor prognosis. However, evidence-based data on HNSCC remain scarce. Moreover, the prognostic value of SMI in patients treated with radiotherapy combined with different systemic treatments remains unclear. **Methods:** This is a post hoc analysis of the REACH trial (NCT02999087), conducted between 2017 and 2020, which treated LAHNSCC in two cohorts. Patients eligible (fit) for cisplatin were randomized between radiotherapy with cisplatin and radiotherapy with cetuximab-avelumab; those ineligible for cisplatin (unfit) were randomized between radiotherapy with cetuximab and radiotherapy with cetuximab-avelumab. Baseline SMI was assessed on a C3 vertebral slice using radiotherapy planning computed tomography and analyzed as a continuous variable. Associations of SMI with disease-free survival (DFS) and overall survival (OS) were assessed using Cox proportional hazards models, with multivariable adjustment for performance status, age, stage, p16 status, treatment and cisplatin fit/unfit status. Model performance was internally validated using bootstrapping. **Results:** Among the 694 patients included in REACH, SMI analysis was available for 623 patients (90%). Only the analyses performed for the 507 men are presented. Among them, 312 (62%) were eligible for cisplatin and 195 (38%) were ineligible. Median SMI was 47 (range 32-66) kg/m^2, with no difference according to the fit/unfit status and treatment received. A higher SMI was observed in patients with ECOG 0 (vs 1, $p<0.0001$), younger patients (<65y, p=0.01) but not according to tumor stage (III vs IV). There was a linear relationship between SMI and DFS with a better DFS as SMI rises in both univariate (HR 0.81 every 5 SMI units, $p<0.0001$) and multivariate analyses (HR 0.88/5 units, p=0.013). Comparable results were observed for OS, with a significant linear relationship between SMI and OS (HR of death 0.76/5 units, $p<0.0001$, univariate analysis; HR 0.86/5 units, p=0.015, multivariate analysis). Other independent factors associated with improved OS were a p16+ oropharynx tumor, ECOG 0 (vs 1), Stage III tumor (vs IV) and eligibility for cisplatin. The prognostic impact of SMI was consistent across fit/unfit cohorts and treatment arms, with no significant interaction detected. **Conclusions:** Baseline SMI determined on C3 is a strong and independent prognostic factor for DFS and OS in patients with LAHNSCC treated with radiotherapy with cisplatin, radiotherapy with cetuximab, or radiotherapy with cetuximab and avelumab. The association between SMI and clinical outcomes is linear, arguing against the use of arbitrary prognostic thresholds for SMI. Research Sponsor: None.

Four cycles of tislelizumab plus GP regimen as neoadjuvant therapy for high-risk (T4/N3) locally advanced nasopharyngeal carcinoma. First Author: Qinhua Zhang Sr., Jiangmen Central Hospital, Jiangmen, China

Background: The efficacy of standard chemoradiotherapy for locally advanced nasopharyngeal carcinoma (LANPC) is still unmet need, especially for stage IVa(T4/N3, AJCC 8th) NPC. The efficacy and safety of the 4 cycles neoadjuvant chemotherapy strategy in stage N2-3 LANPC has been confirmed. Meanwhile, immunotherapy has showed favorable tumor response and survival benefit for patients with LANPC. Therefore, this study investigated the efficacy and safety of four cycles tislelizumab plus GP regimen as neoadjuvant therapy for high-risk LANPC. **Methods:** Patients with stage IVa (T4/N3, AJCC 8th) NPC were enrolled and treated with neoadjuvant therapy (gemcitabine, 1000 mg/m^2, on days 1 and 8, cisplatin, 80 mg/m^2, on day 1, tislelizumab 200mg, on day 1) every 3 weeks for 4 cycles followed by standard concurrent chemoradiotherapy. The primary endpoint was complete response (CR) rate after neoadjuvant therapy. Secondary endpoints included overall response rate (ORR) after neoadjuvant therapy, disease-free survival, overall survival, and tolerance. **Results:** From February 2022 to June 2022, 25 patients were enrolled and 24 evaluable patients (median age 49 years old; 15 men [62.5%]) completed protocol-specified 4 cycles neoadjuvant therapy without delaying radiotherapy. 1 patient was withdrawn from the trial due to treatment of acute viral parotitis. The CR rate was 50% (12/24), achieving the predefined endpoint. The ORR of all evaluable patients was 91.7%. By the cut-off date of Jan 15th 2026, the median follow-up time was 44.8 months. The median disease-free survival was not reached and 36-month disease-free survival was 91.7%(95% CI 70.6%–97.8%). Two patients died of diseases not related to nasopharyngeal carcinoma and treatment, while the other patients still have no disease progression. 13 (52%) of 25 patients had grade 3-4 acute treatment-related adverse events (TRAE). Grade 1-2 immune-related adverse events (irAE) was recorded in 18 patients (72%). No grade 3-4 irAEs occurred. 3 (12%) of 25 patients had long-term TRAEs. **Conclusions:** Four cycles of tislelizumab plus GP regimen as neoadjuvant therapy demonstrated promising tumor response, long-term survival benefit and manageable safety profile in high-risk LANPC patients. Clinical trial information: ChiCTR2200056941. Research Sponsor: None.

Mandibular preservation with neoadjuvant tislelizumab plus platinum-doublet chemotherapy in locally advanced resectable oral squamous cell carcinoma: A prospective phase II trial. First Author: Zhongyu Wang, Department of Head and Neck Surgery, Sun Yat-sen University Cancer Center, Guangzhou, China. Sun Yat-sen University Cancer Centre, State Key Laboratory of Oncology in South China, Guangzhou, China

Background: Segmental mandibulectomy for locally advanced oral squamous cell carcinoma (OSCC) severely compromises quality of life. In patients without radiographic mandibular invasion but still requiring mandibulectomy to achieve negative margins, effective tumor downstaging strategies that enable mandibular preservation are of major clinical importance. Neoadjuvant chemo-immunotherapy may reduce tumor burden, potentially enabling less radical resection and mandibular preservation. This study aimed to evaluate the efficacy and safety of mandibular preservation using neoadjuvant tislelizumab plus platinum-doublet chemotherapy in resectable locally advanced OSCC. **Methods:** This phase II, open-label, single-arm trial enrolled previously untreated patients with locally advanced, resectable OSCC (stage III-IVB, T3-T4N0-3M0) necessitating mandibulectomy based on conventional surgical criteria despite the absence of definitive clinicoradiologic mandibular invasion. Neoadjuvant treatment consisted of tislelizumab (200 mg), docetaxel (75 mg/m^2) and cisplatin (60 mg/m^2) on day 1 of each 21-day cycle for three cycles. All patients then proceeded to surgery. The primary endpoint was mandibular preservation rate. Secondary endpoints included pathological complete response (pCR), major pathological response (MPR), margin-negative resection (R0) rate, objective response rate (ORR), progression-free survival, disease-free survival, overall survival and treatment-related adverse events (TRAEs). **Results:** Between October 2023 and September 2025, a total of 53 patients were enrolled, and 49 were evaluable. All 49 patients completed three cycles of neoadjuvant therapy and underwent surgery. The mandibular preservation rate was 95.9% (47/49), and all patients achieved R0 resection. The ORR was 79.6% (39/49) and the pCR rate was 51.0% (25/49). TRAEs occurred in 100% (49/49) of patients. Grade 3 TRAEs were reported in 10.2% (5/49), including leukopenia, fatigue, and hypertension. No grade 4–5 TRAEs were observed. **Conclusions:** Neoadjuvant tislelizumab combined with platinum-doublet chemotherapy achieved a high mandibular preservation rate and a favorable pathological response profile with manageable toxicity in patients with locally advanced, resectable OSCC. This strategy represents a promising organ-preserving approach. Longer follow-up is ongoing to determine long-term survival outcomes. Clinical trial information: NCT06130007. Research Sponsor: None.

6091 Poster Session

Neoadjuvant immunotherapy in combination with chemotherapy in resectable locally advanced head and neck squamous cell carcinoma: Updated efficacy and safety data from a randomized phase II trial. First Author: Lei Liu, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Neoadjuvant immunotherapy combined with chemotherapy is a promising strategy for resectable LAHNSCC. While most regimens employ single-target PD-1 inhibitors, dual-target agents (PD-1/CTLA-4 or PD-1/VEGF) have shown superior efficacy in recurrent/metastatic HNSCC. Building on our preliminary data (ASCO 2025) which suggested high pathological response rates, this ongoing randomized phase II trial aims to compare single- versus dual-target NAI regimens in an expanded cohort to identify the optimal treatment strategy. **Methods:** This is an ongoing randomized, open-label, phase II trial. Eligible pts were randomized (1:1:1) to receive 3 cycles of neoadjuvant therapy as follows: Cohort 1 will receive ivonescimab (PD-1/VEGF bispecific antibody, 10 mg/kg every 3 weeks), Cohort 2 will receive cadonilimab (PD-1/CTLA-4 bispecific antibody, 6 mg/kg every 3 weeks), and Cohort 3 will receive penpulimab (PD-1 antibody, 200 mg every 3 weeks), all in combination with cisplatin and nab-paclitaxel. After neoadjuvant treatment, Surgery was performed with the surgical margins based on pre-treatment (baseline) evaluation. Pts with pCR received adjuvant immunotherapy for up to 16 cycles. Pts without pCR received adjuvant radiotherapy or chemoradiotherapy, followed by 16 cycles of adjuvant immunotherapy. **Results:** Up to Dec. 2025, all 59 pts completed 3 cycles of neoadjuvant therapy and were evaluable, with a median follow-up of 12 months. The pCR rates were 60% (12/20) in Cohort 1, 42.1% (8/19) in Cohort 2, and 40% (8/20) in Cohort 3. The major pathologic response (MPR) rates were 75% (15/20), 57.9% (11/19), and 55% (11/20) in Cohort 1, 2, and 3, respectively. The ORR was 95% in Cohort 1 (CR: 8/20, PR: 11/20) and 84.2% in Cohort 2 (CR: 5/19, PR: 11/19), while Cohort 3 had an ORR of 80% (CR: 4/20, PR: 12/20). To date, pts have received a median of 6 cycles of adjuvant immunotherapy. The most common treatment-related adverse events (TRAEs) ($>20\%$) were: leukopenia, anemia, neutropenia, thrombocytopenia, lymphocytopenia, hypothyroidism, hypertriglyceridemia, radiation dermatitis, stomatitis, vomiting, decreased appetite, and fatigue. **Conclusions:** Neoadjuvant dual-target (PD-1/VEGF) immunotherapy combined with chemotherapy demonstrated a higher pCR rate compared to dual-target (PD-1/CTLA-4) and single-target PD-1 regimens in resectable LAHNSCC. The treatment was well-tolerated, with all pts completing the intended neoadjuvant therapy and the observed most common TRAEs consistent with expected chemotherapy and radiotherapy profiles. Further analyses are ongoing with continued enrollment. Clinical trial information: NCT06444009. Research Sponsor: None.

Adjuvant nivolumab in addition to postoperative radiation therapy in locally advanced head and neck cancer: Results of the phase II NadiHN trial. First Author: Peter Brossart, University Bonn, Bonn, Germany

Background: The benefit of adding immune checkpoint inhibition to standard post-operative adjuvant radiotherapy in patients with locally advanced head and neck squamous cell carcinoma (HNSCC) with an intermediate risk of recurrence remains unclear. **Methods:** The phase II, open-label, randomized, multicenter national NadiHN trial (EudraCT 2016-004787-20) enrolled participants with resected locally advanced HNSCC (R0 resection with ≥5 mm margins; no extracapsular nodal extension). Patients were stratified by primary site (oropharyngeal vs non-oropharyngeal), p16 status (for oropharyngeal tumors), centrally assessed PD-L1 tumor cell (TC) score (≥1% vs <1%), and center, and were randomized 1:1 to receive nivolumab before, during, and after postoperative radiotherapy (PORT) or PORT alone. Nivolumab (10 cycles of 240 mg q2w, followed by 10 cycles of 480 mg q4w) started 2 weeks prior to PORT. The primary endpoint was disease-free survival (DFS) in the intention-to-treat population. The planned sample size of 176 patients was designed to provide 80% power to detect a significant DFS improvement (log-rank test). Key secondary endpoints included overall survival (OS) and safety. Enrollment remained below target. During the trial, an adaptive interim analysis was implemented and led to early study termination upon Data Monitoring Committee recommendation due to futility. **Results:** Between 2017 and 2022, 84 participants were randomized (42 per arm). After a median follow-up of 37.3 months, median DFS was not reached in either group. The 2-year DFS rate was numerically higher with nivolumab + PORT (80%) than with PORT alone (69%), but the difference was not statistically significant (HR 0.934; 95% CI 0.408–2.140; p = 0.7301). Censoring deaths without documented recurrence yielded similar results. OS also did not differ significantly (HR 2.618; 95% CI 0.892–7.684; p = 0.0827). Grade ≥3 treatment-emergent adverse events occurred in 80.6% of patients in the nivolumab arm and 52.5% in the control arm. One treatment-related death occurred in the nivolumab + PORT arm. **Conclusions:** Interpretation of the trial is limited by early termination, small sample size, and fewer-than-expected DFS events. Adjuvant nivolumab added to standard PORT numerically—but not significantly—improved DFS in locally advanced HNSCC. Signals of potential benefit were observed in the PD-L1–positive subgroup (2y-DFS 82.4 vs. 76.2%) and lymph-node–positive subgroups (2y-DFS 84.2% vs. 70.7%). No new safety signals were identified. Funding: The trial was sponsored by the University Hospital Bonn with financial support from Bristol Myers Squibb. Clinical trial information: EudraCT 2016-004787-20. Research Sponsor: University Hospital Bonn; Bristol Myers Squibb.

Real-world evidence on definitive chemoradiotherapy following neoadjuvant chemoimmunotherapy in locally advanced head and neck squamous cell carcinoma. First Author: Ya-Ni Zhang, Department of Radiation Oncology, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, Guangdong, China

Background: Real-world evidence regarding the efficacy and safety of neoadjuvant chemoimmunotherapy (NACI) in the treatment of curable head and neck squamous cell carcinoma (HNSCC) is currently limited. This multi-center study aimed to evaluate the outcomes of NACI in China. **Methods:** This retrospective study examined stage II-IVB HNSCC patients who underwent NACI followed by radical surgery (Group A) or definitive concurrent chemoradiotherapy (CCRT) (Group B) at four medical centers in China from 2019 to 2025. Propensity score matching was employed to balance baseline covariates between the groups. The primary endpoint was progression-free survival (PFS), while key secondary endpoints included complete pathological response (pCR), major pathological response (MPR), overall survival (OS), and treatment-related adverse events (TRAEs), which were graded according to the CTCAE v5.0 criteria. Survival analyses were conducted using Kaplan-Meier/log-rank tests and Cox proportional hazards models. **Results:** After matching (n=756), baseline characteristics were well-balanced (|SMD|<0.1). Group A (NACI + surgery, n=457) showed a 67% radiological response and MPR rate, with a 38% pCR, while Group B (NACI + CCRT, n=299) achieved a higher 76% radiological response rate. Regimens were similar (taxane-platinum-immunotherapy), but Group A received fewer chemotherapy cycles (3-4 cycles: 66% vs. 90%). Post-NACI progression was lower in Group B (0.7%). Group B demonstrated significantly longer PFS (hazard ratio [HR] 0.68; p=0.036) and markedly improved OS (HR 0.20; p<0.001). Multivariate analysis confirmed NACI + CCRT (Group B) as a significant independent predictor of improved OS (HR=0.20, 95% CI 0.07–0.59; p=0.003), considering factors such as betel nut use, tumor location, and T and N staging. Common grade 3-4 TRAEs were neutropenia and transaminase elevations; among grade 3 immune-related AEs, thyroid dysfunction predominated. **Conclusions:** This multicenter real-world study highlights that the combination of NACI and CCRT (Group B) results in significantly better PFS and OS outcomes compared to the NACI and surgical intervention (Group A), despite a pCR rate of 38% in Group A. These findings support the potential benefit of concurrent chemoradiotherapy as a consolidative approach following NACI. However, it is important to recognize that the observational nature of this study prevents definitive conclusions about causality. Therefore, prospective randomized controlled trials are essential to confirm these findings and to ascertain the optimal consolidative strategy. Additionally, further investigation into biomarker-driven patient selection is vital for enhancing treatment precision and effectiveness. Research Sponsor: None.

Larynx preservation via chemotherapy-free neoadjuvant sintilimab-cetuximab-SBRT and response-adapted treatment in locally advanced laryngeal cancer: A phase II, single-arm clinical trial (the NeoVOICE study). First Author: Shida Yan, Department of Head and Neck Surgery, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: The current standard of care for locally advanced laryngeal squamous cell carcinoma (LA-LSCC), including surgery and chemoradiotherapy, might cause long-term toxicities and laryngeal dysfunctions. The study aims to investigate the efficacy and safety of neoadjuvant cetuximab, sintilimab and stereotactic body radiation therapy (SBRT) treating patients with LA-LSCC for larynx preservation. **Methods:** In this phase II, single-arm trial, patients with LA-LSCC (cT2N1-3M0 or cT3-4aN0-3M0, AJCC 8.0th) were recruited. Eligible patients received SBRT (8 Gy × 3 fractions), followed by sintilimab (200mg, Q3W, 2 cycles) and cetuximab (a loading dose of 400 mg/m^2, followed by 250 mg/m^2, QW, 6 cycles). Further treatment was determined by a radiographic evaluation per RECIST 1.1: patients who reached CR or PR would receive intensity modulated radiation therapy (The initial IMRT dose to the primary tumor was 46 Gy in 23 fractions, with a pre-specified plan to reduce the dose to 37.8 Gy based on early tolerance data from the cohort.) or minimally invasive surgery, while ones with SD or PD would receive radical surgery. The primary endpoint was the larynx-preservation rate (LPR) at 1-year post-radiation. **Results:** Between July 1, 2024 and June 30, 2025, 20 patients were enrolled. 15 (75%) were clinical stage III and 5 were stage IVa. 19 finished neoadjuvant SBRT, sintilimab and cetuximab (one withdrawn due to personal reasons after SBRT), with the ORR of 100% (12 had CR and 7 had PR). Then 18 patients received sequential IMRT, with a median dose of 37.8 Gy (one refused and chose active surveillance). During the whole treatment, grade 3 TRAEs occurred in 5/20 patients (25%), including 3 cases of post-radiation pharyngitis, 1 myocarditis and 1 rash. All 3 cases of grade 3 pharyngitis occurred in the first 6 patients with 46 Gy IMRT. Following a protocol amendment, subsequent patients (n=12) received a reduced dose of 37.8 Gy. In the reduced-dose cohort, no further grade 3+ pharyngitis was observed, while the LPR remained high. After a median follow-up of 7.4 months, 3 patients failed to larynx preservation, including 2 cases with tracheotomies due to pharyngitis and 1 receiving total laryngectomy due to tumor recurrence. Based on results of EORTC QLQ-H&N35 questionnaires, compared to the baseline, most patients reported similar or improved symptoms, including pain, speech and dry mouth, at 6 months post-radiation. **Conclusions:** Neoadjuvant combination of immunotherapy, targeted therapy and SBRT showed excellent efficacy and tolerant toxicity for patients with LA-LSCC. Importantly, dose reduction of sequential IMRT appears to mitigate severe toxicity without compromising laryngeal preservation, outlining a promising de-escalation strategy for future practice. Clinical trial information: ChiCTR2500100185. Research Sponsor: None.

Niraparib and dostarlimab in locally advanced head and neck squamous cell carcinoma (LA-HNSCC) treated with (chemo)radiotherapy (CRT): Results from the phase IB-II TTCC-2022-01 RADIAN trial. First Author: Marc Oliva, Medical Oncology Department, Institut Català d'Oncologia (ICO), L'hospitalet De Llobregat, Barcelona, Spain

Background: Treatment intensification with antiPD-(L)1 agents given concurrently to definitive CRT in LA-HNSCC have failed to improve survival. Beyond radiation sensitization, PARP inhibition is predicted to trigger immune responses via STING pathway activation and synergize with anti-PD-(L)1 agents. TTCC-2022-01 RADIAN Trial evaluates niraparib and dostarlimab in LA-HNSCC patients (pts) treated with CRT (cohort A) or RT alone (Cohort B-cisplatin ineligible) (Oliva M et al ASCO 2024). Results of cohort A are presented. **Methods:** Investigator-initiated, non-randomized phase 1b/II study of niraparib and dostarlimab in LA-HNSCC pts candidates for definitive CRT or RT alone conducted in 7 Spanish sites. In cohort A, pts received 500 mg dostarlimab intravenously on week (w)-3 prior to RT and 200-300 mg/day niraparib from w-2 until 48h before start of CRT (70Gy/35 fractions plus cisplatin 100mg/m^2 w1,4 and 7). Maintenance dostarlimab (500 mg/3w) plus daily niraparib started 4w post-CRT for up to 14 cycles. Eligibility criteria: newly-diagnosed stage III-IVA-IVB HPV-negative oro-hipopharyngeal or laryngeal SCC and stage III HPV-related oropharyngeal, ECOG 0-1, centrally-confirmed PD-L1 CPS$\geq$1, and with no cisplatin/dostarlimab/niraparib contraindications. Primary endpoint was 1-year disease-free survival (1y-DFS). Secondary objectives include safety; overall response rate (ORR) and ctDNA dynamics. 17 pts per cohort were planned. Experimental treatment was expected to increase 1y-DFS up to 75.9 % vs 65% historical control. **Results:** From Dec 23 to Jun 25, 17 pts were enrolled: median age 65 y (41-68); 71% male; 88% smokers; larynx/hypopharynx/oropharynx (HPV-related)= 53/6/41% (43%); stage III/IVA/IVB=29/53/18%. All pts completed dostarlimab and niraparib pre-CRT with no serious or Grade(G) 3-4 treatment-related adverse events (TRAEs); 15/17 completed CRT: 2 pts died during this phase (1 G5 febrile neutropenia cisplatin-niraparib-related; 1 unknown cause); 14/17 pts started maintenance: 2 completed, 7 ongoing and 5 (36%) discontinued due to TRAEs. The most common grade $\geq$3 TRAEs were neutropenia (71%), lymphopenia and dysphagia (29% each). Niraparib dose reductions/interruptions occurred in 12 (71%) pts. Most common TRAEs leading to dostarlimab+niraparib maintenance discontinuation were immune-mediated pneumonitis (18%) and respiratory tract edema (12%). ORR was 100% (14 complete+1 partial response) in 15 evaluable pts. With a median follow-up of 8.5 months (95% CI: 8.3-11.1), 15/17 were alive with no disease recurrence or progression. Intention-to-treat 1y-DFS was 88% (95% CI:74.1-100). **Conclusions:** Dostarlimab and niraparib with CRT showed promising efficacy results in this preliminary analysis. Maintenance post-CRT was poorly tolerated leading to high rate of discontinuation. Clinical trial information: NCT05784012. Research Sponsor: GlaxoSmithKline Research& Development Limited.

Neoadjuvant HPV16-specific viral immunotherapy (HB200) plus chemotherapy with response-adapted de-escalation in HPV16+ oropharyngeal squamous cell carcinoma: TARGET-HPV trial. First Author: Ari Joseph Rosenberg, Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, IL

Background: Neoadjuvant immunotherapy is an emerging strategy in head and neck squamous cell carcinoma to enhance systemic antitumor immunity and enable response-adapted de-escalation. In HPV associated oropharyngeal squamous cell carcinoma (OPSCC), virally encoded oncoproteins represent shared, tumor-specific antigens and a rational immunologic target well suited for the neoadjuvant setting in the presence of intact tumor antigen. We conducted a phase I/II trial evaluating neoadjuvant HPV16-specific viral immunotherapy (HB200; HB201 and HB202 HPV16 therapeutic vaccines) plus chemotherapy followed by response-adapted definitive treatment in non-metastatic HPV16+ OPSCC (NCT05108870). **Methods:** This investigator-initiated phase I/II trial enrolled patients with previously untreated, non-metastatic HPV16+ OPSCC (N1-3 or T3-4; smokers permitted). All patients received three cycles of neoadjuvant HB200 (HB201 alone or alternating HB202/201) with carboplatin/paclitaxel, followed by radiographic response assessment. Patients with T1-2 tonsil or well-lateralized base of tongue tumors achieving $\geq$50% tumor shrinkage underwent transoral robotic surgery (TORS) alone. Remaining patients received response and risk adapted radiotherapy (50-70Gy based on risk/response) with or without cisplatin. The primary endpoint was deep response rate (DRR; $\geq$50% tumor shrinkage). Secondary endpoints included survival and toxicity. Exploratory endpoints included circulating tumor HPV-DNA (ctHPV-DNA), HPV16-specific immunity, and spatial transcriptomics. **Results:** Thirty-five patients were enrolled (median age 58; 89% male); Twelve patients (34%) received HB201 alone and 23 (66%) received alternating HB202/201. Nineteen patients (54%) were current or former smokers, and 49% had stage II-III (AJCC 8th edition). The DRR was 87.9% (95% CI, 71.8-96.6). Thirty (86%) received de-escalated definitive therapy. At a median follow-up of 23 months, 2-year PFS and OS were 86% and 100% respectively. Most common AEs during neoadjuvant HB200/chemo were fatigue (97%), nausea (91%), and fever (76%). Detectable ctHPV-DNA following treatment was significantly associated with disease recurrence ($p<0.01$). HPV16-specific immune responses and spatial transcriptomic analyses will be presented. **Conclusions:** Neoadjuvant HB200 combined with chemotherapy resulted in high deep response rates, frequent treatment de-escalation, and excellent survival outcomes in locoregionally advanced HPV16+ OPSCC. These findings support further evaluation of HPV directed immune therapy in neoadjuvant setting. Clinical trial information: NCT05108870. Research Sponsor: HOOKIPA Pharma, Inc.; University of Chicago Cancer Center.

Patterns of tumor regression after neoadjuvant immunochemotherapy in oral squamous cell carcinoma and their surgical margin implications. First Author: Haotian Cao, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: Neoadjuvant immunochemotherapy (nICT) has been increasingly applied in locally advanced oral squamous cell carcinoma (OSCC), demonstrating promising tumor downstaging and improved pathological response rates. However, the spatial patterns of tumor regression after nICT and their implications for surgical margin design and potential de-escalation of surgery remain poorly defined. **Methods:** We retrospectively analyzed 36 hemiglossectomy specimens from OSCC patients treated with nICT. All specimens were entirely embedded and evaluated using large-format histopathology. Tumor regression patterns were classified based on the distribution of residual viable tumor into central necrotic regression, peripheral regression, and patchy ablation types, each with distinct morphological subtypes. The relationship between pathological residual tumor foci, margin distance (1 mm vs 5 mm), and multicentricity was systematically assessed. **Results:** Distinct tumor regression patterns were observed following nICT. Most cases exhibited predominantly unicentric residual disease, while a small proportion demonstrated multicentric pathological residuals. Using a 1-mm pathological distance threshold, 1 cases were classified as multicentric, whereas no case met multicentric criteria using a 5-mm threshold. Notably, cases achieving major pathological response (MPR) or near pathological response (NPR) showed minimal residual tumor burden, though isolated satellite foci were occasionally detected. These findings suggest that regression morphology directly influences margin risk distribution and surgical safety. **Conclusions:** Tumor regression patterns after nICT in OSCC are heterogeneous and play a critical role in determining optimal surgical resection boundaries. While surgical de-escalation may be feasible in selected responders, careful assessment of residual tumor distribution is essential to ensure oncologic safety. Our findings support the development of an integrated preoperative regression assessment and postoperative margin reconstruction framework to guide individualized, function-preserving surgical strategies in OSCC. GDF-15 levels and clinical correlates in head and neck cancer patients: Developing a risk model for cachexia. First Author: Connor Maxwell Douglas Williams, Supportive Oncology Research Group, Precision Medicine (Cancer), South Australian Health and Medical Research Institute, Adelaide, Australia

Background: Cachexia is a challenging complication of cancer and its treatment, associated with an increased risk of death. Growth differentiation factor 15 (GDF15) is a known driver of cachexia in lung, pancreatic and colorectal cancer. However, we lack information about GDF15 role and temporal dynamics in patients with head and neck squamous cell carcinoma (HNSCC) receiving curative treatments. Here, we aimed to quantify circulating GDF15 in HNC patients and determine the relationship with indicators of cachexia and other prominent clinical correlates, namely oral mucositis (OM). **Methods:** Adults diagnosed with HNSCC, scheduled to receive definitive platinum based chemoradiotherapy (CRT), were recruited from four tertiary hospitals in Australia and Italy. Cachexia was determined using a variety of clinical parameters, including weight, grip strength, and upper arm circumference (UAC). OM was assessed using the World Health Organization (WHO) mucositis scale (grade 0-4). GDF15 was quantified in serially-collected serum using a commercial ELISA. All measures were assessed at baseline, week 3, end of treatment (EOT) and 3 months after treatment end. **Results:** Fifty-nine patients (pts) were enrolled, predominantly male (71%) with a mean age of 64+/-8 years. Main subsite of disease was oropharynx (44 cases, 75%), of whom 68% were HPV positive. Treatment was delivered with definitive intent in 90% of the cases. Median dose of RT was 70 Gy (66-70). At EOT, 77.3% of the pts met the diagnostic criteria for cachexia, with an average weight loss of 8.6% over the course of treatment. This was accompanied by a 7.7% and 5.6% average reduction in grip strength and UAC, respectively. Notably, these reductions continued beyond treatment cessation, with an average baseline weight loss of 9.8% after 3 months. Aligning with these outcomes, serum GDF15 levels were highly elevated following CRT compared to baseline (2.6 fold, $P<0.0001$), and correlated with reductions in weight ($R^2=0.168$, $P=0.0002$), UAC ($R^2=0.1516$, $P<0.0001$), grip strength ($R^2=0.1332$, $P<0.0001$), as well as OM severity ($R^2=0.1013$, $P<0.0009$). **Conclusions:** These data reveal that highly elevated GDF15 production correlates with OM and cachexia, providing strong clinical rationale to explore the biological basis of this new symptom cluster, as well as identifying a new clinical cohort that may benefit from GDF15 targeting agents. Research Sponsor: None.

6100 Poster Session

A multicenter, randomized controlled phase III trial of TPF induction chemotherapy versus PF adjuvant chemotherapy combined with concurrent chemoradiotherapy in locally advanced nasopharyngeal carcinoma: Long-term follow-up analysis. First Author: Huajing Wu, Department of Oncology, Affiliated Tumor Hospital of Guizhou Medical University, Guiyang, China

Background: To investigate whether TPF induction chemotherapy combined with concurrent chemoradiotherapy (CCRT) can provide greater survival benefits compared to CCRT followed by PF adjuvant chemotherapy. **Methods:** Patients with newly diagnosed locally advanced (Stage III–IVA) nasopharyngeal carcinoma (NPC) treated at the Affiliated Tumor Hospital of Guizhou Medical University, the Second Affiliated Hospital of Guizhou Medical University, the Second Affiliated Hospital of Zunyi Medical University, and Guiyang Hospital of Guizhou Aviation from May 2018 to July 2021 were enrolled. Each group included 133 patients. The experimental group received 3 cycles of TPF induction chemotherapy (docetaxel 75mg/m²,intravenous infusion, Day 1; cisplatin 75mg/m²,continuous intravenous infusion over 5 days,10:00–22:00 daily; fluorouracil 750mg/m²/day, continuous intravenous infusion over 5 days, 22:00–10:00 daily) followed by 2–3 cycles of concurrent chemotherapy (cisplatin 100mg/m², continuous intravenous infusion over 2 days, 10:00–22:00 daily). The control group received PF adjuvant chemotherapy (cisplatin 80mg/m², continuous intravenous infusion over 5 days,10:00–22:00 daily; fluorouracil 800mg/m²/day, continuous intravenous infusion over 5 days, 22:00–10:00 daily) combined with 2–3 cycles of concurrent chemotherapy (same as induction chemotherapy).Both groups underwent intensity-modulated radiotherapy (IMRT),with total doses of 69.96 Gy for T1–T2 primary lesions, 72.6 Gy for T3–T4 lesions, and 69.96 Gy for positive lymph nodes. Data were analyzed using SPSS 26.0.Differences in 5-year PFS, OS, LRFS, DMFS, and adverse events were compared between the two groups. **Results:** No significant differences were observed between the two groups in age, sex, Karnofsky Performance Status (KPS) score, T stage, N stage, or overall stage ($P > 0.05$).At a median follow-up of 58 months, the 5-year PFS in both the intention-to-treat and per-protocol populations was similar between the induction chemotherapy (IC) and adjuvant chemotherapy (AC) groups (66.6% vs 66.0%, P= 0.589; 75.3% vs 69.9%, P=0.471). The 5-year OS, LRFS, and DMFS rates were 73.0% vs 71.3% (P=0.582), 87.4% vs 90.8% (P=0.508), and 76.9% vs 72.6% (P=0.267), respectively, with no significant differences. **Conclusions:** Both groups had similar 5-year PFS, OS, LRFS, DMFS, and long-term toxicity profiles. Clinical trial information: NCT03574324. Research Sponsor: None.

5-year observation indicators for two groups.

Observation indicators	IC+CCRT	CCRT+AC	P value	Risk ratio(95% CI)
PFS				
ITT Population	66.6%	66.0%	0.589	0.89 (0.58-1.36)
PP Population	75.3%	69.9%	0.471	0.85 (0.55-1.33)
OS	73.0%	71.3%	0.582	0.88 (0.55-1.39)
LRFS	87.4%	90.8%	0.508	1.30 (0.60-2.80)
DMFS	76.9%	72.6%	0.267	0.75 (0.45-1.25)

OS, LRFS, and DMFS were all calculated in the ITT population.

Comparison of efficacy between 2 and 3 cycles of neoadjuvant immunotherapy combined with chemotherapy for LA HNSCC. First Author: Xiaohong Chen, Beijing Tongren Hospital, Capital Medical University, Beijing, China

Background: To compare efficacy, safety and long-term survival of 2 vs 3 cycles of neoadjuvant PD-1 inhibitor plus chemotherapy for LA HNSCC, providing evidence for optimizing treatment cycles. **Methods:** Retrospective analysis of LA HNSCC patients treated with the above neoadjuvant regimen at Beijing Tongren Hospital (Jan 2022-Dec 2024) was performed. Initially 76 (2-cycle) and 102 (3-cycle) cases were enrolled. Propensity score matching (1:1) balanced baseline differences, resulting in 65 cases per group. Chi-square, Kappa, Kaplan-Meier and Log-rank tests were used for comparisons, consistency analysis and survival assessment. Stratified analyses focused on HPV-negative and poorly differentiated subgroups. **Results:** After matching, 3-cycle group had higher ORR (95.4% vs 80.0%, P=0.008) and pCR rate (72.3% vs 55.4%, P=0.045). Subgroup analyses showed superior pCR in 3-cycle group for HPV-negative (68.9% vs 42.1%, P=0.014) and poorly differentiated (82.6% vs 35.7%, P=0.004) patients. Weak consistency existed between imaging and pathology (Kappa=0.176, P=0.044). Immune-related adverse events were more common in 3-cycle group (24.6% vs 10.8%, P=0.039). No significant 1-/2-year PFS/OS differences were noted, but 3-cycle group showed favorable numerical trend. **Conclusions:** Three cycles of the regimen significantly improve ORR and pCR in LA HNSCC, especially in HPV-negative and poorly differentiated subgroups. Despite higher immune-related adverse events, it is clinically preferable. Multi-dimensional evaluation is needed due to poor imaging-pathology consistency, with longer follow-up required for definitive prognosis assessment. Research Sponsor: None.

Five-year follow-up of neoadjuvant chemoimmunotherapy in locally advanced head and neck squamous cell carcinoma. First Author: Kunyu Yang, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Neoadjuvant chemoimmunotherapy has shown high rates of pathological response in locally advanced head and neck squamous cell carcinoma (LA-HNSCC). However, its long-term survival outcomes, the predictive value of pathological complete response (pCR), and patterns of late failure remain unclear. **Methods:** In this single-arm phase II trial, 30 patients with resectable LA-HNSCC received three cycles of nab-paclitaxel (or docetaxel) plus cisplatin and camrelizumab, followed by surgery and adjuvant radiotherapy. The primary endpoint was pCR rate. With follow-up until January 2026, the median follow-up was 60 months. Analyses included overall survival (OS), recurrence patterns, and incidence of second primary tumors. **Results:** The pCR rate was 37.0% (10/27). Key Finding 1: This study represents the first report of 5-year long-term survival data for this regimen, with a 5-year OS rate of 76.7%. Key Finding 2: None of the patients who achieved pCR and completed adjuvant radiotherapy experienced local recurrence (0/7), whereas the recurrence rate was 33.3% (1/3) among those who did not receive radiotherapy, underscoring the role of radiotherapy even in pCR patients. Key Finding 3: Six patients (20%) developed second or third primary tumors during long-term follow-up (sites included larynx, esophagus, and lung), with incidence increasing over time. Key Finding 4: Two patients developed osteoradionecrosis of the jaw more than two years after radiotherapy, leading to malnutrition and subsequent death, highlighting the importance of long-term toxicity management. **Conclusions:** Neoadjuvant chemoimmunotherapy provides durable survival benefit in LA-HNSCC. pCR is associated with minimal local recurrence. However, with prolonged survival, the risk of second primary tumors becomes significant, and late radiation toxicities can impact outcomes. These findings emphasize the need for establishing lifelong surveillance protocols for multiple primary cancers and systematic management of late toxicities in this population. Clinical trial information: ChiCTR1900025303. Research Sponsor: None.

Induction chemotherapy response–guided selection for hypoxia-directed major radiation de-escalation in T3–T4 HPV-positive oropharyngeal cancer. First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY

Background: De-escalation trials in human papillomavirus associated oropharyngeal carcinoma (HPV+ OPC) often exclude patients with very locally advanced disease. We previously demonstrated in several Phase II study that for patients with T1-T2 HPV+OPC, de-escalation to 30Gy of definitive chemoradiation based on lack of hypoxia on ^{18}F-FMISO (fluoromisonidazole) PET (30-ROC Study) is associated with excellent outcomes (JNCI 2021; JCO 2024). Here, we hypothesized that induction chemotherapy (ICT) response could be used to select appropriate locally advanced (T3-T4) HPV+OPC for de-escalation while simultaneously improving tumor hypoxia. **Methods:** We conducted a pilot study in HPV+ OPC patients with AJCC v7 T3-T4 and/or large volume N2b-N2c-N3 disease (who were ineligible for 30-ROC Study (NCT03323563)). ICT – carboplatin (AUC2), paclitaxel (90 mg/m2), and cetuximab (250 mg/m2 after 400 mg/m2 loading dose) weekly for 6 weeks. To be eligible for de-escalation (30-ROC), after ICT, patients needed to be down-staged (<=T2 and <=N3 disease). ^{18}F-FMISO PET scan done prior to ICT, after ICT, and, if eligible for ROC study, about 2 weeks after start of radiation therapy. If an ^{18}F-FMISO PET scan showed no hypoxia prior to the start of chemoradiation, no further scans were necessary and patients received 30Gy of radiation therapy with 2 cycles of chemotherapy concurrently. Primary outcome is 2-year local control rate in 20 evaluable patients. **Results:** 20 patients were accrued 3/2023-12/2023. Median age - 70 years old (46-88); Male – 95%; ECOG PS 0 – 80%. Tumor stage – T3 (70%); T4a (30%); N2b (70%); N2c (30%). All 20 patients had pretreatment hypoxia by ^{18}F-FMISO. All 20 patients had sufficient downstaging to be treated by 30-ROC Study and converted to no hypoxia by ^{18}F-FMISO. The estimated progression free survival and local control rate at 2 years is 90% (95% CI 76.9%-100%). There were no distant failures. The median follow up is 23 months (range 12-29 months). All patients were alive and without evidence of disease at last follow up. **Conclusions:** Preliminary results suggest that ICT can allow more advanced tumors (T3/T4), that are typically excluded from de-escalation studies, to be de-escalated and may eliminate tumor hypoxia in a large proportion of cases. This small pilot study shows similar results seen in the larger ROC studies published to date, but a larger study is needed to confirm these results and is currently ongoing. Clinical trial information: NCT05491512. Research Sponsor: None.

Zopapogene imadenovec-drba, a novel non-replicating adenoviral vector-based immunotherapy: Effects on complete and durable responses in recurrent respiratory papillomatosis pivotal trial. First Author: Scott Norberg, Center for Immuno-Oncology, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Recurrent respiratory papillomatosis (RRP) is a rare, neoplastic disorder caused by chronic human papillomavirus (HPV) type 6 or 11 infection. Significant morbidity can occur due to airway obstruction and transformation into malignant cancer. Repeat surgical debulking has historically been the most common treatment for RRP symptom management. Zopapogene imadenovec-drba (zopa), a novel adenoviral vector-based immunotherapy, is the first and only FDA-approved treatment for adults with RRP. Zopa is now recommended as the first-line treatment for adults with RRP in an RRP Foundation position statement authored by 16 key opinion leaders (Best *et al.* Laryngoscope 2026). **Methods:** The pivotal trial (NCT04724980) evaluated zopa in patients with RRP requiring ≥3 clinically indicated interventions 12 months (m) prior to treatment. 12m follow-up data was reported and demonstrated that 4 subcutaneous injections of zopa ($5x10^{11}$ particle units per injection; n=35) were well-tolerated, with no serious adverse events, no grade >2 treatment-related adverse events, and no early treatment discontinuations. The most common adverse events were injection-site reaction, fatigue, chills, fever, and myalgia. Robust efficacy was observed following zopa treatment with 51% (34 to 69; 95% CI) of patients achieving a complete response (CR), defined as no requirement for interventions in the 12m following treatment, and 86% (30/35) of patients experiencing a decrease in interventions in the year following treatment as compared to the year prior to treatment. Here we present data up to 51m of follow-up. **Results:** As of December 15, 2025, 83% (15/18) of patients who achieved a CR at 12m remain in CR with no recurrence of papilloma requiring surgical or medical intervention. The median duration of follow-up for patients in CR was 36m (range: 30-51m), with 3 patients having a response lasting more than 4 years. No new safety events were observed during long-term follow-up. **Conclusions:** Zopa treatment demonstrated significant clinical benefit with the vast majority of CR patients experiencing ongoing durable complete responses for up to 4 years with excellent long-term safety. Updated follow-up results for all patients achieving CR will be available at the time of presentation. Clinical trial information: NCT04724980. Research Sponsor: Precigen Inc.

6105 Poster Session

Omitting postoperative radiotherapy after pathologic complete response to neoadjuvant immunochemotherapy for patients with locally advanced head and neck squamous cell carcinoma: Survival and patient-reported outcomes. First Author: Shuwei Chen, Department of Head and Neck Surgery, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: Neoadjuvant immunochemotherapy (NICT) results in high pathologic response rates in locally advanced head and neck squamous cell carcinoma (LA-HNSCC). However, whether it is safe to omit postoperative radiotherapy (PORT) for patients who achieved pathologic complete response (pCR) after NICT and surgery remains unclear. We assessed the survival and patient-reported outcomes (PROs) for LA-HNSCC patients who achieved pCR to NICT. **Methods:** This retrospective cohort study included LA-HNSCC patients who achieved pCR to NICT between July 2019 and June 2025. Patients were categorized into two groups based on whether they received PORT. Propensity score matching (PSM) was performed to minimize confounding and balance baseline characteristics. Kaplan-Meier survival analysis was performed to estimate local recurrence-free survival (LRFS), locoregional recurrence-free survival (LRRFS), distant metastasis-free survival (DMFS), and overall survival (OS). EORTC QLQ-C30 and EORTC QLQ-HN35 questionnaires before NICT, preoperatively, and at month 1, 3, and 12 postoperatively were collected. Least-squares mean (LS mean) changes from baseline were estimated using linear mixed-effects models for repeated measures (group, time, and group×time), adjusting for baseline scores. **Results:** A total of 236 HNSCC patients who achieved pCR after NICT and surgery were included (non-PORT, n = 98; PORT, n = 138). After 1:1 PSM to balance baseline characteristics, 164 patients (82 matched pairs) with comparable baseline characteristics were analyzed. With a median follow-up of 31.67 months (95% CI, 29.57-35.35), survival analysis showed no significant differences between the non-PORT and PORT groups in 2-year LRFS, LRRFS, DMFS or OS (all $p > 0.05$). Longitudinal EORTC QLQ-C30 global health/QOL analyses showed poorer recovery in the PORT group. PORT was associated with significantly greater postoperative QOL decline at 1 and 3 months postoperatively, with a persistent deficit at 12 months , while non-PORT improved above baseline by 12 months whereas PORT remained slightly reduced. On the EORTC QLQ-HN35, PORT was associated with persistently higher symptom burden, peaking at 3 months postoperatively and remaining elevated up to 1 year compared with non-PORT, suggesting potential QOL benefits of omitting PORT in pCR patients. **Conclusions:** In this propensity score-matched cohort of LA-HNSCC patients achieving pCR after NICT and surgery, omitting PORT was associated with comparable 2-year disease control and survival but better recovery of multidimensional QOL and lower symptom burden on head and neck-specific PROs. These findings favor omission of PORT for this patient population, while prospective validation and longer follow-up are warranted. Research Sponsor: None.

Neoadjuvant adebrelimab plus chemotherapy in untreated locally advanced head and neck squamous cell carcinoma: Efficacy and biomarker insights from a single-arm phase 2 trial. First Author: Ruihua Fang, Department of Otorhinolaryngology Head and Neck Surgery The First Affiliated Hospital Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Improving outcomes for locally advanced head and neck squamous cell carcinoma (LA-HNSCC) requires novel strategies. This phase 2 trial evaluated the efficacy and safety of neoadjuvant adebrelimab (a PD-L1 inhibitor) combined with chemotherapy in untreated, resectable LA-HNSCC. **Methods:** In this single-center, single-arm study, eligible patients had newly diagnosed, resectable stage III-IVA/B LA-HNSCC. Patients received three cycles of neoadjuvant adebrelimab (1200 mg), nab-paclitaxel (260 mg/m²), and carboplatin (AUC 5) every 21 days. The primary endpoint was objective response rate (ORR, RECIST v1.1). Secondary endpoints included safety, pathologic response, larynx preservation, and biomarker analysis. **Results:** Twenty-four patients were enrolled (median age 61.5 years; 91.7% male; 70.8% hypopharynx primary). Twenty-three completed all three cycles of neoadjuvant therapy and were evaluated. The ORR was 87.5% (21/24) in the intention-to-treat population and 91.3% (21/23) in the per-protocol population, including 5 complete and 16 partial responses. The larynx preservation rate was 95.8%. Pathologic complete response was observed in 3 of 7 surgical patients (42.9%). Significant downstaging occurred in T-stage (66.7%), N-stage (70.8%), and overall stage (54.2%). All patients with p16-positive tumors (8/8) and those with PD-L1 combined positive score ≥20 (8/8) achieved an objective response. Grade 3 adverse events occurred in 41.7% of patients (primarily hematologic toxicities), with no grade 4/5 events. **Conclusion:** Neoadjuvant adebrelimab plus chemotherapy demonstrated high response rates, promising organ preservation, and manageable toxicity in resectable LA-HNSCC. Biomarker analysis suggests p16 positivity and high PD-L1 expression may correlate with better response. Clinical trial information: ChiCTR2400091171. Research Sponsor: National Natural Science Foundation of China; 82473271.

Long term functional survivorship in oral cavity cancer: Quality of life (QOL) outcomes by return to work (RTW) status. First Author: Karthika Chettuvatti, All India Institute of Medical Sciences (AIIMS), New Delhi, New Delhi, India

Background: Long-term survivors of oral cavity cancer (OCC) often experience persistent physical, functional, and psychosocial impairments despite disease control. Return to work (RTW) reflects real-world functional recovery and social reintegration. We evaluated whether health-related quality of life (QOL) differs between OCC survivors who returned to work and those who did not. **Methods:** This prospective cohort study included OCC survivors ≤65 years who underwent definitive surgery between 2016 and 2023 and were disease-free for ≥2 years. Health-related QOL was assessed using EORTC QLQ-C30, EORTC QLQ-HN43, and UW-QOL questionnaires. QOL domains were compared between survivors who returned to work and those who did not. **Results:** Three hundred OCC survivors were evaluated at a median of 28.5 months after treatment. Survivors who returned to work demonstrated significantly higher global health status and superior physical, role, emotional, cognitive, and social functioning on EORTC QLQ-C30 compared with non-working survivors (all $p<0.0001$). Non-working survivors had substantially greater head-and-neck–specific symptom burden on EORTC QLQ-HN43, including swallowing difficulty, speech problems, shoulder dysfunction, pain, dry mouth, body-image disturbance, social eating limitations, and fear of progression (all $p<0.0001$). UW-QOL confirmed significantly worse pain, activity, recreation, swallowing, chewing, speech, shoulder function, mood, anxiety, and overall health-related QOL in survivors who did not return to work (all $p<0.0001$). **Conclusions:** Return to work is strongly associated with superior multidimensional quality of life in oral cavity cancer survivors. Survivors who do not resume work experience profound physical, functional, and psychosocial impairment, highlighting the need for rehabilitation-centered survivorship care to restore meaningful functional recovery beyond oncologic cure. Research Sponsor: None.

Quality of life scores for European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-Core 43 (EORTC QLQ HN 43).

EORTC QLQ HN 43	Total patients (Overall population)	Returned to work at the time of survey (Mean + SD)	Did not return to work at the time of survey (Mean + SD)	P Value

Barriers and variability in lymphedema therapy for head and neck cancer survivors: Secondary analysis from a randomized trial. First Author: Cristina Kline-Quiroz, Vanderbilt University Medical Center, Nashville, TN

Background: Secondary lymphedema is a significant underrecognized sequela of head and neck cancer (HNC) and its treatments. Lymphedema may impact external structures (head, face, neck) and internal structures (larynx, pharynx), leading to functional impairments impacting breathing, speaking and swallowing resulting in disability, and reduced quality of life. Although therapist guided lymphedema treatment (TGLT) is effective, timely access is frequently limited by financial constraints, geographic barriers, systemic inefficiencies, and shortages of trained therapists. This study evaluates accessibility, implementation, and barriers to TGLT in HNC survivors. **Methods:** This prospective cohort study was nested within a multi-site randomized trial comparing usual care to an advanced pneumatic compression device (APCD). Eligible participants (N=117) were HNC survivors with lymphedema and at least one lymphedema-associated symptom rated ≥4/10. Therapy notes and patient data were abstracted to assess referral patterns, therapy timelines, lymphedema treatment characteristics, documented therapeutic goals, and reported barriers. Descriptive statistics were obtained to depict trends in therapy initiation, implementation, and barriers. **Results:** Of 117 participants referred for therapy, 77 (66%) were evaluated by a therapist. Of these, 11 failed to return for a second visit (56%). Median time from referral to evaluation was 17 days. Median time from evaluation to last recorded visit was 72.5 days (median 10 visits). Many patients experienced protracted wait times (Figure 1) and treatment breaks. Therapy delivery varied substantially; By last documented visit, recommendations included home manual lymphatic drainage (82%), compression garments (65%), APCD (33%), and written self-care instructions (26%). 28% achieved all therapy goals. Documentation inconsistencies and gaps in provider communication hindered effective therapy implementation. Barriers included geographic distance, financial constraints, and therapist shortages. **Conclusions:** Significant variability, limited care access, and delays in TGLT exist for HNC survivors. Standardized protocols, telemedicine, and adjunctive technologies such as APCDs may improve accessibility, adherence, and outcomes. Future studies should focus on optimizing care models including self-care and reducing disparities in therapy delivery. Clinical trial information: NCT04797390. Research Sponsor: Tactile Medical.

Timeframe of therapy implementation in days.

	Provider Referral to Therapy Evaluation	Therapy Evaluation to Second Visit	Provider Referral to Second Visit	Therapy Evaluation to Last Visit
Average	23.7	9.0	32.7	80.0
Standard deviation	21.9	6.8	23.3	44.9
Median	17.0	7.0	27.0	72.5
Minimum	0.0	1.0	1.0	7.0
Maximum	93.0	31.0	108.0	175.0
25th percentile	8.0	4.0	16.3	48.0
75th percentile	31.8	14.0	44.5	103.5

Impact of advanced pneumatic compression devices and usual care on psychosocial outcomes in head and neck cancer survivors with lymphedema. First Author: Cristina Kline-Quiroz, Vanderbilt University Medical Center, Nashville, TN

Background: Head and neck cancer (HNC)-associated lymphedema impairs quality of life (QOL) in survivors, affecting body image, self-management efficacy, work productivity, and psychosocial functioning. Data supports therapist guided lymphedema therapy (TGLT) and technologies such as advanced pneumatic compression devices (APCD) reduce swelling. There is a lack of data on psychosocial and QOL outcomes. This randomized clinical trial compared psychosocial outcomes of TGLT and APCD in treatment-naïve HNC survivors with symptomatic lymphedema over 6 months. **Methods:** Participants (N=236) with HNC-associated lymphedema were randomized 1:1 to receive either TGLT (117) or APCD (119) for 6 months. Psychosocial outcomes were assessed at baseline, 2, 4, and 6 months using validated instruments: the Work Productivity and Activity Impairment Questionnaire (WPAIQ), Perceived Medical Condition Self-Management Scale (PMCSMS), Body Image Quality of Life Inventory (BIQLI), and Linear Analog Self-Assessment (LASA) for QOL. Longitudinal mixed-effects models evaluated within- and between-group changes over time. **Results:** Both treatment groups experienced improvements in psychosocial outcomes over time. Self-management efficacy improved in both arms. The APCD group demonstrated significantly greater self-efficacy managing lymphedema at 6 months (p=0.004). Work and activity impairment decreased in both groups, with no significant between-group differences. BIQLI scores improved across timepoints in both arms, reflecting enhanced body image-related QOL. LASA scores for overall QOL and emotional, physical, and spiritual well-being also improved similarly in both groups. No significant time-by-treatment interactions were observed, indicating comparable trajectories of psychosocial recovery. **Conclusions:** Both TGLT and APCD were associated with meaningful improvement in psychosocial outcomes, including self-management efficacy, body image, and QOL, among HNC survivors with lymphedema. APCD offers ongoing access to a convenient, home-based treatment which may enhance fidelity and self-efficacy through ongoing instrumental support. These findings underscore the value of accessible, patient-centered lymphedema interventions to enhance survivorship care. Future research should explore long-term adherence, cost-effectiveness, and integration of psychosocial support into treatment pathways. Clinical trial information: NCT04797390. Research Sponsor: Tactile Medical.

GDF-15 in oropharyngeal squamous cell carcinoma (OPSCC): Association of an HPV-dependent biomarker with malnutrition and low skeletal muscle. First Author: Lorena Arribas, Clinical Nutrition Unit. Catalan Institute of Oncology (ICO), Hospitalet De Llobregat (Barcelona), Spain

Background: GDF15 is a stress-response cytokine implicated in systemic inflammation and cancer-related wasting. We assessed whether baseline circulating GDF15 captures an HPV-stratified nutritional/body composition phenotype and whether longitudinal GDF15 changes relate to treatment outcome in OPSCC. **Methods:** We analyzed a prospective cohort of OPSCC patients (pts) undergoing curative intent treatment (CIT; surgery and radiotherapy [RT]-based) with available baseline plasma GDF15. HPV status was defined by dual detection ($p16^{INK4a}$ and HPV DNA). Baseline nutritional status (Patient Generated Subjective Global Assessment), symptom burden (nutrition-impact composite score), body mass index (BMI), and CT-derived skeletal muscle index (SMI) were analyzed when available. Response assessment was performed 8-12 weeks after CIT, classifying cases as no evidence of disease (NED) vs evidence of disease (ED). Longitudinal GDF15 was analyzed using linear mixed-effects models (LMEN) (random intercept) including interactions of time with response status and induction chemotherapy. **Results:** We included 138 pts (HPVnegative [−] n=82; HPVpositive [+] n=56). Stage III–IV was more frequent in HPV- vs HPV+ (85.4% vs 30.4%; $p<0.001$) and ECOG 0 less common (9.8% vs 51.8%; $p<0.0001$). RT-based treatment predominated (85.5%) mainly chemoradiotherapy ± induction (82.6%). Baseline GDF15 was higher in HPV- vs HPV+ (median 1591 vs 803 pg/mL; $p<0.001$). HPV− pts showed worse nutritional phenotype: lower BMI (22.7 vs 27.2 kg/m²; p=0.001), more severe malnutrition (37.8% vs 7.1%; $p<0.001$), higher symptom burden (1.90±0.94 vs 1.39±0.71; p=0.002) and higher sarcopenia (34.1% vs 16.1%; p=0.029). In pts with CT body composition (n=89), SMI was lower in HPV− vs HPV+ (45.6 vs 53.6 cm²/m²; p=0.010). Baseline GDF15 differed by nutritional status (p=0.014) and was associated with symptom burden and SMI (both $p<0.05$). In LMEN, GDF15 increased significantly from baseline to end of treatment (β=2264 pg/mL; $p<0.001$). Baseline HPV positivity was independently associated with lower GDF15 (β=−980 pg/mL; $p<0.001$). At the end of treatment, NED was associated with lower GDF15 compared with ED (β=−1141 pg/mL; p=0.011). Induction chemotherapy showed no significant effect on GDF15 change (β=−448 pg/mL at end of treatment; p=0.22). No significant interaction between time and baseline HPV status was observed (p=0.26) indicating comparable longitudinal trajectories of GDF15 in HPV+ and HPV-pts. **Conclusions:** Baseline GDF15 is strongly HPV-dependent and reflects a multidimensional nutritional and muscle phenotype. GDF15 increases during CIT and lower end-of-treatment GDF15 is independently associated with NED, whereas induction chemotherapy does not significantly modify GDF15 change. Research Sponsor: None.

Nonoperative management of locally advanced resectable cutaneous squamous cell cancer of the head and neck with PD-1 blockade. First Author: Fergal Kavanagh, Department of Surgery, Head and Neck Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Head and neck cutaneous squamous cell carcinoma (cSCC) is common, increasing in incidence, and highly immunogenic. Neoadjuvant PD-1 blockade with cemiplimab has demonstrated substantial efficacy prior to surgery; however, its role as a definitive nonoperative strategy in resectable disease remains poorly defined. **Methods:** We conducted a single-institution retrospective study (2018–2023) of patients with locally advanced, resectable stage III/IV head and neck cSCC treated with cemiplimab. Patients received either neoadjuvant cemiplimab followed by surgery or cemiplimab monotherapy without surgery. The primary endpoint was objective clinical and radiologic response rate. Secondary endpoints included disease-specific survival (DSS), progression-free probability (PFP), histopathologic response, and exploratory genomic biomarkers. **Results:** Seventy-three patients were included: 52 received cemiplimab monotherapy (median age, 78.8 years) and 21 received neoadjuvant cemiplimab (median age, 73 years). In the monotherapy cohort, complete response occurred in 68.6%, partial response in 9.8%, stable disease in 5.9%, and progression in 15.7% (median treatment duration, 10 months). Two-year DSS and PFP were 90% (95% CI, 80–100) and 82% (95% CI, 72–94), respectively. In the neoadjuvant cohort, radiographic response was observed in 66.7% and pathologic complete response in 38.1%. Two-year DSS and PFP were 95% (95% CI, 86–100) and 78% (95% CI, 62–100), respectively. DSS and PFP did not differ significantly between cohorts. Tumor-infiltrating lymphocytes (TILs) were higher in complete and partial responders than in patients with stable or progressive disease (p=0.005, q=0.02), with absent TILs more frequent in non-responders. Tumor mutational burden (TMB) was greater in complete (55.7) and partial responders (14.9) than in patients with progressive disease (4.9; p=0.02, q=0.04). **Conclusions:** In the largest reported series to date, cemiplimab monotherapy achieved durable disease control and oncologic outcomes comparable to neoadjuvant cemiplimab in selected patients with resectable, locally advanced head and neck cSCC, supporting further study of definitive immunotherapy as an organ-preserving strategy. Dynamic biological and metabolic response by EBV DNA and ^{18}F-FDG-PET-CT to induction chemotherapy (IC) to enhance prognostication in endemic nasopharyngeal carcinoma (NPC). First Author: Jialing Neo, National Cancer Centre Singapore, Singapore, Singapore

Background: IC followed by concurrent chemoradiotherapy (CCRT) is the current standard of care for locoregionally-advanced NPC (LA-NPC). Nonetheless, evidence suggests that IC response is a strong predictor for risk of relapse in LA-NPC. Here, we characterized the dynamic metabolic and biological responses to IC, and investigated their associations with survival in patients with high-risk LA-NPC. **Methods:** Newly diagnosed patients with non-metastatic, biopsy-proven NPC were enrolled into two prospective ongoing studies (NCT04340024 and NCT06093061). For this analysis, patients who received 2-3 cycles of gemcitabine-cisplatin/carboplatin IC were included; all patients had plasma EBV DNA assessed following every IC cycle, and ^{18}F-FDG-PET-CT performed pre-IC and 1 week before the end of IC. For the latter, standardized uptake values (SUVs) were recorded for the primary tumor (SUVp) and individual nodal lesion(s) (SUVn). Biological (bCR) and metabolic complete response (mCR) were defined as EBV DNA =0 copy/mL and SUV $\leq$2.5, respectively. Prediction accuracy of 2y disease-free survival (DFS) was assessed by area under the receiver operating characteristic curve (AUC). **Results:** 117 patients diagnosed between Jan 2019 to Apr 2025 were included in this analysis; of these, 112 and 106 had SUVp and SUVn at pre- and post-IC. For SUVn, we performed lesion-level analysis for 259 LNs. Median follow-up was 20.5 (interquartile range [IQR]: 11.6-41.3) mo and TNM-8 stage distribution for stage III and IVA were 43% (50/117) and 57% (67/117), respectively. Median SUVp and SUVn pre-IC were 15.0 (IQR: 10.4-18.2) and 8.5 (IQR: 4.5-12.3), respectively, while median EBV DNA level was 4800 (IQR: 914-20598) copies/mL. Post-IC, we recorded mCR at the primary tumor and LNs for 33/112 (29%) and 49/106 (46%), respectively; while 14/117 (12%), 30/117 (26%) and 40/117 (34%) patients manifested bCR post-IC1, IC2, and IC3, respectively. Metabolic response was not correlated with biological response; of 33 patients with primary tumor mCR, 20/33 (61%) had bCR; while for LNs, only 25/49 (51%) patients with mCR manifested bCR post-IC. Additionally, we observed significant intrapatient heterogeneity of mCR between LN lesions post-IC; in 57/106 patients with non-mCR for $\geq$1 of the LNs, SUVn ranged between 0-12.9. Finally, incorporating both post-IC bCR and mCR to TNM-8 stage and pre-IC EBV DNA enhanced AUC of 2y DFS prediction; from 0.58 (95%CI:0.44-0.73) [TNM-8+pre-IC EBV DNA] to 0.77 (95%CI:0.60-0.94). **Conclusions:** Metabolic and biological responses to IC provide unique information on response phenotypes of patients with LA-NPC, and improved the prediction accuracy of 2y DFS compared with TNM-8 stage and pre-IC EBV DNA. Combinatorial ^{18}F-FDG-PET-CT and EBV DNA post-IC may enhance the selection of these patients for treatment intensification. Chrono-chemotherapy combined with IMRT in locoregionally advanced nasopharyngeal carcinoma: A prospective randomized study. First Author: Feng Jin, Affiliated Hospital of Guizhou Medical University/Department of Head and Neck Oncology, Affiliated Cancer Hospital of Guizhou Medical University, Guiyang, GuiZhou, China

Background: Induction chemotherapy followed by radiotherapy with concurrent cisplatin is a standard treatment for locoregionally advanced nasopharyngeal carcinoma (LA-NPC). The TPF induction regimen combined with intensity-modulated radiation therapy (IMRT) improves tumor control but causes substantial toxicity. Circadian rhythms regulate tumor biology and drug metabolism. Docetaxel, cisplatin, and 5-fluorouracil show circadian-dependent pharmacologic properties. Chrono-chemotherapy aligns drug administration with circadian rhythms and may reduce toxicity. This study compared long-term outcomes and late adverse events between chrono-chemotherapy and conventional chemotherapy combined with IMRT in LA-NPC. **Methods:** This single-center, prospective, randomized clinical trial was registered at ClinicalTrials.gov (NCT03196869). Between April 2017 and May 2018, 128 patients with newly diagnosed stage III–IVa nasopharyngeal carcinoma were randomly assigned to chrono-chemotherapy or conventional chemotherapy. All patients received three cycles of TPF induction chemotherapy, followed by IMRT with two cycles of concurrent cisplatin chemotherapy. Survival outcomes were analyzed using the Kaplan–Meier method and compared by log-rank test. Late toxicities were graded using CTCAE v5.0. Quality of life was assessed with the EORTC QLQ-C30 questionnaire. **Results:** A total of 124 patients were included in the survival analysis. No significant differences were observed between groups in 5-year overall survival (P=0.709), progression-free survival (P=0.492), distant metastasis-free survival (P=0.467), or locoregional recurrence-free survival (P=0.697). The chrono-chemotherapy group showed lower rates of xerostomia (P=0.034) and dysphagia (P=0.019). No grade $\geq$4 late toxicities were observed. Global health status scores were higher in the chrono-chemotherapy group (P=0.043). **Conclusions:** Chrono-chemotherapy combined with IMRT achieved long-term survival outcomes comparable to conventional chemotherapy in LA-NPC. This approach reduced selected late toxicities and improved overall health status. Chrono-chemotherapy may represent a toxicity-sparing treatment option. Clinical trial information: NCT03196869. Research Sponsor: None.

Late toxicities and quality of life.

Outcome	Conventional Chemotherapy	Chrono-chemotherapy	P value
Xerostomia, n (%)	24/36 (66.7)	16/38 (42.1)	0.034
Dysphagia, n (%)	24/36 (66.7)	15/38 (39.5)	0.019
Global health status score*	58.33 (50.00–72.92)	75.00 (50.00–83.33)	0.043

*Scores derived from the EORTC QLQ-C30 questionnaire; values are presented as median (interquartile range).

Survival implications of context-dependent oncogenic *PIK3CA* mutations in HNSCC. First Author: Jeremiah Ray Holt, Center for Cancer Research, University of Tennessee Health Science Center, Memphis, TN

Background: Head and neck squamous cell carcinoma (HNSCC) is a heterogenous disease that generally lacks clinically useful stratification methods beyond anatomy and HPV status. *PIK3CA* is the most frequently mutated oncogene in HNSCC, and previous studies have linked *PIK3CA* mutations to survival in HNSCC. Thus, we aimed to investigate overall survival (OS) in a large multi-center cohort of HNSCC as a function of specific *PIK3CA* mutation hotspots to better understand the molecular drivers of risk and prognosis in HNSCC. **Methods:** A subset of oral cavity (OC, n=606) and oropharyngeal (OP, n=480) tumors from the VOYAGER consortium underwent exon sequencing in 1,109 cancer related genes and whole HPV16/18 genomes. Mutations in *PIK3CA* were analyzed using a somatic variant calling and filtering pipeline, and driver alterations were annotated based on gain-of-function variants at recurrent hotspots in specific functional protein domains. HPV status was defined using serology, p16 IHC, RNA ISH, and viral genomics. Multivariable Cox proportional hazards models were used to assess the relationship between *PIK3CA* mutations and five-year OS adjusted for age, sex, HPV status, tumor type, and TNM staging. **Results:** In OP tumors, 289 were HPV(+) and 174 were HPV(-), while only 13 of OC tumors were HPV(+). The overall *PIK3CA*mutation rate was 18% (13% of OC vs 24% of OPs), and among OP cases, *PIK3CA* mutations occurred in 28% of HPV(+) vs 18% of HPV(-) tumors. Of the nine recurrent hotspots in *PIK3CA*, the most common were the APOBEC-associated ones in the helical domain, *p.E545K* (3% OC vs 12% OP) and *p.E542K* (2% OC vs 5% OP), as well as smoking-associated kinase domain mutations at *p.H1047R* (3% OC vs 2% OP). In OC and OP cases combined, tumors harboring *PIK3CA* driver alterations in one of the nine hotspots showed a statistically significant improvement in OS that was independent of age, sex, staging, tumor type, and HPV status (HR 0.72, P=0.048). Among all HPV(+) tumors, driver mutations in *PIK3CA* conferred significantly better OS in the adjusted model (HR 0.42, P=0.02). Likewise, in all OP tumors, *PIK3CA* driver mutations were significantly associated with improved OS in the multivariate models (HR 0.60, P=0.04) and when stratified by HPV status this effect was particularly strong for HPV(+) OP tumors only (HR 0.45, P=0.04). Among the hotspots, *p.E545K* was the only one with improved survival in a univariable analysis of the full cohort (Log-rank P=0.01), but this was not significant in the adjusted model (HR 0.62, P=0.07). **Conclusions:** Our findings validate previously described associations between *PIK3CA* mutation and OS in HNSCC that are dependent on anatomic site and HPV status. Moreover, we provide a new perspective by analyzing OS as a function of recurrent mutation hotspots in *PIK3CA*, which may signify distinct pathologic processes among HNSCCs and thus may be clinically useful for patient stratification with prognostic or therapeutic intent. Survival outcomes with contemporary treatments including immunotherapy for poorly differentiated neuroendocrine carcinomas of the head and neck. First Author: Rushabh Gujarathi, University of Louisville, Louisville, KY

Background: Poorly differentiated Neuroendocrine Carcinomas of the Head and Neck (HN-NECs) are rare aggressive malignancies with limited data guiding therapeutic approaches, particularly in the metastatic setting, with cytotoxic chemotherapy (chemo) comprising the backbone of management. Despite the widespread use of immune checkpoint inhibitors/immunotherapy (IO) in advanced lung NECs, evidence regarding their utility in the extrapulmonary setting, particularly for HN-NECs, is scarce. We explored real-world outcomes with various therapeutic strategies, including IO, in patients with metastatic HN-NECs, using the National Cancer Database (NCDB). **Methods:** Patients with metastatic HN-NECs diagnosed between 2018 to 2023 were identified. Overall survival (OS) was analyzed using Kaplan-Meier estimations and Cox proportional hazards regression. **Results:** A total of 275 patients with metastatic HN-NECs were identified. Primary sites included larynx (n = 75, 27.3%), pharynx (n = 72, 26.2%), nasal cavity + paranasal sinuses (n = 67, 24.4%), and oral cavity (n = 61, 22.2%). Most common metastatic sites were liver (n = 128, 46.5%) and bone (N = 272; n = 116, 42.6%). Of these 275 patients, 212 (77.1%) received chemo, 95 (34.5%) received IO, 122 (44.4%) received radiotherapy (RT), and 46 (16.7%) underwent primary site surgery (surg). Among patients with available survival data (N = 227), receipt of chemo (n = 174) and/or IO (n = 78) were associated with prolonged OS vs. no chemo ($p < 0.001$) and/or no IO ($p = 0.005$), respectively. Use of RT (n = 105; p = 0.17) and surg (n = 39; p = 0.18) were not significantly associated with OS (Table). Among 174 patients who received chemo, concurrent IO (chemoIO; n = 73) was associated with significantly prolonged OS vs. chemo alone (14.1 months [m] vs. 9.9 m; HR, 0.67; 95% CI, 0.47 – 0.96; p = 0.03). On multivariable analysis adjusting for bone metastatic disease (the only other significant prognostic covariate on univariable regression), chemoIO remained associated with reduced mortality risk vs. chemo alone (HR 0.57; 95% CI, 0.39 – 0.82; p = 0.003). **Conclusions:** Akin to lung NECs, IO may improve OS in HN-NECs. Despite NCDB limitations, chemoIO was associated with prolonged OS over chemo alone. Further prospective evaluations are warranted, and results from ongoing studies (e.g., NCT05058651) are awaited. Research Sponsor: None.

Survival comparisons with univariable Cox proportional hazards regression.

Treatment Group	Median OS in months (95% CI)	HR (95% CI)	p
Chemo (vs. No Chemo)	11.3 (9.5 – 14.2) vs. 3.4 (2.7 – 6.2)	0.53 (0.38 – 0.74)	<0.001
IO (vs. No IO)	13.0 (10.8 – 17.1) vs. 8.1 (6.2 – 10.3)	0.63 (0.46 – 0.87)	0.005
RT (vs. No RT)	10.8 (8.8 – 14.6) vs. 8.5 (6.4 – 11.7)	0.81 (0.60 – 1.09)	0.17
Primary Site Surgery (vs. No Surgery)	12.5 (8.7 – 28.5) vs. 9.0 (7.7 – 11.7)	0.76 (0.51 – 1.14)	0.18
ChemoIO (vs. Chemo alone)	14.1 (11.1 – 19.3) vs. 9.9 (8.3 – 13.7)	0.67 (0.47 – 0.96)	0.03

CCL3^{+} neutrophil signature as a predictor of response to neoadjuvant toripalimab plus chemotherapy in hypopharyngeal squamous cell carcinoma: A phase II trial. First Author: Zhenghua Lv, Shandong Provincial ENT Hospital, Shandong University, Jinan, Shandong, China

Background: Hypopharyngeal squamous cell carcinoma (HPSCC) has a poor prognosis. Although neoadjuvant chemoimmunotherapy (nCIT) is promising, responses are heterogeneous and PD-L1 combined positive score (CPS) inadequately stratifies benefit. We sought biomarkers to guide patient selection. **Methods:** In this prospective, single-center, single-arm phase II trial, patients with resectable locally advanced HPSCC received two cycles of neoadjuvant toripalimab, albumin-bound paclitaxel, and nedaplatin. The primary endpoint was the pathological complete response (pCR) rate. Pre-treatment tumor biopsies from a subset of patients (n=13) were analyzed by single-cell RNA sequencing (scRNA-seq) to identify determinants of response. Findings were validated in a larger cohort (n=60) using bulk RNA sequencing and immunohistochemistry. **Results:** Among 70 evaluable patients, the objective response rate was 82.7%. Of the 64 patients who underwent surgery, the pCR rate was 29.7% (95% CI, 18.9%–42.7%). Baseline PD-L1 CPS was not associated with pathological response (P=0.313). Single-cell analysis revealed that the pre-treatment tumor microenvironment of responders was significantly enriched with a pro-inflammatory neutrophil subset characterized by high expression of CCL3 (Neu_CCL3). A gene signature score derived from this subset was a strong and independent predictor of pCR (AUC = 0.788), significantly outperforming PD-L1 CPS (AUC = 0.621). **Conclusions:** The efficacy of nCIT in HPSCC is predetermined by a baseline immune architecture orchestrated by a CCL3+ neutrophil subset. The Neu_CCL3 gene signature is a promising, clinically translatable biomarker that can fill a critical gap in precision immunotherapy for HPSCC. Clinical trial information: ChiCTR2400081826. Research Sponsor: None.

Palliative neck radiation therapy (RT) in combination with lenvatinib/pembrolizumab (L/P) in BRAF wild-type anaplastic thyroid cancer (BRAF-WT ATC). First Author: Anna Lawless, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: BRAF-WT ATC carries a poor prognosis due to limited effective therapies and rapid, often fatal locoregional (LR) progression. Although L/P has shown some efficacy, response rates remain modest (36-52%). Prior studies have shown that complete surgical resection of the primary tumor significantly improves overall survival (OS). **Methods:** We retrospectively reviewed patients with BRAF-WT ATC treated with palliative neck RT (PNRT, $\leq$45 Gy) administered five days before to 21 days after first-line L/P, between January 2016 and August 2025. Primary objective was to evaluate the efficacy and safety of PNRT combined with L/P. Primary endpoints were progression-free survival (PFS), locoregional PFS (LPFS), and OS, defined from RT start, and estimated using Kaplan-Meier method. Secondary endpoints were overall response rate (ORR) and neck response per RECIST v1.1, changes in surgical morbidity assessed by the Thyroid Neck Morbidity and Complexity (TNMC) score, and proportion of patients proceeding to surgery. **Results:** Twenty-six patients met inclusion criteria. Median age was 66 years (range, 36-82) and 14 were male (54%). 23/26 (88%) had stage IVC disease. 21/26 (81%) received 'Quadshot' regimen (14Gy in 4 fractions), two 20 Gy in 5 fractions and three 30 Gy in 10 fractions. Median time from RT to L/P start was 2 days (range, −4 to 21). Median follow-up was 18.5 months (95% CI, 11.7-25.4). After PNRT and L/P, ORR was 72%, and 72% achieved a complete or partial response in the neck. Median OS and PFS were 10.0 (95% CI, 3.4-16.7) and 7.6 (95% CI, 4.4-10.8) months respectively. Median LPFS was not reached. Median TNMC score (0-4 scale, 4=unresectable) decreased from 4 (range, 2-4) at baseline to 3 (range, 0-4) at time of best response with a mean reduction of 1 point (range, 0-3). Ten patients (38%) proceeded to R0/R1 neck surgery after a median of 5.4 months (range, 1.6-9.5) from RT, with absence of residual ATC in the surgical specimens in 70% (7/10). OS and PFS were significantly longer in patients who underwent surgery compared with those who did not, with median OS 22.8 vs 6.1 months (p=0.002) and median PFS 12.7 vs 3.9 months (p=0.034). Seventeen patients (68%) had disease recurrence/progression: 1 LR, 10 distant, and 6 both LR and distant. All but one (6/7) LR recurrences were in patients who did not undergo surgery. PNRT combined with L/P was well tolerated, with most adverse events grade $\leq$ 2. One patient had a fistula 3 months after RT requiring emergency tracheostomy. **Conclusions:** Palliative neck RT combined with L/P for BRAF-WT ATC appears safe and may improve surgical resectability in patients with initially unresectable disease or high baseline surgical morbidity. Patients who proceeded to neck surgery had high pathologic complete response rate (70%) and significantly prolonged OS and PFS with low rate of locoregional relapse. Research Sponsor: None.

Detection, quantification, and subtyping of adenoid cystic carcinoma (ACC) using methylation from liquid biopsies. First Author: Felippe Lazar Neto, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite the common indolent behavior of ACC, some patients will experience aggressive disease with short survival. These distinct clinical behaviors have been linked to two transcriptional profiles: ACC-I, defined by NOTCH1 activation, solid histology, and more aggressiveness, and ACC-II, characterized by predominant myoepithelial p63 expression and generally indolent behavior. DNA methylation has been widely used for tumor identification and subtyping; however, their relevance in distinguishing ACC-I and ACC-II has not yet been explored. **Methods:** Forty-one ACC tissue samples from the original subtype development cohort (41/54) and twenty-three cfDNA samples from a phase II trial of axitinib and avelumab in recurrent/metastatic ACC (NCT03990571) were profiled through target-enriched enzymatic methylation sequencing. ACC subtypes (ACC-I/II) in tissue samples were validated with unsupervised clustering of highly variable regions. To translate these signatures to liquid biopsy, we used the METER (METhylome AnalysER) pipeline to identify tumor-specific differentially methylated sites (DMS) and regions (DMRs) relative to 22 healthy donors, enabling ctDNA detection (METER-positive), tumor proportion score (TPS) quantification, and ACC subtype assignment in cfDNA. Methylation-derived TPS were validated with ichorCNA (copy number alterations) estimates, and cfDNA-assigned subtypes were benchmarked against matched tissue transcriptional signatures. Finally, we investigated if METER detection was associated with progression-free survival (PFS). **Results:** ACC tissue methylation identified two clusters that perfectly matched reference transcriptional subtypes (17/17 ACC-I and 24/24 ACC-II). ACC-I tumors were hypermethylated compared to ACC-II (11,205 hyper and 1,804 hypo DMR, $p<0.05$). Of 23 cfDNA samples, 15 (65.2%) were deemed as METER positive with a higher rate among ACC-I (8/9, 88.9%) compared to ACC-II (7/14, 50.0%), consistent with the more aggressive subtype of ACC-I. The median (range) estimated TPS among METER positive samples was (3.86%; range 0.7%-82%), with a numerical higher TPS among ACC-I (14.8% vs 2.0%, p=0.073). TPS had strong correlation with ctDNA estimation by ichorCNA (spearman 0.86, $p<0.001$). METER subtyping correctly identified ACC-subtypes in 15/15 (100%) METER positive and 4/8 (50%) METER negative samples. METER-positive patients had shorter PFS (HR = 4.32; 95%CI, 1.49–12.5, p=0.007), including among ACC-II patients (HR = 4.84; 95%CI, 1.20–19.5, p=0.026). **Conclusions:** Methylation-based subtyping of ACC is highly concordant with transcriptional profiles and enables detection and subtyping of ACC in liquid biopsies. Beyond subtyping, cfDNA detection may serve as an additional prognostic marker, identifying patients at high risk for progression even within traditionally indolent subgroups. Clinical trial information: NCT03990571. Research Sponsor: U.S. National Institutes of Health; 1R01CA292385-01.

Window of opportunity study of the Notch inhibitor AL101 in Notch1 activated adenoid cystic carcinoma (ACC): Biological effects and biomarker correlates. First Author: Daniel McGrail, Cleveland Clinic, Cleveland, OH

Background: ACC with NOTCH1 pathway activation (ACC-N1) is associated with aggressive clinical behavior and poor outcomes. AL101, an inhibitor of gamma secretase-mediated Notch signaling, previously demonstrated modest clinical activity in metastatic *NOTCH*-mutant ACC. We conducted a window-of-opportunity study to evaluate the biological effects of AL101 in ACC-N1 and to identify biomarkers to inform rational combination strategies. **Methods:** Patients with ACC-N1 received AL101 (4 mg weekly) for 4 to 8 weeks prior to surgery. Eligibility required Notch1 pathway activation by cleaved Notch (NICD1) immunohistochemistry ($\geq$ 70% nuclear staining). Treatment-related adverse events (AEs) were assessed per CTCAE v5.0 and radiographic response per RECIST v1.1. Whole-exome sequencing and RNA sequencing were performed on baseline samples, with paired analysis (pre- and post-treatment) in 12 patients. This report focuses on biomarker analysis; clinical endpoints and feasibility were previously presented. **Results:** 13 patients were enrolled between Nov/21 and Dec/23; 8 were newly diagnosed. The median number of AL101 doses were 6 (range: 4–7), the most common primary site was maxillary sinus (n=4). There were no grade 3-5 AEs. One patient achieved a partial response (ORR 7.7%), 11 had stable disease (including 2 with $>$20% tumor shrinkage), and one had progression in a non-target lesion. Post-treatment NICD1 expression was not significantly reduced (p=0.8). Genomic profiling revealed *NOTCH1* activating mutations in 9/13 tumors and MYB-NFIB fusions in 8/13, with co-occurrence in 6 patients. *MYB-NFIB* fusion with *MYB* overexpression, irrespective of *NOTCH1* mutation status, was associated with tumor shrinkage (p=0.02). Higher baseline NOTCH signaling activity by RNA sequencing (NOTCH signaling signature) correlated with greater tumor shrinkage (p=0.025). Although NICD1 IHC levels did not significantly change, AL101 treatment resulted in significant downregulation of NOTCH signaling activity, and the magnitude of signature reduction correlated with tumor shrinkage (p=0.037). Post-treatment transcriptomic analysis demonstrated upregulation of potentially druggable oncogenic pathways, providing biologic rationale for future combination therapeutic strategies. **Conclusions:** In this first window-of-opportunity study in ACC, AL101 demonstrated biological target modulation. Importantly, *MYB* overexpression and NOTCH signaling activity rather than NICD1 modulation or *NOTCH1* mutation correlated with tumor shrinkage. These findings provide translational insights and support biomarker-driven development of rational combination strategies in NOTCH1-activated ACC. Clinical trial information: NCT04973683. Research Sponsor: U.S. Department of Defense.

6120 Poster Session

Long-term outcomes of SINTART 1 and SINTART 2: Two phase II trials of multimodal treatments in patients with locally advanced sinonasal carcinomas. First Author: Arianna Ottini, Head and Neck Cancer Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Sinonasal carcinomas (SNCs) are rare malignancies with poor prognosis. Multimodal treatments including induction chemotherapy (ICT), surgery and radiotherapy (RT) - modulated by histology and response to ICT - are often used, aiming to improve oncological outcome in terms of local control and survival. Two phase II clinical studies published in 2023 assessed the role of ICT in SNCs, SINTART1 and 2 for resectable and unresectable tumors, respectively [PMIDs: 37164774, 37163806]. The current work aims at reporting the long-term follow-up (FUP) data for both trials. **Methods:** The FUP was updated as of January 2026 for patients enrolled in both clinical studies. Median FUP was estimated with reverse Kaplan-Meier method. The following survival times were analyzed with Kaplan-Meier method in each cohort: overall survival (OS), disease-free survival (DFS), loco-regional-free survival (LRFS), distant metastasis-free survival (DMFS). **Results:** The updated median (m) survival times (in months) with their 95% confidence intervals (CI) and the event rates are detailed in Table 1. Pooling together the 2 studies, 30% of patients (18/60) were alive at last follow-up. **Conclusions:** SINTART 1 and 2 represent, to date, the largest prospective cohorts with long-term survival data in SNCs. With a median FUP exceeding 9 years, these results provide a robust benchmark for ICT-based multimodal strategies in this setting. Survival outcomes remain consistent with the initial reports, indicating that prognosis is largely determined within the first 2-3 years, when most deaths occur (approximately 70%). The near-overlap of mDFS and mLRFS identifies loco-regional failure as the predominant pattern of recurrence. Moreover, the short interval between relapse and death underscores the limited opportunity for salvage. These findings collectively emphasize the need for more effective local-intensification approaches and novel systemic agents. Additional analyses are underway to identify prognostic and predictive factors. Clinical trial information: NCT02099175; NCT02099188. Research Sponsor: None.

Clinicopathologic characteristics and treatment outcomes of adenoid cystic carcinoma (ACC) by different primary sites. First Author: Larissa Passarini, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil
