Symptom Science and Palliative Care 828s

The abstracts contained within are published as an online supplement to *Journal of Clinical Oncology* (*JCO*) and carry *JCO* citations. The format for citation of abstracts is as follows: J Clin Oncol 44, 2026 (suppl 16; abstr 1). The format for citation of late-breaking abstracts is as follows: J Clin Oncol 44, 2026 (suppl 17; abstr LBA1).

LBA1 **Plenary Session**

Perioperative (neoadjuvant and adjuvant) apalutamide (APA) + androgen deprivation therapy (ADT) vs placebo (PBO) + ADT with radical prostatectomy (RP) in high-risk localized or locally advanced prostate cancer (HR LPC/LAPC): Final analysis of the PROTEUS phase 3 study. First Author: Mary-Ellen Taplin, Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

LBA2 **Plenary Session**

SARC041: A phase 3 randomized double-blind study of abemaciclib versus placebo in patients with advanced dedifferentiated liposarcoma. First Author: Mark A. Dickson, Memorial Sloan Kettering Cancer Center, New York, NY

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

LBA3 **Plenary Session**

Event-free survival with adjuvant selpercatinib in stage IB-IIIA *RET* fusion-positive NSCLC: Primary results of the phase 3 LIBRETTO-432 trial. First Author: Jonathan W. Goldman, University of California Los Angeles, Los Angeles, CA

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

LBA4 **Plenary Session**

Ivonescimab plus chemotherapy versus tislelizumab plus chemotherapy in previously untreated advanced squamous non–small cell lung cancer: Overall survival results of the phase 3 HARMONi-6 trial. First Author: Chen Zhiwei, Shanghai Chest Hospital, Shanghai, Jiao Tong University, School of Medicine, Shanghai, Shanghai, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

LBA5 **Plenary Session**

Daraxonrasib, a RAS(ON) multi-selective inhibitor vs chemotherapy in previously treated metastatic pancreatic adenocarcinoma (mPDAC): Primary and final analysis from the phase 3 RASolute 302 study. First Author: Brian M. Wolpin, Dana-Farber Cancer Institute, Gastrointestinal Cancer Center, Boston, MA

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

LBA100 **Clinical Science Symposium**

NHS-Galleri: Primary results from a randomised controlled trial to assess the clinical utility of a multi-cancer early detection (MCED) test in population screening. First Author: Robert Charles Swanton, The Francis Crick Institute and University College London Cancer Institute, London, United Kingdom

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

LBA101 **Clinical Science Symposium**

Osimertinib with/without chemotherapy in patients with persistent ctDNA EGFR mutant (EGFRm) NSCLC at 3 weeks after 1L osimertinib: A randomized phase II study (FLAME study). First Author: Zhijie Wang, Cancer Hospital Chinese Academy of Medical Sciences (Langfang Section), Langfang, Hebei, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

102 **Clinical Science Symposium**

Benefit of adjuvant chemotherapy in resected stage I-IV CRC patients based on ctDNA dynamics across two timepoints: Results from GALAXY study. First Author: Mitsuru Yokota, Department of General Surgery, Kurashiki Central Hospital, Okayama, Japan

Background: In current clinical practice, ACT for stages IIB-III CRC is administered as soon as the patient is medically able, and within 8 weeks post-surgery. However, initiation >8 weeks may be appropriate in some patients. The interim analysis of the CIRCULATE-Japan GALAXY showed that patients with ctDNA-negativity during 2-10 weeks post-surgery do not derive benefit from ACT, although a small subset of these ctDNA-negative patients recurred. In this study, we analyzed early ctDNA dynamics to assess if turning ctDNA-positive at 12 weeks identifies the subgroup of initially (4-weeks post-surgery) ctDNA-negative patients who will benefit from ACT. **Methods:** This analysis included 1,034 patients with stage I-IV CRC undergoing curative-intent surgery from the GALAXY study who were ctDNA-negative at the first timepoint (TP#1; 4 $\pm$ 2 weeks post-surgery) and had subsequent ctDNA results available at the second TP (TP#2; 12 $\pm$ 2 weeks post-surgery). ctDNA was assessed using a personalized, tumor-informed assay (Signatera, Natera). DFS was assessed between TP#1-negative patients receiving ACT versus observation, stratified by ctDNA dynamics (turned positive at TP#2 or remained negative at both TPs). Analysis was landmarked at the TP#2 (12 weeks $\pm$ 2 weeks post-surgery) and Hazard ratios (HRs) were estimated using Cox proportional hazards models. **Results:** Of the 1,034 patients with ctDNA-negativity at TP#1 included in this analysis, 47.8% were females, and 73.8% had colon cancer, whereas 26.2% had rectal cancer. The pathologic stage distribution included: 11% Stage I / Low Risk Stage II, 72% High Risk Stage II / Stage III, and 17% Stage IV. The median patient age was 69 years (range 25-93) and the median follow-up was 33 months. Median time to ACT initiation was 6.7 weeks (range 3-12) post-surgery. Among patients who became positive at TP#2 (N=36), ACT was associated with significantly improved DFS compared with observation (HR 0.3; p=0.0165). Two-year DFS rates were 45.5% in the ACT group and 9.8% in the observation group, with a median DFS of 22 months and 2.5 months, respectively. In contrast, among patients who remained ctDNA-negative at both TPs (N=998), DFS outcomes were favorable regardless of ACT administration (HR 0.8, p=0.1744), with 2-year DFS rates of 87.1% and 84.1%, respectively, and median DFS was not reached in either group. **Conclusions:** A statistically significant and clinically meaningful benefit of ACT in resected stage I-IV CRC patients who were ctDNA-negative at 4 weeks but converted to positive at 12 weeks post-surgery was observed. These results underscore the critical role of both the 4- and 12-week post-surgery time points for risk stratification and indicate that early ctDNA dynamics can identify a subgroup of initially ctDNA-negative patients who may benefit from delayed ACT. Clinical trial information: UMIN000039205. Research Sponsor: Japan Agency for Medical Research and Development: 19ck0106447h0002, 21ck0106711h0001, 21ck0106710h0001, 22lk0201164h0001 and 22lk0201148h0002 National Cancer Center Research and Development Fund; no. 2021-A-6.

103 **Clinical Science Symposium**

Long-term outcomes of ^{18}F-fluoromisonidazole positron emission tomography (FMISO PET)–guided major radiation dose de-escalation in HPV-associated oropharyngeal cancer: The 30 ROC approach. First Author: Nancy Y. Lee, Memorial Sloan Kettering Cancer Center, New York, NY

Background: We previously demonstrated favorable short-term outcomes in patients with human papillomavirus–associated oropharyngeal carcinoma (HPV+ OPC) treated with biologically selected major radiation dose de-escalation, guided by functional hypoxia imaging. We now report mature long-term outcomes from a substantially larger prospective cohort to evaluate the durability and long-term safety of this approach. **Methods:** We conducted a pre-specified integrated analysis of a series of three consecutive phase II trials, each trial representing a progressive refinement with the same therapeutic strategy, enrolling patients with T0–3/N1–2c HPV+ OPC from 10/1/2015 to 11/30/2023. ^{18}F-fluoromisonidazole positron emission tomography (FMISO PET) assessed intratumoral hypoxia to stratify treatment: patients without hypoxia received de-escalated chemoradiotherapy (CRT) to 30Gy, while those with intra-treatment hypoxia received standard CRT to 70Gy. The primary endpoint was 5-year overall survival (OS); secondary endpoints included local, regional, and distant failure, progression-free survival (PFS), treatment-related toxicities, and patient-reported outcomes (PROs). Time-to-event outcomes were analyzed using Kaplan-Meier method and cumulative incidence function. **Results:** A total of 430 patients were enrolled and received treatment. T, N stages were: T0/TX(51), T1(198), T2(173), T3(8); N1 (62), N2a (48), N2b (252), and N2c (68). 96 patients (22.3%) had >10 pack-years of smoking history. There were 323 patients (75%) who had no hypoxia on FMISO PET and received 30Gy while 107 patients (25%) had evidence of intra-treatment tumor hypoxia and received 70Gy. With a median follow-up of 4.05 years (range 1.27–10.03 years), the 5-year OS was 97% in both the 30Gy and 70Gy cohorts. All oncologic endpoints were equivalent in the 30Gy vs 70Gy cohorts: 5-year local failure (2.2% vs 1.9%, p=0.7), regional failure (6.2% vs 3.9%, p=0.4), and PFS (91% vs 89%, p=0.5). Notably, patients with intra-treatment hypoxia, who received 70Gy had higher distant failure rates versus those without intra-treatment hypoxia and received 30Gy (7.5% vs 1.3%, p=0.004). Detailed acute/late toxicities and PROs will be presented at the meeting. **Conclusions:** FMISO PET–guided biological and personalized major radiation dose de-escalation results in durable long-term outcomes, benefiting ~75% of the patients. These findings establish a precision-based paradigm for definitive CRT in HPV+ OPC, currently being validated in an on-going randomized phase III trial (NCT06563479, >1/3 randomized). Patients with intra-treatment hypoxia had a higher rate of distant metastasis where additional therapy can be considered in future trials. Clinical trial information: NCT03323463, NCT05491512. Research Sponsor: U.S. National Institutes of Health.

104 Clinical Science Symposium

Phase 3, multicenter, randomized, controlled open-label study: Efficacy and safety of M701 (EpCAM×CD3 bispecific antibody) intraperitoneal infusion in advanced epithelial solid tumor with malignant ascites vs paracentesis. First Author: Jianming Xu, The First Medical Center, Chinese PLA General Hospital, Beijing, China

Background: Malignant ascites (MA) is a severe complication of advanced epithelial cancers, imposing a heavy symptom burden, compromising systemic therapy efficacy, and correlating with poor survival and impaired quality of life. While only one pharmacologic therapy is approved; guideline-recommended paracentesis provides merely transient symptomatic relief. Consequently, a significant unmet medical need persists for effective therapies that durably control MA. **Methods:** Patients with malignant ascites (MA) secondary to advanced gastric, colorectal, or ovarian cancer after failure of standard anticancer therapy were enrolled. Patients were randomized to Arm T, receiving therapeutic paracentesis plus intraperitoneal M701, or Arm C, receiving paracentesis alone. All patients continued background systemic treatment. The primary endpoint was puncture-free survival (PuFS), defined as the time from Day 18 to the subsequent paracentesis or death. Secondary endpoints included overall survival (OS), time to next paracentesis (TTNP), patient-reported outcomes (PROs) evaluated using the EORTC QLQ-C30 questionnaire and a Likert scale, and safety profiles between the two arms. **Results:** As of January 15, 2026, 312 pts were enrolled (Arm T, n = 206; Arm C, n = 106). Median PuFS was significantly longer in Arm T than in Arm C (87.59 vs 49.96 days; HR = 0.57, 95% CI: 0.42–0.78; p = 0.0003). TTNP was also markedly improved with M701 (186.7 vs 55.1 days; HR = 0.42, 95% CI: 0.29–0.60, p < 0.0001). Overall survival was comparable between arms (p = 0.8407, HR = 0.97, 95% CI: 0.74–1.28). Patient-reported outcomes showed a longer median time to global health status deterioration in Arm T (72.0 vs 39.0 days; HR = 0.73, p = 0.049). A statistically significant between-group difference was observed in the change from baseline in total Likert score at Day 116 (Visit 12) (mean difference −2.45; p = 0.0130), indicating sustained symptom relief with M701. Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 70.39% of patients in Arm T and 51.89% in Arm C. Serious adverse events (SAEs) occurred in 48.54% and 33.02% of patients in the two arms, respectively. Only one grade 1 cytokine release syndrome (CRS) event was reported in Arm T, and the incidence of CRS-like symptoms (e.g., pyrexia and dyspnea) was very low. **Conclusions:** Intraperitoneal M701 was well tolerated when combined with systemic therapy. In patients with epithelial cancer-associated MA, M701 significantly prolonged puncture-free survival with comparable overall survival. These encouraging findings further support the clinical development of M701 and its potential therapeutic role in the management of malignant ascites. Clinical trial information: NCT06432296. Research Sponsor: Wuhan YZY Biopharma Co. Ltd.

105 Clinical Science Symposium

Patient reported outcomes (PRO) during and after multimodal treatment for resectable esophageal adenocarcinoma in the prospective, randomized, controlled, multicenter phase III ESOPEC trial. First Author: Jens Hoeppner, University of Bielefeld, University Medical Center OWL, Campus Hospital Lippe, Bielefeld, Germany

Background: The ESOPEC trial showed that perioperative chemotherapy improved survival compared with preoperative chemoradiotherapy in pts with esophageal adenocarcinoma (EAC). Here we report on PRO which was a key secondary endpoint. **Methods:** Pts with cT1 cN+ cM0 or cT2-4a cNany cM0 EAC were randomized between perioperative chemotherapy with FLOT (5-FU/leucovorin/oxaliplatin/docetaxel) or preoperative chemoradiotherapy with CROSS (41.4Gy/carboplatin/paclitaxel) both plus tumor resection. PRO was measured using the EORTC Quality of Life Questionnaire Core 30 (C30), Oesophageal Cancer Module (OES18) and Chemotherapy-Induced Peripheral Neuropathy Module (CIPN20) at baseline and during treatment and follow-up. The global health status / QOL (GH; C30), physical functioning (PF; C30), fatigue (FA; C30), dyspnoea (DY; C30), eating problems (EP; OES18), and sensory scale (SS; CIPN20) were chosen as primary outcomes. Predefined time points for comparison of PRO between treatment groups were directly before surgery, after discharge from surgery, and 6, 12, 24, and 36 months after start of treatment. Analyses were performed with mixed linear models for repeated measurements. **Results:** Of 438 randomized patients, 401 (197 FLOT, 204 CROSS) were included in the PRO analysis. Differences between The FLOT and CROSS groups are shown in the table. Before, surgery, GH and PF were higher in the FLOT group, while FA, DY, and EP were less pronounced in the FLOT as compared to CROSS group. At discharge from surgery and at follow-up, no significant differences in GH, PF, FA, DY, and EP were measured. Results in SS were worse in FLOT as compared to CROSS at all timepoints. **Conclusions:** Patients treated with FLOT as compared to CROSS reported better PRO results following neoadjuvant therapy and before surgery. In contrast, sensory problems were higher in FLOT versus CROSS over the whole treatment trajectory and follow-up. Clinical trial information: NCT02509286. Research Sponsor: Deutsche Forschungsgemeinschaft.

	Adjusted mean difference in points (FLOT minus CROSS) with 95%-CI and two-sided p-value			
	Preoperatively	Discharge	6 months	36 months

*Higher scores indicate better QOL/function.
**Higher scores indicate more symptoms.

106 Clinical Science Symposium

An actionable machine learning–driven clinicogenomic model as a predictor of brain metastasis risk in breast cancer. First Author: Luke Roy George Pike, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Brain metastasis (BM) is a frequent site of disease progression for patients living with metastatic breast cancer (MBC). Guidelines do not recommend routine MRI brain surveillance in asymptomatic patients. Consequently, patients with MBC who develop BM often present with extensive disease, leading to lasting neurological damage or death. **Methods:** This study included MBC patients without known BM at presentation who underwent genomic sequencing of a non-BM specimen with MSK-IMPACT, a custom tumor-normal next-generation sequencing assay, within one year of M1 diagnosis. We developed an ensemble time-dependent LASSO machine learning (ML) model with BM-free survival (BMFS) as the primary endpoint, integrating baseline clinical, pathologic, and genomic features for risk stratification, using a cross-validation framework. Benchmarking was conducted using a time-dependent neural network designed to model competing risks (DeepHit), and further validation was performed using an independent clinical trial dataset. **Results:** 1594 MBC patients were divided into a training set (n=1118) and a test set (n=476), with 320 events over a median follow-up of 39.7 months. The ensemble ML model identified distinct clinicogenomic features associated with shorter BMFS, including receptor subtype, ER/PR percent positivity, menopausal status, metastatic burden, metastatic site distribution, disease-free interval, and alterations in *TP53*, *ERBB2*, and *RB1*. The model stratified patients into low-, intermediate-, and high-risk groups (training C-index: 0.690; test C-index: 0.696). In the test cohort, 24-month BMFS was 68%, 89%, and 98% in high, intermediate, and low risk groups (HR 19.2, p<0.001 high vs. low risk; HR 6.5, p<0.001 intermediate vs. low risk), with model predictions retaining robust predictive ability beyond 24 months (time-dependent AUC at 10 years of 0.79). These results were confirmed using DeepHit, a competing-risk-specific neural network (training C-index 0.71; test C-index 0.61). The model similarly identified high-risk patients within a single-arm phase II clinical trial dataset utilizing MRI screening in patients with MBC. **Conclusions:** We developed an actionable ML-driven clinicogenomic model that accurately identifies MBC patients at high risk of developing BM. Biologically plausible and readily available features defined a high-risk patient category with a >30% risk of developing BM within 2 years and would likely benefit from MRI screening. The results will be prospectively validated in BRAINSTORM (Breast Cancer Radiologic Assessment and Intervention for Neurological Surveillance, Tracking, and Optimized Risk Management), a phase II randomized clinical trial of intensified MRI surveillance versus standard symptom-based screening in high-risk MBC patients. Research Sponsor: National Cancer Institute; (P30-CA008748).

107 Clinical Science Symposium

External validation of a MMAI model for prognosis and chemotherapy benefit prediction in postmenopausal, node-positive, hormone receptor–positive breast cancer patients: Analysis of SWOG S8814. First Author: Corey Wayne Speers, Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL

Background: Despite effective endocrine therapy, the absolute benefit of adjuvant chemotherapy varies widely in node-positive HR+ disease, particularly among patients with 1-3 positive nodes. Prognostic tools for these patients often rely on genomic assays, which are costly, timely, or inaccessible in many clinical settings. We present a multimodal artificial intelligence (MMAI) model that integrates clinical and histopathological data to quickly stratify risk of distant metastasis and inform therapeutic decisions. Developed in six phase III randomized clinical and validated for chemotherapy benefit in N0 patients, MMAI offers an accessible alternative to genomic tools. Here, we validated MMAI for prognosis and prediction of chemotherapy benefit in SWOG S8814 – a randomized phase III trial of tamoxifen ± chemotherapy (CT) in postmenopausal women with node-positive (N+) HR+ breast cancer. **Methods:** Patients with digitized baseline H&E- stained diagnostic slides and clinical data (age, tumor size, nodal status) were analyzed (N = 413). The locked MMAI generated a continuous risk score and categorical risk groups (low, high). Associations with disease-free survival (DFS; 168 events) and overall survival (OS; 125 events) were assessed using univariable and multivariable Cox Proportional Hazard models. Hazard ratios (HRs) and 95% confidence intervals (CI) were estimated. Differential CT benefit was evaluated by estimating relative risk reduction by MMAI risk groups. **Results:** MMAI was prognostic for DFS (HR per SD 1.73, 95% CI 1.48–2.03; p < 0.001) and OS (HR per SD 1.93, 95% CI 1.60–2.32; p < 0.001), remaining significant after adjustment for age, tumor size, and nodal burden. In the subset of patients with 1–3 positive nodes (n = 253), MMAI identified differential CT benefit: high-risk patients (56% of the patients) demonstrated a 26.3% relative reduction in 10-year DFS risk with CAF-T+TAM versus TAM alone, while low-risk patients (44% of the patients) derived minimal benefit (1.8% relative reduction in 10-year DFS risk). Additionally, the addition of CT resulted in DFS HRs of 1.21 (95% CI: 0.51-2.83) and 0.85 (95% CI: 0.55-1.23) in low- and high-risk patients, respectively. **Conclusions:** In SWOG S8814, a locked MMAI model using routinely available pathology and clinical data independently stratified prognosis and identified node-positive HR+ patients most likely to benefit from adjuvant CT, with minimal benefit among MMAI low-risk patients with 1–3 nodes. These findings support the use of MMAI as a fast (hours instead of weeks), scalable, cost-effective, and non-tissue consumptive alternative to genomic testing to inform adjuvant decisions in HR+ N+ EBC patients. Research Sponsor: None.

108 Clinical Science Symposium

An AI-based pathology classifier to predict benefit from enzalutamide in metastatic hormone-sensitive prostate cancer (mHSPC) from ENZAMET (ANZUP 1304). First Author: Sebastian R. Medina, Wallace H. Coulter Department of Biomedical Engineering at Georgia Tech and Emory University, Atlanta, GA

Background: The ENZAMET trial established that adding enzalutamide (ENZ) to androgen deprivation therapy (ADT) improves overall survival (OS) in mHSPC. However, heterogeneity in treatment response and toxicity complicate clinical decision-making. We evaluated a previously developed Artificial Intelligence Pathology Image Classifier (APIC) to determine whether it could identify ENZAMET participants (pts) more likely to benefit from adding ENZ rather than NSAA to ADT. **Methods:** This AI biomarker study analyzed digitized H&E tumor specimens from ENZAMET (ANZUP 1304, NCT02446405), a phase 3 trial randomizing pts with mHSPC to ADT plus ENZ or a non-steroidal antiandrogen (NSAA), with early docetaxel (EDx) permitted. APIC, a model quantifying nuclear morphology and tumor-immune architecture validated in CHAARTED (Medina et al, Clin Can Res 2025), was applied without modification. The primary multivariable analysis evaluated the treatment-APIC interaction for OS using Cox models adjusted for disease volume (CHAARTED criteria), EDx, and age. Sensitivity analyses excluded pts receiving EDx. APIC associations with 18 circulating immune markers were explored. All tests were two-sided with $p<0.05$ considered significant. **Results:** Among 393 evaluable pts (median follow-up 70 months), 248 (63%) were APIC-negative and 145 (37%) APIC-positive. APIC significantly modified ENZ benefit (interaction p=0.010). APIC-negative was associated with improved OS with ENZ versus NSAA (HR 0.42, $p<0.001$; 5-year OS 82% vs 59%), while APIC-positive showed no benefit (HR 0.98, p=0.92; 5-year OS 57% vs 57%). APIC-treatment interaction was significant (p=0.02) in the multivariable model adjusted for clinical covariates. In low-volume disease, ENZ improved OS in APIC-negative (HR 0.19, p=0.0001) but not APIC-positive (HR 1.12, p=0.8; interaction p=0.002). Excluding EDx use (n=227), APIC-negative was associated with ENZ benefit (HR 0.29, $p<0.001$; 5-year OS 88% vs 60%, interaction p=0.043), while no significant benefit was observed for APIC-positive (HR 0.75, p=0.39; 5-year OS 61% vs 54%) (Table). Analysis of circulating immune markers identified elevated plasma myeloid progenitor inhibitory factor 1 (MPIF1) in APIC-positive pts (1.32-fold, 95% CI 1.11–1.58, p=0.002). **Conclusions:** APIC status was associated with benefit of ENZ for pts with mHSPC. APIC might help guide treatment selection for pts with mHSPC considered for androgen receptor pathway inhibitors and/or docetaxel. Clinical trial information: NCT02446405. Implementing a centralized navigator-led and AI-assisted platform to improve lung cancer screening rates and early detection: A 6-year health system analysis. First Author: Jun Zhang, OSF HealthCare Cancer Institute, Peoria, IL

Background: Despite the known mortality benefits of low-dose computed tomography (LDCT) for lung cancer screening (LCS), national uptake remains stagnant (~15-20%). Significant barriers include primary care burden and geographic disparities in rural areas. This study evaluates the impact of a centralized navigation model combined with AI-assisted electronic health record (EHR) alerts on LCS rates and stage distribution within a large integrated health system. **Methods:** We conducted a retrospective analysis of LCS performance across a 16-hospital system (OSF HealthCare) from 2019 to 2025. The intervention included: 1) centralization of LCS navigators to manage registries and scheduling, and 2) implementation of AI-assisted EHR alerts to identify eligible high-risk patients. Outcome measures included absolute LDCT volume, system-wide screening rates, and AJCC staging at diagnosis. Benchmarks were derived from American Lung Association (ALA) national and state (Illinois) data. **Results:** The system-wide LCS screening rate increased from 18.2% in 2020 to 42.8% in 2025, significantly outperforming the projected 2025 US national average (19.5%) and the Illinois state average (20.8%). Absolute screening volume nearly doubled, rising from 2,257 scans in 2019 to 4,108 in 2025. Notably, the program demonstrated high resilience during the 2020 COVID-19 pandemic, maintaining 98.5% of prior-year volume compared to a 5% national decline. Early-stage detection (Stage I) showed the greatest improvement in rural facilities, with some centers seeing a +21% increase in Stage I diagnoses over the study period. **Conclusions:** A centralized, technology-enabled navigation model effectively doubles the national benchmark for lung cancer screening uptake. By removing administrative burdens from primary care and utilizing AI-assisted EHR alert system to close the "eligibility gap", this model provides a scalable blueprint for improving early cancer detection and addressing rural health inequities. Research Sponsor: None.

OSF HealthCare lung cancer screening performance vs. national benchmarks (2020–2025).

Year	OSF Annual LDCT Volume	OSF Screening Rate (%)	National Screening Rate (%)*	Performance Gap (Percentage Points)
2020	2,223	18.2%	14.5%	+3.7%
2021	2,647	21.4%	14.8%	+6.6%
2022	3,280	27.8%	15.5%	+12.3%
2023	3,406	33.6%	16.0%	+17.6%
2024	3,522	38.2%	18.2%	+20.0%
2025	4,108	42.8%	19.5%	**+23.3%**

*National benchmarks based on American Lung Association "State of Lung Cancer" annual reports and CDC/ACS prevalence estimates.

500 Oral Abstract Session

First results from the OPTIMA phase III randomized non-inferiority trial of test-directed chemotherapy in patients with high clinical risk ER-positive HER2-negative early breast cancer. First Author: Robert C. Stein, National Institute for Health Research University College London Hospitals Biomedical Research Centre, London, United Kingdom

Background: Tumor gene expression tests are widely used to assist adjuvant chemotherapy decisions for women with early breast cancer (EBC). OPTIMA (Optimal Personalised Treatment of early breast cancer using Multi-parameter Analysis) is an international RCT comparing chemotherapy decisions made with the Prosigna (PAM50) gene expression test with standard treatment in mostly node-positive patients. **Methods:** Women and men aged >40 recommended to receive chemotherapy for ER+ HER2- EBC with 0-9 involved axillary nodes and T size >30mm if node negative were eligible. Randomization was between standard chemotherapy followed by endocrine therapy (CET) or to a Prosigna test directed chemotherapy decision. Patients with Prosigna ROR score > 60 tumors were assigned CET whilst those with low ROR score (≤60) tumors received endocrine therapy (ET) alone. ET for premenopausal women included ovarian function suppression (OFS) in the absence of chemotherapy-induced ovarian insufficiency. ROR scores were not disclosed, and patients receiving CET were blinded to their randomization. OPTIMA was designed to demonstrate non-inferiority (NI) of 5-year invasive breast cancer free survival (IBCFS) in the test-directed arm with a 3% margin in the per protocol (PP) population using a 5% 1-sided alpha. Control arm testing allowed treatment comparison within the low ROR score population at a 3.5% NI margin. **Results:** From 16th Jan 2017 to 12th Dec 2025 4429 patients were randomized, 2215 to the control arm and 2214 to the test-directed arm of whom 2061 (93%) and 2097 (95%) were included in the respective PP group. Patient characteristics in the PP population were well-balanced; 62% were postmenopausal, 37% premenopausal and 0.8% male. 73% had pN1/pN1sn, 8% had pN0/pN1mi and 19% had pN2 tumors. 68% had low ROR score tumors. With a median follow-up of 3.9 years (interquartile range 2.0-5.9), 280 IBCFS events occurred (141 on control arm; 139 on test directed arm) of which 66% were distant recurrences. The 5-year IBCFS rate in the control arm was 91.5% [95% CI 89.7- 92.9%] and 90.4% [95% CI 88.6-92.0%] in the test-directed arm, Hazard Ratio (HR) 0.99 [90% CI 0.81- 1.20], NI p = 0.013, thereby meeting the pre-defined NI margin. The corresponding 5-year IBCFS rates for the low ROR score population were 94.9% [95% CI 92.9- 96.4%] and 93.7% [95% CI 91.8- 95.2%] for the two arms respectively, HR 1.06 [90% CI 0.78- 1.46] NI p = 0.0051 again demonstrating non-inferiority. There was no significant outcome heterogeneity between subgroups including for menopausal and nodal status. **Conclusions:** The OPTIMA trial demonstrates that women and men with ER+ HER2-EBC and ROR score ≤60 tumors can safely avoid chemotherapy. It provides evidence for the utility of test-directed chemotherapy in premenopausal women treated with OFS and patients with high levels of nodal involvement. 501 Oral Abstract Session

Prognostic and predictive impact of baseline gene expression (exp) in the NATALEE trial of adjuvant (adj) ribociclib (RIB) + nonsteroidal aromatase inhibitor (NSAI) in HR+/HER2− early breast cancer (EBC). First Author: Stephen K.L. Chia, BC Cancer Agency, Vancouver, BC, Canada

Background: In the NATALEE clinical trial, RIB + NSAI significantly improved invasive disease–free survival (iDFS) vs NSAI alone in patients (pts) with stage II/III HR+/HER2− EBC. We report on the prognostic and predictive value of baseline gene exp in NATALEE. **Methods:** Pts were randomized 1:1 to RIB + NSAI or NSAI alone. Men and premenopausal women received goserelin. Eligible pts had anatomical stage IIA (if N0 with additional risk factors [G3, or G2 with Ki67 ≥20% or high genomic risk] or N1 [1-3 axillary lymph nodes]), IIB, or III disease per AJCC (8th ed). Gene exp in surgical samples was profiled by NanoString BC360 panel. PAM50-based intrinsic subtype × treatment (tx) interaction was estimated by likelihood ratio test. Prognostic and predictive effects of PAM50 subtypes and genomic risk/proliferation signature scores created from gene exp data were assessed with Cox proportional hazards models. Differences in genomic risk and proliferation scores were analyzed by Wilcoxon test. Associations between gene exp and RIB benefit were estimated with Cox models. **Results:** In all, 3022 baseline surgical samples were analyzed. iDFS benefit with RIB + NSAI was consistent in the biomarker (hazard ratio [HR], 0.72) and intent-to-treat populations (HR, 0.71). PAM50 subtype distribution was comparable across tx arms and differed between N0 and N1-N3 in pts with luminal A (LumA; 50% vs 68%), luminal B (lumB; 41% vs 26%), and basal-like (BSL; 6.4% vs 2.5%) disease, with similar percentages for HER2-enriched (HER2E; 2.5% vs 3.0%). PAM50 subtypes were strongly prognostic (HRs vs LumA: LumB, 1.39; HER2E, 2.62; BSL, 3.92). RIB had benefit across all PAM50 subtypes (HRs: LumA, 0.77; LumB, 0.71; HER2E, 0.50; BSL, 0.42), with no significant subtype × tx interaction (P= .34). Higher genomic risk signature or proliferation signature scores showed a trend for increased RIB benefit, again with no significant interaction. Pts with N0 vs N1-N3 had significantly higher genomic risk scores and proliferation scores. Exploratory analysis of the predictive effect of gene exp on RIB benefit identified several genes for which higher (eg, *CEACAM6*, *NOD2*, and *GPX3)* or lower exp (eg, *GATA3*, *SLC39A6*, and *MAPT*) was associated with increased RIB benefit. **Conclusions:** In this analysis of NATALEE, which examined the largest dataset of surgical tumor samples from any adj CDK4/6i trial in HR+/HER2− EBC, RIB had benefit across all PAM50 subtypes, with a trend for increased benefit in pts with higher genomic risk signature or proliferation signature scores. Baseline exp levels of several genes were associated with differential RIB benefit in EBC, showing potential predictive and prognostic value. The findings reinforce the therapeutic benefit of RIB in combination with ET across HR+/HER2− EBC populations. Clinical trial information: NCT03701334. Research Sponsor: Novartis Pharmaceuticals Corporation.

502 Oral Abstract Session

Efficacy and safety of giredestrant (GIRE) in patients (pts) with estrogen receptor–positive, HER2-negative early breast cancer (ER+, HER2– eBC) in the phase III lidERA BC clinical trial: Results by menopausal status. First Author: Peter Schmid, Queen Mary University of London, London, United Kingdom

Background: The lidERA BC trial (NCT04961996) demonstrated a statistically significant, clinically meaningful improvement in invasive disease-free survival (IDFS) with GIRE (a next-generation oral SERD and full ER antagonist) vs standard-of-care endocrine therapy (SOC ET) in ER+, HER2–, Stage I–III eBC (Bardia SABCS 2025). We report efficacy and safety in pre-menopausal (PRE-M) vs post-menopausal (POST-M) pts. **Methods:** Pts with ER+, HER2– eBC who had BC surgery and (neo)adjuvant chemotherapy (if indicated) were randomized 1:1 to once-daily 30 mg GIRE or SOC ET (anastrozole/letrozole/exemestane [aromatase inhibitors; AIs] or tamoxifen [TAM]) for 5 years (y) of treatment (tx). PRE-M pts on GIRE and on AIs received an LHRH. **Results:** In the efficacy-evaluable population (n = 4170), 40.7% of pts were PRE-M and 59.3% POST-M. 58.0% of pts on TAM received LHRH. PRE-M pts generally had a slightly higher baseline risk of recurrence vs POST-M pts (high risk, 70.5% vs 66.4%; medium risk, 28.4% vs 32.5%; higher use of [neo]adjuvant chemotherapy, 91.2% vs 78.9%). GIRE showed IDFS benefit and higher 3-y rates in both PRE-M and POST-M subgroups; a similar trend was observed for distant recurrence-free interval (DRFI) (Table). Adverse events (AE) were comparable in both subgroups and across txs (Table). Fewer pts discontinued GIRE due to AEs compared with pts receiving an AI, regardless of menopausal status. Discontinuation due to musculoskeletal pain occurred in 1.6% vs 4.5% of pts receiving GIRE vs AI, respectively. More pts switched to alternative ET in the SOC ET arm vs GIRE (10.1% vs 5.7%), mainly due to AEs for both arms. **Conclusions:** Adjuvant GIRE improved IDFS and DRFI vs SOC ET; benefit was consistent irrespective of menopausal status. PRE-M pts experienced a 42% reduction in the risk of developing metastatic disease and POST-M pts a 24% reduction. Safety was comparable between menopausal groups and there were few discontinuations, regardless of menopausal status, although PRE-M and POST-M pts receiving GIRE had fewer tx discontinuations than those receiving an AI or TAM in the PRE-M and POST-M settings. Clinical trial information: NCT04961996. Research Sponsor: F. Hoffmann-La Roche Ltd.

Omission of completion axillary dissection in patients with breast cancer and sentinel lymph node macrometastases: Overall survival and patient-reported arm morbidity from the randomized SENOMAC trial. First Author: Jana de Boniface, Department of Surgery, Capio St. Göran's Hospital and Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

504 **Oral Abstract Session**

Surgical de-escalation of implant-based breast reconstruction (IBBR) after mastectomy for breast cancer treatment or prevention: The international randomized phase III PREPEC trial (OPBC-02). First Author: Walter Weber, University Hospital Basel and Faculty of Medicine University of Basel, Basel, Switzerland

Background: The optimal positioning of implants following skin- (SSM) or nipple-sparing mastectomy (NSM) for breast cancer treatment or prevention is unclear. Pre-pectoral IBBR obviates the need to dissect the major pectoral muscle but provides less soft tissue coverage of the implant. The PREPEC trial hypothesized pre-pectoral IBBR would result in improved long-term quality of life (QoL) compared to sub-pectoral IBBR. **Methods:** OPBC-02/PREPEC (NCT04293146) was a pragmatic, international, randomized, phase III superiority trial. Women ≥18 years undergoing SSM or NSM for treatment or prevention of breast cancer were randomized (1:1) to pre-pectoral or sub-pectoral IBBR. Surgery otherwise followed standards of care. The primary endpoint was patient-reported physical well-being chest as assessed by BREAST-Q 24 mo after surgery (prespecified MID 4 points; SD 13). 372 pts provided 80% power (two-sided t-test α = 0.05). Multiple imputation was implemented for missing scores across all timepoints (day 10; 1, 6, 12, 18, 24 mo). The IBBR assignment difference at 24 mo was estimated by linear mixed modeling, adjusted for baseline score, stratification factors, pre-selected covariates, and random center effect. Loss or replacement of expander or implant for any reason within 24 mo was the primary safety endpoint. **Results:** From July 2020 to February 2023, 383 pts were randomized at 26 OPBC centers in 10 countries. The full analysis set comprised 380 pts (191 randomized to pre-pectoral, 189 to sub-pectoral IBBR). Surgery was unilateral in 72.9% of pts and NSM in 58.4%. The setting was therapeutic in 77.9% of pts, therapeutic and preventive in 15.5%, and preventive in 6.6%. BREAST-Q completion was 83-95% across 6 post-baseline timepoints. Pre-pectoral IBBR significantly improved physical well-being at 24 mo compared to sub-pectoral IBBR (least-square means 79.2 [95%CI 75.5-82.8] vs 74.3 [70.7-78.0], respectively). The mean difference of 4.8 (95%CI 1.0-8.7; p = 0.01) surpassed the predefined threshold for a clinically meaningful difference. The effect was robust in sensitivity analyses, and consistent in subgroup analyses. Loss or replacement of expander or implant for any reason within 24 mo occurred in 68 pts, 21.1% vs 14.5% after pre-pectoral and sub-pectoral IBBR, respectively. The covariate-adjusted model estimated 5.7% (95%CI -2.4% - 13.8%) more implant loss with pre-pectoral IBBR. At least one complication occurred in 54.1% vs 55.9% of pts, respectively. Early complications were more frequent after pre-pectoral IBBR (crude estimated increase range 3-5%); late complications were more frequent after sub-pectoral IBBR. **Conclusions:** Pre-pectoral IBBR significantly and relevantly improved long-term QoL at the cost of a higher risk of loss or replacement of expander or implant compared to sub-pectoral IBBR. Clinical trial information: NCT04293146. Research Sponsor: Swiss National Science Foundation; Krebsliga beider Basel; Swiss Cancer Research foundation.

Prediction of axillary response in 5,262 patients with node-positive breast cancer treated with neoadjuvant chemotherapy: Results from the prospective multicenter AXSANA/EUBREAST-03/AGO-B-053 study. First Author: Maggie Banys-Paluchowski, Department of Gynecology and Obstetrics, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany

Background: Axillary lymph node dissection (ALND) for node-positive breast cancer (BC) converting to clinical node-negativity after neoadjuvant chemotherapy (NACT) is increasingly being replaced by less invasive procedures, such as sentinel lymph node biopsy (SLNB) or targeted axillary dissection (TAD). Concerns remain regarding the use of de-escalated procedures in patients with high initial nodal burden. We aimed to determine factors associated with nodal response, with a focus on tumor biology and nodal burden, to enable less extensive surgery without compromising oncological outcomes. **Methods:** AXSANA is an ongoing study investigating oncological and patient-reported outcomes after different axillary procedures in cN+ BC treated with NACT. In the present analysis, the impact of nodal involvement and tumor biology on axillary response was analyzed. The entire dataset is continuously and systematically monitored for data quality assurance. **Results:** 7,071 patients from 288 sites in 26 countries were included between June 2020 and January 7th, 2026. Of these, 5,262 had completed surgery at the time of analysis. 2,341 patients (44.5%) had HR+ HER2- disease, followed by HR+ HER2+ (1,244; 23.6%), triple-negative (1,053; 20.1%) and HR- HER2+ (618; 11.7%). 91.3% of patients had an invasive ductal carcinoma of no special type (NST). 1,158 (22.1%) had ≥ 4 suspicious nodes at time of diagnosis. The highest nodal pCR rate (ypN0) was observed in patients with HR- HER2+ disease (86.1%), followed by HR+ HER2+ (70.7%), triple-negative (68.5%), and HR+ HER2- (30.5%; p < 0.001). Nodal pCR rate was higher in patients with NST tumors (55.6%), compared to those with invasive lobular (35.2%) and mixed histology (43.8%; p < 0.001). Patients with higher Ki67 (p < 0.001), higher grading (p < 0.001), multicentric tumors (p = 0.001), and without lymphangitis carcinomatosa (p = 0.046) were more likely to achieve nodal pCR in the univariate analysis. In contrast, the number of suspicious nodes at the time of diagnosis was not associated with axillary response (ypN0: 54.4% in pts. with 1-3 suspicious nodes vs. 53.6% in ≥ 4 suspicious nodes; p = 0.670). In the multivariable analysis, receptor status, Ki67, and grading, but not the number of suspicious lymph nodes at the time of diagnosis, were significantly associated with axillary response to treatment. **Conclusions:** This large prospective analysis shows that tumor biology, rather than the extent of nodal involvement is associated with axillary response to NACT. This challenges current guidelines and the common approach of restricting surgical de-escalation to patients with a low axillary tumor burden at presentation, and suggests that the selection of candidates for a potential de-escalation should be based on tumor biology rather than the extent of axillary disease at diagnosis. Clinical trial information: NCT04373655. Updated overall survival results from a randomized phase III trial of non–cross-resistant adjuvant chemotherapy plus endocrine therapy versus endocrine therapy alone in HR+/HER2−/lymph node–positive breast cancer with residual disease following neoadjuvant chemotherapy (NCT01019616). First Author: Yang Yang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Breast Center, Peking University Cancer Hospital & Institute, Beijing, China

Background: Patients with HR+/HER2−, node-positive breast cancer and residual disease after neoadjuvant chemotherapy (NAC) represent a high-risk population yet substantial recurrence risk. Whether additional non-cross-resistant chemotherapy after surgery provides long-term survival benefit beyond endocrine therapy remains uncertain. Our previous analysis of this phase III trial (NCT01019616) with shorter follow-up (median, 72.4 months) did not show a statistically significant survival benefit. Here we report updated survival outcomes with extended follow-up. **Methods:** Women aged < 65 years with invasive HR+/HER2−, node-positive breast cancer who completed anthracycline-containing NAC and had residual disease (Miller–Payne grade 1–3 and/or residual nodal involvement) were randomized 1:1 to receive either 4 cycles of non-cross-resistant adjuvant chemotherapy plus endocrine therapy (CT+ET) or endocrine therapy alone (ET). The primary endpoint was distant disease-free survival (DDFS); overall survival (OS) was a secondary endpoint. Hazard ratios (HRs) were estimated using Cox proportional hazards models with multivariable adjustment. **Results:** A total of 379 patients were randomized (CT+ET, *n* = 187; ET, *n* = 192) with balanced baseline characteristics. At median follow-up of 135.0 months, 52 deaths occurred: 18 (9.6%) in CT+ET versus 34 (17.7%) in ET. OS was significantly improved with CT+ET (log-rank *P* = 0.023). Ten-year OS rates were 89.9% versus 82.9% (adjusted HR, 0.56; 95% CI, 0.32–0.99; *P* = 0.048). DDFS showed a favorable trend (*P* = 0.059) with 10-year rates of 85.5% versus 78.3% (adjusted HR, 0.67; 95% CI, 0.41–1.09). Greatest benefit was observed in patients with residual node-positive disease (OS HR, 0.47) and Miller–Payne grade 3 response (OS HR, 0.31). **Conclusions:** This randomized phase III trial demonstrates long-term overall survival benefit from the addition of non-cross-resistant chemotherapy to endocrine therapy for HR+/HER2−, node-positive patients with residual disease after NAC. Clinical trial information: NCT01019616. Research Sponsor: None.

507 **Oral Abstract Session**

Neoadjuvant pembrolizumab or placebo plus chemotherapy followed by adjuvant pembrolizumab or placebo for high-risk early-stage TNBC: Final analysis results from the phase 3 KEYNOTE-522 study. First Author: Peter Schmid, Centre for Experimental Cancer Medicine, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

Background: KEYNOTE-522 (NCT03036488) showed statistically significant and clinically meaningful improvements in pCR, EFS, and OS with the addition of pembrolizumab (pembro) to chemotherapy (chemo) in participants (pts) with high-risk early-stage TNBC. Here, we present updated results from the final analysis. **Methods:** Eligible pts with previously untreated, non-metastatic, centrally confirmed TNBC (stage T1c N1-2 or T2-4 N0-2 per AJCC) were randomized 2:1 to neoadjuvant pembro 200 mg Q3W or placebo (pbo), both given with 4 cycles of paclitaxel + carboplatin, then 4 cycles of doxorubicin or epirubicin + cyclophosphamide. After definitive surgery, pts received adjuvant pembro or pbo for 9 cycles or until recurrence or unacceptable toxicity. Dual primary endpoints are pCR (ypT0/Tis ypN0) and EFS (time from randomization to disease progression that precluded definitive surgery, local/distant recurrence, second primary cancer, or death from any cause); OS is the key secondary endpoint. **Results:** 1174 pts were randomized to pembro (n = 784) or pbo (n = 390). At the data cutoff date (October 14, 2025), median follow-up (range) was 93.8 mo (84.7-102.8). The 7-yr EFS rate (95% CI) was 78.3% (75.3-81.1) in the pembro group vs 69.8% (65.0-74.2) in the pbo group; the HR was 0.68 (95% CI, 0.54-0.86). The 7-yr OS rate (95% CI) was 85.1% (82.5-87.5) in the pembro group vs 77.2% (72.7-81.1) in the pbo group; the HR was 0.64 (95% CI, 0.49-0.85). The benefit of pembro on EFS and OS was generally consistent across most prespecified subgroups, including those defined by PD-L1 expression, nodal status, and disease stage. Rates of grade ≥3 treatment-related AEs were 77.1% in the pembro group and 73.3% in the pbo group (death incidence, 0.5% vs 0.3%, respectively); rates of any grade immune-mediated AEs were 35.0% vs 13.1%, respectively. **Conclusions:** After a median follow-up of 7.8 years, neoadjuvant pembro + chemo followed by adjuvant pembro continues to show a clinically meaningful survival benefit compared with neoadjuvant chemo alone in pts with high-risk early-stage TNBC. Clinical trial information: NCT03036488. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Adjuvant capecitabine and trastuzumab for stage IA HER2-positive breast cancer (IRIS-A): A phase II clinical trial. First Author: Ruoxi Wang, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Weekly paclitaxel and trastuzumab represents a standard option for most stage I human epidermal growth factor receptor type 2 (HER2)-positive breast cancer (BC)s based on results of the single arm phase II APT trial. However, the protocol-induced toxicity was not absent, prompting interest in better tolerated approaches that retain high clinical efficacy. The series of "IRIS" study including cohort A(2020, capecitabine and trastuzumab), B(2020, endocrine therapy and trastuzumab), C (2021, short-period capecitabine and trastuzumab) and D (2021, vinorelbine and trastuzumab) were designed as single arm trials regarding de-escaltion of adjuvant therapy without intravenous chemotherapy in early-stage HER2+ BCs. Herein we reported the results of IRIS-A, a single-group, phase II study to determine whether treatment with capecitabine and trastuzumab was well tolerated and yielded clinically acceptable outcome among stage IA HER2-positive breast cancer. **Methods:** Patients with stage IA (T1N0: hormonal receptor (HR) $<$ 10%, T$\leq$2cm or HR$\geq$10%, 1cm $<$ T$\leq$2cm) confirmed HER2+ BC were received oral capecitabine (1000 mg/m^2 twice daily for two weeks), and trastuzumab(8 mg/kg load$\rightarrow$6 mg/kg) every 3 weeks for 6 cycles, followed by 11 cycles of trastuzumab monotherapy (6 mg/kg once every 3 weeks). The primary end point was survival free from invasive disease (iDFS). **Results:** A total of 187 patients were enrolled in this study between May 20, 2020 and May 27, 2021 at Fudan University Shanghai Cancer Center in China. Among all these patients, 80.2% had tumors that measured 0.5 cm or less in the greatest dimension; a majority of tumors (87.2%) were hormone-receptor-negative. The median follow-up period was 62 months(ranges 56-68). The 5-year rate of survival free from invasive disease was 97.9% (95% confidence interval [CI], 94.4 to 99.2). Among the 4 relapses seen, 2 were due to contralateral primary invasive breast cancer (HER2-negative). Excluding these 2 patients and nonbreast cancers, 2 disease-specific events (1 with ipsilateral axilla and ipsilateral breast) were noted. There was no death in this trial. A total of 5 patients (2.7%) reported at least one episode of grade 3 adverse effect (AE)s, which did not influence the completion of treatment. The most common AE was hand-foot syndrome (46.5%), with 1.1% of patients experiencing a grade 3 event. **Conclusions:** Among patients with stage IA HER2+ BCs, treatment with adjuvant capecitabine plus trastuzumab was associated with an excellent 5-year iDFS of 97.9%. No adverse events that influence treatment continuity were observed. The regimen used in this trial would be an alternative in patients with small size HER2+ tumors with fewer toxic effects than the established regimens. A phase III study using the same protocol is being conducted currently. Clinical trial information: NCT04383275. Research Sponsor: None.

Neoadjuvant pyrotinib vs pertuzumab therapy for HER2-positive early breast cancer: The HELEN HER-013 randomized clinical trial. First Author: Jiujun Zhu, Department of Breast Disease, Henan Breast Cancer Center, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: Docetaxel, carboplatin, trastuzumab, and pertuzumab (TCHP) is a standard neoadjuvant regimen for stage II–III human epidermal growth factor receptor 2 (HER2)–positive breast cancer; however, its use is associated with substantial treatment burden, particularly hematologic toxicity, highlighting the need for alternative strategies that maintain efficacy with different toxicity profiles.This study to determine whether a chemotherapy-de-escalated regimen of nanoparticle albumin–bound paclitaxel, trastuzumab, and the tyrosine kinase inhibitor pyrotinib (nab-PHPy) is noninferior to standard TCHP with respect to pathological complete response (pCR). **Methods:** The HELEN HER-013 trial was a multicenter, randomized, open-label, phase 3 noninferiority trial conducted at 15 centers in China. Women with previously untreated, operable stage II–III HER2-positive breast cancer were enrolled between May 2023 and May 2025.Participants were randomly assigned (1:1) to receive six 21-day cycles of either nab-paclitaxel, trastuzumab, and oral pyrotinib (nab-PHPy group) or TCHP group.The primary end point was pCR (ypT0/Tis ypN0), assessed in the modified intention-to-treat (mITT) population (patients who received $\geq$1 dose of study treatment). The prespecified noninferiority margin was $-$5.5%(ClinicalTrials.gov Identifier: NCT05918328). **Results:** Among 709 screened individuals, 610 were randomized, and 589 were included in the mITT population (295 in the nab-PHPy group and 294 in the TCHP group; all female). Median age was 51 years (interquartile range [IQR], 43–56) in the nab-PHPy group and 52 years (IQR, 45–57) in the TCHP group. The primary end point of pCR was achieved in 186 patients (63.1%; 95% CI, 57.4%–68.4%) in the nab-PHPy group and 174 patients (59.2%; 95% CI, 53.4%–64.8%) in the TCHP group. The between-group difference was 3.9% (95% CI, -4.2% to 11.9%), which met the prespecified criterion for noninferiority (noninferiority P = .01). Grade 3 or higher treatment-emergent adverse events occurred in 113 patients (38.3%) receiving nab-PHPy and 107 patients (36.4%) receiving TCHP. The most common grade 3 or higher adverse events were diarrhea (31.5% vs 17.0%), anemia (1.7% vs 10.2%), and nausea (0% vs 5.8%). No treatment-related deaths were reported. **Conclusions:** Among women with operable stage II–III HER2-positive breast cancer, neoadjuvant treatment with nab-PHPy was noninferior to TCHP with respect to pCR and was associated with a distinct toxicity profile, supporting its role as an alternative neoadjuvant strategy. Clinical trial information: NCT05918328. Research Sponsor: None.

The effects of Mediterranean diet, physical activity, and vitamin D on breast cancer recurrence and cardiometabolic health: A multicenter randomized trial. First Author: Livia Augustin, Istituto Nazionale Tumori IRCCS Fondazione G. Pascale, Napoli, Italy

Background: Low quality diets and physical inactivity are two modifiable lifestyle factors that together with vitamin D deficiency have been associated with unfavorable breast cancer (BC) outcomes and cardiometabolic health. We therefore tested the effect of a lifestyle program on BC recurrence and cardiometabolic risk factors on a background of vitamin D sufficiency. **Methods:** Women aged 30-74 years were enrolled in a phase III trial (NCT02786875) within 12 months of their primary BC diagnosis (stages I-III) in 7 oncologic centres in Italy. Consenting participants were randomized to one of two lifestyle treatments lasting 33 months: 1) positive control (n = 249), standard advice on a Mediterranean diet (MedDiet) and avoidance of sedentary behavior; 2) intervention (n = 243), high intensity advice on low-glycemic index MedDiet and 30-minute additional daily brisk walking. Oral vitamin D3 was administered throughout. Data were collected quarterly on health status, anthropometry, 7-day food records, daily steps, serum 25(OH)D concentrations and metabolic syndrome parameters. The primary outcome was BC recurrence (intention to treat analysis) at 33 months, with cardiometabolic risk factors as secondary outcomes. Hazard ratios (HR) and 95% confidence intervals (CI) for BC recurrence were computed using Cox proportional hazards models adjusted for recruitment center. One-year changes in treatment variables and cardiometabolic risk factors were tested by paired Student's t-test within each treatment arm and by analysis of covariance between treatment arms, adjusted for baseline values. **Results:** Approximately 58% of patients were aged $\geq$50 years, 94% were postmenopausal, 86% had stages I-IIB and 75% hormone-positive BC. A total of 37 recurrences were observed with no differences between arms (HR = 0.94, 95%CI: 0.49-1.79). Independently of randomization arm, women with hormone-positive BC who were more adherent to the intervention program (41%), showed 76% lower risk of BC recurrence (HR = 0.24, 95% CI: 0.06-0.95). Weight loss of 3 kg, representing a 4.2% drop of initial body weight, was significantly greater in the test arm compared to 1.7 kg or 2.4% in the control arm (p = 0.0034). This translated in reductions of body mass index from 27.5$\pm$5.7 to 26.3$\pm$5.4 kg/m^2 in the intervention arm and from 27.2$\pm$5.1 to 26.6$\pm$5.1 kg/m^2 in controls (p = 0.0032). The presence of metabolic syndrome dropped by 65% in the intervention arm and 34% in controls (p = 0.008). The probability of metabolic syndrome remission was 2.5-fold higher in the intervention arm. **Conclusions:** A safe and low-cost lifestyle program with low-glycemic index MedDiet, daily brisk walking and oral vitamin D supplementation resulted in weight loss, reduced metabolic syndrome prevalence and was significantly associated with lower recurrences in women with hormone-positive BC. Clinical trial information: NCT02786875. Research Sponsor: None.

Effect of elinzanetant on sleep disturbance and aspects of quality of life in women with breast cancer experiencing vasomotor symptoms: OASIS-4 subgroup analysis by type of endocrine therapy. First Author: Claudio Soares, Queen's University, Kingston, ON, Canada

Background: In the Phase III OASIS-4 trial, elinzanetant (EZN), a dual neurokinin (NK)-targeted therapy (NK-1 and NK-3 receptor antagonist), significantly improved vasomotor symptoms (VMS), sleep disturbance and menopause-related quality of life (QoL) in women taking endocrine therapy (ET) for breast cancer. This post hoc analysis evaluated the effect of EZN on sleep disturbance and menopause-related QoL by ET type. **Methods:** Women aged 18–70 years with ≥35 moderate-to-severe ET-associated VMS/week were randomized 2:1 to EZN 120 mg daily for 52 weeks or placebo (PBO) for 12 weeks then EZN 120 mg for 40 weeks. Mean change from baseline (BL) to week 12 in Patient-Reported Outcomes Measurement Information System Sleep Disturbance Short Form (PROMIS SD SF) 8b total T-score (range 28.9–76.5; < 55 normal, 55– < 60 mild, 60– < 70 moderate, ≥70 severe) and Menopause-specific QoL questionnaire (MENQOL) total/domain scores (range 1–8; higher score indicates greater bother) were analyzed descriptively by ET type (tamoxifen [TAM], aromatase inhibitor [AI], ovarian function suppression [OFS], no OFS). **Results:** Mean BL PROMIS SD SF 8b total T-scores and MENQOL total scores were numerically similar across ET subgroups (Table), with some variability in MENQOL domain scores (ranges: vasomotor 6.6–6.9; psychosocial 3.3–4.2; physical 4.1–4.6; sexual 3.7–5.5). Greater numerical reductions with EZN vs PBO from BL to week 12 were observed across all subgroups for PROMIS SD SF 8b total T-score and MENQOL total score (Table), as well as MENQOL domain scores (ranges: vasomotor -2.6 to -2.9 vs -1.2 to -1.5; psychosocial -0.8 to -1.0 vs -0.4 to -0.6; physical -0.7 to -0.9 vs -0.3; sexual -0.5 to -0.9 vs -0.3 to 0.0). **Conclusions:** In this post hoc analysis, EZN consistently improved sleep disturbance and menopause-related QoL, including vasomotor, psychosocial, physical and sexual aspects, across all ET subgroups. Taken with previous data, findings suggest to support the efficacy of EZN in reducing VMS, sleep disturbance and improving menopause-related QoL independently of ET type. Research Sponsor: Bayer.

Does resection of cavity shave margins impact survival in breast cancer patients? First Author: Anees B. Chagpar, Yale School of Medicine, New Haven, CT

Background: Randomized controlled trials have shown that resection of cavity shave margins (CSM) halves the margin positivity and re-excision rate in breast cancer (bc) patients (pts), but the impact on overall (OS) and disease-free survival (DFS) remains unclear. **Methods:** Between Oct 21, 2011 and Nov 25, 2013, the SHAVE trial enrolled 235 pts in a single center study. Between Jul 28, 2016 and Apr 13, 2018, SHAVE2 enrolled 396 pts across 9 other US sites. Both studies were similar in their study criteria and methods. Pts ≥ 18 years of age, with planned partial mastectomy (PM) for stage 0-3 bc were eligible. Surgeons performed their standard PM with excision of selective margins as needed based on gross evaluation and specimen radiograph. Pts were then randomized intraoperatively to either "shave" or "no shave" arms. In the former, surgeons were instructed to take additional CSM from ≥4 faces of the cavity; in the latter, to close. Pts were followed for a median of 60.4 months (mo). **Results:** Across both studies (n = 631), the median pt age was 64 (range; 29-94), and the median invasive tumor size was 1 cm (range; 0-8 cm). Forty pts had no further disease at the time of PM either due to all disease being removed in the core biopsy or due to neoadjuvant chemotherapy. Before randomization, margin positivity was similar between the "shave" and "no shave" arms (37.8% vs. 34.8%, p = 0.457). After randomization, the "shave" group had a significantly lower positive margin rate (14.0% vs. 34.8%, p < 0.001) and re-excision rate (9.2% vs. 24.1%, p < 0.001). In the "shave" arm, 13.3% of those with negative margins prior to randomization had cancer found in the CSM. Pts in the "shave" arm were less likely to have positive final margins (after re-excision where performed; 6.3% vs. 15.8%, p < 0.001). Both groups had similar rates of radiation therapy (XRT) (82.8% vs. 81.8%, p = 0.831). Local recurrence rates were nearly identical at a median follow-up of 60.4 mo (1.3% vs. 1.6%, p = 1.000). 5-year DFS (91.9% vs. 92.6%, p = 0.820) and OS were not significantly different between groups (93.5% vs. 93.5%, p = 0.841). On Cox proportional hazard modelling, including randomization arm, final margin (after re-excision), and use of XRT, only the use of XRT significantly improved DFS (5 yr DFS 86.3% vs. 94.4%, HR: 0.47; 95% CI: 0.256-0.865, p = 0.015). **Conclusions:** While CSM reduced margin positivity and re-excision rates, it does not have an impact on DFS or OS at a median of 60.4 mo of surveillance; only the use of XRT significantly improved DFS. Although resection of CSM removed additional disease in 13.3% of margin-negative pts and was associated with a lower final positive margin rate, this did not translate into lower local recurrence rates. These results suggest that XRT may effectively manage small-volume residual disease that remains after PM. Clinical trial information: NCT01452399; NCT02772731. Secondary safety analysis of trastuzumab deruxtecan (T-DXd) vs trastuzumab emtansine (T-DM1) in DESTINY-Breast05: Clinical and demographic risk factors of interstitial lung disease (ILD) and radiation pneumonitis (RP). First Author: Michael Untch, Breast Cancer Center, HELIOS Klinikum Berlin-Buch GmbH, Berlin, Germany

Background: In DESTINY-Breast05 (NCT04622319), T-DXd showed superior efficacy vs T-DM1 in patients (pts) with human epidermal growth factor receptor 2-postive (HER2+) early breast cancer (eBC) with residual invasive disease after neoadjuvant therapy (NAT) and high risk of recurrence—a population in which radiotherapy (RT) is broadly used. Safety was consistent with the established T-DXd profile; ILD remained an important risk, although most cases were low grade. Previous T-DXd pooled analyses suggested potential associations between ILD and clinical and demographic factors. We report additional safety outcomes stratified by these risk factors. **Methods:** Pts with residual invasive HER2+ eBC and at high risk of recurrence after NAT were randomized 1:1 to receive T-DXd 5.4 mg/kg (n = 818) or T-DM1 3.6 mg/kg (n = 817) once every 3 weeks for 14 cycles. All pts underwent low-dose non-contrast chest computed tomography (CT) at screening. Pts who received adjuvant RT (aRT; either concurrently with or sequentially before study therapy) underwent additional low-dose CT during and after treatment completion. CT scans showing ILD or RP underwent blinded central adjudication. **Results:** At data cutoff (July 2, 2025), 806 pts in the T-DXd arm and 801 pts in the T-DM1 arm received ≥1 dose of treatment; no pts were ongoing study treatment. In the T-DXd arm, 93.9% of pts received aRT vs 93.6% in the T-DM1 arm. Adjudicated drug-related (adj DR) ILD rates were generally consistent across global regions (Asia, Europe, North America [NA] + Australia, and Rest of World), though numerically lower in NA + Australia for T-DXd. In both arms, adj DR ILD rates were higher in pts from Japan (n = 147) vs outside Japan (n = 1460; T-DXd: 14.9% vs 8.9%; T-DM1: 6.7% vs 1.2%), Japan vs other Asian countries (T-DXd: 14.9% vs 9.6%; T-DM1: 6.7% vs 2.1%), and in pts with baseline moderate vs normal renal impairment (T-DXd: 14.3% vs 9.7%; T-DM1: 5.0% vs 1.0%). Adj DR ILD incidence was comparable across racial subgroups. In both arms, investigator-reported RP rates were higher in pts from Japan vs outside Japan (T-DXd: 47.1% vs 27.4%; T-DM1: 45.0% vs 27.3%). Most ILD/RP events recovered or were recovering with protocol-specific management. Recovery/resolution was observed in 64.5% vs 75.0% of adj DR ILD events and 38.2% vs 43.2% of RP events in the T-DXd and T-DM1 arms, respectively. **Conclusions:** Adj DR ILD and RP events were mostly low grade and reversible with protocol-specific management guidelines. Adj DR ILD rates were higher with T-DXd than T-DM1 and were influenced by country and baseline renal function, consistent with prior pooled analysis. These findings are consistent with, and further characterize, the safety profile of T-DXd in post-NAT HER2+ eBC. Clinical trial information: NCT04622319. Research Sponsor: This study is sponsored by Daiichi Sankyo, Inc. In March 2019, AstraZeneca entered into a global development and commercialization collaboration agreement with Daiichi Sankyo for trastuzumab deruxtecan (T-DXd; DS-8201).

517 Poster Session

International variation in diagnostic and treatment practices in patients with HER2+ EBC: The RWE PEARL-HER2 study. First Author: Soraia Lobo-Martins, Academic Trials Promoting Team (ATPT), Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Institut Jules Bordet, Brussels, Belgium

Background: Pts with HER2+ EBC achieving pCR post neoadjuvant chemotherapy (NACT) with trastuzumab (H) and pertuzumab (P) show favorable outcomes. Yet, management varies widely within healthcare systems, including access to continuation of adjuvant (adj) P. We compared diagnostic and treatment practices across countries. **Methods:** PEARL-HER2 is an international retrospective real-world cohort including pts with HER2+ EBC achieving pCR (ypT0/isN0) after NACT-HP (Jan 2014 to Dec 2023). This descriptive preliminary analysis (data cut-off Jan-2026) summarizes diagnostic and treatment data stratified by country. **Results:** 1345 pts with pCR were included. Significant heterogeneity in pts and disease characteristics was observed (Table 1). Diagnostic methods also varied: use of breast MRI ranged from 11-97% across countries (>85% in Spain/Portugal; Peru, 11%), while FDG-PET/CT ranged from 0-72% (overall 20%; Turkey, 72%; p<0.001). Anthracycline-based NACT varied from <20% in Argentina and Brazil to >85% in Portugal and Turkey (p<0.001). Adj P was administered to 33% of pts overall (0-97%; p<0.001), with high use in countries with public reimbursement and minimal in those without. Among ER+ pts, ET use was uniformly high (98%; p=0.590), but regimen selection varied substantially (p<0.001): tamoxifen (42%) and aromatase inhibitor (58%). Events occurred in 6% of pts (invasive/non-invasive relapses and death); median FU was 40 months (IQR 24–62). **Conclusions:** This analysis indicates marked cross-country variability in management of HER2+ EBC. Use of adj P closely aligned with national reimbursement policies, highlighting access as a major determinant of care beyond clinical risk and guideline recommendations. Research Sponsor: Association Jules Bordet.

Neoadjuvant atirmociclib plus letrozole versus letrozole alone in HR+/HER2− breast cancer: Results from FourLight-2, a randomized phase 2 window of opportunity study. First Author: Shom Goel, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: In the neoadjuvant setting, endocrine therapy is a standard of care option in patients (pts) with HR+ breast cancer (BC). Atirmociclib (ATI, PF-07220060) is a potent and selective CDK4 inhibitor and has shown favorable tolerability and promising early activity as a first-line treatment in pts with HR+/HER2− metastatic BC. CDK4 selectivity is hypothesized to limit hematologic and gastrointestinal toxicities that may be dose-limiting; therefore, ATI may improve efficacy and tolerability. Ki-67 is a biomarker used to assess the antiproliferative activity of therapies. Complete cell cycle arrest (CCCA, defined as Ki-67-positive tumor cells ≤2.7%) in the neoadjuvant setting is correlated with less BC tumor recurrence. This phase 2 randomized global study evaluated the effects of ATI + letrozole (LET) and LET alone on Ki-67 expression in HR+/HER2− BC tumors after 14 days of treatment in the neoadjuvant setting (FourLight-2; NCT06465368). **Methods:** Postmenopausal women with HR+/HER2− BC and Ki-67 score of ≥10% per local assessment, primary tumor ≥1.5 cm, no prior systemic therapy for BC, and ECOG PS ≤1 were enrolled. Eligible pts were randomly assigned to ATI (300 mg, orally BID) + LET (2.5 mg, orally QD) or LET alone (2.5 mg, orally QD), for 14 days. Baseline breast lesion biopsy and on-treatment biopsy on day 14 were obtained. The primary endpoint was centrally-assessed CCCA rate at day 14; secondary endpoints included Ki-67 expression change, safety, ctDNA assessments, and PK. **Results:** 121 pts were randomized to ATI + LET (n = 59) or LET alone (n = 62) arms; median age was 66 y and 63 y; 90% and 92% had Stage I/II disease, respectively. In Ki-67 evaluable pts (n = 51 and n = 56), 77% and 70% had Ki-67 ≥20% at baseline (centrally assessed) and 71% and 80% had grade 1/2 tumor, respectively. At day 14, the proportion of pts who achieved CCCA was 88.2% (95% CI, 76.6–94.5) for ATI + LET and 17.9% (95% CI, 10.0–29.8) for LET alone, with median relative change of Ki-67 from baseline of -97.3% (range -99.8%, 34.0%) and -72.4% (range -98.3%, 139.9%) in each arm, respectively. CCCA was achieved at a higher rate with ATI + LET than LET alone across baseline subgroups (Table). The most common TEAEs with ATI + LET and LET alone, respectively, were diarrhea (19% and 2%), fatigue (15% and 10%), and nausea (14% and 5%) (all grade 1/2); no grade 3/4 treatment-related TEAEs or treatment discontinuations due to TEAEs were reported. **Conclusions:** ATI + LET demonstrated substantially greater antiproliferative effects than LET alone, with a tolerable safety profile in pts with HR+/HER2− BC, suggesting that ATI + LET may have value in early BC. Clinical trial information: NCT06465368. Research Sponsor: Pfizer Inc.

Overall survival (OS) in premenopausal ER+/PR+, HER2− breast cancer (BC) treated with endocrine therapy (ET) ± chemotherapy (CT): A National Cancer Database (NCDB) analysis. First Author: Lan Lei, Winship Cancer Institute of Emory University, Atlanta, GA

Background: The comparative benefit of ET alone vs ET+CT in premenopausal women with stage I-III ER+/PR+, HER2- BC remains uncertain. Although Oncotype DX recurrence score (RS) guides CT use, management of premenopausal patients (pts) with low/intermediate RS remains challenging. The ongoing NRG-BR009 trial aims to clarify the relative benefit of CT but has faced accrual issues. To address this question, we evaluated OS difference by treatment among pts with N0 (n=0)/intermediate RS and N1 (n=1-3)/low-intermediate RS disease. **Methods:** NCDB data were analyzed for women <50 yrs with ER+/PR+, HER2−, stage I-III BC (2005-2022). Variables included tumor size, grade, nodal status (N0/N1), stage, lymphovascular invasion, Ki67, Charlson-Deyo comorbidity score (CCS), RS category (low=0-17, intermediate=18-30) and treatments (ET, CT, surgery, radiation [RT]). OS was compared between ET+CT vs ET only groups using the log-rank test. Multivariable Cox models (MVA) were conducted to identify predictors of OS. **Results:** Median age was 45 yrs (18-49) among 15591 enrolled pts. In N0/intermediate RS group, 3710 (42.5%) received ET+CT and 5022 (57.5%) received ET alone; 5-yr OS was 98.9% with ET+CT vs 98.7% with ET (p=0.40). In N1/low RS group, 1151 (26.2%) received ET+ CT and 3242 (73.8%) received only ET; 5-yr OS was 98.5% with ET+CT vs 98.6% with ET (p=0.85). In N1/intermediate RS, 1718 (69.7%) received ET+CT and 748 (30.3%) received only ET; 5-yr OS was 96.2% with ET+CT vs 95.0% with ET (p=0.28). On univariable analysis, ET+CT did not improve OS in the N0/intermediate RS, N1/low RS, or N1/intermediate RS groups (all p>0.05). MVA further confirmed ET+CT had no OS benefit compared to ET alone in all groups (all p>0.05, Table 1). Among N0/intermediate RS pts, grade 3 disease was associated with worse OS (p<0.05). In N1/low RS subjects, CCS=2 predicted worse OS (p<0.05). In N1/intermediate RS pts, stage III disease and lack of RT predicted worse OS (p<0.05). **Conclusions:** In premenopausal women with early-stage ER+/PR+, HER2- BC, ET+CT yielded similar OS to ET alone in low/intermediate RS pts. Limitations include inability to assess ovarian function suppression and invasive disease-free survival. Larger studies are needed to validate the above findings and to investigate whether CT could be safely omitted in low-intermediate risk pts. Research Sponsor: None.

Socioeconomic and racial disparities in receipt of treatment among early-stage ER+/PR+ HER2- breast cancer: Insights from invasive breast cancer OncoDX recurrence score database. First Author: Lan Lei, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Oncotype DX Recurrence Score (RS) predicts recurrence risk and potential benefit from chemotherapy (CT) in early-stage ER+ and HER2- breast cancer (BC). However, real-world CT decision patterns remain poorly understood. This work evaluated how socioeconomic, racial and clinical factors influence CT decisions beyond RS-guided recommendations. **Methods:** We analyzed patients with early-stage ER+/PR+, HER2- BC in SEER OncoDX RS Database (2004-2019). Variables included age, rurality, poverty status, socioeconomic status (SES), RS, histology, tumor grade, nodal status, PR status, and CT receipt. Treatment disparities among patients with similar RS were evaluated using chi-square tests. Multivariable logistic regression model (MVA) identified independent predictors of CT utilization among patients with similar RS. **Results:** A total of 208,674 patients were included (median age 60). Median follow up was 4.9 years. Among postmenopausal (post-M, ≥50yrs) women with RS≥26 (CT indicated), lowest SES (60.6% vs 66.5% [highest], P<0.001) and Hispanic ethnicity (63.2% vs 63.3% [White], P=0.016) were associated with lower rate of CT. When CT was not indicated in post-M women (RS<26), Black patients were more likely to receive treatment (9.0% vs 7.9% [White], P<0.001). Among premenopausal (pre-M, <50yrs) women with N0 disease and RS>15, highest SES (41.0% vs 44.2% [lowest], P=0.032) and White race (41.2% vs 46.8 [Black], P<0.001) received less CT. Among pre-M women with N1-3 disease, rural residence (42.9% vs 47.1 [urban], P = 0.004) and White race (44.6% vs 50.1% [Black], P = 0.042) were associated with less CT. MVA showed that invasive ductal carcinoma, grade III tumor, PR-negative status and Black race increased the likelihood of CT irrespective of RS (Table 1). **Conclusions:** CT decisions were frequently influenced by socioeconomic, racial and clinicopathological factors beyond genomic guided recommendations. Our data highlights a gap between clinical guidelines and real-world practice. Future research should focus on understanding the underlying reasons for deviations in treatment selection and examining changes in practice patterns in the post-RxPONDER era. Research Sponsor: None.

Associations between self-efficacy and symptom burden in young women with breast cancer initiating endocrine therapy (ET) on SWOG S2010. First Author: Norah Lynn Henry, University of Michigan Rogel Cancer Center, Ann Arbor, MI

Background: Self-efficacy (SE) is the belief in one's ability to succeed in specific situations or accomplish a task, influencing motivation, behavior, and resilience. Both symptom (sx) burden at the time of ET initiation and lower SE for sx management are associated with ET nonadherence. The SWOG S2010 clinical trial enrolled premenopausal women starting adjuvant ovarian function suppression (OFS) plus ET for breast cancer. We examined associations between sx burden and self-efficacy at the time of ET initiation. **Methods:** All participants completed the FACT GP5 question evaluating bother from side effects of treatment, individual symptom PROMIS measures, and the PROMIS SE for managing sx and for managing medication (meds)/treatment (tx). GP5 is measured on a 5 point scale ranging from "Not at all" to "Very much." T scores were calculated for PROMIS measures (Table), with a mean score of 50 and higher scores reflecting more of the item being assessed. We evaluated associations between baseline sx and SE using logistic regression. **Results:** Of 528 participants with data, mean age was 44.1 years (SD 5.8), 23.5% were Hispanic, 5.5% Black, 6.4% Asian, and 77.7% White. The majority (69.9%) had received chemotherapy. On the FACT GP5 (n=503), only 31.6% reported no treatment side effect burden. Patients reporting a higher side effect burden from tx immediately prior to ET initiation had lower SE for sx (odds ratio (OR) 0.93 (95% CI 0.91-0.96, p<.0001)) and lower SE for meds & tx (OR 0.97 (95% CI 0.95-1.00, p=.04). Increased baseline sx and worse physical function were also statistically significantly associated with worse SE for managing both sx and meds & tx (Table). For example, patients with greater than average fatigue had lower SE for sx (OR 0.32 (95% CI 0.23-0.46, p<.001)). **Conclusions:** Symptom burden at the time of ET initiation is high for premenopausal women starting OFS plus ET, which may partially explain high rates of early ET discontinuation in this patient population. Lower SE was strongly associated with worse individual symptoms. Interventions to improve SE for sx and med management starting at or before ET initiation may improve ET adherence, which could thereby improve disease outcomes and quality of life for young women with breast cancer. Tumor-associated macrophage (TAM) score as an independent predictor of recurrence in residual disease after neoadjuvant chemotherapy and for identification of high-risk patients for adjuvant escalation. First Author: Aruna Korlimarla, Sri Shankara Cancer Foundation, Bangalore, India

Background: Tumor-associated macrophages (TAMs) drive immune evasion and chemotherapy resistance in breast cancer through tumor microenvironment reprogramming. We developed a composite TAM score integrating transcriptional programs with spatial IHC polarization markers to stratify recurrence risk and enrich macrophage-modulating trials, hypothesizing it would improve prognostic accuracy in treatment-naïve disease and predict neoadjuvant chemotherapy (NACT) response. **Methods:** TAM score was derived from scRNA-seq atlases (n=4), filtering survival-associated genes in METABRIC/TCGA (n=2,509), and weighting IHC markers CD163/CD206 normalized to CD68/CSF1R via Cox coefficients. Validation: treatment-naïve invasive carcinomas (n=83; follow-up 57 months; 24 events). Primary endpoint: recurrence-free survival (RFS); multivariable Cox adjusted for age, tumor size, nodal status, grade, subtype, treatment. Predictive utility assessed in matched primary/post-NACT residual tumors (n=45) correlating TAM dynamics with RCB. **Results:** High TAM score (≥median) independently predicted worse RFS (HR 3.8, 95% CI 1.6-9.1, p<0.05) and outperformed CD163/CD68 alone (HR 2.1, p<0.05); 5-year RFS was 68% vs 91% (TAM-high vs TAM-low). Prognostic value persisted in node-negative (HR 4.2, p=0.02) and luminal B (HR 3.5, p=0.01) subsets. In the NACT cohort, baseline TAM score inversely correlated with pCR (12% vs 38%, p=0.04). Among residual disease (RCB-II/III, n=34), persistent TAM-high post-NACT identified 3-year RFS 52% vs 85% in TAM-low/normalized cases (HR 4.1, p=0.01), independent of RCB; CD163+/CD206+ expansion occurred in 76% of RCB-III vs 29% of RCB-I (p=0.008). **Conclusions:** This TAM score predicts recurrence from pre-treatment tissue and identifies macrophage-driven resistance persisting post-NACT, nominating TAM-high residual disease for macrophage-modulating trials. Translational evidence supports this: CSF1R inhibition reduced immunosuppressive TAMs, increased M1-like programs, decreased PD-L1/PD-L2, and enhanced anti-PD-1 efficacy preclinically with ex vivo confirmation. Early-phase data (rebastinib plus chemotherapy in HER2-negative metastatic disease) demonstrate feasibility, supporting prioritization of TAM-high patients with residual disease for trials combining TAM modulation with checkpoint therapy. Research Sponsor: None.

TAM score performance in treatment-naïve and NACT cohorts.

Chemotherapy, endocrine therapy, and cognitive impairment in long-term breast cancer survivors. First Author: Armaan Jamal, Department of Public Health Sciences, The University of Chicago, Chicago, IL

Background: Chemotherapy and endocrine therapy have known neurobiological effects, yet evidence on their associations with long-term cognitive impairment remains limited. This study examined the relationship between prior chemotherapy, endocrine therapy, and cognitive impairment among long-term breast cancer survivors. **Methods:** Between July and September 2025, 1,338 participants from the Chicago Multiethnic Epidemiologic Breast Cancer Cohort were surveyed and completed the Functional Assessment of Cancer Therapy-Cognition (FACT-Cog), a validated self-report instrument assessing 4 specific domains: perceived cognitive impairment (PCI; scores 0–72), cognitive-related quality of life (QoL; scores 0–16), perceived cognitive abilities (PCA; scores 0–27), and comments-from-others (scores 0–16). Lower scores reflect worse cognitive function. Cognitive impairment was defined as a PCI score <54. Multivariable logistic regression was used to evaluate associations between chemotherapy and endocrine therapy with cognitive impairment. Multiple linear regression was used to assess associations with continuous FACT-Cog domain scores. All models were adjusted for age, race/ethnicity, radiotherapy, surgery history, and educational attainment. **Results:** The mean age at survey of the 1,338 study participants was 64.3 years (SD 11.7), and the median time from diagnosis to survey was 9.4 years (IQR 6.1–14.1). Overall, 299 (22.3%) met criteria for cognitive impairment. Additionally, 594 (44.4%) and 851 (63.6%) of the participants had prior chemotherapy and endocrine therapy, respectively. In adjusted analyses, chemotherapy (adjusted odds ratio [aOR] 1.39; 95% CI 1.03 to 1.89; p=0.033) and endocrine therapy (aOR 1.86; 95% CI 1.35 to 2.57; p<0.001) were significantly associated with cognitive impairment. Chemotherapy was associated with lower PCI (β −2.11; 95% CI −3.61 to −0.61; p=0.006), and lower QoL (β −0.60; 95% CI −1.01 to −0.19; p=0.04). Endocrine therapy was associated with lower scores in PCI (β −2.52; 95% CI −4.02 to −1.02; p=0.001), QoL (β −0.55; 95% CI −0.96 to −0.14; p=0.009), PCA (β −1.54; 95% CI −2.29 to −0.79; p<0.001), and comments-from-others (β −0.28; 95% CI −0.49 to −0.07; p=0.008). In joint models, those who received both chemotherapy and endocrine therapy (aOR 2.46; 95% CI 1.46 to 4.18; p=0.001) and those who received endocrine therapy alone (aOR 1.71; 95% CI 1.04 to 2.81; p=0.035) had significantly higher odds of cognitive impairment than participants who received neither therapy. **Conclusions:** In this multiethnic cohort of long-term breast cancer survivors, prior chemotherapy and endocrine therapy were independently associated with worse perceived cognitive functioning across multiple domains. These findings underscore the need for future studies to identify neuroprotective strategies and interventions to mitigate treatment-related cognitive sequelae. Research Sponsor: Breast Cancer Research Foundation; BCRF-20-071; National Cancer Institute; P20CA233307; Susan G. Komen; TREND21675016; National Institute on Aging; T32AG000243.

Adjuvant endocrine therapy omission in ER-positive breast cancer treated with neoadjuvant chemotherapy. First Author: Grace Mei Yee Choong, Mayo Clinic Rochester, Rochester, MN

Background: Adjuvant endocrine therapy (ET) decreases breast cancer (BC) recurrence and improves overall survival (OS) for patients (pts) with estrogen receptor positive (ER+) BC. Omission of adjuvant ET and nonadherence are major issues contributing to worse clinical outcomes. Recent data suggest that the number of pts who omit adjuvant ET may be increasing in Europe [1]. These data have yet to be evaluated in the U.S. We previously reported data from the National Cancer Database (NCDB) that ET omission was more likely in pts with ER+/HER2+ disease who achieved a pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) [2]. Herein we report an updated analysis with a larger cohort designed to examine trends in ET omission over time and the impact on OS in a group of pts at high risk of recurrence. **Methods:** The NCDB was queried from 2010-2022 for pts with stage I-III ER+BC treated with NAC and surgery. pCR was defined as ypT0, ypN0. Use of adjuvant ET and the impact of adjuvant ET omission on OS in pts with and without pCR were assessed separately based on HER2 status. Adjuvant ET initiation by 1 year was summarized using the cumulative incidence estimate to account for the competing risk of death. OS was analyzed with ET as a time-dependent covariate using multivariable Cox proportional hazards regression. **Results:** We identified 130,438 pts with ER+BC (78,778 ER+/HER2-, 51,660 ER+/HER2+) who received NAC. Median follow-up was 5 years. Overall, pCR was achieved in 10.0% of ER+/HER2- and 35.9% of ER+/HER2+. On multivariable analysis, ET omission was significantly associated with worse OS in pts with residual disease (RD) [ER+/HER2- (HR 1.80 $p<0.001$) ER+/HER2+ (HR 1.66 $p<0.001$] and in those with a pCR [ER+/HER2- (HR 1.38 p=0.002) ER+/HER2+ (HR 1.42 $p<0.001$)]. Between 2010-2017, adjuvant ET omission was stable, with approximately 10.0% of pts not having initiated ET by 1 year after surgery. The proportion of pts omitting ET overall increased thereafter to 12.9% in 2018, rising to 24.4% in 2022. A sharp increase in ET omission was observed 2021-2022 in ER+/HER2- BC who achieved pCR, with 42.4% omitting ET compared to 25.1% for 2018-2020 and 18.8% for 2010-2017 ($p<0.001$). Adjuvant ET omission showed more modest but significant increases for other subgroups ($p<0.001$): ER+/HER2- with RD (8.5% 2010-2017, 12.3% 2018-2020, 18.7% 2021-2022), ER+/HER2+ with pCR (15.1% 2010-2017, 14.0% 2018-2020, 24.4% 2021-2022), and ER+/HER2+ with RD (9.5% 2010-2017, 12.5% 2018-2020, 22.2% 2021-2022). **Conclusions:** In ER+BC treated with NAC, omission of ET is increasing over time and associated with a higher risk of death, regardless of HER2, RD, or pCR status. These findings have substantial public health implications as they may result in a reversal of the 4-decade improvements in breast cancer mortality. Additional intervention is critical to improve adherence to guidelines. [1] Verreck et al. Breast 2025 [2] Choong et al. SABCS 2022. Research Sponsor: None.

Impact of *BRCA* pathogenic variants and novel targeted agents on ovarian reserve measured by anti-Müllerian hormone levels in young women with early breast cancer: A biomarker analysis of the PREFER study. First Author: Luca Arecco, Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Institut Jules Bordet, Bruxelles, Belgium

Background: The impact of germline *BRCA* (g*BRCA*) pathogenic variants (PVs) and of novel targeted agents (anti-HER2 therapy, CDK4/6 inhibitors, or immunotherapy) on ovarian reserve in young women treated with chemotherapy (CT) for early breast cancer (BC) remains limited. This biomarker analysis of the PREFER study prospectively evaluated ovarian reserve using anti-Müllerian hormone (AMH) according to main patient and treatment characteristics. **Methods:** We included premenopausal women enrolled in the prospective PREFER study (NCT02895165) and candidates to (neo)adjuvant CT at the coordinating centre, the IRCCS San Martino Policlinic Hospital, Genoa, Italy. Serial serum AMH measurements were performed at baseline (prior to any CT initiation), during, and after systemic treatment. Longitudinal changes in centrally measured AMH were analysed using mixed-effects models on log-transformed values. Analyses explored the impact of patient (including age and *gBRCA* status) and treatment (CT alone or with anti-HER2 therapy, CDK4/6 inhibitors, or immunotherapy) characteristics on AMH levels over time. **Results:** Between 2012 and 2025, 309 premenopausal patients were enrolled at the coordinating centre, of whom 194 were included in the present analysis. Median age at diagnosis was 37 (IQR 33-40) years, with 146 patients (75.3%) aged $\leq$40 years and 48 (24.7%) 41-45 years. Overall, 85 patients (43.8%) had hormone receptor-positive/HER2-negative, 62 (32.0%) HER2-positive, and 47 (24.2%) triple-negative BC. In the entire cohort, AMH levels showed a marked decline during CT, followed by partial recovery during follow-up ($p<0.001$), irrespective of patient and treatment characteristics. Younger women showed higher baseline values (2.31 vs 1.11 μg/L for $\leq$40 years and 41-45 years) and greater post-treatment recovery ($p<0.001$). Among patients with known *gBRCA* status (n=147), patients harbouring *gBRCA* PVs (n=29, 19.7%) showed lower baseline levels (1.60 vs 2.18 μg/L for *gBRCA* carriers vs non-carriers) and a lower post-treatment recovery compared to non-carriers (n=118, 80.3%) (p=0.01). Regarding treatment exposure, 106 patients (54.6%) received CT alone, 62 (32.0%) CT plus anti-HER2 agents, 10 (5.2%) CT plus immunotherapy, and 16 (8.2%) CT followed by CDK4/6 inhibitors. No significant differences over time were observed according to treatment exposure (p=0.41); however, numerically lower mean AMH values after end of CT were observed among patients treated with CDK4/6 inhibitors and immunotherapy. **Conclusions:** In this PREFER biomarker analysis, older age and *gBRCA* PVs were associated with reduced ovarian recovery after treatment. Limited sample size precludes definitive conclusions on the gonadal impact of immunotherapy or CDK4/6 inhibitors; further analyses are urgently needed in this field. Impact of the Breast Cancer Index on extended endocrine therapy recommendations in patients from the BCI Registry study. First Author: Tara B. Sanft, Yale University, New Haven, CT

Background: The Breast Cancer Index (BCI) test is an established genomic assay that provides individualized risks of overall and late distant recurrence and predicts the benefit from extended endocrine therapy (EET) in patients with early-stage, HR+ breast cancer. Previous findings from the large, prospective BCI Registry have shown that physicians changed their EET recommendation in over 40% of patients following BCI testing. This analysis investigates how physicians integrate prognostic and predictive BCI results in real care settings to decide whether or not to recommend extension of endocrine therapy. **Methods:** The BCI Registry study (NCT04875351) is evaluating the long-term clinical outcome, decision-impact and medication adherence in about 3000 patients. Pre- and post-BCI physician treatment recommendations were compared using McNemar's test. Clinicopathologic features of cases were correlated with BCI (H/I) predictive results and post BCI-EET recommendations using Fisher's exact test. Differences in mean BCI prognostic risk were assessed using analysis of variance (ANOVA). **Results:** Pre- and post-BCI testing physician questionnaires were completed for 2850 patients. The percentage of patients recommended for EET decreased from 54.6% before BCI testing to 41.2% after BCI testing, while those not recommended for EET increased from 44.9% to 58.0% ($p<.0001$). Among patients not recommended for EET pre-BCI, physicians cited low risk of recurrence (47.4%), osteoporosis risk (16.7%), side effects (8.6%), or multiple reasons (24.4%). Among BCI (H/I)-High patients (N=1063), recommendations for EET increased from 60.4% pre-BCI to 90.6% post-BCI, while EET non-recommendations decreased from 39.1% to 8.0%. Conversely, in BCI (H/I)-Low patients (N=1787), EET recommendations decreased from 51.1% to 11.8% and EET non-recommendations increased from 48.3% to 87.8%. Post-BCI, BCI (H/I)-High patients who were not recommended EET (8.0%) had more favorable clinicopathological features, including more T1 tumors (83.5% vs. 68.1%, p=.009), more G1 tumors (44.7% vs. 14.4%, $p<.0001$) and lower mean BCI prognostic risk compared to those for whom EET was recommended (4.4% vs 9.2%, $p<.0001$). Conversely, BCI (H/I)-Low patients who were recommended EET (11.8%) had a larger proportion of T2/T3 tumors (40.7% vs. 21.7%, $p<.0001$), more G2/G3 tumors (79.2% vs. 62.8%, $p<.0001$), more N+(1-3) cases (43.6% vs. 15.7%, $p<.0001$) and higher mean BCI prognostic risk (8.1% vs 4.7%, $p<.0001$). **Conclusions:** BCI results meaningfully inform physician recommendations for EET. Post-BCI, physician EET recommendations increased to 91% in BCI (H/I)-High patients and decreased to 12% in BCI (H/I)-Low patients, highlighting the important treatment guidance provided by BCI. Integration of both predictive and prognostic BCI results help further personalize patient care. Research Sponsor: None.

Platinum-based chemotherapy in early-stage, high-risk, triple-negative breast cancer: A systematic review and meta-analysis of randomized trials. First Author: Jesse Lopes da Silva, Division of Clinical Research and Technological Development, Brazilian National Cancer Institute (INCA), Rio De Janeiro, Brazil

Background: The clinical benefit of adding platinum agents to adjuvant chemotherapy for early-stage triple-negative breast cancer (TNBC) remains uncertain. A systematic review and meta-analysis of randomized controlled trials (RCTs) was conducted to evaluate the impact of carboplatin-based adjuvant chemotherapy on survival outcomes in patients with early-stage, high-risk TNBC. **Methods:** RCTs comparing carboplatin plus standard adjuvant chemotherapy versus chemotherapy alone in early-stage, high-risk TNBC were identified through systematic searches of PubMed, Embase, Cochrane CENTRAL, and major oncology meeting proceedings. The primary endpoint was disease-free survival (DFS). Secondary endpoints included recurrence-free survival (RFS), distant disease–free survival (DDFS), and overall survival (OS). Hazard ratios (HRs) were pooled using random-effects models. Absolute survival differences at fixed timepoints were estimated using reconstructed individual patient–level data derived from published Kaplan–Meier curves. **Results:** Five randomized trials enrolling 3,153 patients were included; 1,576 (49.9%) received carboplatin-based chemotherapy. Median age ranged from 47 to 56 years, and most patients had grade 3 tumors and node-positive disease. Carboplatin-based chemotherapy significantly improved DFS compared with chemotherapy alone (HR 0.66, 95% CI 0.62–0.71; $p < 0.001$). Consistent proportional benefits were observed for RFS (HR 0.66, 95% CI 0.62–0.71; $p < 0.001$), DDFS (HR 0.66, 95% CI 0.62–0.71; $p < 0.001$) and OS (HR 0.66, 95% CI 0.62–0.71; $p < 0.001$), with no substantial between-trial heterogeneity ($I^2 < 25\%$ for all endpoints). Reconstructed survival analyses demonstrated increasing absolute benefit over time. At 3 years, carboplatin-based chemotherapy was associated with absolute improvements of approximately 4–6% in DFS and 3–5% in OS. At 5 years, absolute differences favored carboplatin by approximately 7–9% for DFS, 6–9% for RFS, 6–8% for DDFS, and 6–8% for OS (log-rank $p < 0.001$ for all comparisons). DFS benefit was observed across clinically relevant subgroups, including node-negative (HR 0.69, 95% CI 0.53–0.90) and node-positive disease (HR 0.57, 95% CI 0.37–0.86), as well as among patients with and without germline *BRCA1/2* mutations. Greater proportional benefit was observed in patients with grade III tumors and pT2–T3 disease. **Conclusions:** Across RCTs, the addition of carboplatin to standard adjuvant chemotherapy was associated with significant and durable improvements in DFS and OS in patients with early-stage, high-risk TNBC. Absolute survival gains increased with longer follow-up, supporting the clinical relevance of platinum-based adjuvant strategies in selected high-risk populations. Research Sponsor: None.

Real-world treatment patterns and adherence to adjuvant abemaciclib among patients with early hormone receptor–positive (HR+) breast cancer (BC). First Author: Inimfon Jackson, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Adjuvant abemaciclib (2 years) is approved in combination with endocrine therapy (ET) for node-positive high-risk early HR+ BC. Although it improves invasive disease-free and overall survival, its long duration and toxicities increase treatment complexity. As adjuvant regimens become more intensive, long-term adherence is critical for real-world effectiveness. However, data outside clinical trials are limited. We examined treatment patterns and factors associated with adherence to abemaciclib in a younger population of patients with early BC. **Methods:** We conducted a retrospective cohort study using the Merative MarketScan Commercial Claims and Encounters database. Patients aged 18-64 years with early BC who received abemaciclib between 2017 and 2024 were identified. Index date was the date of the first abemaciclib claim. We included patients who underwent breast surgery within one year before the index date and had continuous enrollment for 6 months before and one year after index date. We excluded patients with metastatic disease prior to the index date. Medication adherence was assessed using the proportion of days covered (PDC), with adherence defined as PDC $\geq$80%. Multivariable logistic regression was used to examine factors associated with abemaciclib adherence at one and two years. **Results:** Among 640 patients (median age 51 years) treated with adjuvant abemaciclib (median follow up 1.5 years), 55% were adherent to therapy at one year. Adherence declined from 100% in month 1, to 66%, 57%, 55%, and 50% in months 2, 6, 12, and 24 ($p<0.001$). Overall, 84.5% of patients initiated abemaciclib at 150 mg, and 47.2% had no dose adjustments during treatment. On multivariable analysis of one-year adherence, patients prescribed lower abemaciclib doses (50 or 100mg) were less likely to be adherent compared to those prescribed 150 mg (aOR=0.52; 95%CI 0.31–0.90). Adherence to ET was also associated with higher abemaciclib adherence (aOR=3.63; 95%CI 2.55–5.18). Polypharmacy was associated with reduced abemaciclib adherence among patients taking two (aOR=0.56; 95%CI 0.37–0.85) or $\geq$3 drug classes (aOR=0.51; 95%CI 0.34–0.78) compared with 0–1 drug class. Patients with high-deductible health plans (HDHP) had higher odds of adherence compared to those with PPO insurance (aOR=2.10; 95%CI 1.23–3.59). At two years (n=213), younger age and adherence to ET were significantly associated with greater abemaciclib adherence. **Conclusions:** Abemaciclib adherence was low, 55% in year 1, and 50% in year 2. Although lower abemaciclib doses and polypharmacy were associated with lower odds of adherence, ET adherence was associated with higher odds. Adherence in HDHP patients may reflect demographics (White, young, higher income). These findings highlight the need for close patient monitoring and strategies to support long-term adherence to adjuvant treatment. Research Sponsor: Susan G. Komen Foundation; The Breast Cancer Research Foundation; National Cancer Institute.

Chemotherapy (CT) use by Oncotype DX (O-Dx) recurrence score (RS) in hormone receptor–positive, HER2-negative (HR+/HER2-) invasive lobular carcinoma (ILC): A contemporary National Cancer Database (NCDB) analysis. First Author: Marija Sullivan, Duke University School of Medicine, Durham, NC

Background: ILC has a distinct biology and is considered less chemosensitive than invasive ductal carcinoma (IDC). O-Dx RS can guide adjuvant CT decisions for patients with HR+/HER2- breast cancer (BC); however, pivotal trials largely included patients with IDC. Patients with high RS have been shown to benefit from CT. Whether this genomic risk threshold is applied to patients with ILC in real-world practice is not well understood. We evaluated contemporary CT use by O-Dx RS and its association with overall survival (OS) in patients with ILC. **Methods:** Patients $\geq$18 years with HR+/HER2- ILC diagnosed from 2018-2022 who underwent surgery, had pT1-T3, pN0-N1 disease, and known O-Dx RS were identified in the NCDB. Baseline characteristics were compared by RS groups: 0-10 (low), 11-25 (intermediate), and >25 (high). Multivariable logistic regression models identified factors associated with CT use in the overall cohort and stratified by RS. We evaluated the association between CT use and OS within each RS group, adjusting for covariates using propensity score matching (by year of diagnosis, age, pT, pN). **Results:** A total of 30,393 patients with early-stage HR+/HER2- ILC and O-Dx score were identified. Among them, 21% had low, 72% intermediate, and 7% high RS. Overall, 9.2% received CT, including 2.4% of those with low RS, 5.5% of intermediate RS, and 66% of high RS. CT use did not change over time (p=0.47). On multivariable analysis in all patients, higher RS was the key determinant of CT use (RS 11-25 vs 0-10: aOR=2.98, 95%CI 2.49-3.58; RS >25 vs 0-10: aOR=333.4, 95%CI 266.8-416.7), while older age was associated with lower CT use (aOR=0.91, 95%CI 0.91-0.92). In multivariable models stratified by RS, clinicopathologic features, including younger age, larger tumor size, higher nodal stage, and higher grade, were associated with CT use in low and intermediate RS groups (i.e., pN1 aOR=18.64 for RS 0–10; aOR=7.37 for RS 11–25; both $p<0.001$), whereas in high RS group, age had similar effect; however, tumor size and nodal status had significant but attenuated effects. In propensity-matched cohorts within RS groups, CT use was not associated with different OS in low RS (5-year OS 98% vs 100%, p=0.29) or intermediate RS (5-year OS 97% vs 97%, p=0.68) groups; however, in high RS group, CT use was associated with improved OS (5-year OS 96% vs 90%; p=0.01). **Conclusions:** In clinical practice, CT use in patients with ILC is guided by O-Dx RS but influenced by age and clinicopathologic risk. CT use conferred no OS benefit in patients with low or intermediate RS but was associated with OS benefit in high RS. Despite this, one-third of patients with ILC with high RS did not receive CT. These findings support RS-guided adjuvant CT decision-making in ILC and suggest that increasing CT use in patients with high RS may improve outcomes. Research Sponsor: Susan G. Pyrotinib plus nab-paclitaxel as adjuvant therapy for patients with N0/N1mi, HER2-positive early-stage breast cancer: 3-year iDFS results of the phase II PHAEDRA trial. First Author: Changjun Wang, Peking Union Medical College Hospital, Beijing, China

Background: While dual anti-HER2 therapy is standard in the adjuvant setting for HER2-positive early breast cancer, treatment de-escalation is an attractive strategy for patients with low-risk disease. Previous studies (e.g., APT, ATEMPT) of adjuvant trastuzumab plus chemotherapy or T-DM1 monotherapy in this population reported 3-year invasive disease-free survival (iDFS) rates of 93.4%-98.7%. Pyrotinib, an irreversible pan-HER2 tyrosine kinase inhibitor, is effective in HER2-positive breast cancer; however, data supporting its use in the adjuvant setting for low-risk disease are limited. This study evaluated the efficacy and safety of adjuvant pyrotinib plus nab-paclitaxel in this population. **Methods:** This multicenter, single-arm, phase II trial enrolled women aged 18-75 with primary tumor size $\leq$3 cm and node-negative (N0) or micrometastases (N1mi), histologically confirmed HER2-positive early breast cancer. Patients received nab-paclitaxel (260 mg/m² IV, q3w) plus pyrotinib (400 mg PO, qd) for 12 weeks (4 cycles), followed by pyrotinib monotherapy (400 mg, qd) for one year. The primary endpoint was iDFS. Secondary endpoint was adverse events (AEs) graded by CTCAE v5.0. **Results:** From January 8, 2021, to September 21, 2023, 263 patients were enrolled and received treatment. Median age was 51 years; 60.8% (160/263) were hormone receptor-positive, and 97.7% (257/263) were node-negative. At the data cutoff (December 30, 2025), with a median follow-up of 36.2 months, 9 iDFS events were observed. The estimated 3-year iDFS rate was 96.8% (95% CI 93.4-98.5). One death occurred and overall survival data were immature. The most common grade $\geq$3 treatment-related AEs were diarrhea (50.6%), neutropenia (14.4%), and decreased white blood cell count (14.4%). No serious AEs were reported. Treatment interruption, dose reduction, and discontinuation due to AEs occurred in 12.2%, 3.4%, and 1.5% of patients, respectively. **Conclusions:** Adjuvant pyrotinib combined with nab-paclitaxel showed promising 3-year iDFS and a manageable safety profile in patients with low-risk, HER2-positive early breast cancer. This regimen represents a potential oral de-escalation strategy for this population. Clinical trial information: NCT 04659499. Research Sponsor: General Project of the 2025 Annual Beijing Municipal Education Science; No. CDDB25233; National High Level Hospital Clinical Research Funding; 2025-PUMCH-A-148; Chronic Disease Management Research Project of National Health Commission Capacity Building and Continuing Education Center; No. GWJJMB202510041020.

Efficacy outcomes.

Efficacy outcomes	Pyrotinib + nab-Paclitaxel (n=263)		
Events, n(%)	9 (3.4)		
	24 months	36 months	48 months
iDFS rate, (95% CI)	98.77 (96.24, 99.60)	96.83 (93.42, 98.49)	93.17 (85.03, 96.96)
DDFS rate, (95% CI)	99.18 (96.76, 99.79)	98.77 (96.23, 99.60)	95.03 (86.00, 98.29)
LRFS rate, (95% CI)	99.18 (96.75, 99.79)	98.18 (95.18, 99.32)	94.47 (85.76, 97.92)

iDFS: invasive disease-free survival; DDFS: distant disease-free survival; LRFS: locoregional recurrence-free survival.

Real-world deployment of a multimodal artificial intelligence (AI) model for predicting response to neoadjuvant chemotherapy in early breast cancer. First Author: Bareket Daniel, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Multimodal AI models integrate morphological information from H&E-stained images with clinical information, identifying subtle disease signatures beyond the perceptual limits of human experts. However, the clinical utility of AI tools in real-world settings remains underexplored. Here, we evaluated Ataraxis Breast (ATX), a multimodal AI test predicting response to neoadjuvant chemotherapy, in a prospective silent trial. **Methods:** We previously assembled an international dataset of whole slide images of H&E-stained biopsy specimens and clinical information to develop ATX as a biomarker of neoadjuvant response. To evaluate real-world clinical translation, we conducted a prospective silent trial of ATX in patients with early breast cancer treated with neoadjuvant therapy at our center. None of these patients were included in the original training, validation, or test datasets. The primary outcome was pathologic complete response (pCR). Area under the receiver operating curve (AUROC) analyses were conducted. **Results:** The study cohort included 50 female patients treated during 2025, with a median age of 53.8 years. Tumor subtypes comprised 30% (n = 15) triple-negative breast cancer (TNBC), 24% (n = 12) HER2-positive disease, and 46% (n = 23) hormone receptor–positive (HR+), HER2-negative tumors. Overall, 66% (n = 33) of patients had node-positive disease, and 60% (n = 30) had grade 3 tumors. Notably, all patients with TNBC received pembrolizumab, whereas patients with HER2-positive tumors were treated with chemotherapy combined with HER2-directed therapies. The overall pathological complete response (pCR) rate in this external validation cohort was 34%. ATX scores were significantly higher among patients who achieved pCR (p = 0.005). Moreover, when evaluated as a predictive biomarker across the entire cohort, ATX achieved an AUROC of 0.745 (95% CI, 0.58–0.89) for pCR. These findings were consistent across predefined subgroup analyses, including patients with HR+/HER2− disease (AUROC = 0.73) and TNBC (AUROC = 0.77). **Conclusions:** In this prospective deployment study, among patients with early breast cancer treated with neoadjuvant chemotherapy, higher AI-derived predictions were independently associated with improved neoadjuvant therapy response. Given the accessibility of H&E-slides, ATX may serve as a scalable predictive biomarker in real-world settings. Research Sponsor: Israel Ministry of Health.

Adjuvant antibody-drug conjugate (ADC) eligibility and corresponding prognosis in HER2+ early breast cancer (eBC): A US-based real-world comparison of KATHERINE and DESTINY-Breast05 populations. First Author: Paolo Tarantino, Department of Medical Oncology, Dana-Farber Cancer Institute; Harvard Medical School, Boston, MA

Background: The KATHERINE trial established adjuvant T-DM1 as standard of care (SoC) treatment for patients with HER2+ eBC and residual invasive disease (RD) following neoadjuvant therapy. Recently, DESTINY-Breast05 (DB-05) demonstrated reduced recurrence risk with T-DXd vs. T-DM1 in a high-risk subset. While KATHERINE included any RD, DB-05 restricted eligibility to high-risk patients (inoperable at presentation or ypN+ at surgery). In this analysis, we aim to estimate the prevalence and associated outcomes of patients with HER2+ eBC and RD meeting eligibility for DB-05 vs. KATHERINE in a US real-world setting. **Methods:** This retrospective cohort study utilized the nationwide Flatiron Health electronic health record-derived de-identified database. We included patients diagnosed with stage I–III HER2+ eBC (Jan 1, 2011–Sept 30, 2025) who completed pertuzumab-based neoadjuvant therapy and surgery. RD status was determined via pathology reports. KATHERINE eligibility required any RD in breast/axillary nodes. DB-05 eligibility required high-risk RD: operable at presentation with node-positive disease at surgery (ypN1–3; "DB-05-operable") or inoperable at presentation (cT4 or cT1–3/cN2–3; "DB-05-inoperable"). Distant recurrence-free survival (DRFS) and overall survival (OS) were estimated at 3 years post-surgery. The analysis was conducted on complete cases only. **Results:** The cohort included 9561 patients with HER2+ eBC and RD after neoadjuvant therapy. Overall, 9447 (99%) met KATHERINE eligibility. Conversely, only 4567 (48%) met DB-05 high-risk criteria: 3241 (34%) DB-05-operable and 1326 (14%) DB-05-inoperable. DB-05-ineligible patients mostly presented with cT1–3/cN0–1 disease and had RD confined to the breast (ypN0). In the overall study population, with a median follow-up for DRFS of 44 months, 3-year DRFS and 3-year OS were 88% and 94%, respectively. Patients eligible only for KATHERINE (i.e. DB-05-ineligible) experienced relatively favorable outcomes, with a 3-year DRFS of 94% and 3-year OS of 97%; conversely, DB-05-eligible patients experienced a 3-year DRFS of 82% and 3-year OS of 91%. Within the DB-05-eligible population, the poorest outcomes were observed if patients had inoperable disease at baseline, with a 3-year DRFS of 73% and 3-year OS of 86%. **Conclusions:** Approximately half of the patients with RD did not meet DB-05 high-risk criteria yet would have been eligible for KATHERINE. While T-DXd may become a new option for high-risk patients, T-DM1 remains a SoC for those with operable disease at baseline and node-negative RD at surgery. As ADCs were not widely available for eBC during the study period, these outcomes do not reflect ADCs' treatment effect, and modern 3-year DRFS may possibly exceed 94% for this population. Research Sponsor: F. Hoffmann-La Roche Ltd.

A randomized phase II trial of folate receptor alpha peptide vaccine in early-stage triple-negative breast cancer. First Author: Keith L. Knutson, Department of Immunology, Mayo Clinic Florida, Jacksonville, FL

Background: Folate receptor alpha (FRα) is overexpressed in ~80% of triple-negative breast cancers (TNBC). We previously demonstrated that patients (pts) with breast cancer naturally mount immune responses to FRα. In prior Phase I and II studies, a GM-CSF-adjuvanted FRα peptide vaccine (FRPV) was safe and induced durable FRα-specific T-cell immunity in 83–90% of pts with breast and ovarian cancer. **Methods:** Eligible pts were women $\geq$18 years with TNBC (ER/PR $\leq$10%) with 1+ of the following: stage $\geq$T1c disease, node-positivity, or residual disease after neoadjuvant chemotherapy. Pts were randomized 2:1 to receive FRPV or placebo (GM-CSF alone) every 28 days for cycles 2-7 and then every six months for 7 booster doses, with cycle 1 consisting of cyclophosphamide 50mg orally twice daily for days 1-7 and 15-21 (in both arms). Randomization was stratified by chemotherapy setting (adjuvant only vs neoadjuvant) and stage (I/II vs III). FRα expression was evaluated by immunohistochemistry. The study was designed to detect (at 30 months after the last pt enrolled) a disease-free survival (DFS) difference of 14% assuming a 3.5-year DFS rate of 70% in the control group and with 78% power. **Results:** 280 pts were enrolled (median age 52). The majority had stage I or II tumors (n = 219, 78%). There were numerically more node-positive tumors in the vaccine arm, 78 (41%) vs 27 (32%), p = 0.15. Median follow-up was 3.5 years, and 33 (FRPV: 25, placebo: 8) DFS events were observed; 3.5-year DFS rate was 88% with FRPV and 90% with placebo (HR 1.42, 95% CI 0.64–3.15; p = 0.39). Overall survival (OS) also did not differ by arm (HR 2.48, 95% CI 0.55–11.20; p = 0.22). Among node-positive pts (n = 105), DFS did not differ between arms (HR 0.95, 95% CI 0.34–2.66; p = 0.92). However, a numerical DFS event rate improvement (14% for vaccine vs. 26% for placebo) was observed in 61 patients with stage III disease (HR 0.51, 95% CI 0.16–1.68; p = 0.26). DFS did not differ by chemotherapy setting or by receipt of anthracycline, capecitabine, and/or an immune checkpoint inhibitor. FRPV was well tolerated, with predominantly grade 1–2 adverse events (AEs) and no vaccine-related grade $\geq$4 AEs. FRα expression was available from tumor in 230 pts, with 72% expressing $>$ 0. Overall, DFS was not significantly associated with FRα expression (0 vs $>$ 0; HR 0.55, 95% CI 0.21–1.44; p = 0.21), and no significant differences in DFS by FRα expression were observed between treatment arms. **Conclusions:** FRPV following oral cyclophosphamide was safe, with no vaccine-related high-grade AEs. While no significant improvement in DFS or OS was observed overall, a numeric trend toward improved DFS was observed in pts with stage III TNBC. This finding is hypothesis-generating and supports further evaluation of FRα-targeted vaccination in higher-risk TNBC. Immune correlative analyses are ongoing to better define vaccine immunogenicity and its relationship to clinical outcomes. Clinical trial information: W81XWH-15-1-0293. Disparities in utilization of genomic risk assays in early-stage hormone-positive breast cancer: A retrospective analysis using National Cancer Database (NCDB). First Author: Qi Jin Guo, Medical University of South Carolina, Charleston, SC

Background: Prognostic genomic assays (GA) have become crucial in the management of early-stage hormone receptor positive breast cancer, particularly in guiding adjuvant chemotherapy decisions. Despite this, GA remain underutilized. This study aimed to identify predictors of GA utilization and associated survival outcomes. **Methods:** The 2023 NCDB PUF dataset was used to identify patients aged $\geq$ 18 years with HR positive, HER2 negative breast cancer diagnosed between 2010-2023. Patients with T1-T4, N0-N1 disease who underwent surgical resection were included, while those with T1aN0 stage, M1 disease, unknown GA status, or receipt of BCI alone were excluded. Patients were stratified by the receipt of the GA. Descriptive and multivariable analyses were performed to identify factors associated with GA utilization, and survival was assessed using Kaplan-Meier (KM) analysis. **Results:** 594,872 patients were included in our study, of whom 63.12% (N=375,506) underwent GA testing. GA utilization increased over time from 52.7% in 2010-2015 period to 68.7% in 2021-2023 ($p<0.001$). Using multivariable analysis, higher odds of GA testing were seen among Whites vs Blacks (OR 1.13 (1.11-1.16)), those with T2 tumors vs T1 (OR 1.26 95% CI 1.24-1.27), Grade 2 (OR 1.49 (1.47-1.51) or Grade 3 (1.42 (1.39-1.45)) histology vs Grade 1, receiving regional lymph node surgery vs not (OR 2.47 (2.33-2.62)), hormonal therapy vs not (OR 2.39 (2.34-2.43)), radiation vs not (OR 1.32 (1.30-1.34)), and recent year of diagnosis, 2021+ vs 2010-2015 (OR 2.08 (1.99-2.18)). The odds of GA testing were lower for uninsured vs government insured patients (OR 0.86 (0.82-0.91)), those with higher T stages (T3: OR 0.63 (0.61-0.65) and T4: OR 0.26 (0.24-0.30)) vs T1, N1 disease vs N0 (OR 0.73 (0.72-0.74)) and increasing age with the lowest odds among patients aged$>$80 (OR 0.13 (0.13-0.14)) compared to 18-64 years old. KM analysis showed survival benefit favoring receipt of GA (HR= 0.4 (0.39-0.41), $p<0.001$). **Conclusions:** Our study portrays low utilization of GA despite increasing use over time reflecting the impact of the TAILORx and RxPONDER trials. Significant disparities persisted by age, insurance status, race, and tumor characteristics. Older, Black and uninsured patients were substantially less likely to receive testing, despite an associated survival benefit, underscoring the need for more equitable implementation of guideline-recommended GA. Real-world post-APT trial adoption of de-escalated systemic therapy and outcomes in small HER2-positive breast cancer: An NCDB analysis. First Author: Mengni Guo, Department of Oncology/Hematology, Loma Linda University Medical Center, Loma Linda, CA

Background: The APT trial shifted adjuvant management of small HER2-positive breast cancer towards paclitaxel-trastuzumab, yet real-world uptake and outcomes of de-escalated single-agent chemotherapy (SC) plus anti-HER2 therapy (H) vs multi-agent chemotherapy (MC) plus H remain uncertain. **Methods:** Using NCDB (2013-2022), we identified patients with invasive HER2-positive pT1a-pT1c, pN0/N1mi, M0 disease treated with surgery without neoadjuvant therapy. We compared treatment patterns pre-APT (2013-2014) vs post-APT (2016-2022), excluding 2015 as a washout. Regimens were grouped as local therapy only, H only, chemo only, SC + H, or MC + H. Predictors of SC + H were assessed with multivariable logistic regression in post-APT chemo + H recipients. OS was evaluated using time-varying Cox models (time zero surgery; treatment exposure starting at recorded systemic therapy initiation), adjusted for demographic, tumor, and facility factors. In the overall cohort, each regimen (H only, chemo only, SC+H, and MC+H) was compared with local therapy only. For pT1a tumors, comparisons were limited to H only, chemo only, and any chemo + H vs local therapy. To evaluate whether de-escalation was associated with similar OS, SC + H vs MC + H was compared in separate Cox models restricted to chemo + H recipients in pT1b and pT1c. **Results:** Among 56,455 patients, SC + H use increased from 12.5% pre-APT to 40.3% post-APT, while MC + H decreased from 46.6% to 24.8% ($p< 0.001$). In the post-APT era among chemo + H recipients (N = 24,867), SC + H use increased with age (per 10-year OR 1.32, 95% CI 1.27-1.36) and hormone receptor-positive (HR-positive) status (OR 1.37, 95% CI 1.27-1.49), and less common with pT1c (OR 0.47, 95% CI 0.43-0.51) and N1mi (OR 0.21, 95% CI 0.17-0.24) tumors. In OS analyses of the entire cohort with available systemic start dates (N = 51,078; deaths = 3,246), SC + H (HR 0.62, 95% CI 0.57-0.67) and MC + H (HR 0.63, 95% CI 0.58-0.68) were associated with improved OS vs local therapy only. Additional independent predictors of mortality included Black race, older age, and higher tumor burden (T1c and N1mi), while HR-positive was linked to better OS. In pT1a cohort (N = 10,212; deaths = 461), any chemo + H was associated with improved OS vs local therapy (HR 0.83, 95% CI 0.70-1.00, p= 0.049), while H only (HR 0.85, 95% CI 0.51-1.42) and chemo only (HR 1.14, 95% CI 0.74-1.74) were not. Among chemo + H recipients, OS was similar for SC + H vs MC + H in pT1b (HR 0.96, 95% CI 0.80-1.16) and pT1c (HR 1.09, 95% CI 0.97-1.24) cohorts. **Conclusions:** Since APT, real-world care has shifted towards de-escalated SC + H regimens. Among treated pT1b and pT1c patients, OS was similar with SC vs MC backbones, supporting the feasibility of de-escalation in selected patients. In pT1a disease, the OS association for chemo + H was marginal (p= 0.049) and should be interpreted cautiously given non-random treatment selection and low event rates. Research Sponsor: None.

Adjuvant chemotherapy (CT) benefit in invasive lobular carcinoma (ILC) by Oncotype DX Recurrence Score and menopausal status. First Author: Arya Mariam Roy, The Ohio State University - James Comprehensive Cancer Center, Columbus, OH

Background: The benefit of adjuvant CT in early-stage hormone receptor–positive (HR+) and HER2-negative (HER2–) ILC remains uncertain. The predictive utility of the Oncotype DX Recurrence Score (RS), widely used to guide CT decisions in HR+/HER2 BC, remains debated in ILC. To address these gaps, we analyzed the impact of adjuvant CT on overall survival (OS) across RS categories and by menopausal status. **Methods:** We queried the National Cancer Database for patients (pts) with early-stage HR+/HER2– ILC who had surgery between 2010 and 2021. Pts were grouped by receipt of adjuvant CT (CT+ vs CT–). Analyses were stratified by RS (low 0–15, intermediate 16–25, high ≥26) and menopausal status, using age (<50 vs ≥50 years) as a proxy. Overlap propensity score weighting (OPSW) balanced baseline covariates (race, ethnicity, comorbidities, clinical T and N stage, grade and radiation and hormone therapies), and OPSW Cox models assessed the association between time-varying adjuvant CT and OS. **Results:** Among 141,949 pts with ILC, 19.6% received adjuvant CT. The CT+ cohort was younger (median age 59 vs 67 years) and more often pre-menopausal (21.8 vs 9%), and had high grade tumors (8.7 vs 3.3%), advanced T stage (T2: 39.4 vs 21.8%; T3: 14.9 vs 3.4%), node-positive (N1-3: 22 vs 3.2%) disease and more frequently received radiation (74.6 vs 56.5%) and hormone therapy (93.3 vs 87.5%), all p<0.001. RS testing was available in 38% of pts; CT+ cohort more often had high (9.2 vs 1.2%) or unknown RS (75.4 vs 57.9%), p<0.001. In the high RS group, CT was associated with improved 5-year (93.3 vs 90.5%) and 10-year OS (79.4 vs 71.7%) and lower mortality (adjusted hazard ratio (aHR) 0.69, p <0.001) (Table 1). Among postmenopausal pts, the survival benefit with CT was greatest in pts with high RS (10-year OS: 78.6 vs 69.2%; aHR 0.65, 95% CI 0.52–0.82, p=0.0003). No OS benefit was observed in low (aHR= 1.16, p= 0.31) or intermediate (aHR= 1.07, p= 0.39) RS groups. Among pre-menopausal pts, CT benefit was limited to the intermediate RS group (10-year OS: 94.9 vs 91.3%; aHR 0.57, 95% CI 0.33–1.00, p=0.049); no benefit was observed in low (aHR= 1.11, p= 0.77) or high (aHR= 1.50, p= 0.55) RS. **Conclusions:** In early-stage HR+/HER2– ILC, RS has limited clinical utility. Adjuvant CT benefit was restricted to pts with high RS, predominantly in postmenopausal pts, while RS did not reliably predict benefit in premenopausal pts. No OS benefit was seen in low RS disease, supporting a selective, biology-driven approach to CT use in ILC. CT decisions in pts with unknown RS appear largely driven by clinicopathologic factors. Research Sponsor: None.

10-year survival analysis of ILC patients based on CT receipt and RS.

RS group	OS (%, 95% CI) CT +	OS (%, 95% CI) CT -	aHR (95% CI) Reference: CT-	p-value
Low	87.6 (84.6-90.6)	88.9 (88.0-89.9)	1.13 (0.87-1.47)	0.36
Intermediate	86.2 (84.4-88.1)	86.5 (85.3-87.7)	1.02 (0.87-1.20)	0.78
High	79.4 (76.4-82.5)	71.7 (66.9-76.8)	0.69 (0.55-0.87)	<0.01

Overall survival association of adjuvant endocrine therapy (ET) after pathologic complete response (pCR) to neoadjuvant chemotherapy (NAC) in ER+/HER2+ early-stage breast cancer. First Author: Mengni Guo, Department of Oncology/Hematology, Loma Linda University Medical Center, Loma Linda, CA

Background: In ER+/HER2+ early breast cancer, adjuvant ET is standard; however, its survival benefit for patients achieving pCR after NAC remains uncertain. As pCR is associated with favorable prognosis and may inform postoperative decision-making, it is unknown if pCR identifies a subset in whom the ET survival benefit is reduced. We evaluated ET use patterns and its association with overall survival (OS) in ER+/HER2+ patients with pCR after NAC. **Methods:** Using NCDB, we identified women with ER+/HER2+ M0 breast cancer treated with NAC and definitive surgery (2018-2022) who achieved pCR (ypT0/ypTis and ypN0). The primary endpoint was OS. To reduce immortal time bias, we used a time-varying Cox model with ET initiation as a time-dependent exposure (time zero: surgery). A 6-month landmark analysis was performed as a sensitivity analysis. Multivariable models adjusted for demographic, clinicopathologic, treatment, and socioeconomic variables. Predictors of ET omission were assessed using multivariable logistic regression. Exploratory analyses evaluated ER-low (1-10%) and effect modification using an ET×ER-low interaction term. **Results:** Of 8,981 patients, 7,917 (88.2%) received ET and 1,064 (11.8%) did not. In the time-varying Cox model, ET receipt was associated with improved OS (HR 0.79, 95% CI 0.67-0.93). Worse OS was associated with older age (per 10 years: HR 1.17, 95% CI 1.10-1.24) and stage III disease (HR 1.39, 95% CI 1.16-1.67). In 6-month landmark analysis (n=8,756), ET benefit persisted (HR 0.58, 95% CI 0.39-0.86). There was no differential association by ER-low status (ET×ER-low interaction p=0.73), with similar ET associations in ER-high (HR 0.58) and ER-low (HR 0.63) groups. ET was omitted in 36.9% of ER-low patients compared to only 7.6% of ER-high patients. Logistic regression identified ER-low status as the strongest predictor of ET omission (OR 0.16, 95% CI 0.14-0.19). Omission was also more likely with older age (per 10-year increase: OR 0.92, 95% CI 0.85-0.99) and community facility treatment (OR 0.74, 95% CI 0.55-0.99), while ET receipt was more likely with PR-positivity (OR 1.54, 95% CI 1.32-1.79), radiation (OR 2.78, 95% CI 2.32-3.33) and HER2-targeted therapy (OR 2.62, 95% CI 2.03-3.38). **Conclusions:** In this NCDB cohort, adjuvant ET was associated with improved OS in ER+/HER2+ patients achieving pCR after NAC. The survival association did not differ by ER-low status, though event rates in this subgroup were limited. ER-low status was the strongest predictor of ET omission, highlighting a potential gap between real-world practice and outcomes. These findings support continued consideration of ET in post-pCR ER+/HER2+ patients, including the ER-low population. Research Sponsor: None.

Cohort	Total N	ET (%)	No ET (%)	Death (%)
Overall	8,981	7,917 (88.2%)	1,064 (11.8%)	152 (1.7%)
ER-low	1,316	831 (63.1%)	485 (36.9%)	32 (2.4%)

Three-monthly gonadotropin-releasing hormone agonist for ovarian function suppression in premenopausal breast cancer: A systematic review and meta-analysis. First Author: Pedro C.A. Reis, Universidade Federal do Rio de Janeiro, Rio De Janeiro, Brazil

Background: Ovarian function suppression (OFS) with gonadotropin-releasing hormone agonists (GnRHa) is a cornerstone of endocrine therapy (ET) for premenopausal women with hormone receptor–positive (HR+) breast cancer (BC), most commonly administered on a monthly (1M) schedule. Three-monthly (3M) formulations have been proposed to improve convenience and adherence, but comparative efficacy and safety versus 1M regimens remain uncertain. **Methods:** PubMed, Cochrane, and Embase libraries were systematically searched for randomized clinical trials (RCTs) and non-randomized interventional studies comparing 3M versus 1M GnRHa regimens in premenopausal women with HR+ BC receiving ET. Outcomes included the incidence of ovarian escape (OE), mean estradiol (E2), follicle-stimulating hormone (FSH), and luteinizing hormone (LH) levels, disease-free survival (DFS), progression-free survival (PFS), and adverse events, with a minimum follow-up of 12 weeks. Random-effects models were used to estimate pooled risk ratios (RR) and mean differences (MD) with 95% confidence intervals (CI). Subgroup analyses were performed by estradiol assay type, and a sensitivity analysis restricted to RCTs was conducted. **Results:** Fifteen studies comprising 4,324 patients were included; 2,098 (48%) received a 3M regimen. The overall incidence of OE was low (10%) and did not differ between 3M and 1M schedules (RR 0.86; 95% CI 0.60–1.22). Ultrasensitive assays revealed higher absolute OE rates (31%), without inter-regimen differences (RR 0.90; 95% CI 0.38–2.14). Mean E2 levels at 12 weeks were comparable across dosing strategies (MD 1.36 pg/mL; 95% CI −3.66 to 6.38), with no significant differences in mean FSH or LH levels; analyses restricted to RCTs yielded consistent findings (MD −1.77 pg/mL; 95% CI −5.71 to 2.17). DFS (RR 1.02; 95% CI 0.67–1.56) and PFS (RR 0.86; 95% CI 0.72–1.04) were similar between regimens. The most frequently reported adverse events were hot flashes, arthralgia, headache, and nausea, with no clinically relevant differences between dosing schedules. **Conclusions:** 3M GnRHa achieved OFS comparable to 1M dosing, with similar survival outcomes and safety profiles in premenopausal women with HR+ BC. Real-world effectiveness and safety of adjuvant capecitabine in triple-negative breast cancer (TNBC) patients with residual disease following neoadjuvant chemotherapy. First Author: Anbarasan Sekar, The Advanced Centre for Treatment, Research and Education in Cancer (ACTREC), Homi Bhabha National Institute (HBNI), Kharghar, India

Background: The presence of residual disease in triple-negative breast cancer (TNBC) after neoadjuvant chemotherapy is associated with high recurrence risk and poor prognosis. The CREAT-X study demonstrated improved recurrence risk and survival outcomes with adjuvant capecitabine in this population [1]. We previously reported long-term outcomes in nonmetastatic TNBC, but the population is unselected, and the impact of adjuvant capecitabine is not assessed in the Indian scenario [2]. **Methods:** This single-center retrospective study included TNBC patients with residual disease after neoadjuvant chemotherapy treated between January 2020 and December 2024 with adjuvant capecitabine. Baseline clinicopathological characteristics were analyzed descriptively. Survival outcomes were assessed using the Kaplan–Meier method, and recurrence-free survival (RFS) and overall survival (OS) were estimated. Factors associated with survival outcomes were evaluated using univariate and multivariate Cox proportional hazards regression models. **Results:** Among 1548 patients diagnosed with Stage I-III TNBC, 1044 patients treated with neoadjuvant therapy underwent surgery; 671 patients had residual disease, out of which 315 patients who received adjuvant capecitabine were included in this retrospective analysis. The majority were premenopausal (66.3%), were older than 40 years (59.7%), and had stage III residual disease (71.4%). At a median follow-up of 25 months, the 2-year overall survival (OS) was 79.6%, with a median OS of 49.7 months. The 2-year recurrence-free survival (PFS) was 49.3%, with a median RFS of 23.9 months. On univariate analysis, higher nodal status ($P < 0.001$) and advanced stage ($P < 0.05$) were significantly associated with inferior RFS, while higher nodal status was also associated with inferior OS ($P < 0.05$). Multivariate analysis confirmed nodal status as an independent predictor of poor survival ($P < 0.01$). **Conclusions:** Adjuvant capecitabine demonstrated poor outcomes in our TNBC patients with residual disease compared to the randomized study; nodal status independently predicted poorer outcomes, emphasizing risk stratification and prospective validation. Chemotherapy use among women < 50 years with hormone receptor–positive breast cancer with low (≤15) Oncotype DX 21-gene recurrence score: A National Cancer Database (NCDB) analysis. First Author: Mitali Shah, The Ohio State University James Comprehensive Cancer Center, Columbus, OH

Background: RxPONDER demonstrated a benefit to chemotherapy (CT) in premenopausal women with hormone receptor-positive (HR+) breast cancer (BC) with 1-3 pathological positive lymph nodes (pN1) regardless of Oncotype DX RS. Whether the benefit is due to the cytotoxic effects of CT itself or potentially from the CT-induced ovarian suppression remains to be determined. In the absence of large prospective data evaluating the predictive ability of RS in this population, including pN1mi, we sought to examine adjuvant CT use patterns among premenopausal women and low RS. **Methods:** This retrospective analysis queries the NCDB from 2018-2022 for patients (pts) with BC <50 years old (surrogate for premenopausal status) and clinically node negative disease at the time of diagnosis. Pts with stage I-III HR+ HER2-negative BC who underwent upfront curative breast surgery and had pathologically confirmed lymph node status (pN) were included. Oncotype DX RS was categorized as low if RS ≤15. Multivariable binary logistic regression was used to examine associations between clinicopathological factors and the receipt of adjuvant CT. **Results:** 6040 pts with Oncotype DX RS ≤15 met inclusion criteria. Most pts, 5090 (84.3%), had invasive ductal carcinoma, and high (>51%) ER and PR expression (>93% of patients). Among all low RS, 5081 (84.4%) had pN0 and 939 (15.5%) had pN1 or higher disease, 704 pts (76.6%) having 1 LN involved, of which 317 pts were pN1mi; 148 (16.1%) had 2 LN and 67 (7.3%) had 3+ LN. Accounting for all pts, 265 (4.4%) received CT: 64 (24.2%) were pN0, while 201 (75.8%) were pN1+. Among pts with pN1 BC, older age was associated with lower odds of receiving adjuvant CT (aOR 0.96, 95%CI 0.93-1.00, p=0.03). Other factors including higher pathologic tumor stage (pT3/T4 vs pT1/T2; aOR 4.46, 95% CI 2.34–8.51), higher pN involvement, specifically 2 LN (aOR 2.45, 95% CI 1.60–3.75) and ≥3 LN (aOR 4.65, 95% CI 2.54–8.51) compared to 1 positive regional LN, and poorly (vs well) differentiated tumor (aOR 2.36, 95% CI 1.14–4.88) had higher odds of receiving CT. Similarly, pts with pN0 and low RS that had pT3/T4 tumors (aOR 3.99, 95% 1.16-13.72) and higher grade (moderately and poorly differentiated tumors) had higher odds of receiving CT (aOR 1.84 95% CI 1.03-3.27 and 6.11 95% CI 2.58-14.44, respectively). **Conclusions:** Among women <50 years with low RS (≤15), CT receipt was strongly associated with clinicopathologic risk factors, including higher tumor stage, poorly differentiated grade and higher regional nodal involvement. These findings indicate that despite a low RS, young age and node positivity are associated with adjuvant CT recommendation. These results highlight the importance of ongoing trials such as OFSET, which aims to better answer the appropriateness of CT among premenopausal women. Research Sponsor: None.

Comparative effectiveness of adjuvant chemotherapy on survival in node-positive (N2/N3), stage III ER+/HER2− invasive lobular breast cancer (ILC) versus invasive ductal cancer (IDC). First Author: Sumeet K. Yadav, Mayo Clinic Florida, Jacksonville, FL

Background: ILC is characterized by loss of E-cadherin expression, with distinct biological and clinical features, and is often perceived to be less sensitive to chemotherapy compared with IDC. Oncologists and pts may face a treatment dilemma regarding the benefits of adjuvant chemotherapy in pts with lower biologic risk but higher anatomic risk (N2/N3), stage III ILC. In this study, we sought to compare the benefit of adjuvant chemotherapy in pN2/N3 ILC compared with IDC. **Methods:** We used the National Cancer Database (NCDB) to identify adults with primary, non-metastatic, ER-positive/HER2-negative invasive breast cancer diagnosed between 2010 and 2022 who underwent upfront surgery. Patients receiving neoadjuvant systemic therapy were excluded. Analyses were limited to pathologic stage I–III disease with known nodal involvement (N2–N3) and tumor category (T1–4). Propensity score matching (1:3, caliper 0.2; using R 4.5.1) was performed to balance age, sex, race, insurance status, grade, pathologic stage, nodal category, tumor category, Charlson-Deyo comorbidity score, and year of diagnosis. Overall survival (OS) was assessed using Kaplan–Meier methods and Cox proportional hazards models used to estimate hazard ratios (SPSS v28). **Results:** After propensity matching, we analyzed 28,115 pts with pN2/N3 disease (ILC 9,603 and IDC 18,512). Upstaging from cN0 to pN2/3 was higher for ILC than IDC (20.3% vs 13.3%, $p<0.001$). ILC pts were more likely to undergo mastectomy compared to IDC (80.2% vs 71.2%, $p<0.001$). Receipt of adjuvant chemotherapy for pN2/N3 disease was similar between IDC and ILC (78.0% vs 78.4%, p=0.37), as was use of adjuvant radiation and endocrine therapy. Among patients receiving chemotherapy, treatment was associated with a 65% reduction in death in ILC (HR 0.35, 95% CI 0.32–0.38, $p<0.001$) and a 73% reduction in IDC (HR 0.27, 95% CI 0.26–0.29, $p<0.001$), compared with no chemotherapy. 5-year OS among chemotherapy-treated patients was lower for ILC compared with IDC (HR 1.4, 95% CI 1.33-1.49; $p<0.001$, Table 1). In contrast, no OS difference was observed between ILC and IDC among patients who did not receive chemotherapy (HR 1.03, 95% CI 0.96-1.11; p=0.38). Chemotherapy was associated with higher 5-year OS in both IDC (87.7% vs 58.9%) and ILC (84.3% vs 59.2%). **Conclusions:** Adjuvant chemotherapy was associated with a substantial improvement in 5-year OS among patients with pN2/N3 disease in both IDC and ILC. Pts with ILC and extensive nodal involvement benefit from adjuvant chemotherapy. Research Sponsor: None.

5-year survival of IDC and ILC.

	IDC (18,512)		ILC (9,603)	
	No Chemotherapy (4,078)	Adjuvant Chemotherapy (14,434)	No Chemotherapy (2,071)	Adjuvant Chemotherapy (7,532)
pN2 (18,669)	62.8%	90.1%	64.4%	87.6%
pN3 (9,446)	48.3%	82.2%	51.4%	79.4%

AI-based pre-screening of *BRCA1/2* mutation likelihood from routine H&E histopathology in unselected breast cancer cases using peakPredictBRCA. First Author: Maher Sughayer, Department of Pathology, King Hussein Cancer Center, Amman, Jordan

Background: BRCA1/2 mutation status is essential for precision oncology in breast cancer, directly guiding therapy decisions such as eligibility for PARP inhibitors. However, not all patients globally have reimbursed access to genetic BRCA testing, due to cost and a lack of uniform global implementation, leading to actionable mutations being missed. We developed a scalable artificial intelligence pre-screening algorithm that estimates BRCA1/2 mutation likelihood from routine whole-slide H&E images, to enable systematic prioritization of patients for genetic testing. **Methods:** peakPredictBRCA, a deep learning-based algorithm, was developed to predict likelihood of BRCA1/2 mutations from H&E whole-slide images of primary and metastatic breast cancer cases, independent of hormone receptor or HER2 status. Breast cancer images were collected from 6 institutions across 5 countries using different whole-slide scanners (Argentina, Brazil, Germany, Jordan, and USA), with slide-level BRCA mutation labels derived from clinical sequencing (n=725 images, 60% mutated). Training data was augmented with open-access TCGA datasets for breast, prostate, and ovarian cancer (n = 1,633 images), resulting in 2,358 total images (21% mutated). Model performance was evaluated on the collected breast cancer images using five-fold cross-validation. The model was trained end-to-end without manual annotations using multiple-instance learning. **Results:** On the breast cancer cohort, peakPredictBRCA achieved a mean AUC of 0.81 ± 0.13. At a screening-oriented operating point, the model identified most BRCA1/2 mutated cases (mean sensitivity 0.82 ± 0.23) while excluding a substantial proportion of non-mutated cases (mean specificity 0.56 ± 0.38), without additional calibration on held-out images. Additional analyses during development demonstrated that robust generalization to unseen data depends on appropriate tumor tissue detection and model architecture selection. **Conclusions:** Our results demonstrate that BRCA1/2 mutation likelihood can be effectively triaged from routine H&E breast cancer histology with consistent performance across institutions, scanners, and slide preparations. Implementation of the peakPredictBRCA algorithm in routine pathology workflows could enable systematic prescreening of unselected breast cancer cases at diagnosis and prioritization for confirmatory genetic testing, particularly in resource-constrained settings. Ongoing work focuses on incorporating human-interpretable features and on prospective validation in real-world workflows. Research Sponsor: AstraZeneca International; Mindpeak GmbH.

Recurrence risk prediction using a large, multi-site observational dataset of patients with early breast cancer, including early-onset disease. First Author: Lilia Bouzit, Flatiron Health, New York, NY

Background: Accurate risk stratification in early breast cancer (eBC) is critical to guide adjuvant treatment intensity. In HR+/HER2- stage I-III disease, clinicians use clinical and genomic information to estimate recurrence risk, yet a comprehensive, real-world predictive model that synthesizes these inputs after curative-intent surgery is not established in routine practice. We developed a multimodal predictive survival model in a large, eBC cohort to predict recurrence-free survival (RFS) after surgery and derive risk groups to inform treatment escalation or de-escalation. **Methods:** This study used the US-based EHR-derived deidentified Flatiron Health Research Database (data cutoff: Sep 30, 2025). The cohort consisted of patients (pts) diagnosed with HR+/HER2- stage I-III eBC between Jan 1, 2016, and Jan 1, 2023, who received surgery and no neoadjuvant therapy. An Extreme Gradient Boosting (XGBoost) model was developed using 10-fold cross-validation, reserving 20% for testing, predicted time from surgery to recurrence or death. SHapley Additive exPlanations (SHAP) analysis was used to rank feature importance. Pts were classified into 3 risk groups by prediction percentile, and RFS by group was plotted in the test set using the Kaplan-Meier method. A second XGBoost model identified predictors specific to pts diagnosed with early onset (EO) eBC (age $\leq$ 45 yrs). **Results:** 158,111 pts qualified for the cohort, and the model C-index was 0.76. Top features that contributed to increased predicted hazard include age, higher tumor grade, higher stage, higher OncotypeDx score, longer time from diagnosis to surgery, ECOG score $\geq$2, and smoking history. Higher socioeconomic status (SES) decreased predicted hazard. Age had a non-linear association with predicted hazard; risk was elevated among pts $<$35 and $>$71, with lowest prediction occurring at ages 46-51. The median RFS in the high-risk group was 8.5 yrs (IQR, 8.2-8.8) and was not reached in the medium and low-risk groups. In the early onset subgroup of 12,196 pts, the C-index was 0.71. Top features in the EO model that contributed to increased hazard also included higher tumor grade and stage, and younger age. Importance of race and Ki67 percent staining (PS) superseded that of ECOG and SES in the EO model. Pts of Black or African American race and pts with Ki67 PS $\geq$20% had higher predicted hazard. **Conclusions:** This analysis elucidated key predictors of RFS following surgery in pts with eBC, specifically in non-neoadjuvant–treated pts at higher risk for recurrence, and illustrated predictors that vary in younger pts. Predictors from this large, representative dataset are aligned with known associations with recurrence risk. These findings suggest real-world data models may complement established tools guiding adjuvant treatment intensity, though external validation and prospective evaluation are needed. AI-driven large language models for multimodal prediction of homologous recombination deficiency using clinical features and histopathological whole-slide images. First Author: Zhao Sun, School of Cyber Science and Engineering, Zhengzhou, China

Background: Homologous recombination deficiency (HRD) implies the dysfunction of homologous recombination repair at the cellular level. The assessment of HRD status benefits making treatment plans and fertility counseling of breast cancer patients. Standard diagnostic tests for detecting HRD are expensive and not universally available. **Methods:** We trained a deep learning framework to predict HRD status by integrating routinely collected clinical records and histopathological imaging data, including hematoxylin and eosin (H&E)–stained whole-slide images, from primary breast cancer patients (n = 397) across three independent regional medical centers. The patient cohort was split into a training set (80%) and a validation set (20%). Clinical text as well as whole-slide images were encoded using large language model. This model integrated multimodal representation learning and was applied to generate robust HRD predictions. **Results:** Across breast cancer cohorts from three independent regional medical centers, the proposed approach demonstrated robust and consistent performance in predicting HRD. The reported AUC of 0.82 (95% CI, 0.79–0.84) represents the mean value over ten independent experiments with different random seeds. Notably, the model achieved a precision of 0.84 and a specificity of 0.92, indicating strong discriminatory power with a tendency towards cautious decision-making. **Conclusions:** Our model showed promising HRD predictive performance in breast cancers directly from routine multimodal data integrating clinical characteristics, imaging description with pathological slides. The HRD-positive predictions generated by this model show promise for clinical translation. Research Sponsor: National Natural Science Fund of China; No.82472749.

Prediction of pathologic response using a taxane-based gene expression signature in RNA-sequencing data from breast cancer patients receiving neoadjuvant therapy. First Author: Jan Nart, Aida Oncology, Copenhagen, Denmark

Background: Taxanes are frequently used in both early and advanced breast cancer, but their use has not yet been guided by predictive biomarkers. We have previously validated a microarray-based 113-gene predictive signature for neoadjuvant taxane-based treatment across 6 independent cohorts, including I-SPY2. Here, we present our first validation of this signature in RNA-sequencing data. **Methods:** The study by Park et al. (2020; PMID: 33268821) enrolled 210 women with stage II–III invasive breast cancer, who received four cycles of neoadjuvant doxorubicin plus cyclophosphamide (AC) followed by four cycles of docetaxel (T) with trastuzumab (H) added for HER2-positive disease. We obtained pre-treatment TPM-normalized RNA-sequencing data from GEO (accession ID: GSE123845) for patients with available response data—pathologic complete response (pCR; n = 34) vs. residual disease (RD; n = 62)—following treatment completion (n = 96). To ensure compatibility between the RNA-sequencing data and microarray-based model, we performed frozen quantile normalization using the original training dataset for the model (GSE140494) as reference. We applied the signature on the normalized data to generate a response score for each patient in the range of 0-100 and evaluated the association between treatment response and patient score using logistic regression. **Results:** Increase in patient score was significantly associated with higher odds of pCR after adjusting for ER and HER2 status (one-sided P = 0.003), with a 50-point increase corresponding to an odds ratio of 3.44 (95% CI, 1.46-8.71), and an AUC of 0.74 for predicting pCR. Stratifying patients by median score revealed notable differences in pCR rates between low- and high-scoring patients. For ER+/HER2- patients (n = 28; median score = 26.6), the difference in pCR rates was 29% (0% vs. 29%) for patients below vs. above the median. Corresponding differences for triple-negative (n = 35; median score = 65.6) and HER2-positive patients (n = 33; median score = 51) were 13.8% (33.3% vs. 47.1%) and 39.4% (29.4% vs. 68.8%), respectively. **Conclusions:** We present the validation of a 113-gene predictive signature in RNA-sequencing data for achieving a pCR after taxane-based therapy. This is our first attempt at validating the signature in RNA-sequencing data, and the 7th successful validation overall across independent breast cancer cohorts. This result further highlights the signature's potential as a tool to support taxane-based treatment guidance. Research Sponsor: None.

Evaluating performance of an AI-based recurrence score in early breast cancer patients treated with chemoendocrine therapy: A secondary analysis of the UNIRAD trial. First Author: Thomas Bachelot, Medical Oncology Department, Centre Léon Bérard, Lyon, France

Background: Patients with node-positive HR+/HER2- early breast cancer are at high risk for relapse within 5 years of diagnosis, suggesting the potential need for treatment escalation. However, it is unclear which patients may experience worse recurrence-free outcomes and thus benefit from additional therapy. Ataraxis Breast (ATX) is an artificial intelligence (AI) test that integrates clinicopathologic variables with features extracted from whole-slide H&E images to estimate recurrence risk. Here, we perform a secondary analysis of the control arm of the UNIRAD trial, evaluating the ability of ATX to identify patients treated with standard-of-care therapy who may be candidates for treatment escalation. **Methods:** Clinical information and scanned H&E slides were sourced for 365 patients enrolled in the UNIRAD trial who were randomized to the control arm (standard-of-care therapy). ATX scores were generated using a locked model with pre-specified thresholds. No patients from UNIRAD were used in the training of ATX. Recurrence-free interval (RFI) was used as the primary endpoint. Kaplan-Meier estimators were used to predict the probability of meeting the RFI endpoint. To quantify relative differences in the hazard of experiencing an event contributing to the RFI endpoint associated with ATX scores, Cox proportional hazards models were fitted, from which hazard ratios (HRs) were estimated. The discriminative performance of ATX was evaluated using C-index. **Results:** Of the 365 patients randomized to the control arm of the UNIRAD trial with H&E slides available, 163 (45%) were classified as ATX low risk, and 202 (55%) as ATX high risk. Patients classified as ATX high risk had lower Kaplan-Meier-estimated probability of meeting the RFI endpoint (77%, 95% CI = 70-83%) than patients classified as ATX low risk (93%, 95% CI = 88-97%). Consistent with these findings, when modeled as a continuous variable, higher ATX scores were associated with a significantly higher hazard of an RFI-contributing event (HR = 1.57, 95% CI = 1.29-1.99, p-value $<$ 0.001) and demonstrated strong discriminatory performance (C-index = 0.66, 95% CI = 0.59-0.72). This association remained significant after controlling for receipt of neoadjuvant therapy, tumor, and nodal stage (HR = 1.53, 95% CI = 1.05-2.23, p = 0.027). **Conclusions:** In the clinically homogenous UNIRAD trial cohort of patients with node-positive HR+/HER2- early breast cancer, ATX high risk patients treated with standard-of-care therapy had a significantly increased hazard of an RFI-contributing event. These findings suggest that AI-based risk stratification identifies biologically high risk patients who may derive benefit from adjuvant treatment escalation. Clinical trial information: NCT01805271. Research Sponsor: Ataraxis AI.

Estimating individual benefit from adjuvant chemotherapy in hormone receptor–positive breast cancer using causal multimodal artificial intelligence. First Author: Frederick Howard, University of Chicago, Chicago, IL

Background: Adjuvant chemotherapy decisions in HR+/HER2– early breast cancer are often guided by prognostic gene expression assays. However, assessment of recurrence risk may not yield a predictive biomarker that accurately estimates treatment benefit. Here, we combine advances in deep learning and causality research to address this problem using routine histopathology and clinical data. We develop and validate a causal multimodal artificial intelligence (AI) model that predicts the patient-specific benefit of adding chemotherapy to endocrine therapy in HR+/HER2– early breast cancer. **Methods:** De-identified whole-slide histopathology images (WSIs) and clinical covariates from 9,269 patients across 12 observational cohorts were used to develop the Ataraxis Breast model (ATX). The locked model was then externally validated in a cohort from the University of Chicago (n = 435, stage I-III HR+/HER2– breast cancer, median age = 56, median follow-up = 7.2 years), grouped by adjuvant therapy received (endocrine therapy [ET] n = 322, chemoendocrine therapy [CET] n = 113). The primary endpoint was 5-year recurrence-free interval (RFI). WSIs were encoded via a pathology foundation model and integrated with clinical variables (including T/N stage, age, ductal vs lobular histology). ATX predicted counterfactual RFIs, assuming CET or ET, with the difference taken as the predicted treatment-benefit score. Discrimination was evaluated using Harrell's C-index. Multivariate Cox proportional hazards models were fitted, adjusting for clinicopathological factors (age and T/N stage), to estimate hazard ratios (HR). Subgroup differences were assessed using inverse-propensity-weighted Kaplan-Meier estimates and two-sided log-rank tests. **Results:** In the external validation cohort, ATX was significantly associated with the primary endpoint (adjusted HR = 1.65, 95% CI 1.05-2.6; p = 0.029), and demonstrated good discrimination at the patient-level (C-index = 0.704, 95% CI 0.588-0.821). Notably, ATX stratified patients into subgroups with differential chemotherapy effects: patients in the top tertile of predicted treatment benefit experienced improved RFI with CET (ET RFI = 0.744, CET RFI = 0.980; $p < 0.001$), with no difference observed in patients with low predicted treatment benefit (ET RFI = 0.975, CET RFI = 0.970; p = 0.85). The interaction between ATX and the magnitude of chemotherapy benefit, when adjusted for clinicopathological factors, was significant (p-interaction = 0.005). **Conclusions:** A causal multimodal AI model accurately estimates chemotherapy benefit for patients with HR+/HER2– early breast cancer, meeting the criteria for a predictive biomarker. The causal AI methodology presented here may provide a generalizable framework to optimize scalable, predictive biomarkers for other therapies and cancer types. Research Sponsor: Ataraxis AI.

Evaluating the prognostic performance of an AI-based model in clinically low-risk HR+/HER2− early breast cancer. First Author: Dhruva Biswas, Ataraxis AI, New York, NY

Background: Accurate prediction of recurrence risk in early HR+/HER2- breast cancer remains central to adjuvant treatment decision making. Clinically approved prognostic models largely rely on genomic features, yet their performance remains insufficient for optimal clinical stratification. To address these limitations, AI-based approaches have increasingly been developed to improve risk prediction. Ataraxis Breast (ATX) is a multimodal artificial intelligence test integrating clinical information with morphological information from H&E-stained whole slide images for HR+/HER2- patients. Here, we evaluate ATX's ability to prognosticate recurrence risk in an external cohort of clinically low risk early breast cancer patients from Dordrecht, the Netherlands. **Methods:** Clinical information and H&E images were accessed for 887 patients with HR+/HER2- breast cancer. ATX scores were generated using a locked model and a prespecified cut-off was applied to classify patients into ATX high vs low groups. The primary endpoint was recurrence-free interval (RFI); recurrence-free probabilities were estimated for the two groups using a Kaplan-Meier estimator. Additionally, performance of ATX was assessed using C-index and hazard ratio (HR per 0.1 increase in ATX score). No patients from this dataset were used in the training of ATX. **Results:** The cohort of 887 patients was characterized by low clinical risk, where 631tumors were classified as T1 and 239 as T2, and the majority of patients were node-negative (N0: n = 639). Tumors were predominantly low to intermediate grade (grade 1: n = 296; grade 2: n = 496), with relatively few high-grade cases (grade 3: n = 88). Histological analysis identified invasive lobular carcinoma in 131 patients. The median tumor size was 15 mm (interquartile range, 11-22 mm). Accordingly, most patients (n = 773, 87%) were classified as ATX low risk. Patients in the ATX high risk group had lower estimated 5-year probability of meeting the RFI endpoint (0.88, 95% CI = 0.80-0.93) than patients classified as ATX low risk (0.98, 95% CI = 0.96-0.98). When modeled as a continuous variable, ATX demonstrated strong discriminatory performance for recurrence risk (C-index = 0.740, 95% CI, 0.68-0.80) and was associated with a significantly increased hazard of an RFI-contributing event (HR = 2.68, 95% CI, 2.09-3.45; $p < 0.001$). To account for clinical confounding, we fitted a multivariate Cox proportional hazards model adjusting for T stage, N stage, grade, age at diagnosis, adjuvant endocrine therapy, adjuvant chemotherapy, and tumor size. We found that ATX score remained significant (HR = 1.99, 95% CI = 1.38-2.86, $p < 0.001$) and tumor size was the only other variable that was statistically significant ($p < 0.05$). **Conclusions:** ATX accurately prognosticates recurrence risk in a clinically low risk group of HR+/HER2- breast cancer patients from an external validation cohort. Research Sponsor: Ataraxis AI.

Standardized exam-style benchmarking of large language models in breast cancer clinical decision-making. First Author: Mariam Haji, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Large language models (LLMs) are increasingly used to support clinical reasoning in breast cancer (BC), yet reproducible benchmarking remains limited. In our prior work using complex breast cancer clinical scenarios (BCCS), OpenEvidence (OE) outperformed other LLMs; however, expert Likert-based grading may be influenced by subjective interpretation and human bias. Standardized, board-style multiple-choice questions—required even for expert clinicians—offer an objective framework to assess LLM accuracy and inform readiness for potential clinical decision support. We evaluated the accuracy of four LLMs on a standardized BC question set using binary grading and paired statistical testing. **Methods:** One hundred BC questions reflecting real-world clinical scenarios were submitted to four LLMs: ChatGPT-5.2 (GPT), Google Gemini 3 (Gemini), Claude Sonnet 4.5 (Claude), and OE. Questions were sourced from a hematology–oncology question bank and spanned major BC subtypes and treatment settings. Model responses were graded against bank-designated correct answers using binary scoring (1=correct, 0=incorrect). Overall accuracy with 95% confidence intervals (CI) was calculated. Pairwise comparisons were performed using McNemar's test. **Results:** One hundred clinical scenarios were evaluated spanning all major BC subtypes and treatment settings, including early-stage and metastatic disease, and neoadjuvant and adjuvant therapy. Overall accuracy was highest for Gemini at 94.0% (95% CI, 87.4–97.8), followed by GPT at 90.0% (95% CI, 82.4–95.1), OE at 90.0% (95% CI, 82.4–95.1), and Claude at 89.0% (95% CI, 81.2–94.4). McNemar's test showed no statistically significant differences between models. Compared with Gemini, GPT showed 4% lower accuracy (p=0.289), Claude 5% lower (p=0.267), and OE 4% lower (p=0.289). GPT and OE demonstrated equivalent accuracy (both 90.0%) with no significant difference (p=1.000). GPT vs Claude differed by 1% (p=1.000) and Claude vs OE differed by 1% (p=1.000). All models generated clinical reasoning, while OE was the only model providing citations. **Conclusions:** In standardized BC clinical scenarios, four widely used LLMs demonstrated high accuracy with no significant between-model differences. However, no model achieved 100% accuracy, reinforcing the need for ongoing refinement and clinician oversight prior to clinical use. Future studies should expand question volume, evaluate domain-specific error patterns, and incorporate question banks from multiple countries and geographic regions to improve generalizability before real-world clinical deployment. Incremental prognostic value of an AI-derived histology signature beyond the 21-gene recurrence score: A prospective-retrospective validation in TAILORx. First Author: Magali Iacroix-Triki, Gustave Roussy, Department of Medical Biology and Pathology, IHU-National PRecISion Medicine Center in Oncology, Villejuif, France

Background: The 21-gene recurrence score (RS) is a foundational tool for risk-stratifying HR+/HER2- early breast cancer (EBC). However, clinical outcomes vary within RS categories. RlapsRisk BC (RR), an AI pathology-based test, integrates features from H&E-stained whole-slide images with clinical data (age, tumor size, nodal status) and was developed using 7 retrospective cohorts totaling 6,039 patients. We evaluated the clinical validity of RR and its histology-only component (RR-H) beyond RS and standard clinicopathologic factors. **Methods:** The clinical validity of RR was established through a validation program of 4 cohorts and over 8,521 patients across diverse geographic regions and laboratory settings. This included 3 international cohorts (n=933) and a prospective-retrospective analysis of the TAILORx trial, where RR-H was evaluable in 7,585 (97.5% of analyzable patients). The primary endpoint was distant recurrence-free interval (DRFI). In TAILORX, we assessed the additive value of the RR-H score to a base model (composed of age, tumor size, histological grade and RS) using Cox proportional hazards models and C-index comparison. **Results:** Across international validation cohorts (median follow-up 7.5 years, 9,8% DRFI events), RR successfully stratified patients (HR=4.91; 95% CI: 3.13-7.71; $p < 0.00001$), and identified a low-risk population with a 97.5% (95% CI: 95.8%-98.5%) 5-year DRFI rate. In the TAILORx population (n=7,584), the RR-H score was a highly significant independent predictor of DRFI. Incorporating RR-H as a continuous variable to the base model (including RS) significantly increased the C-index from 0.6730 to 0.7007 ($p < 0.0001$). The estimated HR for a 1-point difference in RR-H was 1.108 (95% CI: 1.078-1.138; $p < 0.0001$). When analyzed by quartiles, patients in the highest risk group (Q4) exhibited a significantly higher risk of distant recurrence compared to the lowest risk group (Q1) HR= 2.656 (95% CI: 2.003-3.522). Concordance analysis revealed that RR-H is independent of stromal TILs (R^2=0.01). While RR-H correlated with increasing histological grade, substantial distribution overlap confirms intra-grade prognostic granularity. Furthermore, RR-H distributions were consistent across ILC and non-NLC. **Conclusions:** RR demonstrated robust and reproducible prognostic value across 8520 patients from diverse populations and settings establishing its clinical validity. Additional findings on TAILORx demonstrate that RR-H provides significant, independent prognostic value that complements existing prognostic tools (including genomic assays and clinicopathological factors), suggesting that integrating AI-pathology can refine precision risk assessment, and thus optimize adjuvant treatment in HR+ HER2- EBC. Research Sponsor: National Cancer Institute; U10CA180820, U10CA180794, UG1CA233329, UG1CA233247; U.S. Postal Service Breast Cancer Stamp Fund; Breast Cancer Research Foundation (USA); CONS-23-007.

Prognostic validation of artificial intelligence (AI)–based Stratipath breast risk stratification in TAILORx. First Author: Johan Hartman, Department of Oncology-Pathology, Karolinska Institutet, and Stratipath, Stockholm, Sweden

Background: Stratipath Breast is an AI-based prognostic medical device for risk stratification of early-stage breast cancer using routine H&E-stained histopathology whole slide images (WSIs). AI-based analyses of histopathology slides offer an alternative to costly and logistically demanding genomic assays. In this study, the prognostic performance of Stratipath Breast was validated in the TAILORx trial (NCT00310180). **Methods:** WSIs from patients enrolled in TAILORx were analyzed by Stratipath Breast. After histopathology quality control and availability of clinical endpoints and WSIs, 5,519 patients were included. Stratipath Breast binary risk category, multi-level risk group, and continuous risk score were evaluated. The prognostic performance was analyzed by Kaplan-Meier statistic and log rank test, as well as concordance index (C-index). Multivariable Cox Proportional Hazard (PH) model adjusting for age, tumor size, histologic subtype and continuous Oncotype DX recurrence score (RS), both without and with histologic grade, was used to assess independent prognostic value. Recurrence-free interval (RFI) and distant recurrence-free interval (DRFI) were evaluated. **Results:** 53.9% (2,975/5,519) of patients were classified as Stratipath low risk and 46.1% (2,544/5,519) as high risk. A significant association of Stratipath risk category and group with RFI and DRFI was confirmed ($p < 0.05$). In multivariable Cox PH analyses, Stratipath high-risk category was an independent prognostic factor associated with worse outcomes (RFI HR = 1.54, 95%CI:1.29-1.84, $p < 0.05$; DRFI HR = 1.61, 95%CI: 1.30-1.99, $p < 0.05$). Stratipath risk category remained significant in multivariable analysis when histologic grade was included, whereas grade did not. RS remained prognostic significant in multivariable analyses together with Stratipath Breast, indicating potentially complementary prognostic information. C-index improved with inclusion of Stratipath Breast together with clinical variables and RS, exceeding that of grade. **Conclusions:** In the TAILORx trial Stratipath Breast was found to provide significant prognostic value. Stratipath Breast also provided independent prognostic value in multivariable analysis adjusting for standard clinicopathologic factors and RS. These findings support the clinical relevance of AI-driven morphology-based biomarkers for breast cancer risk stratification. Deep learning–based classification of benign and malignant breast lesions on ultrasound using knowledge distillation with external validation and global deployment. First Author: Jansi Rani Sethuraj, AIM DOCTOR, Thiruverkadu, India

Background: Breast cancer is the most common malignancy in women worldwide. Although breast ultrasonography is widely accessible, diagnostic accuracy remains limited by operator dependence and interobserver variability ($\kappa \approx 0.6–0.8$), contributing to delayed diagnosis and unnecessary biopsies. While deep learning has shown promise in ultrasound-based lesion classification, many models are computationally intensive and lack external validation, limiting clinical scalability. We developed a deployment-ready deep learning framework that balances diagnostic performance with computational efficiency using structured knowledge distillation. Objectives: To develop and externally validate a computationally efficient deep learning model for binary breast ultrasound lesion classification; to evaluate whether a distilled student model preserves clinically meaningful performance from a high-capacity teacher network; and to assess global clinical feasibility through independent radiologist evaluation. **Methods:** We analyzed 8,116 breast ultrasound images (4,074 benign; 4,042 malignant) independently annotated by two board-certified radiologists with consensus adjudication. A ResNet34 teacher network (21.8M parameters) was trained using ImageNet-pretrained weights. A lightweight ResNet18 student network (11.7M parameters; 46% reduction) was trained using structured knowledge distillation with confidence-aligned soft targets and KL-divergence regularization. External validation was performed on three independent ultrasound datasets not used during training. Performance metrics included accuracy, sensitivity, specificity, precision, F1 score, and AUROC. The model was deployed in a HIPAA-compliant cross-platform application and independently evaluated by physicians across six continents. **Results:** The student model achieved 91.9% accuracy on held-out test data with balanced performance (sensitivity 90.8%, specificity 93.0%, F1 score 0.918). External validation demonstrated stable generalization (accuracy 89–92%). In global clinical deployment, 94.2% of participating physicians rated the system clinically useful and suitable for integration into routine breast ultrasound workflows. **Conclusions:** Knowledge distillation enables substantial model compression while preserving diagnostic accuracy for breast lesion classification on ultrasound. This scalable, deployment-ready approach supports standardized interpretation across diverse clinical environments and warrants prospective evaluation for reducing unnecessary biopsies and improving diagnostic efficiency. Prospective-retrospective HeCOG phase III trial validation of Polaris TME for the prediction of TILs from whole-slide images in high-risk early breast cancer. First Author: Elena Fountzilas, Hellenic Cooperative Oncology Group, Athens, Greece

Background: Tumor-infiltrating lymphocytes (TILs) are an established prognostic and predictive biomarker in early breast cancer. However, manual histopathologic scoring can introduce interobserver variability and limit throughput in analyzing at scale in routine practice. Recent advances in artificial intelligence (AI) offer the potential to standardize TILs quantification and enhance reproducibility. Our aim is to evaluate whether deep learning-based tumor microenvironment (TME) quantification from digitized hematoxylin- and eosin (H&E)-stained slides can accurately classify TILs and assess their prognostic role in patients with early breast cancer. **Methods:** We conducted a prospective-retrospective external validation of Polaris TME, a deep learning model for TME quantification. The analysis included patients with high-risk early breast cancer treated with adjuvant contemporary dose-dense chemotherapy, spanning all histological subtypes, enrolled in four HeCOG trials conducted between 1997 and 2008 (3 randomized and 1 observational). Manual TILs scoring had been centrally performed by pathologists according to International TILs Working Group guidelines, enabling direct comparison between manual and AI-derived scoring. The Polaris foundation model was used for feature extraction, while model performance was assessed using correlation for continuous TILs scores using the Spearman ρ and discrimination for clinically defined TILs categories (thresholds: 5% and 50% using the Area Under the Curve (AUC) with 95% CI. The prognostic value of the model was assessed using the log-rank test for invasive disease-free survival (iDFS). **Results:** Overall, 1,214 patients with whole slide images, TILs quantification and follow-up data were included; median age 53 [22-79]; 638 (63%) were hormone receptor-positive/HER2-negative, 394 (32%) HER2-positive, 176 (14%) triple-negative breast cancer (TNBC), and 6 patients of unknown subtype. Median follow-up was 116.59 (53.45 –157.06) months. When blindly deployed on the external cohorts, the model showed a significant correlation with the manual TILs scoring (ρ=0.60, $p<0.001$). The model yielded an AUC of 0.78 (0.75–0.81) for >5% TILs and AUC of 0.92 (0.88–0.95) for the >50% TILs. Predicted low-TILs tumors were associated with significantly lower 10-year iDFS in TNBC (55.1% versus 70.9%, p=0.034), with a similar pattern observed in HER2-positive (55.3% versus 64.8%, p=0.096), whereas there was no difference in 10-year iDFS between the predicted TILs groups for luminal cancers. **Conclusions:** These results indicate that Polaris TME accurately quantifies TILs derived from digitized H&E slides and provides prognostic measure for long-term iDFS in high-risk early breast cancer. Prospective validation and harmonization efforts to facilitate clinical implementation are warranted. Research Sponsor: None.

AI-driven risk stratification for distant recurrence in node-positive HR+/HER2− early breast cancer: Independent validation in the NSABP B-28 trial. First Author: Priya Rastogi, NSABP Foundation, and the UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Accurate prediction of risk of distant recurrence (DR) in HR+, HER2-negative early-stage breast cancer (EBC) is important for optimizing adjuvant therapy decisions, including treatment escalation with CDK4/6 inhibitors (CDK4/6i). Current guidelines recommend consideration of CDK4/6i for node-positive, clinically high-risk EBC, including N1 patients. However, it is not known which patients will benefit, and guideline recommendations suggest that the risks may outweigh benefits for patients with low risk of distant recurrence. Identification of these patients will help prevent over-treatment. RlapsRisk BC (RR) is an AI pathology-based test that integrates features from H&E-stained whole-slide images with clinicopathologic data (age, tumor size, nodal status) to assess risk of distant recurrence in HR+, HER2-negative EBC. The RR model was previously developed and validated using 7 retrospective cohorts totaling 6,039 patients. Here we report validation of RR in the NSABP B-28 cohort of HR+ HER2-negative N+ patients who received post-operative chemoendocrine therapy. **Methods:** This blinded independent validation study of the pre-specified RR included a subset of NSABP B-28 patients with HR+ and HER2-negative EBC (n=731) and digitized whole slide images from primary tumors. The primary endpoint was distant recurrence-free interval (DRFI). The objective was to validate the prognostic utility of RR score for DR. Univariable and multivariable Cox models were performed. **Results:** The evaluable cohort had a median follow-up of 11.1 years and included 504 (69%) patients with N1 disease, 87% grade 2/3 tumors, and a median tumor size of 21mm. Across the entire cohort, RR classified 58% of patients as low-risk and 42% as high-risk. RR (high vs low) was significantly associated with DRFI: HR=3.1 (95% CI: 2.3-4.3; $p < .001$). Estimated 10-year DR-free was 87.5% (95% CI: 83.9-90.4%) for low-risk vs. 65.0% (95% CI: 59.1-70.2%) for high-risk patients. In a multivariable Cox model, the histology-only score remained significant after adjusting for clinicopathologic data: HR=1.6 (95% CI: 1.4-1.9; $p < .001$). In the N1 subgroup, RR identified 65.7% of patients as low-risk with an estimated 10-year DR-free of 90.6% (95% CI: 86.9-93.4%), compared to 69.8% (95% CI: 62.2-76.2%) for high-risk. **Conclusions:** RR demonstrates robust prognostic performance in clinically high-risk N+, HR+, HER2-negative EBC patients from the NSABP-28 trial, in which the majority of patients had N1 disease. Our results demonstrate that approximately two-thirds of N1 patients, identified as low-risk by RR, exhibited favorable long-term outcomes with standard chemoendocrine therapies alone. As the clinical landscape shifts toward broader CDK4/6i use, RR could be used to identify N1 patients for whom the benefit of treatment intensification may be minimal. Research Sponsor: None.

Prognostic performance of a multimodal artificial intelligence histopathology-based tool versus the 21-gene recurrence score in early-stage breast cancer. First Author: Shayna L. Showalter, University of Virginia (UVA), Department of Surgery, Charlottesville, VA

Background: Genomic classifiers are widely used to assess risk of distant metastasis (DM) and inform chemotherapy (CT) benefit in patients with HR+/HER2- early breast cancer (EBC). While clinically validated, these assays are associated with high cost, long turnaround time, and tissue consumption. This study evaluates the performance of a histopathology based multimodal AI (MMAI) model in real-world institutional cohorts and compares its prognostic performance with the 21-gene recurrence score (RS). **Methods:** We conducted a retrospective analysis of 307 de-identified patients with node-negative HR+/HER2- EBC. Patients were treated at two institutions: Hoag Health System (n = 62) and the University of Virginia (n = 245). Median follow-up was 9.5 years. MMAI risk classifications (low vs. high) were compared to RS risk groups as defined in the TAILORx study (RS 0-10 (low), RS 11-25 (intermediate), RS≥26 (high)). The endpoint was time to DM and was analyzed using Kaplan-Meier (KM) methods and Cox proportional hazards models, including univariable (UVA) and multivariable analyses (MVA) adjusting for clinicopathologic factors. **Results:** In this study, 64% of patients were classified as MMAI low risk and 36% as MMAI high risk. The majority of patients received endocrine therapy alone (86% with low RS and 77% with intermediate RS), while 79% of patients in the high RS group were treated with CT. KM analyses demonstrated significantly lower 10-year DM rates for patients classified as MMAI low risk (1.6%, 95% CI: 0.4%-6.8%) compared with patients classified as MMAI high risk (10.8%, 95% CI: 5.5%-20.6%). Among patients with low RS, the MMAI model classified 84% as low risk, with no DM events observed in this group. In contrast, 16% of patients classified as MMAI high risk within the RS low group experienced a 10-year DM rate of 20% (95% CI: 5.4%-60.0%). MMAI further stratified intermediate RS patients into distinct risk groups: 66% were classified as MMAI low risk and 34% as MMAI high risk, with 10-year DM rates of 2.6% (95% CI: 0.6%-10.9%) and 11.4% (95% CI: 4.5%-27.2%) respectively. In UVA analysis of the intermediate RS group, MMAI high risk classification was associated with DM risk (hazard ratio (HR) of 4.2 (95% CI: 1.1-16.1, p = 0.03). In MVA, adjusting for RS groups, adjuvant systemic therapy, and age, MMAI remained independently associated with DM risk (HR = 5.8, 95% CI: 1.7-19.8, p = 0.005). **Conclusions:** MMAI demonstrated prognostic risk stratification within RS groups, particularly among intermediate RS. Concordance between MMAI low risk and favorable outcomes among patients with low RS suggests MMAI may identify patients with low risk of DM without requiring additional tissue consumption. Further studies are needed to evaluate outcomes among MMAI risk groups within high RS to define the optimal clinical integration of MMAI with existing genomic assays. Research Sponsor: ArteraAI.

Prognostic value of an MRI-derived recurrence assay in women with hormone receptor–positive, HER2-negative breast cancer: A retrospective, multi-center analysis. First Author: Matthew P. Goetz, Mayo Clinic Rochester, Rochester, MN

Background: Patients (pts) with early stage hormone receptor-positive, human epidermal growth factor receptor 2-negative (HR+/HER2-) breast cancer (BC) remain at both short and long term risk of recurrence. While clinico-pathological and gene-based biomarkers provide insight into early and late recurrence risk, additional prognostic tools are needed. We previously developed (Saha et al. *Clin Cancer Res*, 2025) a new breast MRI image-based artificial intelligence prognostic tool (TumorSight Risk) composed of both radiographic and clinical information. Here we sought to validate this tool in an independent cohort. **Methods:** In this multi-center, blinded, prospective/retrospective validation study, we sought to validate the 5-year recurrence-free survival (RFS) according to pre-defined risk scores (0-100) and categories ("high" or "low") via pre-specified cutoff (≥47) for pts with HR+/HER2- BC. Kaplan-Meier and Cox regression analyses were then used to assess the unadjusted and adjusted association between risk category/score and the 5-year RFS. **Results:** 2,129 pts with HR+/HER2- BC diagnosed between January 1, 2010, and December 31, 2024, who underwent breast MRI prior to surgery (no neoadjuvant therapy) were included from four institutions. Median age was 57 years, 16% were Black, 15% had grade 3 disease, 93% were clinical T1 or T2, and 85%/15% were clinical N0/N1. At a median follow up of 6.24 years, the unadjusted hazard ratio (HR) for RFS comparing low (n=1808) and high risk (n=321) pts was 2.71 (95% CI = 1.95 – 3.76, p = $3x10^{-9}$). The estimated 5 year RFS rate according to risk score (low and high) was 95.5% (95% CI: 94.63 – 96.3%) and 89.6% (95% CI = 86.4 – 92.6%) while the 10 year RFS estimates were 88.9% (95% CI = 86.5 - 90.9%) and 69.6% (95% CI = 59.1 – 77.9%). Univariate subgroup analysis demonstrated that the risk score was prognostic by age (< 50 vs. ≥50 years), pathologic nodal status, grade, and surgery type, regardless of chemo-, endocrine, or radiation therapy administration. The observed continuous risk score was strongly associated with risk of recurrence, with a 22% increase in relative risk per 10-unit change in risk score (0-100), translating to a 2.4% (95% CI = 1.2 – 4.5%) and 25.5% (95% CI = 15.4 – 40.4%) risk of recurrence at 5-years for pts at the lowest (0-9) versus highest (90-100) risk score. The prognostic association between risk score and RFS remained after adjusting for pathologic T- and N-stage, grade, age, race, and treatment (p = 0.002). **Conclusions:** TumorSight Risk is a new image-based biomarker for HR+/HER2- BC that provides prognostic information independent of standard clinico-pathological parameters. Given the ready availability of breast MRI in most pts with BC, TumorSight Risk may be a convenient tool for estimating risk for recurrence. Research Sponsor: SimBioSys, Inc.

Association of the 70-gene assay and homologous recombination deficiency in patients with high risk 2 breast cancers. First Author: Steven J. Isakoff, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA

Background: Homologous recombination deficiency (HRD) is a biomarker for impaired DNA repair proficiency and genomic instability, associated with sensitivity to DNA-damaging agents. MammaPrint (MP), a 70-gene assay, stratifies early breast cancer (EBC) by UltraLow, Low, High Risk 1 (H1) or High Risk 2 (H2) of recurrence. Compared to patients (pts) with H1 tumors, pts with H2 tumors derive greater benefit from anthracycline-based chemotherapy. Here we analyze HRD signatures to assess whether MP gene expression profiling may detect pathway activity in H2 tumors indicating DNA repair deficiency. **Methods:** We analyzed tumors from pts enrolled in the FLEX study who consented to full transcriptome and clinical data collection, with available MP and BluePrint (BP; Luminal or Basal) results (N=1298). HRD status assessed using a 228-gene signature was further refined into a 26-gene panel (Jacobson et al., 2023). The R-package Limma was used to preprocess gene expression data. For each gene, the median expression value of probes mapping to the gene was calculated. Differences in HRD scores were compared across MP and BP groups using a t-test. **Results:** Pts with HR+HER2- EBC HRD scores differed significantly by both MP and BP. Using the 228-gene HRD signature, H2 tumors were associated with higher HRD compared with H1 cancers ($p<0.001$). Luminal H2 tumors were also associated with higher HRD scores than Luminal H1 tumors ($p<0.001$). Basal tumors were associated with higher HRD compared with Luminal tumors within both H1 and H2 (Luminal H1 vs Basal H1 and Luminal H2 vs Basal H2; both $p<0.001$), and Basal H2 tumors had higher HRD scores than Basal H1 tumors ($p<0.001$). Similar patterns were observed within the 26-gene HRD panel. H2 tumors were associated with higher scores than MP H1 tumors ($p<0.001$), and Luminal H2 tumors were associated with higher scores than Luminal H1 tumors ($p<0.001$). Basal tumors were associated with higher HRD than Luminal tumors within both MP risk groups (Luminal H1 vs Basal H1, p=0.002; Luminal H2 vs Basal H2, $p<0.001$). Basal H2 tumors demonstrated numerically higher scores than Basal H1 tumors using the 26-gene panel, but did not reach statistical significance (p=0.062). **Conclusions:** In this real-world analysis, MP and BP identified differences in underlying HRD biology, with H2 tumors enriched for HRD and Luminal H1 tumors demonstrating relative homologous recombination proficiency. These findings may provide a biological rationale for the anthracycline chemotherapy and immunotherapy benefit observed in pts with H2 tumors and further evidence for MP as a tool for refined therapy selection. Additional research is warranted to examine MP as a biomarker for HRD-sensitive therapies such as PARP inhibitors and carboplatin. These results further highlight biological diversity within genomically high-risk tumors, uniquely detected by MP and BP. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

Predicting recurrence and survival in hormone receptor–positive (HR+)/HER2-negative (HER2–) early breast cancer (EBC) with machine learning models: Optimization of model complexity. First Author: Frederick Howard, University of Chicago, Chicago, IL

Background: A machine learning model was previously developed to predict distant recurrence (DR) in endocrine therapy–treated patients with HR+/HER2− EBC, with high accuracy achieved using 10 variables (Howard FM, et al. *Clin Cancer Res*. 2026). Here, optimal performance, based on the number and identity of variables, of recurrence models that include survival events (distant relapse–free survival [DRFS], overall survival [OS]) was determined. **Methods:** Retrospective data from patients with stage I-III HR+/HER2− EBC (diagnosed 1 January 2011 to 30 April 2024) were extracted from the Flatiron Health US electronic health record–derived database. Elastic net–penalized Cox proportional hazards–based machine learning models were developed with 2, 5, 10, 15, or 20 variables identified by gradient boosting to predict DR, DRFS, and OS; DRFS was defined according to STEEP criteria v2.0. Model performance was assessed using the C-index and Brier score (BS). **Results:** With modeling based on 7842 patients, DR prediction accuracy plateaued (C-index, 0.857; BS, 0.046) (Table) with 10 variables (N status, T status, tumor grade, Ki-67 score, age, time from diagnosis to surgery, percent estrogen receptor–positive cells, menopausal status [post-], Oncotype DX Recurrence Score, and percent progesterone receptor–positive cells). The DRFS (C-index, 0.740; BS, 0.089) and OS (C-index, 0.781; BS, 0.075) prediction models showed high accuracy with 5 to 10 variables, and accuracy continued to increase with up to 20 variables. In contrast to the DR prediction model, the DRFS and OS prediction models included functional status (ie, Eastern Cooperative Oncology Group performance status, Charlson Comorbidity Index) among the most impactful variables. **Conclusions:** DR model performance plateaued with 10 tumor-intrinsic variables. In contrast, optimal DRFS and OS prediction required expanding the model to 20 variables, including functional and comorbidity domains necessary to capture non-cancer competing risks critical for survival prediction in real-world populations, despite the modest statistical impact. The machine learning model for predicting DR, a reliable proxy for survival in HR+/HER2− EBC, is based on a lower number of risk factors that are commonly accessible in real-world clinics and has good accuracy. Research Sponsor: Novartis Pharmaceuticals Corporation.

Gut microbiome characteristics in patients with hormone receptor–positive (HR+) HER2– breast cancer treated with adjuvant abemaciclib: Biomarker analysis of the TRADE trial. First Author: Ilana Schlam, Dana-Farber Cancer Institute, Boston, MA

Background: Adjuvant abemaciclib reduces recurrence risk and improves overall survival in patients with high-risk node-positive early HR+/HER2- breast cancer. However, treatment-emergent diarrhea may lead to dose modifications, treatment discontinuation, and impaired quality of life. The gut microbiome influences treatment response and toxicity across multiple cancer therapies; its role in abemaciclib-associated diarrhea remains undefined. We evaluated features of the gut microbiome during the initiation of adjuvant abemaciclib and any association with diarrhea. **Methods:** 90 patients with HR+/HER2– early breast cancer enrolled in the TRADE trial (NCT06001762) and were treated with dose-escalated adjuvant abemaciclib (50 mg BID x 14 days, then 100 mg BID x 14 days, then 150 mg BID onwards) plus endocrine therapy. Stool samples were collected at baseline, cycle 2 day 1 (C2D1), and end of treatment (EOT). Whole-genome shotgun metagenomic sequencing was performed, and species-level profiles were generated using MetaPhlAn4. Diarrhea was analyzed as a binary outcome (ever vs none). Associations between microbiome features and clinical variables were evaluated using linear mixed modeling with a random effect for repeated samples from the same individual (alpha diversity) or per-timepoint using PERMANOVA (beta diversity) and MaAsLin3 (species and genes, with false discovery rate correction). Models were adjusted for age, cancer stage, and type of endocrine therapy. **Results:** A total of 142 samples were analyzed (77 baseline, 58 C2D1, and 7 EOT; 77 total subjects, 28 with diarrhea, 49 without). Treatment was associated with a consistent microbiome shift from baseline to C2D1, characterized by a decline in alpha diversity (-0.26, 95% CI -0.39 to -0.14, $p < 0.001$) and a phylum-level shift with increased Bacteroidota and decreased Firmicutes abundance ($p < 0.002$ and $p = 0.001$, respectively, paired T-test). When assessing by timepoint, having any-grade diarrhea was not associated with differences in beta diversity or alpha diversity, nor with individual microbial species; pathway-level enrichment suggested diarrhea-associated functional trends that did not meet FDR significance. Limited EOT samples suggested partial recovery following treatment. **Conclusions:** Adjuvant abemaciclib induced consistent, treatment-related shifts in gut microbiome composition, characterized by reduced diversity and a phylum-level shift from Firmicutes to Bacteroidota, suggesting an early broad ecological treatment effect from exposure to a CDK4/6 inhibitor. This pattern has been reported in patients with inflammatory bowel disease. A species-specific diarrhea signature or predictive relationship between microbiome signature and the development of diarrhea was not observed. Further evaluation of the microbiome's evolution at EOT is ongoing. Clinical trial information: NCT06001762. Research Sponsor: Eli Lilly.

Distinct late recurrence patterns and immune landscape of HER2-positive invasive lobular carcinoma (ILC): Analysis of NCCTG N9831 (Alliance) trial and real-world cohort. First Author: Thiti Susiriwatananont, Jacoby Center for Breast Health, Mayo Clinic Florida, Jacksonville, FL

Background: HER2+ ILC is rare (~5% of ILC), with limited data on long-term adjuvant trastuzumab outcomes. We investigated late recurrence and immune landscapes of HER2+ ILC vs invasive ductal carcinoma (IDC) in the phase III NCCTG N9831 trial (NCT00005970) and a real-world cohort. **Methods:** We evaluated 3304 early-stage HER2+ breast cancer patients (pts) enrolled in N9831 (122 ILC, 3182 IDC). Recurrence-free survival (RFS) and overall survival (OS) were estimated (Kaplan-Meier) and compared using multivariable Cox regression adjusting for age, tumor size, grade, hormone receptor (HR), and nodal status. Findings were validated in a real-world cohort of HER2+ pts (Caris Life Sciences CODEai platform). Immune microenvironments were profiled by WTS deconvolution (Quantiseq). Real-world overall survival was calculated from trastuzumab start to last contact. **Results:** In N9831, ILC pts were older (median 54 vs 49 y), more ER+ (74.6% vs 51.4%), and had more N3 disease (25.4% vs 12.7%) compared to IDC. ILC pts derived a comparable magnitude of benefit from adjuvant trastuzumab compared to the overall population (HR 0.58 vs 0.67). However, long-term outcomes diverged: while the 5-year RFS was similar (77.1% vs 82.7%), ILC pts experienced a steep decline between years 5-15 (77.1% to 57.7%; ~20% decline) vs IDC (82.7% to 72.7%; ~10% decline) after multivariable Cox analysis (Table). In the real-world early/advanced cohort (n=1328; 26 ILC vs 1302 non-ILC [subset IDC n=595]) treated with trastuzumab-based therapy, ILC pts had worse mOS (33.7 vs 68.6 m, HR 2.01, 95%CI 1.00-4.07, p=0.04) compared to non-ILC. However, there was no statistically significant difference when compared specifically to IDC (HR 1.77, 95% CI 0.87-3.61, p=0.11). ILC had: i) numerically lower tumor mutation burden (TMB)-high (4.2% vs 9.5%, p=0.38); ii) higher infiltration of B cells, Tregs, and M2 macrophages ($p<0.05$); iii) upregulated MHC class II expression (HLA-DOA, $p<0.05$); and iv) downregulated proliferative and DNA repair pathways (E2F, G2M, MYC; FDR <0.25) compared to non-ILC. **Conclusions:** HER2+ ILC carries late recurrence risk despite initial trastuzumab benefit. The unique immune landscape (Treg/M2 macrophage enrichment and lower proliferative signatures) distinguishes HER2+ ILC from IDC, highlighting the need for tailored strategies. Research Sponsor: National Institutes of Health (NIH) / National Cancer Institute (NCI); U10CA180821, U10CA180882; Alliance for Clinical Trials in Oncology.

Long-term RFS and OS in HER2-positive ILC vs IDC (N9831 trial).

Population	N	5-year% (95% CI)	10-year% (95% CI)	15-year% (95% CI)
ILC	122	RFS 77.13% (69.9, 85.1) OS 84.04% (77.7, 90.9)	RFS 70.57% (62.7, 79.4) OS 76.0% (68.7, 84.2)	RFS 57.67% (44.2, 75.1) OS 65.22% (56.6, 75.2)
IDC	3182	RFS 82.71% (81.4, 84.1) OS 90.18% (89.1, 91.2)	RFS 77.45% (75.9, 78.9) OS 81.81% (80.4, 83.2)	RFS 72.68% (70.77, 74.6) OS 76.68% (75, 78.4)

Association of patient-reported stress and depression symptoms with ER-specific tumor transcriptional signatures in breast cancer (BC). First Author: Shipra Gandhi, Department of Medicine, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Psychological distress is common among women with BC, yet tumor-level biological correlates remain poorly defined. We used tumor transcriptomics to identify pathways associated with patient-reported stress and depression symptoms. **Methods:** RNA sequencing was conducted on FFPE tumor samples in 195 women with stage I-III BC (152 ER+, 43 ER–) from the Women's Health after Breast Cancer cohort. At diagnosis, participants completed Perceived Stress Scale (PSS-10) and Center for Epidemiologic Studies Depression (CES-D) Scale. High-low stress (PSS-10 >14 vs 0-14) and high-low somatic symptoms (CES-D somatic >3 vs ≤ 3) were defined. Differential expression and gene-set enrichment analyses compared high-stress/low-somatic-symptom (HS/LSS) and low-stress/high-somatic-symptom (LS/HSS) groups with low-stress/low-somatic-symptom controls, stratified by estrogen receptor (ER) status, adjusted for age and education. Caris Life Sciences CODEai evaluated overall survival (OS) from tissue collection to last contact. **Results:** In ER+BC, HS/LSS showed increased humoral-immune activity and checkpoint signatures, with reduced neuroendocrine activation. LS/HSS enriched for a neuroendocrine state, ribosome biogenesis, immune and cell-cycle pathways, with loss of epithelial regulatory programs. In ER– BC, HS/LSS showed growth-factor-driven proliferation with reduced epithelial differentiation and greater immune-checkpoint engagement. LS/HSS exhibited metabolic-stress features with loss of epithelial/immune programs and increased keratinization, consistent with impaired antigen presentation and altered differentiation. Table outlines key up- and down-regulated signatures. Using CODEai, in ER+ (n=11309), higher *PHOX2A* (41 m vs 38.4 m) and *TDGF1 (*42 m vs 37.4 m), and in ER– (n=6402), higher *SCL5A11* (24 m vs 20.7 m) and *KRT40* (23.5 m vs 21.1 m) were associated with better OS, all $p < 0.01$. **Conclusions:** Patient-reported stress and depressive somatic symptoms map to distinct ER-specific tumor transcriptional signatures involving immune regulation, proliferation, metabolism and differentiation. Concordant survival associations support potential clinical relevance and warrant validation to identify actionable targets. Research Sponsor: NIH/NCI and NIH/NCATS; R03TR004607.

Shared and distinct molecular signatures of resistance to different endocrine therapies (Alliance A011106). First Author: Meenakshi Anurag, Baylor College of Medicine, Houston, TX

Background: Endocrine therapy (ET) resistance (ETR) remains a primary challenge in ER+ breast cancer. Analyzing pretreatment tumor transcriptomes across trials with early response endpoints can reveal shared and specific ETR signatures. This study utilizes baseline RNA data from the Phase III ALTERNATE trial (Alliance A011106, NCT01953588; Anastrozole [A], Fulvestrant [F], or AF) and the ACOSOG Z1031B trial (NCT00824941) to identify predictors of early Ki67 response in postmenopausal ER+/HER2– patients. **Methods:** ETR was defined as week-4 on-treatment Ki67 $>10\%$. Baseline gene expression from ALTERNATE was analyzed to identify differentially expressed (DE) genes (Wilcoxon test, $P<0.05$) and Hallmark pathways associated with ETR, both across and within individual treatment arms. Feature selection was performed using mixOmics. A Pan-Endocrine Therapy Signature (PETS) was developed by uniting DE genes identified across all three ALTERNATE arms and Z1031B. All statistical analyses were conducted in R ($P<0.05$). **Results:** Overall ETR rate in the ALTERNATE RNA-seq cohort (n=733) was 26%. ETR was associated with high Risk of Recurrence (ROR), Oncotype RS, and Mammaprint scores (calculated from RNA-seq data in research setting). In luminal tumors (n=649), ETR was linked to chr 3q13.33, 8q24.13, and 20q13.12 cytoband upregulation and 17q21, 18q23, 3p21.1, and 10q24.32 cytoband downregulation. ETR tumors showed T-cell, E2F target, and interferon-γ enrichment; sensitive tumors favored early estrogen response and muscle differentiation. At individual gene level, high *MYBL2*, *PIF1*, *TROAP* and with low HJURP predicted ETR across all samples (AUC>0.70). A deep learning model using all protein-coding genes achieved AUC 0.82 (training) and 0.79 (test) in predicting ETR. Cross-trial integration identified ETR-associated PETS, enriched for genomic instability. PETS performed comparably to established signatures and strongly correlated with *MYBL2* signature (r=0.93). Top ETR predictors were *MYBL2*, *AURKB*, and *EME1* for Arm A and *IL4I1*, *TNFAIP6*, and *ANLN* for Arm AF. AF-resistant tumors were enriched for systemic lupus and RIG-I–like receptor signaling; sensitive tumors favored PI3K–AKT, EGFR TKI resistance, AMPK, and insulin signaling. **Conclusions:** Baseline transcriptomics identify shared and therapy-specific ETR markers. The 15-gene PETS defines a convergent resistance signature, performing similar to established signatures in predicting ETR and correlating with MYBL2. Enrichment of cell-cycle and immune pathways in resistant tumors may suggest patient stratification approach for alternative or combinatorial strategies to overcome early ETR in ER+ breast cancer. Spatial interactions between immune cells as a predictor of pCR to neoadjuvant chemotherapy (NACT) and nivolumab for ER+/HER2− breast cancer (BC): Analysis of the phase II GIADA trial. First Author: Valentina Guarneri, Department of Surgery, Oncology and Gastroenterology, University of Padua and Division of Oncology 2, Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: Adding an immune checkpoint inhibitor (ICI) to NACT increases pathological complete response (pCR) rates in ER+/HER2− high-risk BC, at the cost of immune-related toxicity. Biomarkers are needed to improve patient (pts) selection. We here assess the association between immune cell spatial interactions and pCR in the GIADA trial (Dieci, CCR 2022). **Methods:** In the phase II GIADA trial, 43 premenopausal pts with stage II–IIIA ER+/HER2− Luminal B-like BC (Ki67 ≥ 20% and/or G3) received NACT with ECx3 followed by nivolumab (240mg q2w x8) and endocrine treatment. Tumor biopsies at baseline (T0) and after EC (T1) were assessed using multiplex immunofluorescence panels: (1) CD4, CD8, Granzyme B, FoxP3, CD20, pan-cytokeratin (CK), and DAPI; (2) CD3, CD68, CD163, PD-1, PD-L1, CK, and DAPI. Interactions were quantified using a count-within approach. The number of reference immune cells located in a ≤20 μm radius of cells with a different phenotype (high probability of cell-cell contact) was calculated and normalized to number of reference cells. Association with pCR was assessed by binomial generalized linear models. **Results:** At baseline (T0), spatial interaction of tumor cells (CK+) with multiple immune cells (CD4+, CD8+, FOXP3+, CD68+), including cytotoxic, immunosuppressive and macrophagic subpopulations, was associated with pCR. Moreover, interaction of cytotoxic CD8+GranzymeB+ T-cells with regulatory FOXP3+ cells was associated with pCR. Interactions between PD-1+ and PD-L1+ cells were associated with pCR, mainly CK+PD-L1+/CD3+PD-1+ in tumor area and CD3+PD-1+/CD68+PD-L1+ in stroma. After chemotherapy (T1), only spatial interactions between tumor cells and CD8+ and CD4+ T-cells were associated with pCR. The role of cytotoxic CD8+GranzymeB+ T-cells appeared stronger as interactions with multiple immune subpopulations (CD4+, CD8+, CD8+GranzymeB+, FOXP3+, CD20+) were associated with pCR, overall (OR 1.06-1.73) and in stroma (OR 1.06-1.40). Interaction of CK+ tumor cells with PD-1+ cells in the tumor area and with CD68+ PD-L1+ macrophages in the stromal area was associated with pCR. **Conclusions:** Spatial immune profiling identifies distinct tumor-immune interaction patterns associated with pCR in high-risk ER+/HER2− BC treated with NACT and ICI. Clinical trial information: NCT04659551. Research Sponsor: Bristol Myers Squibb; Fondazione AIRC; 22759; Veneto Institute of Oncology IOV-IRCCS; NA.

Selected spatial interactions significantly associated with pCR.

Characteristics of cancer patients undergoing molecular residual disease testing with a tumor-informed assay. First Author: Gargi D. Basu, Exact Sciences, Phoenix, AZ

Background: Detection of circulating tumor DNA (ctDNA) is strongly associated with recurrence across a variety of cancers. The use of ctDNA testing to measure molecular residual disease (MRD) is still in its infancy, and understanding sample characteristics may help set expectations for oncologists and their patients. **Methods:** For the first thousand patients with MRD testing in Exact Sciences' commercial laboratory, the tumor and first plasma sample were used to record tumor type, tumor sample type (biopsy/surgical), tumor stage, MRD assay panel size (up to 200 variants), cfDNA levels, and ctDNA status (qualitative and quantitative), and, when data were available, presence of targetable alterations (TAs) were recorded. **Results:** A total of 1088 samples with valid results were included. Patients were mostly female (N=703, 64.6%) with a median age of 64 (range 17–97) years, and most had either breast (N=380, 34.9%) or colorectal (N=335, 30.8%) cancer. Most (N=632, 58.1%) tumor samples were surgical, and average number of variants for MRD assays from 86 in ovarian cancer to 189 in melanoma. Plasma cfDNA yield ranged from 15 ng (the minimum required) to 10,709 ng and was significantly higher in 412 ctDNA+ (median 86.1 ng, mean 239.7 ng) compared to ctDNA− (median 73.5 ng, mean 114.6 ng) samples ($p<0.001$). In 13 cancers with at least 10 patient samples, only breast cancer showed a difference in the average number of identified variants between sample types (biopsy: 129.1 versus surgical: 101.5), stage IV cancers had more cfDNA than stage I, range of ctDNA+ samples was from 27% in melanoma to 65% in gastroesophageal cancers, and ctDNA+ proportion tended to increase with stage: 26 (14.2%) of 183 stage I, 84 (32.1%) of 262 stage II, 140 (38.9%) of 360 stage III, and 140 (65.1%) of 215 stage IV. ctDNA+ samples had levels between 2.6 and ≥352,000 parts per million (PPM), with 27 (6.6%) samples below 15 PPM, 40 (9.7%) between 15 and 50 PPM, and 345 (83.7%) above 50 PPM. Genomic profiling was performed on 158 samples, most from breast (N=50, 31.6%) and colorectal (N=17, 10.8%) cancer patients. The mean number of TAs per sample was 4.6, with little difference between the 114 ctDNA+ patients (mean = 4.4, range 0–24) and 44 ctDNA− patients (mean = 5.1, range 1–29). TAs were present in 83 (72.8%) and 36 (81.8%) tumors in ctDNA+ and ctDNA− patients, respectively. Of note, both high microsatellite instability and high tumor mutational burden tumors had numerically higher proportion in ctDNA− (15.9% and 9.1%, respectively) compared to ctDNA+ (5.3% in both) patients. **Conclusions:** ctDNA+ frequency varied by cancer type and cfDNA yields and ctDNA+ proportion increased numerically with stage, though where patients were in their treatment cycles was unknown. Of patients with profiling results, a large proportion of patients had TAs regardless of ctDNA status, indicating a potential for immediate consideration of matched therapies in ctDNA+ patients. Research Sponsor: Exact Sciences.

mTOR activation and racial disparity in early breast cancer survival. First Author: Ekaterina Proskuriakova, University of Illinois Chicago, Department of Hematology and Oncology, Chicago, IL

Background: Black women have lower survival rates following a diagnosis of estrogen receptor-positive (ER+) early breast cancer (EBC) compared with White women, with 80% higher mortality and more frequent genomically high-risk tumors (Hoskins et al, JAMA Oncol, 2021). A whole-transcriptome comparison of 412 luminal tumors from Black women with EBC and age-matched White women showed increased mTOR signaling in tumors from Black patients (Hoskins et al. J Clin Oncol 2021, 39:15_suppl, 1009-1009), suggesting a molecular driver of the survival disparity. This study aimed to confirm increased mTOR pathway activation at the protein level in Black patients with an independent cohort, and to explore factors responsible for racial differences in luminal tumor biology. **Methods:** A breast tumor tissue microarray (TMA) comprising primary tumor cores from diverse patients with EBC was analyzed with multiplex immunofluorescence staining to quantify protein markers of mTOR pathway activation (pS6K and pAkt). Image segmentation was performed with pan-cytokeratin staining to delineate tumor cells from stromal cells. Halo HighPlex image analysis software was used for automated digital image analysis to calculate an H-score for each tumor core. Ancestry admixture analysis was performed with ancestry informative markers that are located within coding regions of genes using RNAseq data generated from tumors represented on the TMA. Data on contextual factors was obtained by geocoding patients' residential address at the time of diagnosis and linking to a census tract-level measure of neighborhood disadvantage (Area Deprivation Index-ADI). mTOR pathway activation levels were compared by self-identified race, proportion of African ancestry, body mass index (BMI), insurance status, and ADI. One-sided t-tests evaluated mean H-scores for pS6K and pAkt in tumor cells for various comparisons. **Results:** Analysis of 70 ER+ primary tumors from Black patients and 43 tumors from White patients showed mean pS6K staining in pan-cytokeratin-positive cells was significantly higher in tumor cores from Black compared with White patients (p-value = .05). Ancestry admixture analysis (dichotomized by the proportion of African ancestry $>$ 0.4 vs. $<$ 0.4) showed significantly increased pS6K staining in patients with greater proportion of African ancestry (p-value = .04). There was no association with ADI (p-value = .30). Analyses of association with insurance status and BMI, multivariable analyses, and survival analyses are ongoing and results will be presented, along with data on pAkt staining. **Conclusions:** This study demonstrated increased mTOR pathway activation at the protein level in Black women with ER+ EBC, confirming the result of a prior gene expression analysis. The underlying cause of this racial difference is unknown, but findings support development of clinical trials targeting the mTOR signaling pathway to mitigate racial disparity in EBC survival. Research Sponsor: None.

Evaluation of whole-exome and whole-genome sequencing tumor-informed circulating tumor DNA MRD assays in patients with early triple-negative breast cancer (TNBC) receiving neoadjuvant chemotherapy (NAC) with or without olaparib: A prospective sub-study of the PARTNER trial. First Author: Andrew Dooley, Precision Breast Cancer Institute, Department of Oncology, University of Cambridge, Cambridge, United Kingdom

Background: Detection of molecular residual disease (MRD), using circulating tumor DNA (ctDNA), following treatment for early-stage TNBC is associated with a high risk of recurrence. ctDNA clearance in response to NAC has shown potential for predicting pathologic compete response (pCR) and improving the prognostic ability of pCR status. PARTNER is a prospective, phase II-III, randomized controlled clinical trial, which recruited early-stage basal TNBC BRCA1/2 wild-type patients (Nature April 2024). Control regimen was neoadjuvant carboplatin–paclitaxel followed by anthracycline-based NAC. Experimental arms added olaparib to the platinum-taxane backbone. A sub-study of serial blood samples for ctDNA analysis during NAC and post-op were analyzed with 2 tumor informed MRD assays using primary tumor and germline sequencing: 1) whole-exome sequencing (WES) to select ≤200 variants and 2) whole-genome sequencing (WGS) to select 400-5000 variants for the two bespoke MRD assays, respectively. Both assays were independently used to assess available plasma samples collected for the presence or absence of ctDNA. **Methods:** This prospective sub study included TNBC patients enrolled within PARTNER with serial blood collections at baseline (prior to NAC), mid-NAC, post-NAC, 2-4 weeks post-op, 3 months post-op and 12 months post-op. Germline and somatic DNA were provided via the Personalised Breast Cancer Program. The primary objective was to determine the association of ctDNA positivity post-op with distant recurrence-free interval (DRFI). The distribution of DRFI by ctDNA status was compared using the log-rank test. The Cox proportional hazards regression model was used to estimate the strength of the relationship between ctDNA positivity and DRFI. **Results:** Median WES MRD assay panel size was 159 variants (range 47 – 200). At baseline ctDNA was detected in 50 of 55 patients (91%). After NAC, 4 of 63 patients had detectable ctDNA. 24 of 28 non-pCR patients were ctDNA negative and 0 of 35 pCR patients were ctDNA positive. Of 61 post-op patients available to assess DRFI distant recurrences developed in 8 patients (13.1%) within a median follow up of 5 years. Post-op 5 patients were ctDNA positive and 3 developed distant recurrences (log-rank $p < 0.0001$, HR = 20.2, 95% CI = 4.3, 95.1). In addition, 56 were ctDNA negative and 51 (91%) were distant recurrence free. Median WGS MRD assay panel size was 2962 variants (range 552 - 5000). At baseline ctDNA was detected in 46 of 47 patients (98%). Additional WGS MRD results are being generated and will be presented at the meeting. **Conclusions:** Post-op detection of ctDNA using a WES MRD assay was highly prognostic for distant recurrence in TNBC patients following NAC. WGS MRD improved baseline detection. Research Sponsor: Exact Sciences.

Molecular profiling of male breast cancer in Brazil: Comprehensive genomic characterization of a Latin American cohort. First Author: Elizabeth Santos, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: Male breast cancer (MBC) is a rare disease, accounting for < 1% of all breast cancers. Current treatment recommendations are largely extrapolated from female breast cancer data, which may not reflect the distinct biological features of MBC. Notably, MBC is associated with higher mortality rates than female breast cancer. Molecular data from Latin America are scarce. This study aimed to characterize the clinicopathological and molecular features of MBC in a Brazilian cohort, addressing an important knowledge gap in an underrepresented population. **Methods:** Medical records of 106 men diagnosed with breast cancer at three Brazilian cancer centers between 2000 and 2022 were reviewed. Tumor samples from 48 patients were available for molecular analysis after centralized histopathological review. FFPE samples with ≥10% tumor cellularity were included. DNA and RNA were extracted using the AllPrep kit (Qiagen). Libraries were prepared using the Oncomine Focus Assay (Thermo Fisher Scientific) and sequenced on the Ion S5 platform. Bioinformatic analysis for single nucleotide variants (SNVs), insertions/deletions, copy number variations (CNVs), and gene fusions was performed using Ion Reporter software. **Results:** The median age at diagnosis was 58.5 years (range: 33–84). A family history of cancer was reported in 64% of patients, including female breast cancer in 32%. Most tumors were invasive ductal carcinomas (87.7%), high grade (grades 2–3; 90%), and hormone receptor–positive (93%). HER2+/HR– and triple-negative subtypes accounted for 0.9% and 3.9%, respectively. Most patients (88.5%) presented with localized or locally advanced disease. The most frequent pathogenic variants were PIK3CA (28%), followed by MAP2K1, BRAF, and AKT1 (6% each), and EGFR, JAK3, and MTOR (3% each). The most common CNV amplifications involved MYC (24%), FGFR1 (20%), CCND1 (16%), and ERBB2 (4%). No gene fusions were identified. Pathway analysis revealed alterations in PI3K/AKT/mTOR (37%), Cell Cycle (40%), FGF signaling (20%), and MAPK (12%) pathways. Overall, 46% of patients harbored potentially actionable SNVs, and 24% harbored potentially actionable CNVs. **Conclusions:** This is the first comprehensive molecular characterization of MBC in Brazil. Our findings confirm PIK3CA as the most frequent alteration, consistent with international cohorts, supporting the central role of the PI3K/AKT/mTOR pathway in MBC. Additional alterations in Cell Cycle and FGF signaling pathways highlight distinct oncogenic drivers. The high prevalence of potentially actionable genomic alterations suggests that molecular profiling may inform treatment selection for a substantial proportion of patients. These findings underscore the limitations of extrapolating treatment guidelines from female breast cancer and support biomarker-driven clinical trials for men with breast cancer in Latin America. Functional domain disruption to define the molecular and clinical spectrum of germline *RAD51* family variants in hereditary breast cancer (BC). First Author: André Luiz Cicilini, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: RAD51 paralogs (RAD51C, RAD51D, XRCC2) and RAD50 are crucial in DNA repair. Germline pathogenic variants (PVs) increase hereditary breast/ovarian cancer risk, but domain-specific impacts remain unclear. **Methods:** Retrospective cohort study (2019-2025) of breast cancer patients undergoing multigene testing. PVs were mapped to functional domains. Tumor features included histology, stage, grade, TILs, and molecular subtype. Associations were assessed using Fisher's exact test. **Results:** Among 495 patients, 23 (4.6%) had RAD51 family PVs (RAD51C = 16, RAD51D = 4, RAD50 = 1, XRCC2 = 1). Median diagnosis age was 49. Synchronous malignancies were significantly more frequent in RAD51 carriers vs. BRCA1 carriers (34.8% vs.; OR 3.51, 95% CI 1.09–11.26). Most variants (22/23) were truncating (11 nonsense, 9 frameshift, 1 splice-site, 1 exon deletion). Domain mapping revealed disruption of critical regions: RAD51-like core domain truncations (RAD51D p.Arg186*; RAD51C p.Arg193*), RAD51C C-terminal truncations removing essential regions for complex integrity, and early RAD50 truncation predicted to abolish MRN complex function. Tumors were predominantly early-stage (65.2% stage I). Histology showed invasive carcinoma of no special type (69%) and invasive lobular carcinoma (25%), with strong enrichment of lobular histology in RAD51C carriers ($p < 0.001$). RAD51C tumors were basal-like or luminal A, while the RAD50 tumor was luminal B HER2-positive. RAD51C tumors often had high nuclear grade (77.3%) but low TILs (71%). **Conclusions:** RAD51 family PVs are primarily truncating, disrupting key HRR domains and supporting loss-of-function as the main mechanism. Domain location correlates with distinct clinicopathological features, refining genotype–phenotype correlations for improved risk assessment. Research Sponsor: None.

Multi-omic profiling to identify RNA-protein concordance and post-transcriptional dysregulation in HER2+ breast cancer. First Author: Pahini Pandya, Panakeia Technologies, Cambridge, United Kingdom

Background: Standard HER2 testing relies on single-modality assays, such as immunohistochemistry (IHC) for protein overexpression and in situ hybridization (ISH) for gene amplification. These tests may fail to capture the regulatory complexity underlying HER2 biology, including post-transcriptional modulation, which may result in RNA-protein discordance and potentially drive therapeutic resistance. We performed a multi-omic analysis to characterize functional HER2 biology and uncover regulatory mechanisms not captured by standard diagnostic testing. **Methods:** We utilized Panakeia's multi-omics platform to analyze a set of 475 breast cancer samples with a complete set of *ERBB2* RNA and protein expression values from the Cancer Genome Atlas (TCGA). HER2+ (n=79) and HER2− (n=396) cohorts were defined using clinical HER2 status assessed via IHC/ISH. Transcriptomic and proteomic over-expression states were binarized by thresholding RNA/protein expression values. RNA-protein concordance was assessed to define four molecular states of the tumor: coordinated activation (RNA+/Protein+), coordinated inactivation (RNA−/Protein−), translation blocks (RNA+/Protein−), or post-transcriptional upregulation (RNA−/Protein+). **Results:** A strong correlation was measured between RNA and protein over-expression (Pearson's correlation r=0.752, $p<0.001$) with 93.7% concordance (445/475). Molecular patterns with respect to HER2 clinical status were observed as follows: (1) coordinated activation (n=48, 10.1%) with 95.8% HER2+ concordance (46/48), validating HER2 over-expression; (2) coordinated inactivation (n=397, 83.6%) with 95.2% HER2− concordance (378/397), confirming HER2 inactivity; (3) RNA+/Protein− translation blocks (n=29, 6.1%) where *ERBB2* RNA was over-expressed but not translated; (4) RNA−/Protein+ (n=1, 0.2%). Among 79 HER2+ patients, only 46 (58.2%) showed functional translation (RNA+/Protein+), while 19 (24.1%) had complete molecular negativity (both inactive) and 14 (17.7%) exhibited translation blocks. Multi-omics profiling identified actionable changes in 35/475 cases (7.4%): 19 potential over-treatment candidates, 14 potential treatment resistance cases, and 2 potential under-treatment cases that are clinically HER2− but exhibit coordinated molecular activity. **Conclusions:** Integrative multi-omic analysis of the HER2 molecular landscape enabled assessment beyond standard-of-care assays, identifying non-responders to HER2-targeted therapy by capturing post-transcriptional dysregulation not detected by single-modality testing. Overall, multi-omic profiling can support precision stratification by confirming active HER2 signalling, identifying potential over-treatment, refining patient selection and guiding treatment decisions. Research Sponsor: None.

Exploring diversity and composition of sulfidogenic gut bacteria in breast cancer. First Author: Tazeena Khan, College of Medicine, University of Illinois at Chicago, Chicago, IL

Background: Sulfidogenic bacteria produce hydrogen sulfide, the excess of which is genotoxic and proinflammatory and is absorbed through the GI tract into the systemic circulation. The role of sulfidogenic bacteria in BC has not been explored. In this study, we aimed to evaluate sulfidogenic bacterial abundance and diversity in BC. We hypothesized that there will be lower alpha and beta diversity in BC groups. We also hypothesized that there will be a higher relative abundance of sulfidogenic bacteria in BC vs. controls. **Methods:** We used high throughput sequencing of the dsrA gene in stool samples of female participants with BC and controls without BC (n=283). Controls were further delineated into normal mammogram, abnormal mammogram with no evidence of BC (e.g. cysts, etc), and controls without BC but with a first degree relative who has BC. To process the sequences, QIIME2 bioinformatics pipelines were used with taxonomy assigned using the SILVA database. We performed alpha diversity analyses with nonparametric statistics, and beta diversity analyses using the Bray-Curtis and weighted/unweighted UniFrac metrics. Differential abundance of sulfidogenic bacteria at the genus level was calculated in R using the DESeq2 package. In the same samples, we used sequencing of the V3-V4 region of the 16s rDNA gene to compare relative abundance of total sulfidogenic bacteria between BC samples and controls in R using the DESeq2 package. **Results:** Using the Chao1 metric, we found higher sulfidogenic alpha diversity in BC vs. all controls ($p < 0.001$), BC vs. controls who have a first degree relative with BC ($p = 0.005$). as well as within controls with a normal mammogram vs. abnormal mammogram without BC ($p = 0.037$). We did not find significant differences in beta diversity between BC vs. controls. When analyzed visually using PCoA of unweighted UniFrac distances, there were two clusters within all patient groups, indicative of two enterotypes across all subjects. We did not find a significant difference in the relative abundance of overall sulfidogenic bacteria as identified by the 16S rDNA gene between BC and controls. However, *Desulfovibrio* was enriched in BC compared to normal mammogram samples with a log fold change of 1.69 ($p = 0.013$). **Conclusions:** These results suggest altered sulfidogenic gut bacterial community composition in individuals with BC, particularly in organisms with lower relative abundance. *Desulfovibrio* appears as a predominating organism in BC. This is supported by prior research, which suggests *Desulfovibrio* becomes less abundant in participants exposed to agents that inhibit BC cell proliferation. We propose that there are two enterotypes of sulfidogenic gut bacteria in women. Research Sponsor: NIH (National Institutes of Health); University of Illinois.

Beyond convolution: Attention-driven vision transformer modeling for breast cancer detection on mammography. First Author: Tanzeela Mariam Shuja, Northwestern McHenry Hospital, Mchenry, IL

Background: Breast cancer is the most commonly diagnosed malignancy among women worldwide, and screening mammography remains central to early detection and mortality reduction. Despite standardized reporting systems, mammographic interpretation is challenged by tissue overlap, subtle lesion morphology, and interobserver variability. Convolutional neural networks (CNNs) have demonstrated strong performance in automated mammography analysis but rely on localized receptive fields that may limit modeling of global spatial relationships critical for detecting architectural distortion and diffuse malignancy. Vision Transformers (ViTs) employ self-attention mechanisms that enable global contextual modeling across entire images. We evaluated the performance of a Vision Transformer for breast cancer classification on mammographic imaging. **Methods:** We analyzed over 8,000 anonymized mammography images obtained from publicly available Kaggle datasets curated and annotated by expert radiologists. Images included malignant and non-malignant breast findings and were preprocessed and resized to 224×224 pixels. Data were split into training and validation cohorts using stratified sampling at the patient level to prevent data leakage. A Vision Transformer B/16 model pretrained on ImageNet was fine-tuned for binary classification. Images were divided into non-overlapping 16×16 patches, embedded into token sequences with positional encodings and a learnable class token, and processed through 12 transformer blocks with multi-head self-attention. Model performance was evaluated using accuracy, sensitivity, specificity, F1 score, and area under the receiver operating characteristic curve (AUROC). **Results:** The ViT-B/16 model achieved high diagnostic performance, with validation accuracy approaching approximately 96% and AUROC exceeding 0.98. Sensitivity for malignant lesions remained robust across dense and non-dense breast tissue. Attention-based global processing reduced misclassification of lesions with diffuse margins, asymmetric density, and architectural distortion—patterns that are challenging for purely convolutional approaches. Performance was comparable to state-of-the-art CNN models, though achieved with higher parameter count and computational cost. **Conclusions:** Vision Transformer–based modeling enables accurate breast cancer detection on mammography by capturing global contextual relationships through self-attention. While computationally heavier than optimized CNNs, ViT offers complementary strengths in modeling complex spatial patterns and provides interpretable attention maps aligned with radiologic reasoning. These findings support further evaluation of transformer architectures in large-scale breast cancer screening and diagnostic workflows. Research Sponsor: None.

ILCness to stratify lobular-like breast cancer biology and as an outcome independent of *CDH1* mutation in early ER-positive/HER2-negative breast cancer. First Author: Masanori Oshi, Yokohama City University Hospital, Yokohama, Japan

Background: Invasive lobular carcinoma (ILC) represents a distinct histological subtype of breast cancer; however, its underlying molecular basis remains incompletely defined. Although loss-of-function mutations in CDH1 are considered a hallmark genetic event, substantial biological heterogeneity persists that cannot be fully explained by histology or mutation status alone. **Methods:** To address this limitation, we developed a continuous transcriptional framework, termed the ILCness score, to quantitatively capture lobular-like tumor biology. A tightly constrained principal component–based model was trained in the METABRIC cohort and fully fixed without retraining, enabling reproducible projection across independent datasets and expression platforms. **Results:** Unsupervised transcriptomic analyses demonstrated that invasive ductal carcinoma (IDC) and ILC did not form discrete expression clusters but instead distributed along a continuous molecular spectrum. The ILCness score robustly captured this continuum, with mixed-histology tumors occupying intermediate positions. Importantly, lobular-like transcriptional programs quantified by ILCness showed limited concordance with CDH1 mutation status. Across tumors, higher ILCness was consistently associated with reduced DNA repair and E2F target activity (Spearman $|\rho| > 0.4$, $P < 0.001$), whereas epithelial–mesenchymal transition displayed a context-dependent pattern. Tumor microenvironment analyses revealed that stromal and immune cell infiltration correlated more strongly with ILCness than with CDH1 mutation status. These associations were reproducibly validated in independent cohorts without model recalibration. Clinically, ILCness stratified prognostically distinct subgroups within histologically defined tumors, including IDC, independent of CDH1 mutation (disease-specific survival, $P < 0.01$). Across multiple neoadjuvant and systemic therapy datasets, higher ILCness showed consistent directional associations with reduced pathological complete response to chemotherapy and differential response patterns to immune checkpoint inhibition and endocrine therapy. **Conclusions:** These findings establish lobular breast cancer as a continuum of transcriptional states rather than a discrete entity defined by histology or single-gene alterations. The ILCness score provides a scalable RNA-based framework for integrating molecular heterogeneity with tumor biology and clinical behavior, with potential implications for biologically informed patient stratification. Neighborhood disadvantage and correlation with differences in somatic mutations in a real-world breast cancer cohort. First Author: Jacquelyn Dillon, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY

Background: African compared to European genetic ancestry is associated with lower prevalence of clinically actionable alterations despite comparable overall prevalence of driver alterations by ancestry group. This likely contributes to breast cancer (BC) disparity. A limitation of prior ancestry studies is lack of neighborhood-level disadvantage (ND) data, a contributor to BC disparity. The objective of this study was to investigate associations between ND and somatic mutations in a real-world BC cohort. **Methods:** Somatic mutations from primary and metastatic BC samples and genetic ancestry data were identified from MSK IMPACT (FDA-authorized sequencing panel). Samples sequenced between 2015-2025 were annotated and linked with census-tract level socioeconomic status (Yost Index 1-100; higher reflects increasing ND). Multivariate logistic regression analyzed associations between ND and somatic mutations, adjusting for covariates (FDR $p<0.05$). **Results:** 6703 samples (62% primary, 38% metastatic) were analyzed. Mean age was 60 (SD 13). Mean Yost was 26 (SD 24). 67% had ER+/HER2- disease, 9.7% had ER+/HER2+, 5.1% had ER-/HER2+, and 19% had ER-/HER2-. Adjusting for age, BMI, ancestry, and subtype, patients from ND had lower odds of CDH1 (OR 0.99, 95% CI 0.98- 0.99, $p<0.001$), BRCA1 (OR 0.96, 95% CI 0.94-0.99, p=0.021), and AKT1 (OR 0.98, 95% CI 0.97- 0.99, p=0.006) somatic mutations in metastatic samples. **Conclusions:** We identify novel associations between ND and somatic mutations. Notably, patients with ND had lower odds of actionable BRCA1 and AKT1 mutations. This highlights the importance of ensuring patients of diverse ancestry and ND have equitable inclusion in clinical sequencing workflows to improve identification of actionable mutations in all populations. Does surgery improve breast cancer–specific survival in low-grade DCIS?: A 20-year population-based analysis by nuclear grade. First Author: Fatih Aydogan, ACIBADEM Health Group Breast Center, Istanbul, Turkey

Background: Active surveillance is increasingly discussed for low-risk ductal carcinoma in situ (DCIS), yet randomized trials report only short-term outcomes. Long-term survival data stratified by nuclear grade remain limited. We evaluated the association between cancer-directed surgery and long-term breast cancer–specific survival (BCSS) and overall survival (OS) in DCIS. **Methods:** We conducted a retrospective population-based cohort study using SEER 17 registries, including patients diagnosed with DCIS between 2000 and 2019 with follow-up exceeding 36 months. Exposure was cancer-directed surgery (yes vs no). Outcomes were BCSS, analyzed using cause-specific Cox models, and OS. Prespecified covariates included age, year of diagnosis, race, tumor size, nuclear grade, estrogen and progesterone receptor status, median household income, and residence type. Missing data were handled using multiple imputation. Confounding was addressed using inverse probability of treatment weighting with stabilized weights. Analyses were stratified by nuclear grade (Grades 1–3). **Results:** Among 51,637 patients, 50,346 (97.5%) underwent surgery and 1,291 (2.5%) did not. Median follow-up was 120 months. In the overall cohort, surgery was associated with improved BCSS (hazard ratio [HR] 0.13; 95% CI, 0.09–0.19) and OS (HR 0.65; 95% CI, 0.56–0.75). Outcomes differed substantially by nuclear grade. In Grade 1 DCIS, surgery was not associated with improved BCSS (HR 0.57; 95% CI, 0.05–6.16), with 20-year BCSS exceeding 99% regardless of treatment, although OS favored surgery. In Grade 2 DCIS, surgery reduced breast cancer–specific mortality (HR 0.22; 95% CI, 0.10–0.45) without an OS benefit. In Grade 3 DCIS, surgery conferred marked improvements in both BCSS (HR 0.10; 95% CI, 0.06–0.15) and OS (HR 0.49; 95% CI, 0.40–0.60). **Conclusions:** In this large population-based study with up to 20 years of follow-up, omission of surgery in low-grade DCIS was not associated with worse breast cancer–specific survival, whereas clear survival benefits were observed in intermediate- and high-grade disease. These findings support risk-adapted management strategies and provide long-term survival context for active surveillance approaches in DCIS. Research Sponsor: None.

Wire-guided versus radio-guided localization for non-palpable occult lesion in breast tissue: A systematic review and meta-analysis. First Author: Mobeen Farooqi, CMH Lahore Medical College, Lahore, Pakistan

Background: Accurate preoperative localization of non-palpable breast lesions is crucial for successful breast-conserving surgery. Wire-guided localization (WGL) has traditionally been the standard technique; radio-guided localization (ROLL) has emerged as an alternative approach with potential benefits in surgical precision and workflow. Current evidence comparing the efficacy and safety of these two techniques remains inconsistent. This systematic review and meta-analysis evaluates WGL versus ROLL for non-palpable breast lesions with respect to surgical and oncological outcomes. **Methods:** A systematic literature search was conducted on electronic databases from inception until January 2026. Outcomes included re-excision rates, margin involvement, specimen volume and weight, accurate localisation of lesions and operative time. We employed risk ratios (RRs) with 95% Confidence Intervals (CIs) for dichotomous outcomes. Mean differences (MDs) or standardized mean differences (SMDs) with 95% CIs were computed for continuous outcomes using Review Manager V.5.4. Quality assessment and risk of bias were assessed using the Cochrane Risk of Bias Tool 2 on all included RCTs. **Results:** This systematic review and meta-analysis included 13 studies with a total of 5,318 patients. There was no statistically significant difference in the re-excision rates between the two interventions (OR = 1.44; 95% CI: [0.73, 2.83], p = 0.143). Localization time (SMD = 1.75; 95% CI: [-1.01, 4.51], p = $<$0.0001) and length of operation time was significantly shorter in the ROLL group (SMD = 0.22; 95% CI: [0.10, 0.34], p = 0.028). There was no statistically significant difference in the margin involvement between the two groups (OR = 0.61; 95% CI: [0.37, 0.99], p = 0.063). ROLL was associated with significantly smaller volume of specimen (SMD = 0.16; 95% CI: [-5.41, 5.73], p = $<$0.0001). **Conclusions:** ROLL and WGL demonstrate comparable oncological outcomes, with no significant differences in the re-excision rates or margin involvement. However, ROLL is associated with significantly shorter localization and operative times, suggesting procedural efficiency over WGL. Research Sponsor: None.

Intraoperative precision margin assessment in breast-conserving surgery using handheld fluorescence microscopy. First Author: Jing Wang, First Affiliated Hospital of USTC, Hefei, China

Background: Breast-conserving surgery (BCS) is the standard treatment for early-stage breast cancer and is increasingly preferred by younger patients. The key challenge in BCS is ensuring complete tumor removal while preserving healthy breast tissue. Surgical margin assessment plays a crucial role in reducing the risk of local recurrence. Traditional intraoperative frozen sections (FS) are time-consuming, limit sampling, and may cause tissue damage. This study evaluates the performance of EndoScell, a handheld fluorescence microscopy system, as a rapid and efficient alternative for intraoperative margin assessment. **Methods:** EndoScell provides real-time, high-resolution imaging of tissue margins during surgery. This system rapidly stains and scans tissue, allowing for micron-level visualization of cellular features. In this study, EndoScell was used to scan marked surfaces of breast tissue during surgery. The surgeon performed an initial assessment, while images/videos were recorded. Specimens were then sent for intraoperative FS analysis for comparison. If FS identified positive margins, the area was re-excised by 3–5 mm, and the process was repeated. Routine paraffin pathology served as the gold standard, with blinded side-by-side reading of ES images to evaluate consistency. **Results:** As of December 31, 2025, 300 patients undergoing BCS were included. EndoScell demonstrated high diagnostic accuracy with a sensitivity of 96.4%, specificity of 95.1%, and AUC of 0.953, showing strong agreement with paraffin pathology. Notably, the time required for EndoScell imaging was significantly shorter than FS, with an average of 3.14 $\pm$ 1.48 minutes compared to 37.50 $\pm$ 13.34 minutes for FS ($P<0.001$), leading to substantial improvements in surgical efficiency. **Conclusions:** This study confirms the feasibility and non-inferiority of EndoScell for intraoperative margin assessment in breast-conserving surgery. The system enables real-time decision-making, reducing secondary surgeries, improving outcomes, and enhancing surgical safety. Its significant clinical and social value supports further development and implementation. Research Sponsor: None.

Key metrics related to diagnostic accuracy and time efficiency between EndoScell and traditional frozen section methods.

Metric	EndoScell (ES)	Frozen Section (FS)
Positive Margin	54	56
Negative Margin	246	244
Sensitivity	0.964	1.000
Specificity	0.951	1.000
AUC	0.953 (95% CI: 0.912–1.003)	1.000
Imaging Time (min)	3.14 $\pm$ 1.48	37.50 $\pm$ 13.34
p-value	$<$0.001	N/A
Cohen's d	-3.64	N/A

Impact of time-to-surgery on survival outcomes in Korean breast cancer patients: A nationwide population-based cohort study. First Author: Je Hyun Chin, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea

Background: The increasing incidence of breast cancer and the resulting surgical workload in South Korea have led to concerns regarding surgical delays. While the clinical impact of time-to-surgery (TTS) remains debated, defining an optimal threshold is crucial for health policy and patient outcomes. This study aimed to investigate the impact of TTS on overall survival (OS), disease-free survival (DFS), and breast cancer-specific survival (BCSS) using nationwide claims data. **Methods:** This study utilized a merged dataset from the National Health Insurance Service and Korean Statistical Information Service database. We identified 11,683 women newly diagnosed with Stage I-III primary breast cancer in 2016, excluding prior history or concurrent malignancies. TTS was defined as the interval from breast cancer diagnosis to the definitive surgical procedure. To determine the optimal clinical cutoff, the Contal and O'Quigley method was applied. Multivariable Cox proportional hazards models were used for OS. To account for competing risks, the Fine-Gray subdistribution hazard model was employed for DFS and BCSS, with non-breast cancer death treated as a competing event. Covariates included physical activity, type and region of institution, systemic treatments, income decile, and Charlson Comorbidity Index (CCI) score. **Results:** Initial analysis using 30-day and 60-day thresholds showed significant differences in survival outcomes. The Contal and O'Quigley method identified 68 days as the optimal cutoff for TTS. Patients with TTS $>$ 68 days exhibited significantly worse OS compared to those with TTS $\leq$ 68 days (adjusted Hazard Ratio [HR], 3.396; 95% CI, 2.402-4.802; $p<0.001$). In the competing risk regression, TTS $>$ 68 days was associated with inferior DFS (adjusted subdistribution HR [sHR], 1.496; p= 0.001) and BCSS (adjusted sHR, 5.868; $p<$ 0.001). The negative impact of delayed surgery remained consistent across various subgroups regardless of income level or comorbid status. **Conclusions:** Delays in surgery exceeding 68 days are significantly associated with poorer survival outcomes in Korean breast cancer patients. These findings suggest that every effort should be made to perform surgery within 68 days of diagnosis to optimize long-term prognosis. Clinicians should prioritize streamlining the diagnostic-to-treatment pathway to minimize surgical wait times. Research Sponsor: None.

Can robotic surgery better preserve sensory function?: The significance and strategy of nerve preservation in axillary lymph node dissection. First Author: Qiwen Liu, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Conventional axillary lymph node dissection (C-ALND) carries a high risk of damaging the intercostobrachial nerve (ICBN), which remains a critical clinical issue affecting both psychological recovery and quality of life in breast cancer patients. While advancements in minimally invasive surgery provide improved visualization and precision, evidence supporting its clinical benefit in preserving sensory function is lacking. **Methods:** A retrospective analysis was conducted on breast cancer patients who underwent robotic-assisted axillary lymph node dissection (R-ALND, n = 53) and endoscopic-assisted axillary lymph node dissection (E-ALND, n = 58) between 2021 and 2025 (total n = 111). The anatomical integrity of the ICBN (T1-3) was systematically identified and recorded during surgery. Additionally, a blinded evaluator performed standardized bedside sensory testing (BST) on four key ICBN areas (medial upper arm, axilla, upper chest, and lateral chest wall) three months postoperatively, using a scoring system adapted from the ISCIPS consensus group for the current study. A multivariate linear regression model was applied for analysis. **Results:** Compared with E-ALND, R-ALND demonstrated a significantly higher ICBN-trunk preservation rate (77.4% vs. 63.1%, p = 0.033) and a greater proportion of areas with normal sensation at three months postoperatively (89.2% vs. 74.6%, p = 0.025). Multivariate linear regression revealed that T2-ICBN trunk preservation was the strongest independent predictor of sensory recovery at three months (β = 0.571, 95% CI 0.477–0.664, P $<$ 0.001), with an effect size (standardized β = 0.720) far exceeding other factors. Patients with T2-ICBN preservation achieved a 77.4% rate of completely normal sensation across all four key ICBN areas at three months. After adjusting for variables including T2-ICBN preservation, tumor stage, age and so on, robotic surgery showed a tendency to be an independent protective factor for sensory recovery at 3 months postoperatively compared with endoscopic surgery. (β = 0.110, p = 0.016). **Conclusions:** Through three-dimensional visualization and tremor-filtering technology, R-ALND significantly reduces the risk of iatrogenic ICBN injury and outperforms E-ALND in preserving short-term postoperative sensory function recovery. In the early phase with a limited learning curve, preserving the ICBN trunk (particularly the T2-ICBN) is recommended to retain most of the patient's sensory function. Research Sponsor: None.

Synergistic efficiency of methylene blue and carbon nanoparticles for sentinel lymph node biopsy in early breast cancer: A large-scale real-world cohort study of 1,355 patients. First Author: Hongjin Liu, Peking University First Hospital, Beijing, China

Background: Sentinel lymph node biopsy (SLNB) using radioisotopes and fluorescence imaging is the gold standard but remains inaccessible in many resource-limited regions due to high costs and the lack of nuclear medicine infrastructure. Methylene blue (MB) is a globally available, low-cost tracer, but often lacks consistent nodal yield. This study evaluates a radiation-free, dual-tracer protocol combining MB with carbon nanoparticles (CN) to provide a highly accessible and reliable axillary staging method for diverse clinical settings. **Methods:** In this single-center retrospective cohort study, 1,355 female patients with cT1-2N0M0 breast cancer (May 2019 to December 2022) were stratified into the MB group (n=675) or the MB+CN group (n=680). Primary endpoints were the SLN detection rate and mean node retrieval (MNR). Sensitivity analyses adjusted for confounders, including Ki67 status, using multivariate regression. The goal was to determine if this dual-dye approach could match the reliability of high-cost methods without specialized equipment. **Results:** The MB+CN group achieved a comparable detection rate to MB alone (96.32% vs. 96.44%; P=0.905). Crucially, the dual-tracer protocol significantly increased the MNR (2.43±1.64 vs. 2.10±1.35; P<0.001). Adjusted linear regression confirmed a robust increase in node count (β=0.36, 95% CI: 0.19–0.52, P<0.001). Subgroup analysis demonstrated enhanced utility in aggressive molecular profiles, with significantly higher node retrieval in high-Ki67 (P=0.002), T2 stage (P=0.032), and ER-positive (P<0.001) cohorts. No significant differences in detection rates were observed across any clinicopathological subgroups. **Conclusions:** The MB+CN dual-tracer strategy significantly enhances nodal yield while maintaining high detection rates. By eliminating the need for radioactive tracers and expensive imaging hardware, this approach offers a precise, safe, and cost-effective SLNB solution. It is particularly suited for large-scale implementation in developing countries and rural healthcare systems, bridging the gap in breast cancer surgical standards globally. Research Sponsor: None.

Comparison of SLNB outcomes between MB and MB+CN groups.

Outcome	MB Group (n=675)	MB+CN Group (n=680)	Univariate *P*	Adjusted Estimate (95% CI)	Multivariate *P*
Detection Rate, % (n_1/n)	96.44% (651/675)	96.32% (655/680)	0.905	OR: 0.83 (0.64–1.09)	0.182
Mean Node Retrieval (SD)	2.10 (1.35)	2.43 (1.64)	<0.001	β: 0.36 (0.19–0.52)	<0.001

Oncological safety of oncoplastic breast conservation surgery: Experience of over a decade in early and locally advanced breast cancer from a tertiary care cancer center in India. First Author: Shalaka Prakash Joshi, Tata Memorial Hospital and Homi Bhabha National Institute, Mumbai, India

Background: Oncoplastic breast conservation surgery (O-BCS) is the norm. O-BCS improves cosmetic outcomes by restoring the shape, size, contour and symmetry of the breast and hence, quality of life. Carefully selected patients with locally advanced breast cancers (LABC) can be offered O-BCS after systemic therapy. We retrospectively evaluated our prospective dataset for oncological outcomes of patients who had O-BCS. **Methods:** Patients undergoing O-BCS between January 2013 and December 2023 were included. They received (neo)adjuvant chemotherapy, targeted and radiotherapy along with endocrine treatment as per standard institutional protocol and decision of Breast Cancer-Disease Management Group (BC-DMG). Clinico-pathological characteristics, type of oncoplastic procedure and follow-up details were updated from Electronic Medical Records. Data was collected and analyzed in SPSS-V29. **Results:** A total 1483 patients underwent O-BCS during the study period. The median age of the cohort was 45 (21- 86) years. Of 1483, 670 (45.2%) were operated upfront and 573 (38.6%) post-chemotherapy whereas 240 (16.2%) had had prior excision biopsy elsewhere. Clinically, 939 (63.3%) were early (EBC-T1/2, N0/1), 518 (34.9%) locally advanced (LABC-T3/4, N2/3) and 26 (1.8%) oligometastatic breast cancers. 1016 (68.5%) were HR+, 289 (19.5) TN and 396 (26.7%) HER2+. Median pT in upfront versus post-chemotherapy operated patients was 3 cm (0.1–8.5) and 2.7 cm (1-10) respectively. Upfront, 45.8% patients were node positive (median-2 {1-54}) and post-chemotherapy 38.3% (median-3 {1-38}). The median specimen volume was 432 cm^3(56.8–3528) in upfront and 270 cm^3(3–2875) in post-chemotherapy operated patients. The overall margin positive rate was 5.5% (81/1483). Of 1483, 573 (38.6%) patients had type-1 oncoplastic parenchymal closure, 377 (25.4%) had local dermo-glandular flaps, 344 (23.2%) a latissimus dorsi myo-cutaneous flap, and 189 (12.7%) bilateral reduction mammoplasty. At median follow-up of 47 months, there were 245 (16.5%) recurrences–77(5%) local and 211(14%) distant–and 153 (10.3%) deaths, and the disease-free survival (DFS) and overall survival (OS) were 84.1% and 89.5% respectively. The local recurrence rate in EBC was 4% and LABC 7.4%. The 5-year DFS was 82.1%(95%CI-79.75%-84.84%) and OS was 88.5%(95%CI-86.54%-90.46%) across the whole cohort. On Cox regression, high clinical nodal stage (HR-1.47, 95%CI-1.04-2.08, p=0.03) and histological grade 3 (HR-1.87, 95%CI-1-07-3.29, p=0.03) were predictors of poor DFS whereas type of O-BCS did not have impact on survival. **Conclusions:** The local recurrence rate in O-BCS was 5.3% in our setting which is reassuring considering that 1/3rd patients had locally advanced disease. A longer follow-up of this cohort of patients and future PROMs and QOL studies will be consolidatory. Research Sponsor: None.

Surgical outcomes and postoperative complications of robotic versus conventional nipple-sparing mastectomy in breast cancer: A meta-analysis. First Author: Fahad Amin, King Edward Medical University, Lahore, Pakistan

Background: Breast cancer is the most common type of cancer, affecting millions of women worldwide. Nipple-sparing mastectomy has emerged as a technique that leaves most of the healthy breast skin, areola, and nipple. This technique is widely used but there is little evidence comparing conventional and robotic nipple-sparing mastectomy. This meta-analysis aimed to compare the efficacy, safety, and postoperative complications of conventional and robotic nipple-sparing mastectomy. **Methods:** A systematic search of PubMed, Scopus, Web of Science, and the Cochrane Library was conducted to identify studies comparing robotic and conventional nipple-sparing mastectomy. The primary outcome was nipple and skin necrosis; secondary outcomes included operative time and Clavien-Dindo Grade III complications. Pooled estimates were calculated using a random-effects model, and heterogeneity was assessed using the I2 statistic. **Results:** A total of nine studies encompassing 1,220 participants (423 in the robotic group and 797 in the conventional group) were included in the final analysis. Robotic nipple-sparing mastectomy (RNSM) was associated with a significantly lower risk of nipple and skin necrosis compared to conventional nipple-sparing mastectomy (CNSM), with a pooled odds ratio of 0.47 (95% CI: 0.26–0.86; P = 0.01) and low heterogeneity (I2 = 20.5%). Conversely, RNSM was associated with a significantly longer operative time, with a weighted mean difference of 52.86 minutes (95% CI: 20.28–85.43; P = 0.001) and substantial heterogeneity (I2 = 96%). Regarding safety, there was no statistically significant difference in Clavien-Dindo Grade III complications between the two techniques (OR = 0.60; 95% CI: 0.35–1.05; P = 0.07; I2 = 0%), although the results showed a trend favoring the robotic approach. **Conclusions:** Robotic nipple-sparing mastectomy demonstrates a superior safety profile regarding ischemic complications, significantly reducing the risk of nipple and skin necrosis compared to the conventional approach. However, it is associated with longer operative times. The incidence of major complications (Grade III) is comparable between both techniques. Research Sponsor: None.

Evaluation of a novel diagnostic kit using the semi-dry dot-blot method with an automated reader for detecting breast cancer metastases in sentinel lymph nodes: A combined analysis of two multicenter prospective studies in Japan. First Author: Ryota Otsubo, Nagasaki University Hospital, Nagasaki, Japan

Background: The semi-dry dot-blot (SDB) method is a diagnostic procedure for detecting lymph node (LN) metastases using an anti-cytokeratin (CK) antibody, based on the premise that epithelial components such as CK protein are not present in normal LNs. Thus, the presence of CK protein in the lavage fluid of sectioned LNs indicates metastasis. Because this method does not involve loss of LN tissue, it can be used in parallel with conventional histopathological diagnosis. We developed a novel diagnostic kit utilizing the SDB method and a newly developed anti-CK19 antibody to detect macrometastases over 2.0 mm in diameter. Two multicenter prospective studies were conducted to evaluate the diagnostic performance of this kit, and we herein report a combined analysis of the two studies. **Methods:** A total of 825 sentinel LNs were dissected between January and December 2021, and 909 LNs between August 2023 and November 2024, at seven institutions in Japan from 880 patients with breast cancer. Patients who received neoadjuvant chemotherapy or endocrine therapy were excluded. LNs were sliced at 2-mm intervals and washed with phosphate-buffered saline. Cells in the lavage fluid were centrifuged and lysed, and the extracted proteins were applied to the SDB kit. Absorbance was measured using an automated reader to determine the presence of metastases. The washed LNs underwent blinded intraoperative and permanent histopathological examination. Diagnostic performance of the SDB kit was compared with permanent histology, with primary endpoints being sensitivity, specificity, and overall concordance for detecting macrometastases. **Results:** Of the 1,734 LNs analyzed, 199 were diagnosed as macrometastases and 1,535 as non-macrometastases, including 64 micrometastases measuring more than 0.2 mm and not up to 2.0 mm in diameter, based on permanent histopathology. Using a CK absorbance cutoff of 11.9, the SDB kit correctly identified 185 of the 199 macrometastatic LNs and 1,496 of the 1,535 non-macrometastatic LNs. This corresponded to a sensitivity of 93.0%, specificity of 97.5%, and overall concordance of 96.9%. Additionally, the kit enabled diagnosis within approximately 20 minutes, at a cost of under $30 per test and less than $3,000 for the reader device. **Conclusions:** The novel SDB kit with an automated reader demonstrated high accuracy, rapid turnaround, and cost-effectiveness in detecting breast cancer LN metastases, while preserving LN tissue. It proved particularly effective in identifying macrometastases. Commercial availability of the kit and reader is planned in the near future. Research Sponsor: None.

Distant recurrence–free survival in invasive lobular carcinoma (ILC) with isolated tumor cells: Does pN0(i+) behave like node-negative or node-positive disease? First Author: Jason A. Mouabbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: ILC is a distinct breast cancer subtype with unique biology and clinical behavior compared with invasive ductal carcinoma. The prognostic significance of isolated tumor cells (ITCs; pN0(i+)) in ILC remains unclear, creating a management gap regarding whether patients with ITCs should be risk-stratified and treated similarly to node-negative (pN0) or node-positive (pN1) disease. **Methods:** We performed a retrospective analysis of patients with ILC treated at The University of Texas MD Anderson Cancer Center (Protocol PA20-0040). Distant recurrence-free survival (DRFS) was assessed using Kaplan-Meier methods and compared using log-rank testing. Univariate and multivariable Cox proportional hazards models evaluated associations between clinicopathologic and treatment variables and DRFS. The multivariable model included age, pathologic nodal stage, grade, HER2 status, histologic subtype (classical vs non-classical), and receipt of endocrine therapy, chemotherapy, radiation therapy, and definitive surgery. **Results:** The cohort included 4,217 patients (mean age 56.8 years). Most tumors were classical ILC (89.1%). ITCs were present in 169 patients; comparator groups included pN0 (n=1,799) and pN1 (n=1,040). In univariate analysis, there was no evidence that pN0(i+) were associated with worse DRFS versus pN0 (ITC negative) (HR 0.71, 95% CI 0.45-1.13; p=0.135), whereas pN1 was associated with inferior DRFS versus pN0 (HR 1.85, 95% CI 1.62-2.10; p$<$0.001). In multivariable analysis, there remained no evidence that pN0(i+) were associated with inferior DRFS versus pN0 (HR 0.661, 95% CI 0.404-1.081; p=0.099), while pN1 was independently associated with worse DRFS versus pN0 (HR 1.922, 95% CI 1.589-2.326; p$<$0.0001). **Conclusions:** In this large ILC cohort, pN0(i+) (ITCs) did not confer inferior DRFS compared with pN0, and outcomes were clearly distinct from pN1 disease. These findings support prospective validation and may inform nodal-status-driven risk stratification and treatment de-escalation strategies for pN0(i+) patients with ILC. Research Sponsor: None.

Key DRFS comparisons (reference = pN0).

Comparison	Univariate HR (95% CI)	Univariate p-value	Multivariable HR (95% CI)	Multivariable p-value
pN0(i+) vs pN0	0.71 (0.45-1.13)	0.135	0.661 (0.404-1.081)	0.099
pN1 vs pN0	1.85 (1.62-2.10)	$<$0.001	1.922 (1.589-2.326)	$<$0.0001

Can we omit surgical axillary staging in early-stage invasive lobular carcinoma?: Results from a large multicenter retrospective cohort study. First Author: Massimo Ferrucci, Breast Surgical Unit, Veneto Institute of Oncology IRCCS, Padova, Veneto, Italy

Background: The SOUND, INSEMA and BOOG 2013-08 randomized trials demonstrated that, in selected patients with clinically node-negative (cN0) early-stage breast cancer, omission of sentinel lymph node biopsy (SLNB) results in non-inferior disease-free and invasive disease-free survival. However, invasive lobular carcinoma (ILC) was underrepresented in these three studies, and the safety of this approach in ILC remains uncertain due to concerns about a potentially higher axillary nodal burden and risk of undertreatment. We evaluated the axillary nodal burden in ILC patients who met the trials eligibility criteria. **Methods:** This retrospective multicenter study included patients with cT1-2 cN0 ILC, undergoing upfront surgery between 2012 and 2025 across three high-volume Italian institutions. All patients underwent preoperative axillary ultrasound (US), with needle biopsy performed for US-suspicious lymph nodes. Uni- and multivariable logistic regression analyses identified factors associated with advanced nodal disease (pN2/3). **Results:** A total of 1886 patients (median age 65 years) were included. The median radiologic tumor size was 16 mm (IQR 11-23). Most patients underwent SLNB (84%), while the remaining were treated with axillary dissection. The overall rate of pN2/3 disease was 2.5% (48/1886). On univariable analyses, a palpable mass on physical exam (OR 3.59; p $<$ 0.001), the presence of US-suspicious axillary nodes (OR 8.19; p $<$ 0.001), tumor size $>$ 2 cm (OR 2.96; p = 0.002), multicentric disease (OR 4.5; p $<$ 0.0001), high tumor grade (OR 2.15; p = 0.03), the presence of lymphovascular invasion (LVI) (OR 3.25; p = 0.001) and HER2 positivity (OR 3.81; p = 0.022) were significantly associated with pN2/3 disease. On multivariable analysis, tumor size $>$ 3 cm (p = 0.003), the presence of US-suspicious axillary nodes (OR 6.29; p = 0.002), the presence of LVI (OR 3.65; p = 0.006), multicentric distribution (OR 5.19; p $<$ 0.0001), and HER2 positivity (OR 3.86; p = 0.041) were independently associated with pN2/3 disease. **Conclusions:** In this large real-world cohort of SOUND/INSEMA eligible patients with ILC, the rate of pN2/3 disease was 2.5%, higher than that reported in the aforementioned trials. Omission of axillary surgical staging in patients harboring high risk features may result in understaging, with potential implications for adjuvant treatment decisions and oncologic outcomes. Meticolous selection is critical to identify patients who are not at risk of potential undertreatment. Research Sponsor: None.

Changes in metastatic breast cancer (MBC) bone lesions and SREs/fractures via a single intratumoral injection for a first-of-its-kind drug: Preliminary phase 2a results. First Author: Manraj Heran, University of British Columbia, Vancouver, BC, Canada

Background: Lytic bone metastases develop in ~70% of breast cancer patients that lead to pain, functional decline, and skeletal-related events (SREs) that reduce quality of life (QoL) and survival. Prophylactic denosumab/bisphosphonate treatment offers limited protection, and current local palliative interventions, EBRT and surgery, don't reverse lytic destruction. Zeta-BC-003 is a first-in-class intratumoral (IT) injectable biomaterial infused with N-allyl noroxymorphone, a small molecule drug that acts through the p21 pathway to drive bone healing and local tumor control. Reports on two Compassionate Use patients (7 lesions, 2-yr follow-up; Palma et al, Pain Manag 2023) showed no SREs/fractures or tumor activity coupled with neo-trabecular bone regeneration and therapeutic spread to other lesions within treated bone, which align with these Phase 2a results. **Methods:** ZGMBC (NCT05280067), an open-label Phase 2a study, enrolled women (N=10; 8/23-3/25) with MBC lytic lesions and a Spinal Instability Numeric Score (SINS) $\geq$3 - $\leq$9. A single intratumoral (IT) Zeta-BC-003 injection was administered via fluoroscopic guidance. CT & MRI were obtained at Days 0, 84, and 180. Primary endpoints: SREs/fractures; defect volume; pain via the Numeric Rating Scale (NRS); post-op pain control via the Morphine Equivalent Dose (MED); and AE/SAEs. Secondary endpoints: QoL (SF-12v2); SINS; and tumor response. **Results:** Subjects (mean age 52) had the following MBC subtypes: HR+ (N=6), HR+/HER2+ (N=2), HER2+/HR- (N=1), and TNBC (N=1). Breakthrough lesions were seen in 5 subjects despite bisphosphonate therapy and 1 subject died from pleural edema prior to study end. Zeta-BC-003 was injected into 10 subjects with 11 lesions with additional therapeutic effect seen in 4 adjacent untreated lesions. A CR was shown for all lesions and there were no SREs/fractures. The bone defect volume decreased 65.4% ($\pm$20.5%; p=0.0003) and 84.1% ($\pm$13.1%; p$<$0.0001) at Days 84 and 180. NRS pain scores decreased 4.2% (p$<$0.05) and MED decreased $\geq$33% in opioid-treated subjects. SINS scores improved 18.5% (p$<$0.05), indicating increased stability. Increased PCS (24%) and MCS (12%) scores showed increased QoL. There were no treatment emergent SAE/AEs. **Conclusions:** Zeta-BC-003 prevented SREs/fractures in all lesions, reduced lytic defect volume, improved spinal stability, decreased pain/opioid use, improved QoL, ceased tumor activity, and demonstrated therapeutic spread to untreated lesions in the same vertebral body. These findings contrast with historical SRE rates of 53% in MBC and align with the durable CR seen in our Compassionate Use patients. Zeta-BC-003 may represent a first-of-its-kind intratumoral drug that ceases lytic activity, stimulates neo-trabecular bone growth, and improves QoL by eliminating SREs/fractures while also increasing overall survival. Clinical trial information: NCT05280067. National real-world adoption of 5-fraction breast radiotherapy in the United States (2020–2023). First Author: Pragya Jain, Baptist Hospitals of Southeast Texas, Beaumont, TX

Background: The landmark FAST-Forward trial demonstrated that ultra-hypofractionated whole-breast irradiation with 26 Gy in 5 fractions over 1 week was non-inferior to 40 Gy in 15 fractions for local control (HR 0.67, 95% CI 0.38–1.16), with similar normal tissue effects at 5 years. In response, major international guidelines incorporated 26 Gy in 5 fractions as a standard approach or recommended option for selected patients. Despite robust randomized evidence and guideline endorsement, U.S. real-world adoption patterns and equity of uptake across patient populations remain incompletely characterized. This study evaluated national trends in 5-fraction breast radiotherapy and sociodemographic differences from 2020 to 2023. **Methods:** The National Cancer Database radiotherapy fractionation fields were used to identify radiotherapy (RT) courses with evaluable fraction counts, and a binary indicator for 5-fraction RT (yes/no) was created. Temporal trends by diagnosis year (2020–2023) were assessed, and associations between 5-fraction RT and sociodemographic factors (primary insurance, urban or rural status, neighborhood income quartile, and race) were examined using chi-square testing. **Results:** Among 536,783 RT courses with complete data from 2020 to 2023, use of 5-fraction RT increased substantially over time: 4.3% in 2020, 8.1% in 2021, 12.7% in 2022, and 17.4% in 2023, resulting in an overall adoption rate of 10.7% (p $<$ 0.001). In the subset eligible for fractionation (5, 15–16, 25–28 fractions; N = 31,448), 5-fraction RT accounted for 11.7% and differed significantly by insurance type (p $<$ 0.001): Medicare 17.4%, Private 7.6%, Medicaid 5.9%, and Uninsured 6.9%. Geographic variation was notable (p $<$ 0.001), ranging from 7.3% in mid-size metropolitan areas (250,000–1 million population) to 17.7%–18.1% in more remote or non-adjacent areas; large metropolitan areas ($\geq$1 million) had 12.8% uptake. Neighborhood income showed a gradient (p $<$ 0.001): 10.1% in the lowest quartile compared to 12.5% in the highest. Race was also associated with uptake (p $<$ 0.001), with lower use among Black patients compared to White patients (9.4% vs 12.2%). **Conclusions:** In routine U.S. practice, adoption of 5-fraction breast RT increased rapidly from 2020 to 2023, with the most pronounced growth after 2021, reflecting the swift translation of trial evidence into clinical practice. However, uptake varies by insurance, geography, income, and race, indicating that diffusion is not uniform. Given the potential benefits of ultra-hypofractionation in reducing treatment burden and supporting timely completion, targeted implementation strategies, such as provider education, reimbursement alignment, and facility-level operational support, may be necessary to ensure equitable access as 5-fraction regimens become more widely adopted and potentially become the standard of care. Research Sponsor: None.

A response-adapted and genomically informed strategy to optimize neoadjuvant chemotherapy versus endocrine therapy plus CDK4/6 inhibition in high-risk HR+/HER2− breast cancer. First Author: Zhengjun Yang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Premenopausal patients with locally advanced hormone receptor–positive, HER2-negative (HR+/HER2−) breast cancer are routinely recommended neoadjuvant chemotherapy (NAC) despite heterogeneous and often limited response. In advanced disease, endocrine therapy (ET) plus CDK4/6 inhibition has replaced chemotherapy as first-line treatment. Whether patients with poor early response to NAC may benefit from chemotherapy-sparing strategies remains unclear. We conducted a prospective response-adapted study integrating early chemosensitivity assessment with exploratory genomic profiling to guide neoadjuvant treatment selection. **Methods:** A total of 116 premenopausal patients with stage II-III HR+/HER2− breast cancer received two initial cycles of TAC chemotherapy (docetaxel, doxorubicin, and cyclophosphamide). Radiologic response was assessed after two cycles. Patients achieving partial response (PR) continued TAC. Patients with stable disease (SD) were randomized to either continue TAC (NAC) or switch to 16 weeks of ET consisting of dalpiciclib (CDK4/6 inhibitor), exemestane, and goserelin (NET). Whole-exome sequencing was performed in an exploratory subset. The primary endpoint was objective response rate (ORR). **Results:** After two cycles of TAC, 30 patients achieved PR, while 86 exhibited SD and were subsequently randomized. Among evaluable patients, the ORR was 68.3% in the NET group (41 evaluable patients) compared with 48.7% in the continued NAC group (39 evaluable patients), indicating a higher response rate with NET in tumors demonstrating poor early chemosensitivity. Exploratory genomic analyses further showed that NET-sensitive tumors were predominantly TP53 wild-type and lacked PIK3CA or AKT alterations, consistent with a highly endocrine-dependent biology. In contrast, nonresponders to NET frequently harbored TP53 mutations, often in combination with PIK3CA/AKT pathway alterations, whereas patients who responded to continued chemotherapy commonly exhibited TP53 or TTN mutations, suggesting a chemotherapy-responsive but endocrine-refractory phenotype. **Conclusions:** Taken together, our findings indicate that in premenopausal patients with stage II-III HR+/HER2− breast cancer who demonstrate suboptimal early response to intensive neoadjuvant chemotherapy, continued cytotoxic treatment may not be optimal for all patients. A response-adapted strategy integrating early functional assessment with genomic features, particularly TP53 and PI3K/AKT pathway status, distinguishes endocrine-sensitive from chemotherapy-sensitive disease. These results provide a biologically informed framework for neoadjuvant treatment selection and support biomarker-enriched randomized trials evaluating chemotherapy-sparing strategies in selected patients. Clinical trial information: NCT06009627. Research Sponsor: None.

Impact of age on breast cancer outcomes in the neoadjuvant I-SPY2 trial. First Author: Kelsey H. Natsuhara, University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: Historically, young women with early-stage breast cancer (EBC) have had worse outcomes than older women. This is based largely on population-based or adjuvant studies, with limited neoadjuvant data. **Methods:** Patients (pts) with Stage 2-3 EBC treated with neoadjuvant chemotherapy +/- immunotherapy (Cx-IT) on the I-SPY2 trial between 2010-2022 were included (data cutoff 07/2025). Pts were stratified by age at trial screening (<40 vs ≥ 40 yrs), and clinical/molecular subtypes, including ImPrint, an immune signature predictive of Cx-IT response. Pathologic complete response (pCR), residual cancer burden (RCB), and event-free survival (EFS) were evaluated by age and disease subtypes using Kaplan-Meier methods and Cox proportional hazard ratios (HR). **Results:** Among 2117 evaluable pts, 510 (24%) were <40 yrs and 1607 (76%) were ≥ 40 yrs. Overall, 43% of tumors were HR+/HER2-, 35% HR-/HER2- (TN), 22% HER2+. 34% / 66% were ImPrint +/- (27% / 73% for HR+; 44% / 56% for HR-), with similar rates of ImPrint+/- between age groups. Rates of pCR (31% vs 35 %) and RCB 0/1 (48% vs 51%) were similar between pts <40 and ≥ 40. Overall, pts < 40 had worse EFS ($p < 0.01$) vs pts ≥ 40; however, in pts who achieved pCR, there was no difference in EFS in all biologic subgroups (HR 0.90, p=0.77). In contrast, in pts with residual disease, those <40 had worse EFS than pts ≥ 40 (HR 0.72, $p<0.01$). The worse EFS in pts<40 with residual disease was limited to pts with ImPrint- disease, in both HR+/HER2- (HR 0.64, p=0.02) and TN (HR 0.62, p=0.04) subtypes, where response rates were lower. In ImPrint+ pts, no differences in EFS by age were observed (HR 1.01, p=0.98). Similar results were seen for pts with HR+/HER2- disease when stratifying by RCB (RCB 0/I vs 2/3). There was no difference in EFS by age for pts with RCB 0/1 disease in any subtype (HR 0.66, p=0.09). For ImPrint-, pts<40 with RCB 2/3 disease had worse EFS than pts ≥ 40 (HR 0.61, p=0.01). For HR+/HER2-, 64% of tumors were MammaPrint (MP) High 1 vs 36% MP High 2, and 74% were Luminal. When stratifying by pCR or RCB 0/1, similar age-related EFS differences were observed in HR+/HER2- Luminal or MP High 1 tumors, as in ImPrint- tumors. **Conclusions:** Overall, young pts <40 yrs with high-risk EBC in the I-SPY2 trial had worse 5-yr EFS than pts ≥ 40; however, when taking response into account, there were no age-related EFS differences for pts who had an excellent response to neoadjuvant Cx-IT (i.e. pCR or RCB 1). The EFS difference was driven by pts with residual disease, specifically in the subset with ImPrint- disease, which is associated with less response to Cx-IT. Whereas, for pts with ImPrint+ disease, there was no difference in EFS by age, regardless of pCR or RCB. This highlights the unmet need for more effective therapies for immune-negative tumors. Our results reinforce the importance and prognostic value of neoadjuvant therapy, particularly in our youngest pts, to better risk-stratify and optimize treatment based on tumor biology and response to therapy. Clinical trial information: NCT01042379. Research Sponsor: None.

Pathologic complete response in rare histologic subtypes of early-stage triple-negative breast cancer in the era of immunotherapy. First Author: Maeve Hennessy, Section of Hematology & Oncology, Department of Medicine, University of Chicago, Chicago, IL

Background: The addition of immunotherapy (IO) to chemotherapy has improved outcomes in early-stage triple-negative breast cancer (eTNBC). Rare histologic subtypes, like lobular and metaplastic, are managed using the same treatment algorithms as ductal TNBC but historically have been associated with worse outcomes. Whether the benefits of IO extend to these rare subtypes in real-world practice remains unclear. **Methods:** We used the National Cancer Database to retrospectively identify patients diagnosed with stage II-III TNBC who received neoadjuvant therapy from 2021 to 2022, after FDA approval of IO for eTNBC. TNBC was categorized as ductal, lobular, metaplastic or other. Logistic regression was used to assess pathologic complete response (pCR) stratified by IO use. All models were controlled for key demographic and clinicopathologic factors. **Results:** We identified 17,006 patients with stage II–III TNBC (mean age 55.0 years). Most patients had ductal histology (91.1%), with smaller proportions of metaplastic (2.5%), and lobular (1.9%). Overall, 11,132 (65.5%) patients received IO and achieved a higher pCR rate than those who did not receive IO (45.2% vs 33.1%). pCR rate differed significantly by histologic subtype treated with neoadjuvant chemotherapy, both with and without IO. Among patients who received IO, pCR rate was highest in ductal TNBC (47%) and was significantly lower in lobular (18.9%) and metaplastic (17.6%) tumors ($p<0.001$). Similarly, in patients who did not receive IO, ductal TNBC had the highest pCR rate (34.6%) with metaplastic and lobular subtypes having lower pCR rates (12.5% and 14.3%, respectively; $p<0.001$). After covariate adjustment, all non-ductal subtypes had significantly lower odds of pCR compared to ductal TNBC regardless of receipt of IO. This was most notable for metaplastic TNBC with an odds ratio [OR] of 0.19 (95% CI 0.10–0.33) with IO and OR 0.13 (95% CI 0.04–0.44) without IO. Lobular TNBC was also associated with significantly lower odds of pCR in IO-treated patients (OR 0.50, 95% CI 0.28–0.90) with similar trends observed in patients treated without IO. **Conclusions:** In this national real-world cohort, we demonstrate that despite the adoption of neoadjuvant IO for eTNBC and improved pCR rates overall, rare histologic subtypes continue to experience inferior treatment outcomes. Metaplastic and lobular TNBC had persistently low pCR rates, regardless of IO use. These results highlight the urgent need for novel therapeutic strategies and dedicated clinical trials for these rare histologic subtypes. Research Sponsor: National Institute on Aging; T32AG000243.

Association of immunotherapy infusion timing with outcomes in early-stage triple-negative breast cancer. First Author: Xianghui Zou, NYU Long Island School of Medicine Program, Perlmutter Cancer Center, Mineola, NY

Background: Circadian regulation of immune function has been shown to influence the efficacy of immune checkpoint inhibitors (IO) in several malignancies. However, the clinical relevance of IO infusion timing in breast cancer remains unclear. We evaluated the association between IO timing, baseline characteristics, pathologic complete response (pCR), and recurrence outcomes in patients with early-stage triple-negative breast cancer (TNBC). **Methods:** We conducted a retrospective cohort study of 139 patients with early-stage TNBC treated at Manhattan and Mineola campuses alongside with four sites in Queens, Brooklyn, and Long Island using a KEYNOTE-522-based neoadjuvant regimen including pembrolizumab, chemotherapy, and surgery between July 2021 and June 2025. IO infusion timing was dichotomized using the cohort median time (12:22 PM); patients receiving all first three IO infusions after this cutoff were classified as late. Baseline characteristics including age, body mass index (BMI), race, ECOG performance status, clinical T/N stage, and chemotherapy backbone were compared between groups. pCR was defined as absence of residual invasive disease. Recurrence outcomes included local recurrence, distant recurrence, or death. Multivariable analyses adjusting for baseline clinical factors were performed. **Results:** Amongst our 139 patients, 108 received early IO and 31 received late IO. Patients receiving early IO were younger (mean age 55.9 vs 63.5, p = 0.025) and had lower BMI (27.4 vs 30.6, p = 0.017), while ECOG performance status 0-1 (early: 98.1% vs late: 90.3% respectively, p = 0.075), non-white race (52.5% vs 56%, p = 0.825), clinical T/N stage ($T\geq 2$: 88.7% vs 90.3%, p = 0.999; $N\geq 1$: 37.4% vs 38.7%, p = 0.999), carboplatin/paclitaxel chemotherapy backbone distributions (93.5% vs 90.3%, p = 0.693) were similar between groups. pCR occurred in 63% of patients receiving early IO and 45.2% receiving late IO (p = 0.098). Recurrence outcomes occurred in 3.7% of the early IO group and 16.1% of the late IO group (p = 0.026), driven primarily by distant recurrence (0.9% vs 12.9%, p = 0.009). After adjusting for age, BMI, and clinical T/N stage, late IO remained associated with distant recurrence (adjusted odds ratio 16.1; 95% CI, 1.39–186.4; p = 0.026). **Conclusions:** In this retrospective analysis, early IO infusion timing was associated with significantly lower recurrence risk, particularly distant recurrence. While pCR rates were not statistically significant between early vs late IO, we observed a numerical difference favoring early IO. These findings may suggest that circadian timing of IO may influence long-term outcomes beyond pathologic response. Given the retrospective design and limited number of events, these results are hypothesis-generating and warrant prospective validation. Neoadjuvant chemotherapy combined with toripalimab for triple-negative breast cancer: A prospective, single-arm, multi-center study (NEOTORCH-BREAST02). First Author: Zhijun Dai, Department of Breast Surgery, College of Medicine, The First Affiliated Hospital, Zhejiang University, Hangzhou, Zhejiang, China

Background: Neoadjuvant de-escalation chemo-immunotherapy with abbreviated cycles remains unclear. We aimed to assess the efficacy and safety of toripalimab, a novel PD-1 antibody, combined with an abbreviated course of epirubicin–cyclophosphamide (2 cycles) followed by nab-paclitaxel (2 cycles), as a neoadjuvant regimen for early-stage TNBC patients. **Methods:** This phase II trial, conducted from 2024 to 2025, involved stage II–III TNBC. The neoadjuvant regimen included epirubicin, cyclophosphamide, and toripalimab for 2 cycles, followed by nab-paclitaxel and toripalimab for another 2 cycles. Patients achieving a pathological complete response (pCR) received up to 13 cycles of adjuvant toripalimab, while those with residual disease received additional chemotherapy and toripalimab. Whole-exome sequencing (WES) and circulating tumor DNA (ctDNA) monitoring were also performed. The primary endpoint was the total pCR (tpCR) rate (ypT0/is ypN0). Secondary endpoints included breast pCR (bpCR; ypT0/is), residual cancer burden (RCB 0−1), objective response rate (ORR), and event-free survival. This trial was registered with ClinicalTrials.gov (NCT06682195). **Results:** As of January 20, 2026, 48 patients were enrolled, and 40 underwent surgery (median age: 48 years; 87.5% stage II). WES analysis in 37 patients identified BRCA1 mutations in 12 (32.4%). Baseline ctDNA was positive in 32 of 34 (94.1%) patients, and 24 (75%) achieved ctDNA negativity after neoadjuvant therapy. Among 40 surgical patients, tpCR, bpCR, RCB 0-I, and ORR rates were 55%, 60%, 70, and 92.5%, respectively. Subgroup analyses showed tpCR rates of 25% for CPS <1, 58.3% for CPS ≥1, 72.7% for CPS ≥10, and 80% for CPS ≥20. For TILs <10, tpCR was 25%, increasing to 66.6% for TILs ≥10, 82.3% for TILs ≥30, and 85.7% for TILs ≥50. Among BRCA1 mutation carriers, 75% achieved tpCR, and 62.5% of patients with ctDNA negativity also achieved tpCR. Grade ≥3 AEs occurred in 6 (15%) patients, most commonly vomiting (7.5%) and leukopenia (7.5%). Hypothyroidism was the most frequent immune-related AE (17.5%, all grade 1–2). **Conclusions:** Preliminary findings indicate that this 4 cycles de-escalation neoadjuvant strategy is effective and safe for early-stage TNBC, warranting further investigation in randomized trials. Clinical trial information: NCT06682195. Research Sponsor: None.

Response endpoints for the entire cohort (N = 40).

Efficacy endpoint	N (%)	95% CI(%)
tpCR(ypT0/is, ypN0)	22(55.0)	38.5–70.4
bpCR(ypT0/is)	24(60.0)	43.3–75.0
Miller–Payne (MP) grades		
MP score 1	2 (5.0)	0.6-23.2
MP score 2	3 (7.5)	1.6-27.3
MP score 3	7 (17.5)	7.3-34.7
MP score 4	4 (10.0)	2.8-23.7
MP score 5	24 (60.0)	43.3.-75.0
Residual cancer burden (RCB) class		
RCB class 0–I	28(70.0)	53.3–83.4
RCB class II	6 (15.0)	5.7-31.9
RCB class III	6 (15.0)	5.7-31.9

Application of a neoadjuvant 21-gene breast recurrence score assay to redirect surgical and systemic treatment pathways in early breast cancer: A multicenter prospective study. First Author: Natasha Caminsky, University of Montreal, Montréal, QC, Canada

Background: The 21-gene Oncotype DX Breast Recurrence Score assay is well established for determining use of adjuvant chemotherapy in hormone receptor (HR)-positive, HER2-negative breast cancer patients. However, the role of the 21-gene assay in the neoadjuvant setting has yet to be established. We previously reported the impact of the 21-gene assay in the neoadjuvant setting in node-negative breast cancer patients, which led to a reduction in the recommendation of chemotherapy in about one-third of patients. Here, we report the impact of the assay on neoadjuvant treatment pathways including surgery, endocrine therapy, and chemotherapy, in addition to overall costs. **Methods:** We performed a multicentre, prospective observational trial of HR-positive, HER2-negative breast cancer patients with T2-T3 disease and clinically negative axillary lymph nodes. Physicians completed questionnaires prior to and after Recurrence Score (RS) results, indicating their treatment choice for neoadjuvant endocrine or chemotherapy, or upfront surgery. Data was also collected at 6 months after initiation of therapy, to verify treatment received. The primary and secondary objectives were to evaluate impact of RS results on physician's treatment decisions and on drug (anti-emetics and pre-medication), and nursing (counselling and infusion time) costs, respectively. **Results:** A total of 70 patients were enrolled in the study as part of five hospital centers of the McPeak Sirois Group in the province of Quebec from 2018-2021. Feasibility of the 21-gene assay from core biopsy samples was 98.6%. At 6-month follow-up, the 21-gene assay led to a change in treatment decision in 52.2% of patients, including de-escalation from neoadjuvant chemotherapy to either upfront surgery in 21.7%, or to neoadjuvant endocrine therapy in a further 21.7%. The use of upfront surgery changed from 10.0% at baseline to 33.3% at 6-month follow-up (p = 0.0004). Use of neoadjuvant endocrine therapy also changed from 12.9% to 29.0% (p = 0.02). Among patients treated with upfront surgery or neoadjuvant endocrine therapy, 52.2% and 55.0% of patients, respectively, had a RS$\geq$16. At baseline, for all patients, total chemotherapy-associated drug costs were $190,656 CAD, and nursing-associated costs were $96,918 CAD. RS-guided treatment recommendation reduced chemotherapy-associated drug costs by 32.3% and nursing resource utilization by 44.1%. **Conclusions:** The use of the 21-gene assay reclassified treatment pathways in 52.2% of patients, including shifting patients from neoadjuvant chemotherapy toward upfront surgery or neoadjuvant endocrine therapy, while reducing chemotherapy-related resource utilisation. These data support the use of the 21-gene assay as a clinical decision-making tool in the neoadjuvant setting. Additional information: Coauthor André Robidoux, MD, died in July 2020. Evaluation of a taxane mRNA-based profile in neoadjuvant therapy across I-SPY2 investigational arms. First Author: Jacob Niklassen, Aida Oncology, Copenhagen, Denmark

Background: Neoadjuvant chemotherapy is standard in early-stage breast cancer (eBC), enabling tumor downstaging and treatment tailoring. Taxanes are a core component of standard neoadjuvant regimens across breast cancer subtypes, and biomarkers of taxane response may inform treatment strategies. In I-SPY2, high-risk eBC patients (pts) were randomized to standard taxane-anthracycline-cyclophosphamide (T-AC) or investigational regimens (IRs). A 113-gene model has been validated in multiple cohorts and in the I-SPY2 T-AC arm. Here, we extend these analyses to nine I-SPY2 IRs, which all include a T-AC backbone. **Methods:** Agilent gene expression data from 987 high-risk eBC pre-treatment tumors (GSE194040) were analyzed from pts treated with T-AC $\pm$ nine IRs. Pts were scored on a scale from 0-100 and association of score (per 50-point increase) with pCR was assessed using logistic regression. For benchmarking, the raw score was Z-scaled, and OR was calculated per 1 standard deviation increase (OR/1SD) to enable comparison with published I-SPY2 biomarkers. **Results:** In a pooled multivariable logistic model including all treatment arms (N = 987), a 50-point increase in score was strongly associated with higher odds of pCR after adjusting for treatment arm, hormone receptor (HR) and HER2 (OR = 2.99, p = 7.93e-13). Allowing for treatment-specific score effects did not reveal statistically significant interactions. The score was benchmarked against 27 I-SPY2 qualifying biomarkers using OR/1SD increase. In the full cohort (N = 987), it ranked among biomarkers with the largest effect sizes for pCR. When analyses were stratified by treatment arm, the score was the top-ranked biomarker by effect size in the T-AC arm (N = 210) and trebananib arm (N = 134), while effect estimates in other arms were directionally consistent but not uniformly statistically significant. Furthermore, the score provided independent predictive information beyond I-SPY2 Response Predictive Subtypes (RPS). In multivariable models adjusting for RPS, the score remained significantly associated with pCR in the full cohort and the T-AC arm. As an illustrative example, using score quartiles defined in the full cohort, pCR rates among HR+/HER2− pts (N = 379) increased from 6.0% (8/134) in the lower quartile to 43.1% (28/65) in the upper quartile. Similarly, among TN pts (N = 363), pCR rates increased from 16.7% (5/30) in the lower quartile to 48.7% (77/158) in the upper quartile. **Conclusions:** A taxane-specific gene expression score was strongly associated with pCR across all taxane-containing I-SPY2 regimens and provided information beyond established response predictive subtypes. These findings suggest that taxane sensitivity contributes substantially to treatment response across I-SPY2 therapies and highlights the potential value of incorporating additional drug-specific biomarkers to further refine response prediction. Research Sponsor: None.

Efficacy and safety of neoadjuvant disitamab vedotin (DV) in combination with toripalimab (Tor) and concurrent/sequential chemotherapy (chemo) in patients with HR-negative, HER2-low breast cancer: A randomized multi-center phase 2 study. First Author: Zhi-Ming Shao, Fudan University Shanghai Cancer Center, Shanghai, China

Background: For patients (pts) with triple-negative early breast cancer (BC), recommended neoadjuvant regimens include chemo with or without immunotherapy, which achieve a modest rate of pathological complete response (pCR). Emerging data suggest that anti-HER2 antibody-drug conjugates (ADCs) have antitumor activity in HER2-low advanced BC. Notably, DV (anti-HER2 ADC) has shown encouraging efficacy both as monotherapy and in combination with Tor (PD-1 inhibitor) in pts with HER2-low advanced disease. We evaluated the efficacy and safety of neoadjuvant DV-containing regimens in pts with hormone receptor (HR)-negative HER2-low BC in a randomized phase 2 trial. Here, we report results from the pts receiving DV plus Tor combined with concurrent/sequential chemo. **Methods:** Eligible pts were aged $\geq$18 years with untreated histologically confirmed HR-negative and HER2-low (centrally confirmed as IHC 1+, or IHC 2+/ISH-) BC (T1cN1-2M0 or T2-3N0-2M0 as per AJCC 8th edition) who were planned to undergo curative-intent breast cancer surgery. Pts randomized to group A received DV (2.0 mg/kg Q2W) + Tor (3.0 mg/kg Q2W) + carboplatin (AUC 3 Q2W or AUC 1.5 QW) for 18 weeks. Pts randomized to group B received DV + Tor for 12 weeks followed by epirubicin (90 mg/m^2 Q3W) + cyclophosphamide (600 mg/m^2 Q3W) + Tor for additional 12 weeks. Stratification factors were PD-L1 status (positive or negative) and clinical staging (stage II or III). After neoadjuvant treatment, surgery was performed. Enrollment in group B was closed after 28 pts had been randomized to this group, while enrollment in group A continued. The primary endpoint was total pCR (tpCR, defined as ypT0/TisN0) rate; secondary endpoints included breast pCR (bpCR, defined as ypT0/Tis) rate, objective response rate (ORR), and safety. **Results:** 40 pts were enrolled in group A (median age: 46.0 years; clinical stage III: 37.5%; clinical N+: 82.5%; IHC 1+: 72.5%; PD-L1 CPS $<$ 10: 37.5%) and 28 in group B (54.0; 42.9%; 82.1%; 67.9%; 32.1%). The tpCR was achieved in 25 pts (62.5% [95% CI: 45.8-77.3]) in group A and 14 pts (50.0% [31.9-71.3]) in group B. The bpCR rate was 65.0% (95% CI: 48.3-79.4) and 53.6% (35.3-74.5) for groups A and B, respectively. The corresponding ORR was 92.5% (95% CI: 79.6-98.4) and 75.0% (55.1-89.3), respectively. Grade 3-4 treatment-related adverse events (TRAEs) occurred in 29 (72.5%) of pts in group A and 23 (82.1%) in group B. Serious TRAEs occurred in 6 (15.0%) and 7 (25.0%) of pts, respectively. Immune-related adverse events occurred in 3 (7.5%) of pts in group A and 7 (25.0%) in group B. No grade 5 TRAEs occurred. **Conclusions:** Both treatment regimens showed manageable safety profiles; DV + Tor + carboplatin showed numerically better efficacy in pts with previously untreated, HR-negative, HER2-low, early BC. Clinical trial information: NCT06227117. Research Sponsor: RemeGen Co., Ltd.

Efficacy and safety of a short-course (12-week) de-escalated neoadjuvant regimen (weekly paclitaxel/trastuzumab/pertuzumab) in early HER2-positive breast cancer: Interim analysis of a prospective study. First Author: Maxim Ruban, P. Hertsen Moscow Oncology Research Institute –Branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: Standard neoadjuvant regimens for HER2-positive early breast cancer (EBC), such as 6 cycles of TCHP, achieve high pathological complete response (pCR) rates but carry significant toxicity risks. De-escalation strategies aiming to reduce treatment intensity and duration without compromising efficacy are clinically relevant. We present the interim analysis of a prospective study evaluating a shortened (12-week), carboplatin-free and anthracycline-free regimen (THP). **Methods:** We enrolled patients (pts) with histologically confirmed HER2-positive (IHC 3+ or ISH+) EBC, clinical stages T0-1N1M0 or T2-3N0-1M0. Pts received a de-escalated regimen consisting of 12 weekly infusions of paclitaxel (80 mg/m²) combined with trastuzumab and pertuzumab administered every 3 weeks for 4 cycles (12 weeks total). The primary endpoint was pCR rate (ypT0/is ypN0). Secondary endpoints included safety and treatment adherence. This interim analysis reports data from the first 70 pts who completed surgery. **Results:** Median age was 50 years. The cohort included 69% stage IIA and 31% stage IIB pts; 57% were cN0. 60% had HR-positive and 40% had HR-negative disease. Treatment compliance was excellent: 100% of pts completed the full 12-week course. The overall pCR rate was 60.0% (42/70). Efficacy was strongly associated with hormonal status: the pCR rate reached 82.1% (23/28) in the HR-negative subgroup, compared to 45.2% (19/42) in the HR-positive subgroup. The safety profile was exceptionally favorable compared to historical TCHP data. Grade ≥3 neutropenia occurred in only 4% of pts. No cases of febrile neutropenia or symptomatic cardiotoxicity were observed. Grade ≥3 non-hematological toxicity (diarrhea/rash) was limited to 8%. Peripheral neuropathy was predominantly grade 1, with occasional grade 2 events; no grade ≥3 neuropathy occurred. **Conclusions:** The short-course (12-week) de-escalated THP regimen demonstrated high efficacy, particularly in HR-negative/HER2-positive pts (pCR 82.1%), comparable to longer, more toxic multi-agent regimens. With a 0% rate of febrile neutropenia and 100% completion rate, this regimen represents a promising "chemo-light" option for selected patients, potentially guiding future de-escalation strategies in personalized oncology. Research Sponsor: None.

Baseline characteristics and clinical outcomes (N=70).

Characteristic / Endpoint	N (%) or Median (Range)
Median Age, years	50 (29–75)
Node-positive disease (cN+)	30 (43%)
HR-negative / HER2-positive	28 (40%)
Completed full 12-week NACT	70 (100%)
Breast-conserving surgery	34 (49%)
Pathological Complete Response (Total)	42 (60.0%)
pCR in HR-negative subgroup	23/28 (82.1%)
pCR in HR-positive subgroup	19/42 (45.2%)
Grade 3-4 Neutropenia	3 (4%)
Febrile Neutropenia	0 (0%)

Neoadjuvant penpulimab combined with taxanes and carboplatin in triple-negative breast cancer: Updated efficacy and safety results from the phase II NeoTAPPL study. First Author: Guozhi Zhang, Department of Breast and Thyroid Surgery, Southwest Hospital, Army Medical University, Chongqing, China

Background: The KEYNOTE-522 and IMpassion031 trials established that adding immune checkpoint inhibitors to neoadjuvant chemotherapy significantly improves pathologic complete response (pCR) rates and survival outcomes in triple-negative breast cancer (TNBC). In our previously reported phase II NeoTAPPL trial, an anthracycline-free neoadjuvant regimen of penpulimab (anti-PD-1 antibody), carboplatin, and taxanes demonstrated promising efficacy and manageable safety. Here, we present updated efficacy and safety outcomes from the full trial cohort. **Methods:** In this open-label, multi-center phase II study, patients with untreated, histologically confirmed TNBC in stage II-III were enrolled. Patients received 6 cycles of neoadjuvant therapy with penpulimab (200 mg, d1, q3w) plus taxanes (docetaxel 75 mg/m2 or nab-paclitaxel 260 mg/m2, d1, q3w) and carboplatin (AUC=6, d1, q3w). Patients who either completed or discontinued the neoadjuvant treatment would undergo breast surgery. Adjuvant chemotherapy and immunotherapy were at the discretion of the treating physician, and radiation therapy was per standard of care. The primary endpoint was the rate of pCR based on the definition of ypT0/Tis ypN0. Secondary endpoints included residual cancer burden (RCB), event free survival (EFS), overall survival (OS), adverse events (AE), and immune response biomarkers. **Results:** 64 patients were enrolled, all of whom received neoadjuvant treatment and underwent surgery. The median age was 53 years (range, 32-73). At diagnosis, 54 patients (84.4%) had stage II disease. pCR was achieved in 41 of 64 patients (64.1%; 95% CI, 51.1%-75.7%), and 50 patients (78.1%; 95% CI, 66.0%-87.5%) achieved RCB 0-1. The objective response rate (ORR) and disease control rate (DCR) were 93.8% (95% CI, 84.8%-98.3%) and 98.4% (95% CI, 91.6%-100%), respectively. Subgroup analyses revealed pCR rates of 64.8% (35/54) in patients with stage II disease and 60.0% (6/10) in those with stage III disease. The pCR rate was 64.9% (24/37) in node-negative patients and 63.0% (17/27) in node-positive patients. Treatment-emergent adverse events (TEAEs) of any grade occurred in all 64 patients, with grade ≥3 TEAEs reported in 24 patients (37.5%). The most common grade ≥3 TEAEs were alopecia (20.3%), anemia (14.1%), neutropenia (10.9%), and leukopenia (10.9%). **Conclusions:** The NeoTAPPL trial demonstrates that an anthracycline-free neoadjuvant regimen is an effective and tolerable treatment strategy for patients with TNBC. The regimen achieved a high pCR rate, which remained consistent across key prognostic subgroups, including disease stage and nodal status. The safety profile was manageable, with no new safety signals identified. Clinical trial information: ChiCTR2300071925. Outcomes after recurrence on neoadjuvant chemo-immunotherapy (NCIT) in patients (pts) with high-risk early-stage triple-negative breast cancer (eTNBC). First Author: Chiara Corti, Dana-Farber Cancer Institute, Boston, MA

Background: NCIT improves survival in high-risk eTNBC; however, trial-based data show that most relapses after NCIT are early. Real-world data are lacking. **Methods:** This retrospective study included pts from the DFCI Multicenter TNBC registry with eTNBC or estrogen receptor (ER)-low (≤10%), HER2-negative breast cancer (BC) treated with NCIT who underwent surgery before 7/1/2025. Aims were to evaluate (1) patterns of relapse; (2) BC–specific event–free survival (BC-EFS) from the first NCIT dose to relapse, contralateral BC, or death; (3) first-line (1L) metastatic systemic treatment patterns, and (4) time to progression (TTP). **Results:** 220 pts were identified, with median age of 50.1 yrs (IQR: 40.5-60.8). Median follow-up (FU) was 32.7 months (mo) (IQR, 30.4–34.4). At last FU, 29 pts (13.2%) had relapsed (locoregional, n=2; distant, n=27). Among these, 86.2% had not experienced pathologic complete response. Among relapsed pts with PD-L1 assessment (n=16), 43.8% (n=7) had a Combined Positive Score (CPS) <10; 56.2% (n=9) had a CPS ≥10. BC-EFS is shown in the Table. 1L therapy consisted of antibody-drug conjugate (ADC) in 51.7% (n=15), Poly ADP-ribose Polymerase inhibitor (PARPi) in 13.8% (n=4), chemotherapy in 13.8% (n=4), ADC+PARPi in 3.4% (n=1), CIT in 3.4% (n=1), and HER2-directed in 3.4% (n=1); 10.3% (n=3) died before 1L therapy. Median (m)TTP in 1L (n=26) was 7.7 mo (95% CI, 6.0–13.0) and detailed in the Table. Among pts with disease-free interval (DFI) ≤6 mo (n=8), mTTP was 5.1 mos (2.7–NR), with TTP rates of 50.0% (25.0–100.0) at 6 mo and 16.7% (2.9–95.3) at 12 mo. In those with DFI 6–12 mo (n=9), mTTP was 9.7 mo (7.4–NR); TTP rates were 88.9% (70.6–100.0) at 6 mo and 25.4% (7.7–83.8) at 12 mo. For DFI >12 mo (n=9), mTTP was 8.6 mo (5.6–NR), with TTP rates of 71.4% (44.7–100.0) at 6 mo and 28.6% (8.9–92.2) at 12 mo. Among pts treated with 1L ADC (n=16), mTTP was 8.6 mo (7.4–NR); TTP rates were 77.9% (58.4–100.0) at 6 mo and 26.0% (9.9–68.3) at 12 mo. In non-ADC-treated pts (n=10), mTTP was 6.2 mo (3.78–NR), with TTP rates of 60.0% (36.2–99.5) at 6 mo and 20.0% (5.8–69.1) at 12 mo. Median overall survival (from diagnosis) among pts with relapse was 26.3 mo (95% CI, 25.0–NR). **Conclusions:** Relapse after NCIT was predominantly early with poor metastatic outcomes, underscoring an urgent need for new strategies in this population largely excluded from clinical trials. Predicting chemotherapy benefit in premenopausal women with intermediate genomic scores using deep learning. First Author: Arkadi Piven, Technion - Israel Institute of Technology, Haifa, Israel

Background: The TAILORx trial demonstrated that adjuvant chemotherapy can be safely omitted in postmenopausal women with node-negative HR+/HER2- breast cancer and a 21-gene Recurrence Score (RS) of 11–25. However, chemotherapy benefit could not be excluded for pre/peri-menopausal women with RS 16–25, creating a clinical dilemma that may lead to overtreatment. Using TAILORx data, we have shown that deep learning (DL) applied to hematoxylin and eosin (H&E) can accurately identify women with low or high RS (Shamai et al., Lancet Oncol, 2026). We hypothesized that DL applied to H&E could be used to predict chemotherapy benefit in pre/peri-menopausal women with RS 16–25, thereby facilitating precise treatment de-escalation. **Methods:** We trained a DL model using H&E slides of both post- and pre/peri-menopausal women from TAILORx, with low (RS<16) and high (RS>25) genomic scores (N=5811), to predict distant recurrence-free interval (DRFI), while excluding patients with RS 16–25 from the training process. The test cohort consisted of women from TAILORx with RS 16–25. Within TAILORx, this test group was originally randomized to either endocrine therapy alone or chemo-endocrine therapy, enabling a direct evaluation of the model's ability to predict chemotherapy benefit. For comparison, RSCLIN was also computed. **Results:** When testing on pre/peri-menopausal women with RS 16–25 (N=1234), the model classified 942 (76%) and 292 (24%) as low and high risk. For patients receiving no chemotherapy, the model demonstrated high prognostic performance for DRFI (C-index=0.75; 95% CI: 0.67–0.82), and strong risk stratification (HR=5.43; 95% CI: 2.87–10.29, p<0.001). In the low-risk group, no benefit from chemotherapy was observed (HR=1.07, 95% CI: 0.54–2.15, p=0.84). In the high-risk group, chemotherapy was associated with a significant improvement in DRFI (HR=3.57, 95% CI:1.54–8.30, p=0.003). A significant interaction between treatment and risk group was observed (p=0.024). The model outperformed RSCLIN (p-interaction=0.314). When testing on postmenopausal patients with RS 16–25 (N=2249), the model could not predict chemotherapy benefit (p-interaction=0.926). **Conclusions:** This digital pathology signature provides prognostic information for distant recurrence and predictive information for chemotherapy benefit in pre/peri-menopausal women with HR+/HER2-, node-negative early breast cancer with RS 16–25. These findings support the potential use of histopathology-based DL to guide chemotherapy de-escalation in this clinically challenging subgroup. The inability of the model to predict chemotherapy benefit in postmenopausal women suggests that the deep learning signature may be identifying tumors sensitive to chemotherapy-induced ovarian suppression, highlighting a subset who could benefit from OFS as an alternative to chemotherapy. EA1181: Accuracy of pre-surgery MRI to predict pathologic complete response after taxane, trastuzumab, and pertuzumab (THP) in HER2-positive breast cancer. First Author: Nadine M. Tung, Dana-Farber Cancer Institute, Boston, MA

Background: Accurate prediction of pathologic complete response (pCR) after preoperative therapy for HER2-positive (HER2+) breast cancer can help triage patients to immediate surgery vs additional preoperative therapy. Pre-surgery (i.e., after neoadjuvant therapy) imaging studies may help estimate the likelihood of pCR. In EA1181, patients (pts) with stage II-IIIA HER2+ breast cancer received four cycles of preoperative taxane, trastuzumab, and pertuzumab (THP×4). Pre-surgery imaging was required, though the specific imaging modality was not mandated. Here, we report the accuracy of pre-surgery breast MRI to predict pCR (ypT0/Tis, ypN0). **Methods:** Among 2,141 pts treated with THPx4, 1,378 had pre-surgery breast MRI and were representative of the overall cohort, although T3 tumors were more common (16% vs 9%). MRI reports were available for 1,351 pts; all reports were centrally reviewed and classified as radiologic complete response (rCR; no residual tumor enhancement and normalization of lymph nodes, if applicable) or radiologic residual disease (rRD). Reports with indeterminate radiologic response were independently reviewed by two study radiologists blinded to pathology outcomes. Among pts with rCR who had pathologic residual disease (pRD), we also assessed the extent of residual disease by residual cancer burden (RCB) score. Among pts with rRD who had a pCR, we determined the proportion who only had residual ductal carcinoma in situ (DCIS). **Results:** See Table. **Conclusions:** After neoadjuvant therapy, preoperative MRI accurately predicted pCR in 86% of patients with HER2+/ER− disease and may help identify patients who can proceed directly to surgery. MRI is insufficient to predict pCR for pts with HER2+/ER+ disease, as only 55% with complete response on MRI had a pCR at surgery. A pre-surgery MRI that indicated residual disease was accurate in 80% of pts with HER2+/ER+ disease, but in only 45% of pts with HER2+/ER- cancer. Accurately predicting residual disease after THPx4 allows for consideration of additional therapy that may increase the chance of pCR. Combining imaging like MRI with other biomarkers, such as tissue-based markers or circulating tumor DNA, may improve prediction of pCR and facilitate personalization of treatment decisions in HER2+ breast cancer. Research Sponsor: National Cancer Institute; Breast Cancer Research Foundation; Susan G. Komen.

All pts with pre-surgery MRI (n=1351)
pCR rate overall in this cohort = 47%

MRI result	pCR	Pathology	pRD
rCR	**70.6%** (341/483)		29.4%(142/483) *78% had RCB1*
rRD	34%(295/868) *21% of 295 had DCIS only*		**66.01%** (573/868)

ER- (n=589)*

Biological subtype discordance after neoadjuvant therapy in early breast cancer: Findings from a 1,500-patient cohort with residual disease. First Author: Katarzyna Pogoda, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Although biomarker reassessment is standard in recurrent breast cancer, its role in early breast cancer with residual disease (RD) after neoadjuvant therapy (NAT) remains not well established, despite potential implications for adjuvant treatment decisions in the post-NAT setting. **Methods:** We retrospectively analyzed patients with early breast cancer who underwent surgery after NAT and had RD between January 2019 and May 2025. Only patients with estrogen receptor (ER), progesterone receptor (PR), and HER2 status assessed on both pretreatment biopsy and matched surgical specimens were included. Biological subtype discordance was analyzed across luminal, HER2-positive, and triple-negative breast cancer (TNBC). Multivariable logistic regression was used to identify clinicopathological factors associated with subtype change. **Results:** Among 1,504 eligible patients with residual disease, biomarker discordance involving ER, PR, and/or HER2 was observed in 502 cases (33.4%). A change in biological subtype occurred in 221 patients (14.7%). Subtype discordance was most frequent in tumors initially classified as HER2-positive (39.3%), compared with TNBC (10.6%) and luminal disease (6.2%) ($p<0.001$). Accordingly, patients with HER2-positive breast cancer at diagnosis were significantly more likely to experience subtype discordance after NAT compared with luminal tumors (absolute difference 33.1%, $p<0.001$) and TNBC (absolute difference 28.7%, $p<0.001$), with a smaller but statistically significant difference also observed between TNBC and luminal disease (absolute difference 4.4%, p=0.023). HER2-positive and TNBC tumors predominantly shifted toward a luminal phenotype, whereas luminal tumors more commonly converted to HER2-positive or TNBC subtypes, indicating substantial post-treatment biological heterogeneity. On multivariable analysis, baseline biological subtype remained the strongest independent predictor of subtype change, with higher odds for HER2-positive (OR = 9.14, $p<0.001$) and TNBC tumors (OR = 1.71, p=0.029) compared with luminal disease. Lobular histology was associated with a significantly lower likelihood of subtype discordance (OR = 0.50, p=0.040), whereas type of NAT, tumor grade, and Ki-67 were not associated with subtype change. **Conclusions:** In this large cohort of patients with residual disease after NAT, approximately one in seven experienced a change in biological subtype, with the highest discordance observed in initially HER2-positive tumors. These findings support routine biomarker reassessment in early breast cancer with residual disease to better inform adjuvant treatment decisions and to account for post-treatment biological heterogeneity. Treatment patterns and oncologic outcomes in patients with triple-negative (TN) lobular breast cancer. First Author: Laura Burns Amin, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Triple-negative breast cancer (TNBC) with invasive lobular carcinoma (ILC) histology represents an exceedingly rare (<1% of breast cancers) and aggressive disease subtype with poorly described outcomes. In an effort to better understand treatment patterns and prognosis for these patients, we conducted an analysis using the National Cancer Database to assess treatments and outcomes in this high-risk, understudied population. **Methods:** We identified patients ≥18 years with stage I-III TNBC diagnosed between 2017-2022 who underwent mastectomy or lumpectomy with ILC or invasive ductal histology (IDC) (n=80,589). Of these patients, 69,940 were treated with chemo- or immunotherapy (CTx/IO). Subgroup analysis included patients treated with neoadjuvant chemotherapy (NACT) ± IO (n=47,822). Among this subgroup, trends in NACT±IO and pathologic complete response (pCR) rates by histology were assessed using the Cochran-Armitage test. Associations between histology and NACT use or pCR were evaluated with multivariable logistic regression. Impact of pCR on overall survival (OS) was examined via Kaplan-Meier estimates and multivariable Cox models with propensity score weighting and matching (1:1 by stage and NACT type). **Results:** Among 80,589 patients with TNBC (median age 58 years), 79,645 (98.8%) had IDC and 944 (1.2%) had ILC. Patients with ILC were older (66 vs 58 years) and less likely to receive CTx/IO compared to those with IDC (75.5% vs 86.9%). Among 69,940 patients treated with CTx/IO, those with ILC were older (median age 65 vs 56 years), had higher clinical tumor stage, and were less likely to receive NACT compared to those with IDC (61.9% vs 68.4%; $p<0.001$). Among 47,822 patients who received NACT ± IO, patients with ILC had significantly lower pCR rates (16.1% vs 40.2%; aOR=0.44, 95% CI 0.34-0.57). The addition of IO showed a trend toward improved pCR rates in ILC (aOR=1.69, 95%CI 0.95-3.01, p=0.07). In 29,330 matched patients, pCR was associated with improved 5-year OS (94% vs 78%, $p<0.001$). However, in 108 matched ILC patients, no survival difference was observed by pCR status (5-year OS: 66% with pCR vs 69% without pCR, p=0.54). In a multivariable Cox model with inverse probability weighting among patients who received NACT±IO, ILC was associated with increased mortality risk (aHR=1.34, 95%CI 1.05-1.70, p=0.02), after adjustment for pCR, IO, age, race, tumor size, and insurance status, among other factors. **Conclusions:** Patients with TN-ILC who received NACT had lower pCR rates and worse OS compared to those with TN-IDC. Although limited by small sample size, this is the largest analysis of its type in the current NACT and IO era. These data suggest that pCR in TN-ILC may lack the prognostic significance it has in TN-IDC. These findings highlight the need for larger studies and novel therapeutic approaches tailored to the distinct biology of this rare subtype. Early results of neoadjuvant therapy with pyrotinib, subcutaneous trastuzumab, and capecitabine for HER2-positive early breast cancer from a prospective, single-arm, multicenter trial. First Author: Lina Zhang, The Second Department of Breast Cancer, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Tianjin, China

Background: Neoadjuvant therapy has become a standard approach for HER2-positive early breast cancer, improving outcomes, pCR, and survival. Prior studies show pyrotinib combined with trastuzumab and chemo is effective and safe, but mainly via intravenous routes, impacting quality of life. This trial is the first to assess a fully oral regimen—pyrotinib, SC trastuzumab, and capecitabine—in low- to intermediate-risk patients, focusing on efficacy and safety. **Methods:** This single-arm, multicenter phase II trial (NCT06483386) will enroll 109 treatment-naïve adults with stage I-II, T1c-2N0-1 HER2-positive EBC (IHC 3+ or IHC 2+/FISH+). From May 2024 to June 2026, patients will receive 6 cycles of neoadjuvant pyrotinib (400mg daily), SC trastuzumab (600mg q3w), and capecitabine (1000mg/m² BID, days 1-14 followed by a 7-day break). The primary endpoint is pathological complete response (pCR) rate, as defined by RECIST 1.1. Secondary endpoints include event-free survival (EFS), objective response rate (ORR), breast-conserving rate (BCR) and safety. **Results:** A total of 47 patients were enrolled from May 2024 to December 2025, of whom 43 underwent surgery and 43 had pathologic assessment available. The median age was 51 years (range 33-65), and 97.9% had an ECOG PS of 0. The majority of patients had stage II disease (89.4%), with T2 tumors (91.5%); 57.4% were clinically node-positive. The pCR rate among pts with evaluable pathology was 48.8% (21/43), and ORR was over 90%. The BCR was 65.1% (25/48). In biomarker-defined subgroups, total pathological complete response (tpCR) was achieved in 53.6% (15/28) of ER negative, HER2 positive patients, and in 40.0% (6/15) of ER positive, HER2 positive patients. The most common AEs were diarrhea, nausea, anorexia, and gastrointestinal dysfunction. The incidence of grade 3 diarrhea is 19.1%, and all cases are controllable with medication, confirming good safety profile. **Conclusions:** The fully non-intravenous neoadjuvant regimen combining pyrotinib, SC trastuzumab, and capecitabine is an efficacious and safe regimen for patients with low- to intermediate-risk HER2-positive early breast cancer. This regimen offers a more convenient and less burdensome treatment for this patient population, potentially improving quality of life and treatment adherence. Clinical trial information: NCT06483386. Research Sponsor: None.

Health-related quality of life with low-dose pembrolizumab plus chemotherapy in early triple-negative breast cancer: Findings from the PLANeT trial. First Author: Adhip Arora, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Background: The PLANeT trial randomized stage II–III TNBC patients to neoadjuvant chemotherapy with or without low-dose pembrolizumab. Primary efficacy end point results were presented at ESMO Congress 2025. QoL was assessed at baseline, mid-treatment, and end-treatment using the EORTC QLQ-C30 across seven domains. Longitudinal changes were analyzed using mixed-effects models with LS-mean estimates and change from baseline at each timepoint. **Methods:** Stage II–III TNBC patients were randomized in a 1:1 ratio to receive standard NACT with or without pembrolizumab (50 mg Q6W ×3 cycles) prior to surgery. QoL was assessed at baseline, mid-NACT (after 4 cycles), and at the end of NACT (after 8 cycles) using the EORTC QLQ-C30 questionnaire. Seven key QoL domains were analyzed: global health status/QoL (GHS), physical, role, emotional, cognitive, social functioning, and pain. Longitudinal QoL changes were compared between arms using mixed-effects models (MMRM) adjusted for nodal status. Least-squares (LS) mean scores and changes from baseline were estimated for each timepoint. **Results:** Among 157 patients (median age 49), baseline QoL was high and comparable between arms. QoL declined during neoadjuvant therapy in both groups, with the greatest burden mid-treatment and partial recovery by cycle 8. LS-mean global QoL fell by 14 points in each arm, with no meaningful separation between treatments across any functioning domain. Pain increased in both groups, and financial difficulty peaked mid-treatment before improving by cycle 8. Overall, low-dose pembrolizumab did not compromise QoL compared with chemotherapy alone. **Conclusions:** Adding low-dose pembrolizumab to neoadjuvant chemotherapy in TNBC did not worsen patient quality of life. The trajectory of functioning and symptom scores was nearly identical to chemotherapy alone, indicating that incorporating reduced-dose immunotherapy does not add to the treatment burden from the patient's perspective. Clinical trial information: CTRI/2024/01/062088. Research Sponsor: Indian counsel of medical research; grant numbers Development; Research/Small/5411/2023-2024, EM/Dev/SG/170/1232/2023/JJC].

Least-squares mean (LS-mean) scores at cycle 8 and changes from baseline for all EORTC QLQ-C30 domains, comparing pembrolizumab + chemotherapy vs chemotherapy alone in the PLANeT trial.

Domain	Pembro + Chemo (C8 LS-mean)	Change	Chemo Alone (C8 LS-mean)	Change	Between-Arm Δ (Change)
Global QoL	39.61	−14.19	41.27	−13.61	−0.58
Physical Functioning	73.09	−19.92	74.49	−18.14	−1.78
Role Functioning	85.68	−10.90	85.65	−12.66	+1.76
Emotional Functioning	78.31	−11.11	77.00	−10.34	−0.77
Cognitive Functioning	88.03	−5.99	83.97	−8.44	+2.45
Social Functioning	83.33	−13.04	82.07	−12.87	−0.17
Pain	67.31	+20.73	52.11	+12.45	+8.28

Taxane and platinum combination as a predictor of pathologic complete response in I-SPY2 by gene expression breast cancer signatures. First Author: Jacob Niklassen, Aida Oncology, Copenhagen, Denmark

Background: Carboplatin is part of NCCN-preferred neoadjuvant chemotherapy (NAC) for stage II-III triple negative (TN) early-stage breast cancer (eBC) as addition to taxane-containing standard-of-care, and significantly improves pathologic complete response (pCR) rates in multiple trials. In hormone receptor (HR)+/HER2− disease, platinum addition has been explored in investigational settings but is not standard. In I-SPY2 (NCT01042379), high-risk eBC pts were randomized to standard taxane-anthracycline (T-AC) with or without investigational agents. One arm evaluated carboplatin plus the PARP inhibitor veliparib added to T-AC (VC arm; 32 HR+/HER2- and 39 TN pts, n = 71). Two gene signatures, a 205-gene Platin Drug Response Predictor (Platin-DRP) and a 113-gene taxane response predictor, have been validated for association with response to platinum agents and taxane-based regimens, respectively. This study evaluated their combined association with pCR in the I-SPY2 VC arm and their potential to inform platinum benefit in taxane-based NAC. **Methods:** Agilent gene expression data (GSE194040) from 987 high-risk eBC tumors were analyzed, focusing on 71 VC-arm pts and 179 HER2- T-AC pts. Samples were scored using each gene signature on a percentile scale (0–100). Associations between a 50-point increase in score and pCR were assessed using logistic regression with one-sided tests and 90% confidence interval (CI) lower bound (LB), unless otherwise specified. **Results:** The pCR rate in the VC arm was 38% (27/71), compared with 17.3% (31/179) in the control arm. In the VC arm, both the Platin-DRP (OR = 3.4, p = 0.016, 90% CI LB = 1.36) and the taxane predictor (OR = 3.88, p = 0.01, 90% CI LB = 1.54) were associated with pCR after adjustment for HR status and retained independent predictive value after adjustment for MammaPrint risk. The platinum and taxane scores were moderately correlated (r = 0.53). In a bivariable model, inclusion of the Platin-DRP trended toward improved fit beyond the taxane score alone (two-sided (2s) p = 0.082). Dichotomization at 50 showed highest pCR in double-high pts (55%, 16/29), intermediate rates in discordant pts (33%, 7/21), and lowest rates in double-low pts (19%, 4/21). Quartile stratification further separated outcomes, with 78% pCR (7/9) in the high-high quartile and 0% (0/8) in the low-low quartile.The taxane score showed no evidence of arm-specific effects (control vs VC; 2s p = 0.97), whereas the Platin-DRP showed directionally stronger associations in the VC arm (2s p = 0.12). **Conclusions:** Taxane and platinum gene expression signatures showed complementary associations with pCR in the I-SPY2 veliparib-carboplatin arm. Joint modeling and stratification identified subgroups with distinct responses, supporting the potential utility of combining drug-specific biomarkers to refine patient selection for platinum addition in taxane-based NAC. Research Sponsor: None.

Delayed serplulimab combined with nab-paclitaxel and epirubicin in high-risk, early HR+/HER2− breast cancer (HELEN-B 018): A multicenter, single-arm, phase 2 trial. First Author: Hao Dai, The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China

Background: Novel treatment options are needed to improve long-term outcome of high-risk early HR+/HER2− breast cancer. Evidence shows a programmed death 1 inhibitor combined with chemotherapy increases pCR rates in this subtype. We aimed to evaluate the efficacy and safety of serplulimab combined with nab-paclitaxel and epirubicin in high-risk, early HR+/HER2− breast cancer. **Methods:** This multicentre, single-arm, phase 2 trial was conducted in China at 6 hospitals. Patients were eligible if they were 18 years or older, with previously untreated early HR+/HER2- breast cancer, and Ki-67 greater than or equal to 20%, and had an Eastern Cooperative Oncology Group (ECOG) performance status of 0–1. Participants were allocated to intravenous nab-paclitaxel (260 mg/m^2) and intravenous epirubicin (75 mg/m^2) on the first day and intravenous serplulimab (4.5mg/kg) on the third day of the treatment cycle. 6 cycles of neoadjuvant treatment were administered. The primary outcome was pCR (defined as ypN0 or ypT0/is), assessed in the full analysis set, which included all patients who had started the trial treatment. We estimated that with enrollment of 109 participants, this trial would have 80% power to detect a true difference in the percentage of patients with a pCR of 10% at a one-sided alpha level of 0.025, with a dropout rate of 10%. This study is registered with ClinicalTrials.gov (NCT06394661). **Results:** Between Apr 28, 2024, and May 24, 2025, 136 patients were assessed for eligibility; 27 were ineligible and 109 participants were enrolled in this study, of whom 101 participants started trial treatment. Median age of the participants was 49 [range, 30 to 72] years at the time of enrolment, and 45 (44.6%) were PD-L1 positive (CPS ≥1). pCR was achieved in 23 patients (22.8%, 95%CI 15.3%-32.4%). PCR rate was numerically higher in patients with PD-L1 positive tumors (44.4%, 95%CI 30.0%-59.9%). During the neoadjuvant phase, 30 (29.7%) patients experienced grade 3 or higher treatment-related adverse events. The most common grade 3–4 adverse events were increased alanine aminotransferase (ALT; six [5.9%]), increased aspartate aminotransferase (AST; five [5.0%]), and diarrhea (four [4.0%]), There were no treatment-related deaths. **Conclusions:** Delayed serplulimab combined with nab-paclitaxel and epirubicin showed promising anti-tumour activity and manageable safety in patients with HR+/HER2− breast cancer; the pCR rate was higher in PD-L1 expression tumor. These findings support further evaluation of this regimen in randomized controlled trials. Clinical trial information: NCT06394661. Research Sponsor: None.

Impact of pembrolizumab infusion timing on outcomes in early-stage triple-negative breast cancer: A real-world exploratory analysis (Neo-Real). First Author: Natalia Nunes, Instituto Americas, Rio De Janeiro, Brazil

Background: Neoadjuvant pembrolizumab combined with chemotherapy is the standard of care for early-stage triple-negative breast cancer (TNBC) based on KEYNOTE-522, improving pathologic complete response (pCR) and event-free survival (EFS). Emerging data suggest that immunotherapy timing may influence oncologic outcomes; however, evidence in early-stage TNBC and in combination regimens is limited. We conducted an exploratory real-world analysis to evaluate the association between infusion timing and clinical outcomes. **Methods:** Neo-Real/GBECAM-0123 is a multicenter real-world cohort including patients with early-stage TNBC treated with neoadjuvant pembrolizumab-based chemotherapy in Brazil and Argentina. In this analysis, patients treated between 2019 and 2024 with available infusion timing data were included. Infusion timing was classified as Early (≤20% of pembrolizumab infusions initiated at or after 14:00) or Late (>20% initiated at or after 14:00). The primary endpoint was pCR (ypT0/Tis ypN0). Secondary endpoints included EFS, defined according to KEYNOTE-522 criteria. Sensitivity analyses using timing definitions were performed. **Results:** Among 419 patients with available infusion timing data (Early: n=265; Late: n=154); 385 underwent surgery and were evaluable for pCR. Baseline clinicopathologic characteristics were largely balanced between groups, although stage III disease was numerically more frequent in the Early group (30.9% vs 23.6%, p=0.134). Treatment features, including use of dose-dense chemotherapy and number of neoadjuvant pembrolizumab cycles (median 8 in both groups), were similar. pCR rates did not differ according to infusion timing (Early: 62.5% vs Late: 64.1%; p=0.827). Late infusion timing was associated with improved EFS, with a 2-year EFS of 90.7% versus 82.7% (p=0.013). In multivariable Cox regression adjusting for age, clinical stage, pathologic response, tumor grade, histology, and number of neoadjuvant pembrolizumab cycles, Late infusion timing remained associated with improved EFS (HR 0.34; 95% CI 0.15–0.80; p=0.013). Sensitivity and subgroup analyses, including evaluation of the timing of the first pembrolizumab infusion using an earlier cut-off (11:00), as well as analyses by histology, clinical stage, and pathologic response, yielded consistent results. **Conclusions:** In this exploratory real-world analysis of patients with early-stage TNBC treated with neoadjuvant pembrolizumab-based chemotherapy, infusion timing was not associated with pCR. However, later infusion timing was associated with improved EFS. These findings contrast with observations reported in other tumor types and underscore the need for further studies to clarify the impact of immune checkpoint inhibitor infusion timing on clinical outcomes in TNBC. Research Sponsor: None.

DCE-MRI for assessment of pathologic complete response after completion of neoadjuvant therapy in triple-negative breast cancer patients. First Author: Xiaofei Huo, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Triple-negative breast cancer (TNBC) is an aggressive molecular subtype that accounts for approximately 15%-20% of all breast cancer diagnoses. We aimed to investigate the utility of presurgical DCE breast MRI as a predictive marker for pathologic complete response (pCR) after neoadjuvant treatment (NAT) in TNBC patients and to compare the predictive value of early versus delayed enhancement for residual tumor detection. **Methods:** A total of 308 Stage I–III TNBC patients who underwent pre-operative DCE-MRI after completion of NAT followed by surgery were enrolled in an IRB-approved prospective clinical trial (NCT02276433). Tumor size was measured using three-dimensional measurements of the index lesion during both the early (1 min) and delayed (6 min) phases of DCE-MRI. Treatment response at surgery (pCR vs. non-pCR) and the pathologic size of residual disease were documented. Correlation between pCR and residual enhancement on DCE-MRI was assessed using McNamar's test. Spearman's rank correlation coefficient was used to assess concordance between the longest diameter on MRI and pathology. Differences between longest diameter on DCE-MRI and pathology were compared using the Wilcoxon signed-rank test. **Results:** Among the 308 TNBC patients, 47% (145/308) achieved pCR following treatment. Residual disease detection on the early phase of DCE-MRI demonstrated higher sensitivity for predicting pCR compared to the delayed phase (79% vs. 69%, $p < 0.001$); however, it had lower specificity (78% vs. 84%, p = 0.008). Absence of enhancement in both early and delayed phase DCE-MRI predicted pCR with positive predictive values (PPV) of 80% and 83%, respectively. Residual enhancement in both phases predicted non-pCR with negative predictive values (NPV) of 77% and 71%, respectively. Both early and delayed DCE-MRI phases demonstrated a similar moderate positive correlation with pathology (r = 0.64 vs. 0.62). There was no significant difference between the longest diameter measured on early phase DCE-MRI and pathology (p = 0.706), whereas a significant difference was observed for the delayed phase ($p < 0.001$), which over estimated residual disease. **Conclusions:** Presurgical DCE-MRI demonstrated strong performance in predicting pCR among TNBC patients following NAT. The early and delayed phases of DCE-MRI may each capture different aspects of tumor characteristics, potentially providing complementary information for prediction. Clinical trial information: NCT02276433. Research Sponsor: National Cancer Institute.

Development of a multivariable prognostic model for pathological response using anatomical and pathological variables in early triple-negative breast cancer treated with neoadjuvant chemo-immunotherapy: Initial results. First Author: Dana Narvaez, Alexander Fleming Institute, Ciudad De Buenos Aires, Argentina

Background: The combination of chemotherapy and immune checkpoint inhibitors is the standard of care for most patients with early triple negative breast cancer (eTNBC). Higher residual cancer burden (RCB) after receiving neoadjuvant chemo-immunotherapy (NCI) is associated with worse outcomes; however, reliable tools to predict pathological response remain limited. **Methods:** We conducted a multicenter prospective cohort study including patients with eTNBC treated with NCI. Anatomical and pathological variables were collected. Multivariable logistic regression was used to develop a prognostic model for pathological response. RCB 0–1 was the primary outcome. $p < 0.1$ was used for the selection of candidate parameters, and $p < 0.05$ for the final assessment of the multivariate model. ROC curves and the Hosmer-Lemmershow tests were applied to assess the model performance **Results:** A total of 109 patients with eTNBC with NCI from six centers in Argentina were included, with tumor samples centrally collected and reviewed for centralized pathological assessment. Regarding the immune microenvironment, qualitative tumor-infiltrating lymphocytes (TILs) were categorized according to the International Immuno-Oncology Biomarker Working Group classification as low (score 1) in 44.4% and intermediate-to-high (scores 2–3) in 55.6% of patients. Pathologic complete response (pCR) was achieved in 64.8% of patients. Histological grade (Grade 3 vs. 2: OR 3.2; 95% CI 0.95–11), TIL categories (TILs score 2: OR 3.4; 95% CI 0.84–14 and score 3: OR 6.3; 95% CI 1.1–37) and axillary node involvement (present vs. absent: OR 0.28; 95% CI 0.083–0.95) were selected for the final multivariate model. The final model showed good discrimination (AUC = 0.82) with adequate calibration, confirmed by a non-significant Hosmer–Lemeshow test ($\chi^2 = 3.28$, p = 0.35). **Conclusions:** The model enabled stratification of patients into distinct risk groups with significantly different probabilities of achieving RCB scores of 0 or 1. This approach may provide additional information for risk stratification and prognosis, improving our understanding of which patients are more likely to achieve pathological response. Further studies will assess the external validation of the model. Research Sponsor: Conquer Cancer, the ASCO Foundation.

Efficacy and safety of the pertuzumab biosimilar BCD-178 versus the originator pertuzumab in patients with HER2-positive locally advanced breast cancer: Results from the international, double-blind, randomized, phase III PREFER trial. First Author: Lyudmila Zhukova, Moscow Clinical Scientific Center Named After A.S. Loginov, Moscow, Russian Federation

Background: Pertuzumab, a HER2-targeting monoclonal antibody, significantly improves outcomes for patients with HER2-positive breast cancer (HER2+ BC) in different settings in combination with another HER2-agents with/without chemotherapy. BCD-178 is a biosimilar of the originator pertuzumab (OP). Preclinical and phase I clinical studies have demonstrated its equivalence to OP. The phase III PREFER trial compared the efficacy and safety of BCD-178 and OP as neoadjuvant and adjuvant therapy in HER2+ BC. **Methods:** The study hypothesized that neoadjuvant therapy containing BCD-178 would yield a pathological complete response (pCR) rate equivalent to that of therapy containing OP in women aged 18–75 years with stage II–III HER2+, hormone receptor-negative invasive BC and a primary tumor > 2 cm. Patients were randomized 1:1 to receive neoadjuvant therapy with either BCD-178 or OP, combined with trastuzumab and chemotherapy (TCHP regimen). The primary endpoint was the pCR rate (ypT0/is, ypN0) assessed by central independent review. Safety was monitored throughout, with adverse events (AEs) graded by CTCAE v5.0. Immunogenicity and pharmacokinetics were also evaluated (NCT05802225). **Results:** Of 398 randomized patients, 201 received BCD-178 and 197 received OP. The median age was 53 years; over one-third of patients in each group had stage IIIB/IIIC disease. pCR rates were 75.0% with BCD-178 and 72.2% with OP (risk ratio [RR] 2.7, 95% CI: -6.0 to 11.6). The 95% CI for the between-group difference in pCR rate fell within the predefined equivalence margins, confirming equivalent efficacy. The safety profiles were comparable. The most common AEs ($\geq$10%) were diarrhea and anemia. Immunogenicity was low and similar between groups: binding antibodies were detected in 1.6% (BCD-178) vs. 1.1% (OP) of patients, and neutralizing antibodies in 1.1% in both groups. The concentration-time profiles and pharmacokinetic profiles (Cmin, Ceoi) were also comparable. **Conclusions:** In patients with HER2+, hormone receptor-negative locally advanced breast cancer, the biosimilar BCD-178 demonstrated equivalent efficacy, safety, immunogenicity, and pharmacokinetics to the originator pertuzumab within a neoadjuvant TCHP regimen. Clinical trial information: NCT05802225. Research Sponsor: JSC BIOCAD.

Response to neoadjuvant chemotherapy in both the breast and lymph nodes in patients with inflammatory breast cancer. First Author: Megan McClanahan, Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Optimal outcomes in Inflammatory Breast Cancer (IBC) are achieved with trimodal therapy. We sought to evaluate how differences in response to neoadjuvant chemotherapy (NAC) in the breast and axilla impact locoregional recurrence-free, distant recurrence-free and overall survival in patients with IBC. **Methods:** A retrospective analysis was performed on patients with IBC enrolled in a prospective registry from 2007-2025. All patients underwent NAC followed by modified radical mastectomy. Comparisons between three pathologic response groups—(A) pCR, no residual disease in breast or lymph nodes, (B) complete response in breast but not axillary nodes, and (C) complete response in axillary nodes, but not breast—were performed using Kaplan-Meier and pairwise Cox proportional hazards models. **Results:** 545 patients were included; median age was 50 (IQR:41-58). pCR was identified in 150 (28%) patients, while 34 (6%) were in group B, and 55 (10%) were in group C. Of patients with pCR, 6 (4%) had locoregional recurrence (LRR), compared to 6 (17%) of patients in group B, 5 (9%) of patients in group C, and 79 (25%) in patients without pCR. There was decreased risk of LRR in patients with pCR compared to no pCR, or group B (HR:0.118 CI 0.05-0.27 $P<0.001$; HR:0.18 CI 0.06-0.55 P=0.017). A similar decreased risk of LRR was observed in patients with group C compared to no pCR (HR:0.297 CI 0.12-0.73 P=0.01). Of patients with pCR, 31 (20%) had distant recurrence, compared to 14 (41%) of patients in group B, 23 (41%) of patients in group C, and 183 (60%) in patients who did not have pCR. There was decreased risk of distant recurrence in patients with pCR compared to no pCR, or patients in group C (HR0.25 CI 0.17-0.37 $P<0.0001$; HR0.43 CI0.25-0.74 P=0.007). There was also a decreased risk of distant recurrence in patients with group C compared to no pCR (HR0.59 CI 0.38-0.91 P=0.027). Mean OS was longer in patients with pCR compared to partial response or no pCR (12.4 vs 7.95 years). The risk of death was lower in patients with pCR compared to partial or no pCR, as well as those with group C compared to no pCR. **Conclusions:** In patients with IBC, the lowest risk for recurrence was achieved with pCR. However, even with pCR, there was still a 20% chance of distant recurrence. Partial response through clearance of the lymph node disease provided some reduction in risk of recurrence compared to no pCR. Research Sponsor: None.

Preoperative combination radiotherapy (RT) and immune checkpoint inhibitor (ICI) in early-stage breast cancer: Influence of RT and ICI treatment sequencing (NCT04454528 post-hoc analysis). First Author: Julia C. Tchou, University of Pennsylvania, Philadelphia, PA

Background: The anti-tumor immune effects of combination radiotherapy (RT) and immune checkpoint inhibitors (ICI) are synergistic. Optimal treatment sequencing, i.e. RT before ICI vs. RT after ICI, remains unclear. Assuming clinical equipoise, we conducted a phase 1b/2 multi-arm adaptive window of opportunity study to evaluate feasibility and treatment response after preoperative (preop) RT before ICI vs. RT after ICI vs. ICI alone. **Methods:** Participants with early-stage breast cancer planning for upfront surgery were eligible to enroll to receive a single preop intravenous dose of pembrolizumab (pembro, an ICI), 200 mg, either alone (Arm 3) or in combination with RT (single fraction, 7 Gy) given before (Arm 1) or after pembro (Arm 2). Primary outcome measures included 1) feasibility of administration of combination RT + pembro in a 21-day preoperative window, and 2) tumor response as measured by % tumor size change post-treatment, including the proportion achieving $>$ 30% tumor reduction (TΔ30). Secondary endpoints included pathologic response as measured by residual cancer burden (RCB). Study sample size was powered for proportion of participants with TΔ30. Assuming 40% of treated participants would achieve TΔ30 compared to untreated participants, 15 subjects would yield 80% power at α = 0.05. Comparison of proportions was performed using Chi-squared test. **Results:** Between 1/6/2021 and 1/28/2025, 30 participants enrolled and completed the preop regimen assignment. Median follow-up was 634 days (IQR 256 –1120 days). All participants proceeded to surgery without delay. There were no adverse events (AEs) $\geq$ grade 3. There was one grade 2 immune-related AE (hypothyroidism). The proportion of participants achieving TΔ30 was 8 of 14 (57.1%), 6 of 11 (54.5%) and 0 of 5 (0%) in Arms 1, 2, and 3 respectively. For TNBC, TΔ30 rate was 6 of 7 (85.7%), 4 of 6 (66.7%) and 0 of 4 (0%) in Arms 1, 2, and 3 respectively. Compared with Arm 3, overall TΔ30 rate was significantly higher for those treated in Arm 1 or 2, p = 0.0307 and p = 0.0433; and for TNBC, p = 0.0088 and 0.0454, respectively. TΔ30 rate was similar in those treated with RT before (Arm 1) or RT after (Arm 2) ICI. The proportion of participants with major pathologic response (MPR) defined as RCB class 0 or 1 (RCB 0/1) treated in Arms 1, 2, and 3 were 7 of 14 (50%), 1 of 10 (10%), and 0 of 4 (0%) overall and 4 of 7 (57%), 0 of 5 (0%), and 0 of 3 (0%) for TNBC, respectively. The proportion of participants with RCB 0/1 in Arm 1 was numerically and statistically higher than Arm 2 overall and for TNBC, p = 0.0448 and p = 0.0479, respectively. **Conclusions:** RT given before ICI is more effective than RT given after ICI and resulted in MPR in 57% of participants with TNBC. This chemotherapy-free preop regimen may possibly facilitate chemotherapy omission decision in those achieving MPR in future studies. Clinical trial information: NCT04454528. Research Sponsor: None.

De-escalation of neoadjuvant chemotherapy for HER2-positive breast cancer: A systematic review and meta-analysis. First Author: Maria Clara Périco Perez, Faculdade de Ciências Médicas e da Saúde da Pontifícia Universidade Católica de São Paulo, Sorocaba, Brazil

Background: The addition of carboplatin to taxane-based dual HER2 blockade (TCbHP) is a standard neoadjuvant regimen for high-risk, HER2-positive breast cancer. However, this combination incurs significant hematological toxicities. Whether omitting carboplatin (THP) preserves efficacy while enabling de-escalation of toxicity remains a critical unanswered question. **Methods:** A comprehensive search of PubMed, Embase, Cochrane CENTRAL, and major oncology conference abstracts was conducted through June 15, 2025, for studies comparing THP with TCbHP. The primary endpoint was pathologic complete response (pCR). Secondary endpoints included grade $\geq$3 hematological toxicities. A non-inferiority margin for pCR was pre-specified at a risk ratio (RR) of 0.85. Data were pooled using a DerSimonian-Laird random-effects model. The study was registered on PROSPERO (CRD420251084035). **Results:** Seven studies (2 RCTs, 5 observational) comprising 2,061 patients (989 THP; 1,072 TCbHP) were included. The pooled pCR rate was 61.9% for THP versus 63.9% for TCbHP (RR 0.92, 95% CI 0.79–1.07). Statistical non-inferiority was not met, as the lower bound of the 95% CI crossed the pre-specified margin. The absolute pCR difference was a modest -2.0%. Although pCR showed substantial heterogeneity (I^2 = 69%), this was largely driven by study design differences (RCTs: RR 1.06 vs. observational: RR 0.80). In stark contrast, the THP regimen demonstrated a profound and remarkably consistent safety advantage, with an 82% reduction in grade $\geq$3 thrombocytopenia (RR 0.18, 95% CI 0.09–0.39), a 69% reduction in anemia (RR 0.31, 95% CI 0.17–0.57), and a 56% reduction in neutropenia (RR 0.44, 95% CI 0.33–0.58). Crucially, all three major hematological toxicity endpoints showed a complete absence of statistical heterogeneity (I^2 = 0% for all), indicating a robust and generalizable safety benefit. **Conclusions:** While the carboplatin-free THP regimen did not meet the strict criteria for statistical non-inferiority in pCR, the small absolute efficacy decrement is substantially offset by a large, clinically meaningful, and highly consistent reduction in severe hematological toxicities. These findings provide strong evidence to support THP as a reasonable and safer de-escalation strategy for selected patients with HER2-positive breast cancer, particularly those where toxicity is a major concern. Structural determinants compared with genetic ancestry and self-reported race in triple-negative breast cancer disparities: A multilevel analysis in an admixed population. First Author: Patrick De Cerqueira, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: Triple-negative breast cancer (TNBC) exhibits marked racial disparities in outcomes. However, the contributions of genetic ancestry, self-reported race, and structural determinants remain unclear, particularly in admixed populations. We aimed to disentangle the independent and combined impact of these factors in a Brazilian cohort. **Methods:** We retrospectively studied 156 women with TNBC treated with neoadjuvant chemotherapy at a tertiary center in São Paulo, Brazil (2007-2022). Genetic ancestry was estimated using ancestry-informative markers (AIMs) from an unpublished dataset. Self-reported race followed national census categories. Healthcare system type (public/private) served as a proxy for socioeconomic status. Primary outcomes were pathologic complete response (pCR), overall survival (OS), and disease-free survival (DFS). Multivariable models were adjusted for age, stage, Ki-67, and year of diagnosis. Statistical techniques included multiple imputation, propensity score matching, LASSO regression, and causal mediation analysis. **Results:** The cohort was highly admixed: 27% had $\geq$20% African ancestry (AA). Discordance was observed between genetic and social classifications: 48% of self-identified Black patients had $<$20% AA, while 24% of non-Black patients had $\geq$20% AA. Patients with $\geq$20% AA had higher tumor proliferation (median Ki-67 90% vs 80%) and higher pCR (50.0% vs 41.2%, p=0.42) but higher mortality (35.7% vs 25.4%). Black patients more often to use public healthcare (48.4% vs 15.9%, p$<$0.001) present with stage III disease (45.2% vs 35.6%), and receive less dose-dense chemotherapy (41.9% vs 76.1%, p$<$0.001). In adjusted analyses, neither AA nor self-reported race independently predicted pCR, OS, or DFS. Public healthcare use was the strongest independent predictor of worse OS (HR 2.45, 95%CI 1.12-5.36, p=0.025) and DFS (HR 2.18, 95%CI 1.08-4.40, p=0.03). Clinical stage (OR 0.66, p=0.022) and carboplatin use (OR 2.8, p=0.018) were the only independent predictors of pCR. Causal mediation analysis showed that 60.1% of the detrimental effect of public healthcare on pCR was mediated by advanced stage at presentation. **Conclusions:** In this pre-immunotherapy Brazilian cohort, TNBC outcome disparities are primarily driven by structural determinants related to healthcare access rather than genetic ancestry or self-reported race. While ancestry and race capture relevant biological and social dimensions, delayed diagnosis and suboptimal treatment delivery were the main mechanisms underlying outcomes. These findings underscore the need to address structural inequities and ensuring equitable access to timely, evidence-based cancer care in admixed populations. Future prospective studies integrating genetic ancestry, socioeconomic factors, and tumor immune profiling are needed. Predicting treatment effect on distant recurrence free survival from functional tumor volume change during neoadjuvant therapy: A Bayesian hierarchical model of I-SPY 2 MRI and survival data. First Author: Keli Siqueiros Santos-Parker, Department of Surgery, University of California, San Francisco, San Francisco, CA

Background: In neoadjuvant cancer trials, early endpoints that predict treatment effect on survival identify promising agents early and support accelerated regulatory approval. However, binary endpoints like pathologic complete response inadequately characterize the full distribution of residual disease in breast cancer, while promising continuous biomarkers like MRI derived functional tumor volume (FTV) are associated with survival outcomes but not widely collected. Using a Bayesian hierarchical model, long-term treatment effects on distant recurrence free survival (DRFS) can be predicted from continuous MRI-derived functional tumor volume (FTV) in the I-SPY 2 platform trial. **Methods:** I-SPY 2 treated 2117 patients from 2010-2022 (12 weeks of paclitaxel $\pm$ experimental agent followed by 4 cycles of doxorubicin + cyclophosphamide), and 1,859 underwent dynamic contrast-enhanced MRI at baseline and after 12 weeks of neoadjuvant therapy. MRI-derived functional tumor volume provided volumetric quantification of dynamic tissue enhancement. ΔFTV was defined as the ratio of 12-week to baseline FTV. A Bayesian joint hierarchical model (brms) fit treatment effects on ΔFTV and DRFS for each treatment regimen by HR/HER2 subtype, controlling for clinical nodal status, clinical T stage, grade, and calendar year. Arms with $<$ 8 subjects are excluded. Performance was assessed using cross-validation, predicting DRFS treatment effects in one held out fold at a time from the learned ΔFTV-DRFS association in the remaining data, then comparing predicted to actual DRFS treatment effect. Sensitivity analyses on priors will be presented. **Results:** Across 1753 patients and 45 treatment–subtype combinations, the estimated treatment effects on ΔFTV and DRFS were highly correlated (posterior correlation -0.91; 95% CrI -1.00 to -0.23). Predicted DRFS treatment effect from ΔFTV demonstrated strong concordance with actual DRFS treatment effects (Pearson r = 0.94 in TNBC; 0.97 HER2+; 0.80 HR+HER2-). The top 5 treatment-subtype regimens ranked by predicted and actual DRFS were identical. 20 regimens predicted to have $>$ 70% probability of DRFS benefit over subtype specific controls showed DRFS improvement, yielding 100% specificity and 69% sensitivity at this decision threshold. **Conclusions:** We demonstrate internally validated prediction of neoadjuvant treatment effect on DRFS from MRI-derived change in functional tumor volume in the I-SPY 2 trial of high-risk early breast cancer. This suggests continuous imaging measures capture a range of response to therapy while Bayesian approaches can be effective for predicting treatment effects. This encourages collecting MRI biomarkers in trials to facilitate validation as early endpoints supporting decisions in screening platform trials as well as regulatory accelerated approval. Systemic cytokine dynamics during neoadjuvant chemotherapy versus endocrine therapy and CDK4/6 inhibition in high-risk luminal breast cancer: Results from the GEICAM/2019-01-CARABELA trial. First Author: Angel Guerrero-Zotano, Instituto Valenciano de Oncología (IVO), Valencia, Spain; GEICAM Spanish Breast Cancer Group, Madrid, Spain

Background: Chemotherapy (CT) and CDK4/6 inhibitors modulate antitumor immunity primarily within the tumor microenvironment. Whether these effects are reflected systemically during neoadjuvant therapy, differ by treatment, or are associated with response remains unclear. **Methods:** CARABELA is a randomized neoadjuvant trial comparing letrozole (ET) + the CDK4/6 inhibitor abemaciclib vs standard CT in high-risk HR+/HER2− breast cancer. Plasma cytokines were measured at baseline (BL), 2 weeks (wks), 12 wks, and end of treatment (EOT) using multiplex proximity extension assay (Olink Target 96 Immuno-Oncology panel). Analyses included: (1) BL cytokine profiles by menopausal status, Oncotype DX Breast Recurrence Score test result (RS $\leq$25 vs $>$25), and Ki67 ($<$40% vs $\geq$40%); (2) longitudinal cytokine changes (BL to 2 and 12 wks, Δ) by residual cancer burden (RCB 0/I vs II/III), overall and by treatment; (3) EOT cytokine profiles by RCB. Group comparisons were adjusted by false discovery rate (FDR) threshold of 5% controlled by the q-value method. Multivariable logistic regression models were adjusted for menopausal status. Treatment–cytokine interactions were evaluated. **Results:** At BL, 40 cytokines were differentially expressed by menopausal status, with most showing higher levels in postmenopausal patients, including myeloid-associated inflammatory chemokines (CXCL9, CXCL10, MCP-1, MCP-4), angiogenic/matrix-remodeling factors (VEGFA, HGF, MMP7, MMP12), and TNF-related/immune regulatory molecules (TNFRSF12A, TNFRSF9, Galectin-9), indicating chronic systemic inflammation, without enrichment of cytotoxic immune effector programs. No BL cytokine differences met FDR threshold by RCB, RS or Ki67. Early cytokine changes (BL-2 wks) were not associated with RCB. In the ET + abemaciclib arm, no significant changes were observed between BL and 12 wks. In the CT arm, 25 cytokines had a significant increase (BL-12 wks) in patients with RCB II/III with respect to patients with RCB 0/I. These included inflammatory chemokines (IL8, CXCL1, CXCL5, CCL3, CCL4, MCP-3, MCP-4), angiogenic/growth factors (VEGFA, ANGPT1, EGF, PDGF-B), and stress-/TNF-related signaling molecules (CASP-8, TNFSF14, ADA). These cytokines were associated with RCB II/III in multivariable models adjusted for menopausal status. Cytokine–treatment interaction tests did not meet FDR threshold. **Conclusions:** Postmenopausal women display a distinct cytokine profile consistent with chronic systemic inflammation. Neoadjuvant CT induces pronounced systemic cytokine changes, while ET + CDK4/6 inhibition does not. Increased inflammatory and angiogenic cytokines during CT are associated with residual disease, supporting longitudinal systemic immune profiling as a marker of treatment resistance in high-risk luminal breast cancer. Clinical trial information: NCT04293393. Research Sponsor: GEICAM Spanish Breast Cancer Group.

Neoadjuvant mitomycin C plus carboplatin followed by paclitaxel vs. standard doxorubicin–cyclophosphamide followed by paclitaxel–carboplatin in BRCA1/2-associated breast cancer. First Author: Petr Krivorotko, "N.N. Petrov National Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation, Saint Petersburg, Russian Federation

Background: Triple-negative breast cancer (TNBC) associated with BRCA1/2 mutations is an aggressive disease subtype characterized by high sensitivity to chemotherapy. Accumulating evidence suggests the efficacy of mitomycin C, both as monotherapy and in combination with platinum agents, in BRCA1/2-driven tumors. This clinical study aimed to compare mitomycin C–based chemotherapy regimens with standard neoadjuvant chemotherapy in patients with BRCA1/2-associated TNBC. **Methods:** A total of 52 patients with BRCA1/2 pathogenic variants and TNBC stage T1-3N0-3M0 were enrolled. Patients were randomized to an experimental arm (n=26) receiving mitomycin C (10 mg/m²) plus carboplatin (AUC 5) (MCbP) for four cycles followed by weekly paclitaxel (80 mg/m²) for 12 cycles (MCbP-T), or to a control arm (n=26) receiving doxorubicin (60 mg/m²) and cyclophosphamide (600 mg/m²) (AC) for four cycles followed by weekly paclitaxel (80 mg/m²) plus carboplatin (AUC2) for 12 cycles (AC-TCbP). Treatment efficacy was assessed according to RECIST criteria and the rate of pathological complete response (pCR) after surgery. **Results:** After four cycles of MCbP/AC, clinical complete response (cCR) was observed more frequently in the MCbP group compared with the AC group (58% vs 7.7%; p = 0.0002). Upon completion of neoadjuvant chemotherapy, cCR remained significantly higher in the experimental arm (65.4% vs 42%; p = 0.037). The pCR rate was 81% versus 62% (p = 0.12), while Miller–Payne grade V pathological response was achieved in 77% and 65% of patients, respectively (p = 0.084). During a 26-month follow-up, adverse events occurred in 3.8% of patients in the experimental group and 12% in the control group; one death was reported only in the AC-TCbP arm (p = 0.6). Grade III leukopenia and neutropenia were more frequent in the AC-TCbP group (42% and 46%) compared with MCbP-T (4% and 8%; p = 0.002 and p = 0.003, respectively). Thrombocytopenia of any grade occurred more frequently in the MCbP-T group (36% vs 0%; p $<$ 0.001). Grade II alopecia was observed in all patients in the control group and in none of the MCbP-T patients (p $<$ 0.001). **Conclusions:** In BRCA1/2-associated TNBC, the MCbP-T regimen demonstrates efficacy comparable to standard anthracycline-based chemotherapy with platinum agents, while providing a more favorable safety profile and a lower incidence of adverse events. Integration of molecular subtyping and immune profiling to predict pathologic complete response in HER2+ breast cancer treated with neoadjuvant dual HER2 therapy. First Author: David B. Page, Providence Cancer Institute, Portland, OR

Background: Neoadjuvant outcomes are variable in human epidermal growth factor receptor 2-positive (HER2+) early breast cancer (EBC), highlighting the unmet need for predictive biomarkers. The BluePrint (BP) assay classifies tumors by molecular intrinsic subtype, whereas the ImPrint hormone receptor-positive (HR+) and ImPrint triple-negative genomic signatures predicted immune sensitivity in the ISPY2 trial. Because HER2+ EBCs are genomically heterogeneous, and because anti-HER2 has an immunologic mechanism of action, we hypothesized that BP and ImPrint could be used to predict outcomes (pathologic complete response, pCR) following neoadjuvant chemotherapy + anti-HER2 (trastuzumab + pertuzumab, HP). **Methods:** We evaluated n=252 HER2+ EBCs receiving neoadjuvant chemotherapy + HP in the prospective, observational FLEX study. Tumors were classified by BP subtype (HER2, Luminal A/B, or Basal) and ImPrint (+ or -). Fisher's exact test was used to compare pCR rates across BP/ImPrint results. Multivariable logistic regression was used to evaluate independent associations with pCR, adjusting for nodal status and tumor size. **Results:** 72% of HER2+ EBCs were HR+ and 28% were HR−. In HR+/HER2+ EBC, 52% were classified by BP as non-HER2 (Luminal A 6%, Luminal B 44%, Basal 2%), whereas in HR-/HER2+ EBC, 14% were classified genomically as non-HER2, all of which were Basal. In the HR+/HER2+ subgroup, pCR rates differed significantly by BP subtype and ImPrint, with the highest pCR observed in BP-HER2/ImPrint+ tumors (Table). Similar significant differences were observed in HR-/HER2+ EBC. In a multivariable model of the HR+/HER2+ subgroup, BP and ImPrint independently predicted pCR after controlling for node status and tumor size (BP-HER2 odds ratio/OR: 8.23 [95% CI: 3.47–21.44]; p$<$0.001; ImPrint+ OR: 4.48 [95% CI: 1.48–14.89]; p$<$0.05). **Conclusions:** An integrated genomic approach that combines BP and ImPrint maximizes prediction of pCR outcome in this dataset, particularly for the HR+/HER2+ subgroup. Further evaluation is warranted, as these data could be useful for guiding clinical decision-making, including selection of chemotherapy backbone and adjuvant therapy. Importantly, this approach may help identify patients who are overtreated or undertreated with current strategies, including those with exceptional treatment sensitivity who may be candidates for chemotherapy de-escalation. Clinical trial information: NCT03053193. Research Sponsor: Agendia, Inc.

pCR rates by genomic subtypes within HR+/HER2− EBC (Fisher's exact test).

Biomarker	Subtype*	N	pCR rate (%)	p-value
BluePrint	HER2	87	55	$<$ 0.001
	Luminal B	80	20	
ImPrint	Positive	30	60	0.006
	Negative	151	32	
BluePrint + ImPrint	HER2, ImPrint+	14	79	$<$ 0.001
	HER2, ImPrint-	73	51	
	Luminal B, ImPrint+	14	43	
	Luminal B, ImPrint-	66	15	

*Excluded Luminal A and Basal due to small N.

Event-free survival from the randomized phase 2 neoHIP trial evaluating neoadjuvant taxane, HER2-targeted therapy, +/- pembrolizumab in early-stage HER2-positive breast cancer. First Author: Heather L. McArthur, UT Southwestern Medical Center, Dallas, TX

Background: In early-stage HER2–positive breast cancer, achieving a pathological complete response (pCR) after neoadjuvant therapy is strongly associated with improved event-free survival (EFS); however, a substantial proportion patients (pts) fail to achieve pCR, requiring subsequent adjuvant systemic therapy and remaining at higher risk for recurrence. Pembrolizumab (pembro) is well-tolerated, invigorates anti-tumor immunity, and may enhance response of chemotherapy and/or anti-HER2. We previously reported the positive primary outcome of the randomized phase 2 neoHIP trial, showing an improvement in pCR with the addition of pembro to neoadjuvant paclitaxel, trastuzumab, and pertuzumab (4 cycles, THP–pembro, pCR: 67% v. THP: 48%, p=.026). With long-term follow-up now mature, we now report EFS outcomes. **Methods:** Pts aged $\geq$ 18 years with stage II–III HER2–positive breast cancer were randomized, stratified by hormone receptor status and nodal status, to receive neoadjuvant THP or THP–pembro. EFS was defined as the time from randomization to progression of disease precluding surgery, local or distant recurrence, or death from any cause. EFS was estimated using the Kaplan–Meier (KM) method and compared between arms using a two-sided stratified log-rank test. Data were analyzed with a cutoff date of January 23, 2026. **Results:** Among 116 pts (58 per arm) randomized to THP +/- pembro, median follow-up was 37 months (range, 33–43). The 36-month EFS rate was 95% (95% CI, 89–100) for THP and 100% (95% CI, 100–100) for THP-pembro, with a trend towards significance (p=.099). Three EFS events were observed, all occurring in the THP arm, with one death related to recurrence and n=2/3 events occurring in patients with non-pCR. **Conclusions:** THP + pembro was associated with 100% EFS after a median follow-up of 37 months, whereas recurrences were observed in the THP arm, consistent with historical EFS expectations for neoadjuvant chemotherapy + dual HER2-targeted therapy. Although not powered for EFS, these findings support definitive evaluation of THP +/- pembro in a phase III trial. Clinical trial information: NCT03747120. Neoadjuvant DAN-222 plus niraparib in high-risk HER2-negative breast cancer: Results from the I-SPY 2 adaptive platform trial. First Author: Kay T. Yeung, UC San Diego Moores Cancer Center, La Jolla, CA

Background: I-SPY 2 is a multicenter phase II adaptive platform trial evaluating novel agents for stage II-III high-risk breast cancer using response-predictive subtypes (RPS) and a sequential neoadjuvant treatment design of up to three blocks (A/B/C). Investigational regimens are given in Block A, followed by response-guided escalation to standard-of-care (SOC) therapy (tx) in subsequent blocks or early surgery for responders. Topoisomerase I (TOPO1) inhibition plus PARP inhibition may enhance DNA damage and tumor response. DAN-222 is a tumor-targeted polymeric camptothecin conjugate designed to improve the therapeutic index of TOPO1 inhibition. Based on favorable phase 1 safety and preliminary activity in metastatic breast cancer, DAN-222 plus niraparib was evaluated as Block A tx in HER2− disease. Notably, the neoadjuvant regimen used a higher dose of niraparib (200 mg daily) than the prior phase 1 metastatic study. **Methods:** Patients (pts) with HER2− breast cancer were randomized to DAN-222 plus niraparib for up to 12 weeks in Block A. Response was assessed by serial MRI and biopsy. Inadequate responders escalated early to SOC tx in Blocks B/C. Primary endpoint was pathologic complete response (pCR). Secondary endpoints included residual cancer burden, safety, early discontinuation, and treatment-strategy performance versus subtype-specific SOC tx controls. Given established PARPi sensitivity in *BRCA*mut disease, the key objective was to assess clinically meaningful activity of DAN-222 plus niraparib in *BRCA*wt pts. Accordingly, a prespecified Bayesian interim futility analysis focused on *BRCA*wt and tested the probability of the true pCR rate after Block A alone exceeded 15% after 50 pts. **Results:** Fifty pts enrolled from Sep to Dec 2024. In *BRCA*wt (n=47), estimated Block A pCR was 3%, with posterior probability of 0.02 that that true pCR exceeded 15%, meeting futility criteria and prompting arm closure. Across all blocks, pCR rate was 57% (8/14) for HR-HER2−; 11% (4/36) for HR+ HER2−, largely after SOC tx. 2/3 BRCA*mut* pts achieved pCR. Treatment strategies initiating with DAN-222 plus niraparib underperformed subtype-specific controls. 68% discontinued Block A early, mainly due to toxicity. Grade ≥3 cytopenias were common: neutropenia (n=25; 50%), anemia (24%), and thrombocytopenia (18%). Cystitis occurred in 36% (1 grade ≥3). **Conclusions:** Neoadjuvant DAN-222 plus niraparib showed insufficient activity and no treatment-strategy benefit in *BRCA*wt HER2− breast cancer, underscoring challenges for TOPO1–PARP inhibitor combinations. Although not supported for further development in this setting, these results highlight the strength of I-SPY 2 in rapidly enrolling patients and quickly distinguishing ineffective from promising therapeutic strategies to accelerate progress toward improved outcomes for patients with curable breast cancer. Clinical trial information: NCT01042379. Research Sponsor: None.

Maternal and neonatal complications associated with breast cancer systemic treatments: A VigiBase disproportionality analysis study. First Author: Rayan Kabirian, Department of Medical Oncology, Institut Curie, Saint Cloud, France

Background: Pregnancy-associated breast cancer (PrBC) presents unique diagnostic and therapeutic challenges, with rising incidence due to delayed childbearing. Understanding maternal-fetal safety of systemic anticancer therapies during pregnancy is critical for informed treatment planning. **Methods:** We performed a case/non-case disproportionality analysis using VigiBase, the WHO global pharmacovigilance database up to January 2024, to evaluate maternal and fetal/neonatal outcomes associated with breast cancer (BC) systemic treatments. We included reports involving pregnancy, antineoplastic treatment during pregnancy, and cancer. The exposure group consisted of reports mentioning a BC treatment at any time during pregnancy. The primary outcome was the reporting odds ratio (ROR) of maternal-fetal complications in the BC treatment group involving at least one of the four main BC treatments: doxorubicin, epirubicin, docetaxel, paclitaxel, compared to other anticancer treatments. Secondary analyses assessed outcomes with all BC treatments and trimester-specific risks of the four main treatments. **Results:** Of 3,310 pregnancy-related reports, 1,789 involved BC treatments. Median maternal age was 27.4 years (standard deviation SD 13.8) in the BC treatment group versus 29.3 years (SD 11.7) in the other anticancer treatment group. Adverse pregnancy or neonatal outcomes were reported in 998 (55.8%) BC treatment reports versus 470 (30.9%) in other anticancer treatments. Anthracyclines were associated with neonatal immunodeficiency (ROR=11.0, 95%CI 3.2–40), hematologic disorders (ROR=1.7, 95%CI 1.1–2.5), infections (ROR=2.3, 95%CI 1.4–3.8), and pregnancy complications including IUGR (ROR=2.1, 95%CI 1.7–2.7) and hypertension/pre-eclampsia (ROR=1.9, 95%CI 1.2–2.9). Epirubicin was linked to craniofacial (ROR=7.6, 95%CI 2.5–23.5) and genitourinary malformations (ROR=6.3, 95%CI 2.1–18.9). Taxanes were associated with IUGR (paclitaxel ROR=2.8; docetaxel ROR=2.8), with paclitaxel linked to sensory defects (ROR=5.2, 95%CI 2.2–12.3) and hyperbilirubinemia (ROR=4.1, 95%CI 2.0–8.4), and docetaxel to neonatal neurologic disorders (ROR=3.6, 95%CI 1.4–9.3). First-trimester exposure (n=26) markedly increased risks of congenital malformations, i.e. face (ROR=13, 95%CI 2-79) and musculoskeletal malformation (ROR=8, 95%CI 1.1-60). **Conclusions:** BC treatments during pregnancy are associated with increased specific maternal and neonatal risks, with distinct drug- and trimester-specific variations. These findings highlight the need for individualized treatment planning and targeted fetal surveillance. Research Sponsor: "Contrats ED: Programme blanc Institut Curie PSL" during this study.; "SHS INCa", and is part of a research project on young women funded by Monoprix*; France 2030 Grant for the Women's Cancers Institute, referenced ANR-23-IAHU-0006.

Optimal timing of endocrine therapy interruption for pregnancy in young women with hormone receptor–positive early breast cancer. First Author: Floriane Jochum, Department of Gynecologic and Breast Surgery, INSERM U1109, Strasbourg University Hospital, Strasbourg, France

Background: The POSITIVE trial showed that temporary interruption of adjuvant endocrine therapy (ET) after 18–30 months to attempt pregnancy did not increase short-term recurrence risk in young women with hormone receptor–positive (HR+) breast cancer (BC). However, whether this effect varies by baseline recurrence risk and the timing of interruption remains uncertain. **Methods:** Using the French National Health Data System (SNDS), we emulated two target trials among women aged ≤42 years with early-stage HR+ BC diagnosed between 2011 and 2020. Trial 1 emulated the POSITIVE design, comparing ET interruption at 18–30 months with uninterrupted ET for ≥24 months. Trial 2 compared nine ET-interruption windows (6-month intervals) with uninterrupted ET for ≥24 or ≥60 months. The primary endpoint was the 5-year risk of BC events. Analyses used a clone–censor–weight approach with marginal structural models. **Results:** In Trial 1 (n = 10,835), ET interruption at 18–30 months was associated with a 5-year BC event risk of 17.2%, compared with 16.0% for uninterrupted ET ≥24 months (risk difference, 1.2 percentage points; 95% CI, −0.7 to 3.1). Risk varied by baseline recurrence risk: interruption had minimal impact in low- or intermediate-risk women (risk difference, −0.6 percentage points; 95% CI, −2.7 to 1.6) but increased risk in high-risk women (risk difference, 5.8 percentage points; 95% CI, 1.8 to 10.0). In Trial 2 (n = 22,916), earlier ET interruption was associated with higher 5-year BC risk, which decreased with longer prior ET duration. Compared with uninterrupted ET ≥24 months, interruption at 6–12 months increased risk by 8.3 percentage points, whereas interruption at 24–30 months increased risk by 2.7 percentage points. Low- or intermediate-risk women showed comparable risk when interruption occurred at 24–30 months, whereas high-risk women required ≥36–42 months of ET to achieve similar safety. Among pregnancy-seeking women, 64% conceived, and 47% resumed ET. **Conclusions:** The oncologic impact of temporary ET interruption depends on baseline recurrence risk and prior ET duration. Interruption after 24 months appears safe for low- or intermediate-risk women, whereas high-risk patients may benefit from delaying interruption to at least 36 months. These findings support a risk-adapted approach to fertility counseling. Research Sponsor: None.

GLP-1 RA for primary prevention of post-mastectomy lymphedema in breast cancer patients: A multicenter real-world analysis. First Author: Dawit Hailemariam Yesho, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Post-mastectomy lymphedema (PML) remains a significant morbidity for breast cancer (BC) survivors, particularly following axillary lymph node dissection (ALND). Complications, including recurrent cellulitis, lymphangitis, and chronic pain, significantly impair quality of life. While weight optimization is a cornerstone of PML management, the specific role of Glucagon-like Peptide-1 Receptor Agonists for the primary prevention of PML is poorly characterized. Data is limited to single-center retrospective studies (1) and case reports. This is the first, large-scale, multi-center, real-world analysis to evaluate the efficacy of GLP-1 RA for the primary prevention of PML in BC patients. **Methods:** Utilizing the TriNetX Global Collaborative Network, a retrospective cohort study was conducted on a population of 150 million patients across 108 healthcare organizations (Jan 2000 – Jan 2025). We evaluated the impact of GLP-1 RAs on the incidence of PML in BC patients. Patients were stratified into two cohorts: those who underwent mastectomy and received GLP-1 RAs, and a control group of mastectomy patients without GLP-1 RA exposure. 1:1 Propensity Score Matching (PSM) was used to balance cohorts for demographics, BMI, comorbidities, concurrent medications, and laboratory values. Following a median 650-day follow-up, hazard ratios (HR) and 95% Confidence Intervals (CI) were calculated using Kaplan-Meier survival analysis and Cox proportional hazards models to assess PML risk. **Results:** After 1:1 propensity score matching, 61,630 patients were included (n = 30,815 per cohort). The GLP-1 RA cohort had a mean age of 62.1 ± 10.8 years and was mainly female (99.2%). Racial distribution was 71.0% White, 18.0% Black or African American, and 2.9% Asian. Standardized mean differences for all matched covariates were <0.1, indicating excellent balance within the cohort. Kaplan-Meier survival analysis demonstrated a 63% significant reduction in incident PML among GLP-1 RA users compared to the control group (HR 0.373; 95% CI, 0.324–0.429; $p < 0.0001$). The absolute incidence of PML was 0.88% (258/29,259) in the GLP-1 RA cohort vs 2.58% (779/30,237) in the control group, yielding an absolute risk reduction of 1.7% and a number needed to treat (NNT) of 59. **Conclusions:** In this large-scale, real-world analysis, GLP-1 RA use was associated with a profound 63% reduction in the risk of PML. These findings suggest that GLP-1 RAs may serve as a potent primary preventive role in BC survivorship, potentially through mechanisms beyond weight loss, including systemic anti-inflammatory effects and a disease-modifying role in the lymphatic microenvironment. With a NNT of 59, incorporating GLP-1 RAs into the supportive care of high-risk BC patients could significantly reduce the burden of chronic lymphedema. Prospective randomized controlled trials are warranted to validate these results. Research Sponsor: None.

Real-world treatment patterns and mortality associated with GLP1-RAs in breast cancer patients. First Author: Jasmine S. Sukumar, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: GLP1 Receptor Agonists (GLP1) are widely used for type 2 diabetes (DM2) and obesity in adults. However, data on modern utilization and associated health outcomes, including all-cause mortality, in breast cancer (BC) patients is limited. We evaluated these endpoints in a BC population from a large US national healthcare database. **Methods:** Using Truven MarketScan, a commercial insurance claims database which includes over 270 million patients, we extracted eligible invasive BC patients diagnosed between 2014 and 2023 who were ≥ 18 years old, completed definitive BC surgery (index date), received GLP1 for at least 3 continuous months, and had available mortality data. Overall survival (OS) was defined as the time from BC surgery to death from any cause; patients alive at the time of analysis or lost to follow-up were censored at last contact date. Propensity score matching (1:1 ratio) was used to match patients who received GLP1 with those who did not, based on clinical prognostic factors (age; sex; deyo comorbidity index (CI); receipt of immunotherapy, chemotherapy, adjuvant endocrine therapy; DM2; weight category; stroke; myocardial infarction (MI)/coronary artery disease (CAD); heart failure); Kaplan-Meier estimates and log-rank tests were used to compare OS between groups and hazard ratios (HR) were estimated using multivariable Cox proportional hazards models. **Results:** In 137,493 BC patients, 7,249 (5.3%) received a GLP1 and over half (n=4,019; 55.4%) initiated it after BC surgery. The median follow up time in GLP1 users was 32 (IQR 15-57) months. In GLP1 users the median age was 59 (IQR 53-64) years; 5,860 (80.8%) had DM2 and 1,825 (25.2%) had a CI ≥3; in those with weight data available (n=4,687), 4,609 (98.3%) were in the overweight or obese category. A total of 3,828 (52.8%) received GLP1 concurrent with anti-cancer systemic therapy (chemotherapy, immunotherapy, or adjuvant endocrine therapy). The median duration of GLP1 use was 2.1 (IQR 0.8-6.1) years. GLP1 use increased over time (3.2% in 2014, 5.2% in 2018, 7.2% in 2023). Semaglutide was the most common agent prescribed across all years (35.8%) and exhibited the greatest annual increase in use after 2018. In the propensity score matched cohort, OS was significantly higher in GLP1 users vs non-users (n=7,248 per group): 5 year OS 95.8% GLP1 vs. 89.5% non-users (adjusted HR 0.41, 95% CI: 0.34-0.49, p<0.001). **Conclusions:** We describe one of the largest observational studies on real-world GLP1 prescription patterns and associated mortality in a BC cohort. Use of these agents is increasing over time in BC patients. Our research supports other emerging epidemiologic data suggesting a potential all-cause mortality benefit with these incretin mimetics in this population. Prospective studies are warranted to clarify the biological mechanisms underlying this association, including metabolic health implications and effects on BC tumor biology. Research Sponsor: None.

Real-world cumulative exposure of various endocrine-disrupting chemicals and association with breast cancer risk via common carcinogenic pathway. First Author: Lijuan Tang, Department of Breast Surgery, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China

Background: Convergent evidence suggests carcinogenicity of endocrine disrupting chemicals (EDCs). But there is a lack of large-scale epidemiological evidence concerning real-world EDCs mixture exposure and breast cancer (BC). A dataset of emerging knowledge of toxic pathways provides a valuable toolkit to infer the carcinogenicity of chemicals, but current studies of this thus filed are rare. We test whether real-world EDCs exposure, independently or in mixture, increases BC risk in the population, through carcinogenic toxic pathways. **Methods:** A total of 234,273 women from the UK Biobank cohort were followed for a median of 13.85 years. The annual monitoring record from UK Water Quality Sampling Harmonised was used to estimate the exposure to 13 EDCs (e.g., lead and chlorpyrifos-methyl) for each woman by Kriging interpolation model. The association between EDCs and breast cancer was analyzed by Cox proportional hazard model (for single EDC) and weighted quantile sum (WQS) regression (for mixture). The EDCs were also added to the modified Gail model to test their additional contribution. Twenty-seven Olink proteins were selected via EDC-BC toxic pathway dataset and BC genetic propensity score model to examine their correlation with EDCs. Interaction between EDCs and these proteins and SNPs within their sequence were analyzed by multiplicative model. **Results:** During the follow-up period, 9,282 women developed BC, 984 of whom died. All the 13 EDCs showed association with increased BC risk. Each unit increase of the 13-EDC mixture was associated with 2.15 fold (95% CI, 2.01-2.31) of BC risk and 4.18 fold of BC-related mortality (95% CI, 3.39-5.17), and 34.38 % of total morbidity and 59.6% of BC-related mortality in the population were attributable to EDC mixture. The risk of hormone receptor-positive BC was higher than that of hormone receptor-negative BC (HR: 2.87 vs HR: 2.03, p = 0.002). The EDCs provided 2.1 % improvement to the modified Gail model of BC prediction. For the 27 Olink proteins referring to BC toxic pathway and genetic propensity score, 26 (96.3%) correlated with at least one EDC (average number ≥8), among which NACC1 protein mediated up to 98.8% (chlorpyrifos-methyl) of the individual EDC's effect on BC. The EDC mixture showed interaction with multiple proteins, including NACC1 and estrogen receptor 1, on BC-related mortality. **Conclusions:** Various EDCs in the real world may increase BC morbidity and mortality via common carcinogenic pathways. Future policies of novel EDC emission and safety evaluations must consider the cumulative EDC stressor in the environment because they may act as a whole. Impact of fertility concerns on endocrine therapy. First Author: Kathryn Jean Ruddy, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: Adolescent and young adult (AYA) women with breast cancer who have not completed their desired childbearing pre-diagnosis may be more likely to decline adjuvant endocrine therapy (ET) and/or to temporarily or permanently stop ET to pursue pregnancy. Fertility counseling and use of fertility preservation strategies (e.g., oocyte/embryo cryopreservation) might impact these decisions. **Methods:** In the Valuing Opinions and Insights from Cancer Experiences (VOICE) Study, we investigated whether use of fertility preservation strategies were associated with ET initiation and early discontinuation amongst AYAs with fertility concerns. Eligible females were diagnosed with stage 1–3 estrogen-receptor positive breast cancer at age 15-39 during 2013-2022 and responded to a survey in 2023-2024. Those who reported that they had not completed their desired family size or had been unsure about having completed their desired family size at the time of their cancer diagnosis were categorized as having had fertility concerns. ET initiation was defined as 2+ ET prescription fills within 18 months after diagnosis. Among ET initiators, we assessed early discontinuation (defined as lack of ET prescription fill over any 180 day period until 5 years after their first ET fill date). Due to inadequate power, we did not model the relationship between oocyte/embryo cryopreservation and ET initiation. However, we did have power to assess the association between oocyte/embryo cryopreservation and ET discontinuation using multivariable Cox regression to calculate Hazard Ratios (HR) and 95% Confidence Intervals (CI). HRs for discontinuation were adjusted for age at diagnosis, stage, study site, diagnosis year, income, and children before diagnosis (yes/no). **Results:** Among 518 AYA breast cancer survivors, 56% (N = 290) had fertility concerns at diagnosis. Of these 290, 41% had 1+ child before diagnosis, 90% received fertility counseling, 27% froze eggs or embryos, and 10% had 1+ child after diagnosis. The majority (89%) initiated ET. Among the 32 who did not initiate ET, 7 (22%) reported that fertility concerns impacted that decision. Oocyte/embryo cryopreservation was used by 26% of ET initiators and 34% of ET non-initiators. Among the 258 ET initiators, 89 (35%) discontinued ET early. Compared to those who did not use fertility preservation strategies, patients who froze oocytes/embryos were more likely to discontinue ET (HR 1.89; 95% CI 1.18–3.05). Among those who discontinued ET, 19% had 1+ child after diagnosis (compared to 2% among those who did not discontinue ET). **Conclusions:** This study confirmed prior studies showing that many AYAs with breast cancer have fertility concerns, and these concerns may impact decisions about ET. In our analysis, those who cryopreserved oocytes/embryos were more likely to discontinue ET early, and a higher proportion who discontinued ET had 1+ live birth after breast cancer. Long-term safety outcomes of pregnancy among young breast cancer survivors: Results from a prospective, multicenter cohort study. First Author: Kimia Sorouri, Dana-Farber Cancer Institute, Boston, MA

Background: Prospective data on the risk of breast cancer (BC) recurrence among young BC survivors who have a subsequent pregnancy are limited. We sought to evaluate the long-term impact of pregnancy and live birth on BC outcomes in the Young Women's Breast Cancer Study (NCT01468246), a prospective multicenter study of women aged ≤40 years at BC diagnosis. **Methods:** Women with stage 0-III BC without prior hysterectomy were included. The primary endpoint was breast cancer-free interval (BCFI) between patients with and without a (a) pregnancy and (b) live birth after BC. Secondary endpoints were distant recurrence-free interval (DRFI) and overall survival (OS). A time-varying Cox proportional hazards model was performed by estrogen receptor (ER) status, controlling for age at diagnosis, tumor stage, HER2 status, tumor grade, parity at diagnosis, and germline pathogenic variant status. **Results:** Among 1,016 BC survivors at a median follow-up of 12 (range, 0.5-18.5) years, 198 reported ≥1 pregnancy and 165 reported ≥1 live birth post-diagnosis. Among survivors who reported a post-diagnosis pregnancy, median age at diagnosis was 32 (range, 17-40) years; most had stage I (35%) or II (40%) BC, with 72% hormone receptor (HR)-positive and 25% HER2+; 42% were nulligravid and 60% were nulliparous at diagnosis. Among BC survivors who did not become pregnant post-diagnosis, median age at diagnosis was 37 (range, 21-40) years; most had stage I (35%) or II (43%) BC, with 75% HR-positive and 28% HER2+; 25% were nulligravid and 29% were nulliparous at diagnosis. Among BC survivors with ER-positive tumors (n = 737), pregnancy after BC was not associated with a difference in BCFI (adjusted hazard ratio [HR] 0.60, 95% CI 0.31-1.16, *P*= 0.130), DRFI (HR 0.73, 95% CI 0.35-1.55, *P*= 0.416), or OS (HR 0.58, 95% CI 0.24-1.40, *P*= 0.227). Similarly, live birth after BC did not impact BCFI (HR 0.83, 95% CI 0.45-1.55, *P*= 0.560), DRFI (HR 1.04, 95% CI 0.52-2.06, *P*= 0.923), or OS (HR 0.77, 95% CI 0.34-1.76, *P*= 0.541). Outcomes among BC survivors with ER-negative tumors (n = 278) were also not affected by post-diagnosis pregnancy (BCFI [HR 1.48, 95% CI 0.70-3.14, *P*= 0.304], DRFI [HR 1.59, 95% CI 0.68-3.75, *P*= 0.287], OS [HR 0.99, 95% CI 0.39-2.49, *P*= 0.975]) or live birth (BCFI [HR 1.02, 95% CI 0.41-2.53, *P*= 0.974], DRFI [HR 0.80, 95% CI 0.24-2.69, *P*= 0.722], OS [HR 0.39, 95% CI 0.09-1.69, *P*= 0.208]). **Conclusions:** In this multicenter, prospective study with 12 years of median follow-up, pregnancy and live birth after BC did not impact BC events or overall survival, irrespective of ER status. These long-term data from a modern cohort provide reassurance for young BC patients interested in future fertility. Clinical trial information: NCT01468246. Research Sponsor: None.

Impact of an artificial intelligence–based management model on psychological and behavioral outcomes in breast cancer patients undergoing home CDK4/6 inhibitor therapy: A multicenter randomized controlled trial. First Author: Li Zhang, Department of Breast Internal Medical, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Patients receiving CDK4/6 inhibitors (CDK4/6i) often face significant psychological and physical challenges. This study evaluated the multi-dimensional impact of an AI-based management model (Group A), a customized active follow-up model (Group B), and conventional care (Group C) on the psychological status, quality of life (QoL), and biological indicators of patients with HR+/HER2- breast cancer and their primary caregivers. **Methods:** In this randomized controlled trial (2024–2025), 140 patient-caregiver dyads were enrolled and randomized into Group A (n=47), Group B (n=45), or Group C (n=48). Longitudinal assessments were conducted using the Self-Rating Anxiety/Depression Scales (SAS/SDS), EORTC QLQ-C30, and PRO-CTCAE. Statistical analyses included mixed-design ANOVA for longitudinal changes, multiple correspondence analysis (MCA) for caregiver coping patterns, and Pearson correlation for psychological and serological indicators. **Results:** Baseline characteristics were balanced across groups ($P > 0.05$). Mixed-design ANOVA revealed significant time-by-group interaction effects for anxiety ($F=5.961$, $P < 0.001$) and depression ($F=4.931$, $P < 0.001$). During follow-up, Groups A and B showed significantly better psychological stability and depression relief compared to Group C; Group C's psychological status deteriorated over treatment cycles, peaking at T3 (16 weeks), while Groups A and B remained stable or improved ($P < 0.001$). Regarding QoL, Groups A and B significantly outperformed Group C in cognitive, emotional, social functioning, and global health ($P < 0.05$), with Group A showing superior cognitive function scores. MCA identified a strong clustering between the AI-based model and "positive coping strategies" among caregivers, whereas Group C was associated with "severe psychological stress". Pearson analysis showed SAS/SDS scores positively correlated with ALT ($r=0.178$, $P < 0.05$) and glucose ($r=0.221$, $P < 0.05$). Furthermore, Group A achieved a higher capture rate of adverse events via AI monitoring, effectively mitigating high-grade toxicity risks. **Conclusions:** AI-based management and customized follow-up significantly improve psychological outcomes and QoL in breast cancer patients on CDK4/6i. The correlation between psychological stress and physiological markers (ALT, Glucose) highlights the necessity of a "bio-psycho-social" approach in oncology management. These findings support integrating AI models into precision survivorship care. Research Sponsor: None.

Temporal trends in adherence to adjuvant endocrine therapy across age groups in hormone receptor–positive breast cancer. First Author: Michael M. Caplan, Herbert Irving Comprehensive Cancer Center, Columbia University Irving Medical Center, New York, NY

Background: Adjuvant endocrine therapy (ET) reduces recurrence and mortality in hormone receptor–positive breast cancer, yet adherence remains suboptimal. Adherence varies by age, with younger patients at higher risk for non-adherence. Whether increased awareness has improved adherence over time is unclear. We evaluated temporal trends in ET adherence. **Methods:** We conducted a retrospective cohort study using the MarketScan claims database. Eligible patients were 18–100 years old with non-metastatic breast cancer (2009–2022), treated with surgery within 6 months of diagnosis, and began adjuvant ET (aromatase inhibitor [AI] or tamoxifen) within 1 year of diagnosis. The analysis included patients insured 1 year prior to and 1 year following ET initiation. ET was assessed using proportion of days covered (PDC) and defined as adherent (PDC $\geq$0.80) vs non-adherent for the year after ET initiation. Trends in adherence were evaluated using the Cochran–Armitage trend test and logistic regression with an age–calendar year interaction. Age was categorized as $<$50 vs $\geq$50 years. Multivariable logistic regression was used to identify factors associated with ET adherence, reported as adjusted odds ratios (ORs). **Results:** Among 88,994 patients receiving ET (57,002 AI, 31,992 tamoxifen) from 2010–2022, the average adherence rate was 77.7% (79.3% AI, 74.9% tamoxifen). Adherence was lower in patients $<$50 vs $\geq$50 years (74.1% vs 78.8%; OR 0.85, 95% CI 0.81–0.89). In patients $<$50 on an AI, adherence increased over time from 66.6% in 2010 to 76.8% in 2022 (OR per year 1.07, 95% CI 1.05–1.09, $p < 0.001$), whereas no increase in adherence over time was seen in young patients on tamoxifen or in any patients aged $\geq$50 years. In a multivariable analysis of the entire cohort (Table), younger age and polypharmacy ($>$10 concurrent medications) were associated with lower odds of adherence, while receipt of 90-day prescription supplies, chemotherapy (neoadjuvant/adjuvant), and CDK4/6 inhibitors were associated with higher odds of adherence. **Conclusions:** Young women remain at high risk for ET non-adherence. While tamoxifen adherence did not improve over time, AI adherence increased over time in younger patients. This likely reflects heightened awareness, better supportive care, and clinician–patient discussions emphasizing AI adherence in young, high-risk populations. In contrast, despite similar increases in awareness, AI adherence has not improved in postmenopausal patients. These results highlight a persistent gap in ET adherence and the need for targeted interventions across age groups. Research Sponsor: None.

Factors associated with adherence to adjuvant endocrine therapy.

Covariate	Adjusted OR	95% CI
Age <50 vs ≥50 years	0.85	0.81–0.89
Polypharmacy	0.80	0.78–0.84
90-day prescription supply	2.80	2.71–2.89
Neoadjuvant chemotherapy	1.30	1.19–1.43
Adjuvant chemotherapy	1.29	1.23–1.34
CDK4/6 inhibitor use	1.55	1.15–2.08

Patient-reported outcomes from the adjuvant ado-trastuzumab emtansine (T-DM1) for older patients with HER2+ breast cancer (ATOP) trial. First Author: Kathryn Jean Ruddy, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: Prospective data on efficacy, quality of life, and treatment-related toxicities in older adults with breast cancer are limited. The ATOP trial (NCT03587740) evaluated T-DM1 in older adults and demonstrated favorable 5-year invasive disease-free survival. Here, we report patient-reported adverse events (AEs) and health-related quality of life (HRQOL) findings from ATOP. **Methods:** ATOP was a single-arm, phase II, multicenter study of adjuvant T-DM1 for those aged 60 with stage I-III HER2+ breast cancer. Protocol therapy included postoperative administration of T-DM1 (3.6 mg/kg) every 21 days for one year (17 cycles). PRO-CTCAE (assessing specific symptoms) and EQ-5D (a measure of HRQOL) surveys were administered electronically or on paper at baseline (pre-treatment), on Day 1 of each treatment cycle, and at a single 6–12-month post-treatment time point. Participants who responded to the baseline and at least one follow-up survey were included in the PRO analysis. EQ-5D changes from baseline were assessed using general linear mixed models. Summary statistics were used to assess PRO-CTCAE scores to evaluate which symptoms developed between baseline and 1 subsequent survey(s) and their severity. **Results:** Among the 111 patients enrolled on ATOP (median age=71, range 60-88 years), 98 responded to the baseline survey and 1 subsequent survey(s). 1435 surveys were returned that included at least one PRO-CTCAE response, and 1661 surveys were returned that included EQ-5D. The Table displays the % of participants who reported PRO-CTCAE symptoms that worsened from baseline to any severity level (scores $>$0) or to a severe level (scores $\geq$3). More than 60% of survey respondents reported new or increased dry mouth, fatigue, muscle aches, decreased appetite, nausea, pain, and/or numbness/tingling at some point during or after treatment, but these were usually not severe. EQ-5D scores did not change significantly from baseline at any time point. **Conclusions:** In this adjuvant trial for patients aged $>$60, participation rates for PRO data collection were high. Reassuringly, global HRQOL was not impacted by T-DM1, and though frequently reported, the vast majority of patient-reported symptoms were mild. Future analyses of this trial will focus on duration and predictors (clinical and biomarker-based) of severe AEs, agreement between patient-reported and clinician-reported AEs, and whether sharing PRO reports with clinicians impacted clinician-reported AE grades. Clinical trial information: NCT03587740. Research Sponsor: Genetech; Gateway for Cancer Research; Gloria Spivak Advancement Fund; Susan G Komen for the Cure; Bakes for Breast Cancer.

Most common new or worsening symptoms reported via PRO-CTCAE in ATOP (n=95).

Symptom	% with score >0	n (%) with score 3+
Dry mouth	79%	26%
Fatigue	71%	29%
Muscle aches	69%	20%
Decreased appetite	69%	12%
Nausea	67%	6%
Pain	66%	21%
Numbness/tingling	65%	9%
Blurry vision	60%	4%
Mouth or throat sores	60%	5%

Breast cancer–specific mortality in invasive lobular versus ductal carcinoma over 30 years. First Author: Jose Pablo Leone, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Invasive lobular carcinoma (ILC) differs biologically from invasive ductal carcinoma (IDC) and has been associated with delayed recurrence. However, long-term patterns of breast cancer-specific mortality (BCSM) following ILC remain incompletely described. We aimed to characterize temporal patterns of BCSM associated with ILC vs IDC over extended follow-up. **Methods:** We conducted a population-based study using the SEER program. Women diagnosed with stage I–III IDC or ILC from 1990 to 2012 were included. BCSM was the primary endpoint, with death from other causes treated as a competing event. Unadjusted cumulative incidence functions estimated BCSM by histology. Fine-Gray competing risks models were used to compare histologies overall and within hormone receptor (HR)-defined subgroups, with all models adjusted for age at diagnosis, year (y) of diagnosis, HR status (where applicable), tumor size, nodal status, tumor grade, surgery, radiation, and chemotherapy. Non-proportional effects were identified visually and modeled using time-varying coefficients. Landmark competing risks analyses assessed late BCSM among long-term survivors. **Results:** Among 423,479 women included, 41,027 (9.7%) had ILC and 382,452 (90.3%) had IDC; median follow-up was 16.7 y (range 0.1–33 y). During follow-up, 77,926 breast cancer deaths and 111,814 deaths from other causes occurred. In unadjusted analyses of the overall population, BCSM was lower for ILC than IDC at 5 and 10 years and higher for ILC at 20 and 30 years (Table). In adjusted Fine-Gray models, lobular histology demonstrated a significant time-varying association with BCSM ($p<0.001$). Associations between histology and BCSM differed by HR status (p for interaction=0.0029). In time-varying models restricted to HR+ disease, the adjusted subdistribution hazard ratio (sHR) for ILC versus IDC increased over time, reaching 1.19 (95% CI 1.15–1.23) at 10 y, 1.34 (1.28–1.41) at 20 y, and 1.44 (1.36–1.54) at 30 y. In landmark analyses among HR+ survivors, ILC remained associated with higher late BCSM beyond 10 y (sHR 1.36, 95% CI 1.29–1.43) and beyond 15 y (sHR 1.32, 95% CI 1.20–1.45). **Conclusions:** ILC is associated with a distinct temporal pattern of BCSM compared with IDC. Although unadjusted early BCSM is lower for ILC, adjusted risk increases over time and exceeds that of IDC in the late post-diagnosis period, particularly among HR+ disease. These findings highlight the importance of long-term risk assessment and survivorship strategies tailored to lobular histology. Research Sponsor: None.

Unadjusted cumulative incidence of BCSM by histology (%; 95% CI).

	Overall population		HR+	
Y since diagnosis	IDC	ILC	IDC	ILC
5	9.8 (9.7–9.9)	7.3 (7.0–7.5)	6.5 (6.4–6.6)	6.4 (6.1–6.6)
10	15.0 (14.9–15.2)	14.3 (13.9–14.6)	11.9 (11.8–12.0)	13.4 (13.1–13.8)

From treatment to survivorship: The CORE randomized study of a supervised exercise intervention in early-stage breast cancer. First Author: Maria Torrente, Universidad Francisco de Vitoria, Facultad de Ciencias de la Salud, Madrid, Spain

Background: Physical exercise is recommended by international guidelines to mitigate treatment-related toxicity and improve quality of life in patients with breast cancer (BC). However, adherence to physical activity recommendations remains low, and evidence from randomized studies conducted in real-world clinical settings is limited. The CORE study evaluated the impact of a structured, supervised exercise program on fatigue and health-related quality of life (HRQOL) in patients with early-stage BC. **Methods:** CORE is a single-center, randomized controlled trial enrolling patients with early-stage BC undergoing or recently completing curative treatment. Seventy patients were randomized 1:1 to usual care (control, n = 45) or a 3-month supervised exercise intervention (exercise, n = 45). Primary endpoints were physical fatigue (EORTC QLQ-BR45), cardiorespiratory fitness and muscle strength, and HRQOL (EORTC QLQ-C30 summary score). Secondary analyses explored changes in additional symptom and functional scales, as well as health status assessed by the EQ-5D questionnaire. Between-group differences in change from baseline to 3 months were analyzed with adjustment for multiple comparisons. **Results:** At 3 months, patients assigned to the exercise intervention experienced a statistically significant reduction in physical fatigue compared with usual care (mean difference −5.3; 95% CI −10.0 to −0.6; adjusted P = 0.027). HRQOL significantly improved in the exercise group (mean difference 4.8; 95% CI 2.2–7.4; adjusted P = 0.0003). In addition, within the exercise group, significant pre–post improvements were observed across several EORTC QLQ-C30 symptom and function scales, including fatigue, pain, dyspnea, nausea/vomiting, physical functioning, and role functioning, indicating a broad positive impact of the supervised strength training program on overall health status and daily functioning. Consistently, pre–post analyses in the exercise group using the EQ-5D demonstrated significant improvements in mobility, daily activities, and pain/discomfort dimensions. **Conclusions:** A 3-month supervised exercise program significantly reduced physical fatigue and improved HRQOL in patients with early-stage breast cancer. These findings reinforce the role of structured, supervised exercise as a key component of survivorship and supportive care, offering a scalable and effective strategy to reduce symptom burden, enhance functional capacity, and promote overall patient well-being. Impact of GLP1 receptor agonists on survival of breast cancer patients. First Author: Tim Prior, Mayo Clinic Arizona, Phoenix, AZ

Background: Large cohort studies have shown a survival benefit with the use of GLP1 receptor agonists (GLP1 RA) in cancer patients. The impact of GLP1 RA usage in breast cancer (BC) and the different subtypes is unknown. To investigate the potential influence of GLP1 RA usage on BC survival, a study was conducted on a large institutional database. **Methods:** A de-identified institutional database identified newly diagnosed Stage I, II, and III BC patients from 2005 to present and use of GLP1 RA. The study compared survival rates for BC patients with and without GLP1 RA and further stratified by BC subtype [ER+HER2-, HER2+, ER-PR-HER2-(triple negative BC (TNBC))], BMI, and age. Kaplan-Meier survival curves were used to estimate overall survival. This study analyzed de-identified data accessed through Mayo Clinic Platform Discover. Per 45 CFR 46.102, this activity did not require IRB review. Data was extracted using an established privacy-preserving protocol and de-identified via expert determination under the HIPAA Privacy Rule. Raw EHR data and other unreported data cannot be shared due to de-identification parameters. **Results:** 88015 BC patients were identified, of which 3919 (4.5%) received GLP1 RA. The 5-year survival rate was 98.5% with vs 85.5% without GLP1 RA (p-value <0.0001). The survival benefit persisted for different BMI's and ages: BMI >30 (98.4% vs 85.1%), >25 (98.4% vs 85.4%), and age <50 (99.5% vs 89.3%) and >50 (98.1% vs 84.8%) [all $p<0.0001$]. 21770 patients with ER+ disease were identified, of which 1412 (6.5%) received GLP1 RA. The 5-year survival rate was 99.0% vs 87.7% (p-value <0.0001). The survival benefit persisted by BMI and age: BMI >30 (99.0% vs 86.2%), >25 (98.9% vs 87.1%) and age <50 (99.6% vs 90.5%) and >50 (98.7% vs 87.2%) [all $p<0.0001$]. 3599 patients with HER2+ disease were identified, of which 202 (5.6%) received GLP1 RA. The 5-year survival rate was 99.3% vs 80.1% (p-value <0.0001). The survival benefit persisted by stratification: BMI >30 (100.0% vs 80.0%, p-value <0.0004), and <25 (97.7% vs 76.2%, p-value <0.019), and age <50 (100% vs 87.0%, p-value <0.043) and >50 (99.0% vs 77.2%, p-value <0.0002). 8389 patients with TNBC disease were identified, of which 360 (4.3%) received GLP1 RA. The 5-year survival rate was 91.0% vs 71.9% (p-value <0.0001). The survival benefit persisted by stratification: BMI >30 (96.4% vs 72.9%, p-value <0.0001), >25 (93.2% vs 71.8%, p-value <0.0001), and age <50 (96.0% vs 73.0%, p-value <0.0028) and >50 (88.9% vs 71.8%, p-value <0.0001). For those TNBC patients who received GLP1 RA, having a BMI >30 conferred a protective effect with a 5-year survival rate was 97.9 vs 89.8% (p-value <0.0014). **Conclusions:** The study suggests that GLP1-RA improves 5-year survival rates of patients with BC and this applies to all subtypes of BC. These results suggest that further study of the impact of GLP1-RA on BC patients is warranted. Research Sponsor: None.

Lymphopenia in breast cancer and association with clinical outcomes: An analysis from over 30,000 patients. First Author: Alexis Ann LeVee, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Lymphopenia is an independent prognostic factor for overall survival in patients with solid tumors. Low circulating lymphocytes represents impaired adaptive immunity, which can compromise antitumor immune responses and increase the risk of treatment-related toxicity. Despite having an ICD-10 code (D72.810), lymphopenia as a diagnosis might be often underrecognized and overlooked. We aimed to analyze the prevalence and concordance of lab-defined lymphopenia with the clinical diagnosis and the association of lab-defined lymphopenia with clinical outcomes in a large cohort of patients with breast cancer. **Methods:** We identified patients with breast cancer between 1/1/2011-12/31/2024 in a single institution using ICD-10 codes. Stage and subtype was determined using ICD codes, with recurrence defined by any ICD code for metastatic disease at least 6 months after initial diagnosis. Lab-defined lymphopenia was defined by absolute lymphocyte count (ALC) <1000 cells/μL. Baseline and on-treatment lymphopenia using ICD codes was compared to lab-defined baseline and on-treatment lymphopenia using Cohen's κ concordance statistic (0-1). Univariate logistic regression was performed to evaluate the association of lab-defined lymphopenia with recurrence. Overall mortality was analyzed using Cox proportional hazards regression. **Results:** 36,496 patients with breast cancer were included in the analysis. Most (89.7%) patients had early-stage breast cancer and estrogen receptor (ER)-positive disease (50.5%). At breast cancer diagnosis, 2,368 (6.5%) patients had lab-defined lymphopenia and 56 (0.02%) had lymphopenia diagnoses, demonstrating significantly low concordance by ICD codes (κ = 0.0268). Similarly, on-treatment lymphopenia was also discordant by ICD codes, with lab-defined on-treatment lymphopenia occurring in 5,564 (15.2%) of patients and 257 (0.7%) by ICD codes (κ = 0.0459). In early-stage breast cancer, baseline lab-defined lymphopenia was associated with increased risk of recurrence (OR 1.74; 95% CI 1.42-2.06; $p<0.001$) and increased risk of mortality (HR 2.13; 95% CI 1.92-2.37; $p<0.001$). In the metastatic setting, baseline lab-defined lymphopenia was associated with increased risk of mortality (HR 1.50; 95% CI 1.32-1.69; $p<0.001$). Multivariable analysis demonstrated that lab-defined lymphopenia at diagnosis was associated with increased mortality (HR 2.47; 95% CI 2.01-3.02, $p<0.001$), after adjusting for ER status, stage, and type of treatment. **Conclusions:** Lymphopenia is significantly underdiagnosed during breast cancer treatment, and is independently associated with increased risk of recurrence and death. These findings highlight the need for improved recognition of lymphopenia as a prognostic factor and tailored strategies to augment systemic immunity and potentially improve long-term outcomes for patients. Research Sponsor: None.

Impact of social marginalization on stage at presentation and survival for invasive lobular versus ductal breast carcinoma. First Author: David Wai Lim, Women's College Hospital, Toronto, ON, Canada

Background: We aim to determine how indices of social marginalization impact stage at diagnosis, health services use, and overall survival comparing invasive ductal (IDC), pure (pILC) and mixed lobular (mILC) breast carcinoma (ILC) between 2005 and 2025 in the province of Ontario, Canada. **Methods:** Using population-based administrative healthcare datasets at Institute of Clinical Evaluative Sciences (ICES) Ontario, we identified all cases of IDC, pILC and mILC in Ontario, Canada between 2005 and 2025 using ICD-O-3 codes. We compared prior healthcare utilization between groups. We further compared clinical and healthcare utilization measures between four Ontario Marginalization (ON-MARG) indices: household and dwellings (includes % living alone, housing density), material resources (includes unemployment and education level), age and labour force (includes % seniors and not participating in the work force), and racialized and newcomer populations (includes % of recent immigrants). Using a multivariable Cox proportional hazards regression analysis incorporating sociodemographic, tumour and treatment factors, we assessed the impact of social marginalization indices on survival for the overall cohort and for ILC cases. Statistical analysis was performed using SAS and P values < 0.05 were significant. **Results:** We identified 16,122 (9%) pILC, 7,284 (4%) mILC and 156,870 (87%) IDC cases. At diagnosis, increasing marginalization for household and dwellings, material resources, and age and labour force correlated with less likelihood to having had a mammogram within 1 and 5 years prior to diagnosis ($P < .0001$). Increasing marginalization in these three quintiles correlated with worse clinical stage at diagnosis for both IDC and ILC ($P < .001$). Patients diagnosed with pure ILC breast cancer had 1.14 times (95%CI: 1.11 - 1.18) the likelihood of mortality in the follow-up relative to females diagnosed with IDC breast cancer. Increasing marginalization in the ON-MARG indices had a worse mortality for the overall cohort and for ILC cases, except for the racialized and newcomer populations quintile ($P < .0001$). **Conclusions:** In Ontario, Canada, the indices of social marginalization found to be associated with worse survival after a breast cancer diagnosis were household and dwellings, material resources, age and labour force but not racialized and newcomer populations. These findings highlight personalized risk factors for worse stage at presentation and survival for both IDC and ILC, independent of clinical and treatment factors. Research Sponsor: Conquer Cancer, the ASCO Foundation.

TPS642 **Poster Session**

HIGHLIGHT 1: A randomized, placebo-controlled, double-blind, phase 3 clinical study to investigate the efficacy and safety of fezolinetant for treatment of moderate to severe vasomotor symptoms (hot flashes) in women with stage 0 to 3 hormone receptor–positive breast cancer who are receiving adjuvant endocrine therapy. First Author: Céline Bouchard, Clinique RSF Inc, Québec, QC, Canada

Background: Breast cancer is the most common cause of death due to malignant neoplasms in women globally. Adjuvant endocrine therapy, e.g., tamoxifen and aromatase inhibitors, can lead to premature menopause and vasomotor symptoms (VMS). Fezolinetant is a non-hormonal neurokinin 3 receptor antagonist that is an approved treatment option for moderate to severe VMS due to menopause in multiple regions worldwide, including North America, Europe, Asia, and Australia, at a dose of 45 mg once daily. The pathophysiology of VMS in women undergoing cancer treatment is not fully elucidated but is hypothesized to have similar etiology to VMS associated with menopause, i.e., rapid decline of estrogen. **Methods:** This global, double-blind, placebo-controlled phase 3 study (HIGHLIGHT 1 [NCT06440967]) was designed to assess efficacy and safety of fezolinetant 45 mg once daily in moderate to severe VMS associated with tamoxifen or aromatase inhibitors for hormone receptor-positive breast cancer from stage 0 (cancer cells have not spread to nearby tissue) to stage 3+ (cancer has spread from breast to lymph nodes near the breast or the chest wall). HIGHLIGHT 1 comprises screening (28 days), treatment (52 weeks), follow-up (3 weeks after final treatment), and extension follow-up (until week 104). Eligible participants will be randomized 1:1 to fezolinetant 45 mg or placebo and stratified by adjuvant endocrine therapy and prior chemotherapy. Participants will record their VMS daily on an electronic diary. The study is currently recruiting. Participants are women (target enrollment n = 540; 382 enrolled as of 24 Nov) ≥18 years with ≥7 moderate to severe VMS episodes/day receiving hormone therapy for stage 0-3 hormone receptor-positive breast cancer. Key exclusions: history/current malignancy other than hormone receptor-positive breast cancer (stage 0 to 3) or basal cell carcinoma. Co-primary endpoints: mean change from baseline to week 4 and 12 in frequency and severity of moderate to severe VMS. Key secondary endpoints: mean change from baseline to week 12 in MENQOL VMS domain score and PROMIS Total Score Sleep Disturbance–Short Form 8b. Co-primary endpoints and key secondary endpoints will be analyzed using mixed models for repeated measures. Treatment-emergent adverse events (TEAEs) assess fezolinetant safety and tolerability. The DMC last reviewed the study in November 2025 and suggested that the study continue as planned. Clinical trial information: NCT06440967. Research Sponsor: Astellas Pharma Inc.

TPS643 **Poster Session**

Precision DC: Personalized neoantigen dendritic cell vaccine pilot trial for high-risk triple-negative breast cancer after neoadjuvant therapy. First Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Treatment for stage II-III triple negative breast cancer (TNBC) uses neoadjuvant chemoimmunotherapy (NCT) with the goal of achieving pathologic complete responses. TNBC patients with significant residual cancer burdens (RCB II/III) after NCT have a high risk of early relapse/death despite use of adjuvant therapies like capecitabine. Moffitt Cancer Center's breast program uses a highly immunogenic dendritic cell vaccine platform (DC1) against HER2 overexpressing tumors in previous studies demonstrating antitumor efficacy (Han, JAMA Onc 2025). TNBC often has multiple somatic mutations leading to expression of altered immunogenic proteins known as neoantigens. We hypothesize that the residual primary TNBC after NCT can be sequenced to identify the most immunogenic neoantigens and include them as targets in an adjuvant DC1 vaccine to stimulate cytotoxic T cell responses that eliminate residual micrometastatic disease. The PRECISION DC trial was initiated to study the feasibility of adjuvant neoantigen DC1 vaccines for high risk TNBC. Correlatives include immune response to neoantigens using ELISPOT and immunopeptidomics to study processing of peptides by the dendritic cells (NCT06435351). **Methods:** PRECISION DC is a single-arm pilot study open at the Moffitt Cancer Center enrolling stage II-III TNBC patients with RCB II/III disease and who are within 18 months of their last dose of KEYNOTE-522 chemotherapy without known metastatic disease. Eligible patients will have their residual tumor tissue whole exome sequenced, and mutated 25 mer long peptides are analyzed using a modified NetMHCII pipeline to rank these mutations based on a combined score representing multiple factors including expression, predicted MHC binding, and agretopicity. The top ten scoring peptides that also pass a peptide synthesis screen for excessive hydrophobicity are selected for inclusion in each patient's personalized DC1 vaccine. The relevant peptides for each patient are used to stimulate pheresed autologous dendritic cells ex-vivo. Moffitt's GMP cell therapy facility creates cryopreserved aliquots of 50 million cells to create DC1 vaccine doses. Patients get three intranodal DC1 inguinal injections q2weeks under ultrasound guidance in the priming phase and then two booster shots at 6 and 12 months either before or after adjuvant capecitabine (if given) per treating physician guidance. PRECISION DC opened 10/2024 and accrual to date is 22/26 planned patients with 4 remaining patients already identified. Primary endpoint is feasibility (% pts with successful vaccine administration w/ goal > 60%); secondary endpoints include safety, immune responses, and 5-year disease-free outcomes. If successful, PRECISION DC will set the stage for a prospective randomized trial of personalized autologous DC1 neoantigen vaccines to prevent recurrence of residual TNBC following NCT. Clinical trial information: NCT06435351. Research Sponsor: None.

TPS644 **Poster Session**

ASPRIA: A single-arm phase 2 trial of atezolizumab with sacituzumab govitecan to prevent recurrence in triple-negative breast cancer. First Author: Payal Deepak Shah, Penn Medicine Abramson Cancer Center, Philadelphia, PA

Background: Despite marked improvements in neoadjuvant chemoimmunotherapy (NACT) and adjuvant treatment for patients with early-stage triple negative breast cancer (TNBC), over 30% of patients with residual disease after NACT experience disease recurrence or death within 36 months. Understanding which patients are at greatest risk of relapse and designing effective interventions to prevent disease recurrence are major unmet needs. Circulating tumor DNA (ctDNA) can detect molecular residual disease (MRD) in TNBC and has demonstrated prognostic and predictive ability in the neoadjuvant setting; ctDNA thus represents a promising biomarker to select at-risk patients. Sacituzumab govitecan is a Trop-2 targeted antibody-drug conjugate leveraging a topoisomerase 1 payload that is approved for metastatic HR+ breast cancer and TNBC. Atezolizumab is an immune checkpoint inhibitor that interferes with the binding of PD-L1 to PD-1. The ASPRIA trial hypothesizes that ctDNA can identify patients with TNBC and residual disease after NACT at greatest risk for relapse, and that the combination of sacituzumab govitecan and atezolizumab may effectively treat MRD through cytotoxicity and anti-tumor immunity, leading to ctDNA clearance and improved clinical outcomes. **Methods:** The ASPRIA trial is an open-label, single-arm phase II trial evaluating sacituzumab govitecan in combination with atezolizumab in patients with early-stage TNBC. Eligible patients have residual invasive disease in the breast and/or lymph nodes following curative-intent therapy and detectable ctDNA, as assessed by a personalized, tumor-informed assay (Signatera, Natera, Inc.). The study includes a screening phase, with ctDNA presence assessed for the first 60 individuals to ensure feasibility, with a minimum prevalence threshold of approximately 15%. Patients with detectable ctDNA will undergo restaging imaging, and those without evidence of metastatic disease proceed to treatment. Up to 32 ctDNA-positive patients will receive atezolizumab 1200 mg IV on day 1 plus sacituzumab govitecan 10 mg/kg IV on days 1 and 8 of a 21-day cycle for 6 cycles. On-treatment ctDNA assessments will occur at weeks 3, 9, and at end of therapy. Participants will be followed for recurrence and survival every 6 months for 3 years. The primary objective is to determine the rate of ctDNA clearance after 6 cycles of therapy. Secondary objectives include estimating the ctDNA prevalence, assessing clearance after 1 and 3 cycles, evaluating recurrence risk and survival outcomes (iDFS, RFI, DMFS), and characterizing safety (per CTCAE v5). Correlative studies will examine predictors of ctDNA positivity, associations between treatment response and Trop-2 or PD-L1 expression in primary and residual tumors, temporal ctDNA dynamics in relation to relapse, and patient perspectives on ctDNA testing. Clinical trial information: NCT04434040. Research Sponsor: Stand Up to Cancer (SU2C); Natera, Inc.

TPS645 **Poster Session**

NoLEEta: No chemotherapy in intermediate-risk HR+ HER2− early breast cancer treated with ribociclib in the adjuvant setting—A non-inferiority phase III trial. First Author: Francois Clement Bidard, Institut Curie, Paris, France

Background: Historically, the treatment paradigm for hormone receptor-positive, HER2-negative early breast cancer (HR+ HER2− eBC) has relied on endocrine therapy (ET) and adjuvant chemotherapy. However, the absolute benefit of adjuvant chemotherapy is closely tied to baseline risk, being notably modest in intermediate risk eBC, while associated with significant short- and long-term toxicities. The phase III NATALEE trial demonstrated the efficacy of an adjuvant three-year treatment with ribociclib and ET in prolonging invasive disease-free survival (iDFS) in patients with high-risk HR+ HER− eBC. Contrarily to similar studies of CDK4/6 inhibitors in this setting, NATALEE included a group of patients with intermediate clinical risk (pT1-2 pN1, pT3-4 pN0 or pT2 pN0 with histological grade 3 or grade 2 with Ki67≥ 20%). These patients are usually treated with adjuvant chemotherapy based on the tumor clinicopathological characteristics or the results of a genomic signature. Nevertheless, the absolute benefit of adjuvant chemotherapy in these patients is uncertain (and likely reduced) in the context of an adjuvant treatment strategy that includes a CDK4/6 inhibitor. The NoLEEta trial aims at demonstrating that patients with intermediate-risk HR+ HER2− eBC treated with ribociclib and ET could be spared chemotherapy side effects while ensuring similar survival outcomes. **Methods:** NoLEEta is an international, randomized, open-label, non-inferiority phase III trial. Main inclusion criteria are: HR+ HER2− eBC after curative surgery, at intermediate risk of relapse (pT0-2 pN1, pT3-4 pN0, pT2 pN0 G3 or pT2 pN0 G2 with Ki67≥20%), eligible for adjuvant chemotherapy (per investigator decision, based on clinicopathological parameters or using a genomic signature). Eligible patients are randomized (1:1) to either receive ribociclib and ET (investigational arm without chemotherapy) or chemotherapy followed by ribociclib and ET (control arm). Primary endpoint is invasive breast cancer-free survival (iBCFS), defined in accordance with the STEEP system as the interval between randomization and the earliest occurrence of ipsilateral invasive breast tumor recurrence, local–regional invasive recurrence, distant recurrence, invasive contralateral breast cancer, or death from any cause. Secondary endpoints include invasive disease-free survival, distant disease-free survival, overall survival, interval and type of iBCFS events, incidence and severity of adverse events, and health-related quality of life. Enrollment in NoLEEta started in December 2025, with a target objective of 3902 randomized patients across 8 countries. One interim analysis is planned. Clinical trial information: NCT07237256. Research Sponsor: Novartis; Menarini Silicon Biosystems; Women's Cancer Institute of Institut Curie.

TPS646 **Poster Session**

Interception of molecular relapse in breast cancer: The SURVIVE HERoes study (NCT06643585). First Author: Wolfgang Janni, University Hospital of Ulm, Ulm, Germany

Background: Current research on circulating tumor DNA (ctDNA) in the adjuvant setting of early breast cancer (eBC) demonstrates its strong prognostic significance. Patients who are ctDNA-positive in the absence of radiological evidence of disease recurrence (i.e., molecular relapse) have significantly reduced disease-free and overall survival. Secondary adjuvant intervention trials employing highly potent therapeutic agents represent an innovative and promising strategy to intercept disease recurrence at the molecular stage. **Methods:** SURVIVE HERoes is a phase III, randomized clinical trial comparing the antibody–drug conjugate trastuzumab deruxtecan (T-DXd) with standard of care (SoC) in patients with molecular residual or recurrent disease. Eligible patients must have a positive circulating tumor DNA (ctDNA) result detected using a tumor-informed assay (RaDaR), while staging examinations show no evidence of residual or recurrent disease. Participants must have HER2-positive, HER2-low, or—following an approved study amendment—HER2-ultralow early breast cancer (eBC), irrespective of hormone receptor (HR) status, and must have completed primary therapy, including surgery with R0 resection, with or without chemotherapy and/or radiotherapy. 180 participants are randomized in a 2:1 ratio to receive T-DXd (+ endocrine therapy for HR positive patients) or standard of care for 48 weeks, followed by a 48-week follow-up phase. Stratification factors include hormonal receptor status (positive versus negative) and HER2-status (positive versus low versus ultralow). Staging examinations and ctDNA assessments will be performed every 12 weeks during the 2-year study phase per patient. The study is accompanied by a comprehensive translational research program. The primary endpoint is the ctDNA clearance rate after 48 weeks, comparing participants in the experimental arm (receiving T-DXd) with those in the control arm (receiving standard of care), irrespective of ctDNA test results at other time points. Secondary endpoints include invasive disease-free survival, overall survival, ctDNA clearance at other time points, safety, and quality of life (QoL), as assessed by EORTC QLQ-C30 and PA-F12. Recruitment: Recruitment began in Q2/2025 and is anticipated to continue until 2030. Fifty sites across Germany are planned for participation. Discussion: Treating ctDNA-positive patients without radiographic evidence of recurrence is a novel therapeutic strategy. If SURVIVE HERoes and similar studies targeting molecular relapse yield positive results, they could pave the way for a new molecularly driven personalized surveillance and treatment approach. Clinical trial information: NCT06643585. Research Sponsor: Astra Zeenca; NeoGenomics; tosoh Bioscience; Menarini Silicon Biosystems.

TPS647 **Poster Session**

PREDICT-RD: Postoperative molecular residual disease by ctDNA surveillance in TNBC with residual disease (TBCRC-071). First Author: Yara Abdou, Division of Oncology, Lineberger Comprehensive Cancer Center, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Patients with residual triple-negative breast cancer (TNBC) post-neoadjuvant therapy, particularly those with higher residual cancer burden (RCB II/III), remain at high risk of recurrence despite standard adjuvant therapy. Current post-treatment surveillance relies primarily on clinical follow-up and imaging, which have limited sensitivity to detect disease at a subclinical stage and rarely enable early therapeutic intervention. Circulating tumor DNA (ctDNA)-based molecular residual disease (MRD) assessment allows detection of tumor-derived DNA in the absence of radiographic disease and offers a framework to identify patients at high risk of recurrence, who may be candidates for early, biomarker-informed treatment escalation prior to overt metastatic recurrence. PREDICT-RD is designed to evaluate the clinical implications of post-surgical ctDNA surveillance in patients with high-risk, early-stage TNBC. We hypothesize that longitudinal monitoring with a tumor-informed, high sensitivity ctDNA assay will identify an MRD-only state in at least 10% of patients, defined by ctDNA positivity in the absence of clinical or radiographic recurrence. A secondary objective is to assess outcomes among patients with ctDNA-detected molecular relapse who undergo adjuvant treatment escalation with datopotamab deruxtecan (Dato-DXd). Dato-DXd is an antibody-drug conjugate composed of a monoclonal antibody targeting TROP2 linked to a topoisomerase I inhibitor payload. In TNBC, Dato-DXd has demonstrated a manageable safety profile and promising efficacy, including an improvement in median PFS of 5.3 months over SoC chemotherapy in the first line setting for patients who are not candidates to receive immunotherapy (TROPION-Breast02). **Methods:** PREDICT-RD (TBCRC-071) is a prospective phase II, interventional, open-label, single-arm, multi-center study. The trial will enroll 78 patients with Stage II or III TNBC with residual disease (RCB II/III) following neoadjuvant chemo-immunotherapy and surgery. Patients will undergo serial blood sampling for ctDNA assessments using a clinically available tumor-informed personalized assay (Signatera Genome, Natera, Inc.) at predefined intervals during adjuvant therapy and subsequent surveillance. ctDNA test results will be disclosed to both the treating provider and the patient. A positive ctDNA result will prompt consideration of imaging for distant disease. The primary endpoint is the prevalence of MRD-only relapse. Patients meeting these criteria will be considered for treatment escalation with Dato-DXd (up to eight cycles), with ctDNA clearance as a secondary endpoint. Patient-reported fear of recurrence and quality of life will be serially evaluated. Post-treatment surveillance will continue for up to three years following initial consent. Recruitment is anticipated to begin in early 2026 (NCT07069595). Clinical trial information: NCT07069595. Research Sponsor: Gateway for Cancer Research; G-24-800; Daiichi Sankyo; Conquer Cancer, the ASCO Foundation; Natera; Daiichi Sankyo.

SIGNAL-ER-101: Signatera-guided CDK4/6 inhibitor therapy in breast cancer. First Author: Marla Lipsyc-Sharf, University of California, Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: The monarchE and NATALEE trials showed that the addition of a CDK4/6 inhibitor (CDK4/6i; abemaciclib or ribociclib) to adjuvant endocrine therapy (ET) improves invasive disease-free survival (iDFS) in patients with ER+/HER2- high-risk and high-intermediate risk early breast cancer (eBC), including those with node-positive disease and select high-risk node negative tumors. However, the absolute benefit was modest (monarchE: 6.4% at 4 years; NATALEE: 3.3% at 3 years) suggesting that while a subset of patients derive benefit, many high-risk patients will not recur following ET alone. Improved strategies are needed to more precisely identify patients most likely to benefit from adjuvant CDK4/6i. Circulating tumor DNA (ctDNA) is an established biomarker of molecular residual disease (MRD) in eBC; its detection is associated with a significant risk of recurrence, and lack of detection with highly sensitive assays is associated with excellent prognosis. The SIGNAL-ER-101 trial evaluates whether tumor informed ctDNA detection during post-surgical adjuvant therapy can identify ER+/HER2- patients at highest risk of recurrence who are most likely to benefit from the addition of a CDK4/6i to standard-of-care (SOC) adjuvant ET and avoid overtreatment in patients who are likely to benefit with ET alone. **Methods:** SIGNAL-ER-101 is a Natera-sponsored prospective, open-label, single-arm, multicenter phase II treat-on-MRD study that aims to enroll 725 patients with intermediate-risk, stage II ER+/HER2- eBC who have undergone surgical resection and have no prior exposure to a CDK4/6i. Patients will be enrolled before receipt of any planned chemotherapy and/or radiation and within 6 months of initiating ET. Personalized, tumor-informed ctDNA testing will be performed using the Signatera Genome assay (Natera, Inc.), developed from archived tumor tissue and matched normal DNA to detect tumor-specific variants in plasma. Patients who are ctDNA-positive at baseline will be initiated on adjuvant CDK4/6i (ribociclib or abemaciclib) plus ET for a minimum of two years. Patients who are ctDNA-negative will receive ET alone and undergo MRD surveillance with ctDNA testing every three months. Upon detection of ctDNA during surveillance, patients will undergo staging scans to exclude distant metastatic disease prior to the addition of CDK4/6i therapy to ET. Selection of the specific CDK4/6i and ET will be at the discretion of the treating physician based on available SOC adjuvant therapy options. Patients will be followed for up to nine years to assess outcomes, including the study primary endpoint (iDFS) and key secondary endpoints (e.g., overall survival). The primary endpoint will be met if 4-year IDFS is non-inferior to that from NATALEE (3% non-inferiority margin: 93.9% vs 90.9%), aiming to evaluate whether ctDNA-guided treatment preserves efficacy while reducing over-treatment. Recruitment is expected to begin in March 2026. Clinical trial information: NCT07214532. Research Sponsor: Natera Inc.

TPS649 **Poster Session**

GEMINI-BREAST: Evaluating minimal residual disease (MRD) through longitudinal circulating tumor DNA (ctDNA) profiling in breast malignancies. First Author: Matthew E. Campbell, Tempus AI, Inc., Chicago, IL

Background: While advancements in early-stage breast cancer (ESBC) treatment have improved survival, disease recurrence and therapeutic resistance remain significant challenges. Current biomarkers guide initial treatment, yet novel diagnostics are required to improve risk stratification and recurrence prediction. Circulating tumor DNA (ctDNA) offers a non-invasive method for detecting minimal residual disease (MRD), potentially enabling the identification of molecular relapse before radiographic progression. However, deeper validation of ctDNA kinetics across the treatment continuum is needed to inform precision oncology strategies in ESBC. Additionally, the logistical complexity of tissue-dependent assays presents a barrier to scalability. In order to address these gaps, the purpose of the GEMINI-BREAST study is to evaluate a methylation-based, tissue-free ctDNA assay (Tempus xM) and integrate this with comprehensive clinical and multi-omic data to determine prognostic utility for invasive disease-free survival (iDFS) and long term outcomes in patients with ESBC. **Methods:** GEMINI-BREAST (NCT07211178) is a prospective, non-interventional, multi-center study enrolling up to 900 participants with ESBC treated with curative intent. Eligible patients enroll into one of three analytical cohorts (n ~ 300 each): Cohort 1 enrolls pre-neoadjuvant therapy (high-risk HR+/HER2- [Stage II-III], HER2+ [Stage II-III], or TNBC [Stage I-III]); Cohort 2 enrolls post-surgery/pre-adjuvant therapy (same subtypes, no evidence of disease); and Cohort 3 enrolls long-term survivors (high-risk HR+/HER2- [Stage II-III], $\geq$ 5 years since diagnosis). Longitudinal blood samples for ctDNA analysis and archival tissue for NGS are collected at standard-of-care intervals, including, as applicable: pre-neoadjuvant, neoadjuvant on-treatment (weeks 3, 6, 12) and post-treatment, post-surgical/pre-adjuvant, adjuvant on-treatment (every 3 months), end of definitive therapy, surveillance for up to 5 years (every 3-6 months for Cohorts 1/2; every 6-12 months for Cohort 3), and at progression/recurrence. The primary objective is to evaluate the association between ctDNA dynamics (Cohort 1) or MRD status (Cohort 2/3) and iDFS, with secondary endpoints assessing overall survival, lead time to recurrence, and the predictive value of ctDNA clearance for pathological complete response. Recruitment is currently ongoing at U.S. sites. Clinical trial information: NCT07211178. Research Sponsor: Tempus AI.

TPS650 **Poster Session**

A phase III trial evaluating addition of adjuvant chemotherapy to ovarian function suppression + endocrine therapy in premenopausal women with pN0-1, HR+/HER2− breast cancer and Oncotype recurrence score ≤ 25 (OFSET): NRG-BR009. First Author: Eleftherios P. Mamounas, AdventHealth Cancer Institute, Orlando, FL

Background: The TAILORx and RxPONDER trials showed that recurrence score (RS) identifies many postmenopausal pts who do not benefit from addition of ACT to endocrine therapy (ET); however, RS also identifies subsets who do benefit (node-neg/high clinical risk/RS 16-20, node-neg/RS 21-25, and node-pos/RS ≤25). Most premenopausal pts in these trials did not receive ovarian function suppression (OFS) as part of their ET regimen. Given the observed benefit from OFS in high-risk premenopausal pts with HR+/HER2− BC in SOFT/TEXT, we question whether the ACT benefit in TAILORx/RxPONDER was due to chemotherapy-induced OFS. To address this, we developed OFSET, a phase III clinical trial comparing OFS+ET to ACT+OFS+ET. **Methods:** We hypothesize that addition of ACT to OFS+ET is superior to OFS+ET in improving invasive breast cancer-free survival (IBCFS) among premenopausal pts with early-stage HR+/HER2− tumors, and a 21-gene RS between 16-25 (for pN0 pts) and 0-25 (for pN1 pts). Secondary objectives include invasive disease-free survival, overall survival, distant recurrence-free interval, breast cancer-free interval, and health-related quality of life (HRQOL). Pts must be node-neg with RS 16-20 (plus high clinical risk), RS 21-25, or have 1-3 positive nodes with RS ≤25. Stratification is by nodal status/RS status (pN0 RS 16-25; pN1 RS 0-15; pN1 RS 16-25), intent to receive CDK4/6 inhibitor (yes; no), and age (18-39; ≥40). Pts are randomized after surgery to either OFS+ET or ACT+OFS+ET. ET is an aromatase inhibitor (AI) per physician discretion; or tamoxifen if AI is not tolerated or if OFS is incomplete. Radiotherapy will be administered per protocol guidelines. An HRQOL sub-study will assess severe menopausal symptoms (measured by FACT ESS-19) and pain severity (PROMIS) between arms. Blood and tumor specimens will be collected for future research. We anticipate accrual of 3,960 pts in 7 yrs, 7 mos. Per NSABP B-28/RxPONDER data, 5-yr IBCFS of pN1 pts on the ACT+OFS+ET arm is estimated at 92.3%. Per TAILORx data, 5-yr IBCFS of pN0 pts on the ACT arm is ~95%. Assuming 56% of pts to be pN0 and 44% pN1, and a 0.5% annual loss-to-follow-up rate, the definitive analyses to detect a hazard ratio: 0.75 with ACT+OFS+ET *v* OFS+ET, with 1-sided α of 0.025 and 80% power, will require 380 IBCFS events, expected to occur ~11 yrs after study initiation. Accrual is 496/3,960 (from 8/2023 to 1/2026). NCT #: NCT05879926. Clinical trial information: NCT05879926. Research Sponsor: U.S. National Institutes of Health; U10 CA180868; U.S. National Institutes of Health; U10 CA180822; U.S. National Institutes of Health; UG1 CA189867; U.S. National Institutes of Health; U24 CA196067.

TPS651 **Poster Session**

A randomized trial of sentinel node biopsy omission after neoadjuvant systemic therapy in clinically node-negative or selected node-positive breast cancer. First Author: Ji-Jung Jung, Department of Surgery, Seoul National University College of Medicine, Seoul, South Korea

Background: Omission of axillary surgery has been established as a safe option in selected patients with early-stage breast cancer undergoing upfront surgery. In the neoadjuvant systemic therapy (NST) setting, however, axillary surgery remains standard practice. Ongoing trials, including EUBREAST-01, ASICS, and ASLAN, are evaluating the safety of omitting sentinel lymph node biopsy (SLNB) after NST, but these studies have largely been limited to single-arm designs and to patients with confirmed breast pathologic complete response (pCR). Retrospective studies suggest that axillary nodal clearance after NST may be predicted using tumor subtype, treatment response, and post-NST imaging, independent of breast pCR. The NeoNAUTILUS trial was designed to prospectively evaluate the safety of omitting SLNB after NST in patients predicted to have no residual axillary disease, using axillary response–based selection rather than breast pCR. **Methods:** NeoNAUTILUS is a prospective, multicenter, randomized, controlled, non-inferiority trial being conducted at 23 centers in Korea. Eligible participants are women aged ≥20 years with clinical T1–T3 invasive breast cancer who have completed NST and are candidates for breast-conserving surgery (BCS). Patients with clinical N0 disease of any subtype are eligible. Selected patients with clinical N1 disease are eligible if they have HER2-positive, triple-negative, or estrogen receptor–low-positive tumors and demonstrate a >30% reduction in primary tumor size on post-NST magnetic resonance imaging. All participants must have no suspicious lymph nodes on post-NST axillary ultrasound. Participants are randomized 1:1 to BCS with SLNB or BCS without axillary surgery, stratified by clinical nodal status (cN0 vs cN1) and tumor subtype. Patients remain blinded to treatment allocation until surgery. Whole-breast irradiation is planned for all patients, with protocol-defined axillary radiation fields in the no-SLNB group according to initial nodal status. The primary endpoint is 5-year invasive disease-free survival. Secondary endpoints include overall survival, distant metastasis-free survival, ipsilateral axillary recurrence, locoregional recurrence, and patient-reported quality of life. A total of 464 patients are planned for enrollment over 3 years with a minimum follow-up of 5 years. Enrollment began in May 2025 and is ongoing. Clinical trial registration: NCT06704945; KCT0010174. Clinical trial information: NCT06704945. Research Sponsor: None.

TPS652 **Poster Session**

MELODY: A prospective non-interventional multicenter cohort study to evaluate different imaging-guided methods for localization of malignant breast lesions (EUBREAST-4/iBRA-NET/AGO-B-062; NCT05559411). First Author: Maggie Banys-Paluchowski, Department of Gynecology and Obstetrics, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany

Background: In the last decades, the proportion of breast cancer patients receiving breast-conserving surgery has increased, reaching 70-80% in developed countries. In case of non-palpable lesions, surgical excision requires some form of breast localization. While wire-guided localization has long been considered gold standard, it carries several limitations, including logistical difficulties, the potential for displacement and patient discomfort, and re-excision rates reaching 21% (in DCIS up to 30%). Other techniques (radioactive seed or radio-occult lesion localization, intraoperative ultrasound, magnetic, radiofrequency, and radar localization) have been developed with the aim of overcoming these disadvantages. However, comparative data on the rates of successful lesion removal, negative margins, and re-operations are limited. In most studies, the patient perspective, addressing e.g. discomfort and pain, has not been evaluated. The aim of MELODY (MEthods for LOcalization of Different types of breast lesions) is to evaluate different imaging-guided localization methods with regard to oncological safety, patient-reported outcomes, surgeon and radiologist satisfaction and economic impact. **Methods:** The EUBREAST and the iBRA-NET have initiated the MELODY study to assess breast localization techniques and devices from several perspectives (NCT05559411, http://eubreast.org/melody). MELODY is a prospective intergroup cohort study which enrolls female and male patients planned for breast-conserving surgery with imaging-guided localization for invasive breast cancer or DCIS. Multiple or bilateral lesions and neoadjuvant chemotherapy are allowed. Primary outcomes are: 1) Intended target lesion and/or marker removal, independent of margin status on final histopathology, and 2) Negative resection margin rates at first surgery. Secondary outcomes are, among others: rates of second surgery and secondary mastectomy, Resection Ratio (defined as actual resection volume divided by the calculated optimum specimen volume), duration of surgery, marker dislocation rates, rates of marker placement or localization failure, patient-reported outcomes, rates of "lost markers", radiologist and surgeon satisfaction, and health economic evaluation of the different techniques. Enrollment started in January 2023. Up to 26 January 2025, 9727 patients from 27 countries were enrolled in the study. The study is expected to complete patient enrollment in year 2026. The study will be conducted in 30 countries and is supported by the Oncoplastic Breast Consortium (OPBC), AWOgyn, AGO-B, SENATURK, the American Society of Breast Surgeons (ASBS) and the Korean Breast Cancer Study Group (KBCSG). Clinical trial information: NCT05559411. Research Sponsor: None.

TPS653 **Poster Session**

A molecular subtype–guided, chemotherapy-free neoadjuvant strategy using SHR-A1811 plus pertuzumab for hormone receptor–positive/HER2-positive breast cancer: A phase II trial in progress. First Author: Zhengjun Yang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Hormone receptor–negative/HER2-positive breast cancer achieves high pathological complete response (pCR) rates with chemotherapy-based HER2-targeted therapy, whereas hormone receptor–positive (HR+)/HER2-positive disease consistently demonstrates lower pCR rates and substantial chemotherapy-related toxicity, representing an unmet clinical need. Antibody–drug conjugates (ADCs) may address this gap by enhancing HER2-directed cytotoxic delivery while potentially avoiding conventional chemotherapy. SHR-A1811 (ruikang-trastuzumab) is a next-generation HER2-directed ADC conjugated to a topoisomerase I inhibitor with a high drug-to-antibody ratio (≈6) and has demonstrated superior preclinical activity compared with trastuzumab emtansine. HER2-directed ADCs may be particularly advantageous in HR-positive/HER2-positive tumors, including those with HER2 immunohistochemistry (IHC) 2+ and in situ hybridization (ISH)–positive status, through bystander killing effects that may overcome heterogeneous or lower-level HER2 expression. Emerging evidence suggests that ADC activity is retained in HR-positive/HER2-positive breast cancer and may be enhanced when combined with pertuzumab, providing the rationale for evaluating neoadjuvant SHR-A1811 plus pertuzumab in this population. **Methods:** This prospective, open-label, single-arm phase II trial enrolls women aged > 18 and < 70 years with previously untreated stage II–III HR-positive/HER2-positive breast cancer. All patients receive neoadjuvant SHR-A1811 (4.8 mg/kg intravenously every 3 weeks) plus pertuzumab (840 mg loading dose followed by 420 mg every 3 weeks) for four cycles. Baseline BluePrint profiling classifies tumors as luminal or non-luminal. Treatment is adaptively tailored based on molecular subtype and RECIST v1.1 response after four cycles. Patients with luminal subtype and stable disease switch to a chemotherapy-free regimen of trastuzumab, pyrotinib (a HER2-directed tyrosine kinase inhibitor), dalpiciclib (a CDK4/6 inhibitor), and an aromatase inhibitor, while patients with luminal subtype achieving partial or complete response and all non-luminal tumors continue SHR-A1811 plus pertuzumab for two to four additional cycles before surgery. Circulating tumor DNA (ctDNA) is assessed at baseline, after four cycles, and preoperatively. The primary endpoint is pCR (ypT0/is ypN0); secondary endpoints include event-free survival, objective response rate, and safety, with exploratory analyses evaluating associations among molecular subtype, ctDNA dynamics, and treatment response. Clinical trial information: NCT07307287. Research Sponsor: None.

TPS654 **Poster Session**

NOGA: Neoadjuvant treatment optimization via MRI-guided de-escalation in stage II–III TNBC—A phase 2 study. First Author: Tal Sella, Sheba Medical Center, Ramat Gan, Israel

Background: Pembrolizumab combined with neoadjuvant chemotherapy improves pathological complete response (pCR) rates and survival in stage II–III triple-negative breast cancer (TNBC), establishing the KEYNOTE-522 regimen as the standard of care. This regimen consists of two phases: four cycles of paclitaxel/carboplatin with pembrolizumab (TCa+P), followed by four cycles of adriamycin/cyclophosphamide with pembrolizumab (AC+P). However, anthracycline-containing chemotherapy contributes substantial short- and long-term toxicity. A subset of patients may achieve pCR after the initial TCa+P phase, raising the possibility that treatment intensity may be reduced in selected responders. Breast MRI demonstrates high concordance with pCR in hormone receptor–negative breast cancer and represents a promising, noninvasive biomarker to guide response-adapted de-escalation strategies. **Methods:** This is a prospective, investigator-initiated, multicenter, single-arm phase II trial evaluating MRI-guided de-escalation of neoadjuvant chemotherapy plus immunotherapy in patients with early TNBC. Eligible patients have Stage II-III (T2-T3N0 or T1-T3N1) TNBC and are candidates for the KEYNOTE-522 regimen. All patients receive four cycles (12 weeks) of TCa+P, followed by mid-treatment breast MRI. Patients achieving radiologic complete response (MRI-CR) proceed directly to surgery, omitting anthracycline-containing chemotherapy. Patients with radiologic residual disease (MRI-RD) complete the full neoadjuvant regimen including AC+P. The primary endpoint is pCR rate among patients with MRI-CR undergoing early surgery. Key secondary endpoints include recurrence-free survival, overall survival, toxicity, and patient-reported outcomes. Exploratory analyses include longitudinal circulating tumor DNA (ctDNA) dynamics to assess early molecular response, minimal residual disease, and correlates with MRI-CR, pCR, and long-term outcomes. The expected pCR rate among patients achieving MRI-CR is $\geq$87%, compared with a benchmark rate of 65%. The study uses a Simon's optimal two-stage design (one-sided α=0.05, 80% power). In stage 1, 10 MRI-CR patients proceeding directly to surgery will be evaluated, with early stopping for futility if the efficacy threshold is not met. If successful, stage 2 will enroll an additional 17 MRI-CR patients, for a total of 27 evaluable patients. Assuming an MRI-CR rate of ~50%, 54 patients will be enrolled overall. The study is open for recruitment at two tertiary academic hospitals in Israel, and 9 of the planned 54 patients have been enrolled. The NOGA trial represents a novel precision oncology approach in early TNBC, with the potential to minimize toxicity without compromising efficacy in selected responders. Clinical trial information: NCT07327021. Research Sponsor: None.

TPS655 **Poster Session**

A phase 2 clinical trial in progress of (Z)-endoxifen plus goserelin as neoadjuvant therapy in premenopausal women with ER+/HER2– breast cancer (EVANGELINE). First Author: Steven Quay, Atossa Therapeutics, Inc., Seattle, WA

Background: Early (14-28 day) on-treatment suppression of tumor proliferation during neoadjuvant endocrine therapy (NET) is strongly associated with favorable long-term outcomes in estrogen receptor–positive (ER+) HER2– breast cancer. In premenopausal women, tamoxifen with or without ovarian function suppression (OFS) results in suboptimal Ki-67 suppression compared with aromatase inhibitor + OFS. (Z)-endoxifen (ENDX), the active metabolite of tamoxifen, dually inhibits ER signaling and PKCβ1-mediated AKT activation, supporting its evaluation as an alternative NET strategy in this population. **Methods:** EVANGELINE (NCT05607004) is an ongoing, multicenter, open-label Phase 2 study evaluating daily 40 mg ENDX plus goserelin administered every 28 days as neoadjuvant therapy in premenopausal women with ER+/HER2–, cT2–3, cN0–1 breast cancer. The primary objective is to determine the proportion of patients with baseline Ki-67 $>$10% who achieve Ki-67 $\leq$10% after 4 weeks of therapy. A Simon two-stage design is used to test whether the Week 4 Ki-67 $\leq$10% rate is at least 65%, with 20 patients enrolled into the first stage and, if promising, another 25 patients enrolled into the second stage (cohort A). A parallel cohort of 20 patients with baseline Ki-67 $\leq$10% (cohort B) is enrolled to assess objective response rate (ORR) at 24 weeks per RECIST v1.1. Secondary objectives include examining safety and tolerability, residual cancer burden, and PEPI score. Correlative analyses include examining effect of treatment on select tumor and plasma biomarkers. Clinical trial information: NCT05607004. Research Sponsor: Atossa Therapeutics Inc.

TPS656 **Poster Session**

ETHAN: A phase II study comparing different endocrine therapies for male breast cancer. First Author: Jose Pablo Leone, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Male breast cancer is a rare disease, and most cases are hormone receptor-positive (HR+). Due to a lack of clinical trials, male breast cancer has historically been treated based on data extrapolated from women. However, there are substantial knowledge gaps in the comparative efficacy, safety, and patient-reported outcomes of endocrine therapies for men. While tamoxifen is the current standard of care, additional data are warranted for aromatase inhibitors (AI), gonadal suppression, and cyclin-dependent kinase 4/6 (CDK4/6) inhibitors. **Methods:** This is an open-label, multicenter, randomized, phase II trial designed to evaluate different endocrine therapies in men with HR+ and human epidermal growth factor receptor 2 (HER2)-negative breast cancer. A total of 60 men will be enrolled across 9 sites within the Translational Breast Cancer Research Consortium (TBCRC). Key eligibility criteria include male sex and stage I, II, or III HR+/HER2- breast cancer before surgical resection of the primary tumor and axillary nodes. Key exclusion criteria include prior anti-cancer therapy within the past 12 months, and inflammatory breast cancer. The trial has two phases. The first phase is a window of opportunity in which newly diagnosed men are randomized 1:1:1 to either tamoxifen (Arm A), anastrozole (Arm B), or anastrozole plus degarelix (Arm C) given for 3 weeks. The primary endpoint for the window phase is Ki-67 reduction from the baseline diagnostic biopsy to the research biopsy at the end of the window phase. The second phase consists of neoadjuvant treatment, in which the tamoxifen group is randomized 1:1 to tamoxifen (Arm D) vs tamoxifen plus abemaciclib (Arm E), and the anastrozole alone (Arm B) and anastrozole plus degarelix (Arm C) groups are merged and then randomized 1:1 to anastrozole plus degarelix (Arm F) vs anastrozole plus degarelix plus abemaciclib (Arm G). The duration of the neoadjuvant phase is 4 months, and the primary endpoint of this phase is residual cancer burden (RCB) index at time of surgery. The trial is powered for the RCB endpoint in a 2 x 2 factorial design to detect a 0.6 unit decrease in RCB index with 80% power and alpha = 10%. For the Ki-67 endpoint, we assume an approximately 50% reduction in Arms A and B; Arm C will be of interest if it leads to $\geq$80% reduction in Ki-67. Secondary endpoints include: change in estradiol and testosterone levels from baseline, preoperative endocrine prognostic index (PEPI) score at surgery, adverse events, and patient-reported outcomes (including quality of life). Tumor tissue will be collected for correlative analyses. The study opened at Dana-Farber in October 2023, and is also open at Mayo Clinic, MD Anderson Cancer Center, Georgetown University, University of North Carolina, University of Pennsylvania, University of Pittsburgh, and Vanderbilt University. One more site will open in 2026. Clinical trial information: NCT05501704. Research Sponsor: TBCRC; BCRF; Eli Lilly; U.S. National Institutes of Health; Male Breast Cancer Global Alliance.

TPS657 **Poster Session**

Stereotactic body radiotherapy (SBRT) combined with PD-1 inhibitor and chemotherapy in early-stage treatment-naive triple-negative breast cancer patients: A multicenter phase III clinical study. First Author: Lei Liu, West China Hospital of Sichuan University, Chengdu, China

Background: Early-stage triple-negative breast cancer (TNBC) carries a high risk of locoregional recurrence and distant metastasis. The KEYNOTE-522 trial established that adding an immune checkpoint inhibitor to neoadjuvant chemotherapy in high-risk early-stage TNBC yields a pathologic complete response (pCR) rate of 64.8%. However, nearly 40% of patients still fail to achieve pCR. Radiotherapy not only directly eradicates tumor cells but also can induce systemic immunomodulatory effects, such as promoting tumor antigen release and enhancing T-cell infiltration. Therefore, combining radiotherapy with immune checkpoint inhibitors and chemotherapy represents a promising strategy to improve outcomes in early-stage TNBC. Preliminary data from small-sample, single-arm studies suggest that neoadjuvant stereotactic body radiotherapy (SBRT) combined with an anti-PD-L1 antibody and chemotherapy can increase pCR rate to 90%(Liu C., et al., *Elife*, 2023). However, this therapeutic modality lacks large-scale clinical data to further confirm the radiosensitizing effect of radiotherapy on immune checkpoint inhibitors. This phase III, randomized, controlled, multicenter study aims to evaluate the efficacy and safety of toripalimab (an anti-PD-1 monoclonal antibody) plus chemotherapy with or without SBRT in treatment-naïve TNBC patients. **Methods:** Eligible patients are treatment-naïve, non-metastatic TNBC with clinical stage cT1cN1-2M0 or cT2N0-2M0 (AJCC 8th edition). Patients are randomized 1:1 to receive toripalimab (240 mg, intravenously, every 3 weeks for 8 cycles) plus nab-paclitaxel (260 mg/m^2, intravenously, every 3 weeks for cycles 1-4) and carboplatin (AUC=5, intravenously every 3 weeks for cycles 1-4) and epirubicin (90-100 mg/m^2, intravenously, every 3 weeks for cycles 5-8) and cyclophosphamide (600 mg/m^2, intravenously every 3 weeks for cycles 5-8), with or without SBRT (8 Gy $\times$ 3 fractions). All patients undergo surgery 4-8 weeks after completing neoadjuvant therapy. The primary endpoint is investigator-assessed pCR. Secondary endpoints include breast conservation rate, ipsilateral breast recurrence or locoregional recurrence, overall survival (OS), and safety. Sample size was calculated assuming a pCR rate of 64.8% in the control arm (based on KEYNOTE-522) and 80% in the experimental (SBRT) arm. With a one-sided α of 0.025, 80% power, 1:1 allocation, and accounting for a 20% dropout rate, 159 patients per arm (total N=318) are enrolled. The study was initiated in November 2024. Clinical trial information: NCT06627712. Research Sponsor: National Major Science and Technology Projects.

TPS658 **Poster Session**

The SURVIVE study: Re-evaluating follow-up in early breast cancer. First Author: Sophia T. Huesmann, Department of Gynecology and Obstetrics, University Hospital Ulm, Ulm, Germany

Background: For decades, international guidelines unanimously recommended limiting routine follow-up in early breast cancer (EBC) to clinical exams and breast imaging, to detect potentially curable local relapse early. Additionally, guidelines explicitly advise against screening for distant recurrence in asymptomatic patients, as there remains no survival benefit in patients with earlier detected metastatic disease to date, at the cost of quality of life (1). However, as most of this data was published over 30 years ago, a re-evaluation of EBC follow-up strategies is urgently needed, considering numerous novel treatment options for both EBC and metastatic breast cancer patients. **Methods:** Study Design: The SURVIVE study is a prospective, multicenter, randomized controlled trial investigating a liquid-biopsy based follow-up in intermediate- to high-risk EBC patients. 3.500 EBC patients after completion of primary therapy (surgery, chemo- or radiotherapy) are randomized 1:1 to either standard or liquid-biopsy guided (intensified) follow-up. All patients receive guideline-based follow-up procedures. Additionally, blood samples are taken every 3 months (years 1–3), later every 6 months (years 4–5). While samples from patients in the standard-arm are biobanked, samples from the interventional arm are analyzed longitudinally for tumor markers (CA 27.29, CEA, CA 125, Tosoh Bioscience), CTCs (CellSearch, Menarini), and ctDNA (RaDaR, Neogenomics). The detection of abnormalities via liquid biopsy leads to staging examinations. For patients with confirmed recurrence, treatment hereafter follows national guidelines. The detection of true molecular relapse (positive liquid biopsy without clinical evidence of recurrence) leads to further monitoring within the SURVIVE protocol and creates the unique opportunity for treatment-intervention studies, such as SURVIVE HERoes (NCT06643585). Endpoints: The two co-primary endpoints are overall survival (OS) and the lead time, measured as the time from positive biomarker to positive imaging in the interventional arm. Secondary endpoints include breast cancer-specific survival, quality of life, and biomarker performance. Recruitment: As of January 2026, recruitment is active in 98 study centers in Germany. Currently, nearly 2,400 patients have been randomized since December 2022. **Conclusion:** The SURVIVE study is a long-anticipated study assessing whether intensified follow-up, guided by liquid biopsy, leads to earlier detection of recurrence and improved overall survival in EBC. TPS659 **Poster Session**

Pre-operative chemotherapy versus surgery first with peri-operative interventions in early triple-negative and HER2-positive breast cancer: An open-label, phase 3, randomized controlled trial (PRaCTiSE). First Author: Shalaka Prakash Joshi, Tata Memorial Hospital and Homi Bhabha National Institute, Mumbai, India

Background: Surgery is a mainstay of treatment of breast cancer. Neoadjuvant chemotherapy (NACT) has not proven to be more effective in improving long-term outcomes when compared with adjuvant (EBCTCG, Lancet Oncol, 2018). Although pathological complete response (pCR) is surrogate at the individual patient level, it has not translated into improved outcomes across trials (BMJ, 2021).Triple-negative (TN) and HER2-positive breast cancer patients with non-pCR are treated with risk-adapted maintenance regimens (NEJM, 2025; NEJM, 2017). We previously proved efficacy of pre-operative progesterone and intra-operative peri-tumoural lignocaine in improving disease-free and overall survival (JCO, 2011; JCO, 2023). We are currently testing the effectiveness of a “Surgery first” versus “PRe-operative ChemoTherapy” approach in patients with early TN and HER2-positive tumours. **Methods:** This is a prospective, open-label randomized trial. Patients with cT1c/2,cN0/1, histologically proven, TN or HER2-positive breast cancer are screened. The study is approved by Institutional Ethics and has been registered on CTRI (CTRI/2024/02/063118). Eligible patients fit for surgery and NACT are randomized after consenting. Stratification criteria are menopausal status (pre-peri/post), cN stage (N0/N1), and TN/HER2+. “Surgery first” arm receives intramuscular progesterone injection 4-14 days before surgery and peri-tumoral 0.5% lignocaine infiltration intra-operatively. All patients are treated with standard adjuvant chemotherapy and targeted therapy and radiotherapy protocols. “PRe-operative ChemoTherapy” arm receives standard NACT. Chemotherapy backbone is anthracycline, cyclophosphamide, and paclitaxel in all patients, with addition of carboplatin and pembrolizumab in NACT for TN and anti-HER2 targeted therapy (dual if node positive) in HER2+ setting. Response assessment is done clinically after each cycle and with imaging after every 3-4 cycles. Maintenance pembrolizumab/capecitabine for TN and anti-HER2 targeted therapy/t-DM1 for HER2+ tumours as per response is offered for standard duration. Surgery in both arms is breast conservation surgery with or without oncoplasty or mastectomy with or without reconstruction, depending on imaging findings, response, and patient choice. All primary tumors are clipped in NACT arm. Axillary staging procedure is carried out and, if positive macro-metastatic nodes on frozen section, level I-III axillary dissection is done. A total sample size of 1350 (1500 accounting for loss-to-follow-up) split equally between two groups, or 257 events, achieves 80% power to detect hazard rate of 0.70173 when the proportions surviving in each group are 0.78 and 0.84 at a significance level (alpha) of 0.05 using a two-sided log rank test. An interim is planned at 50% DFS events. Clinical trial information: CTRI/2024/02/063118. Research Sponsor: None.

1001 **Oral Abstract Session**

Progression-free survival after next line of treatment (PFS2) and subsequent therapies (subs tx) in the ASCENT-03 study of participants (pts) with previously untreated metastatic triple-negative breast cancer (mTNBC) treated with sacituzumab govitecan (SG) vs chemotherapy (chemo). First Author: Sara A. Hurvitz, Department of Medicine, UW Medicine, Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, WA

Background: In ASCENT-03, first-line (1L) SG led to a clinically meaningful improvement in PFS vs chemo (median, 9.7 vs 6.9 months [mo]; hazard ratio [HR], 0.62; 95% CI, 0.50-0.77; $P < .0001$) in previously untreated pts with mTNBC who were not candidates for PD-(L)1 inhibitors. Since overall survival data are immature, PFS2 can be used to assess long-term benefit as it accounts for the impact of initial and subs tx, including trial crossovers. We report PFS2 and subs tx from ASCENT-03. **Methods:** Pts (N = 558) were randomized 1:1 to SG (10 mg/kg IV, days 1 & 8 in 21-day cycles) or chemo (paclitaxel, nab-paclitaxel, or gemcitabine + carboplatin); primary end point was PFS by blinded independent central review (BICR). Eligible pts in the chemo group could receive 2L SG provided on study via crossover following BICR-verified progressive disease or in any subs line commercially; other subs txs per local practice were also permitted. PFS2 was defined as the time from randomization to the first documented progression on next-line therapy per investigator assessment or death due to any cause, whichever occurred first. **Results:** Median follow-up for OS was 13.2 mo; 75 (27%) pts remained on study treatment in the SG group (n = 279) and 39 (14%) in the chemo group (n = 279). Of the 204 pts in the SG group who discontinued tx, 126 received any subs tx, the most frequent of which were platinum chemo (40%), taxanes (29%), and gemcitabine (19%). Of 240 pts in the chemo group who discontinued tx, 179 received any subs tx, the most frequent of which were SG (82%), capecitabine (16%), platinum chemo (9%), and trastuzumab deruxtecan (9%). Median (95% CI) PFS2 was 18.2 mo (15.9-not reached [NR]) in the SG group and 14.0 mo (12.5-17.4) in the chemo group (stratified HR, 0.70; 95% CI, 0.55-0.90). PFS2 rates are in the Table. Median (95% CI) time to first subs tx was 11.2 mo (10.0-13.0) and 7.9 mo (7.2-9.0) for SG and chemo, respectively; median (95% CI) time to second subs tx was 17.3 mo (15.2- NR) and 16.6 mo (13.6-18.5). **Conclusions:** PFS2 was improved in the SG group compared with the chemo group despite crossover tx, with most pts who initiated subs tx in the chemo group receiving SG. The benefit of first-line SG is clinically relevant and sustained until the next line of therapy, which further supports SG as a potential new standard of care in pts with previously untreated mTNBC who are not candidates for PD-(L)1 inhibitors. Clinical trial information: NCT05382299. Research Sponsor: Gilead Sciences, Inc.

1002 **Oral Abstract Session**

First-line datopotamab deruxtecan (Dato-DXd) vs chemotherapy in patients with locally recurrent inoperable or metastatic triple-negative breast cancer (TNBC) for whom immunotherapy was not an option: Additional efficacy endpoints from the TROPION-Breast02 study. First Author: David W. Cescon, Princess Margaret Cancer Centre/UHN, Toronto, ON, Canada

Background: In the primary analysis of the phase 3 TROPION-Breast02 study (NCT05374512), first-line Dato-DXd demonstrated statistically significant and clinically meaningful improvements in overall survival (OS; hazard ratio [HR]: 0.79 [95% confidence interval [CI]: 0.64–0.98]; p = 0.0291) and progression-free survival (PFS; HR: 0.57 [95% CI: 0.47–0.69]; p < 0.0001) compared with investigator's choice of chemotherapy (ICC) in patients with locally recurrent inoperable or metastatic TNBC for whom immunotherapy was not an option. Both median OS and PFS by blinded independent central review (BICR) were ≥5 months longer with Dato-DXd compared with ICC. Moreover, with Dato-DXd vs ICC, the confirmed objective response rate was more than double and median duration of response was > 5 months longer. The Dato-DXd safety profile was manageable and generally consistent with the known profile. Here we report additional efficacy endpoints. **Methods:** Adult patients with previously untreated locally recurrent inoperable or metastatic TNBC, for whom immunotherapy was not an option, were randomized 1:1 to Dato-DXd (6 mg/kg IV every 3 weeks) or ICC ([nab]-paclitaxel/capecitabine/eribulin mesylate/carboplatin). Dual primary endpoints were OS and PFS by BICR per RECIST 1.1; secondary endpoints included time to second progression or death (PFS2), time to first subsequent therapy or death (TFST), and time to second subsequent therapy or death (TSST). The planned sample size was approximately 600 randomized patients. A stratified log-rank test was used to analyze PFS2, TFST, and TSST. HRs and 95% CIs were estimated from a stratified Cox proportional hazards model. **Results:** A total of 644 patients were randomized (Dato-DXd: 323; ICC: 321). At data cutoff (25 Aug 2025), median study follow-up was 27.5 months and 53 (8.4%) patients remained on treatment (Dato-DXd: 45 [14.1%]; ICC: 8 [2.6%]). PFS2 was longer with Dato-DXd vs ICC: median 15.6 vs 11.8 months (HR: 0.61 [95% CI: 0.50–0.74]). Both TFST and TSST were prolonged in the Dato-DXd vs ICC arm: median TFST was 10.9 vs 5.6 months with Dato-DXd vs ICC (HR: 0.49 [95% CI: 0.41–0.59]) and median TSST was 16.7 vs 12.6 months (HR: 0.67 [95% CI: 0.55–0.81]). **Conclusions:** In TROPION-Breast02, improvements in the secondary endpoints of PFS2, TFST, and TSST were observed for patients receiving Dato-DXd compared with ICC, consistent with the dual primary endpoints of OS and PFS by BICR. Alongside the manageable safety profile for Dato-DXd, these data further support Dato-DXd as the new first-line standard of care in this setting. Clinical trial information: NCT05374512. Research Sponsor: This trial is sponsored by AstraZeneca. In July 2020, Daiichi Sankyo entered into a global development and commercialisation collaboration with AstraZeneca for datopotamab deruxtecan (Dato-DXd).

Izalontamab brengitecan (iza-bren) versus physician's choice of chemotherapy in patients with unresectable locally advanced or metastatic triple-negative breast cancer (TNBC): A randomized phase III study. First Author: Jiong Wu, Fudan University Shanghai Cancer Center, Shanghai, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

1004 Oral Abstract Session

Prevalence of symptomatic skeletal events (SSE) with reduced denosumab (Dmab) dose density (every 12 weeks versus every 4 weeks): A randomized phase III non-inferiority trial SAKK 96/12 REDUSE. First Author: Roger Anton Fredy Von Moos, Kantonspital Graubünden, Chur, Switzerland

Background: Clinical guidelines recommend Dmab 120 mg every 4 weeks (Q4W) for patients (pts) with bone metastases. While dosing every 12 weeks (Q12W) is established for zoledronic acid based on phase III trials, prospective trials with Dmab evaluating the efficacy endpoint of skeletal-related events (SRE) for a Q12W schedule are missing. The results of an early dose-finding study of Dmab demonstrated a similar suppression of bone-turnover markers for 60 mg Q12W as for 120 mg Q4W at weeks 13 and 25, suggesting that Q12W dosing might be sufficient. The SAKK 96/12 REDUSE trial investigated whether a de-escalated Dmab schedule is non-inferior to the standard Q4W regimen in preventing symptomatic skeletal related events (SSEs; symptomatic pathological fracture, radiation or surgery to bone, or spinal cord compression). **Methods:** In this international, multicenter, randomized, phase III trial, pts with metastatic breast cancer (BC) or castration-resistant prostate cancer (CRPC) and at least three bone metastases were randomized 1:1. Arm A (standard) received Dmab 120 mg Q4W. Arm B (reduced) received 4 loading doses Q4W, followed by Q12W dosing. The primary endpoint was time to first on-trial SSE. The sample size of 1,380 pts was calculated to demonstrate non-inferiority using a log-rank test with a non-inferiority margin of 1.20 (80% power, 5% type I error). Secondary endpoints included time to first and subsequent on-trial SSE, and toxicity focusing on hypocalcemia and osteonecrosis of the jaw (ONJ). A health economic analysis is ongoing. **Results:** 1,380 pts were enrolled between 7/2014 and 3/2024 (784 and 596 with BC and CRPC, respectively). Median follow-up time was 37 months (mo) (42 mo for BC and 29 mo for CPRC). The trial met its primary endpoint, demonstrating that denosumab Q12W is non-inferior to Q4W. Median time to first on-trial SSE for arm A was 56.6 mo (95% CI (40.7, not reached [NR]) and for arm B 56.5 mo (95% CI 47.7, NR). The stratified HR and 90% CI calculated using a Cox regression model is 1.023 (0.874, 1.197) with the upper limit remaining below 1.20. Also, for time to first and subsequent on-trial SSE, non-inferiority was shown with a stratified HR 1.043 (90% CI 0.907, 1.198). Safety analysis showed less toxicity for the Q12W arm: Hypocalcemia occurred in 46% (Arm A) vs 30% (Arm B), and ONJ was reported in 8.5% vs 6.9% of pts, respectively. **Conclusions:** The SAKK 96/12 REDUSE trial demonstrates that a Dmab Q12W schedule, following a 3-month loading phase, is non-inferior to the Q4W regimen in pts with bone-metastatic BC or CRPC. The observed lower rates in ONJ and hypocalcemia indicate a more favorable safety profile for the Q12W schedule. These data indicate that Dmab Q12W represents the new standard of care in pts with bone metastasis from BC or CRPC, offering comparable efficacy while reducing toxicity, treatment burden, and costs. Clinical trial information: NCT02051218. Research Sponsor: Santesuisse; CSS and Helsana health insurance; Swiss Cancer Institute, Switzerland.

1005 Oral Abstract Session

Efficacy and safety of tucatinib (TUC) vs placebo (PBO) combined with trastuzumab and pertuzumab (HP) as maintenance therapy for HER2+ metastatic breast cancer by stratified subgroups. First Author: Erika P. Hamilton, Breast Cancer Research Program, Sarah Cannon Research Institute, Nashville, TN

Background: In the phase 3 HER2CLIMB-05 study (NCT05132582), TUC + maintenance HP demonstrated a statistically significant improvement in progression-free survival (PFS) vs control treatment (Tx) (hazard ratio: 0.641, $P < 0.0001$) in patients (pts) with HER2+ locally advanced or metastatic breast cancer (MBC). Here we report additional efficacy and safety outcomes by stratified subgroups. **Methods:** Pts with centrally confirmed HER2+ MBC without evidence of progression following chemotherapy-based induction Tx (taxane + HP) were randomly assigned 1:1 to TUC (300 mg) or PBO BID + HP. Randomization was stratified by diagnosis (*de novo*/recurrent), hormone receptor (HR) status (positive/negative), and presence or history of brain metastases (BM; yes/no). Endocrine therapy (ET) is permitted for pts with HR+ disease. The primary endpoint is investigator-assessed PFS. Confirmed objective response rate (cORR), duration of response (DOR), and safety were evaluated in stratified subgroups. **Results:** Among pts assigned to TUC + HP (n = 326) or PBO + HP (n = 328), ~69% had *de novo* MBC, ~53% had HR+ status with ~45% having received concurrent ET, and ~12% had baseline BM. At data cutoff (Sep 5, 2025), median PFS was longer with TUC than PBO + HP in all stratified subgroups; TUC + HP consistently improved cORR vs PBO + HP (Table). Safety outcomes in subgroups aligned with the overall population. **Conclusions:** TUC + HP demonstrated clinically meaningful efficacy vs PBO + HP in pts with *de novo* or recurrent disease, HR+ or HR− disease, and baseline BM or not, with no new safety signals identified. Results were consistent with the overall population and support TUC + HP as a potential new maintenance therapy across pts with HER2+ MBC. Clinical trial information: NCT05132582. Research Sponsor: Pfizer Inc.

1009 Clinical Science Symposium

Efficacy and safety of camrelizumab combined with docetaxel and carboplatin as neoadjuvant therapy for triple-negative breast cancer: The HELEN-Trio 011 randomized clinical trial. First Author: Zhenzhen Liu, The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China

Background: The KEYNOTE-522 trial demonstrated that adding a PD-1 inhibitor to neoadjuvant chemotherapy significantly improves pathological complete response (pCR) rates, albeit with notable toxicity. The phase III Camrelief trial further confirmed that camrelizumab combined with sequential neoadjuvant chemotherapy significantly improved pCR compared with placebo in early-stage triple-negative breast cancer (TNBC). This study aimed to evaluate the efficacy and safety of camrelizumab plus neoadjuvant docetaxel and carboplatin in previously untreated stage II–III TNBC. **Methods:** This multicenter, randomized, open-label, phase III trial (ClinicalTrials.gov identifier: NCT05475678) enrolled eligible female patients aged 18-70 years with previously untreated stage II-III TNBC. Patients were randomized (2:1) to receive six 21-day cycles of docetaxel (75 mg/m²) and carboplatin (area under the curve=6) on day 1, with or without camrelizumab (200 mg intravenously on day 3). The primary endpoint was pCR (ypT0/Tis ypN0), assessed in the modified intention-to-treat (mITT) population, which included all patients who received at least one dose of the trial treatment. **Results:** Between December 2022 and June 2025, 369 patients from fourteen hospitals in China were enrolled and randomized to the camrelizumab-chemotherapy group (n=245) or the chemotherapy-alone group (n=124), of whom 352 comprised the mITT population. The pCR rate was 57.5% (134 of 233) in the camrelizumab-chemotherapy group versus 45.4% (54 of 119) in the chemotherapy-alone group (absolute difference, 12.2 percentage points; 95% CI, 1.4-22.9; one-sided P= 0.014). In the prespecified exploratory subgroup (CPS $\geq$1), pCR rates were 69.8% (97/139; 95% CI, 62.2%-77.4%) with camrelizumab-chemotherapy and 51.9% (41/79; 95% CI, 40.9%- 62.94%) with chemotherapy-alone (absolute difference, 17.9%; 95% CI, 5.3%-30.5%; one-sided P = 0.004). In the PD-L1-negative subgroup (CPS $<$1), pCR rates were 37.8% (31/82; 95% CI, 27.4%-48.2%) and 28.1% (9/32; 95% CI, 12.5%-43.7%), respectively (absolute difference, 9.7%; 95% CI, -10.5%-29.9%; one-sided P = 0.165). Grade 3 or higher treatment-related adverse events occurred in 24.8% (58/233) of patients in the camrelizumab-chemotherapy group, and 21.8% (26/119) in the chemotherapy-alone group. No treatment related deaths were reported. **Conclusions:** The addition of camrelizumab to neoadjuvant docetaxel and carboplatin significantly improved pCR rates in patients with stage II–III TNBC with a manageable safety profile. This anthracycline-free regimen represents a promising neoadjuvant treatment option for early TNBC. Clinical trial information: NCT05475678. Research Sponsor: None.

1010 Clinical Science Symposium

Time-of-day administration of immunotherapy in early-stage triple-negative breast cancer: Immune-dependent chronotherapy effects in the phase III A-BRAVE trial. First Author: Maria Vittoria Dieci, Department of Surgery, Oncology and Gastroenterology, University of Padova; Division of Oncology 2, Istituto Oncologico Veneto IRCCS, Padova, Italy

Background: Circadian rhythms regulate immune functions, and morning (AM) administration of immunotherapy (IO) is associated with survival in several solid tumors. However, whether time-of-day (ToDa) of IO delivery influences outcomes in early-stage triple-negative breast cancer (TNBC), and whether this effect depends on immune biomarkers, remains unknown. **Methods:** A-BRAVE randomized patients with high-risk early-stage TNBC to 1 year of adjuvant avelumab or observation. Infusion time of avelumab was retrieved from eCRF. AM-rate was calculated for each patient as the proportion of the first 4 infusions occurring before 12:30 PM (cohort median ToDa) and patients categorized as AM-dominant (AM-rate $\geq$50%) or PM-dominant. Tumor-infiltrating lymphocytes (TILs) and PD-L1 (Dako 73-10) were centrally assessed on treatment-naive tumor samples. We analyzed distant disease-free survival (DDFS) and overall survival (OS) by adjusted Cox models. **Results:** ToDa data were available for 221 avelumab-treated patients (94.0%); TILs and PD-L1 were evaluable in 188 (85%) and 195 (88%) of these, respectively. AM-rate was not associated with outcomes. However, ToDa effects were strongly immune-dependent. Increasing AM-rate was associated with improved DDFS and OS in immune-hot tumors (TILs [$\geq$20%] or PD-L1 [$\geq$21] high), but with worse outcomes in immune-cold tumors (TILs or PD-L1 low) (AM-rate*TILs interaction: DDFS p=0.008, OS p=0.001; AM-rate*PD-L1 interaction: DDFS p=0.030, OS p=0.039). These findings were concordant using AM-dominant vs. PM-dominant categorization (Table). Patients receiving immune-aligned treatment (immune-hot/AM-dominant OR immune-cold/PM-dominant) had superior survival compared with immune-misaligned (immune-hot/PM-dominant OR immune-cold/AM-dominant) and the observational arm (TILs-based: 3-year OS 95.7% vs 75.2% vs 78.0%; p$<$0.001; PD-L1-based: 3-year OS 93.4% vs 79.4% vs 76.1; p=0.035). **Conclusions:** In early-stage TNBC, time of IO administration may be a driver of efficacy, with opposing effects according to baseline immune milieu. Immune-informed circadian alignment may represent a previously unrecognized determinant of IO efficacy in TNBC. Clinical trial information: NCT02926196. Research Sponsor: Merck KGaA; CrossRef Funder ID: 10.13039/100009945.

1011 Clinical Science Symposium

Primary results from the triple-negative cohort of TBCRC-053 (P-RAD): A randomized trial of no, low, or high dose preoperative radiation with pembrolizumab and chemotherapy in node-positive breast cancer. First Author: Alice Yoosun Ho, Houston Methodist Academic Institute, Houston, TX

Background: Approximately one-quarter of patients with node-positive, triple-negative breast cancer (TNBC) did not experience a complete nodal response to neoadjuvant chemo-immunotherapy in KEYNOTE-522. We conducted a randomized trial to evaluate whether no-, low-, or high-dose preoperative radiotherapy (RT) to the breast primary tumor combined with pembrolizumab (pembro) enhances tumor T-cell infiltration (TCI) and pathologic response in non-irradiated lymph node (LN) metastases (NCT04443348). **Methods:** Between 2021-2025, 55 patients with cT1c-T4c, cN1-3, cM0, ER/PR $<$ 10%, HER2-negative breast cancer and biopsy-proven, clipped axillary LN metastasis were randomized to no RT (0 Gy), low-dose RT (9 Gy) or high-dose RT (24 Gy) to the primary tumor with concurrent pembro, followed by an on-treatment tumor biopsy at 2 wks. Stratification factors included cT stage (T1c vs. T2-4) and cN stage (N1 vs. N2-3). Patients subsequently received pembro (200 mg q3w or 400 mg q6w) with 12 wks of paclitaxel/carboplatin, followed by four cycles of doxorubicin-cyclophosphamide (q2w or q3w) with pembro, surgery and adjuvant therapy. Primary endpoints were 2-wk tumor TCI and nodal pathologic complete response (ypN0) at surgery. TCI was assessed by multiplexed immunofluorescence (panCK/CD3/CD8) using a rank-based Immunoscore. 2-wk TCI for each treatment arm was compared to a common reference cohort of pretreatment TCI measurements. The study was powered to detect an increase in upper-quartile TCI from 25% to 55%. Statistical comparisons used two-tailed Fisher's exact tests. ypN0 and secondary endpoints pCR (ypT0/TisN0) and Residual Cancer Burden (RCB) 0/1 were underpowered for a statistical test. **Results:** Among 55 enrolled patients, 48 were evaluable for TCI and 51 for ypN0. Median age was 50 years (range 28-77). 81.8% had cT2-4 disease, 20% had cN2-3, and 87.3% had grade 3 tumors. The proportion of tumors with upper-quartile TCI was significantly increased with RT plus pembro, but not pembro alone, when compared to the pretreatment cohort: 44% (0Gy; p = NS), 80% (9Gy, p $<$ 0.0001), and 82% (24Gy; p $<$ 0.0001). ypN0 rates were 73.3% (0Gy), 88.2% (9Gy) and 78.9% (24Gy). pCR/RCB 0-1 rates were 66.6%/66.6% (0Gy), 76.5%/82.4% (9Gy) and 68.4%/84.2% (24Gy). Tumors with upper-quartile TCI at the 2-wk timepoint had a significantly higher ypN0 rate relative to tumors without upper-quartile TCI (94% [31/33] vs. 46% [6/13]; p = 0.0009). **Conclusions:** The addition of preoperative RT to pembro significantly increased 2-wk TCI and yielded high rates of ypN0 and pCR after chemo-immunotherapy, with the numerically highest ypN0 rate observed in the 9Gy arm. 2-wk TCI correlated strongly with surgical ypN0 status. A larger study that tests whether preoperative RT and pembro increases pCR should be conducted in node-positive TNBC. Clinical trial information: NCT04443348. 1012 Clinical Science Symposium

Trastuzumab deruxtecan (T-DXd) + durvalumab (D) in patients (pts) with previously untreated HER2+ unresectable/metastatic breast cancer (mBC): Final analysis from DESTINY-Breast07. First Author: Sherene Loi, Breast Unit, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: T-DXd is approved for adult pts with HER2+ mBC who received a prior anti-HER2–based regimen, or as 1L therapy when given in combination with pertuzumab (P). DESTINY-Breast07 (NCT04538742) is a Phase 1b/2, open-label, platform study exploring the safety, tolerability, and antitumor activity of T-DXd $\pm$ other anticancer agents in HER2+ mBC. 1L T-DXd $\pm$ P recently showed encouraging clinical activity and safety profiles consistent with previous reports. D, an anti-PD-L1 antibody, has shown efficacy in combination with T-DXd in HER2-low, hormone receptor (HR)–negative mBC. As part of the DESTINY-Breast07 final analysis, here we report the dose-expansion phase for T-DXd + D as a 1L treatment in HER2+ mBC. **Methods:** Pts had locally assessed HER2+ (IHC 3+ or IHC 2+/ISH+) mBC. A disease-free interval of $\geq$12 months (mo) from (neo)adjuvant therapy was required; no prior therapy for mBC was allowed. Pts were stratified by HR (positive vs negative), disease (recurrent vs de novo), and PD-L1 status (positive vs negative; positive defined as $\geq$1% IHC). Pts received T-DXd 5.4 mg/kg IV, in combination with D 1120 mg IV, every 3 weeks. Primary endpoints were safety and tolerability; secondary endpoints included confirmed ORR (cORR), duration of response (DOR) and progression-free survival (PFS) per RECIST 1.1 by investigator, time to progression on subsequent therapy or death (PFS2) by investigator, and overall survival (OS). **Results:** At data cutoff (DCO) (January 31, 2025), 64 pts were randomized to the T-DXd + D module, and 63 received treatment. Median follow up was 30.1 mo; median total treatment duration was 26.7 mo for T-DXd and 24.6 mo for D. Efficacy results are given in the Table. The most common adverse events (AEs) were nausea (79.4%), vomiting (46.0%), neutropenia (46.0% by grouped term [GT]), anemia (44.4% by GT), and fatigue (38.1%). Grade $\geq$3 AEs occurred in 58.7% (n=37/63) and serious AEs in 30.2% (n=19/63) of pts. There were two deaths due to AEs (3.2%): one pt with neutropenia and septic shock and one pt with sepsis. Adjudicated drug-related interstitial lung disease (ILD)/pneumonitis events occurred in 11 (17.5%; Grade 1, n=1; Grade 2, n=8; Grade 3, n=2) pts. Additional data by subgroups (stratification factors and biomarkers) will be presented. **Conclusions:** Encouraging clinical activity was seen for T-DXd + D as a 1L treatment for HER2+ mBC. Safety profiles were consistent with the known profiles for each therapy, with no fatal ILD events. These promising results provide a rationale for further investigation of this treatment combination. Clinical trial information: NCT04538742. Research Sponsor: AstraZeneca.

1013 Rapid Oral Abstract Session

ASCENT-04: Analysis of efficacy by biomarker subgroups with sacituzumab govitecan (SG) + pembrolizumab (pembro) vs chemotherapy (chemo) + pembro in participants (pts) with previously untreated PD-L1+ metastatic triple-negative breast cancer (mTNBC). First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: In the phase 3 ASCENT-04/KEYNOTE-D19 study (NCT05382286) SG + pembro showed significant and clinically meaningful progression-free survival (PFS) improvement vs chemo + pembro in pts with previously untreated PD-L1+ mTNBC. SG + pembro exhibited a manageable safety profile consistent with prior studies for each agent. We present preplanned exploratory efficacy analyses in ASCENT-04 by biomarker subgroups. **Methods:** 443 pts received (1:1 ratio) SG + pembro in 21-day cycles or chemo (gemcitabine + carboplatin; taxane) + pembro. From centrally tested fresh or archival tumor samples, Trop-2 expression was determined by immunohistochemistry (IHC), tumor BRCA (tBRCA) status by whole exome sequencing, and HER2 expression by in situ hybridization (ISH) + IHC. Pts were grouped by Trop-2 expression quartiles, tBRCA status (wild-type [WT] or mutant [mut] in *BRCA1/BRCA2*/both), and HER2 status (IHC 0 vs Low [IHC 1+ or IHC 2+/ISH−]). Biomarker subgroups were analyzed descriptively for association with PFS by blinded independent central review (BICR); other outcomes by biomarker status are forthcoming. **Results:** Median Trop-2 H-score was 280, ranges: quartile 1 (Q1) 0-224, Q2 225-279, Q3 280-298, Q4 299-300. SG + pembro demonstrated longer PFS by BICR in Q3/Q4 vs Q1/Q2, and benefit was observed for SG + pembro vs chemo + pembro in all quartiles (Table). Hazard ratios (HR; 95% confidence interval [CI]) were: Q1, 0.81 (0.48-1.36); Q2, 0.73 (0.44-1.22); Q3, 0.46 (0.27-0.80); Q4, 0.57 (0.33-0.99). Proportion of pts with tBRCA mutations (~20%) was similar between treatment groups. Longer PFS was observed with SG + pembro with HR (95% CI) of 0.67 (0.49-0.91) in the tBRCA WT and 0.88 (0.45-1.74) in the tBRCA mut subgroups. PFS was longer with SG + pembro vs chemo + pembro in the HER2 IHC 0 and HER2 low subgroups, HR (95% CI) 0.69 (0.46-1.04) and 0.67 (0.48-0.92), respectively. **Conclusions:** SG + pembro demonstrated longer PFS vs chemo + pembro across all Trop-2, tBRCA, and HER2 subgroups. These analyses strengthen support for the significant, clinically meaningful benefit of SG + pembro as first-line treatment for mTNBC across subgroups. Clinical trial information: NCT05382286. Research Sponsor: Gilead Sciences, Inc.

ASCENT-03: Efficacy by biomarker subgroup with sacituzumab govitecan (SG) vs chemotherapy (chemo) in participants (pts) with previously untreated advanced triple-negative breast cancer (TNBC) who are not candidates for PD-(L)1 inhibitors (PD-[L]1i). First Author: Carlos H. Barrios, Latin American Cooperative Oncology Group, LACOG, Porto Alegre, Brazil

Background: SG demonstrated significant and clinically meaningful progression-free survival (PFS) improvement vs chemo in pts with previously untreated, locally advanced unresectable or metastatic TNBC who were not candidates for PD-(L)1i in ASCENT-03 (NCT05382299). We report preplanned exploratory efficacy analyses in ASCENT-03 by Trop-2 expression, BRCA status, and HER2 expression. **Methods:** 588 pts randomized 1:1 to SG or chemo (taxane or gemcitabine + carboplatin). Trop-2 expression was measured by immunohistochemistry (IHC), tumor BRCA (tBRCA) status by whole exome sequencing, and HER2 expression by in situ hybridization (ISH) and IHC, all in centrally tested tumor samples (fresh or archival; 43% from metastatic sites). Pts were subgrouped by Trop-2 expression quartile, tBRCA wild-type (WT) or mutant (mut; mut in *BRCA1, BRCA2,* or both) status, and HER2 status (IHC 0 vs Low [IHC 1+ or IHC 2+/ISH-]). Biomarker status was analyzed to determine association with PFS by blinded independent central review (BICR). Other efficacy outcomes by biomarker status will be presented. **Results:** Median Trop-2 H-score: 240; H-scores by quartile (Q): Q1 0-184, Q2 185-239, Q3 240-283, Q4 284-300. Trop-2 expression was available in 499 pts. PFS by BICR was longer with SG vs chemo in all Trop-2 expression quartiles (Table). Hazard ratio (HR; 95% confidence interval [CI]) was 0.54 (0.35-0.84) in Q1, 0.62 (0.40-0.97) in Q2, 0.84 (0.54-1.31) in Q3, and 0.60 (0.38-0.95) in Q4. tBRCA status was available in 423 pts; proportion of pts with tBRCA mutations was comparable between treatment groups (~18%). PFS was longer with SG vs chemo in tBRCA WT and mut subgroups, with HR (95% CI) 0.70 (0.54-0.92) in tBRCA WT and 0.59 (0.32-1.09) in tBRCA mut. HER2 status was available in 551 pts; PFS was longer with SG vs chemo in both HER2 subgroups. HR was 0.63 (0.46-0.85) in the IHC 0 subgroup and 0.74 (0.55-1.01) in the HER2 Low subgroup. **Conclusions:** PFS was longer with SG vs chemo across all Trop-2 categories, tBRCA genotypes, and HER2 subgroups. These results reinforce the significant, clinically meaningful benefit of SG as first-line treatment for pts in this population across multiple biomarker subgroups. Clinical trial information: NCT05382299. Research Sponsor: Gilead Sciences, Inc.

1015 Rapid Oral Abstract Session

Impact of food access and poverty on somatic genomic profiles and clinical outcomes in metastatic breast cancer. First Author: Emily L. Podany, Washington University in St. Louis, St. Louis, MO

Background: Patients living in food deserts or experiencing food insecurity have higher cancer mortality rates. While neighborhood poverty correlates with more aggressive tumor biology, including higher OncotypeDX scores and rates of *TP53* mutations, the associations among food access, somatic genomic profiles, and clinical outcomes in metastatic breast cancer (MBC) remain understudied. **Methods:** This multi-institutional retrospective cohort study included patients with MBC and circulating tumor DNA (ctDNA) testing through the Guardant360 assay from Washington University in St. Louis (N = 651), Massachusetts General Hospital (N = 349), Weill Cornell Medicine (N = 187), and Northwestern University (N = 86). Patient census tracts were linked with the USDA Food Access Research Atlas, which provides data on census-level food access throughout the United States. Deidentified data were shared across sites. We categorized patients by: Food access: Low access (LA) if ≥33% of the census tract lived > 1 mile (urban) or > 10 miles (rural) from a food store Income and food access: Low-income and low access (LILA) if the census tract was both LA and poverty rate was ≥20% We assessed descriptive differences and determined associations between LA/LILA and ctDNA profiles using multivariate analysis adjusted for race, stage, and subtype. **Results:** Of the 851 patients with census tract data, 46.8% lived in LA and 8.0% lived in LILA areas. Although White patients were more likely to live farther from food stores than Black patients (48.9% vs 34.4%, p = 0.003), Black patients were significantly more likely to live in LILA areas (19.2% vs 6.1%, p = < 0.001). On multivariate analysis, patients in the overall cohort living in LA areas were more likely to have *RTK/RAS* pathway mutations (Odds ratio [OR] 2.05, 95% confidence interval [CI] 1.36-3.09, p = 0.001), confirmed in the hormone receptor positive, HER2 negative (HR+/HER2-) cohort (OR 2.18, 95% CI 1.34-3.55, p = 0.002). Patients in the overall cohort living in LILA areas were more likely to have *CCNE1* copy number variants [cnv] (OR 2.81, 95% CI 1.18-6.73, p = 0.02). Patients in LA areas had significantly shorter overall survival (OS) after first ctDNA test (24 months [mos] vs 31 mos, p = 0.01). In HR+/HER2- MBC, Black patients in LA areas had the shortest OS (11 mos) compared to those in high access areas (38 mos) and White patients in either setting (27-33 mos, p = 0.02). **Conclusions:** Patients with MBC living in food deserts appear to have distinct ctDNA profiles, including higher rates of *RTK/RAS* pathway mutations, which drive tumor growth, and *CCNE1* cnv, associated with poor prognosis. We also found a significant survival disadvantage associated with living in LA areas, particularly among Black patients. These findings demonstrate the necessity of considering the intersection of tumor biology and social determinants of health in understanding and treating MBC. Research Sponsor: None.

1016 Rapid Oral Abstract Session

Post-progression treatment (tx) analyses of evERA Breast Cancer (BC): A phase III trial of giredestrant (GIRE) + everolimus (E) in patients (pts) with estrogen receptor–positive, HER2-negative advanced BC (ER+, HER2– aBC) previously treated with a CDK4/6 inhibitor (i). First Author: Komal L. Jhaveri, Memorial Sloan-Kettering Cancer Center and Weill Cornell Medical College, New York, NY

Background: evERA BC (NCT05306340) is the first Phase III trial to demonstrate a statistically significant and clinically meaningful improvement in investigator-assessed progression-free survival (INV-PFS) with an all-oral, selective ER degrader and full ER antagonist combination (GIRE + E) compared with standard-of-care endocrine therapy combinations (SOC ET + E) in pts with ER+, HER2– aBC post-CDK4/6i + ET (Mayer ESMO 2025). Improvement in INV-PFS was seen in all pts (hazard ratio [HR], 0.56) and in pts whose tumors had a detectable *ESR1* mutation (*ESR1*m; HR, 0.38), with no unexpected safety findings. We report exploratory post-progression tx analyses. **Methods:** Pts with ER+, HER2– aBC who had disease progression (PD) or relapse during/post-CDK4/6i + ET were randomized 1:1 to once-daily oral 30 mg GIRE + 10 mg E or SOC ET (exemestane/ fulvestrant/tamoxifen) + E until PD/unacceptable toxicity. Exploratory analyses included PFS2 (time from randomization to PD on next-line tx, or death), chemotherapy-free survival (CFS; time to first subsequent chemotherapy and/or antibody–drug conjugate [ADC], or death), and types of cancer tx following discontinuation from study tx. **Results:** Median PFS2 and CFS were longer with GIRE + E vs SOC ET + E in all pts (PFS2 HR, 0.69; CFS HR, 0.61), including in the *ESR1*m (PFS2, 0.61; CFS, 0.46) and *ESR1*m not detected populations (PFS2, 0.77; CFS, 0.80; Table). Of those receiving follow-up cancer therapy in all pts, and in the *ESR1*m and *ESR1*m not detected populations, 69.1%, 63.3%, and 73.8%, respectively, received chemotherapy in the GIRE + E arm vs 71.5%, 65.3%, and 79.0% in the SOC ET + E arm; 24.5%, 18.4%, and 29.5% received an ADC in the GIRE + E arm vs 31.4%, 25.3%, and 38.7% in the SOC ET + E arm. **Conclusions:** Delaying chemotherapy improves clinical and quality of life outcomes in ER+ aBC. These analyses further support the superior INV-PFS of GIRE + E over SOC ET + E observed in all pts and in the *ESR1*m population. Improvements in PFS2 and CFS, regardless of *ESR1*m status, suggest that the clinical benefit of GIRE + E is sustained beyond initial progression. Clinical trial information: NCT05306340. Research Sponsor: F. Hoffmann-La Roche Ltd.

1017 Rapid Oral Abstract Session

Effectiveness of first-line ET+CDK4/6i continuation beyond disease progression in a large cohort of patients with HR+/HER2− advanced breast cancer: Results from the multicenter, real-world, Italian study PALMARES-2. First Author: Claudio Vernieri, Fondazione IRCCS Istituto Nazionale dei Tumori; IFOM ETS the AIRC Institute of Molecular Oncology; University of Milan, Milan, Italy

Background: Endocrine therapy (ET) plus Cyclin-Dependent Kinase 4/6 inhibitors (CDK4/6i) is the standard 1st line treatment for patients (pts) with Hormone Receptor-positive, Human Epidermal growth factor Receptor 2-negative, advanced Breast Cancer (HR+/HER2- aBC). ET+CDK4/6i continuation beyond progressive disease (PD) detection, plus/minus locoregional therapies, is often used in clinical practice for selected pts with oligoprogressive disease or minimal PD. However, the effectiveness of this approach has never been investigated in large studies. **Methods:** In this analysis of the multicenter, real-world study PALMARES-2 (NCT06805812), we evaluated clinical characteristics and outcomes in HR+/HER2- aBC pts who continued 1st line ET+CDK4/6i after detection of PD, as defined by physicians based on clinical-radiological assessment. The primary endpoint was real-world progression-free survival (rwPFS) beyond PD, defined as the time between the detection of the first PD event during 1st line ET+CDK4/6i and the occurrence of subsequent PD leading to definitive ET+CDK4/6i discontinuation, or patient death. We used multivariable Cox regression models to explore the association of 15 covariates with rwPFS beyond PD. We also assessed real-world overall survival (rwOS), as defined as the time between 1st line ET+CDK4/6i initiation and patient death. **Results:** Of 4,236 consecutive pts who initiated ET+CDK4/6i between January 2016 and September 2024 in 27 Italian Institutions, 2,434 pts experienced a PD event. Of these pts, 454 (18.7%) continued the same ET+CDK4/6i beyond PD and underwent radiotherapy (n = 306; 67%), surgery (n = 39; 9%), other locoregional treatments (n = 28; 6%) or no local therapies (n = 81; 18%). Pts continuing ET+CDK4/6i beyond PD were more likely to be younger and premenopausal, to have higher tumor estrogen receptor (ER) and/or progesterone receptor (PgR) expression, to have bone/lymph node metastases, and less likely to have liver metastases ($p < 0.05$ for all covariates). Median rwPFS beyond PD was 10.5 months (95% CI: 9.7-12). At multivariable analysis, higher tumor ER (p = 0.031)/PgR (p = 0.001) or lower Ki-67 ($p < 0.001$) expression, better ECOG Performance Status (p = 0.009) and the use of locoregional treatments ($p < 0.001$) were associated with longer rwPFS beyond PD. Pts continuing ET+CDK4/6i therapy beyond PD had better median rwOS than those discontinuing it after first PD detection (71.3 and 44.7 months, respectively; $p < 0.001$). **Conclusions:** This is the largest real-world study to show the effectiveness of 1st line ET+CDK4/6i continuation beyond PD in HR+/HER2- aBC pts. Our findings support the use of this well-tolerated and effective approach in selected pts, such as those with less biologically aggressive tumors and/or amenable to locoregional therapies. Clinical trial information: NCT06805812. Research Sponsor: Italina Ministry of Health; AIRC, the Italian Association of Cancer Research; Scientific Directorate of Fondazione IRCCS Istituto Nazionale dei Tumori.

Palbociclib plus tamoxifen ± goserelin in women with hormone receptor (HR)-positive, HER2-negative advanced breast cancer (BC): PATHWAY, an Asian international double-blind randomized phase 3 trial—Final overall survival (OS) analysis. First Author: Yen-Shen Lu, National Taiwan University Hospital, Taipei, Taiwan

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

1019 Rapid Oral Abstract Session

Paclitaxel plus bevacizumab with or without atezolizumab for hormone receptor-positive/HER2-negative advanced breast cancer: JCOG1919E (AMBITION) phase III trial. First Author: Fumikata Hara, Aichi Cancer Center Hospital, Nagoya, Japan

Background: Hormone receptor-positive/HER2-negative (HR+/HER2-) advanced breast cancer (aBC) is immunologically "cold," with limited clinical benefit from immune checkpoint inhibitors. Since VEGF-mediated angiogenesis promotes an immunosuppressive tumor microenvironment, we hypothesize that inhibiting VEGF could reverse immunosuppressive state thereby augmenting response to immunotherapy. The JCOG1919E (AMBITION) phase III trial evaluates whether adding the anti-PD-L1 antibody: atezolizumab (ATZ) to paclitaxel (PTX) plus anti-VEGF antibody: bevacizumab (BEV) improves outcomes in patients (pts) with HR+/HER2- aBC. **Methods:** This multicenter, open-label, randomized phase III trial enrolled pts with HR+/HER2-aBC who had no prior chemotherapy for aBC and were endocrine-resistant or visceral crisis. Pts were randomized in a 1:1 ratio to PTX plus BEV (Arm A) or PTX plus BEV with ATZ (Arm B). Randomization was stratified by disease status (de novo stage IV vs. recurrent), liver metastasis (presence vs. absence), and PD-L1 expression (SP142 assay; negative [<1% on immune cells (ICs)] vs. positive [>=1%]). PTX was administered on days 1, 8, and 15 of a 28-day cycle, BEV on days 1 and 15, and ATZ on days 1 and 15 in Arm B. The primary endpoint was investigator-assessed progression-free survival (PFS). Secondary endpoints included overall survival (OS), objective response rate (ORR), PFS by blinded independent central review, and safety. Clinical trial information: NCT04732598. **Results:** From Sep 2021 to Sep 2023, 281 pts were randomized. At baseline, 33.1% were de novo stage IV, 68.0% had liver metastases, and 16.0% were PD-L1 positive. At a median follow-up of 30 months, median investigator-assessed PFS was 11.2 months in Arm A and 12.4 months in Arm B (hazard ratio [HR] 0.88; 95% CI, 0.67–1.15; p=0.17). Median OS was immature, but numerically longer in Arm B than in Arm A (39.1 vs. 31.2 months; HR 0.80, 95% CI, 0.58–1.11). The ORR was high and comparable between arms (71.9% vs. 73.0%). Grade ≥3 adverse events (AEs) were similar between arms. The most common immune related AEs (any grade) with ATZ were rash (17.3%), adrenal insufficiency (11.5%) and hypothyroidism (10.8%). No treatment-related deaths were observed, and no new safety signals emerged. **Conclusions:** PTX plus BEV with ATZ did not demonstrate a statistically significant improvement in PFS compared to PTX plus BEV as a frontline treatment for HR+/HER2- aBC, although a numerical extension in OS was observed. The safety profile of PTX plus BEV with ATZ was consistent with the known profiles. Clinical trial information: NCT04732598. Research Sponsor: None.

1020 Rapid Oral Abstract Session

Impact of bevacizumab on the efficacy of antibody–drug conjugates as later-line treatment of basal-like immune-suppressed triple-negative breast cancer. First Author: Yin Liu, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Basal-like immune-suppressed (BLIS) triple-negative breast cancer (TNBC) is associated with a poor prognosis; however, prior analyses from the FUTURE and FUTURE-SUPER clinical trials indicated clinical responsiveness to anti-angiogenic therapy. We conducted this study to evaluate the safety and efficacy of combining bevacizumab with antibody–drug conjugates (ADCs) in patients with the BLIS subtype. **Methods:** The FUTURE 2.0 study (NCT05749588) is an ongoing, open-label, multi-arm phase II platform trial evaluating novel molecularly targeted agents in patients with histologically confirmed TNBC who progressed after ≥1 line of systemic therapy for recurrent or metastatic disease. This report presents results from the BLIS arms: arm C (HER2-low) and arm D (HER2-zero). In arm C, patients received either SHR-A1811 (anti-HER2 ADC, 4.8 mg/kg IV q3w) alone (C1) or with bevacizumab (15 mg/kg IV q3w) (C2). In arm D, patients received either SHR-A1921 (Trop2-targeted ADC, 3.0 mg/kg IV q3w) alone (D1) or with bevacizumab (7.5 mg/kg IV q3w) (D2). The primary endpoint was confirmed objective response rate (ORR). Safety was assessed in all treated patients with available safety data. **Results:** From April 2022 to October 2025, 100 women were enrolled: 60 assigned to bevacizumab-combination arms (C2 and D2) and 40 to ADC monotherapy arms (C1 and D1). All 100 patients completed at least one post-baseline assessment. Confirmed ORR was 40.0% (8/20; 95% CI: 21.9–61.3%) in C1, 86.7% (26/30; 95% CI: 70.3–94.7%) in C2, 40.0% (8/20; 95% CI: 21.9–61.3%) in D1, and 83.3% (25/30; 95% CI: 66.4–92.7%) in D2. All four arms met the protocol-specified ORR success criterion with high posterior probability. Median PFS was 9.2 months in the combination group versus 4.6 months in the monotherapy group (HR = 0.47; 95% CI: 0.30–0.74), indicating a clinically meaningful improvement. Grade ≥3 treatment-related adverse events occurred in 27.5% (11/40) of monotherapy patients and 33.3% (20/60) of combination patients. No treatment-related deaths occurred. **Conclusions:** This study provides preliminary evidence of synergy between bevacizumab and ADCs, supporting a promising new strategy—especially for basal-like, immune-suppressed TNBC. Phase III trials are ongoing to confirm the efficacy and safety of this combination. Clinical trial information: NCT05749588. Research Sponsor: National Natural Science Foundation of China; 82403912.

1021 Rapid Oral Abstract Session

A DESTINY-Breast09 analysis of treatment duration and clinical outcomes by best response to trastuzumab deruxtecan (T-DXd) + pertuzumab (P). First Author: Yeon Hee Park, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: In DESTINY-Breast09 (NCT04784715), first-line (1L) T-DXd + P demonstrated durable responses, a near doubling of complete response (CR) rates, and significantly improved progression-free survival (PFS) vs taxane + trastuzumab + pertuzumab for patients (pts) with HER2+ advanced/metastatic breast cancer (a/mBC). Pts had a median treatment duration of 21.7 months (mo) with T-DXd + P. Safety was consistent with the known profiles of each treatment. These results led to US approval in Dec 2025. Here, we report an exploratory analysis of efficacy and safety outcomes by pts' best confirmed response to T-DXd + P. **Methods:** Pts had no prior systemic therapy for a/mBC (1 line of endocrine therapy was allowed). Endpoints included PFS and duration of response (DOR), both by blinded independent central review per RECIST 1.1, and safety. Best response subgroups included CR, partial response (PR), and stable disease / progressive disease (SD/PD). **Results:** Of 377 evaluable pts assigned to T-DXd + P, 58 (15.4%) had a CR, 268 (71.1%) had a PR, and 51 (13.5%) had SD/PD at interim data cutoff (Feb 26, 2025). Median time to PR was 1.5 mo (95% CI 1.4, 1.5), and median time to CR was 8.4 mo (95% CI 5.6, 11.1). Additionally, median time to achieve maximum tumor reduction (nadir) in the overall population (n=383) was ~11 mo (~16 cycles). Pts with a CR or PR had favorable PFS (see Table) and a longer median treatment duration (CR, 28.0 mo [range 4.8–44.5]; PR, 22.2 mo [range 2.8–42.7]) vs those with SD/PD (4.4 mo [range 0.3–37.2]). Exposure-adjusted incidence rates (EAIRs) of drug-related Grade ≥3 adverse events (AEs) were 0.30, 0.30, and 0.57 per pt-year, respectively. EAIRs of any AEs leading to discontinuation were 0.14, 0.11, and 0.16 per pt-year. Rates of adjudicated drug-related interstitial lung disease (ILD)/pneumonitis by CR, PR, or SD/PD were similar: 12.1% (n=7, all Grade 1/2), 11.9% (n=32, all Grade 1/2), and 12.2% (n=6, two Grade 5), respectively. Pts with a CR had a longer median time to first onset of ILD/pneumonitis (484 days [d] [range 84–967]) than those with a PR (227 d [17–1028]) or SD/PD (99 d [37–211]). **Conclusions:** In this exploratory analysis of DESTINY-Breast09, achieving a durable CR or PR was associated with favorable PFS outcomes and prolonged treatment duration. Complete response or maximum tumor reduction (nadir) was achieved with sustained T-DXd + P treatment. Safety findings were consistent with previously reported profiles of T-DXd and P. Clinical trial information: NCT04784715. Research Sponsor: AstraZeneca in collaboration with Daiichi Sankyo.

1022 Poster Session

Identifying patients with human epidermal growth factor receptor 2 (HER2)–low and –ultralow breast cancer (BC): Use of digital, artificial intelligence (AI)–based computational algorithms to assist HER2 scoring by pathologists. First Author: Savitri Krishnamurthy, Department of Pathology, Division of Pathology and Laboratory Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Trastuzumab deruxtecan is approved in HER2-low (IHC 1+ or 2+/ISH negative) or -ultralow (IHC 0 with membrane staining in ≤10% of tumor cells) metastatic BC per DESTINY-Breast04 and -06 trials. Manual HER2 IHC scoring can be time-consuming and subjective. This retrospective, real-world study assessed manual scoring (ground truth) vs standalone AI-computational pathology-assisted (CPa) tools for scoring. **Methods:** Whole slide images (WSIs; N = 600, scanned with Aperio AT2) of BC samples stained with PATHWAY HER2 (4B5) assay, originally scored as HER2 IHC 0 (n = 400) or 1+ (n = 200), were rescored by 3 pathologists and using 4 CPa/AI tools in development as either IHC 0 absent membrane staining, 0 with membrane staining in ≤10% of cells, 1+, or 2+. Using 2023 ASCO/CAP guidelines, each pathologist performed 2 blinded readings per WSI; a reconciled score was used if the 2 readings differed. Manual consensus required ≥2/3 agreement. Concordance between pathologist manual consensus vs standalone CPa scoring was measured by positive and negative percentage agreement (PPA; NPA), overall percentage agreement (OPA), and Cohen κ, with review time recorded. **Results:** Of 600 WSIs, 586 (97.7%) had manual consensus. CPa tools were faster (Table) than manual scoring (manual median review time: 7.0 min; range, 3.0-11.5). PPA was high (≥92.5%) between manual consensus scoring and CPa tools; NPA across the tools was 79.1%, 68.9%, 67.4%, and 23.1%. Overall concordance varied across CPa tools; OPA ranged from 48.5% to 75.4% and Cohen κ from 0.26 to 0.61. **Conclusions:** Integrating CPa/AI tools as decision support aids for pathologists may reduce pathologist review time and augment pathologist inter-observer reproducibility, especially in HER2-ultralow identification. Refinement of CPa/AI algorithms in development may improve scoring to an even greater extent. Research Sponsor: This study was sponsored and led by AstraZeneca.

Biology-informed predictive modeling and resistance monitoring in trastuzumab deruxtecan–treated metastatic breast cancer. First Author: Josh Wheeler, Genialis, Inc., Boston, MA

Background: The antibody-drug conjugate (ADC), trastuzumab deruxtecan (T-DXd), produces meaningful responses in metastatic breast cancer (mBC), yet current biomarkers inadequately identify likely responders or elucidate resistance mechanisms. We developed a biology-informed survival model to predict T-DXd benefit in real-world data, assess treatment specificity, and characterize resistance evolution at time of progression. **Methods:** We analyzed RNA-seq and clinical outcomes from 150 de-identified T-DXd–treated mBC patients in the Tempus real-world multimodal database. Baseline expression profiles were embedded into biology-structured biomodules using a large molecular foundation model trained on over 1-million transcriptomes, capturing processes relevant to ADC activity: DNA damage response (DDR), intracellular trafficking, cellular stress adaptation, and tumor microenvironment signaling. These biomodules informed a survival model trained to predict T-DXd–specific clinical benefit. Predictive specificity was evaluated in a matched cohort of T-DXd–eligible mBC patients treated with taxane-based chemotherapy and HER2-targeting therapy. Longitudinal tumor profiling from 15 patients with progressive disease were analyzed to monitor resistance evolution. **Results:** The survival model predicted and identified biologically distinct benefit groups within the T-DXd cohort, with minimal separation observed in a control standard-of-care cohort, confirming treatment-specific predictive value (HR 2.22 [95% CI 1.14–4.35], p = 0.017). Predicted-benefit patients had longer rwTTNT (median=345 vs 245 days), and no prognostic signal appeared in control cohorts (C-index = 0.51), suggesting predictive specificity. Longitudinal analysis of progressed patients revealed reproducible biological shifts at progression, including attenuation of programs associated with effective ADC engagement and upregulation of adaptive stress-response pathways. These molecular transitions correlated with clinical deterioration and earlier transition to subsequent therapy. **Conclusions:** This study delineates the biology associated with durable T-DXd benefit and captures resistance evolution at progression in real-world patients. These findings highlight opportunities to refine patient selection and identify therapeutically actionable biology driving acquired resistance to T-DXd in the mBC setting. Research Sponsor: None.

Organ- and histology-specific molecular and immune landscape of metastatic breast cancer. First Author: Guilherme Nader Marta, Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Invasive lobular carcinoma (ILC) is a distinct breast cancer (BC) subtype with dissemination patterns differing from invasive breast carcinoma of no special type (IBC-NST). While genomic differences between ILC and IBC-NST have been described, the extent to which molecular and immune profiles vary by metastatic organ and histology is poorly characterized. **Methods:** We conducted a retrospective analysis to evaluate organ- and histology-specific molecular features of metastatic BC (mBC). Patients with metastatic IBC-NST or pure ILC underwent NGS (592, NextSeq; WES/WTS, NovaSeq; Caris Life Sciences). Tumor mutational burden (high ≥10 mut/Mb), PD-L1 expression (22C3), and immune cell fractions (RNAseq deconvolution, quanTIseq) were assessed. Analyses were restricted to sites with ≥10 biopsies per histology. Comparisons used chi-square or Mann–Whitney U tests with multiple testing correction ($q < 0.05$). **Results:** A total of 2645 mBC biopsies (605 ILC; 2040 IBC-NST) were analyzed (Table). In ILC, *ERBB2* mut frequency differed by metastatic site ($q<0.01$), with higher prevalence in liver (32.7%) and lower in gastrointestinal (GI) lesions (3.7%). In IBC-NST, *ESR1* and *GATA3* mut and *FGFR1* amplification were enriched in liver metastases, whereas PD-L1 expression was highest in skin (20.7%) and lowest in liver (5.0%). No organ-specific differences were observed for *PIK3CA, AKT, PTEN, BRCA1/2* or *RB1*. Across metastatic sites, both ILC and IBC-NST showed differences in B cells, macrophages (M1/M2), neutrophils, NK cells, dendritic cells, CD8+ T cells, and Tregs (all $q < 0.05$); CD4+ T-cell differences were observed only in IBC-NST (q = 0.002). In organ-specific ILC vs IBC-NST comparisons, *CDH1* mut were more frequent in ILC across sites, along with higher *PIK3CA* mut in skin (ILC 51.3% vs IBC-NST 34.4%) and higher *ERBB2* mut in liver (32.7% vs 3.3%), whereas a higher *TP53* mut frequency was observed in IBC-NST in skin (28.5% vs 52.3%) and lymph nodes (LND) (23.5% vs 55.5%) (all $q < 0.01$). **Conclusions:** mBC exhibits marked organ-specific molecular and immune heterogeneity that differs by histology. These findings support histology- and site-aware interpretation of metastatic biopsies and may inform biomarker assessment and treatment decisions in advanced disease. Research Sponsor: None.

Using ML to predict rapid progression for patients (pts) with HR+/HER2- metastatic breast cancer (mBC) treated with frontline (1L) CDK 4/6 inhibitors (CDK 4/6i). First Author: Michael Peng, Gilead Sciences, Morris Plains, NJ

Background: CDK4/6i ± aromatase inhibitors is a preferred tx for pts with HR+/HER2- mBC in the 1L setting. While a subset of pts experience rapid progression on standard tx, addressing the unmet need remains challenging due to difficult pt identification. While multimodal data have predicted fast progressors in prior work, routinely collected electronic health record (EHR) variables may be more practical for clinical trial design and enrichment use cases. Thus, we performed a feasibility assessment to determine if EHR data can adequately predict fast progressors. **Methods:** Models were trained on pts in the Flatiron Health Research Database with 1L CDK4/6i start on February 3, 2015, or later and an event ≤12 months (mos) or follow-up ≥12 mos after tx start. Fast progression was defined as real-world progression or death ≤12 mos after tx start. Baseline demographics, clinical characteristics, and laboratory/vital signs were used to train a logistic regression (LR) and a full-feature XGBoost (XGB) model. A feature-reduced XGB model was also developed by sequentially removing least important features until area under the curve (AUC) declined. Hyperparameters were optimized by grid search. Performance was evaluated via AUC, with feature importance assessed via LR coefficients and SHapley Additive exPlanations. Test-set analyses included rwPFS comparisons between predicted fast progressor (pFPs) and predicted non-fast progressors (pNFPs) using Kaplan-Meier methods. **Results:** Among 10,811 included pts, 3,782 were identified as fast progressors, split 80/20 for train/test datasets. The 3 models had comparable performance for predicting fast progression and effectively stratified pts into risk groups (Table). LR and XGB models used 48 and 76 features, respectively, while a feature-selected XGB model retained 30 features with minimal performance loss. Top LR predictors included advanced age, BRCA/ESR1/AKT positivity, and de novo stage IV disease. Important XGB features were consistent across models and emphasized continuous measures, including shorter time to metastatic diagnosis, greater metastatic burden, elevated AST and alkaline phosphatase, and bone-only metastases. **Conclusions:** While these models are not optimized as point-of-care clinical risk scores, their ability to identify high- and low-risk groups using scalable, routinely captured variables highlights their potential utility for clinical trial design, enrichment strategies, and cohort stratification. These findings establish a real-world benchmark and support the feasibility of practical, EHR-only approaches to rapid progression prediction. Research Sponsor: None.

Model	AUC	pFP rwPFS, median (95% CI), mos	pNFP rwPFS, median (95% CI) mos

Development and evaluation of a novel digital pathology image analysis pipeline for prediction of clinical outcomes with the TROP2-directed antibody-drug conjugate (ADC) sacituzumab tirumotecan (sac-TMT) in triple-negative breast cancer (TNBC). First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Digital pathology (DP), including artificial intelligence (AI)-based image analysis methods, enables IHC biomarker assessment on a continuous scale, potentially improving precision and accuracy versus conventional IHC scoring. DP may also capture features relevant to ADC response that traditional methods miss. As proof of concept, we developed and evaluated an AI-assisted DP image analysis pipeline to explore the association between target antigen expression and clinical outcomes of sac-TMT, a TROP2-directed ADC with a unique bifunctional linker, in TNBC. **Methods:** We analyzed whole-slide images of IHC-stained tumor samples from participants with TNBC enrolled in the phase 1/2 MK-2870-001 study (NCT04152499) evaluating sac-TMT in pretreated advanced solid tumors. We established a set of prespecified human-interpretable features (HIFs), including IHC signal intensity, subcellular localization, and spatial patterns of cell and signal distribution. To mitigate overfitting, we prioritized a subset of 35 HIFs based on correlation structure and biological hypotheses, and in a blinded fashion, assessed their association with clinical outcomes (BOR; PFS) in a development cohort (DC) (n = 58). After unblinding clinical outcome data, additional HIFs and a multivariate model trained to predict clinical outcomes in the DC were prioritized for validation. Both sets of HIFs (identified from blinded and unblinded analyses) were assessed for their relationship to clinical outcomes in an independent validation cohort (IVC) from the same study (n = 34). In both cohorts, DP HIFs were compared with conventional TROP2 H-scores (on paired slides) for prediction of clinical outcome using the area under the receiver operating characteristic curve (AUROC) and Harrell C-index. **Results:** The blinded approach identified a HIF that was positively associated with BOR (multiplicity-adjusted $P = 0.023$), with an AUROC higher than TROP2 H-scores (0.76 vs 0.70). After unblinding, 5 additional HIFs and a multivariate model were selected for their associations with BOR (AUROC, 0.70-0.80). In the IVC, the 6 prioritized HIFs and 1 multivariate model were associated with response to sac-TMT (AUROC, 0.60-0.69); each outperformed TROP2 H-scores with respect to association with BOR (H-score AUROC, 0.57) and demonstrated incrementally better association with PFS than TROP2 H-scores (Harrell C-index, 0.64-0.66 vs 0.62). **Conclusions:** In this proof-of-concept study, DP-derived HIFs were associated with response to sac-TMT in TNBC and showed incrementally better nominal performance than conventional TROP2 H-scores. While the sample size was small, data from this study suggest that DP-based image analysis can identify novel biomarkers of response to sac-TMT in TNBC. Antibody-drug conjugate (ADC) after ADC: Predicting survival in patients with HER2-low metastatic breast cancer with lung metastasis using artificial intelligence (AI) and radiomics. First Author: Rishi Dakarapu, Emory University School of Medicine, Atlanta, GA

Background: With the approval of multiple antibody drug conjugates (ADCs) for HER2-low metastatic breast cancer (MBC), defining which patients (pts) will benefit from an ADC after ADC approach is essential. No reliable biomarker exists to predict overall survival (OS) in the ADC after ADC setting. This study investigates whether AI informed radiomic texture features derived from CT scans prior to ADC therapy in pts with lung metastases who received both trastruzumab deruxtecan (T-DXd) and sacituzmab govitecan (SG) are associated with OS in HER2-low MBC. **Methods:** A single-institution retrospective study was conducted including pts with HER2-low MBC treated with both T-DXd and SG at Winship Cancer Institute of Emory University between 2020 and 2024. Among 44 pts reviewed (median age, 55 years), 21 pts with evaluable lung lesions were included. Radiomic texture features characterizing tumor heterogeneity were extracted from baseline pre-treatment CT scans of lung metastases before ADC initiation. A least absolute shrinkage and selection operator Cox regression model was applied within a 50-fold cross-validation framework to identify prognostic features associated with OS. OS was defined as the interval from initiation of first ADC therapy to death from any cause and was censored at the date of last follow-up for patients who were alive. A radiomic risk score (RRS) was calculated as a linear combination of the selected features weighted by their corresponding coefficients. Pts were stratified into high- and low-risk groups based on the median RRS. Cox proportional hazards regression was used to evaluate associations with OS. **Results:** Among the total 44 pts, the median duration of response was 6.1 months for the first ADC and 2.7 months for the subsequent ADC. 59.1% received SG as ADC1. For the 21 pts with lung metastasis, mOS was 20.8 months (95% CI: 14.33–30.8). In univariable analysis, the RRS was significantly associated with OS (HR = 2.5, 95% CI: 1.3–4.8; P = 0.006). In multivariable analysis adjusting for clinicopathologic factors including race, ER status, number of prior lines of therapy before ADC treatment, and relapsed vs de novo metastatic disease, RRS remained the only variable independently associated with OS (HR = 2.6, 95% CI: 1.2–5.5; P = 0.01). **Conclusions:** These preliminary findings suggest that CT-derived radiomic features may serve as a non-invasive biomarker to identify pts at higher risk of poor OS in the ADC after ADC setting for HER2-low MBC, for whom we need better, novel therapeutics after resistance develops to initial ADC therapy. This radiomics approach has the potential to inform treatment sequencing and risk stratification. Future work will include prospective validation in a larger cohort which includes other sites of metastatic disease. Research Sponsor: None.

Cross-modality AI modeling of histopathology images to stratify outcomes among patients treated with hormonal or chemo-hormonal therapy in ER+/HER2− breast cancer. First Author: Hassan Muhammad, PATHOMIQ, Inc., Cupertino, CA

Background: Oncotype DX (ODX) is widely used to guide adjuvant treatment decisions in early-stage ER+/HER2− breast cancer. However, ODX provides limited stratification of residual metastatic risk within patients receiving hormonal therapy (HT) alone or hormonal therapy following chemotherapy (HT+CT). We developed a cross-modality AI approach that derives risk scores directly from routine H&E-stained whole-slide images (WSIs) to stratify metastatic outcomes among patients receiving standard adjuvant therapies. **Methods:** Using a cross-modality transfer learning framework, we first developed genomic biomarkers by mapping RNA-seq data to distant metastatic outcomes by integrating thousands of genes and signaling pathway activities in the publicly available ScanB dataset. Deep learning models were then trained to infer these biomarkers directly from WSI of breast tumors using the TCGA dataset. External validation was performed in an independent cohort of 287 early-stage ER+/HER2−, node-negative patients from MD Anderson Cancer Center. Among these, 147 patients with ODX<25 received HT alone, while 140 patients with ODX>25 were included, 121 of whom received HT+CT. Kaplan–Meier survival analysis, log-rank tests, and Cox proportional hazards models were used to evaluate outcome stratification within each treatment group. **Results:** Among patients treated with HT alone, AI score stratified metastatic outcomes (HR=2.75; $p < 0.01$), identifying patients who developed distant recurrence despite low ODX scores. Among patients treated with HT+CT, AI score also stratified outcomes (HR=3.94; $p < 0.03$), identifying patients who experienced metastasis despite combination therapy. Across treatment groups, AI score provided prognostic information beyond ODX and clinicopathologic variables. In multivariable analyses adjusting for ODX and clinical covariates, AI score remained independently associated with metastatic risk and demonstrated consistent stratification across clinically relevant subgroups. Validation of these findings in an expanded cohort is ongoing. **Conclusions:** This AI-based approach further stratifies outcomes among patients receiving HT or HT+CT as guided by ODX, directly from routine histopathology images in early-stage ER+/HER2− breast cancer. Thus, integration of AI-derived outcome stratification with ODX scores may improve individualized treatment decision-making and support consideration of alternative therapies. Integrating artificial intelligence to evaluate outcomes and disparities in young-onset breast cancer: A SEER-based retrospective cohort study. First Author: Jahnavi Ethakota, Henry Ford Allegiance Health System, Jackson, MI

Background: Young-onset breast cancer (YOBC), defined as breast cancer diagnosed in women <40 years, is associated with aggressive tumor biology and affects patients differently depending on race, ethnicity, and socioeconomic status (SES). Traditional risk models may insufficiently predict disease severity and survival in this population. Artificial intelligence (AI) can integrate multidimensional clinical and demographic data to improve outcome prediction and identify high-risk subgroups. We evaluated AI-based prediction of advanced-stage disease and 5-year survival in a large U.S. cohort over two decades. **Methods:** We conducted a retrospective study using the SEER database, identifying women aged <40 years diagnosed with invasive breast cancer from 2000–2021. Variables included age, race, ethnicity, marital status, tumor stage, grade, receptor status, treatment, and county-level SES. A machine learning model was trained to predict advanced-stage disease (stage III–IV) and 5-year overall survival. Model performance was compared with multivariable logistic regression using area under the receiver operating characteristic curve (AUC). We also explored differences by race, ethnicity, and SES to understand disparities. **Results:** Our cohort included 97,462 women–38.9 percent non-Hispanic White, 26.7 percent non-Hispanic Black, 22.3 percent Hispanic, 11.1 percent Asian/Pacific Islander, and 1 percent American Indian/Alaska Native. Overall, 33 percent presented with advanced-stage disease, with higher rates among non-Hispanic Black (42 percent) and Hispanic (37 percent) patients compared with non-Hispanic White patients (26 percent, $p<0.001$). Women living in the lowest SES areas were 30 percent more likely to have advanced-stage disease than those in the highest SES areas. The AI model predicted advanced-stage disease (AUC 0.81) and 5-year survival (AUC 0.84) better than traditional regression (AUC 0.67 and 0.71, respectively). Importantly, 23 percent of high-risk patients identified by AI would have been missed by conventional criteria. Survival disparities persisted: 5-year survival was 77 percent for non-Hispanic Black women versus 89 percent for non-Hispanic White women, and 75 percent for women in the lowest SES areas versus 91 percent in the highest. The AI model's predictions were consistent across all subgroups. **Conclusions:** As per the study AI-based models improved prediction of advanced-stage disease and survival while highlighting persistent racial, ethnic and socioeconomic disparities. These findings suggest AI-driven risk assessment can help identify high-risk young women and support equity-focused interventions to improve outcomes in YOBC. Research Sponsor: None.

Association between HER family expression and clinical outcomes with trastuzumab deruxtecan (T-DXd) in patients with hormone receptor–positive/HER2-negative (HR+/HER2-) metastatic breast cancer (mBC). First Author: Shivani K. Thaker, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: T-DXd improves outcomes in HR+/HER2- mBC, yet response remains heterogeneous. Treatment selection is based on HER2 IHC. Preclinical models suggest signaling from HER family dimerization partners like EGFR drive resistance; specifically, *EGFR* overexpression impairs T-DXd internalization by favoring EGFR/HER2 heterodimerization. Because clinical data linking HER dimerization partners to T-DXd outcomes are limited, investigation is warranted to understand how expression of these partners may serve as predictive biomarkers. **Methods:** The Tempus Lens Platform was used to identify and analyze a cohort of patients (pts) with HR+/HER2- mBC treated with T-DXd (n = 224) and sacituzumab govitecan (SG) (n = 81, comparator) who underwent RNA (Tempus xR) and DNA (Tempus xT) sequencing within one year of treatment initiation. HER family gene expression (*EGFR/ERBB1, ERBB2/3/4*) was quantified as transcripts per million (TPM) and reported as log2(TPM+1). High vs low groups were defined using median expression. Median real-world time to next treatment (rwTTNT) with T-DXd and real-world overall survival (rwOS) were calculated using Kaplan–Meier curves and compared using log-rank tests. Hazard ratios (HR) were calculated using Cox proportional hazards models. **Results:** The cohort (n = 305) had a median age of 60; 83% of pts' race was reported as White, 9.6% Black or African American, 2.7% Asian, 7.6% Hispanic or Latino, and 4.3% unknown. Median HER family gene expression values were: *ERBB1* (*EGFR*): 3.92; *ERBB2* 7.75; *ERBB3* 7.65; *ERBB4* 4.72. *EGFR* RNA expression was negatively correlated with *ERBB2/3/4* ($p < 0.0001$). *ERBB2/3/4* RNA expression was positively correlated with one another ($p < 0.0001$). Among pts treated with T-DXd, the *EGFR*-high group had shorter median rwTTNT (7.76 vs 13.25 months; HR = 2.17 95% CI 1.42-3.34, $p < 0.001$) and rwOS (13.71 vs 22.55 months, HR = 2.21; 95% CI 1.50-3.24, $p < 0.001$) compared to the *EGFR*-low group. In contrast, increased RNA expression of other HER family members was not associated with a significant difference in rwTTNT or rwOS. Among pts treated with SG, the *EGFR*-high group did not have significantly different rwTTNT (median 4.34 vs 5.56 months; HR = 1.30 95% CI 0.72-2.36, p = 0.4) or rwOS (median 14.47 vs 11.28 months; HR = 0.86, 95% CI 0.47-1.55, p = 0.6) compared with the *EGFR*-low group. **Conclusions:** Among pts with HR+/HER2- mBC treated with T-DXd, elevated *EGFR*, but not *ERBB2/3/4*, RNA expression was associated with worse outcomes. *EGFR* overexpression did not modulate outcomes in pts treated with SG, highlighting a potential differential impact based on antibody target rather than payload. Further research is needed to confirm the utility of pre-treatment *EGFR* expression as a predictive biomarker for T-DXd treatment. Research Sponsor: None.

Concordance between circulating tumor DNA and tissue biopsy in patients with newly diagnosed recurrent breast cancer. First Author: Ana Elisa Lohmann, University of Western Ontario, London, ON, Canada

Background: Accurate determination of tumor origin and molecular subtype are recommended for patients with suspected recurrent breast cancer (BC). Circulating tumor DNA (ctDNA) provides a non-invasive alternative to tissue biopsy that offers identification of molecular tumor type (MTT) and molecular breast cancer subtype (MBS). This study aimed to assess the concordance between ctDNA and tissue biopsy in participants with suspected distant BC recurrence. **Methods:** This cross-sectional study evaluated patients with a previous history of primary BC who presented with suspected distant BC recurrence at least six months after initial BC diagnosis and underwent both tissue and liquid biopsy at enrollment. Blood samples were collected within 30 days before, or within 7-28 days after tissue biopsy and before any systemic or radiation treatment. Objectives were to assess concordance between tissue biopsy of the suspicious distant recurrent sites and liquid biopsy MTT and MBS (hormone receptor (HR)+/HER2−, HER2+ and triple negative BC (TNBC)). Patient blood samples were analyzed using the Guardant360 Liquid assay, reporting methylation-based prediction of MTT and MBS for samples predicted to be of BC origin. **Results:** A total of 120 patients (119 female, 1 male, median age 66 years) underwent biopsy a median 6.5 years after primary BC diagnosis. ctDNA was detected in 88% (105/120) subjects. Of these, 92% (97/105) yielded an evaluable MTT result with a high confidence score, with results as follows: Agreement between tissue pathology and ctDNA MTT was observed in 95 of 96 cases with diagnostic tissue pathology, including 99% agreement for breast cancer (88/89), and 100% agreement in lung adenocarcinoma (4/4), gynecological/ovarian (1/1), liver (1/1) and biliary (1/1). The non-diagnostic tissue biopsy was treated as BC by the oncologist. Among the 89 cases predicted BC by ctDNA, 88% (78/89) were evaluable for MBS while 2 did not have pathologic subtype available. In these 76 patients, positive predictive value for MBS predictions of HR+/HER2−, HER2+ and TNBC were 47/55 (85%), 6/11 (55%) and 8/10 (80%), respectively. Pathological tissue subtype of discordant HR+/HER2− cases were HER2+ (n = 7), TNBC (n = 1); of HER2+ cases were HR+/HER2− (n = 2), TNBC (n = 3) and of TNBC were HR+/HER2− (n = 2). **Conclusions:** Liquid biopsy demonstrated high agreement with tissue pathology for MTT classification, including identification of non-breast primary tumors. Differences in MBS classification between the two modalities warrant further investigation to assess potential contributing factors, including tumor heterogeneity. ***TP53* status and licensing complex/IFNγ transcriptional profiles to stratify endocrine-related outcomes with CDK4/6i exposure in 10,833 real-world ER+/HER2- breast cancers and a treatment-naïve subset.** First Author: Alekya Raghavan, Baylor College of Medicine, Houston, TX

Background: Endocrine therapy (ET) durability for ER+/HER2- breast cancer (BC) with CDK4/6 inhibitor (CDK4/6i) exposure is vastly heterogeneous. Aberrant activation of CDK4/6-Rb axis is mechanistically linked to DNA replication origin licensing programs, and IFNγ-mediated signaling has been observed at onset of CDK4/6i resistance (PMID 33536276). We previously reported licensing complex (LC) mRNA to be predictive of ET benefit in primary ER+/HER2- BC (SABCS24-P1-03-20). Here we assessed these findings in a large, real-world cohort of primary and metastatic ET±CDK4/6i-treated tumors. **Methods:** ER+/HER2- BC biopsies (N=10833 all-comers and a treatment-naïve subset of N=1960) with DNA- and RNA-seq profiling from Caris Life Sciences were reviewed. LC score was calculated as a mean z-score across 14 LC genes; IFNγ score of PMID 28650338 was used. Groupings of Q1 (low) and Q4 (high) LC and IFNγ score quartiles were compared (i.e., Q1/Q1, Q4/Q4, Q1/Q4, Q4/Q1). Endpoints inferred from claims data were time on 1st ET (To1) and cumulative time on ET (start of 1st ET to end of last ET; ToT). Logrank p-values and HRs were derived from Cox proportional hazard models. Immune microenvironment (TME) proportions were estimated via quanTIseq deconvolution. Corrected q-values were calculated for quanTIseq and genomic analyses. **Results:** For all-comers, LC score Q4 vs Q1 predicted shorter ToT for ET with or without CDK4/6i exposure (HR 1.27 [$p<0.0001$]; 1.13 [$p=0.0019$]). LC-Q1~IFNγ-Q1 tumors demonstrated longer ToT (ET HR 1.76 [$p=0.0015$]; ET+CDK4/6i HR 1.32 [$p=0.022$]) relative to Q4/Q4 when *TP53* was not mutated (^{mut}). In the treatment-naïve subset, the distribution of LC and IFNγ scores, PAM50 luminal subtype, and *TP53*^{mut} appeared similar to all-comers. IFNγ-Q4 vs Q1 predicted shorter To1 with CDK4/6i exposure (14.4 vs 19.9 months, HR 1.28 [$p=0.0074$]). LC/IFNγ profiles significantly stratified both To1 and ToT only with CDK4/6i exposure. Relative to Q1/Q1, all other quartile groups had shorter To1 (HR 1.53 [$p=0.071$], 1.88*, and 2.15* [*$p<0.01$]) and shorter ToT (HR 1.89, 2.33, and 1.98; all $p<0.05$). Relative to Q1/Q1, the Q4/Q4 cohort was enriched for *TP53*^{mut} (44.2% vs 12.5% [$q=0.002$]). In *TP53*^{WT} tumors, Q4~Q4 trended toward shorter ToT than Q1~Q1 (42.7 vs 26.5 months, HR 1.67 [$p=0.075$]). Finally, LC-Q4/IFNγ-Q4 vs Q1/Q1 tumors exhibited a more inflamed TME with higher M2 macrophages, myeloid DCs, and Tregs (all $q\leq0.01$). **Conclusions:** Real-world validation confirms the LC and IFNγ-stimulated transcriptional state jointly stratify outcomes in the CDK4/6i-treated setting, predicting shorter time on ET. Though enriched for *TP53*^{mut}, convergence of LC/IFNγ may hold potential predictive value in *TP53*^{WT} disease. The LC-Q1/IFNγ-Q1 CDK4/6i response predictor in the *TP53*^{WT} setting remains to be validated prospectively. Research Sponsor: None.

1033 Poster Session

Rapid digital patient-derived organoid testing for guiding therapy in patients with metastatic breast cancer receiving antibody drug conjugates (ADCs). First Author: Yuan Yuan, Cedars-Sinai Medical Center, Los Angeles, CA

Background: MBC remains incurable despite recent incorporation of ADCs. The optimal sequencing of FDA-approved ADCs such as trastuzumab deruxtecan (T-DXd) or sacituzumab govitecan (SG) are lacking and real-world data have shown cross resistance between the ADCs. The current study aims to develop a clinical diagnostic assay to guide optimal treatment for patients with MBC using digital patient organoid (DPO) in patients with MBC receiving or progressed on ADCs for a precision tool to guide therapy in post-ADC resistance setting. **Methods:** An institutional IRB was established for prospective collection of fresh tumor biopsies in patients with MBC undergoing ADC therapy. DPO drug sensitivity tests were conducted and analyzed for association with clinical outcome using progression free survival (PFS). DPO tests include ADCs (T-DXd, SG, Dato-DXd) or single agent chemo dosing experiments to determine drug sensitivities (AUC values calculated from CTG readouts) for downstream correlation analyses. **Results:** Between 09/2024–01/2026, 41 fresh tumor tissues were collected and processed. 22 samples had sufficient viable cells to pass QC for DPO establishment and were successfully assayed and 12 failed QC, giving a DPO establishment success rate of 64.71%. DPO success rates varies by breast cancer subtypes: 100% in HER2+, 73% in TNBC and 56% in HR+HER2- BC. and sites of metastasis. Sites of metastasis (met) also impacted DPO success rates: lymph node 0%, liver met 33%, skin met 60%, breast/ascites 100%. Organoids typically established and expanded within 7-14 days post-biopsy. The DPO drug assays were conducted for ADCs, payloads, and chemotherapy agents testing. Analysis revealed that prior clinical exposure and progression on an ADC correlated with reduced DPO sensitivity to the same agent, consistent with acquired resistance. The platform was capable of delineating between target- versus payload-based resistance. Notably, DPOs from heavily pretreated patients were often resistant to both ADCs but remained responsive to alternative agents, highlighting potential therapeutic opportunities. **Conclusions:** The DPO platform shows promise in predicting treatment responses and differentiating resistance mechanisms to ADCs in MBC. This approach provides a foundation for rational treatment selection in patients with MBC with prior ADC resistance. Research Sponsor: None.

1034 Poster Session

Real-world outcomes and tumor gene expression analysis of sacituzumab govitecan (SG)- and trastuzumab deruxtecan (T-DXd)-treated metastatic breast cancer (MBC). First Author: Greydon Arthur, BC Cancer Agency, Vancouver, BC, Canada

Background: While the antibody-drug conjugates (ADCs) SG and T-DXd have transformed MBC care, predictive biomarkers of ADC response are lacking. This retrospective study evaluates real-world outcomes of MBC patients treated with SG or T-DXd and explores potential genomic and transcriptomic correlates of response. **Methods:** MBC patients treated with SG or T-DXd at BC Cancer who underwent tumor whole genome and transcriptome sequencing (WGTS) between January 2020 - May 2025 were included. Biopsy for WGTS was obtained either before (ADC-naïve) or after ADC exposure (ADC-exposed). Progression free survival (PFS) was clinically evaluated and assessed using Kaplan-Meier analysis. Treatment response was classified into 2 groups using PFS benchmarks from ASCENT (Bardia et al 2021, SG: expected $\leq$6 months (mo), favorable $>$6 mo) and DESTINY-Breast04 (Modi et al 2022, T-DXd: expected $\leq$12 mo, favorable $>$12 mo). RNA-seq data were assessed with DESeq2 differential expression and gene pathway enrichment analyses. Immune cell deconvolution was performed using CIBERSORT, with group comparisons by Wilcoxon rank-sum tests. **Results:** Forty-three patients met eligibility for inclusion (17 SG, 24 T-DXd, 2 treated with both agents). Median PFS was 4.0 mo (95% CI 2.0-6.0) for those treated with SG and 7.4 mo (95% CI 4.6-10.7) for those treated with T-DXd. Among T-DXd-naïve patients, *ESR1* expression was higher in those with poor ADC response (69.8 vs 7.8 transcripts per million, p = 0.049). Oxidative phosphorylation gene cluster expression was reduced in T-DXd-exposed vs T-DXd-naïve patients (normalized enrichment score -1.9, p = 0.005). ADC target expression did not differ by response in either treatment cohort (*TACSTD2* p = 0.86, *ERBB2* p = 0.67). Whole genome sequencing identified 12 tumors with *FGFR1* amplifications, all with poor ADC response, and demonstrated homologous recombination deficiency in half of those with favorable SG response. While not statistically significant, the post-ADC tumor microenvironment of favorable responders trended toward enrichment with naïve B-cells and T-cell infiltrate in T-DXd-treated patients (p = 0.28, 0.33) and both monocytes and NK cells in SG-treated patients (p = 0.1, 0.27). **Conclusions:** This study highlights the heterogeneity of outcomes among SG- and T-DXd-treated MBC patients and identifies potential predictive and prognostic biomarkers warranting exploration in prospective trials of first-line ADC (NCT07299409) and ADC sequencing (NCT06665178). Dominant chromosomal abnormalities in breast cancer metastasis to CNS as compared with systemic metastasis demonstrated by liquid biopsy. First Author: Maher Albitar, Genomic Testing Cooperative LCA, Lake Forest, CA

Background: Breast cancer (BrC) central nervous system (CNS) metastases are believed to be biologically and therapeutically distinct from systemic metastases. Detecting BrC metastasis to CNS using liquid biopsy (LBx) of the CSF is emerging as a reliable approach not only for confirming metastasis, but also for defining the molecular and biological characteristics of this metastasis. We compared the findings of LBx performed on CSF with those obtained by peripheral blood (PB) LBx. **Methods:** LBx was performed by next generation sequencing (NGS) of cell-free DNA and RNA (cfDNA/cfRNA) in PB plasma or CSF as well as RNA sequencing of CSF cell pellet. RNA sequencing was performed using a panel of almost 1600 genes and DNA sequencing using 302 genes. **Results:** Of the 339 tested CSF samples, 29 (8.5%) were negative for any mutation and 57 (16.8%) showed low level mutations characteristic of CHIP (clonal hematopoiesis of indeterminate potential). However, two samples showed only chromosomal gain or loss without mutations and 2 showed chromosomal abnormalities with CHIP but no cancer-related mutations. In contrast, 19 of 279 PB samples (6.8%) were negative for any abnormality and 33 (11.8%) had CHIP. One sample of the PB cases showed chromosomal abnormalities without cancer-related somatic mutations. Of the 253 positive CSF samples 207 (82.1%) showed chromosomal structural abnormalities while only 71 of the 227 positive PB samples (31.2%) showed chromosomal structural gain or loss ($P < 0.0001$). The most common chromosomal abnormality was 1q gain, detected in 42.8% of CSF and in 18.5% of PB samples. 17p (TP53) deletion was detected in 25.4% of CSF and in 6.6% of PB samples. 10q (PTEN) deletion was detected in 9.4% of CSF and 3.1% of PB samples. ERBB2 gene amplification was detected in 6.3% of CSF cases and in 1.3% of PB cases. In CSF positive samples, the most mutated genes were TP53, KMT2C, PIK3CA, DNMT3A, CDH1, NF1, PTEN and ESR1, detected in 37.3%, 29%, 27.8%, 10.3%, 8.7%, 8.3%, 7.9%, and 7.5%, respectively. These genes were detected in positive PB samples at 51%, 35.2%, 42.7%, 81.1%, 11.8%, 8.8%, 9.6%, and 20.2%, respectively. Variant allele frequency in all mutations was significantly higher in CSF (P=0.0001) than PB. Germline mutations in BRCA1/2 were detected in 5.1% of CSF and in 4.8% of PB. Ten patients had their PB and CSF tested concurrently. Two were positive by CSF and negative by PB and one was positive by PB but negative by CSF. The rest had concordant results. **Conclusions:** BrC with CNS involvement represents a distinct subgroup whose biological characteristics may best be defined using LBx to evaluate chromosomal abnormalities and gene gain/loss. As such, optimal characterization and qualification minimal residual disease in patients with BrC with CNS involvement warrants integration of CSF LBx-defined genetic abnormalities as it may permit earlier and targeted interventions. Prognostic impact of *PIK3CA* amplifications and co-occurring mutations detected through circulating tumor DNA (ctDNA) in metastatic breast cancer (MBC). First Author: Lorenzo Foffano, Weill Cornell Medicine, New York, NY

Background: Activating *PIK3CA* mutations are established oncogenic drivers and predictive biomarkers in MBC. In contrast, *PIK3CA* amplifications are rare, poorly characterized, and of unclear clinical significance. Tissue-based studies report a prevalence of 1–7%, but their detection and relevance in ctDNA are largely unexplored. Moreover, whether amplifications interact with co-occurring mutations to define a distinct high-risk subset is unknown. We therefore aimed to characterize the impact of *PIK3CA* amplifications detected in ctDNA through a multi-institutional cohort of patients (pts) with MBC. **Methods:** This retrospective study analyzed a multi-institutional cohort of 1579 pts with MBC and baseline ctDNA testing with the Guardant360 NGS panel within a large academic consortium (PMAC). Hormone Receptor positivity (HR+) and HER2 status were defined based on the most recent biopsy. Associations between SNVs, CNVs, and clinical characteristics were assessed using multivariable logistic regression. The impact of prognosis, adjusted for the number of prior treatment lines, was evaluated through Cox regression for overall survival (OS), defined from time of baseline ctDNA collection. **Results:** Among 1,579 pts, 1,121 (71%) were HR+/HER2−, 214 (13.5%) HER2+, and 244 (15.5%) had triple-negative breast cancer (TNBC). *PIK3CA* CNVs were detected in 7.7% of pts, and 44.7% harbored a concomitant *PIK3CA* SNVs. *PIK3CA* CNVs were significantly enriched in TNBC compared with other subtypes (Odds Ratio [OR] 2.02, p=0.011). In the overall population, *PIK3CA* CNVs were associated with significantly worse OS (HR 2.46, $p<0.001$), an effect observed across all subtypes, including HR+/HER2− (HR 2.21, $p<0.001$), HER2+ (HR 5.23, $p<0.001$), and TNBC (HR 1.81, p=0.018). In multivariable analysis, *PIK3CA* CNVs remained independently associated with inferior OS in the overall cohort (HR 1.61, p=0.015) and in HR+/HER2− disease (HR 1.38, p=0.048). Notably, the coexistence of a *PIK3CA* CNV and mutation identified a subset with particularly poor prognosis. Compared with patients harboring *PIK3CA* SNVs alone, those with concurrent SNVs and CNVs had significantly worse OS in the overall population (HR 1.80, p=0.002), in HR+/HER2− disease (HR 1.51, p=0.037), and in TNBC (HR 5.72, $p<0.001$). **Conclusions:** *PIK3CA* amplifications detected in ctDNA are relatively frequent in MBC and are associated with significantly worse survival across molecular subtypes. The coexistence of *PIK3CA* amplification and mutation identifies a distinct high-risk subset with particularly poor prognosis, beyond the effect of mutations alone. Further mechanistic understanding and real-world outcome analyses are needed to determine whether *PIK3CA* amplifications, alone or in combination with mutations, have predictive relevance for response or resistance to PI3K-pathway inhibitors. Research Sponsor: None.

HRD-positive breast cancer genomics: Cross-application of ovarian cancer HRD scores. First Author: Xin Liu, Molecular Diagnosis Center, Yunnan Cancer Hospital, Third Affiliated Hospital of Kunming Medical University, Peking University Cancer Hospital Yunan, Kunming, China

Background: Homologous recombination deficiency (HRD) is a well-established biomarker for PARP inhibitor (PARPi) therapy in ovarian cancer and is increasingly being explored in breast cancer. However, current definitions of HRD positivity in breast cancer rely heavily on ovarian cancer–derived thresholds, raising questions about their biological relevance. Here, we characterize the genomic landscape of HRD-positive breast cancer and assess the applicability of ovarian cancer–based HRD scoring criteria. **Methods:** We performed next-generation sequencing on 1,159 breast cancer samples to evaluate HRD status, somatic alterations, and germline variants. HRD scores were calculated as the sum of loss of heterozygosity (LOH), telomeric allelic imbalance (TAI), and large-scale state transitions (LST), using established ovarian cancer cutoffs. These results were compared with HRD scores from 617 ovarian cancer cases analyzed using the same methodology. **Results:** Pathogenic or likely pathogenic BRCA mutations were detected in 105 breast cancer patients (9.1%), including 33 somatic and 80 germline events, all of which occurred in HRD-positive tumors. Overall, 26.2% (304/1,159) of breast cancer cases were classified as HRD-positive, with a median HRD score of 21. HRD scores were significantly higher in triple-negative breast cancer (TNBC) than in non-TNBC subtypes ($P < 0.001$). HRD-positive tumors exhibited elevated genomic instability, marked by significantly higher copy number variation burden ($P < 0.001$) and tumor mutational burden (TMB) ($P < 0.001$), along with enriched TP53 alterations. Comparative analysis revealed that ovarian cancers had significantly higher HRD scores than breast cancers (median: 43 vs. 21, $P < 0.001$), suggesting that applying ovarian cancer–derived thresholds may underestimate HRD positivity in breast cancer. **Conclusions:** HRD-positive breast cancer displays distinct genomic features, including increased genomic instability and TP53 alterations. However, HRD scores in breast cancer are markedly lower than those in ovarian cancer, indicating that ovarian cancer–based cutoffs may not be optimal for breast cancer. Future studies should refine breast cancer–specific HRD thresholds to improve patient selection for PARPi therapy. 1038 Poster Session

Characterization of genomic alterations between local breast cancers and cutaneous metastases. First Author: Francesca Thau, Yale Cancer Center, New Haven, CT

Background: Cutaneous metastases (CM) are a distinct manifestation of advanced breast cancer (BC), yet their genomic alterations (GA) relative to primary tumors are incompletely defined. In this study, we aimed to identify similarities and differences between GA in local BC and CM. **Methods:** Local BC and CM were profiled by comprehensive next-generation sequencing (FoundationOne CDx). Genomic biomarkers included tumor mutational burden (TMB), microsatellite instability (MSI), homologous recombination deficiency signature (HRDsig), reported as a laboratory professional service, and GA prevalence. Odds ratios (ORs) for enrichment in local BC versus CM were calculated using Fisher's Exact Test with false discovery rate (FDR) correction. **Results:** Across 14,769 BC and 1,731 CM cases, most had TMB-low (<10 mutations/Megabase; 94% vs 90%), were not MSI-high (99%), and were HRDsig-negative (83% vs 87%), respectively. Among BC cases, the most prevalent GA included *TP53* (54.1%), *PIK3CA* (34.5%), *MYC* (20.9%), *RAD21* (19.0%), *CCND1* (16.7%), and recurrent 11q13/8p12 amplicon–associated genes (*FGF19*, *FGF3*, *FGF4*, *NSD3*, *ZNF703*, and *FGFR1*; each 13–15%). Among CM cases, the most prevalent GA included *TP53* (48.4%), *PIK3CA* (37.6%), *MYC* (22.7%), and *RAD21* (20.0%), and also *CDH1* (18.8%) and *ESR1* (12.5%). Multiple genes differed significantly in prevalence between BC and CM, including enrichment of *ESR1*, *CDH1*, *NOTCH1*, *MAP3K1*, *CTNNA1*, *CBFB*, *NFE2L2*, *AKT1*, *BRAF*, and *GATA4* in CM, and higher frequencies of *TP53*, *MCL1* and *KDM5A* in BC biopsies (Table 1). In addition, several therapeutically relevant GA were observed at lower but clinically meaningful frequencies between BC and CM, such as alterations in the *PI3K/AKT* pathway beyond *PIK3CA*, including *AKT2* (1.8% vs 2.4%), *AKT3* (3.2% vs 3.6%), and *PTEN* (13.1% vs 13.0%); DNA damage repair genes, including *BRCA1* (3.9% vs 2.7%), *BRCA2* (4.1% vs 3.9%), *PALB2* (1.1% vs 0.8%), *RAD51* (*RAD51B/C/D* combined 1.3% vs 1.1%), *ATM* (2.6% vs 1.9%), *ATR* (0.9% vs 0.7%), *CHEK1* (0.1% vs 0%), and *CHEK2* (1.5% vs 2.2%); and additional potentially actionable GA, such as the *MTAP* (4.0% vs 3.8%), *SMARCA4* (1.0% vs 0.8%), *CCNE1* (4.2% vs 5.3%), and *ERBB2* (11.1% vs 11.3%) genes in local BC and CM biopsies, respectively. **Conclusions:** CM largely retain the GA profile of local BC, but may exhibit distinct enrichment of alterations in estrogen signaling, likely from selective pressure, cell adhesion, possibly due to more frequent lobular *CDH1*-mutated BC involving skin, and oncogenic pathways. A substantial proportion of both BC and CM samples harbor targetable GA, underscoring opportunities for precision therapy not only in advanced disease, but also in early stages. Research Sponsor: None.

Clinically significant genes with significant differences between local BC and CM.

Gene	BC (%)	CM (%)	Odds Ratio (CM vs BC)	p-value (FDR adjusted)
TP53	54.1	48.4	0.79	<0.001
CDH1	11.4	18.8	1.80	<0.001
ESR1	4.7	12.5	2.89	<0.001

1039 Poster Session

Serum HER2 level as a predictor of treatment efficacy and prognosis in advanced breast cancer patients treated with trastuzumab deruxtecan (T-DXd). First Author: Yehui Shi, Department of Breast Internal Medical, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: No validated liquid biopsy biomarker currently exists to predict the efficacy of trastuzumab deruxtecan (T-DXd) in advanced breast cancer (aBC). Consequently, the role of serum HER2 (sHER2) in this setting remains unclear. This study aimed to determine whether baseline levels and early on-treatment dynamics of sHER2 are associated with progression-free survival (PFS) and objective response rate (ORR) in aBC patients receiving T-DXd. **Methods:** We analyzed 43 aBC patients treated with T-DXd who had baseline sHER2 data available. As the established 15 ng/mL cut-off was not associated with PFS in our preliminary analysis, the optimal baseline sHER2 cut-off for predicting PFS was determined using the maximally selected log-rank statistics method. Patients were stratified by this cut-off, and a multivariable Cox model adjusted for clinicopathological factors was used to evaluate the independent prognostic value of baseline serum HER2. In a subgroup of 20 patients, serum HER2 changes after two treatment cycles were assessed for association with efficacy outcomes. **Results:** Using the maximally selected log-rank statistics method, 10.94 ng/mL was identified as the optimal predictive cut-off, with PFS differing significantly between groups defined by this threshold (P=0.015). Multivariable Cox analysis confirmed that a baseline sHER2 level ≥10.94 ng/mL was an independent protective factor for longer PFS (Hazard Ratio [HR] = 0.129, 95% Confidence Interval [CI]: 0.019-0.875, P=0.038), corresponding to an approximately 87.1% reduction in disease progression risk. This predictive value was independent of primary tumor HER2 status, metastatic burden, and liver metastasis. Primary tumor HER2 status itself was not a significant prognostic factor in the model (P=0.530). Regarding ORR, no statistically significant difference was found between high and low sHER2 groups using the 10.94 ng/mL cut-off (P=0.392). In the 20-patient subgroup, early on-treatment sHER2 dynamics showed no significant association with PFS (P=0.455) or ORR (P=0.256). **Conclusions:** In aBC patients treated with T-DXd, a baseline serum HER2 level ≥10.94 ng/mL is a strong and independent predictive biomarker for PFS, with prognostic value potentially surpassing primary tumor HER2 status. This newly identified cut-off may help to better select patients who are most likely to benefit from T-DXd therapy using a convenient liquid biopsy approach. Clinical trial information: NCT06492447. Research Sponsor: None.

PD-L1 upregulation as a reflection of distinct immune contexts in luminal and basal breast cancer. First Author: Lynne Chapman Cook, Department of Medicine, Section of Hematology and Oncology, Baylor College of Medicine, Houston, TX

Background: PD-L1 immunohistochemistry (IHC) is an approved biomarker to select patients with metastatic triple-negative breast cancer for immune checkpoint blockade (ICB). However, PD-L1 performs poorly in Luminal breast cancer, suggesting that PD-L1 upregulation may reflect distinct immune contexts across intrinsic subtypes. We hypothesized that PD-L1 expression can arise in either a canonical T-cell–inflamed state or a discordant PD-L1–high, T-cell–non-inflamed state. Discordance between PD-L1 expression and T-cell inflammation highlights the complexity of tumor–immune interactions, and accumulating evidence supports that malignancies can induce immune alterations systemically. To explore these broader immune features with a noninvasive approach, we examined plasma extracellular vesicles (EVs). **Methods:** We analyzed 1,084 primary invasive breast cancers from TCGA, focusing on Luminal (LumA/LumB) and Basal subtypes (n=867). PD-L1 status was defined using CD274 mRNA tertiles as a transcriptomic proxy for IHC, and a T-cell–inflamed signature (Ayers 18-gene TIS) classified tumors as inflamed (top 20th percentile), consistent with prior transcriptomic studies. Biomarker concordance was defined as the proportion of PD-L1-high tumors that were also TIS-high. Because CD274 is included in the TIS, analyses were interpreted conservatively with planned sensitivity analyses excluding CD274. For translational feasibility, EV profiling workflows were developed using plasma from the PyMT-N mouse model (immune-cold, myeloid-dominant TIME; method-development model, n=1). Plasma EVs from two patients with advanced breast cancer and one healthy control were profiled using proteomic and targeted EV RNA assays. **Results:** In Basal tumors, PD-L1 expression aligned with T-cell inflammation: 75.6% (65/86) of PD-L1-high tumors were TIS-high. In contrast, Luminal tumors showed reduced concordance, with only 39.4% (80/203) of PD-L1-high tumors classified as TIS-high. Basal PD-L1-high tumors were significantly more likely to be TIS-high than Luminal tumors (OR 4.76; 95% CI 2.70–8.39; $p=1.90\times10^{-8}$). These findings indicate frequent uncoupling of PD-L1 expression from T-cell inflammation in Luminal breast cancer. In PyMT-N plasma EVs, proteomic profiling detected myeloid-suppressive proteins with minimal T-cell–inflamed signals. In exploratory human plasma EVs, both proteomic and RNA assays captured immune-related signals, supporting EV profiling feasibility. **Conclusions:** PD-L1 upregulation occurs in distinct immune contexts that differ by intrinsic subtype, with reduced T-cell–inflamed concordance in Luminal breast cancer. This discordance may explain the limited utility of PD-L1 as a stand-alone biomarker in this subtype. Plasma EV profiling may capture systemic immune biology and provide orthogonal information to tumor-based assays, supporting further prospective evaluation. 1041 Poster Session

A phase II study of trastuzumab emtansine (T-DM1) combined with ribociclib in patients with HER2-positive metastatic breast cancer (RibHER). First Author: Yuan Huang, Department of Breast Medical Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: HER2-targeted therapy has significantly improved outcomes for patients with HER2-positive metastatic breast cancer (MBC). Cyclin D and cyclin-dependent kinases 4/6 (CDK4/6) act as downstream effectors of HER2 signaling, providing a rationale for combining CDK4/6 inhibitors with anti-HER2 therapies. However, combining CDK4/6 inhibitors with anti-HER2 antibody–drug conjugates (ADCs) raises the concerns of hematologic toxicities. This prospective, single-center, single-arm, phase II study evaluated the antitumor activity and safety of trastuzumab emtansine (T-DM1) plus ribociclib in patients with HER2-positive MBC previously treated with trastuzumab and a taxane, and with no prior ADC exposure. **Methods:** Patients received T-DM1 (3.6 mg/kg IV, day 1 of each 21-day cycle) and ribociclib (400 mg orally, days 8-21). Those with ER-positive disease could receive concomitant endocrine therapy (aromatase inhibitor or fulvestrant) per prior treatment; premenopausal patients also received ovarian function suppression. The primary endpoint was overall response rate (ORR). Secondary endpoints included clinical benefit rate (CBR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** From August 2020 to October 2024, 12 patients were enrolled. With the subsequent availability of trastuzumab deruxtecan (T-DXd), the study was terminated prematurely due to difficulties in patient enrollment. As of December 1, 2025, the median follow-up was 22.5 months (range: 8.7-25.2). The overall ORR was 41.7% and the CBR was 58.3%. Median PFS was 5.25 months (95%CI: 3.3-NA). In subgroup analyses, ORR (28.6% vs. 60.0%), CBR (57.1% vs. 60.0%), and median PFS (6.0 months, 95% CI: 3.5-NA vs. 4.5 months, 95% CI: 3.0-NA) differed between ER-positive and ER-negative subgroups, respectively. Median OS was not reached. All patients experienced treatment-related adverse events (TRAEs), most commonly thrombocytopenia (75.0%), neutropenia (66.7%), leukopenia (66.7%), anemia (50.0%), fatigue (50.0%), and elevated aspartate aminotransferase (50.0%). Grade ≥3 TRAEs included neutropenia (33.3%), leukopenia (25.0%), and thrombocytopenia (16.7%). Thrombocytopenia led to dose reduction in 5 patients and discontinuation in 2; one patient required platelet transfusion and another experienced grade 3 intracranial hemorrhage attributed to thrombocytopenia. No treatment-related deaths occurred. **Conclusions:** In this small preliminary study, T-DM1 plus ribociclib achieved an ORR of 41.7% in HER2-positive MBC. No clear PFS benefit was observed regardless of ER status. Overlapping hematologic toxicities, especially thrombocytopenia, were notable and warrant consideration in future combination strategies. Clinical trial information: NCT06481956. Research Sponsor: None.

Tucatinib (TUC) combined with trastuzumab and pertuzumab (HP) as first-line (1L) maintenance therapy for HER2+ metastatic breast cancer (MBC): An in-depth safety analysis of HER2CLIMB-05. First Author: Veronique C. Dieras, Medical Oncology Department, Centre Eugène Marquis, Rennes, France

Background: The primary analysis of the phase 3 HER2CLIMB-05 study (NCT05132582) showed the addition of TUC to 1L maintenance HP yielded a statistically significant improvement in progression-free survival (per investigator) versus control treatment (hazard ratio: 0.641, $P < 0.0001$) in patients with HER2+ MBC. Here we report our findings from an in-depth safety analysis of HER2CLIMB-05. **Methods:** Patients with centrally confirmed HER2+ MBC without evidence of progression following chemotherapy-based induction treatment (taxane + HP) were randomly assigned 1:1 to TUC (300 mg) or placebo (PBO) BID, both in combination with HP. The safety analysis set included all randomly assigned patients who received ≥1 dose of any study treatment. Treatment-emergent adverse events (TEAEs), laboratory values, and TUC/PBO dose modifications and discontinuations were examined. **Results:** Among patients in the safety analysis set (TUC arm = 326; PBO arm = 324), median treatment durations of TUC and PBO were 17.1 months (range: 0.4–36.5) and 15.5 months (range: 0.5–41.3), respectively. Grade (G) ≥3 TEAEs occurred in 42.3% of patients in the TUC arm and 24.4% in the PBO arm; the most frequent G ≥3 TEAEs in the TUC arm were elevated alanine aminotransferase (ALT; 13.5%) and aspartate aminotransferase (AST; 7.1%). TUC was discontinued in 13.5% of patients due to a TEAE. Cardiac TEAEs were similar between TUC and PBO arms (4.3% vs 6.2%). TEAEs of hepatic events (43.6% vs 15.7%) and diarrhea (72.7% vs 51.2%) occurred at higher incidence in the TUC arm versus the PBO arm (Table). In the TUC arm, increased ALT (28.2%) and AST (25.8%) accounted for the majority of hepatic TEAEs. Most hepatic and diarrhea TEAEs were managed with TUC dose modifications and/or discontinuation; 7.7% of patients discontinued TUC due to hepatic TEAEs and 1.5% discontinued due to diarrhea (Table). Among the patients with a TEAE of diarrhea, 57.7% and 29.9%, respectively, in the TUC and PBO arms used antidiarrheals; the most used medication was loperamide. Further details of the in-depth safety analysis will be presented. **Conclusions:** TUC addition to 1L HP maintenance therapy may be an effective option for HER2+ MBC with a clinically manageable safety profile. Clinical trial information: NCT05132582. Research Sponsor: Pfizer Inc.

1043 Poster Session

Risk factors and long-term prognostic impact of trastuzumab deruxtecan-related interstitial lung disease in metastatic breast cancer. First Author: Takayuki Kobayashi, Breast Oncology Center, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Trastuzumab deruxtecan (T-DXd) has demonstrated substantial efficacy in HER2-positive and HER2-low metastatic breast cancer (MBC). Interstitial lung disease (ILD), however, remains a clinically significant safety concern. While ILD incidence has been reported, its long-term prognostic impact and associated risk factors are not well established. **Methods:** This retrospective, single-center study evaluated patients with MBC treated with T-DXd. ILD was defined as clinically and radiologically confirmed ILD, which led to T-DXd discontinuation per institutional protocol. Time to treatment failure (TTF) and overall survival (OS) were analyzed according to ILD occurrence. Potential clinical and treatment-related risk factors for ILD were assessed using univariable and penalized multivariable Cox regression models. **Results:** At a median follow-up of 12.7 months, 15 of 132 patients (11.4%) developed ILD leading to treatment discontinuation. Among these 15 patients, 9 (60%) had grade 1 disease, 3 (20%) had grade 2, and 3 (20%) had grade 3 disease; no grade 4 or fatal events were observed. There were no significant differences in TTF (P = 0.59) or OS (P = 0.21) between patients with and without ILD. Among patients who developed ILD, onset occurred significantly earlier in those with HER2-low disease compared with HER2-positive disease (median 6.0 vs. 14.6 months, P = 0.029). In univariable analyses, age ≥65 years (HR 3.39, 95% CI 1.18-9.68; P = 0.023), prior immune checkpoint inhibitor (ICI) therapy (HR 4.74, 95% CI 1.01-22.34; P = 0.049), and prior abemaciclib exposure (HR 4.11, 95% CI 1.19-14.14; P = 0.025) were significantly associated with ILD. In the penalized multivariable model, prior abemaciclib exposure remained the only independent risk factor (HR 10.38, 95% CI 1.07-NA; P = 0.042). **Conclusions:** Although ILD onset tended to occur earlier in HER2-low MBC, its development did not significantly affect long-term TTF or OS. Prior exposure to abemaciclib is a significant independent risk factor for T-DXd-related ILD, warranting careful monitoring in this population. Research Sponsor: None.

1044 Poster Session

Zongertinib combination therapy in HER2-positive metastatic breast cancer (mBC): First results from a phase Ib/II trial. First Author: Shigehisa Kitano, Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Zongertinib, an irreversible TKI, selectively inhibits HER2 while sparing wild-type EGFR, thereby minimizing associated toxicities. Beamion BCGC-1 (NCT06324357) is an ongoing Ph Ib/II multicohort trial investigating zongertinib as monotherapy or in combination with other agents in HER2-positive mBC, metastatic colorectal cancer, and metastatic gastric, gastroesophageal junction, or esophageal adenocarcinoma. Here, we report the first data from 4 Ph Ib cohorts evaluating zongertinib plus antibody-drug conjugates (ADCs) or trastuzumab-based therapy in patients (pts) with HER2-positive mBC, focusing on ADC combinations, as well as supporting preclinical data. **Methods:** Preclinical activity of zongertinib combinations was assessed in xenograft mouse models. Beamion BCGC-1 includes pts with confirmed, unresectable HER2-positive mBC who progressed following HER2-directed therapy. Pts received escalating doses of zongertinib plus fixed doses of T-DM1 (Cohort A; 3.6 mg/kg), T-DXd (Cohort B; 5.4 mg/kg), trastuzumab (Cohort K; 8 mg/kg loading dose followed by 6 mg/kg) or capecitabine (1000 mg/m^2) plus trastuzumab (Cohort G; 8 mg/kg loading dose followed by 6 mg/kg). The primary endpoint is the occurrence of DLTs during the MTD evaluation period. Secondary endpoints included further safety assessments and objective response (investigator-assessed; RECIST v1.1). **Results:** In xenograft mouse models, the addition of zongertinib to T-DM1 or T-DXd led to increased antitumor activity. As of November 4, 2025, 12 pts had been enrolled to Cohort A (median age: 58 years), 16 to Cohort B (median age: 58 years), 4 to Cohort G (median age: 48 years) and 7 to Cohort K (median age: 58 years). Most pts were heavily pretreated, with prior exposure to T-DXd, T-DM1 and/or TKIs. In Cohort A, treatment emergent adverse events (TEAEs) and zongertinib-related AEs (any grade [G]/G3) were reported in 12/5 (100%/42%) and 11/5 (92%/42%) pts, respectively. Three (25%) pts had AEs leading to zongertinib dose reduction. No pts had an AE leading to zongertinib discontinuation. The most common TEAEs (any G/G3) were increased AST (7/1 [58%/8%] pts), decreased platelet count (5/2 [42%/17%] pts) and increased ALT (5/1 [42%/8%] pts). In Cohort B, TEAEs and zongertinib-related AEs (any G/G3) were reported in 14/7 (88%/44%) and 14/5 (88%/31%) pts, respectively. Three (19%) pts had AEs leading to zongertinib dose reduction and 3 (19%) had AEs leading to zongertinib discontinuation. The most common TEAEs (any G/G3) were anemia (8/2 [50%/13%] pts), diarrhea (8/2 [50%/13%] pts) and nausea (8/1 [50%/6%] pts). No grade 4 or 5 TEAEs occurred in Cohorts A and B. Efficacy analyses are ongoing and will be presented. **Conclusions:** No new safety signals were observed with zongertinib plus T-DXd or T-DM1. Dose escalation was ongoing in Cohorts A and B at data cutoff. Clinical trial information: NCT06324357. Research Sponsor: Boehringer Ingelheim.

Overall survival by genomic profile in HER2-positive (HER2+) metastatic breast cancer (mBC): A large US clinico-genomic database study. First Author: Paolo Tarantino, Department of Medical Oncology, Dana-Farber Cancer Institute; Harvard Medical School, Boston, MA

Background: Over the past few years, the landscape of treatment for HER2+ breast cancer has evolved significantly. Multiple active 1L treatment options have emerged, including T-DXd plus pertuzumab, maintenance palbociclib or tucatinib, providing an opportunity to tailor treatment according to the disease profile. This study aims to describe real-world treatment patterns and evaluate overall survival (OS) in a modern cohort of patients with HER2+ mBC, with sub-analysis by genetic profile of the disease. **Methods:** This retrospective study used the Flatiron Clinico-Genomic database (CGDB), where each patient received at least one Foundation Medicine next generation sequencing (NGS) test along the course of disease. Adults (≥18 years) diagnosed with HER2+ mBC between 1 January 2018 and 31 March 2024 (one year prior to the data cutoff) were included. OS was examined using the Kaplan-Meier method, with descriptive analyses by genetic alteration. **Results:** Among 7,933 mBC patients who underwent NGS profiling, 732 (9.2%) patients with HER2+ mBC were included. The median age at diagnosis was 59 years (range: 23-85); 68.3% had hormone receptor positive disease, and 37% had de novo mBC. Patients received a median of 3 lines of therapy (range: 1–14). The use of anti-HER2 antibodies ranged from 59.4% to 33.6% across 1L through 5L. Trastuzumab deruxtecan was prescribed more often in later lines (23.9% for 3L, 19.6% for 4L, and 23.0% for 5L) compared to 2L and 1L (11.3% and 4.2%). Similarly, the use of anti-HER2 tyrosine kinase inhibitors increased in later lines. The median (95% CI) OS for the entire population was 48 (41.6-53.1) months, with notable differences based on the detection of key genetic alterations. Patients with mutations in DNMT3A (14.2%), ARID1A (11.9%), MLL2 (10.9%), and CHEK2 (9%) had numerically longer mOS (64 [49.5-NE], 51.4 [35.8-69.4], 51.4 [36.1-68.9], 51.4 [40.1-NE] months, respectively) while patients with mutations in BRCA1 (6.6%), CDH1 (10.9%), BRCA2 (10.9%), PIK3CA (37.4%), TP53 (59.6%), ERBB2 (11.5%), and ATM (12.7%) experienced numerically shorter mOS (36 [25.0-56.3], 40.1 [28.0-70.1], 40.1 [34.1-62.5], 40.1 [35.2-46.9], 40.6 [35.9-48.7], 43.3 [36.2-58.9], 44.3 [36.5-62.8] months, respectively). **Conclusions:** The present study provides key insights into clinico-genomic characteristics, modern treatment patterns and OS for HER2+ mBC patients in the US. Although survival was 4 years in the overall cohort, patients with mutations in key DNA repair genes (BRCA1, BRCA2, ATM, TP53), in CDH1, PIK3CA or ERBB2 experienced a numerically worse prognosis, representing key unmet needs for drug development. Research Sponsor: Boehringer Ingelheim.

1046 **Poster Session**

A phase Ib/IIa study of BAT8010+BAT1006, an anti-HER2 monoclonal antibody-exatecan conjugate combined with an ADCC-enhanced HER2 mAb in patients with advanced solid tumors: Results from the 1L HER2-positive breast cancer cohort. First Author: Wen Xia, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: BAT8010 is an ADC targeting HER2, while BAT1006 is a humanized monoclonal antibody targeting another epitope of HER2, with ADCC enhancement activity via completely devoid of fucose. Expansion cohort of 1st-line HER2-positive breast cancer (BC) patients enrolled, treated with BAT8010 + BAT1006. **Methods:** Patients in this open-label, multicenter clinical trial received BAT8010 + BAT1006 on day 1 of a 21-day cycle until intolerable or disease progression occurred. The study objectives included assessing tolerability, safety, pharmacokinetic characteristics, immunogenicity, and preliminary efficacy. **Results:** As of January 9, 2026, 46 HER2-positive BC patients were enrolled, and received BAT8010 2.4 mg/kg in combination with BAT1006 15 mg/kg. Favorable efficacy was observed with a manageable and predictable safety profile; dose optimization is ongoing in the BAT8010 2.1 mg/kg in combination with BAT1006 15 mg/kg dose cohort. Safety: Among the 46 patients who received at least one dose of BAT8010 in combination with BAT1006, at least one treatment-emergent adverse event (TEAE) was reported in 41/46 (89.1%) patients. The most common TEAEs (≥30%) were neutropenia, leukopenia, anemia, infusion-related reaction (IRR), thrombocytopenia, elevated alanine aminotransferase and diarrhea. Most TEAEs were Grade 1/2; however, Grade 3 or higher AEs were reported in 67.4% of patients, including neutropenia (27/46, 58.3%), leukopenia (16/46, 34.8%), and anemia (7/46, 15.2%). No cases of interstitial lung disease (ILD)/pneumonitis were reported. Efficacy: Among 46 patients with at least one tumor assessment, 1 patient achieved CR, 34 PR, and 11 SD, yielding an ORR of 76% (35/46) and a DCR of 100% (46/46); mPFS: not yet mature. **Conclusions:** BAT8010 in combination with BAT1006 is well-tolerated with manageable toxicity, and demonstrates promising preliminary antitumor activity in HER2-positive BC. Dose expansion studies in this patient population are ongoing, and further confirmatory clinical trials are planned to initiate for the additional validation of its safety and efficacy. Clinical trial information: NCT06376136. Research Sponsor: None.

Efficacy, safety, and immunogenicity of pertuzumab biosimilar versus reference pertuzumab in combination with trastuzumab and docetaxel in HER2-positive metastatic breast cancer: A randomized, double-blind, multicenter, parallel group, phase III clinical trial. First Author: P. K. Chaithanya, MNJ Institute of Oncology & Regional Cancer Centre, Hyderabad, India

Background: Pertuzumab plus trastuzumab and docetaxel is a standard first-line treatment regimen for HER2-positive metastatic breast cancer (MBC). This phase III trial evaluated the therapeutic equivalence of pertuzumab biosimilar (manufactured by Intas Pharmaceuticals Ltd., Ahmedabad, India) versus Perjeta when combined with trastuzumab and docetaxel. **Methods:** This was a randomized (1:1), double-blind, multicenter, parallel-group, phase III equivalence study. Adults with HER2-positive MBC were enrolled and received pertuzumab I.V. (biosimilar or reference product) 840 mg loading dose in cycle 1, then 420 mg every 3 weeks for 24 weeks, in combination with trastuzumab and docetaxel as first-line therapy. Primary endpoint was independently assessed objective response rate (ORR) at week 24 per RECIST v1.1. Secondary endpoints included PFS, OS, duration of response, time-to-event outcomes, pharmacokinetics (T_{max}, C_{max}, AUC_{0-t}), safety, and immunogenicity (anti-drug antibodies, ADA). **Results:** A total of 213 patients were randomized (pertuzumab biosimilar n=106; reference product n=107). ORR at week 24 was comparable between the biosimilar and reference pertuzumab arms: in the mITT set, ORR was 71.3% (72/101) versus 65.0% (67/103), respectively. 6-months PFS rate was 90.1% vs 89.3% in biosimilar and reference pertuzumab arms respectively. Pharmacokinetic parameters (T_{max}, C_{max}, AUC_{0-t}) and immunogenecity were comparable between both the arms. Treatment-emergent adverse events (AEs) occurred in 65.1% (pertuzumab biosimilar) and 72.9% (reference product) of patients; most common AEs observed in ≥5% patients in pertuzumab biosimilar vs reference product arm were the following: diarrhea (32.1% vs 30.8%), alopecia (17.0% vs 12.1%), anaemia (8.5% vs 18.7%), vomiting (10.4% vs 11.2%), pyrexia (8.5% vs 10.3%), fatigue (8.5% vs 7.5%), neutropenia (6.6% vs 8.4%), leukopenia (6.6% vs 8.4%), nausea (4.7% vs 7.5%), cough (4.7% vs 5.6%) and headache (3.8% vs 5.6%). **Conclusions:** Pertuzumab biosimilar demonstrated therapeutic equivalence to reference product in combination with trastuzumab and docetaxel for first-line HER2-positive MBC. Efficacy, safety, pharmacokinetic similarity, and comparable immunogenicity support biosimilarity and its potential as an effective treatment option. Clinical trial information: CTRI/2022/12/048133. Research Sponsor: Intas Pharmaceuticals Limited, Ahmedabad, India.

Summary statistics for objective response rate (ORR) at week 24 (mITT set, N=204).

Parameter	Pertuzumab biosimilar (N=101), n (%)	Reference product (N=103), n (%)
Complete response	4 (4%)	1 (1%)
Partial response	68 (67.3%)	66 (64.1%)
Overall response rate	72 (71.3%)	67 (65.0%)
Difference in ORR (95% CIs)	-7.50, 19.97	

1048 **Poster Session**

Phase Ia study of VRN101099, a brain-penetrant, highly selective covalent HER2 inhibitor, in HER2-positive or HER2-mutant advanced solid tumors. First Author: Jee Hung Kim, Division of Medical Oncology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea

Background: Despite advances in HER2-targeted therapies, including trastuzumab deruxtecan (T-DXd), unmet needs remain in patients with HER2-driven solid tumors who develop treatment resistance, particularly those with central nervous system (CNS) metastases. VRN101099 is an orally bioavailable, brain-penetrant covalent HER2 inhibitor that irreversibly inhibits HER2 and induces receptor internalization and degradation. Preclinical studies demonstrated antitumor activity in subcutaneous and intracranial xenograft models of HER2-positive breast and gastric cancers. **Methods:** This open-label phase Ia study assesses the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity of VRN101099 in patients with HER2 IHC 1+/2+/3+ or HER2-activating mutant advanced solid tumors. A standard 3+3 dose-escalation design determines the maximum tolerated dose and recommended phase 2 dose (RP2D), with dose-limiting toxicities assessed during the first 21-day cycle. VRN101099 is given orally once daily in continuous 21-day cycles. Optional backfill cohorts may enroll up to 12 patients at tolerated dose levels to characterize safety, PK, and PD further. Data are descriptive as of the 18 January 2026 cutoff and inform ongoing dose escalation, backfill enrollment, and RP2D selection; early reporting reflects emerging safety and activity. Safety is overseen by a Safety Review Committee defined by protocol. **Results:** As of January 2026, 17 patients received VRN101099 (80–320 mg). Median age was 63 years; 65% were female, and 35% had breast cancer. HER2 IHC 3+ expression was seen in 29% of patients; 35% were ISH-positive, and 24% had HER2-activating mutations. Patients had received a median of 3 prior systemic therapies (range 0–10); 58% had prior anti-HER2 therapy, including T-DXd (47%). No Grade ≥3 treatment-related adverse events occurred. The most common treatment-related adverse event was Grade 1–2 diarrhea. Among eleven patients with at least one post-baseline tumor assessment at data cutoff, five with HER2 IHC 3+ expression or HER2-activating mutations experienced tumor size reduction after two cycles. Confirmed partial responses were observed in two patients previously treated with T-DXd: one with HER2 IHC 3+ breast cancer and one with HER2 S310Y-mutant NSCLC. PK analyses showed dose-dependent exposure, with trough concentrations at 240 mg exceeding preclinically defined HER2 inhibitory thresholds. **Conclusions:** VRN101099 was well tolerated across evaluated dose levels and demonstrated encouraging antitumor activity in heavily pretreated HER2-driven solid tumors, including patients previously treated with T-DXd. These findings support continued dose escalation and expansion to define the RP2D and further characterize the therapeutic potential of VRN101099. Clinical trial information: NCT06806982. Research Sponsor: Voronoi Inc.

Phase II study of T-Bren (BL-M07D1) monotherapy or in combination with pertuzumab in patients with treatment-naïve HER2-positive unresectable locally advanced or metastatic (LA/M) breast cancer. First Author: He-Rui Yao, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: T-Bren is a HER2-directed antibody-drug conjugate (ADC) consisting of an anti-HER2 monoclonal antibody linked to a potent topoisomerase I inhibitor (Ed-04). In phase I study, T-Bren demonstrated encouraging antitumor activity with a manageable safety profile in patients (pts) with HER2-positive unresectable LA/M breast cancer (BC) who had failed standard treatments. Results of safety and efficacy from a phase II study assessing T-Bren monotherapy or in combination with pertuzumab in treatment-naïve HER2-positive unresectable LA/M BC are presented. **Methods:** Treatment-naïve pts with HER2-positive (IHC3+, or IHC2+/ISH+) unresectable LA/M BC were treated with T-Bren monotherapy at 4.4mg/kg Q3W (cohort A) or T-Bren 4.4mg/kg Q3W in combination with pertuzumab (cohort B). Primary endpoints were ORR and RP2D for combination treatment. **Results:** As of Nov 30, 2025, a total of 83 pts were enrolled and treated in cohort A (n = 43) and cohort B (n = 40). All pts were included in the analysis (see table below). The median follow-up was 10.6 months. In cohort A, ORR was 93.0%, confirmed ORR (cORR) was 86.0%. In cohort B, ORR and cORR were 87.5%. Median PFS have not reached in either cohort. The landmark PFS rate at 12-months was 79.1% in cohort A and 90.8% in cohort B. The most common grade 3 and above hematologic TRAEs in both cohorts were neutropenia (51.8%), anemia (37.3%), leukopenia (36.1%), and thrombocytopenia (26.5%); the most frequent grade 3 and above non-hematologic TRAEs were weight decreased (7.2%), hypokalemia (6.0%), and nausea (6.0%). Grade 3 and above TRAEs were able to be effectively managed with standard supportive measure including dose reductions, as demonstrated by the TRAE leading to discontinuation rate of 4.8%. No treatment related death or ILD was reported. **Conclusions:** T-Bren as monotherapy or in combination with pertuzumab has demonstrated a promising antitumor activity and a manageable safety profile in pts with treatment-naïve HER2-positive unresectable LA/M BC. Phase III study assessing T-Bren in treatment-naïve HER2-positive unresectable LA/M BC is in preparation. Clinical trial information: NCT06445400. Research Sponsor: Baili-Bio (Chengdu) Pharmaceutical Co., Ltd.

	Cohort A: T-Bren 4.4 mg/kg D1Q3W (N=43)	Cohort B: T-Bren 4.4 mg/kg D1Q3W+ pertuzumab D1Q3W (N=40)	Total (N=83)
ORR, % (95% CI)	93.0 (80.9, 98.5)	87.5 (73.2, 95.8)	90.4 (81.9, 95.7)
cORR, % (95% CI)	86.0 (72.1, 94.7)	87.5 (73.2, 95.8)	86.7 (77.5, 93.2)
DCR, % (95% CI)	100 (91.8, 100)	97.5 (86.8, 99.9)	98.8 (93.5, 100)

12-mo OS rate, % (95% CI)	100 (100, 100)	95.0 (81.5, 98.7)	97.4 (89.9, 99.3)

1050 **Poster Session**

Efficacy and safety results of a prospective phase II study (IPUtrial) of inetetamab and pyrotinib in combination with utidelone for first- or second-line treatment of HER2-positive metastatic breast cancer. First Author: Hui Cao, Department of Oncology, Cancer Hospital of Dalian University of Technology, Cancer Hospital of China Medical University, Liaoning Cancer Hospital and Institute, Shenyang, China

Background: Despite standard anti-HER2 regimens with chemotherapy, therapeutic challenges persist in HER2-positive metastatic breast cancer (MBC). Inetetamab (anti-HER2 monoclonal antibody) and pyrotinib (tyrosine kinase inhibitor) demonstrate established efficacy in advanced disease. Utidelone, a novel epothilone analog, exhibits antitumor activity with a differentiated safety profile. This phase II study assessed the triplet combination in first- or second-line HER2-positive MBC. **Methods:** This multicenter single-arm phase II trial enrolled HER2-positive MBC patients for first- or second-line therapy. Patients who have previously used trastuzumab must meet the followings: for first-line treatment, neoadjuvant therapy was effective, and relapse occurred over 1 year after the end of adjuvant therapy; for second-line treatment, progressed in previous adjuvant/neoadjuvant therapy or progressed within 1 year of completion of trastuzumab therapy; disease progression occurred after 6 months of treatment with trastuzumab in advanced setting. Patients with stable brain metastases were enrolled with or without prior local treatment. ECOG PS 0-1, and measurable disease (RECIST v1.1). Eligible patients received inetetamab (8 mg/kg cycle 1, then 6 mg/kg, IV, day 1), pyrotinib (400 mg, PO, daily), and utidelone (30 mg/m², IV, days 1-5) every 21 days until progression or intolerance. Primary endpoint was investigator-assessed ORR. Secondary endpoints included PFS, OS, and safety. **Results:** By data cutoff (December 31, 2025), the recruitment has been completed. 94 patients were enrolled. Median treatment cycles were 11 (range 4-57). 56 (65.9%) and 29 (34.1%) patients were in first- and second-line settings, respectively. 85 patients were evaluable for response with 6 CR, 64 PR and 7 SD. The ORR was 82.4% (95% CI, 72.6%-89.8%). Median PFS was 13.1 months (95% CI, 10.420-15.780). Median OS was not reached. The OS rate of 12-month, 26-month and 35-month was 94.6% (95% CI, 89.5%-99.7%), 85.2% (95% CI, 76.6%-93.8%) and 78.5% (95% CI, 67.7%-89.3%), respectively. Predominant Grade ≥3 TRAEs were diarrhea (28.2%) and peripheral neuropathy (4.7%). Other Grade ≥3 TRAEs included nausea (3.5%), transaminitis (2.4%) and neutropenia (1.2%). Treatment discontinuations due to TRAEs occurred in 6 patients (6.6%). No treatment-related deaths occurred. **Conclusions:** The regimen demonstrated clinically meaningful activity of this triplet regimen for the first/second-line treatment of HER2-positive MBC, evidenced by high ORR (82.4%), durable median PFS (13.1 months), with encouraging 35-month OS rate (78.5%). Predominant toxicities (diarrhea, neuropathy) were controllable through supportive measures and dose adjustments. These data support phase III evaluation of this combination strategy. Research Sponsor: Beijing Biostar Pharmaceuticals Co., Ltd.

Real-world brain metastasis outcomes with T-DXd versus tucatinib-based therapy in second-line HER2-positive metastatic breast cancer. First Author: Zunairah Shah, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Brain metastases (BM) remain a major cause of morbidity and mortality in HER2+ metastatic breast cancer (MBC). HER2CLIMB established tucatinib/trastuzumab/capecitabine (TTC) as a standard regimen with CNS activity, including improved outcomes in patients (pts) with active BM. DESTINY-Breast12 further demonstrated clinically meaningful intracranial outcomes with trastuzumab deruxtecan (T-DXd) in pts with stable and active BM. However, real-world (RW) comparative estimates of incident BM risk and timing between these two regimens among pts without baseline BM are limited, particularly in the second-line (2L) setting. **Methods:** We conducted a retrospective cohort study using TriNetX, a federated electronic health record network. Eligible pts had HER2+ MBC previously treated with first-line THP (taxane + trastuzumab + pertuzumab) and were BM-free at index. To approximate a 2L comparison, index was the first dose of T-DXd or TTC; cohorts were mutually exclusive and prior T-DM1 exposure was excluded. Pts with documented BM prior to index were excluded. To reduce misclassification from occult baseline BM, a landmark sensitivity analysis excluded BM events within 60 days post-index. Cohorts were balanced using 1:1 propensity score matching (PSM) for age, comorbidity burden, and lines of treatment. Incident BM was compared using risk-based measures (risk difference, risk ratio [RR]) and time-to-event analyses (Kaplan–Meier [KM]; Cox [HR]; log-rank). OS was assessed from index to death using KM and Cox regression. **Results:** In the PSM cohorts (n=540 per arm; mean age 57.8±12.4 vs 59.2±12.3 years), median follow-up was 13.4 months. Incident BM occurred in 12.6% (68/540) with T-DXd vs 20.9% (113/540) with TTC, corresponding to an absolute risk difference of −8.3% (95% CI −13.34% to −2.90%; p=0.0015) and RR 0.62 (95% CI 0.46–0.83). 1-year BM-free survival probability was 72.65% with T-DXd vs 67.89% with TTC (log-rank p=0.03), with an HR of 0.72 (95% CI 0.54–0.97). Among pts who developed BM, TTC was associated with higher BM-associated healthcare encounter burden compared with T-DXd (mean 9.64 vs 5.20; p=0.03). CNS morbidity events were less frequent with T-DXd vs TTC, including seizures (4.77% vs 13.06%; OR 0.33, 95% CI 0.23–0.49; p<0.0001) and cerebral edema (5.47% vs 14.22%; OR 0.35, 95% CI 0.24–0.51; p<0.0001). OS did not differ significantly between T-DXd and TTC (HR 0.89, 95% CI 0.76–1.04; p=0.16). **Conclusions:** In HER2+ MBC pts without baseline BM following first-line THP, T-DXd was associated with significantly lower incident BM, delayed onset, and reduced CNS morbidity compared with TTC. These findings warrant validation using standardized CNS surveillance and may help inform treatment selection in pts at high risk for BM. Research Sponsor: None.

BM outcomes in HER2+ MBC.

	T-DXd	TTC	
Incident BM	12.6%	20.9%	RR 0.62 (0.46–0.83)
1-year BM-free	72.65%	67.89%	HR 0.72 (0.54–0.97)

1052 **Poster Session**

Molecular imaging as a tool to predict patient outcomes in advanced HER2-low breast cancer on trastuzumab deruxtecan (T-DXd): The FHERAD trial. First Author: Xiaoyi xiaoyi Guo, NMPA Key Laboratory for Research and Evaluation of Radiopharmaceuticals, Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, Beijing, China

Background: The DESTINY-Breast04 trial demonstrated for the first time that trastuzumab deruxtecan (T-DXd), a HER2-targeting antibody-drug conjugate (ADC), benefits patients with HER2-low metastatic breast cancer (mBC). This efficacy in HER2-low disease (45–65% of cases) has spurred research into optimal methods for identifying eligible patients. We propose molecular imaging to explore intra-/interpatient heterogeneity in HER2 mapping of metastatic disease and to identify patients unlikely to benefit from T-DXd. **Methods:** HER2-low mBC patients with IHC1+ or IHC 2+/FISH ≤ 2.2 scheduled for T-DXd underwent paired HER2-targeted [^{18}F]AlF-HER2-BCH PET/CT (HER2−PET) and [^{18}F]FDG−PET/CT (FDG−PET) at baseline and 2 cycle follow-up. High-uptake was defined as having >50% of tumors with a baseline SUVmax >6.0 on HER2−PET; otherwise, it was low uptake. HER2-PET was defined as nonresponding showed no significant reduction of HER2 uptake (10%) at 2 cycle follow-up. Negative (NPV) and positive predictive values (PPV) of HER2−PET, FDG−PET, early HER2/FDG response, and their combination were assessed to predict morphological response (RECIST 1.1) after two T-DXd cycles and time-to-treatment failure (TTF). **Results:** In the 32 HER2-low mBC patients analyzed, 24 (75%) had high baseline HER2-PET uptake (SUVmax >6.0), while 8 (25%) had low uptake. Of 24 high-uptake patients, 14 (58.3%) achieved a complete response (CR), 7 (29.2%) initially reached a partial response (PR) after two T-DXd cycles but later developed progressive disease (PD) between cycles 5–10, and 3 (12.5%) experienced PD as early as cycle 2. In the low-uptake group (n=8), one patient (12.5%) with isolated pulmonary metastases maintained stable disease (SD) through 14 cycles, whereas 7 (87.5%) patients with multiple metastases developed rapid PD. Compared with RECIST1.1, respective NPV/PPV for baseline HER2−PET were 87.5%/87.5% for predicting treatment response at 2 cycles. When combining baseline HER2-PET uptake with early 2 cycles, patients with high baseline uptake and a ΔSUVmax >40% had a median TTF of 15.3 months [n = 14, 95% confidence interval (CI) 7.7−−not calculable], those with high baseline uptake and a 10% < ΔSUVmax <40% a median TTF of 4.8 months [n = 7, 95% CI: 3.8−9.8]; and patients with a ΔSUVmax <10% a median TTF of only 1.3 months [n = 10, 95% CI: 1.3, 3.9]. Baseline FDG uptake was not associated with lesion response status, and while trends in ΔSUVmax aligned with those observed in HER2-PET, no clear cutoff value was established in this study. **Conclusions:** Baseline HER2-PET uptake, especially when combined with early on-treatment ΔSUVmax, not only improves the understanding of tumor heterogeneity but also offers an imaging-guided strategy to personalize management and select patients most likely to benefit from T-DXd in HER2-low mBC. Clinical trial information: NCT06909604; NCT04547309. Research Sponsor: None.

Intracranial efficacy and safety of trastuzumab deruxtecan in HER2-positive and HER2-low metastatic breast cancer with central nervous system involvement: A systematic review and proportional meta-analysis. First Author: Dua Azim, Department of Medicine, Rochester General Hospital, Rochester, NY

Background: Central nervous system (CNS) metastases and leptomeningeal disease (LMD) are major drivers of morbidity and mortality in metastatic breast cancer (MBC). Trastuzumab deruxtecan (T-DXd) has demonstrated intracranial activity across multiple studies; however, evidence remains fragmented across heterogeneous CNS subgroups. We conducted a systematic review and meta-analysis to assess intracranial efficacy and survival outcomes, along with interstitial lung disease (ILD) risk with T-DXd monotherapy in CNS-involved HER2-positive and HER2-low MBC. **Methods:** Following PRISMA guidelines, prospective trials and retrospective cohorts reporting CNS outcomes with T-DXd monotherapy were included. Fifteen unique cohorts met eligibility criteria. The primary endpoint was intracranial objective response rate (iORR). Secondary endpoints included progression-free survival (PFS) and overall survival (OS). Safety analysis included ILD incidence. Random-effects proportional meta-analyses and prespecified subgroup and sensitivity analyses were performed (RevMan 5.4.1). **Results:** In patients with active brain metastases (11 cohorts), pooled iORR was 0.61 (95% CI 0.55–0.66; I^2=0%). Similarly, in stable brain metastases (6 cohorts), pooled iORR was 0.61 (95% CI 0.50–0.71; I^2=75%); exclusion of an influential cohort increased pooled iORR to 0.65 (95% CI 0.55–0.75) and reduced heterogeneity. In LMD (3 cohorts), pooled CNS response was 0.53 (95% CI 0.35–0.70; I^2=0%). HER2-low cohorts demonstrated a pooled iORR of 0.51 (95% CI 0.33–0.69), which did not differ significantly from HER2-positive CNS subgroups (p=0.75). Where comparative data were available, treatment with T-DXd was associated with improved PFS (HR 0.33, 95% CI 0.19–0.58) and overall survival (log HR −0.32, 95% CI −0.55 to −0.09; ≈HR 0.73). Safety analyses showed a pooled incidence of ILD (any grade) of 0.12 (95% CI 0.09–0.15), with higher rates observed in high-risk (0.16) and intermediate-risk (0.13) cohorts compared with low-risk cohorts (0.04). **Conclusions:** Across 15 cohorts, T-DXd demonstrates consistent and clinically meaningful intracranial activity in active and stable brain metastases, substantial activity in LMD, and a survival signal where comparative data exist, with quantifiable ILD risk. These findings support T-DXd as a key systemic therapy for CNS-involved HER2-positive and HER2-low MBC and underscore the need for standardized CNS endpoints and ILD mitigation strategies in future studies. Research Sponsor: None.

Neoadjuvant dalpiciclib combined with letrozole and dual HER2 blockade in HR+/HER2+ breast cancer: First-stage results of the HELEN HER2 017 trial. First Author: Jiujun Zhu, Department of Breast Disease, Henan Breast Cancer Center, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: Triple-positive breast cancer (TPBC; HR+/HER2+) represents a distinct subtype with suboptimal responses to conventional neoadjuvant chemotherapy combined with anti-HER2 therapy, with reported pCR rates of only 26%–43.8%, and is associated with significant treatment-related toxicities[1-3]. This highlights an urgent need for more effective and less toxic therapeutic strategies. We hypothesize that simultaneously targeting ER, HER2, and CDK4/6 pathways may enhance antitumor efficacy while enabling chemotherapy de-escalation. This phase II study investigates a response-guided, chemotherapy-free neoadjuvant regimen using dalpiciclib (a CDK4/6 inhibitor), aromatase inhibitor (AI), and dual HER2 blockade. **Methods:** This prospective, single-arm, two-stage Simon optimal design study planned to enroll 71 patients. In stage one, 20 patients were enrolled; proceeding to stage two required ≥6 pCRs. The final success threshold is ≥24 pCRs in 71 patients (α=0.05, power=80%, H0: pCR≤25% vs. H1: pCR≥40%). Eligible patients had stage II–IIIa HR+/HER2+ invasive breast cancer. Treatment included oral dalpiciclib (150 mg/day, 3 weeks on/1 week off), oral letrozole (2.5 mg/day; with ovarian suppression if premenopausal), and IV trastuzumab (loading 8 mg/kg, then 6 mg/kg) plus pertuzumab (loading 840 mg, then 420 mg) every 3 weeks. This was a response-adaptive design: after 2 cycles, MRI assessed tumor response. Patients achieving PR (≥30% reduction per RECIST 1.1) continued the same regimen for 6 cycles; non-responders switched to TCHP chemotherapy (docetaxel, carboplatin, trastuzumab, pertuzumab). The primary endpoint was pCR (ypT0/is ypN0) in the all-treated population. Secondary endpoints included ORR, RCB 0-1, EFS, and safety. **Results:** In the first stage, 20 patients were enrolled. Median age was 48 years (range 34–59). All were ER+ and HER2+ by central review. After 2 cycles, 15 of 20 patients (75%) achieved PR and continued on the dalpiciclib, letrozole, and dual HER2 blockade regimen. Of the 20 patients, 8 achieved pCR, with a rate of 40%. Among the MRI responders who continued the experimental arm, the pCR rate was 40% (6/15). Treatment was generally well-tolerated; the most common adverse events were neutropenia, leukopenia, anemia, and thrombocytopenia. No treatment-related discontinuations or cardiac toxicity of grade 3 or higher were observed. **Conclusions:** The first stage of this response-guided study met its predefined efficacy threshold (≥6 pCR in 20 patients). The neoadjuvant regimen combining dalpiciclib, an AI, and dual HER2 blockade shows promising pCR rates and a favorable safety profile in TPBC, supporting continued evaluation in the second stage of the trial. Clinical trial information: NCT06276868. Research Sponsor: None.

Safety and efficacy of ZN-A-1041, a highly blood-brain barrier (BBB)–permeable HER2 tyrosine kinase inhibitor (TKI), + trastuzumab deruxtecan (T-DXd) or pertuzumab-trastuzumab (PH) in HER2-positive metastatic breast cancer (HER2+ mBC): Phase Ic expansion results from the ZN-A-1041-101-US trial. First Author: Nancy U. Lin, Dana-Farber Cancer Institute, Boston, MA

Background: Brain metastases (BMs) are a common site of progression in HER2+ mBC due to limited BBB penetration of systemic therapies. ZN-A-1041 is an oral, selective HER2 TKI designed for high intact BBB permeability. We report ZN-A-1041-101-US (NCT05593094) Phase Ic expansion results of ZN-A-1041 + T-DXd in patients (pts) with HER2+ mBC refractory to prior treatments (txs), or + PH as maintenance therapy after first-line taxane + H ± P induction. Phase Ia and Ib (dose-escalation as single agent or in combination therapies) results have been reported (Anders ASCO 2023). **Methods:** The study enrolled pts with HER2+ mBC, with or without BMs (including leptomeningeal disease). Pts in Phase Ic received ZN-A-1041 800 mg twice daily (BID) + PH (Arm C), or were randomized to ZN-A-1041 800 mg or 600 mg BID, + T-DXd 5.4 mg/kg every 3 weeks (Arms A and B, respectively). Primary objectives: safety and tolerability. Secondary objectives included systemic objective response rate (ORR) and disease control rate (DCR) per Response Evaluation Criteria in Solid Tumours version 1.1. **Results:** As of July 31, 2025 (last pt in), enrollment in Arms A, B, and C was 24, 23, and 20 pts, respectively; median age was 57, 54, and 46 years; 50, 36, and 70% had *de novo* stage IV disease. Baseline central nervous system (CNS) metastases were present in 58, 59, and 16% of pts. Median prior lines of therapy for metastatic disease was 1, 1, and 0. Median ZN-A-1041 tx duration was 23.0, 24.6, and 42.9 weeks. The most frequent all-grade tx-emergent adverse events (TEAEs) across Arms A, B, and C, respectively, were nausea (83, 96, and 47%), diarrhea (62, 77, and 68%), and vomiting (46, 64, and 47%); diarrhea (17, 9, and 5%) was the most frequent Grade ≥3 TEAE. Preliminary systemic efficacy is summarized in the Table. Intracranial lesion shrinkage was observed in pts with BMs across all tx arms. **Conclusions:** ZN-A-1041 showed manageable safety profiles and promising clinical activity when combined with standard anti-HER2 therapies in pts with HER2+ mBC, both with or without CNS metastases. High disease control in pts pretreated with T-DXd and notable continued responses in the PH maintenance setting support further clinical evaluation of these combinations. Clinical trial information: NCT05593094. Research Sponsor: F. Hoffmann-La Roche Ltd.

Arm	n	ORR, % (95% CI)	Complete response, % of pts	DCR, % (95% CI)
A: ZN-A-1041 800mg + T-DXd	20	**65.0** (40.8, 84.6)	**10.0**	**95.0** (75.1, 99.9)
B: ZN-A-1041 600mg + T-DXd	21	**76.2** (52.8, 91.8)	**9.5**	**90.5** (69.6, 98.8)
C: ZN-A-1041 800mg + PH	13*	**30.8** (9.1, 61.4)	**5.6**	**100** (75.3, 100.0)

*Efficacy reported for 13 pts with measurable disease receiving maintenance therapy with ZN-A-1041 + PH after taxane + H ± P induction.
CI, confidence interval.

TBCRC 050: A phase 1b/2 trial of niraparib and trastuzumab in HER2-positive metastatic breast cancer (MBC): Efficacy and correlative analyses. First Author: Erica Michelle Stringer-Reasor, O'Neal Comprehensive Cancer Center at The University of Alabama at Birmingham, Birmingham, AL

Background: Resistance to HER2-directed therapies remains a major challenge in HER2-positiveMBC. In preclinical models, HER2+ tumors overexpress poly (ADP-ribose) polymerase (PARP), and PARP inhibition induces apoptosis through NF-κB suppression even in the absence of pathogenic mutations in *BRCA 1/2*. We evaluated the safety, efficacy, and translational correlates of niraparib combined with trastuzumab in patients (pts) with refractory HER2+ MBC. **Methods:** This open-label Phase 1b/2 trial (NCT03368729) enrolled pts with HER2+ MBC (IHC 3+ and/or FISH amplified), measurable disease, LVEF ≥50%, and progression on ≥1 prior HER2-targeted therapy; stable CNS disease was allowed. Pts with germline BRCA1/2 mutations or prior PARP inhibitor exposure were excluded. Niraparib 300 mg orally was administered on Days 1–21 of a 21-day cycle with trastuzumab 6 mg/kg IV every 3 weeks (loading dose 8 mg/kg on cycle 1). The Phase 2 portion used a Gehan/Simon two-stage design with early stopping for futility (P0=24%); ≥1 response among the first 20 patients triggered expansion to 40 patients. ORR was assessed by RECIST v1.1, meeting the primary endpoint and allowing response rate estimation with <7% standard error and a two-sided 95% exact CI width of 0.28. Gene expression profiling of paired tumor tissue and peripheral blood mononuclear cells (PBMCs) was performed using the NanoString nCounter Tumor Signaling 360 panel at pretreatment compared to cycle 2. **Results:** Forty-six pts were enrolled (9/2019–2/2025); 41 were evaluable for response. Pts were heavily pretreated (median 3 prior regimens), including trastuzumab deruxtecan in 22 pts; 33% had brain metastases. Treatment-related adverse events were predominantly grade 1–2 and manageable. Clinical benefit rate (CBR) was 44% (18/41) including 1 complete response, 2 partial responses, and 15 stable disease. Eleven patients achieved disease control ≥ 6 months; 1 patient remained on treatment at data cutoff. Tumor profiling revealed enrichment of a B-cell–driven tertiary lymphoid structure signature with reduced hypoxia signaling in responders. Matched PBMC analyses demonstrated coordinated downregulation of interferon signaling, DNA damage response, metabolic activation, angiogenesis, and resistance pathways in clinical responders, whereas non-responders retained signatures of chronic stress and immune exhaustion. **Conclusions:** Niraparib plus trastuzumab demonstrated a favorable safety profile and durable clinical benefit in heavily pretreated HER2+ MBC. Integrated tumor and blood-based analyses identify immune-organized tumor microenvironments and systemic immune normalization as key correlates of prolonged response, supporting further investigation of PARP inhibition strategies. Real-world cardiotoxicity with HER2 antibody–drug conjugates and survival after treatment continuation. First Author: Sumbal Aziz, AdventHealth Sebring, Sebring, FL

Background: HER2 antibody–drug conjugates (ADCs) are central to HER2-positive breast cancer (BC) treatment, yet cardiotoxicity remains a clinically relevant complication that may prompt treatment interruption. While HER2-related cardiac dysfunction is frequently reversible, uncertainty persists regarding the safety and survival impact of treatment continuation, particularly with newer ADCs. We assessed real-world cardiotoxicity and the association between treatment continuation and overall survival (OS), focusing on trastuzumab deruxtecan (T-DXd) and trastuzumab emtansine (T-DM1). **Methods:** Using the TriNetX Research Network (2010–2025), adults with BC treated with HER2-targeted therapy and no prior diagnosis of heart failure or cardiomyopathy were identified. Incident cardiotoxicity (heart failure or cardiomyopathy) within one year of therapy initiation was captured. OS from cardiotoxicity diagnosis was compared between patients (Pts) who resumed versus discontinued HER2-targeted therapy. Kaplan–Meier methods were used to estimate survival, and Cox proportional hazards models generated hazard ratios (HRs) with 95% confidence intervals (CIs). **Results:** Among 31,656 HER2-treated Pts, 4,593 (14.5%) developed cardiotoxicity within one year; 629 (11.1%) occurred with HER2 ADCs. Incidence was lower with ADCs than non-ADC therapy (T-DM1 11.6%, T-DXd 9.9%). After cardiotoxicity, 3,374 Pts (73.5%) resumed HER2 therapy, including 48.5% with T-DM1 and 47.7% with T-DXd. 5-year OS was significantly higher with HER2-targeted treatment resumption versus discontinuation (79.5% vs 66.9%; absolute difference 12.6%; $p<0.0001$), with a 55% mortality risk reduction (HR 0.45, 95% CI 0.39–0.51). ADC-specific analyses showed benefit, greatest for T-DXd (HR 0.25, 95% CI 0.14–0.43; absolute 5-year OS difference 19.3%) and T-DM1 (HR 0.34, 95% CI 0.23–0.50; absolute difference 21.0%). Pts who resumed therapy were younger than those who discontinued (58.0±13.1 vs 61.8±13.5 years). After multivariable adjustment, treatment resumption remained independently associated with improved OS (adjusted HR 0.45, 95% CI 0.39–0.51), though residual confounding cannot be excluded. **Conclusions:** In this large real-world cohort, continuation of HER2 ADCs after cardiotoxicity was associated with substantially improved OS. These findings support a multidisciplinary cardio-oncology approach and suggest that, when feasible, resuming HER2 ADCs—particularly T-DXd and T-DM1—may confer meaningful survival benefit. Research Sponsor: None.

Cardiotoxicity and survival outcomes with HER2/ADCs.

Agent	Total Treated (N)	Cardiotoxicity (%)	Therapy Resumed (%)	5-year OS % (Resumed vs Not)	Absolute OS Difference	HR (95% CI)
All HER2	31,656	14.5	73.5	79.5 vs 66.9	+12.6%	0.44 (0.39-0.51)
T-DM1	4,085	11.6	48.5	74.9 vs 53.9	+21.0%	0.34 (0.23-0.50)
T-DXd	1,558	9.9	47.7	48.0 vs 28.7	+19.3%	0.25 (0.14–0.43)

1058 Poster Session

HER2-targeted tyrosine kinase inhibitors in breast cancer: Real-world analysis of gastrointestinal and musculoskeletal toxicities using the FAERS database. First Author: Sneha Singh, Sunrise Hospital and Medical Center, Las Vegas, NV

Background: Human Epidermal Growth Factor Receptor 2 (HER2)-targeted tyrosine kinase inhibitors (TKIs) lapatinib, neratinib, and tucatinib are approved for HER2-positive breast cancer but have distinct adverse event (AE) profiles. We analyzed the Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) database to characterize gastrointestinal (GI) and musculoskeletal (MSK) toxicities associated with these agents. **Methods:** We conducted a retrospective FAERS data review to assess GI and MSK AEs associated with the three TKIs from 2020-2025. The chi-square test was used to compare categorical variables across drugs and age groups (<65 vs ≥65 years). **Results:** Among 9,045 total cases (lapatinib n=1,897; neratinib n=1,113; tucatinib n=6,035), neratinib demonstrated the highest GI toxicity rate at 64.2%, compared to 40.4% for tucatinib and 31.3% for lapatinib (χ^2=319.3, $p<0.001$). Diarrhea was the predominant GI AE across all agents, affecting 82.1% of neratinib-treated patients, 64.8% of tucatinib-treated patients, and 55.6% of lapatinib-treated patients. Other common GI AEs included nausea (33.2 neratinib, 34.6 tucatinib, 23.1 lapatinib) and vomiting (21.1% neratinib, 19.5% tucatinib, 23.9 lapatinib). MSK AE rates were comparable across all three agents (lapatinib 10.5%, neratinib 11.3%, tucatinib 10.5%; χ^2=0.72, p=0.70). The most frequent MSK AEs were pain in extremities (23% overall), arthralgia (18% overall), back pain (17.8% overall), and muscle spasms (17.6% overall). Age-stratified analysis revealed significant differences in GI toxicity. In patients <65 years, neratinib showed the highest GI AE rate at 63.1%, versus 34.8% for tucatinib and 28.1% for lapatinib (χ^2=74.0, $p<0.001$). In patients ≥65 years, this pattern persisted with neratinib at 73.7%, tucatinib at 36.9%, and lapatinib at 40.1% (χ^2=49.4, $p<0.001$). Moreover, older patients (≥65 years) experienced significantly higher rates of both GI and MSK AEs with lapatinib (GI: 40.1% vs 28.1%, $p<0.001$; MSK: 19.3% vs 9.6%, $p<0.001$) and neratinib (MSK: 25.3% vs 6.3%, $p<0.001$). Tucatinib showed no significant age-related differences in AE rates. **Conclusions:** The findings in this study highlight trends for selected AEs with various TKIs in order to help guide shared decision-making and tailored management strategies for patients with HER2-positive breast cancer. Research Sponsor: None.

1059 Poster Session

Dual HER2 blockade with or without taxane induction in HR+/HER2+ metastatic breast cancer: A comparative analysis of clinical outcomes. First Author: Mariah Black, Texas Tech University Health Sciences Center El Paso, El Paso, TX

Background: In the era of modern dual HER2 blockade, the necessity of taxane induction for ER+/HER2+ metastatic breast cancer (MBC) remains debated. While CLEOPATRA established pertuzumab/trastuzumab plus taxane as a standard backbone, emerging de-escalation strategies suggest that endocrine therapy (ET) combined with HER2 blockade may provide durable disease control in this favorable-prognosis subgroup (SYSUCC002, PERTAIN). Robust real-world comparative data addressing the survival–toxicity trade-off between chemotherapy-free versus taxane-induction approaches are limited. **Methods:** The TriNetX Global Collaborative Network (168 healthcare organizations; data updated Dec 2025) was queried for adults (≥18 years) with incident HR+/HER2+ MBC treated with dual HER2 blockade (trastuzumab + pertuzumab) plus ET. Patients receiving induction taxane (paclitaxel or docetaxel) comprised the induction cohort (IND); those treated with dual blockade + ET without induction comprised the chemotherapy-free cohort (Chemo-Free). 1:1 propensity-score matching (greedy nearest-neighbor; caliper 0.10) on demographics and comorbidities yielded 137 well-balanced pairs (N=274) with all post-match standardized mean differences <0.10. The primary endpoint was 3-year overall survival (OS; 1095-day window). Secondary outcomes included neutropenia, sepsis, heart failure, emergency department (ED) visits, and ICU admission. **Results:** Among 957 eligible patients, 153 received Chemo-Free and 804 received IND; 137 matched pairs were analyzed. Three-year OS was similar between cohorts with no statistically significant separation of survival curves (3-year OS 89.1% Chemo-Free vs 82.0% IND; HR 0.65 [0.32–1.31]; p=0.219). Deaths within 3 years were 13/137 (9.5%) in Chemo-Free versus 19/137 (13.9%) in IND, corresponding to an absolute death risk difference of −4.4% (95% CI −12.0% to +3.2%). Omitting induction was associated with reduced neutropenia (12.4% vs 21.9%; absolute risk reduction 9.5%; OR 0.51 [0.26–0.97] and a lower time-to-neutropenia hazard (HR 0.50 [0.28–0.91]; p=0.020). Serious adverse events and acute care utilization were not increased with Chemo-Free: heart failure 16.1% vs 16.1%; sepsis 10.9% vs 13.1%; ICU admission 11.7% vs 13.9%; ED visits 40.9% vs 45.3%. **Conclusions:** In a propensity-matched real-world cohort receiving contemporary dual HER2 blockade plus ET, a chemotherapy-free strategy demonstrated similar 3-year OS compared with taxane induction, with a clinically meaningful reduction in neutropenia (number needed to treat ≈11 to prevent one event) and no signal for higher sepsis, heart failure, or acute care utilization. These data support the feasibility of chemotherapy de-escalation in selected HR+/HER2+ MBC patients and motivate prospective validation to refine patient selection and minimize treatment-related toxicity. Research Sponsor: None.

Nanochemo-immunotherapy of ER-positive metastatic breast cancer (MBC) with PEG-liposomal doxorubicin (PLD) and pembrolizumab (PEM). First Author: Alberto A. Gabizon, Shaare Zedek Medical Center - Oncology Institute, Jerusalem, Israel

Background: PLD is a nanomedicine containing doxorubicin, a potent immunogenic cell death inducer. Based on the pharmacological profile of PLD, we hypothesized that PLD-based chemotherapy should allow for improved immune recognition of tumor cells and activation of T cells by PD1 blockade. We report here the results of a phase 1B study with a combination of PLD and PEM in ER+/Her2 negative MBC. **Methods:** Patients with MBC, whose disease progressed on hormonal, CDK 4/6 inhibitors and up to 3 lines of chemotherapy, were eligible for enrollment. Primary objectives were evaluation of safety and tumor response, and secondary objectives were overall survival and pharmacokinetic analysis of PLD and PEM. In a first cohort of 15 patients, PLD 30 mg/m^2 was infused along with PEM 200 mg on day 1 every 3 weeks. In a second cohort of 20 patients, PLD 40 mg/m^2 was infused on day 1 every 4 weeks without change of PEM dose-schedule. Responding and stable patients continued treatment until disease progression or treatment intolerance. All patients were followed up on for survival. **Results:** 35 patients were enrolled. A total of 201 PLD and 257 PEM treatments were administered until data lock. Treatment was well tolerated with no grade 3-4 neutropenia, no cardiac events, and no grade 2 hair loss. In one patient, a severe infusion reaction to PLD was observed forcing discontinuation of PLD in the 2nd cycle. There were 2 cases of grade 4 hepatitis, 1 case of grade 4 hemolytic anemia, and 5 cases of grades 1-2 hypothyroidism, possibly or probably related to PEM. PLD-related skin toxicity (palmar-plantar erythema, grades 1-2) was observed after 3 or more cycles, forcing treatment delays. Among evaluable patients receiving ≥3 cycles of PEM (n=30), we observed 8 partial and 2 complete responses with a long median duration of response (11 mo) and survival (28 mo). In 5 patients, near complete responses of large liver metastases were observed. Median survival was 25 mo for all patients and 26 mo for evaluable patients. Eight patients, including 1 patient still under treatment, remain alive at data lock with survival in the range of 10+ to 51+ mo. The plasma clearance of PLD was mono-exponential with high Cmax, long $T^1/_2$ (~3 days), slow clearance, and small Vcc. There was a significant increase of ~20% in the average AUC of PLD between the 1st and 3rd cycle indicating delayed clearance upon PLD retreatment. Analysis of PEM plasma levels revealed a mean $T^1/_2$ of ~11 days with high trough concentration by end of the cycle implying saturation of all accessible PD1 receptors. **Conclusions:** The combination of both dose levels of PLD with PEM is well tolerated, active, and feasible for extended treatment with durable responses. The favorable response and survival data in this heavily pretreated patient group suggest that PEM has significant contribution to the anti-tumor effect. A randomized study in ER+ MBC patients based on this regimen is warranted. Clinical trial information: NCT03591276. Research Sponsor: Merck USA; MK-3475 733.

Effectiveness outcomes by treatment-free interval among patients receiving palbociclib plus endocrine therapy in HR+/HER2− advanced breast cancer in the real-world setting: Results from the PERFORM study. First Author: Rupert Bartsch, Medical University of Vienna, Department of Medicine 1, Division of Oncology, Vienna, Austria

Background: Combination of CDK4/6 inhibitors (CDK4/6i) plus endocrine therapy (ET) is first-line (1L) standard of care for patients (pts) with HR+/HER2- advanced breast cancer (ABC). Treatment-free interval (TFI) is an established prognostic factor in ABC. Shorter TFI is associated with more aggressive disease biology, inferior treatment outcomes, and reduced overall survival (OS). Real-world (RW) evidence complements clinical trials by providing insights into pts underrepresented in clinical trials. We present interim analysis 5 (IA5) of the PERFORM study, evaluating outcomes by TFI in pts receiving 1L palbociclib + ET. **Methods:** The prospective, non-interventional study PERFORM (NCT04767594) enrolled pts across Germany and Austria receiving 1L palbociclib + ET. Primary endpoint is progression-free survival (PFS). Secondary endpoints include second line (2L) PFS, PFS2 (time from 1L start to progression on 2L or death) and OS. Tumor assessments followed local medical standards. Quality of life (QoL) was assessed using FACT-B questionnaires. Pts were stratified by TFI, defined as time from last (neo) adjuvant treatment to recurrence: >12 months, ≤12 months, and de novo advanced disease. Time-to-event endpoints were estimated using the Kaplan-Meier method. **Results:** At database cutoff (Sep 30th, 2025), 1268 pts were included in IA5 and 1010 pts had available TFI data for subgroup analysis (TFI >12 months: 373 pts; ≤12 months: 133 pts; de novo: 504 pts). Median age was 69.5, 64.4, and 68.8 years, respectively. Pts with TFI ≤12 months showed a more aggressive disease profile such as higher rates of G3 tumors, N2-3 nodal status and liver metastasis compared to other TFI subgroups. Overall median PFS was 25.5 months (95% CI: 23.0-28.6), while median PFS was 29.2 months (95% CI: 23.3-33.1) for TFI >12 months, 14.6 months (95% CI: 9.3-19.4) for TFI ≤12 months, and 31.5 months (95% CI: 26.5-36.7) for pts with de novo disease. Median PFS2 was 39.0 (95% CI:33.7-51.4), 21.2 (95% CI: 17.4-37.0), and 40.9 months (95% CI: 37.0-46.9) for TFI >12, ≤12, and de novo, respectively. Median OS was not reached for TFI>12 months and was 37.4 and 52.8 months for TFI ≤12 and de novo, respectively. QOL with 1L therapy was maintained in all subgroups. **Conclusions:** The PERFORM IA5 supports TFI as a relevant prognostic factor for pts treated with palbociclib + ET in the 1L RW setting. QOL was maintained in TFI subgroups. Longest clinical benefit was observed in pts with TFI > 12 months and those with de novo disease. Treatment was associated with shorter clinical outcome in pts with TFI≤12 months compared to those in other TFI subgroups. These results complement those in the RCT setting. Research Sponsor: Pfizer Pharma GmbH, Germany.

Clinical efficacy of a novel oral SERD TFX06 in prior fulvestrant-treated ER+/HER2− advanced breast cancer patients in a dose expansion study. First Author: Wenxing Qin, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Patients with ER+/HER2- advanced breast cancer who have progressed on prior endocrine therapies, including fulvestrant, represent an area of unmet medical need, particularly those harboring ESR1 mutations. As far as we know, there was limited reports on efficacy of oral SERD in prior fulvestrant treatment progressed patients. TFX06 is an investigational next-generation oral SERD. Here, we report results from a Phase I/II study of TFX06 in patients with ER+/HER2- advanced breast cancer who had progressed from prior fulvestrant treatment (NCT05927779). **Methods:** Eligible patients regardless of their menopausal status, who had received ≥1 lines of endocrine therapy (ET), prior fulvestrant (fulv) treated with or without CDK4/6i, and ≤2 line of chemotherapy in metastatic disease, were allowed to enroll. TFX06 tablets were orally administered at 150mg once daily (QD) in 28-day cycles until disease progression or intolerable toxicity. This analysis focuses on the subgroup with prior fulvestrant exposure. As of cut-off date December 22, 2025, 42 patients received TFX06 monotherapy at 150mg. Median age was 60.5 years (range, 34-73), 76.2% had an ECOG performance status of 1. 88.1% had visceral metastasis, and 16.7% had brain metastasis. The median number of prior endocrine therapies in the advanced or metastatic setting was 2 (range, 1-3), including fulvestrant (100%), CDK4/6i (85.7%) with combination (76.2%). Tumor assessments by investigators according to RECIST v1.1 were performed every eight weeks. **Results:** Of the 42 enrolled patients, 40 were evaluable for efficacy. In the full analysis set (n=40), median progression-free survival (PFS) was 5.5 months (95% CI, 3.2−7.8). The objective response rate (ORR) was 7.5% (3/40), disease control rate (DCR) was 60.0% (24/40), and clinical benefit rate (CBR) was 44.1% (15/34). In the ESR1-mutant subgroup (n=23), median PFS was 5.7 months (95% CI, 2.5−8.8), ORR was 8.7% (2/23), DCR was 65.2% (15/23), and CBR was 47.1% (8/17). Treatment emergent adverse events (TEAEs) occurred in 95.2% of patients (40/42), with grade ≥3 events in 26.2% (11/42). Most common TEAEs (≥20%) are laboratory abnormalities; they included hypertriglyceridemia (47.6%), increased AST (31.0%), anemia (31.0%), decreased lymphocyte count (23.8%), and decreased white blood cell count (21.4%). No TEAEs led to treatment termination. **Conclusions:** TFX06 showed promising clinical activity and a manageable safety profile in patients who progressed from prior fulvestrant-treatments including combination with CDK4/6i in ER+/HER2- advanced breast cancer, including those with ESR1 mutations. These findings support further development of TFX06 as a potential therapeutic option in this population. Clinical trial information: NCT05927779. Research Sponsor: None.

1063 **Poster Session**

Impact of adherence to interstitial lung disease (ILD)/pneumonitis toxicity management guidelines (TMGs) on ILD/pneumonitis outcomes: A retrospective analysis of patients (pts) treated with trastuzumab deruxtecan (T-DXd) in DESTINY-Breast06 (DB-06). First Author: Carla Mateo, Chief Medical Office, Patient Safety, Oncology R&D, AstraZeneca, Barcelona, Spain

Background: DB-06 (NCT04494425) showed a progression-free survival benefit with T-DXd vs physician's choice of chemotherapy for pts with hormone receptor–positive, HER2-low/-ultralow metastatic breast cancer, with no new safety signals. We report adherence rates to ILD/pneumonitis TMGs and their impact on ILD/pneumonitis outcomes. **Methods:** We retrospectively analyzed pts who received ≥1 dose of 5.4 mg/kg T-DXd and had adjudicated drug-related ILD/pneumonitis by the Mar 18, 2024 data cutoff. Adherence criteria were defined by ILD/pneumonitis severity at diagnosis (per investigator assessment) and associated TMGs (Table); adherence was classified as complete (CA), partial (PA), or non-adherence (NA) by TMG criteria met (all, ≥1 but not all, or none, respectively). Investigator-reported ILD/pneumonitis outcomes were 'recovered' (± sequelae), 'recovering', 'not recovered', and 'fatal'. **Results:** Of 49 pts with adjudicated drug-related ILD/pneumonitis, respective rates of CA, PA, and NA were 73.5% (n=36), 14.3% (n=7), and 12.2% (n=6). By Mar 24, 2025, 66.7% (n=24) of pts with CA and 71.4% (n=5) with PA had an outcome of recovered ± sequelae, with no fatalities. Of pts with NA, 50% (n=3) did not recover, including one fatality. At diagnosis, 31 (63.3%), 15 (30.6%), and 3 (6.1%) pts had Grade (Gr) 1, 2, and 3 ILD/pneumonitis, respectively. Across all cases, 38.8% (n=19) progressed to a worse grade after diagnosis; progression from Gr 1 to Gr 2 represented 84.2% of progressions. Of 25 pts with Gr 1 ILD/pneumonitis and CA (optional steroid use), 16 received steroids and 9 did not; recovery rates were comparable (68.8% with steroids vs 66.7% without). For pts with Gr ≥2 ILD/pneumonitis and CA or PA (n=18), steroid use as recommended was associated with improved recovery rates (66.7% with steroids vs 33.3% without). Two pts with Gr 1 ILD/pneumonitis at diagnosis were rechallenged with 4.4 mg/kg T-DXd; both had recurrent Gr 1 ILD/pneumonitis but recovered. **Conclusions:** Adherence to ILD/pneumonitis TMGs was associated with improved ILD/pneumonitis outcomes in this small subset of pts. Steroid use as recommended for Gr ≥2 cases was associated with improved recovery. While further investigation of patient-level determinants of recovery is needed, these data demonstrate that adhering to ILD/pneumonitis TMGs may optimize ILD/pneumonitis outcomes. Clinical trial information: NCT04494425. Research Sponsor: AstraZeneca in collaboration with Daiichi Sankyo.

Adherence criteria by ILD/pneumonitis grade at diagnosis.

	Gr 1	Gr 2	Gr ≥3
T-DXd interrupted after AE onset	Yes	–	–
T-DXd discontinued after AE onset	–	Yes	Yes
500–1000 mg/day methylprednisolone for 3 days	–	–	Yes
≥1 mg/kg/day prednisone*	–	Yes	Yes
Steroid duration ≥14 days	–	Yes	Yes

CAPTURE: A phase II trial evaluating alpelisib + fulvestrant vs capecitabine in advanced breast cancer patients with *PIK3CA*-mutant circulating DNA following CDK4/6 inhibition. First Author: Eileen Geoghegan, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: *PIK3CA* mutations are a key therapeutic target in ER+ advanced breast cancer (ABC) readily detectable through circulating tumor DNA (ctDNA). The PI3Kα inhibitor alpelisib is approved in ER+ HER2- ABC but it remains unclear when to incorporate it into the current treatment algorithm. To address this, we conducted a phase II study assessing superiority of alpelisib + fulvestrant vs capecitabine in ABC pts with detectable *PIK3CA* mutant ctDNA following CDK4/6i plus aromatase inhibition (AI). **Methods:** Eligible pts had ER+ HER2- ABC, prior progression on CDK4/6i+AI and *PIK3CA* mutations detected via ctDNA ddPCR. Pts were randomized 1:1 to receive alpelisib (300mg daily) + fulvestrant (Arm A), or capecitabine (1000-1250mg/m^2 BD D1-14 q21d) (Arm B); strata were prior chemo for ABC and visceral disease. Primary endpoint was progression free survival (PFS) defined from randomization until progressive disease per RECIST 1.1 or death. Secondary endpoints included objective response rate (ORR), clinical benefit rate (CBR) and adverse events (AE). Imaging was q8 weeks. Exploratory objectives included efficacy according to baseline ctDNA levels. Sample size was reduced from 140 to 66 pts randomized for 53 PFS events to detect median PFS of 9 vs 5 mo (HR=0.56;1-sided α=0.1,80% power). Interim inefficacy analysis (60% events) estimated HR>1.0 and IDMC recommended early termination. Follow-up continued until all pts completed alpelisib. Reported are stratified Cox model HR (2-sided 80% CI) and 2-sided log rank test. **Results:** From July 2020-Oct 2024, 396 pts were screened, 113 (29%) had PIK3CA mutant ctDNA, 58 were randomized and 55 initiated treatment (Arm A: 29/30; Arm B: 26/28). Median age was 56 (32-82 yrs), 75% had visceral disease; 87% had no prior chemo for ABC. At final analysis, 43 PFS events occurred. Median PFS was 7.4 mo for alpelisib + fulvestrant vs 9.4 mo for capecitabine (HR 1.28, 80% CI: 0.84-1.96, p=0.45). For pts with visceral disease, median PFS was 5.4 mo (80% CI:3.7-5.1) for alpelisib + fulvestrant and 12.1 mo (80% CI:5.4-15) for capecitabine. ORR was 24.1% vs 50.0% and CBR 55.2% vs 61.5% for alpelisib + fulvestrant vs capecitabine. Overall, 79.3% pts on alpelisib + fulvestrant had grade 3/4 AEs with 24% grade 3 hyperglycemia vs 46.2% on capecitabine with 12% grade 3 palmar-plantar erythrodysesthesia. Six of 30 pts discontinued alpelisib due to AEs; 5 of the 6 continued fulvestrant. There was no evidence of association between baseline ctDNA levels (PIK3CA mutant copies/ml; median 90; range 2-13678) and PFS (HR 1.03; 90%CI:0.90-1.19). **Conclusions:** In our trial of pts with *PIK3CA* mutant ABC after progression on CDK4/6i plus AI, targeted therapy with alpelisib + fulvestrant was not superior to standard chemotherapy with capecitabine. Compared with the targeted therapy, capecitabine was better tolerated and resulted in longer PFS. Clinical trial information: ACTRN12619001117101. Research Sponsor: National Health and Medical Research Council (NHMRC); #1143025.

1065 Poster Session

Subgroup analysis of participants (pts) with HER2 IHC0 in the ASCENT-07 study of sacituzumab govitecan (SG) vs chemotherapy in HR+/ HER2− metastatic breast cancer (mBC). First Author: Yeon Hee Park, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: SG was evaluated in the phase 3 ASCENT-07 study (NCT05840211) of pts with HR+/ HER2−, locally advanced unresectable or mBC who had received prior endocrine therapy (ET) and were eligible for first chemotherapy; the primary end point (PFS by blinded independent central review [BICR] vs chemotherapy treatment of physician's choice [TPC]) was not met (HR 0.85; 95% CI, 0.69-1.05; P = .130). We report exploratory outcomes in pts with HER2 IHC0 expression status. **Methods:** Pts were randomized 2:1 to receive SG 10 mg/kg IV or TPC (capecitabine, nab-paclitaxel, or paclitaxel). Descriptive analyses of pts with HER2 IHC0 were performed for the primary end point of PFS by BICR, secondary end points of PFS by investigator (INV), overall survival (OS), objective response rate (ORR) and duration of response (DOR) by BICR, and safety. HER2 status was tested locally. **Results:** Of 690 pts enrolled, 292 (42%) had HER2 IHC0 (SG: 192; TPC: 100). Baseline demographics and pt characteristics were similar to the overall population. Median age was 58 yrs; 176 (92%) and 91 (91%) pts in SG and TPC groups, respectively, received prior ET + CDK4/6i in the metastatic setting; 88% and 86% had visceral disease. At 15.4-mo median f/u, SG showed numerical improvement in PFS vs TPC by BICR (HR 0.75; 95% CI 0.55-1.02; nominal P = .0601) and by INV (HR 0.66; 95% CI 0.50-0.86; nominal P = .0024). Although OS data were not mature (maturity rate for IHC0 subgroup, 28%), an early improvement trend favoring SG was observed. ORR by BICR was similar for SG and TPC, and median DOR by BICR was longer for SG vs TPC. Despite a higher proportion of pts experiencing grade ≥ 3 treatment-emergent adverse events (TEAEs) with SG vs TPC, the rate of treatment discontinuation was lower with SG (Table). The most common grade ≥ 3 TEAEs were neutropenia (SG: 54%; TPC: 21%), leukopenia (12%; 7%), and anemia (11%; 5%). Safety profile was consistent with overall population and prior reports. **Conclusions:** In this exploratory analysis from ASCENT-07, numerical trends of improved efficacy vs TPC and the overall population as well as a manageable safety profile support further investigation into the potential benefit of SG in patients with HR+/HER2− mBC and HER2 IHC0 status who are candidates for first chemotherapy. Clinical trial information: NCT05840211. Research Sponsor: Gilead Sciences, Inc.

1066 Poster Session

First disclosure of frontline treatment (1L tx) with the selective CDK4 inhibitor BGB-43395 in combination with letrozole for metastatic HR+/ HER2− breast cancer (BC): A phase 1 safety expansion. First Author: Shom Goel, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: BGB-43395, a highly selective CDK4i, showed preclinical antitumor activity characterized by improved CDK4 target coverage and selectivity over CDK6. This enhanced selectivity may reduce off-target toxicity and the need for tx modifications. BGB-43395 is being evaluated as monotherapy or with endocrine therapy in patients (pts) with HR+/HER2− BC and other advanced solid tumors in an ongoing phase 1a/1b open-label, international study (NCT06120283). We report on the safety, preliminary anti-tumor activity, and pharmacodynamics (PD) of BGB-43395 + letrozole as 1L tx for BC. **Methods:** In safety expansion cohort 2, CDK4/6i-naive pts with advanced/metastatic HR+/HER2− BC were randomized to receive BGB-43395 240, 400, or 600 mg PO BID + letrozole to determine the recommended dose for further development. The objectives were to assess safety, preliminary anti-tumor activity, and PD. **Results:** As of Nov 11, 2025, 58 pts received study tx (240 mg n = 19; 400 mg n = 19; 600 mg n = 20). Treatment emergent adverse events (TEAEs) occurred in 98% of pts; grade (G)≥3 TEAEs in 32%, 37%, and 65% of pts on 240 mg, 400 mg, and 600 mg, respectively. The most common TEAEs (mostly G1/2) were (240 mg / 400 mg / 600 mg): diarrhea (79% / 95% / 90% [G3 5% / 11% / 30%]), nausea (53% / 68% / 85% [G3 0% / 5% / 0%]), and vomiting (26% / 47% / 60% [G3 0% / 0% / 0%]). Rates of TEAE hematologic toxicities (mostly G1/2) were low; neutrophil count decreased/ neutropenia (240 mg 26% [G3 0%]; 400 mg 21% [G3 0%]; 600 mg 20% [G3 10%]); anemia (240 mg 5% [G3 0%]; 400 mg 21% [G3 0%]; 600 mg 20% [G3 5%]); platelet count decreased/thrombocytopenia ([all G1 or 2] 240 mg 5%; 400 mg 0%; 600 mg 5%). TEAEs led to dose modification in 53% of pts (median relative dose intensity: 240 mg 100%; 400 mg 97%; 600 mg 69%), tx discontinuation in 3% (240 mg, 1 pt; 600 mg, 1 pt), and 0 deaths. BGB-43395 + letrozole demonstrated early efficacy (Table) and strong PD effects, indicated by TK1 reduction and ctDNA decrease. Median study follow-up was 6.8 (range 3.2-9.7) mo, median time-to-response was 3.6 (range 1.6-8.4) mo, and median PFS was not reached. **Conclusions:** The CDK4-selective inhibitor BGB-43395, in combination with letrozole, demonstrated a favorable safety profile, with low hematologic and manageable gastrointestinal toxicity. Antitumor activity in 1L tx of pts with advanced HR+/HER2− BC was promising. Doses of 400 mg and 240 mg BID demonstrated efficacy and safety that support further development in combination with letrozole. Clinical trial information: NCT06120283. Research Sponsor: BeOne Medicines, Ltd.

Vepdegestrant, a proteolysis targeting chimera (PROTAC) estrogen receptor (ER) degrader, plus abemaciclib (ABE) in ER+/human epidermal growth factor receptor 2-negative (HER2−) advanced breast cancer (ABC): TACTIVE-U phase 1b/2 results. First Author: Rachel M. Layman, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Substudy A of the open-label, phase 1b/2 TACTIVE-U umbrella study is evaluating vepdegestrant, an oral PROTAC ER degrader, in combination with ABE for treatment of ER+/HER2− ABC (NCT05548127). Here, we report results for all patients (pts) in phases 1b and 2 treated with vepdegestrant (200 mg orally once daily) plus ABE (150 mg orally twice daily). **Methods:** Eligible pts were adults (age ≥18 years) with ER+/HER2− ABC who had received 1–2 prior lines of therapy in the ABC setting; 1 prior cyclin-dependent kinase 4/6 inhibitor (CDK4/6i)-based regimen (in any setting) was required. The primary endpoint of phase 1b was dose-limiting toxicities during the first cycle. The primary endpoint of phase 2 was objective response rate (ORR); secondary endpoints included clinical benefit rate (CBR), progression-free survival (PFS), safety, and pharmacokinetics (PK). **Results:** As of October 10, 2025, 37 female pts (median age, 59 years [range, 38–84]; 20 pts [54.1%] had *ESR1*-mutated [*ESR1*m] tumors) received vepdegestrant plus ABE in phases 1b and 2, with 26 pts treated for ≥5 28-day cycles; 10 remain on treatment. All pts received prior CDK4/6i (ribociclib, 48.6%; palbociclib, 43.2%; ABE, 8.1%) in any setting; prior treatments in the metastatic setting included aromatase inhibitors (64.9%), fulvestrant (35.1%), and chemotherapy (21.6%). Among pts with measurable disease at baseline, the ORR was 30.6% (95% CI, 18.0–46.9) in all pts and 45.0% (95% CI, 25.8–65.8) in pts with *ESR1*m tumors. The CBR was 59.5% (95% CI, 43.5–73.7) in all pts and 65.0% (95% CI, 43.3–81.9) in pts with *ESR1*m tumors. Median PFS was 7.2 months (95% CI, 5.5–16.5) in all pts and 10.9 months (95% CI, 5.5–not estimable) in pts with *ESR1*m tumors. Five pts (13.5%) discontinued treatment due to treatment-emergent adverse events (TEAEs). TEAEs led to dose reduction of vepdegestrant in 6 pts (16.2%) and dose reduction of ABE in 19 pts (51.4%). Treatment-related adverse events of any grade that occurred in ≥20% of pts were diarrhea (73.0% [grade 1/2, 70.3%; grade 3/4, 2.7%]), fatigue (54.1% [grade 1/2, 40.5%; grade 3/4, 13.5%]), neutropenia (54.1% [grade 1/2, 21.6%; grade 3/4, 32.4%]), nausea (35.1% [grade 1/2, 32.4%; grade 3/4, 2.7%]), anemia (32.4% [grade 1/2, 29.7%; grade 3/4, 2.7%]), vomiting (24.3% [grade 1/2, 21.6%; grade 3/4, 2.7%]), and decreased appetite (21.6% [grade 1/2, 18.9%; grade 3/4, 2.7%]). There were no grade 5 TEAEs. PK data showed that vepdegestrant was associated with a modest 22% increase in exposure of ABE and its active metabolites, indicating no significant drug-drug interaction. **Conclusions:** In this phase 1b/2 study of pts with ER+/HER2− ABC, vepdegestrant plus ABE demonstrated antitumor activity and a safety profile that was generally consistent with the known profiles of each agent. Clinical trial information: NCT05548127. Research Sponsor: Pfizer Inc.

Long-term safety results and adverse event (AE) management recommendations in patients with ER+/HER2− metastatic breast cancer (mBC) receiving prifetrastat, a first-in-class KAT6 inhibitor, at the recommended phase 3 dose (RP3D) of 5 mg once-daily (QD). First Author: Rachel M. Layman, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Prifetrastat (PF-07248144) is a first-in-class, potent, and selective inhibitor of the epigenetic modifiers KAT6A and KAT6B. In an ongoing phase 1/2a study (NCT04606446), prifetrastat has demonstrated encouraging antitumor activity and manageable safety when combined with fulvestrant (FUL) in patients with heavily pretreated ER+/HER2− mBC (Mukohara T, et al. *Nat Med.* 2024;30:2242-50). Here, we report comprehensive and long-term safety results and AE management recommendations after extended follow-up of patients receiving prifetrastat (± FUL) in this phase 1/2a study. **Methods:** This dose escalation (part 1)/expansion (part 2) study included patients with ER+/HER2− mBC whose disease progressed after prior treatment with a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) and endocrine therapy. In part 1, patients received prifetrastat at varying doses as monotherapy or in combination with 500 mg FUL. In part 2, patients received prifetrastat (± FUL) at the recommended dose for expansion (RDE; 5 mg QD) identified in part 1. Primary objectives were safety/tolerability assessment and RDE selection. **Results:** 5 mg QD prifetrastat was previously identified as the RDE and RP3D in combination with FUL based on safety, PK/PD, and antitumor activity. As of Oct 13, 2025, a total of 92 patients were treated at the 5 mg QD dose (43 as monotherapy and 49 in combination with FUL). The most common treatment-related AEs (TRAEs) were dysgeusia (84.8%; all grade [G] 1 [66.3%] or 2 [18.5%]), neutropenia (68.5%), and anemia (50.0%). Weight loss was reported infrequently as a TRAE (5.4%). The most common G3/4 TRAEs were neutropenia (G3, 34.8%; G4, 6.5%), anemia (G3, 15.2%; no G4), and leukopenia (G3, 12.0%; no G4); no G5 TRAEs were reported. TRAEs led to dose reductions in 45 (48.9%) patients, 75.6% (n = 34/45) of whom reduced their dose due to reversible neutropenia. TRAEs led to discontinuation in 2 patients (G2 neutropenia [n = 1]; G3 myocardial injury/troponin increased [n = 1]). G3/4 neutropenia was reversible and well-managed with dose modifications and supportive care. No febrile neutropenia was reported. Dysgeusia was managed with supportive care, including patient education, weight monitoring, and nutrition consultation, as clinically indicated. Dysgeusia did not lead to any treatment discontinuations or dose reductions. **Conclusions:** After extended follow-up of the phase 1/2a study, the RP3D of prifetrastat (5 mg QD) maintained a manageable safety profile when dose modifications and supportive care measures were implemented for AEs such as neutropenia and dysgeusia. These AE management strategies have been incorporated into the ongoing phase 3 study (KATSIS-1; NCT07062965) in patients with HR+/ HER2− mBC after progression on CDK4/6i-based therapy. Clinical trial information: NCT04606446. Research Sponsor: Pfizer Inc.

HRS-8080, an oral selective estrogen receptor degrader (SERD), in ER+/HER2− advanced breast cancer (aBC) with *ESR1* mutations (*ESR1*m): Results from a first-in-human phase 1 trial. First Author: Zefei Jiang, Department of Breast Oncology, Fifth Medical Center of PLA General Hospital, Beijing, China

Background: HRS-8080 is a novel, potent oral SERD that binds ER with high affinity. We conducted a multi-part, first-in-human phase 1 trial of HRS-8080 in ER+/HER2- aBC, and here report findings in the *ESR1*m subset from the dose-escalation/expansion parts for HRS-8080 monotherapy. **Methods:** This multicenter, open-label, single-arm phase 1 study enrolled patients (pts) with locally advanced/metastatic ER+/HER2- BC previously treated with ≥1 line of endocrine therapy (ET) and ≤2 lines of chemotherapy for aBC; *ESR1*m status was centrally assessed by ctDNA. In Part A (i3+3 design), pts received HRS-8080 QD (50, 150, 300, 600, or 900 mg) or BID (300 mg); in Part B, 300 mg BID/600 mg QD were selected for expansion. Safety was a primary objective. **Results:** 40 pts with *ESR1*m were treated (≥2 prior lines of therapy, 70.0%; ≥2 prior lines of ET for aBC, 42.5%; chemotherapy for aBC, 57.5%), including 32 at expansion doses. Overall, grade ≥3 treatment-related adverse events (TRAEs) occurred in 8 (20.0%) of 40 pts; the most common were decreased lymphocyte count and decreased neutrophil count (2 [5.0%] pts each). TRAEs led to dose reduction in 1 (2.5%) pt. There were no treatment-related deaths. Efficacy in the *ESR1*m subset is shown in Table 1. At expansion doses of 300 mg BID/600 mg QD, the confirmed objective response rate was 34.4% (11/32; 95% CI 18.6–53.2) and the disease control rate was 75.0% (24/32; 95% CI 56.6–88.5). Median duration of response was 11.1 mo (95% CI 6.5–not reached), with over half of responses remained ongoing. As of data cutoff, 21 (65.6%) pts had disease progression or died; median progression-free survival was 7.2 mo (95% CI 3.6–11.1). **Conclusions:** HRS-8080 demonstrated a favorable safety and tolerability profile and encouraging antitumor activity in ESR1m ER+/HER2− aBC, supporting ongoing clinical development both as monotherapy and in combination regimens. Clinical trial information: NCT05189717. Research Sponsor: None.

Real-world survival benefit of glucagon-like peptide-1 receptor agonists (GLP-1 Ras) concomitant with cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) and endocrine therapy in hormone receptor-positive (HR+)/HER2− metastatic breast cancer: A large propensity-matched analysis. First Author: Michela Palleschi, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: Obesity increases hormone receptor-positive (HR+) breast cancer risk through adipose-derived estrogens and inflammation. In metastatic HR+/HER2- disease, endocrine therapy (ET) combined with cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) is standard first-line therapy, improving survival. The widespread use of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) for diabetes and obesity management induces meaningful weight loss and may enhance ET efficacy by reducing body fat mass, which modulates estrogen levels and cancer-related inflammation, albeit their impact on mBC survival in patients receiving ET plus CDK4/6i remains unclear. **Methods:** Using the TriNetX Global Collaborative Network, we retrospectively identified two cohorts of patients with mBC receiving endocrine therapy (ET) plus a CDK4/6i: 26,689 patients treated with ET+CDK4/6i alone and 604 patients who also received a GLP-1 RA initiated within 3 months of CDK4/6i start. Propensity score matching (PSM) was applied to balance cohorts for age, race, body mass index, heart failure, hypertension, diabetes mellitus, fulvestrant use, and type of CDK4/6i. Overall survival (OS) was estimated using the Kaplan–Meier method, and hazard ratios (HRs) were calculated to compare OS between cohorts. **Results:** After PSM, 604 matched pairs of patients were identified in the ET plus CDK4/6i and GLP-1 RA groups, respectively (mean age +/- standard deviation:61.4 ±11.3 and 61.8 ±11.8 years), with well-balanced baseline characteristics. After a median follow-up of 18.8 months (interquartile range, IQR 27.9) in the non-exposed cohort and 15.8 months (IQR 24.5) in the non-exposure and in the exposure cohorts, median OS was 67,9 months among patients receiving GLP-1 RA compared with 49 months in those not receiving GLP-1 RA (HR 0.70; 95% CI,0.56–0.89; P=0.003), corresponding to a 30% reduction in the risk of death mortality risk. **Conclusions:** This is the largest real-world, propensity-matched analysis demonstrating a significant OS benefit with GLP-1 RAs added to ET+CDK4/6i in HR+/HER2− mBC. These provocative findings warrant prospective validation to elucidate underlying mechanisms—such as metabolic reprogramming or immune modulation—and explore GLP-1 RAs as a novel therapeutic strategy in this setting. Research Sponsor: None.

Beyond *ESR1*: Multi-pathway genomic drivers of endocrine resistance in HR$^+$/HER2$^-$ breast cancer. First Author: Humaid Obaid Al-Shamsi, Burjeel Cancer Institute, Abu Dhabi, United Arab Emirates

Background: Endocrine resistance in HR$^+$/HER2$^-$ breast cancer is often associated with acquisition of *ESR1* point mutations, but many patients at progression remain *ESR1* wild type. Identifying *ESR1*-independent, multi-pathway acquired resistance mechanisms is critical for guiding subsequent therapy. **Methods:** We analyzed 1,429 HR$^+$/HER2$^-$ breast cancer samples (468 tissue, 1,171 cfDNA), including 210 paired cases, from patients with metastatic breast cancer undergoing molecular testing for treatment guidance or disease monitoring. Next-generation sequencing performed at Datar Cancer Genetics assessed SNVs, CNAs, and gene fusions. Alterations implicated in endocrine resistance were analysed for incidence, specimen type, and co-alteration patterns. **Results:** *ESR1*-wild-type tumors frequently harbored clinically relevant endocrine resistance mechanisms, most commonly involving the *PI3K/AKT, FGFR, ERBB2, MAPK*, and cell-cycle pathways. At least one resistance-associated alteration was identified in 40.4% (473/1172) of evaluable *ESR1*-wild-type cases, while 14.8% (173/1172) harbored alterations across multiple resistance pathways, highlighting substantial *ESR1*-independent resistance biology. Among *ESR1*-driven mechanisms, *ESR1* SNVs were detected slightly more frequently in cfDNA than tissue (13.7% vs 12.8%), despite inclusion of cfDNA samples obtained during clinical surveillance, supporting the sensitivity of liquid biopsy for detecting emergent resistance. *ESR1* fusions represented a distinct, non-overlapping resistance mechanism, identified in 7.4% (28/379) of tissue samples, most commonly *ESR1–CCDC170* (71%) and *ESR1–AKAP12* (14%); 21 fusion-positive cases lacked *ESR1* SNVs, underscoring the need for fusion assessment to fully capture *ESR1*-driven resistance. Dynamic pathway activation was further supported by acquired *PI3K* pathway mutations, detected in cfDNA in 3.3% (4/122) of cases initially *PIK3CA*-wild-type in paired tissue samples. **Conclusions:** Endocrine resistance in HR$^+$/HER2$^-$ breast cancer is mediated by multiple actionable genomic pathways beyond *ESR1*, including *PI3K/AKT, FGFR, ERBB2, MAPK*, and cell-cycle alterations. These findings expand opportunities to personalize therapy and guide clinical trial selection by targeting non-*ESR1* resistance mechanisms. Research Sponsor: None.

Incidence of endocrine resistance-associated genomic alterations beyond *ESR1* point mutations in tissue and liquid biopsy for HR$^+$/HER2$^-$ breast cancer.

Endocrine Resistance Biomarker	*ESR1*-Mutant Cases (%)	*ESR1* Wild-Type Cases (%)
***ESR1* fusions**	11.1	6.7
***FGFR1* alterations**	13.2	7.0
***CCND1* amplification**	15.2	7.0
***FGFR2/3* alterations**	3.7	2.0
***HER2*-mutant, non-amplified**	2.5	2.6
***PIK3CA* mutation**	43.7	25.1
***PTEN* mutation**	2.0	1.6
***AKT1* mutation**	5.6	3.6
***MAPK* Pathway (*RAS/RAF/MEK*)**	4.6	4.0

1072 Poster Session

A phase 1/2 trial of tersolisib (LY4064809/STX-478), a pan-mutant-selective PI3Kα inhibitor (PI3Kαi), in *PIK3CA*-mutant advanced solid tumors: Updated results from PIKALO-1. First Author: Komal L. Jhaveri, Memorial Sloan Kettering Cancer Center and Weill Cornell Medicine, New York, NY

Background: PI3Kαi have demonstrated clinical benefit in ~40% of patients (pts) with HR+, HER2- advanced breast cancer (ABC) with *PIK3CA* mutations (*PIK3CA*m). However, broad use is often constrained by toxicities mediated through wild-type PI3Kα inhibition, and exclusion of pts with diabetes (DM) or prediabetes (pDM). Here we report updated results from PIKALO-1 evaluating tersolisib (terso), an oral, allosteric CNS-penetrant, pan-mutant-selective PI3Kαi in pts with *PIK3CA*m HR+ HER2- ABC. **Methods:** PIKALO-1 enrolled pts to receive terso (≥1 prior treatment [tx]), terso + fulvestrant (fulv, 1-2 prior txs), or terso + fulv/imlunestrant (imlu) and CDK4/6i (≤2 prior txs). Pts with pDM/DM (HbA1c <8% /FBG <140mg/dL) were eligible. **Results:** As of 6 Jan 2026, 193 pts with *PIK3CA*m HR+ HER2- ABC were treated: terso (n=52; 20-160 mg QD); terso (60 mg or 100 mg QD) + fulv (n=45) and terso (20-100 mg QD) + fulv + CDK4/6i (palbociclib, n=70; ribociclib, n=21; abemaciclib, n=5) (n=96). Median age was 62 yrs (Range: 27-84), 54% had pDM/DM. Median prior txs was 2 (0-7) including: CDK4/6i (81%) and SERD (47%). Hyperglycemia (HG) rates (any Grade [G]/G≥3) were 16%/0% in pts without pDM+DM and 37%/1% in pts with pDM+DM. TEAEs (any G/G≥3) ≥25% of all pts; neutropenia (39%/27%), fatigue (35%/4%), diarrhea (34%/<1%), and nausea (31%/1%). Incidence of PI3Ki-class toxicities (rash; 4%/0% and stomatitis; 12%/<1%) were relatively low. TEAEs led to terso dose reduction/discontinuation in 11%/<1%. T. no significant drug-drug interactions. *PIK3CA*m ctDNA was reduced at all dose levels. Updated data, including dose escalation data with terso + imlu+ abemaciclib, will be presented. **Conclusions:** Terso, alone or combined with fulv ± CDK4/6i, continues to be well-tolerated, with lower incidence of PI3Ki-class toxicities and no 3 HG in pts with normal baseline glycemic control. Target engagement was robust and clinical benefit continues to mature favorably in heavily pretreated pts with *PIK3CAm* HR+ HER2- ABC, supporting further study in the Phase 3 PIKALO-2 trial (NCT07174336). Clinical trial information: NCT05768139. Research Sponsor: Eli Lilly and Company.

(RW) post-progression outcomes following first-line (1L) ribociclib (RIB) + aromatase inhibitor (AI) versus AI alone in African American and low socioeconomic status (SES) patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2−) metastatic breast cancer (MBC) in US. First Author: VK Gadi, University of Illinois Cancer Center, Chicago, IL

Background: RIB + endocrine therapy (ET) demonstrated significant overall survival over ET alone in all three phase III MONALEESA trials for HR+/HER2− MBC. RW studies can provide insight into pt subgroups who may be under-represented in clinical trials. This is particularly important for African American pts and those with low SES, groups who often face disparities in access and outcomes. This study assessed RW post-progression outcomes among these under-represented populations in the US, to guide treatment (tx) for those affected by social determinants of health. **Methods:** This retrospective study used deidentified data from the Flatiron Health Research Database, including 5,649 US women with HR+/HER2− MBC who began 1L RIB + AI or AI monotherapy between Jan 1, 2020 and Jan 31, 2025, with follow-up through Jul 31, 2025. Analyses of RW progression-free survival 2 (rwPFS2; time from start of 1L to first disease progression during 2L, or death during 1L or 2L, whichever occurred first) and RW chemotherapy-free survival (rwCFS) used unadjusted and adjusted time-to-event methods (Kaplan-Meier and Cox regression), with baseline differences addressed using inverse probability tx weighting with stabilized weights (sIPTW). Key pt demographics and characteristics were used for adjustment; details to be provided in the full presentation. **Results:** A total of 520 African American pts were included in the analysis; 243 received RIB + AI and 277 received AI monotherapy. After sIPTW, median rwPFS2 was 19.4 months longer for the RIB + AI group vs AI monotherapy (median 36.8 vs 17.4 months; HR, 0.44; 95% CI, 0.29–0.67). Median rwCFS was also extended by 14.3 months with RIB + AI (median 39.5 vs 25.2 months; HR, 0.49; 95% CI, 0.33–0.72). Among 1805 pts with low SES index (pts area-level SES categorized in the lowest two quintiles to represent the lowest 40% of block groups in terms of SES), 810 received RIB + AI and 995 received AI monotherapy. The median rwPFS2 was 14.2 months longer for those receiving RIB + AI vs AI monotherapy (median 37.2 vs 23.0 months; HR, 0.54; 95% CI, 0.44–0.67) after sIPTW adjustment. Similarly, median rwCFS was prolonged by 22.0 months for the RIB + AI group vs AI monotherapy (median 51.4 vs 29.4 months; HR, 0.58; 95% CI, 0.47–0.71). **Conclusions:** This study demonstrates that treating African American pts and individuals with low SES using 1L RIB + AI, compared with AI alone, leads to longer rwPFS2 and rwCFS. These results support 1L RIB + AI as an effective tx choice for these pt groups and underscores the importance of ensuring access to optimal tx for better outcomes. Research Sponsor: Novartis Pharmaceuticals Corporation.

1075 **Poster Session**

Vepdegestrant, a proteolysis-targeting chimera (PROTAC) estrogen receptor (ER) degrader, plus atirmociclib (ATI) in ER+/HER2− advanced breast cancer (ABC): TACTIVE-K phase 1b/2 results. First Author: Melinda L. Telli, Department of Medicine, Stanford University School of Medicine, Stanford, CA

Background: There is unmet need for therapies that improve clinical outcomes in patients (pts) with ER+/HER2− ABC and disease progression on existing endocrine therapies (ETs). Both vepdegestrant, and ATI, a selective cyclin-dependent kinase (CDK) 4 inhibitor (CDK4i), have shown antitumor activity in pts with ER+/HER2− ABC previously treated with CDK4/6i plus ET. This study evaluated the efficacy and safety of vepdegestrant plus ATI in pts with ER+/HER2− ABC. **Methods:** This open-label, multicenter, phase 1b/2 study (NCT06206837) enrolled pts with ER+/HER2− ABC who received >1 (phase 1) or 1–2 (phase 2) prior lines of therapy in the ABC setting; 1 prior CDK4/6i-based regimen in any setting was required in phase 2. The study included a dose escalation/de-escalation phase 1b to select recommended doses, and a randomized phase 2 to further assess efficacy, safety, and PK. Baseline *ESR1* mutation status (via ctDNA) and its association with efficacy outcomes were also assessed in phase 2. **Results:** As of Sep 5, 2025, 70 pts (median age, 60 y) received vepdegestrant 200 mg daily plus ATI 100 mg BID (ATI100; n = 36), or 300 mg BID (ATI300; n = 34). Pts received a median of 1.0 prior regimens in the ABC setting. Most pts previously received an aromatase inhibitor (ATI100, n = 33, 91.7%; ATI300, n = 26, 76.5%) and/or a CDK4/6i (ATI100, n = 36, 100%; ATI300, n = 32, 94.1%). Confirmed objective response rate (ORR), clinical benefit rate (CBR; complete response, partial response, or stable disease for ≥ 24 wks), and median progression-free survival (mPFS) are shown in the Table. Efficacy outcomes for pts with baseline *ESR1* mutations (n = 27) were consistent with the total population (Table). Two dose-limiting toxicities were reported in phase 1b: a grade (G) 3 platelet count decreased (ATI100) and a G3 neutrophil count decreased (ATI300). Most treatment-related adverse events (TRAEs) were G1/2; G3/4 TRAEs were mainly neutropenia (ATI100, 16.7%; ATI300, 35.3%). PK parameters including AUC_{tau} and C_{max} for vepdegestrant and ATI100/300 at steady state were consistent with previous reports, indicating no clinically impactful drug-drug interactions. **Conclusions:** In previously treated pts with ER+/HER2− ABC, vepdegestrant plus ATI showed clinical activity in the full pt population and in pts with *ESR1* mutations. The safety profile of the combination was consistent with each agent. Clinical trial information: NCT06206837. Research Sponsor: Pfizer Inc.

Efficacy and safety of SPH4336 plus endocrine therapy in HR-positive/HER2-negative metastatic breast cancer with brain metastases: A multicenter, single-arm, phase II study. First Author: Kuikui Jiang, Department of Internal Medicine, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Cyclin-dependent kinase 4/6 (CDK4/6) inhibitors plus endocrine therapy are standard first-line treatment for HR-positive/HER2-negative ($HR^+/HER2^-$) metastatic breast cancer (MBC). However, patients with brain metastases have poor prognosis and limited treatment options due to inadequate blood-brain barrier penetration of most agents and limited evidence for intracranial efficacy. SPH4336, a novel oral CDK4/6 inhibitor, exhibits potent CDK4/6 inhibition in preclinical models with favorable blood-brain barrier penetration. It has shown acceptable safety profiles and preliminary antitumor activities in advanced solid tumors, including $HR^+/HER2^-$ MBC. This study assessed the efficacy and safety of SPH4336 plus endocrine therapy in $HR^+/HER2^-$ MBC with brain metastases. **Methods:** This open-label, single-arm, phase II study enrolled patients aged 18-75 years with histologically confirmed $HR^+/HER2^-$ and radiologically confirmed brain metastases at 25 centers in China. Prior CDK4/6 inhibitor exposure before brain metastases was limited to <2 agents. Patients received SPH4336 (400 mg orally once daily) plus physician's choice of endocrine therapy (letrozole, fulvestrant, or exemestane) in 28-day cycles until disease progression or unacceptable toxicity. Primary endpoint was intracranial objective response rate (ORR) per RANO-BM criteria. **Results:** Between September 19, 2023, and August 22, 2025, 30 patients were enrolled. Two patients (6.7%) had a history of palliative radiotherapy for brain metastases. As of December 10, 2025, the median follow-up was 11.7 months (range: 1.6-26.7). Per RANO-BM criteria in 29 evaluable subjects, the intracranial ORR, disease control rate (DCR), and clinical benefit rate were 37.9% (95% CI: 20.7-57.7), 72.4% (95% CI: 52.8-87.3), and 44.8% (95% CI: 26.4-64.3), respectively. Based on RECIST 1.1, the extracranial ORR and DCR were 33.3% (95% CI:17.3-52.8) and 66.7% (95% CI: 47.2-82.7), respectively. The overall ORR was 33.3% (95% CI: 17.3-52.8), and the overall DCR was 60.0% (95% CI: 40.6-77.3). The median intracranial, extracranial, and overall progression-free survival were 8.4 months (95% CI: 1.9-not reached [NR]), 11.0 months (95% CI: 1.9-NR), and 8.1 months (95% CI: 1.9-11.0), respectively. Grade ≥3 treatment-related adverse events occurred in 70.0% of patients, most commonly γ-glutamyltransferase elevation (43.3%), aspartate aminotransferase elevation (20.0%), and neutrophil count decrease (20.0%). No treatment-related death occurred. **Conclusions:** SPH4336 plus endocrine therapy demonstrated clinically meaningful intracranial antitumor activity with a manageable safety profile in $HR^+/HER2^-$ MBC with brain metastases. These findings warrant further investigation in randomized studies for this patient population with high unmet medical need. Clinical trial information: NCT05872347. Research Sponsor: Shanghai Pharmaceuticals Holding Co., Ltd.

[^{18}F] Fluoroestradiol PET/CT to guide second-line treatment decision-making in patients with estrogen receptor–positive, HER2-negative advanced breast cancer after progression on first-line aromatase inhibitor and CDK4/6 inhibitor: Primary results of ESTROTIMP. First Author: Francois Clement Bidard, Institut Curie, Paris, France

Background: Despite availability of novel endocrine treatment (ET) options for patients with ER+ HER2- ABC, many patients experience early disease progression under 2nd line ET-based regimen after AI+CDK4/6i, underscoring a significant rate of endocrine resistance. Timely identification of endocrine-refractory disease at progression under 1st line is critical to optimize treatment selection and consider non-ET strategies, such as antibody-drug conjugates or chemotherapy. FES PET/CT enables a non-invasive, whole-body assessment of ER expression; absent or heterogeneous FES uptake may indicate ER loss or downregulation, key mechanisms of resistance. Our objective was to evaluate the impact of FES PET/CT on 2nd line treatment decisions. **Methods:** In this non-randomized prospective multicenter trial (NCT05486182), patients with ER+ HER2- ABC progressing on 1st line AI+CDK4/6i underwent standard-of-care FDG PET/CT followed by FES PET/CT. Oncologists prospectively documented therapeutic management plans, before and after FES PET/CT. Patients rated pain and apprehension for FES PET/CT vs. biopsy on a Visual Analogue Scale. Primary endpoint was the proportion of patients with a therapeutic management change after FES PET/CT, and primary objective was to demonstrate that at least 10% of patients had their therapeutic management changed after FES PET/CT (Wald test). **Results:** Of 153 patients enrolled, 129 were evaluable for the primary endpoint. When compared with FDG PET/CT, FES uptake was classified as "all lesions ER+" in 65 (50%), "mixed ER+/- lesions" in 38 (30%), and "all lesions ER-" in 25 (19%) patients. Therapeutic management was changed based on incorporation of FES PET/CT results in 46/129 patients (35.7%; 96% CI [27.0-44.3], p<0.0001), including treatment type (n=38), diagnostic modalities (n=8), and planned follow-up (n=12). Treatment changes mostly consisted of using chemotherapy instead of ET (n=16), ET instead of chemotherapy (n=3), adding targeted therapy to single agent ET (n=2), changing the targeted therapy paired with ET (n=8), adding radiation therapy to disease sites (n=4), and performing surgery (n=2). Oncologist confidence in FES PET/CT was on average 7.8/10 (Q1-Q3: 7-9). Patients reported significantly lower pain and apprehension for FES PET/CT vs. biopsy (Pain: Mean 0.8 vs 4.5; Apprehension: Mean 1.8 vs 5.2; both p<0.0001). **Conclusions:** ESTROTIMP shows that, at progression under AI+CDK4/6i, ER expression is completely or partially lost in about half of patients with ER+ HER2- ABC. The trial reached its primary endpoint, demonstrating a clinically meaningful impact on therapeutic management, and supporting the use of FES PET/CT as a standard workup at time of progression under 1st line AI+CDK4/6i. Clinical trial information: NCT05486182. Research Sponsor: GE HealthCare.

1078 Poster Session

BL0175, a novel nano-mediated polypeptide conjugate of protein degrader, in patients (pts) with locally advanced/metastatic HR+/HER2− breast cancer (HR+, HER2- LA/mBC): Initial results from a phase 1 study. First Author: Nanya Wang, The First Hospital of Jilin University, Jilin, China

Background: BL0175 is a novel nano-conjugate (~10 nm) composed of PEG-modified poly (amino acid), enzyme-responsive peptide linkers, and the protein-degrader payload fulvestrant. It accumulates in the tumor microenvironment (TME), where enzymatic cleavage releases fulvestrant continuously. The released fulvestrant penetrates tumor cells, effectively inducing cell death. Nonclinical studies demonstrated that BL0175 provides superior tumor distribution of fulvestrant, enhanced tumor growth inhibition, and greater progesterone receptor suppression compared with conventional fulvestrant injection at equivalent doses. This first-in-human Phase I study reports preliminary safety, efficacy, and pharmacokinetic (PK) data for BL0175. **Methods:** Postmenopausal pts with HR+, HER2- LA/mBC received intramuscular BL0175 (Cycle 1: Days 1, 15; thereafter every 4 weeks) at doses ranging from 50 mg to 500 mg. Data are summarized across all cohorts unless otherwise specified. **Results:** As of January 14, 2026, 22 pts were treated (50 mg: n=1; 100, 200, 300, 400, 500 mg: n=3 each; 250 mg: n=6). The median number of prior lines of therapy was 3 (range: 1–7). Safety: Adverse events (AEs) and treatment-related AEs (TRAEs) occurred in 64% of pts (14/22). All AEs were Grade 1–2, with no dose-dependent trends or unexpected safety signals. Efficacy: Eleven pts had post-baseline tumor assessments (50 mg & 300 mg: n=1 each; 100, 200, 400 mg: n=3 each). Disease control rate (DCR) was 100% in cohorts receiving $\geq$200 mg. Three partial responses (PR) were observed in cohorts $\geq$200 mg, yielding an objective response rate (ORR) of 42.9% (3/7). The pts who achieved PR comprised individuals with prior progression on standard CDK4/6 inhibitor (CDK4/6i) plus endocrine therapy (aromatase inhibitor or fulvestrant injection), as well as those presenting with brain metastases at baseline. These data suggest that 200 mg may be an effective therapeutic dose. Pharmacokinetics: PK exposure (C_{max} and AUC_{0-336h}) of both released and total fulvestrant increased dose-proportionally. BL0175 was stable in systemic circulation (release rate $\leq$0.03% across doses). Notably, in two pts (50 mg and 100 mg cohorts), released fulvestrant concentrations in tumor tissue were 9-fold and 18-fold higher, respectively, than in plasma, confirming tumor-specific enrichment. **Conclusions:** BL0175 demonstrated promising efficacy in pts with HR+, HER2- LA/mBC, including those with prior progression on fulvestrant injection and CDK4/6i-based therapy and in brain metastases. The preliminary results validate BL0175's design rationale, supporting its tumor-targeted delivery and potential for enhanced efficacy at lower doses. These findings warrant further investigation of BL0175 in this patient population. Clinical trial information: NCT06738966. Research Sponsor: None.

1079 Poster Session

Outcomes by lobular (lob) histology status at initial diagnosis in patients (pts) in the INAVO120 phase 3 trial with *PIK3CA*-mutated (mut), hormone receptor-positive (HR+), HER2-negative (HER2−), endocrine-resistant advanced breast cancer (aBC) treated with inavolisib (INAVO)/placebo (PBO) + palbociclib (PALBO) + fulvestrant (FULV). First Author: Nicholas C. Turner, Royal Marsden Hospital, Institute of Cancer Research, London, United Kingdom

Background: INAVO (a highly potent and selective PI3Kα inhibitor that also promotes mut p110α degradation) + PALBO + FULV is approved for *PIK3CA*mut, HR+, HER2−, endocrine-resistant aBC based on statistically significant and clinically meaningful investigator-assessed progression-free survival (PFS) benefit over PBO + PALBO + FULV in INAVO120 (NCT04191499). We report exploratory analyses of treatment (tx) outcomes by lob histology status documented at initial diagnosis. **Methods:** Baseline characteristics, PFS, overall survival (OS), objective response rate (ORR), and duration of response (DoR) were evaluated for 53 pts with reported lob only and 64 with reported lob only or mixed lob (lob + $\geq$1 other selected subtype) histology at initial diagnosis. *PIK3CA*mut distribution, and association of histology and PFS with *CDH1* alteration (alt) status, were also assessed. **Results:** At the clinical data cut-off for the updated PFS and final OS analyses (Nov 15, 2024), 24 and 29 pts with lob only histology, and 29 and 35 pts with mixed lob histology, were randomized to the INAVO and PBO arms, respectively. Baseline characteristics were balanced across tx arms. Median follow-up was 34.2 and 32.3 months (m) in the INAVO and PBO arms, respectively. Pathogenic *CDH1*alts were more frequent in the lob only (65.2%) and mixed lob (58.9%) subgroups compared with no lob histology (6.3%). Efficacy by lob status is shown in the Table. *PIK3CA*mut distribution was similar across histologies. PFS benefit of INAVO over PBO was observed regardless of baseline *CDH1*alt status (hazard ratio 0.3 for *CDH1*alt and 0.5 for no alt detected). **Conclusions:** In this INAVO120 exploratory analysis, efficacy was improved with INAVO vs PBO, regardless of lob histology status at initial diagnosis and *CDH1*alt status. This further supports the benefit of INAVO + PALBO + FULV in *PIK3CA*mut, HR+, HER2−, endocrine-resistant aBC. Clinical trial information: NCT04191499. Research Sponsor: F. Hoffmann-La Roche Ltd.

Impact of FES-PET imaging in the management of estrogen receptor–positive breast cancer: Real-world experience. First Author: Joanne E. Mortimer, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: F18 labeled estradiol PET imaging (FES-PET) is endorsed by NCCN guidelines to identify advanced/recurrent estrogen receptor positive (ER+) breast cancer, especially invasive lobular disease. As an adjunct to conventional imaging, FES-PET may provide information about estrogen dependence in lesions that are not readily biopsied. We reviewed the use of FES-PET imaging at City of Hope, Southern California and how it impacted treatment. **Methods:** This is a retrospective chart review study of pts undergoing FES-PET imaging in the management of ER+ breast cancer. Demographic data, indications for FES-PET imaging, and impact on subsequent care were extracted from the electronic medical record. **Results:** Between 1/21/22 and 12/31/25, 191 patients with a median age of 52 (Range 32-89) underwent an initial FES-PET scan at City of Hope and its Southern California Network. All had a diagnosis of estrogen receptor + (ER+) breast cancer; 124 were Invasive Ductal Carcinoma (IDC), 59 Invasive Lobular Carcinoma (ILC), 7 mixed IDC with ILC features, and 1 adenocarcinoma. FES-PET was used to stage "high-risk" local disease in 85, 76 continued their initial treatment plan, 8 were found to have metastatic disease, and 1 underwent additional surgical resection for residual disease in the breast. Of 102 pts. with metastatic disease, 58 were FES positive; 44/50 responded to endocrine therapy, 7 received chemotherapy and 1 refused treatment; 44 were FES negative and 23 received chemotherapy, 10 had no response to endocrine therapy, and 11 received no further treatment. Four patients had synchronous primary tumors and FES was used to distinguish lesions that were attributable to breast cancer. Of the patients with metastatic FES+ disease, 33 underwent serial FES-PET imaging; 3 were part of a clinical trial assessing radiation therapy in oligometastatic disease, 3 had been on prolonged treatment with chemotherapy and FES-PET was obtained to assess potential for reintroduction of endocrine therapy, 27 had response evaluation to aromatase inhibitor therapy where conventional staging did not adequately assess the measurable/evaluable disease as well as FES-PET. **Conclusions:** Our data support the use of FES-PET which altered treatment in 11% of patients with high-risk localized and identified patients for whom chemotherapy was the appropriate choice of systemic therapy. In select pts, serial FES-PET imaging was more helpful in monitoring disease response to AI-based therapy than conventional imaging and should be considered in future guideline recommendations. Oral selective estrogen receptor degraders in HR+/HER2- advanced breast cancer and impact of ESR1 mutation status: A systematic review and meta-analysis. First Author: Amal AlJuhani, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: Oral selective estrogen receptor degraders (SERDs) are a promising therapeutic class for hormone receptor positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) advanced breast cancer. Several randomized controlled trials (RCTs) have evaluated oral SERDs, but results have varied across agents and populations. **Methods:** We searched MEDLINE, EMBASE, CENTRAL, and conference proceedings until December 31st 2025 and identified RCTs comparing oral SERDs with standard endocrine therapy in adults with HR+/HER2- advanced breast cancer. Two reviewers independently screened studies, extracted data, and assessed risk of bias using Cochrane RoB 2. Random effects meta-analysis was performed using generic inverse variance for hazard ratios for progression-free survival (PFS). Odds ratios for safety outcomes were pooled using Mantel-Haenszel (fixed effect). **Results:** A total of 9 trials comprising 4,258 participants were included. Overall, oral SERDs demonstrated a statistically significant improvement in PFS compared with standard endocrine therapy (HR 0.76, 95% CI 0.60 to 0.97; p=0.03). In the estrogen receptor 1 gene mutated (ESR1m) subgroup (7 trials, n=1,273), oral SERDs showed a more pronounced PFS benefit (HR 0.53, 95% CI 0.39 to 0.70; I^2=53.4%; p=0.002). In contrast, patients with ESR1 wild-type tumors (6 trials, n=1,212) derived no significant benefit (HR 0.95, 95% CI 0.81 to 1.12; I^2=0%). The interaction between ESR1m and treatment was statistically significant ($p<0.001$). Grade $\geq$3 adverse events were similar between groups (RR 1.09, 95% CI 0.87 to 1.38). Treatment discontinuation due to adverse events was significantly higher with oral SERDs (RR 1.65, 95% CI 1.02 to 2.65). **Conclusions:** Oral SERDs lead to a statistically significant improvement in PFS over standard endocrine treatments albeit with the effect seemingly limited to patients with ESR1m. These results support the use of biomarkers to determine which patients are most likely to receive clinical benefits from oral SERD therapy and underscore the importance of ESR1 testing in order to tailor treatment optimally. Research Sponsor: None.

ESR1 mutation status subgroup analysis.

Subgroup	Trials	Participants	HR	95% CI	P-value
ESR1 Mutant	7	1,273	0.53	0.39 – 0.70	0.0015
ESR1 Wild-Type	6	1,212	0.95	0.81 – 1.12	0.4684

Culmerciclib (CDK2/4/6 inhibitor) plus fulvestrant in HR+/HER2− advanced breast cancer after progression on CDK4/6i: Preliminary results from a phase II trial. First Author: Tao Sun, Liaoning Cancer Hospital & Institute, Shenyang, China

Background: CDK4/6 inhibitors (CDK4/6i) in combination with endocrine therapy (ET) have been the standard first line treatment for HR+/HER2- advanced breast cancer (ABC). However, there is currently no established standard treatment after progression on a CDK4/6i–based regimen. Culmerciclib (Culm), a novel potent CDK2/4/6 inhibitor, has shown significant PFS benefits when combined with Fulvestrant (Ful) in both first-line and later-line settings for HR+/HER2− ABC (ESMO 2025; CSCO 2024). Here we evaluated the combination in HR+/HER2- ABC following disease progression on prior CDK4/6i + ET. **Methods:** In this prospective, multicenter, single-arm phase II trial (TQB3616-II-04), eligible patients (pts) who had progressive disease on a CDK4/6i + ET as initial therapy for ABC or relapse on/after a CDK4/6i + ET as adjuvant therapy for early BC, previous up to 2 lines of ET and 1 line of chemotherapy for ABC, received Culm (180mg, qd) + Ful. The primary endpoint was ORR, and secondary endpoints included DCR, PFS, DOR, CBR and safety. Assuming a power of 0.9 to test the hypothesis that ORR would be 30.0% against the null hypothesis that it would be 8.0% or lower, with 0.025 as one-sided significance level; considering the dropout rate of 20%, a total of 33 pts was required. **Results:** 35 female pts were enrolled and treated, 31.4% were pre- or perimenopausal (received a concomitant GnRH agonist), 71.4% had visceral metastases (including 45.7% with liver metastases and 5.7% with brain metastases). All pts had received prior CDK4/6i +ET (AI and/or SERM) therapies, prior CDK4/6i was 68.6% palbociclib, 28.6% dalpiciclib, and 8.6% ribociclib (2 pts with dual CDK4/6i); 28.6% had received prior two lines endocrine therapy, also 37.1% had received prior chemotherapy for metastatic disease. As of data cutoff on Jan 17, 2026, median follow-up time was 7.3 months. Among 34 evaluable pts, the overall ORR was 29.4% (95% CI: 15.1, 47.5, $p < 0.0001$), meeting the predefined primary endpoint, which significantly rejected the null hypothesis of ORR. The overall DCR was 88.2% (95% CI: 72.6, 96.7), and the CBR was 82.4% (95% CI: 65.5, 93.2). Median TTR was 3.7 months, mPFS and mDOR were not yet reached, while 6-month PFS rate was 72.5% (95% CI: 52.7, 84.7). Grade≥3 TRAEs and serious TRAEs were reported in 14 (40.0%), 3 (8.6%) pts, respectively. The most common TRAEs included diarrhea, neutropenia, vomiting etc. No new safety signals were observed, with findings consistent with the known safety profile of Culm. Dose reductions due to TRAEs occurred in 14.3% of pts, and no deaths or discontinuations related to TRAEs were reported. **Conclusions:** Culm combined with Ful demonstrated promising antitumor activity in HR+/HER2- ABC after progression on previous CDK4/6i + ET, offering a potential targeted therapeutic strategy for this population (NCT06702618). Clinical trial information: NCT06702618. Research Sponsor: None.

Genomic markers of resistance to first-line (1L) therapy with a CDK4/6 inhibitor (CDKi) and endocrine therapy (ET) in patients (pts) with hormone receptor−positive (HR+) metastatic breast cancer (MBC). First Author: Albert Grinshpun, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Pts with HR+ MBC exhibit variable responses to 1L ET + CDKi therapy. We analyzed clinicopathologic features and genomic landscapes of biopsies obtained at the time of the diagnosis of MBC to identify determinants of sensitivity/resistance to 1L CDKi, with a focus on distinguishing endocrine-sensitive from endocrine-resistant (ETR) disease. **Methods:** A single center cohort included pts with biopsies obtained within 3 months of diagnosis of HR+, HER2-negative MBC (distant recurrent and de-novo [DNIV]), diagnosed between 2013 - 2020. Tumors underwent targeted DNA sequencing (OncoPanel). Clinical data were obtained from the EMBRACE database. **Results:** The entire cohort included 666 pts, of them 321 (48%) treated with 1L ET + CDKi. Among pts who received adjuvant ET (n = 347), 54 (15.6%) had primary ETR, 140 (40.3%) secondary ETR, and 153 (44.1%) were endocrine-sensitive. Of these pts, 56% (n = 191) received 1L CDKi therapy. The median time to next treatment (TTNT) in pts treated with 1L CDKi differed significantly by disease presentation, with a median of 1.3 years (95% CI, 0.9–1.5) for recurrent MBC and 2.3 years (95% CI, 1.7–3.6) for DNIV (log-rank p = 0.0005). TTNT also varied significantly according to endocrine sensitivity, with median TTNT of 0.6, 0.9, and 1.8 years for primary ETR, secondary ETR, and endocrine-sensitive disease, respectively (p = 0.0005). In the entire cohort, SNVs/indels were most frequent in *PIK3CA*, *TP53*, and *CDH1*. *CCND1*, *FGFR1*, and *MYC* amplifications were most frequent amplifications. *TP53* and *ESR1* mutations were enriched in ETR tumors, compared with ET sensitive cancers ($q < 0.2$). *ESR1* mutations were detected in 15% of ETR tumors, versus 8% in endocrine-sensitive cancers and 3% in DNIV. Prior adjuvant aromatase inhibitor exposure occurred in 39%, 61%, and 44% of patients with primary ETR, secondary ETR, and ET-sensitive tumors, respectively. When comparing poor and exceptional responders to 1L CDKi, TTNT <6 months versus >36 months, mutations in *TP53* and *NF*1 were significantly enriched in the poor responders ($q < 0.2$). We also evaluated the association between specific genomic alterations and TTNT on 1L CDKi; mutations in *TP53*, *NF1*, and *ERBB2*, as well as amplifications of *RAD21*, *FGFR1* and deletions of *RB1*, *CDKN2A* were associated with shorter TTNT on 1L ET plus CDKi ($q < 0.2$). **Conclusions:** In our cohort, distinct genomic alterations were associated with ETR and shorter TTNT on 1L CDKi. These findings underscore the biology of ETR and support the clinical relevance of early genomic profiling to refine risk stratification and guide therapeutic decision-making. Notably, the high prevalence of *ESR1* alterations in ETR tumors carries important implications for adjuvant and 1L treatment strategies, particularly the potential role of oral selective estrogen receptor degraders in this setting. Impact of oral SERDs, including giredestrant, on survival in HR+ HER2− metastatic breast cancer: A meta-analysis. First Author: Changtai Tian, Stony Brook University Hospital, Stony Brook, NY

Background: Oral selective estrogen receptor degraders (SERDs) are designed to overcome endocrine resistance in HR+ HER2- breast cancer due to ESR1 mutations. Several SERDs have been evaluated in recent trials. We performed a meta-analysis evaluating oral SERDs in previously treated patients with HR+ HER2- metastatic breast cancer (MBC). **Methods:** Randomized controlled trials comparing oral SERDs to standard endocrine therapy in previously treated HR+, HER2- MBC, reporting progression-free survival (PFS) or overall survival (OS) and adverse events (AEs), were identified via a systematic PubMed search. To incorporate the latest SERDs data, results from the recently presented giradestrant trial were included. Meta-analysis was performed for the overall intention-to-treat (ITT) population and the ESR1-mutant (ESR1m) subgroups. Leave-one-out analyses excluding giradestrant were conducted to highlight its specific impact. Rates of serious adverse events (grade ≥3) and treatment discontinuation were also analyzed. **Results:** A total of 2324 patients from six phase III trials were included in this analysis. Oral SERDs improved PFS compared with standard endocrine therapy in the ITT population (HR 0.734, CI 0.620-0.869, p<0.001) with greater benefit observed in the ESR1m subgroup (HR 0.538, CI 0.430-0.673, p<0.001). Excluding giradestrant data from the evERA trial led to modest reduction in PFS benefit in both the ITT (HR 0.755, CI 0.661-0.908, p<0.05) and the ESR1m (HR 0.582, CI 0.471-0.718, p<0.05) subsets, though overall PFS benefit remained. Additionally, SERDs were associated with an OS advantage in pooled analyses for the ITT population (HR 0.743, CI 0.621-0.889, p<0.05) and ESR1m population (HR 0.584, CI 0.433-0.768, p<0.001). Excluding giradestrant did not result in significant changes in OS estimates. Grade ≥3 AEs were more frequent with SERDs (OR 1.53, CI 1.20-1.95, p<0.001) while discontinuation rates were similar between groups (OR 1.53, CI 0.99-2.37, p=0.06). **Conclusions:** Oral SERDs significantly improve PFS in previously treated HR+ HER2- MBC with the greatest benefit in patients with ESR1 mutations. Pooled analysis suggests an OS advantage favoring SERDs. Giradestrant contributes to the observed PFS class effect without altering OS outcomes. SERDs are associated with increased toxicity. Although a trend towards higher discontinuation rates was noted, it did not reach statistical significance, and discontinuation rates remain comparable to standard endocrine therapy. These findings support the use of oral SERDs in the second- and third-line treatment of HR+ HER2- MBC, particularly in ESR1-mutant disease. Research Sponsor: None.

Ethnicity-based comparative analysis of treatment endpoints of 30,000 HR+/HER2− metastatic breast cancer patients on CDK4/6 inhibitors (palbociclib/ribociclib/abemaciclib). First Author: Olivia Benny, School of Medicine, Keele University, Staffordshire, UK, United Kingdom

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i), in combination with endocrine therapy, are the mainstay for HR+/HER- metastatic breast cancer (MBC). However, ethnically diverse populations remain underrepresented in randomised clinical trials, limiting the ability to stratify by ethnicity. This meta-analysis utilises real-world evidence to compare treatment endpoints i.e., overall survival (OS), progression-free survival (PFS), objective response rate (ORR) and adverse effects (AE) across ethnic groups. **Methods:** 116 studies from MEDLINE and Embase were included (Palbociclib: 67, Abemaciclib: 29, Ribociclib: 20). 31580 HR+/HER- MBC patients (Asian [AS]:22067; White [WH]: 8993; Black [BL]: 510) were included. Median survival and response rates were calculated using a random effects model to account for between-study variability. Parentheses represent 95% confidence intervals (CI). **Results:** Pooled analysis shows disparities in efficacy and significant variation in haematological toxicity. Maximum mOS benefit for AS was on palbociclib (61.8mo) whereas for WH was ribociclib (63.9mo), primarily driven by long-term follow-up in MONALEESA. mPFS benefit was longest in BL patients on abemaciclib (17mo), WH patients on palbociclib (27.7mo), AS patients on ribociclib (25.2mo). ORR was highest for ribociclib across all ethnic groups (Table). Meta-regression indicated ethnicity was not a significant independent moderator of AE risk (p > 0.05). AS cohorts demonstrated the highest incidence of Grade 3+ neutropenia across all agents: Palbociclib (72.0%; 49.5–87.1), Abemaciclib (52.8%; 46.1-59.4), and Ribociclib (45.8%; 39.1-52.5; p < 0.0001). In contrast, WH and BL patients exhibited significantly lower G3+ neutropenia rates, ranging from 12.0% to 33.8% (p < 0.0001). AS patients also showed the highest rates of leukopenia and anaemia across all CDK4/6i. **Conclusions:** Our large-scale meta-analysis findings establish a novel, evidence-based ethnicity-informed CDK4/6i selection framework to optimize treatment endpoints in HR+/HER2- MBC patients. This highlights the urgent need for prospective trials focused on underrepresented populations to close the survival gap. Research Sponsor: None.

Metric	Subgroup	Palbociclib	Abemaciclib	Ribociclib
ORR (%)	AS	34.0 (27-42)	28.7 (16.1-41.3)	52.4 (46.4-58.5)
	WH	34.0 (28-65)	41.9 (14.9-68.9)	44.9 (32.1-57.7)

An early resistance genomic state (ERGS) as an identifier of primary CDK4/6 inhibitor failure in HR+/HER2− metastatic breast cancer. First Author: Mobina Shrestha, Sentara Albemarle Medical Center, USACS, Elizabeth City, NC

Background: CDK4/6 inhibitors combined with endocrine therapy are the standard first-line treatment for patients with hormone receptor-positive (HR+), HER2-negative metastatic breast cancer (mBC). However, a substantial subset of patients experience early disease progression, and there are currently no clinically practical tools available at treatment initiation to identify patients unlikely to derive lasting benefit. In this study, we attempt to define a clinically actionable genomic resistance phenotype using routine tumor sequencing. **Methods:** We conducted a retrospective real-world analysis using the MSK CHORD 2024 cohort, including 1,690 patients with HR+/HER2− mBC treated with first-line CDK4/6 inhibitors (palbociclib, ribociclib, or abemaciclib). An Early Resistance Genomic State (ERGS) was pre-specified based on alterations in five genes with established roles in endocrine and cell-cycle resistance: TP53, ESR1, RB1, PTEN, and NF1. The primary endpoint was time to first documented progression following CDK4/6 initiation, with early progression defined as progression within 6 months. Multivariable Cox proportional hazards models were adjusted for age, visceral disease, and central nervous system (CNS) involvement. Model performance was assessed using internal validation with resampling. **Results:** ERGS alterations were present in 41% of patients. ERGS demonstrated a graded, dose-dependent association with progression risk. Compared with ERGS-negative patients, those with one ERGS alteration had a 29% higher risk of progression (Hazard Ratio (HR) = 1.29, 95% CI: 1.15-1.45), those with two alterations had a 58% higher risk (HR = 1.58, 95% CI: 1.30-1.91), and those with three or more alterations had more than double the risk (HR = 2.19, 95% CI: 1.24-3.87; global log-rank $p<0.0001$). Twelve-month progression rates were 48%, 62%, 71%, and 85% across ERGS 0, 1, 2, and $\geq$3 groups, respectively. The prognostic impact of ERGS remained consistent across endocrine partner (aromatase inhibitor vs fulvestrant) and metastatic pattern subgroups. Incorporation of ERGS significantly improved model discrimination beyond clinical covariates alone, increasing the concordance index from 0.61 to 0.85 in internal validation analysis. **Conclusions:** ERGS defines a systems-level intrinsic CDK4/6 resistance phenotype identifiable using routine tumor sequencing at treatment initiation. This parsimonious genomic state provides clinically meaningful risk stratification beyond standard clinicopathologic features and identifies patients unlikely to derive lasting benefit from CDK4/6-based therapy. Therefore, ERGS may serve as a practical biomarker to prioritize enrollment on escalated first-line trials or alternative therapeutic strategies in HR+/HER2− metastatic breast cancer. Research Sponsor: None.

Oral estrogen receptor (ER) degraders compared to standard endocrine therapy (ET) in ER-positive, human epidermal growth factor receptor 2 (HER2)−negative metastatic breast cancer (MBC): A systematic review and meta-analysis. First Author: Hadar Goldvaser, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Treatment with ER-positive HER2-negative (ER+HER2-) MBC has evolved during the past decade. Several novel oral ER degraders have shown to modestly improve progression free survival (PFS) compared to standard ET, with significant results specifically in patients carrying activating *ESR1* mutations. However, whether overall survival (OS) is also improved is unknown. **Methods:** This was a PRISMA guided meta-analysis. We identified all randomized controlled trials (RCTs) comparing ER degraders to standard ET in patients with ER+HER2- MBC. Efficacy outcomes included PFS and OS for the intention to treat (ITT) population, as well as for patients with *ESR1* mutation, and for patients with wildtype *ESR1*. Hazard ratios (HRs) and 95% confidence intervals (CI) for PFS and OS were extracted, and pooled into meta-analysis using RevMan Version 9.18.0. Statistical tests were two-sided, and statistical significance was defined as $p<0.05$. Subgroup analyses comparing outcomes based on *ESR1* mutation were also performed. In trials with multiple investigational arms, the monotherapy ER degrader arm (EMBER-3) and the dose selected for further development (SERENA-2) were include. **Results:** Seven RCTs comprising 3926 patients were analyzed. Compared to standard ET, ER degraders were associated with statistically significant improvement in OS in the ITT population, HR 0.74, 95% CI 0.62-0.89, p=0.001. Analysis by *ESR1* status demonstrated that ER degraders were associated with significant improvement in OS for patients with *ESR1* mutation (HR 0.60, 95% CI 0.47-0.77, $p<0.001$), but not for patients with *ESR1* wild type (HR 0.87, 95% CI 0.66-1.15, p=0.33), p=0.05 for the subgroup difference. ER degraders were associated with significant improvement in PFS in the ITT population, HR 0.80, 95% CI 0.66-0.98, p=0.03. Analysis based on *ESR1* status demonstrated significant improvement is PFS for patients with *ESR1* mutation (HR 0.54, 95% CI 0.43-0.68, $p<0.0001$), but not for patients with *ESR1* wild type (HR 0.95, 95% CI 0.82-1.09, p=0.46), p=0.001 for the subgroup difference. **Conclusions:** Compared to standard ET, ER degraders were associated with statistically significant improvement of OS and PFS. While this impact was notable in the ITT population, subgroups analyses confirmed the statistically significant benefit is limited to patients with *ESR1* mutations. Research Sponsor: None.

Capivasertib plus fulvestrant in Chinese patients with HR+/HER2− advanced breast cancer: Interim analysis of CAPItrue. First Author: Peng Yuan, Department of VIP Medical Services, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: After disease progression on cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) plus endocrine therapy (ET), patients (pts) with HR+/HER2- advanced breast cancer (ABC) face limited treatment options and poor prognosis, particularly those with PI3K/AKT pathway tumor alterations, which are major drivers of disease progression and treatment resistance mediated centrally by AKT. Targeting the PI3K/AKT pathway represents a mechanism-driven precision strategy to overcome CDK4/6i/ET resistance, with potential to maximize ET benefit and delay subsequent chemotherapy. In the phase III CAPItello-291 trial, capivasertib (CAPI) plus fulvestrant (FUL) improved progression free survival (7.3 vs 3.1 months, HR 0.50) versus placebo plus FUL in pts with *PIK3CA/AKT1/PTEN*-altered tumors. CAPItrue (NCT06635447) is an ongoing phase IIIb study of CAPI plus FUL in Chinese pts with HR+/HER2- ABC progressing on ET, with a focus on *PIK3CA/AKT1/PTEN-altered* disease, aiming to inform precision 2nd line treatment following CDK4/6i progression. **Methods:** CAPItrue enrolled Chinese pts with HR+/HER2- ABC progressing on ET$\pm$CDK4/6i. All pts received oral CAPI (400 mg BID, 4 days on, 3 days off) and intramuscular FUL. This pre-specified interim analysis was performed in the cohort (C1) without prior FUL (conducted after the last C1 pt received $\geq$1 dose of study treatment). Baseline characteristics, biomarker profiles, preliminary efficacy (interim objective response rate [ORR] was evaluated in pts with $\geq$4 months of follow-up) and safety were summarized. **Results:** By Aug 20, 2025, 195 pts were enrolled in C1 and received study treatment. *PIK3CA/AKT1/PTEN* alterations were detected in 115 (59.0%) pts (altered group). The median age was 55.0 yrs; 64.1% were post-menopausal. Prior therapy for ABC included: 75.4%/8.7% 1/2 prior lines of ET; 65.1% CDK4/6i, 17.9% chemotherapy. The altered group showed similar characteristics. In patients with $\geq$4 months of follow-up, ORR was 35.6% overall (37/104, 1 complete and 36 partial responses [PR]) and 43.1% in the altered group (25/58, 25 PR). Overall, at a median follow-up of 4.1 months,92.8% had $\geq$1 adverse event (AE); 88.7% had AEs possibly related to CAPI; and 34.9%/11.8% had grade $\geq$3/serious AEs (SAE). A similar safety profile was seen in the altered group (any AE: 92.2%, grade $\geq$3 AE: 30.4%, SAE: 11.3%). No new safety signal was observed. **Conclusions:** In Chinese pts with *PIK3CA/AKT1/PTEN*-altered HR+/HER2- ABC previously treated with ET$\pm$CDK4/6i, CAPI plus FUL showed encouraging preliminary efficacy and safety. Follow-up is ongoing. Clinical trial information: NCT06635447. Research Sponsor: AstraZeneca AB.

***CBFB* mutations as a predictive biomarker of endocrine therapy benefit in hormone receptor−positive (HR+) breast cancer: Discovery and validation in 3,799 patients.** First Author: Adar Yaacov, Helmsley Cancer Center, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Endocrine therapy (ET) is the mainstay approach for treating HR+ breast cancer, yet resistance frequently limits efficacy. Identifying reliable genomic biomarkers to predict superior treatment response remains an unmet clinical need. **Methods:** We performed unbiased genomic analysis of HR+ patients from the MSK-CHORD cohort (n=2,058), stratified by disease stage (metastatic vs. non-metastatic). Outcomes included progression-free survival (PFS), recurrence-free survival (RFS), and overall survival (OS). FDR-corrected Cox models were used for gene-level discovery. A chemotherapy-treated subset of the MSK-CHORD cohort served as a control to assess treatment specificity. Findings were externally validated in the independent METABRIC cohort (n=1,741). **Results:** Beyond known resistance biomarkers (ESR1, TP53, RB1), loss-of-function mutations in CBFB emerged as a significant predictor of ET benefit. CBFB mutations were present in 6.7% of metastatic breast cancer (MBC; n=80) and 6.3% of non-MBC (n=54). In MBC patients, CBFB mutations were associated with significantly longer PFS (HR=0.44; p=0.0002); in the adjuvant setting, RFS was similarly improved (HR=0.48; p=0.009). OS was prolonged in both settings (HR=0.49 and 0.50; $p<0.05$ for both). CBFB mutations were enriched in lobular histology (OR=2.3; $p<0.0001$); however, multivariable Cox regression confirmed CBFB as an independent predictor after adjusting for histology (HR=0.46; p=0.0003). To provide biological validation, we analyzed RUNX1, the obligate functional partner of CBFB in the CBF transcription complex. Combined CBFB/RUNX1 mutations (n=122, 10.2% in MBC; n=82, 9.5% in non-MBC) demonstrated consistent predictive benefit (HR=0.48 and 0.56; $p<0.0001$ and p=0.007, respectively). Notably, the survival benefit associated with CBFB or CBF-complex mutations was absent in chemotherapy-treated controls, confirming treatment-specific predictive value rather than general prognostic effect. In the METABRIC validation cohort, CBFB mutations (5.9%; 103/1,741) independently predicted longer relapse-free survival (HR=0.59; p=0.005) and OS (HR=0.52; $p<0.0001$). Gene expression analysis revealed that CBFB mutations were associated with significantly lower APOBEC gene family expression ($p<0.001$), suggesting a mechanistic link between CBF-complex loss and reduced APOBEC-mediated mutagenesis, an established driver of endocrine resistance. **Conclusions:** We identify CBF-complex (CBFB/RUNX1) mutations as a novel genomic biomarker of ET benefit in HR+ breast cancer, independent of disease stage and histology, and validated across two large cohorts. These findings highlight a subset of patients with exceptional outcomes and provide a potential mechanistic link between CBF alterations and APOBEC-mediated resistance. Research Sponsor: None.

First-line fovinaciclib versus placebo combined with aromatase inhibitor for advanced breast cancer: A randomized, double-blind phase 3 study. First Author: Peng Yuan, Chinese Academy of Medical Sciences Cancer Hospital, Beijing, China

Background: Endocrine therapy combined with a cyclin-dependent kinases 4 and 6 (CDK4/6) inhibitor is the standard first-line therapy for hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer. Fovinaciclib is a novel CDK4/6 inhibitor that showed survival benefit when added to fulvestrant in the later-line setting. This randomized, double-blind, placebo-controlled phase 3 trial evaluated the efficacy and safety of fovinaciclib plus an aromatase inhibitor (AI) as initial therapy. **Methods:** Adult women with HR-positive, HER2-negative advanced breast cancer who had no prior systemic therapy in the advanced setting were enrolled across 63 centers. Eligible patients were randomized in a 1:1 ratio to receive oral fovinaciclib (200 mg, once daily, days 1–21) or placebo plus an AI (letrozole 2.5 mg or anastrozole 1 mg, orally, once daily, days 1–28) in 28-day cycles. Pre- or perimenopausal patients also received goserelin (3.6 mg, subcutaneous, day 1). The primary endpoint was progression-free survival (PFS) assessed by blinded independent central review (BICR). Secondary endpoints included other efficacy endpoints and safety. **Results:** A total of 417 patients were assigned to the fovinaciclib (n = 208) or placebo arm (n = 209) with balanced baseline characteristics. At the protocol-specified interim analysis (median follow-up 16.6 months, data cutoff date June 25, 2024), adding fovinaciclib significantly improved PFS (hazard ratio 0.55, 95% CI 0.38–0.77; p = 0.0003): median PFS was not reached in the fovinaciclib arm and 20.2 months (95% CI 16.4 months–not evaluable) in the placebo arm. The 2-year PFS rates were 65.5% (95% CI 55.3%–73.9%) and 38.9% (95% CI 27.5%–50.2%), respectively. Consistent PFS benefit was observed in investigator assessments (hazard ratio 0.49 [95% CI 0.36–0.68], p $<$ 0.0001) and across most subgroups. Fovinaciclib also showed favorable results across secondary efficacy endpoints. OS data remain immature. Treatment-emergent adverse events (TEAEs) occurred in 207 (99.5%) and 199 (95.2%) patients in the fovinaciclib and placebo arms, respectively, with serious adverse events (SAEs) reported in 30 (14.4%) and 24 (11.5%). Discontinuation due to TEAEs was only 1.4% in both arms. The most common TEAEs were hematologic toxicities, which did not lead to SAEs or study drug discontinuation. Grade ≥3 gastrointestinal toxicities (2.4% versus 0) or renal toxicities (0 versus 0.5%) were rare. **Conclusions:** Adding fovinaciclib to first-line AI therapy provided a significant and clinically meaningful PFS benefit, along with consistent improvements in other survival outcomes and a manageable safety profile. These findings support fovinaciclib as a first-line treatment option for patients with HR-positive, HER2-negative advanced breast cancer. Clinical trial information: NCT05439499. Effects of SGLT2 inhibitor dapagliflozin on anticancer resistance and alpelisib- and fulvestrant-induced cardiomyocyte injury under hyperglycemic conditions. First Author: Vincenzo Quagliariello, Division of Cardiology, Istituto Nazionale Tumori-IRCSS-Fondazione G. Pascale, Naples, Italy

Background: Activating PIK3CA mutations occur in approximately 40% of hormone receptor–positive (HR+)/HER2-negative breast cancers and drive resistance to endocrine therapy. The PI3Kα-selective inhibitor alpelisib combined with fulvestrant significantly improves progression-free survival, as demonstrated in the SOLAR-1 trial, but its clinical benefit is limited by frequent treatment-induced hyperglycemia. Beyond metabolic toxicity, hyperglycemia promotes oxidative stress, inflammation, and mitochondrial dysfunction, thereby increasing cardiovascular vulnerability and potentially reactivating oncogenic PI3K/AKT signaling through compensatory hyperinsulinemia. Retrospective clinical evidence suggests that sodium–glucose cotransporter-2 (SGLT2) inhibitors may mitigate these effects. We investigated the direct redox-dependent cardiotoxic effects of alpelisib and fulvestrant under hyperglycemic conditions and evaluated whether dapagliflozin confers cardioprotection in human cardiomyocytes. **Methods:** Human iPSC-derived cardiomyocytes were exposed to alpelisib and fulvestrant under hyperglycemic conditions (25 mM glucose) in the absence or presence of dapagliflozin. Cell viability (MTS), mitochondrial membrane potential, reactive oxygen species generation, lipid peroxidation (MDA and 4-HNE), intracellular antioxidant defenses (GSH/GSSG, SOD, catalase/GPx), inflammatory and inflammasome-related mediators (IL-1β, IL-18, IL-6, TNF-α, NLRP3, MyD88), and apoptotic signaling (caspase-3/7 activity) were quantified. Cardiac injury was assessed by high-sensitivity cardiac troponin I and T release. Transcriptomic profiling was performed to interrogate cardiometabolic and redox signaling pathways. **Results:** Alpelisib and fulvestrant synergistically induced a pro-oxidative and pro-inflammatory injury phenotype characterized by mitochondrial depolarization, increased ROS and lipid peroxidation, depletion of antioxidant defenses, activation of the NLRP3/IL-1 axis, and caspase-dependent apoptosis. Dapagliflozin markedly restored redox homeostasis, preserved mitochondrial integrity, suppressed inflammasome and cytokine signaling, and reduced troponin release, indicating robust cardioprotection. Transcriptomic analysis confirmed coordinated downregulation of oxidative stress, inflammatory, and insulin-stress pathways. **Conclusions:** Dapagliflozin directly protects human cardiomyocytes from hyperglycemia-driven, PI3Kα inhibitor–associated oxidative injury by restoring redox and mitochondrial homeostasis. These findings provide a strong mechanistic rationale for repurposing SGLT2 inhibitors as dual cardio-metabolic protectants in precision oncology. Prognostic impact of tumor recurrence dynamics in patients with HR+/HER2- advanced breast cancer treated with ET+CDK4/6i: Results from the multicenter, Italian study PALMARES-2. First Author: Claudio Vernieri, Fondazione IRCCS Istituto Nazionale dei Tumori; IFOM ETS the AIRC Institute of Molecular Oncology; University of Milan, Milan, Italy

Background: Endocrine sensitivity/resistance (ES/ER) is a key prognostic and predictive factor in patients (pts) with Hormone Receptor-positive, Human Epidermal growth factor Receptor 2-negative advanced Breast Cancer (HR+/HER2- aBC). Cyclin Dependent Kinase 4/6 inhibitors (CDK4/6i)+Endocrine Therapy (ET) are standard 1st line therapy for HR+/HER2- aBC pts regardless of tumor ES/ER status at diagnosis. However, the prognostic value of tumor recurrence dynamics within ES/ER groups has never been investigated. **Methods:** We conducted a pre-planned analysis of the multicenter, real-world, Italian study PALMARES-2 (NCT06805812) to evaluate the prognostic role of tumor recurrence dynamics, de novo aBC presentation and distant recurrence-free interval (DFRI) in pts with HR+/HER2- aBC treated with 1st line ET+CDK4/6i between January 2016 and September 2024. DRFI was defined as the time from surgery to the detection of aBC. The primary endpoint was real-world progression-free survival (rwPFS), defined as the time between ET+CDK4/6i initiation and disease progression (PD) or patient death. Results were adjusted through Multivariable Cox regression for 16 relevant covariates. **Results:** Of 4,234 pts enrolled, 2,858 (67.5%) had ES and 1,376 (32.5%) had ER disease at aBC diagnosis. Median follow-up was 38.6 and 42.7 months, respectively. After adjustment, ER was associated with poorer rwPFS compared to ES (adjusted hazard ratio [aHR] 1.78, 95% CI 1.60-1.96). In the ER cohort, secondary tumor resistance with recurrence during years (y) 3-5 of adjuvant (adj) ET or $<$1 y from its end, and recurrence during extended adj ET or $<$1 y from its end, were associated with increasingly better rwPFS when compared to primary resistance (Table). In the ES cohort, pts with tumor recurrence $>$10 y from adj ET end had significantly longer rwPFS when compared to pts recurring $<$10 y from adj ET end, or pts with no prior adj ET or de novo aBC (Table). Among pts with recurrent disease (N=2,792), any additional y of DRFI resulted in 3% reduction in the risk of disease progression (aHR:0.97, 95% CI: 0.96-0.99). **Conclusions:** The current ES/ER classification fails to capture the whole spectrum of prognostic heterogeneity in HR+/HER2- aBC pts treated with 1st line ET+CDK4/6i. Recurrence dynamics, including DRFI, improve prognostic classification and may inform treatment selection and personalised patient management in this clinical context. Clinical trial information: NCT06805812. Research Sponsor: Associazione Italiana per la Ricerca sul Cancro; Italian Health Ministry.

Recurrence dynamic	N	rwPFS (mo)	aHR (95% CI)
Primary resistant	334	13.4	Ref
Secondary resistant-during 5 y adj ET	668	15.7	0.85 (0.72-0.99)
Secondary resistant-during extended adj ET	375	19.4	0.73 (0.61-0.89)
No adjuvant ET	288	30.0	0.46 (0.36-0.59)
1-5 y from adj ET end	453	29.3	0.54 (0.45-0.65)
5-10 y from adj ET end	377	32.6	0.50 (0.40-0.61)
>10 y from adj ET end	275	45.2	0.30 (0.23-0.40)

Association of *ESR1* amplification with survival and benefit from CDK4/6 inhibition in breast cancer. First Author: George W. Sledge Jr., Caris Life Sciences, Phoenix, AZ

Background: While ESR1 mutations are established mediators of endocrine resistance in breast cancer (BC), the significance of ESR1 amplification (amp) remains poorly understood with reported amp rates vary widely due to platform-specific differences. We leveraged a large clinico-genomic real-world database and applied a stringent NextGen sequencing (NGS) approach to test ESR1 amp. We identify ESR1 amp as a molecular entity distinct from canonical estrogen-driven resistance mechanisms. **Methods:** Breast tumors underwent NGS of DNA and RNA (WES/WTS; NextSeq and NovaSeq; Caris Life Sciences, Phoenix, AZ). Gene copy number was determined by CNVKit with $>$=6.0 copies defined as amp to identify focal, high-level copy number events, minimizing misclassification of chromosome 6 copy gains. Real-world clinical data were obtained from insurance claims. Time on treatment (TOT) was defined treatment start to end; overall survival (OS) from tissue collection to last contact. Cox proportional hazards model and log-rank tests were used for survival analysis. Molecular comparisons used χ^2 or Mann-Whitney U with multiple-testing adjustment (q$<$0.05). Gene set enrichment analysis was performed, with significance defined as FDR$<$0.05. **Results:** Among 27,979 BC tumors, 165 were ESR1 amp (0.6%), a prevalence much lower than prior reports. ESR1 amp was significantly enriched in the Luminal B (LumB) subtype (1.4%, 81/5,915) versus other subtypes (0.1–0.4%, p$<$0.0001). ESR1 amp tumors exhibited features of genomic instability, including higher genomic loss of heterozygosity (61% vs 24%), TP53 mutations (59% vs 27%), and amplifications on chromosomes 6, 8, and 11 (q$<$0.05). Transcriptomically, ESR1 amp tumors had significant enrichment of G2M checkpoint and MYC target gene sets by GSEA in the overall cohort (G2M NES 2.61, MYC NES 2.41,) and in LumB (G2M NES 3.18; MYC NES 3.04, all FDR$<$0.001), consistent with CDK4/6-independent cell-cycle progression. Unlike ESR1 mutations, ESR1 amplification was not associated with increased GREB1 expression (4.4 vs 4.2 TPM, p$>$0.05), consistent with the absence of estrogen-response pathway enrichment. Clinically, ESR1 amp was associated with reduced OS in the overall cohort (HR 1.296, p=0.016) and LumB subset (HR 1.43, p=0.009). Palbociclib TOT was significantly shorter in ESR1 amp vs. non-amp tumors (all BC: 7.0 vs 11.0 months, HR 1.39 [95% CI 1.045–1.85], p=0.023; LumB: 4.9 vs 11.4 m, HR 1.57 [1.1–2.2], p=0.01). This effect was significant after adjusting for TP53, gLOH, and CDH1 alterations (adjusted HR 1.47 [1.04–2.06], p=0.027). No TOT difference was observed with aromatase inhibitors. **Conclusions:** In this large real-world analysis, ESR1 amplification defines a rare, genomically unstable breast cancer subset with proliferative signaling and reduced clinical benefit from CDK4/6 inhibition, supporting its potential role as a negative predictive biomarker. Research Sponsor: None.

1094 Poster Session

A phase 1/2, first-in-human study of AVZO-021, a selective cyclin-dependent kinase 2 inhibitor (CDK2i), as monotherapy and in combination for patients with advanced solid tumors, including hormone receptor–positive (HR+)/human epidermal growth factor receptor 2–negative (HER2–) breast cancer (BC) and cyclin E1 (CCNE1)–amplified solid tumors: Updated safety and efficacy results. First Author: Manish R. Patel, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL

Background: AVZO-021 is a potent, once-daily, oral CDK2i with high selectivity against CDK1, thus minimizing off-target toxicity. Initial Phase 1 data from the ongoing first-in-human Phase 1/2 study of AVZO-021 (NCT05867251) showed clinical responses and a favorable tolerability profile. **Methods:** The ongoing Phase 1 portion of the study is evaluating the safety, pharmacokinetics (PK), and preliminary efficacy of AVZO-021 alone and in combination with fulvestrant. As of January 20, 2026, the safety population included all patients treated with AVZO-021 monotherapy (n=50) or in combination with fulvestrant (n=13). Efficacy evaluable population included patients treated at ≥150 mg once daily (QD) with HR+/HER2- breast cancer or CCNE1-amplified solid tumors with at least 1 post-baseline scan (n=23 in monotherapy and n=12 in combination with fulvestrant). **Results:** The median age was 63 years for monotherapy patients and 60 years for combination with fulvestrant. Overall, 95% of patients were female, 78% had BC, 10% had ovarian/fallopian tube cancer, and 5% had endometrial/uterine cancer. AVZO-021 monotherapy patients had a median of 3 prior lines of systemic therapy and those in combination therapy had a median of 4 prior lines, in the metastatic setting. All patients with HR+/HER2- BC received prior CDK4/6i and hormonal therapy. Most common (>25%) all-grade treatment-emergent adverse events (TEAEs) were nausea (51%), fatigue (43%), anemia (33%), and vomiting (32%); 13 patients required dose reductions due to TEAEs and 2 patients discontinued due to TEAEs (1 unrelated Grade 3 intestinal obstruction, 1 related Grade 4 neutropenia). Four patients with HR+/HER2- BC and CCNE1-amplified solid tumors had confirmed partial responses and remain ongoing, demonstrating prolonged clinical benefit. Additionally, 23 patients had stable disease for a disease control rate of 77%. Continuous CDK2 target coverage and significant decreases in ctDNA were observed at ≥90 mg QD monotherapy and in combination with fulvestrant. **Conclusions:** With longer follow-up, AVZO-021 as monotherapy and in combination with fulvestrant continues to show an encouraging tolerability profile and clinically meaningful efficacy. Gastrointestinal and hematologic adverse events continue to be of low incidence and severity allowing for prolonged treatment and potential safe combination with AVZO-023, a highly potent and selective CDK4i currently enrolling patients with HR+/HER2- BC in combination with fulvestrant. Clinical trial information: NCT05867251. Research Sponsor: Avenzo Therapeutics.

1095 Poster Session

Liquid-based methylation profiling of molecular breast cancer subtypes (MBS) in hormone receptor positive (HR+) metastatic breast cancer (MBC) treated with CDK4/6 inhibitor (CDK4/6i). First Author: Daniel L. Abravanel, Dana-Farber Cancer Institute, Boston, MA

Background: MBC remains incurable due to the invariable development of resistance, with most deaths resulting from HR+ MBC that acquires resistance to endocrine therapy (ET) combinations. HR and HER2 remain the most important biomarkers in MBC but, while it is known that receptor status and expression based molecular subtypes (e.g. PAM50) can vary over an individual patient's (pts) disease course, serial evaluation is currently limited in routine clinical care by tissue requirements. **Methods:** The EMBRACE cohort study collects biospecimens with matched clinical annotations from pts with MBC at Dana-Farber Cancer Institute. A subset of 510 plasma samples collected around CDK4/6i treatment (tx; pre-tx: -90 to +30 days from start; on-tx; post-tx: -30 to +90 days from end) from 323 pts with HR+ MBC were assessed with Guardant360 Liquid. MBS calls were generated using a previously described cell-free DNA methylation-based deconvolution model that classifies HR and HER2 status in cases with tumor fraction (TF) ≥0.5% with accuracy >85%, and compared with tissue-based HR and HER2 status by immunohistochemistry (IHC). **Results:** Of 510 samples profiled, 308 (60.4%) were evaluable for MBS with TF ≥0.5%. The evaluable rate was lowest in on-tx samples at 48.7%, in line with lower median TF in this set. Of evaluable samples, 285 (92.5%) aligned with sufficient confidence to report a subtype: 273 (88.6%) of evaluable samples were classified as HR+, 23 (7.5%) undetermined, and only 12 (4.9%) HR-, all of which were either from on- or post-tx timepoints. MBS calls on pre-tx samples showed high concordance with clinical IHC, with higher concordance at metastatic diagnosis (91%) than primary diagnosis (86%). Notably, all discordances were cases abstracted as HR+/HER2- at metastatic diagnosis by IHC where MBS yielded HR+/HER2+. Overall, samples from 28 pts were assigned a HER2+ MBS and, in 9 (32%) of these, a concordant genomic alteration in *ERBB2* (copy number gain, gain-of-function mutation and/or fusion) was detected on Guardant360 Liquid. Out of 48 pts with multiple classifiable samples, 11 (22.9%) showed differences in MBS across serial samples including 9 with changes in HER2 (5 gaining and 4 losing HER2 MBS), and 2 with changes in HR (both with an on-tx sample classified as HR- but the subsequent post-tx sample HR+). **Conclusions:** A methylation-based liquid biopsy assay can classify MBS with high correlation to clinical pathology in pre-tx samples and facilitate identification of discordant, or perhaps heterogenous, subtype while capturing the dynamics of MBS over disease course and treatment. Future studies are indicated to investigate the clinical utility of this assay as a biomarker for therapy selection. Research Sponsor: None.

1096 Poster Session

Time on treatment for systemic therapies for patients with hormone receptor-positive breast cancer and *BRCA1*, *BRCA2*, or *PALB2* pathogenic variants. First Author: Gerneiva Parkinson, Stanford Cancer Institute, Stanford, CA

Background: For patients with hormone receptor-positive/HER2- (HR+) metastatic breast cancer and pathogenic variants (PVs) in *BRCA1*, *BRCA2* or *PALB2* (mBRCA), data suggests longer cancer-specific survival compared to patients without PVs (wtBRCA). One hypothesis is that their innate DNA repair deficiency improves response to cytotoxic therapy, as seen in poly (ADP-ribose) polymerase inhibitors (PARPi), which results in longer progression free survival (PFS). However, it remains unclear whether mBRCA is associated with a longer PFS with other therapies such as endocrine therapies (ET), including aromatase inhibitors (AI) and Selective Estrogen Receptor Degraders (SERDs). Some data suggests a shorter PFS with CDK 4/6-inhibitors (CDK4/6i) for mBRCA. Therefore, we compared time-on-treatment (TOT), a real-world surrogate for PFS, for mBRCA vs wtBRCA treated with ET, CDK4/6i, or PARPi. **Methods:** DNA and RNA somatic sequencing were performed on tumors submitted to Caris Life Sciences. HR+ was defined by IHC per ASCO/CAP. TOT was calculated from first to last of treatment time based on insurance claims. Univariable Cox-proportional hazard analyses were utilized to assess TOT between mBRCA vs wtBRCA for each therapy (ET, PARPi and CDK4/6i). Protocol was approved prior by Caris research committee. **Results:** From 8263 HR+ breast cancer patients, 628 were mBRCA+ (median age: 57 years; range 23-90; 96% Female, 4% Male), and 7635 were wtBRCA (median age: 63 years; range 22-89; 98% Female, 2% Male). PVs were *BRCA2*: 66%, *BRCA1*: 19% and *PALB2*: 15%. As shown in Table 1, there was a shorter TOT for AI, SERDs and CDK4/6i, but a longer TOT with PARPi among mBRCA. Patients with mBRCA and high tumor mutational burden (TMB-Hi ≥10 mutations/Mb) had shorter TOT across all analyzed treatments vs low TMB (27.9 vs 35.8 mos, HR=1.47 95%CI 1.14-1.89; p = 0.003), except AI where TMB-Hi had longer TOT (23.5 vs 16.9 mos; HR=0.79, 95% CI 0.62-1.021; p = 0.07). **Conclusions:** This real-world data analysis demonstrates distinct TOT patterns among ET, CDK4/6i and PARPi for mBRCA patients when compared to wtBRCA. This calls for further studies in this specific patient population to understand the various treatment responses, associated tumor biology and immunologic landscape of mBRCA. Research Sponsor: None.

TOT comparisons by therapy between mBRCA and wtBRCA patients.

	Therapy	TOT (months) mBRCA	TOT (months) wtBRCA	Hazard Ratio (HR), Confidence Interval (CI) at 95%
Samples collected at all sites (including breast)	AI	21.7	25.8	HR=1.16 (CI 1.04-1.29 p=0.009
	SERDs	7.6	11.1	HR=1.40 (CI 1.21-1.62) p<0.00001
	CDK4/6i	10.3	13.6	HR=1.39 (CI 1.22-1.59) p<0.001
	PARPi	5.8	2.1	HR=0.51 (CI 0.36-0.73) p<0.001
Samples collected at metastatic sites	AI	25.2	28.3	HR=1.14 (CI 0.994-1.30; p=0.06
	SERDs	6.4	11.5	HR=1.40 (CI 1.20-1.68; p<0.0001
	CDK4/6i	10.3	13.6	HR=1.31 (CI 1.12-1.54; p<0.001
	PARPi	5.8	1.8	HR=0.46 (CI 0.31-0.70; p<0.001

1097 Poster Session

Influence of *TONSL* on tumor suppressor function of *RAD51* and resistance to CDK4/6 inhibitors in ER+ breast cancer. First Author: Harikrishna Nakshatri, Indiana University School of Medicine, Indianapolis, IN

Background: Homologous Recombination (HR) and Replication Stress (RS) resolution mechanisms help to maintain genomic stability. TONSL, MMS22L, RAD51, BRCA1/2 are the few proteins that cooperatively coordinate HR and RS resolution. Therefore, genes in these pathways are expected to function as tumor suppressors. However, only *BRCA*1/2 function as tumor suppressors as their germline mutations increase cancer susceptibility. *TONSL* and *RAD51* are frequently overexpressed in tumors. Here, we investigated the relationship between *TONSL-RAD51* axis in breast cancer (BC) outcome and response to CDK4/6 inhibitors (CDK4/6i) and endocrine therapy (ET). **Methods:** 10,980 ER+ BC samples tested by NGS (592, NextSeq; WES/WTS, NovaSeq, Caris Life Sciences). Dual expression group *TONSL/RAD51*-high (H), *TONSL*-H/*RAD51*-low (L), *TONSL*-L/*RAD51*-H, and *TONSL/RAD51*-L were classified by RNA expression above or below median. HRD score and *TONSL*/HRD-H/L survival was analyzed using METABRIC (ER+ BC, n = 1904) dataset. *TONSL-RAD51* role in sensitivity to CDK4/6i was determined using *TONSL*-amplified ER+ MCF-7 cells. Real-world median overall survival (mOS) of *TONSL/RAD51* groups was derived from insurance claims and calculated from biopsy, start of ET or CDK4/6i to last contact using Kaplan-Meier. Statistical significance was assessed using chi-square and Mann-Whitney U with multiple comparison adjustments (q<0.05). **Results:** *TONSL*-H had higher HRD score (33.7 vs 21.1, p<0.01) compared to *TONSL*-L (n=952 each). *TONSL*/HRD-H (n=573) had worse mOS (109 m vs 138 m, p<0.05) compared to *TONSL*/HRD-L (n=630). *TONSL*-H had higher frequency of LOH (31.6% vs 19.8%), *BRCA2* (5.1% vs 2.9%) and *BRCA1* (1.5% vs 0.8%) mutation, all q<0.05. *TONSL/RAD51*-H had worse mOS compared to *TONSL*-H/*RAD51*-L, *TONSL*-L/*RAD51*-H or *TONSL/RAD51*-L (Table). *TONSL*-H/*RAD51*-L had worse survival with ET compared to other groups. With ET+CDK4/6i, *TONSL/RAD51*-H and *TONSL*-H/*RAD51*-L had similar but worse mOS compared to *TONSL*-L/*RAD51*-H and *TONSL/RAD51*-L (Table). *TONSL* knockdown in CDK4/6i resistant MCF-7 cells created *TONSL*-L/*RAD51*-H phenotype and cells regained the sensitivity to CDK4/6i. **Conclusions:** These findings suggest that *TONSL*-H independent of *RAD51* expression is associated with poor response to ET or ET+CDK4/6i. Therapeutic targeting of TONSL to create TONSL-L/RAD51-H status may improve response to ET+CDK4/6i. Moreover, as the activity of TONSL is regulated by various protein complexes, destabilizers of TONSL-protein complexes could potentially help in sensitizing ER+ BC to ET or CDK4/6i. Research Sponsor: Susan G Komen for the Cure; SAC232147.

Elacestrant in combination with capivasertib in patients with ER+/HER2− advanced breast cancer: Update from ELEVATE, a phase 1b/2, open-label, umbrella study. First Author: Wassim McHayleh, AdventHealth Cancer Institute, Orlando, FL

Background: Disease progression in patients (pts) with ER+/HER2- ABC on 1L ET+CDK4/6i is associated with several mechanisms of resistance, including intrinsic alterations in the PI3K/AKT/mTOR or cell cycle pathways, and/or *ESR1* mutations, a type of acquired resistance that emerges in up to 50% of pts. Elacestrant is the only single-agent oral SERD to significantly improve PFS vs SOC ET in all pts (HR 0.70; 95% CI 0.55-0.88; P=0.0018) and in those with *ESR1m* tumors (HR 0.55; 95% CI 0.39-0.77; P=0.0005) with manageable safety in EMERALD, a trial that required prior ET+CDK4/6i [Bidard 2022]. In CAPItello-291, capivasertib + fulvestrant showed a mPFS of 7.3 mo (AKT-pathway altered) and 5.5 mo (prior CDK4/6i exposure) [Turner 2023]. In ER+ BC MCF7 CDX and CTG-2308 PDX models (*ESR1*wt/*PIK3CAm*), elacestrant + capivasertib showed superior antitumor activity compared with single-agent treatment, including an improvement in activity vs fulvestrant + capivasertib, further supporting the rationale to combine elacestrant with an AKT inhibitor in ER+ BC [Data on file]. This analysis reports updated Ph 1b safety and preliminary efficacy for elacestrant + capivasertib. **Methods:** ELEVATE is evaluating elacestrant in combination with everolimus, alpelisib, capivasertib, abemaciclib, ribociclib, or palbociclib to address different resistance mechanisms. Pts with ER+/HER2- ABC and 1-2L of prior ET±CDK4/6i are eligible regardless of *ESR1m* status; no prior chemo allowed in the ABC setting. Objectives are to identify the RP2D (Ph 1b) and evaluate PFS (Ph 2). **Results:** As of Dec 2025, 31 pts have been enrolled in the Ph 1b elacestrant (258-345 mg) + capivasertib (320-400 mg) cohorts. Key baseline characteristics include pts with visceral mets (90%), primary endocrine resistance (23%), *ESR1m* (45%), prior CDK4/6i (94%), and prior fulvestrant (45%). The most common (≥35%) TEAEs were diarrhea (81%; 6% Gr 3), nausea (74%; 0% Gr 3), rash (61%; 13% Gr 3), fatigue (58%; 3% Gr 3), vomiting (42%; 0% Gr 3); observed hyperglycemia was 29% (10% Gr 3). Elacestrant 345 mg QD + capivasertib 320 BID [4 days on/3 days off] was determined as the RP2D based on the safety profile and PK analysis; no DLTs were observed. In RP2D response-evaluable pts (n=9), preliminary efficacy showed an ORR of 22%, CBR24 wk at 67% (1 CR, 1 PR, and 6 SD), and a mPFS of 11.3 mo. Median follow-up is 10.2 mo [1.8-12.0]. Updated results and additional data will be reported. **Conclusions:** Elacestrant + capivasertib shows a manageable safety profile, consistent with known capivasertib + fulvestrant Gr 3 AEs, and clinically important efficacy in pts with AKT-pathway altered ER+/HER2- ABC with progressive disease. Enrollment in Ph 2 is ongoing. Elacestrant + capivasertib combination therapy offers pts the benefit of receiving both drugs with manageable safety and potential extended clinical benefit as an all-oral treatment option. Clinical trial information: NCT05563220. Research Sponsor: Menarini Group.

Real-world comparative safety and outcomes of ribociclib versus palbociclib in hormone receptor-positive, HER2-negative metastatic breast cancer: A propensity score–matched sensitivity analysis. First Author: Noura Abbas, American University of Beirut Medical Center, Beirut, Lebanon

Background: Cyclin-dependent kinase 4/6 (CDK4/6) inhibitors are widely used in hormone receptor-positive (HR+) / HER2-negative (HER2-) metastatic breast cancer, yet real-world differences in survival and clinically relevant toxicities across agents remain unclear. We performed a propensity score-matched (PSM) sensitivity analysis comparing ribociclib and palbociclib, focusing on mortality and selected safety endpoints. **Methods:** Using the TrinetX database, a federated real-world data network, adult patients with HR+/HER2- metastatic breast cancer treated with ribociclib (cohort 1) or palbociclib (cohort 2) were identified. 1:1 propensity score matching was performed on more than 20 baseline characteristics. Outcomes were evaluated using (1) risk analyses excluding patients with the outcome prior to the time window and (2) Kaplan-Meier time-to-event analyses with hazard ratios (HRs). Endpoints included all-cause mortality, prolonged QT, cardiac arrest, liver injury, hospital admission, and emergency department (ED) visits. **Results:** Patient counts were 2,819 vs 11,871 before matching and 2,696 vs 2,696 after matching. In the matched cohorts, ribociclib was associated with significantly lower all-cause mortality compared with palbociclib (HR 0.65, 95% CI 0.552-0.758, $p<0.0001$). No statistically significant differences were observed in major cardiovascular safety outcomes. Specifically, rates of cardiac arrest were comparable between groups (HR 0.76, 95% CI 0.384-1.505, $p=0.43$), as were rates of long QT syndrome (HR 0.837, 95% CI 0.425-1.648, $p=0.61$). With respect to hepatic and healthcare utilization outcomes, liver injury occurred numerically more often in the ribociclib group, but this difference did not reach statistical significance (HR 1.209, 95% CI 0.896-1.632, $p=0.21$). Ribociclib was associated with numerically lower rates of hospitalization (HR 0.845, 95% CI 0.700-1.021, $p=0.08$) and ED visits (HR 0.82, 95% CI 0.659-1.02, $p=0.07$), though neither outcome met conventional thresholds for statistical significance. **Conclusions:** In this PSM analysis of HR+/HER2- metastatic breast cancer, ribociclib was associated with significantly lower all-cause mortality compared with palbociclib. Rates of hospitalization, ED visits, prolonged QT, and cardiac arrest were not significantly different. These real-world findings support clinically meaningful heterogeneity across CDK4/6 inhibitors and highlight the importance of individualized agent selection, balancing survival, hepatic toxicity, and healthcare utilization. Impact of GLP-1 receptor agonists in hormone receptor–positive breast cancer patients receiving CDK4/6 inhibitors. First Author: Kiara Patino, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are increasingly prescribed for type 2 diabetes and obesity due to their efficacy in weight reduction and glycemic control. Beyond their metabolic benefits, GLP-1 RAs delay gastric emptying, which may affect the absorption of oral medications like cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i). Additionally, CDK4/6i and GLP-1 RAs share overlapping gastrointestinal (GI) toxicities such as diarrhea and nausea, which could impact medication tolerability and clinical outcomes. This investigation aimed to characterize the safety of concomitant GLP-1 RA and CDK4/6i use in patients with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer. **Methods:** We performed a single-center, retrospective chart review evaluating adult patients prescribed a CDK4/6i for HR+ breast cancer at Winship Cancer Institute between October 2022 and May 2025. Patients receiving concomitant GLP-1 RA and CDK4/6i (Group 1) were matched 1:1 to patients receiving a CDK4/6i without GLP1-RA (Group 2). Matching criteria included prescribed CDK4/6i, treatment indication (adjuvant or metastatic), age (≥65 years, 45-64 years, and <45 years), and race. The primary outcome was safety, assessed by adverse drug reactions, dose reductions, and discontinuations. **Results:** 82 patients were reviewed, median age 54 years old. Half (41 patients, 50%) were prescribed abemaciclib, 21 (25.61%) palbociclib, and 20 (24.39%) ribociclib. 41 patients receiving concomitant GLP-1 RA and CDK4/6i (Group 1) were matched to 41 patients receiving a CDK4/6i without GLP1-RA (Group 2). Of those in Group 1, 20 were prescribed a GLP-1 RA for diabetes and 18 for obesity. Median BMI was 32.76 kg/m2 (range, 28.44-36.28 kg/m2) in Group 1 compared to 26.32 kg/m2 (range, 23.74-28.05 kg/m2) in Group 2. Semaglutide and tirzepatide were the most prescribed GLP-1 RAs. 38 patients (51.35%) in Group 2 experienced an ADR associated with CDK4/6i compared to 36 patients (48.65%) in Group 1 (p-value, 0.457). Median time to first documented ADR was 14 days (range, 8-21 days) in Group 2 compared to 18 days (range, 11-36 days) in Group 1 (p-value, 0.086). 24 patients (55.81%) in Group 1 experienced a GI ADR compared to 19 patients (44.19%) in Group 2 (p-value, 0.269). **Conclusions:** Patients receiving CDK4/6i without GLP-1 RA experienced earlier onset and a numerically higher incidence of ADRs compared with those receiving concomitant GLP-1 RA and CDK4/6i therapy, though differences did not reach statistical significance. Ongoing analyses of treatment adherence and progression-free survival will be reported out at a later date. Larger, multi-center studies are warranted to further characterize safety and potential pharmacologic interactions between GLP-1 RAs and CDK4/6i. Research Sponsor: None.

Fovinaciclib versus placebo combined with fulvestrant for advanced breast cancer after endocrine therapy: A randomized, double-blind phase 3 trial. First Author: Xichun Hu, Fudan University Shanghai Cancer Center, Shanghai Medical College, Fudan University, Shanghai, China

Background: Approximately 70% breast cancer (BC) patients have hormone receptor (HR)-positive and human epidermal growth factor receptor 2 (HER2)-negative disease. Fovinaciclib is a novel, potent, oral selective cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitor. A multicenter, randomized, double-blind, placebo-controlled phase 3 trial was conducted to compare fovinaciclib versus placebo plus fulvestrant in patients with advanced BC that relapsed or progressed on previous endocrine therapy. **Methods:** Eligible patients were randomly assigned (1:1) to receive 200 mg fovinaciclib (fovinaciclib arm) or placebo (placebo arm) orally once daily on days 1–21 in 28-day cycles. All patients also received intramuscular fulvestrant 500 mg (cycle 1: days 1 and 15; subsequent cycles: day 1). Premenopausal or perimenopausal patients also received subcutaneous goserelin 3.6 mg (day 1). The primary endpoint was blinded independent central review (BICR)-assessed progression-free survival (PFS). Secondary endpoints included other efficacy endpoints and safety. Exploratory endpoints included patient-reported outcomes. **Results:** A total of 319 patients were randomized to the fovinaciclib (n = 160) or placebo arm (n = 159). Baseline characteristics were balanced. Interim analysis at 9-month median follow-up (data cutoff date May 11, 2023) showed significant PFS benefit from adding fovinaciclib (p = 0.0001). Sustained PFS benefit of greater extent (median 14.0 months versus 5.6 months, hazard ratio 0.48, 95% confidence interval 0.36–0.65) was observed at updated analysis at 23-month follow-up (data cutoff date August 30, 2024). Trends of the PFS benefit were observed in all subgroups. Consistent improvements were observed in investigator-assessed PFS and objective response rate, disease control rate, clinical benefit rate, duration of response, and time to progression according to BICR or investigator's assessments. At updated analysis, all patients in the fovinaciclib arm and 148 (93.7%) in the placebo arm reported at least 1 treatment-emergent adverse event (TEAE). The most common TEAEs were hematological toxicities. TEAEs leading to study drug discontinuation were reported in 9 (5.6%) and 2 (1.3%) patients in the respective arms. No grade ≥3 venous thromboembolism or interstitial lung disease was reported. The two arms showed similar overall longitudinal profiles of global health status, function domains and symptom domains assessed with the European Organisation for Research and Treatment of Cancer Core Quality of Life questionnaire. **Conclusions:** Adding fovinaciclib to fulvestrant conferred statistically significant and clinically meaningful PFS benefit and consistent improvements in other survival outcomes, along with manageable safety. These findings support fovinaciclib as a later-line option. Clinical trial information: NCT05438810. Research Sponsor: Avanc Pharmaceutical Co., Ltd.

Should CDK4/6 inhibitor plus endocrine therapy be standard of care for ER-low (1–10%) HR+/HER2− metastatic breast cancer? A multicenter registry cohort. First Author: Kelvin K.H. Bao, Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong, Hong Kong

Background: ER-low (1–10%) HR+/HER2− metastatic breast cancer (MBC) is increasingly recognized as a distinct clinical subgroup with limited endocrine sensitivity, yet ER-low–specific evidence to guide optimal first-line treatment is sparse. We assessed real-world effectiveness of CDK4/6 inhibitor (CDK4/6i) plus endocrine therapy (ET) in ER-low MBC and benchmarked outcomes against contemporaneous ER-high disease treated with the same approach. **Methods:** We performed a multicenter cohort study using a prospective institutional registry of women with HR+/HER2− MBC who initiated CDK4/6i (palbociclib/ribociclib/abemaciclib) plus an aromatase inhibitor or fulvestrant between January 2018 and October 2024, with follow-up through December 2024. ER expression by immunohistochemistry was categorized as low (1–10% or Allred 3–4), intermediate (10–66% or Allred 5–6), or high (>66% or Allred 7–8). Primary endpoints were progression-free survival (PFS) and overall survival (OS), analyzed by Kaplan–Meier/log-rank methods and multivariable Cox regression adjusting for age, ECOG performance status, progesterone receptor status, disease extent, CDK4/6i choice, and other clinicopathologic factors. **Results:** Among the 540 women with advanced HR+ HER2- breast cancer, 75% received CDK4/6i+ET in the first-line setting; ER-low tumors comprised 4.8% (n=26). ER-low disease had poor outcomes on CDK4/6i+ET with median PFS 2.9 months (95% CI 1.2–4.7) and median OS 12.6 months (95% CI 7.24–18.0), versus ER-high median PFS 23.3 months (95% CI 18.8–27.8) and median OS 49.7 months (95% CI 40.6–54.9) (log-rank $p<0.001$). ER-low status remained independently associated with inferior PFS (HR 10.6, 95% CI 5.02–22.4; $p<0.001$) and OS (HR 4.66, 95% CI 3.03–7.95; $p<0.001$) compared with ER-high after adjustment. Within the ER-low patients, the poor outcome was universally observed regardless of ET partner (AI vs fulvestrant), disease extent (visceral vs bone only), ECOG and HER2 status (low vs 0). **Conclusions:** ER-low HR+/HER2− MBC demonstrated very poor outcomes with CDK4/6i+ET, suggesting CDK4/6i plus AI/ET should not be assumed to be an effective default "standard HR+" approach for this subgroup. Given reported clinicopathologic and molecular similarities between ER-low/HER2− tumors and triple-negative breast cancer, ER-low–dedicated prospective trials and evaluation of TNBC-oriented strategies (including prioritization of chemotherapy-based regimens and TNBC clinical trial enrollment) are urgently needed. Optimizing denosumab treatment strategies to balance skeletal-related events for prevention and osteonecrosis of the jaw risk in metastatic breast cancer patients: A Korean nationwide target trial emulation. First Author: Ji Eun Lee, Division of Medical Oncology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea

Background: Administration of bone-modifying agents (BMAs) is essential for reducing the incidence of skeletal-related events (SREs) in breast cancer bone metastases patients. As denosumab showed superior effect for prevention of SREs compared to zoledronic acid, denosumab is commonly used BMA in this setting; however, the optimal administration interval and treatment duration of denosumab remain unclear. **Methods:** This study utilized the Health Insurance Review and Assessment Service (HIRA) database and emulated a target trial using the clone–censor–weight approach. Among the overall breast cancer population, 2,023 metastatic breast cancer patients who received regular denosumab administration were identified during Jan 2009 to Aug 2023. We examined the administration patterns and duration of denosumab therapy and evaluated their associations with the incidence of skeletal-related events (SREs) and osteonecrosis of the jaw (ONJ). **Results:** During follow-up, approximately 23% of patients continued regular denosumab administration at intervals of less than 8 weeks. Patients who received denosumab for ≥25 months exhibited a low risk of skeletal-related events (SREs) (3.42–6.15%, according to treatment compliance); however, the cumulative risk of osteonecrosis of the jaw (ONJ) increased to 19.47% (95% confidence interval [CI], 13.79–26.75) at 4 years of follow-up. Among patients treated with denosumab for 13–24 months, the risk of SREs was comparable to that observed in those treated for ≥25 months (5.15–6.77% vs. 6.15%), while the risk of ONJ remained relatively low (10.02–10.19%, depending on compliance). In contrast, patients who received denosumab for less than 12 months demonstrated a substantially higher risk of SREs, reaching 19.44% (95% CI, 6.47–45.69). Shorter administration intervals were associated with increased ONJ risk but did not significantly affect SRE prevention. **Conclusions:** This nationwide real-world study is the largest to date to evaluate the optimal duration and administration interval of denosumab in metastatic breast cancer patients with bone metastases. To effectively prevent SREs while minimizing the risk of ONJ, a denosumab treatment duration of 13–24 months appears to offer the most favorable benefit-risk balance and may be considered an optimal treatment strategy in clinical practice. Real-world insights into bone marrow carcinomatosis in metastatic breast cancer: A retrospective analysis from two large university breast cancer centers. First Author: Nikolas Tauber, Department of Gynecology and Obstetrics, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany

Background: Bone marrow carcinomatosis (BMC) is a rare but severe manifestation of metastatic breast cancer (mBC) characterized by diffuse bone marrow infiltration and hematologic dysfunction. Data on incidence, clinical presentation, and treatment outcomes remain limited. **Methods:** This bicentric retrospective real-world study included breast cancer patients diagnosed with BMC between 2010 and 2023 at two German university centers. BMC was diagnosed using bone marrow biopsy and/or leukoerythroblastic blood smear in the presence of cytopenia. Clinical characteristics, systemic treatments, and overall survival (OS) were analyzed descriptively. Survival was estimated using Kaplan–Meier method. **Results:** During the study period, 1,399 patients presented with mBC at one of two participating centers. Among these, 37 were diagnosed with BMC, corresponding to an incidence of 2.6% (0.5% of all breast cancer cases). Median age was 58 years (range 30 – 76). Most patients had hormone receptor (HR)–positive HER2-negative disease (89%). At BMC diagnosis, anemia occurred in 84%, thrombocytopenia in 76%, and pancytopenia in 57% of patients. Median OS after BMC diagnosis was 12.0 months (95% CI: 6.0, 38.0). Patients with bone-only metastases showed longer survival compared with those with additional visceral involvement (median OS not reached vs. 9 months). In HR-positive HER2-negative disease, patients receiving endocrine-based therapy including CDK4/6 inhibitors demonstrated numerically longer survival compared with chemotherapy-based approaches; however, subgroup sizes were small and analyses exploratory. **Conclusions:** BMC is an uncommon but clinically relevant manifestation of mBC associated with substantial morbidity and limited prognosis. This largest European real-world cohort highlights heterogeneous treatment approaches and outcomes. Endocrine-based strategies combined with targeted agents appear feasible in selected patients. Multicenter registries and prospective studies are needed to optimize diagnostic and therapeutic strategies in this patient group. Research Sponsor: None.

Final results of a phase II study of utidelone capsule, the first solid oral microtubule stabilizer, in metastatic breast cancer patients. First Author: Binghe Xu, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: Attempts to develop oral microtubule inhibitors have not made significant progress in decades. Utidelone is a novel microtubule inhibitor insusceptible to P-glycoprotein, enabling higher oral bioavailability and response against multidrug-resistant tumors. Utidelone injection (UTD1) has been approved for metastatic breast cancer (mBC) in China in 2021; utidelone capsule (UTD2) is the first solid oral formulation of microtubule stabilizer in clinical stage globally. Our previous phase I study of UTD2 showed promising activity with no DLTs being observed in late line metastatic solid tumors, and 75 mg/m^2/d*5 was recommended as monotherapy dose (ASCO 2025). PopPK analysis indicated that AUC of UTD2 of 75 mg/m^2/d reached 80%-125% of the AUC of UTD1. The absolute bioavailability of UTD2 vs. UTD1 was 35.1%. Here we report the final results of a phase II study of UTD2 in combination with capecitabine (CAP) in mBC. **Methods:** This is a single-arm, multi-center phase II trial. The key inclusion criteria included patients with metastatic breast cancer, refractory to anthracycline or taxane treatment, ≤ 4 lines of prior chemotherapy, ECOG score of 0-1 and an expected survival of ≥ 12 weeks. Eligible patients received UTD2 at 60mg/m^2/d*5 in combination with CAP at 1000mg/m^2 bid*14 in a 21-day cycle. The primary endpoint was ORR; the secondary endpoints included PFS and safety. **Results:** By data cutoff on October 8, 2025, the recruitment had been completed. 50 mBC pts were enrolled with 72% of HR+/HER2-, 24% of TNBC, and 2% of HR+/HER2+. Twenty-one (21) pts (42%) had received ≥3 lines of treatment. 100% of the patients had received taxane or anthracycline and 86% had visceral metastases. Forty-four (44) pts were evaluated for efficacy with the best responses of 27 PR and 12 SD. The confirmed ORR was 52.3% (95%CI 36.7, 67.5) and DCR was 88.6% (95%CI 75.4, 96.2). Median PFS was 8.25 (95%CI 5.36, 10.58) months and median DoR was 7.62 months (95%CI 4.17, NE) (median treatment cycles was 9.0), demonstrating better efficacy than UTD1 +CAP (ORR 40.4%, CBR 53.9%, PFS 7.72 months, Lancet Oncol 2017) in mBC pts. The most prominent ≥ Grade 3 TEAEs was diarrhea (28%). However, the incidence of peripheral neuropathy (PN) was significantly decreased compared with UTD1+CAP (Grade 3 PN only 2% vs 25.1%) while maintaining the characteristic of low hematological toxicity (only 10% for both ≥ Grade 3 Neutropenia and Leukopenia). Treatment related discontinuations occurred in only 2 pts (4%). **Conclusions:** This study demonstrated excellent efficacy of UTD2+CAP in mBC pts. The safety profile with significantly decreased PN and low hematological toxicity highlighted another advantage of this regimen. Utidelone capsule is anticipated to dramatically improve medication convenience and enhance patient compliance. Clinical trial information: NCT05700084. Research Sponsor: Beijing Biostar Pharmaceuticals Co., Ltd.

ADAPT-T-DXd: Multi-institutional real-world study of dose-adapted trastuzumab deruxtecan in HER2-positive and HER2-low metastatic breast cancer. First Author: Minakshi Roy, NH RN Tagore Hospital, Kolkata, India

Background: Trastuzumab deruxtecan (T-DXd) has demonstrated substantial efficacy in HER2-positive and HER2-low metastatic breast cancer (MBC) at a standard dose of 5.4 mg/kg in the DESTINY trials. But high treatment cost remains a major barrier to access in low/middle-income countries. We evaluated the clinical activity and safety of dose-adapted T-DXd in a multi-institutional real-world Indian cohort, where dose modification was primarily driven by financial constraints. **Methods:** This retrospective analysis included 63 patients with HER2+ or HER2-low MBC treated with dose-adapted T-DXd across multiple Indian centers. Dose-adapted T-DXd refers to the administration of T-DXd at doses lower than the standard 5.4 mg/kg dose in DESTINY trials. Dose selection was based on affordability. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints were progression-free survival (PFS), duration of response (DoR), and safety. An evaluable cohort (n = 53) was defined as patients receiving ≥2 cycles of therapy. DoR measured from treatment initiation to radiologic progression or last drug exposure. **Results:** The median age was 57 years; 42.9% had hormone receptor–positive disease. HER2 subtypes included HER2 3+ (63.5%), HER2 2+/ISH+ (11.1%), and HER2-low (22.2%). Patients had received a median of three prior lines of therapy. The median administered dose of trastuzumab deruxtecan was 3.7 mg/kg, corresponding to 68% of the standard dose. At a median follow-up of 8.3 months, the objective response rate (ORR) was 58.7% (95% CI, 46–71%) in the full cohort and 66.0% (95% CI, 53–79%) in the evaluable cohort. The highest ORR was observed in HER2 3+ disease (76.5%). Median progression-free survival was 5.3 months (95% CI, 4.2–6.4) in the full cohort and 7.1 months (95% CI, 5.8–8.4) in the evaluable cohort. Median duration of response was 8.3 months, with 40–45% of responses ongoing at data cutoff. Grade ≥3 neutropenia occurred in 9.0% of patients, and interstitial lung disease occurred in 7.0%; no grade 5 pulmonary events were observed. Dose reductions due to toxicity were uncommon. **Conclusions:** Dose-adapted trastuzumab deruxtecan demonstrated clinically meaningful activity with a manageable safety profile in patients with HER2-positive and HER2-low metastatic breast cancer in a real-world setting. The shorter median PFS likely reflects reduced dose intensity, limited follow-up and real-world heterogeneity, rather than loss of intrinsic drug activity. These findings support further prospective evaluation of dose-adapted strategies to improve treatment accessibility in resource-limited settings. Research Sponsor: None.

Quality of life and treatment tolerability of Bria-IMT + CPI in metastatic breast cancer. First Author: Saranya Chumsri, Jacoby Center for Breast Health, Mayo Clinic Florida, Jacksonville, FL

Background: Bria-IMT is an allogeneic whole cell immunotherapy expressing tumor associated antigens and GM-CSF to stimulate adaptive and innate immunity. The phase 3 Bria-ABC trial (NCT06072612) evaluates Bria-IMT + retifanlimab vs physician's choice in MBC w/ no meaningful therapeutic options. Characterization of on-trial pt experience, including quality of life (QOL) and tolerability, remains clinically relevant yet underreported. We evaluated QoL and toxicity to assess feasibility of home self administration. **Methods:** EORTC QLQ-C30 at baseline (BL) and subsequent visits. Raw item responses were aggregated into domain scores. Changes quantified as absolute point differences; domain scores defined as medians of constituent items. Lower functional/symptom and higher global scores indicate better outcomes. Wilcoxon matched pairs test assessed change from BL. Missing QoL data handled by observed cases approach. QoL evaluated at BL, V3, V6, and V9. TWiST and TOX summarized descriptively. TOX defined as cumulative time w/ grade ≥3 TEAEs w/o progression; TWiST as time w/o grade ≥3 toxicity or progression. TOX and TWiST constitute component health states for planned QTWiST analysis pending mature OS. **Results:** At submission, 251 pts screened, 173 randomized, 147 treated. 75% Caucasian, 20% other, 5% not reported; median 6 prior lines (2-15); ECOG 2 -6%; intracranial mets 9%; 42% HR+, 37% TNBC, 12% HER2+. Median 5 QoL assessments/pt completed. 127 pts completed ≥2 assessments. Paired data available at V3 52%, V6 17%, V9 6%. Global health medians BL 5.0, V3 5.0, V6 5.0, V9 4.5. Score maintenance/improvement: @V3 63% (p=0.7), V6 62%, V9 71%. Functional domains: role (BL 1.5, V3 2.0, V6 2.0, V9 2.0; maintenance 62.7% [p=0.02], 52.4%, 71.4%). Physical (BL 1.0, V3 2.0, V6 2.0, V9 2.0; maintenance 68.7% (p=0.002), 47.6% (p=0.03), 71.4%), cognitive (BL 1.5, V3 1.5, V6 1.5, V9 1.5; maintenance 63.6%, 61.9%, 85.7%). Emotional (BL 1.5, V3 1.5, V6 1.5, V9 1.5; maintenance 75.8% (p=0.9), 81.0%, 85.7%). Social (BL 1.5, V3 1.5, V6 2.0, V9 2.5; maintenance 58.5%, 75.0%, 57.1%). Symptoms: nausea/vomiting (1.0 throughout; maintenance V3 73%, V6 86%, V9 86%), fatigue median 2.0 all timepoints; maintenance 61%, 67%, 71%), pain (BL/V3 1.5, V6/V9 2.0; maintenance V3 57% [p=0.03], V6 62% [p=0.9], V9 86%). TWiST and TOX restricted mean 3.12 mo and 0.63 mo, respectively; 83.2% and 16.8% of observed follow-up. Pts w global health maintenance demonstrated longer median TWiST v deterioration (4.3 v 2.7 mo). ECOG stable in 78% (n=99). **Conclusions:** Heavily pretreated MBC pts in Bria-ABC demonstrated stable global health and key functional domains. Findings support sustained QoL in advanced disease. TWiST demonstrates meaningful benefit w/o significant toxicity. Ongoing follow up will further characterize durability of pt-reported outcomes and clinical correlation. Results support decentralized care and potential home self administration. Clinical trial information: NCT06072612. Research Sponsor: None.

Survival with Bria-IMT + CPI in advanced metastatic breast cancer at 12 and 24 months. First Author: Chaitali Nangia, Hoag Memorial Hospital Presbyterian, Newport Beach, CA

Background: Metastatic breast cancer (MBC) remains limited by resistance and cumulative toxicity in heavily pretreated patients. Bria-IMT combines a whole-cell vaccine (SV-BR-1-GM) with anti-PD-1 (CPI) to enhance tumor antigen presentation and overcome immune exhaustion. SV-BR-1-GM is an irradiated breast cancer cell line engineered to secrete GM-CSF, promoting HLA class I and II antigen presentation and T-cell activation. We identified a subset with durable clinical benefit and biologic correlates. **Methods:** Phase I/II evaluating the Bria-IMT regimen (SV-BR-1-GM with CPI (pembrolizumab or retifanlimab). In the phase II portion, pts were randomized 1:1 to CPI initiation at cycle 1 (C1) or delayed start at cycle 2 (C2). Two SV-BR-1-GM formulations were administered: IFNγ-stimulated (IFγ) or unstimulated (≠IFγ). Baseline circulating tumor cells (CTCs) and delayed-type hypersensitivity (DTH) responses to SV-BR-1-GM were assessed as biomarkers. Progression free survival (PFS) and overall survival (OS) were analyzed using Kaplan Meier (KM). Subgroup comparisons (CPI sequencing, IP formulation, DTH status, and baseline CTC status) are exploratory. **Results:** 32 phase 2 pts were randomized: median age 61 (range 41-80); median prior lines 6 (range 2-13); PFS 3.5 mo (95% CI 3.0 - 4.2); OS 9.5 mo (95% CI 7.0 - 17.4). Among CPI C1 vs C2 starts: median OS 13.3 v 7.4mo (HR 0.8; 95% CI 0.4-1.9, p = 0.6); OS KM probability at 12 mo 47% v 58%. Median OS w ≠IFγ v IFNγ IP =16.6 v 9.1 mo (HR 0.58; 95% CI 0.2-1.4, p = 0.23); OS KM at 12 mo 52.4% v 27.3%. DTH+ v DTH- median OS 11.9 v 4.7 mo (HR 0.0009; p = <0.001), OS KM @12 mo 48% v 0%. CTCs <5 v > 5 at baseline had median OS 16.6 v 5.5 mo (HR 0.005; 95% CI 0.0003-0.09, p < 0.001), OS at 12 mo 49% vs 33%. Among long term survivors @12mo, OS probability 44.0% (95% CI 26.2-59.7%) and @24 mo 26% (95% CI 12.1-42.4%). Median follow up 25.8 with PFS 5.4 mo. 5 received ≠IFγ formulation v 1 w IFNγ. All 6 (3 with CPI @C1, 3@C2) experienced delayed type hypersensitivity reaction to inoculation. 67% of long responders matched HLA at >1 allele, 33% no match. Grade ≥3 AEs in 47% of pts, most common injection site rxn, nausea, fatigue; no tx related D/C; no unexpected safety signals. **Conclusions:** In heavily pretreated MBC, Bria-IMT demonstrated a tolerable safety profile and the emergence of a long-term survivor cohort. Durable survival was observed beyond 12 and 24 months. Differential survival favoring Ph3 formulation, DTH positivity, lower baseline CTC burden, and early CPI sequencing was observed. These findings support prospective validation of DTH and CTC as predictive biomarkers and the continued use of the Ph3 IP formulation in the ongoing phase 3 study Bria-ABC (NCT06072612). Clinical trial information: NCT06072612. Research Sponsor: None.

Health-related quality of life. First Author: Erinne Wasalski, Rutgers University, School of Health Professions, Newark, NJ

Background: Trials typically pool patient-reported outcomes across demographics, assuming baseline differences reflect normal variation. When adequate enrollment permits disaggregation, nuanced patterns emerge across quality-of-life domains. **Methods:** Individual participant data meta-analysis of 15 breast cancer trials (N=12,656). HRQoL domains (Physical, Emotional, Social, Role, Cognitive) and breast symptoms assessed via EORTC QLQ-C30/FACT-B at baseline, treatment, and post-treatment. Comparisons: Hispanic vs Not-Hispanic; White vs Asian vs Black vs Other. Dual approach: 1) direct between-group comparisons, 2) pooled within-group trajectories revealing between-group mean differences and absolute changes. **Results:** Population: 2.3% Black, 9.6% Hispanic, 19.9% Asian. Baseline disparities were substantial and domain-specific. Hispanic demonstrated higher cognitive functioning (MD 2.72, $p<0.05$). Black had superior role functioning versus White (84.11 vs 67.19, MD -7.80, $p<0.001$); all minority groups scored lower on emotional functioning (Black MD -4.76, Asian MD -3.34, Other MD -1.88, all $p<0.001$). During treatment, Hispanic maintained physical (MD 1.99, $p<0.05$) and role functioning (MD 3.67, $p<0.05$); Asian showed less role decline (MD 2.61, $p<0.01$). All groups experienced similar symptom improvement and cognitive decline. Post-treatment divergence: Black patients' breast symptoms worsened (change +1.27) while Asian showed highest improvement (change -2.09, $p<0.05$). Hispanic cognitive advantage eroded (MD -1.77, $p<0.05$), and treatment resilience disappeared. Uniform 60% attrition across all groups. **Conclusions:** Equal treatment response does not equal equity when groups enter with disparate baselines and experience differential post-treatment trajectories. Post-treatment divergence was striking: Black patients' symptoms worsened while Asian improved most—invisible in binary White vs Not-White comparisons. Hispanic treatment resilience disappeared in survivorship and cognitive advantages eroded. Uniform 60% attrition demonstrates recruitment, not retention, is the barrier requiring redirection of diversity initiatives. Even pooling 15 trials, Black and Hispanic representation remained inadequate. Equal treatment perpetuates existing disparities from unequal starting points or creates new disparities through differential recovery. Trial equity requires adequate diverse enrollment and interventions addressing pre-enrollment disparities and post-treatment survivorship needs. Research Sponsor: None.

1110 Poster Session

Potential BMI-dependent overall survival differences in postmenopausal breast cancer patients treated with CDK4/6 inhibitors: A Mayo Clinic platform study. First Author: Chenyu Sun, Mayo Clinic Rochester, Rochester, MN

Background: CDK4/6 inhibitors with endocrine therapy are widely used for HR+/HER2− metastatic breast cancer (BC). While studies have shown similar progression-free outcomes across agents, overall survival (OS) data are limited. Since OS is a definitive endpoint and BMI may influence outcomes, this study examines BMI-dependent OS differences among CDK4/6 inhibitors. **Methods:** A retrospective cohort study was conducted using the Mayo Clinic Platform full AMC1 dataset. Postmenopausal women with BC receiving palbociclib/ribociclib/abemaciclib plus aromatase inhibitor (AI) were included. Patients with prior use of fulvestrant, anthracyclines, radiation therapy, GnRH agonists, or history of MACE, heart failure, myocardial infarction, or stroke before BC diagnosis were excluded. Patients were stratified by BMI and CDK4/6 inhibitor. The primary outcome was 5-year OS. **Results:** Among 1,989 patients (palbociclib: 868; ribociclib: 465; abemaciclib: 656), palbociclib was associated with significantly worse OS compared to ribociclib in BMI <25 (HR 2.91; 95% CI: 1.76–4.79; $P < 0.01$) and BMI ≥ 30 (HR 1.91; 95% CI: 1.21–3.01; $P < 0.01$). Compared to abemaciclib, palbociclib showed worse OS: BMI <25 (HR 1.73; $P < 0.01$), BMI 25–30 (HR 1.56; $P < 0.01$), and BMI ≥ 30 (HR 1.82; $P < 0.01$). No significant OS differences were observed between ribociclib and abemaciclib. Palbociclib patients were older, particularly in BMI <25 (Cohen's D = 0.39 vs. ribociclib; 0.27 vs. abemaciclib) and BMI ≥ 30 (0.28 vs. ribociclib; 0.23 vs. abemaciclib). In the BMI 25–30 group, palbociclib group was also older than ribociclib group (Cohen's D = 0.26). **Conclusions:** In postmenopausal BC patients on AIs and CDK4/6 inhibitors, palbociclib was associated with worse OS in BMI < 25 and BMI ≥ 30 groups, while ribociclib and abemaciclib showed similar outcomes across BMI groups. Palbociclib patients were older than those on other drugs, which may partially confound results; however, in the BMI 25–30 group, despite similar age differences, no survival difference was observed between palbociclib and ribociclib, suggesting age alone may have limited impact. These findings indicate a potential interaction between BMI and drug choice, and highlight the need for prospective studies to confirm and adjust for these variables. Limitations include the observational design and inability to perform multivariable regression analyses to adjust for confounders. Research Sponsor: None.

Overall survival comparisons by CDK4/6 inhibitor and BMI subgroup.

Comparison	BMI Group	Hazard Ratio (95% CI)	P-value
Palbociclib vs Ribociclib	<25	2.91 (1.76 – 4.79)	< 0.01
	25 – 30	1.34 (0.87 – 2.071)	0.17
	≥30	1.91 (1.21 – 3.01)	< 0.01
Palbociclib vs Abemaciclib	<25	1.73 (1.29 – 2.32)	< 0.01
	25 – 30	1.56 (1.09 – 2.23)	< 0.01
	≥30	1.82 (1.15 – 2.88)	< 0.01
Ribociclib vs Abemaciclib	<25	1.27 (0.81 – 1.99)	0.29
	25 – 30	0.87 (0.54 – 1.43)	0.59
	≥30	1.05 (0.63 – 1.75)	0.85

Baseline circulating tumor cells and association with early resistance in patients with metastatic breast cancer undergoing palbociclib therapy. First Author: Qiang Zhang, Department of Medicine, Division of Hematology and Oncology, CTC Core Facility, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL

Background: Palbociclib has significantly improved outcomes in metastatic breast cancer (MBC); however, a substantial proportion of patients experience early treatment resistance. Reliable biomarkers to identify high-risk patients prior to therapy initiation remain limited. Our previous work has demonstrated that circulating tumor cell (CTC) and ctDNA monitoring is associated with poor prognosis in MBC (ASCO 2025 #1042; AACR 2025 #3613). Here, we report new findings of the association between baseline CTC level and timing of resistance in patients receiving palbociclib. **Methods:** This study included 178 patients with ER+/HER2− MBC treated with palbociclib at the Robert H. Lurie Cancer Center between 2016 and 2025 (IRB: NU16B06), all of whom developed treatment resistance. Time to resistance was defined as the interval from treatment initiation to first documented resistance; the median follow-up period was 8.0 months. Patients were stratified a priori into early resistance ($\leq$6 months; n = 71) and later resistance ($>$ 6 months; n = 107). Baseline CTCs were enumerated prior to treatment using FDA-approved CELLTRACKS system (Menarini). Associations between baseline CTC levels and time to resistance were assessed using Spearman rank correlation, treating CTC as a continuous variable and analyzing early and later resistance groups separately. **Results:** Among patients with early resistance, the median time to resistance was 3.25 months (range, 0.16–6.0), compared with 16.0 months (range, 6.5–57) among those with later resistance. Patients with early resistance exhibited higher baseline CTC levels on average than those with later resistance (mean CTC: 36.7 vs 25.8), although CTC distributions were highly right-skewed with substantial overlap between groups. Within the early resistance group, 29 of 71 patients had baseline CTC $\geq$5, with markedly higher mean CTC levels compared with patients with CTC $<$ 5 (88.6 vs 0.8). In contrast, baseline CTC $\geq$5 was not associated with timing of resistance among patients with later resistance. Using Spearman rank correlation, higher baseline CTC levels were significantly associated with earlier resistance among patients with early resistance ($\rho = -0.24$, P = 0.043), whereas no association was observed in patients with resistance occurring beyond 6 months ($\rho = 0.04$, P = 0.71). **Conclusions:** Baseline CTC levels were associated with the timing of treatment resistance in patients with metastatic breast cancer receiving palbociclib, with a significant inverse correlation observed exclusively among patients experiencing early resistance within 6 months. These new findings suggest that elevated baseline CTC burden reflects aggressive disease biology underlying rapid treatment failure. Time-dependent assessment of CTC may provide clinically relevant insights into early resistance risk and inform clinical decision-making. Research Sponsor: None.

Prognostic impact of digitally quantified tumor-infiltrating lymphocytes in HR+/HER2- metastatic breast cancer treated with CDK4/6 inhibitors. First Author: Yeon Gil Jeong, Division of Medical Oncology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea

Background: Cyclin-dependent kinase 4/6 (CDK4/6) inhibitors plus endocrine therapy are the first-line treatment for hormone receptor (HR)-positive/HER2-negative metastatic breast cancer(MBC). Prognostic biomarkers are needed to guide treatment decisions. Although Tumor-infiltrating lymphocytes (TILs) have been studied in breast cancer, their prognostic value in HR+/HER2- MBC remains unclear. Therefore, we aimed to assess the prognostic value of TILs in this patient population. **Methods:** We retrospectively analyzed patients with HR+/HER2- MBC receiving CDK4/6 inhibitors (palbociclib, ribociclib, or abemaciclib) plus endocrine therapy at Gangnam Severance Hospital, Seoul, Republic of Korea, from 2017 to 2025. We included 180 of 326 treated patients who met prespecified criteria. TILs were assessed according to the International Immuno-Oncology Biomarker Working Group guidelines using the digital pathology software QuPath (v0.6.0). Stromal TILs were quantified in two representative regions of interest (ROIs; each approximately 1,000 μm wide) using the formula TIL (%) = [immune cell area / (annotation area − tumor cell area)] $\times$ 100, and the values were averaged across ROIs. Patients were classified into high- and low-TIL groups using the median TIL as the cutoff. Progression-free survival (PFS) and overall survival (OS) were compared using Kaplan-Meier analyses and log-rank tests. Hazard ratios (HRs) were estimated using Cox proportional hazards models. **Results:** Among 180 patients, the median age was 53.9 years (range, 28.0–87.5) and the median follow-up was 32.4 months (range, 4.6–104.4). Median PFS was 23.2 months (98 progression events) and median OS was 32.4 months (28 death events). Using a median TIL cutoff of 7.31%, 90 patients were classified into each group. The high-TIL group showed numerically longer PFS than the low-TIL group (median 35.2 vs. 28.1 months, 95% confidence interval [CI] 25.6–not reached[NR] vs. 22.7–42.0; log-rank p=0.15; HR 0.75, 95% CI 0.50–1.12; Cox p=0.154). For OS, the high-TIL group had significantly longer survival (median NR in both groups; log-rank p=0.028; HR 0.41, 95% CI 0.18–0.93; Cox p=0.033). In the primary breast tumor subset (n=111), similar trends were observed for PFS (median 42.2 vs 27.6 months; 95% CI 24.8–NR vs 19.3–61.4; log-rank p=0.072; HR 0.62, 95% CI 0.36–1.05; Cox p=0.075) and OS (median NR in both groups; log-rank p=0.073; HR 0.41, 95% CI 0.15–1.13; Cox p=0.083). **Conclusions:** Higher TIL levels may be associated with more favorable outcomes in patients with HR+/HER2- MBC treated with CDK4/6 inhibitor-based therapy. In contrast, patients with low TILs, who may derive less benefit, could be considered for alternative targeted therapies or chemotherapy. These findings suggest TILs may have prognostic value in this setting and warrant confirmation in further prospective, multicenter studies. Research Sponsor: None.

Analysis of information received and perceived by patients with metastatic breast cancer: Results of the Croyances et Réalités 3 French survey. First Author: Claudia Plesse Lefeuvre, Centre Eugène Marquis, Rennes, France

Background: Despite therapeutic advances, metastatic breast cancer (mBC) and its treatments substantially impact quality of life. This impact, as well as prognosis and treatment strategies, varies by histological subtype. The Croyances et Réalités 3 (R3) survey, building on the 2015 and 2020 editions (R1 and R2), provides a longitudinal perspective on how French mBC patients perceive information and the support they receive. **Methods:** R3 was a multicenter, cross-sectional mirror survey involving patients with recurrent or *de novo* mBC (HR+/HER2−, HER2+, Triple-negative (TN)), and oncologists who completed paired questionnaires. Subgroup analyses were prespecified by histological subtype. **Results:** The survey was completed by 331 patients with mBC and 56 oncologists, enabling robust patient–physician comparisons with 80% mirroring. Mean patient age was 64 and 37% lived alone. Only 10% were still in the workforce while 58% were retired. The mean medical consultation duration was 40 minutes and in 26% of cases, was followed by a consultation with a nurse. Patients showed good understanding of their histological subtype, with 62% able to report it correctly (vs 37% in R2). Communication metrics also improved: 86% of patients felt their physician took time to explain, 79% felt listened to, and 69% reported good comprehension, closely matching physicians' perceptions ($>$80%). For 28% of patients, the treatment decision was shared, while 35% would like to be more involved. Supportive care and disease information brochures were the most common resources handed out (60% and 47% respectively). Uptake of supportive care increased to 65% overall (53% in R2). Psychologist (48% vs 36% in R2), dietitian (44% vs 26%), oncology aesthetician (35% vs 26%), and adapted physical activity (28% vs 18%) use increased. Among patients who did not seek supportive care, 37% stated that it was not offered to them, while 38% stated that they did not wish to receive it. Regarding impact of the disease on daily life, patients with HER2+ and TN mBC reported greater physical burden, including general fatigue and pain with significant impact (HER2+: 52%, TN: 50% vs HR+/HER2−: 33%), and reported greater use of supportive care (HER2+: 67%+, TN: 72% vs HR+/HER2−: 49%). The use of patient associations remained limited, at 11%. **Conclusions:** This current study R3 documents meaningful progress—patients' knowledge of their disease has improved, and oncologists have enhanced communication and supportive care delivery. However, despite recent improvements, supportive care remains underutilized, while the burden of the disease and its treatments remain substantial, underscoring the need to formalize care pathways that systematically integrate supportive care. Further progress is needed to improve shared decision-making, a recognized patient priority. Research Sponsor: PFIZER SAS.

Data-driven precision prognostic stratification in breast cancer leptomeningeal metastasis: The BC-LGPA model and treatment refinement. First Author: Jian Zhang, Department of Medical Oncology/Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Breast cancer leptomeningeal metastasis (BCLM) lacks data-driven prognostic models integrating diagnostic certainty with molecular features, resulting in empirical treatment limitations. **Methods:** We analyzed 403 BCLM patients (Nov 2013-Nov 2025) from four centers, constructing the Breast Cancer Leptomeningeal Graded Prognostic Assessment (BC-LGPA) based on diagnostic criteria (CSF cytology, symptoms, MRI patterns) and molecular subtype, validated externally. **Results:** The median overall survival (OS) was 7.5 months. As the first data-driven prognostic classification for BCLM, the BC-LGPA integrates diagnostic certainty scores (0–2) and molecular scores (0–1). ECOG performance status and extracranial metastases were excluded owing to collinearity with neurological symptoms and because leptomeningeal metastasis itself constitutes the primary survival-limiting factor. The model stratifies patients into high-risk (0 points, 4.7 months), intermediate-risk (1–2 points, 8.0 months), and low-risk (3 points, 16.6 months) groups (training p=0.001; validation: 4.1 vs. 7.9 vs. 16.0 months, p=0.003). Key innovations include: (1) Granular diagnostic stratification into Class A (cytology-proven), B (clinical-radiological), and C (incidental-radiological), with subclasses A1/A2/A3, B1/B2, and C1/C2/C-special; (2) Ultra-indolent entity identification: Class C-special (localized calvarial-meningeal disease without diffuse LM) shows exceptional median OS of 68.0 months, representing a distinct clinical entity unsuitable for conventional prognostic models; (3) Treatment refinement: Intrathecal therapy improved survival in Class A and Class B-Linear subgroups, whereas focal radiotherapy demonstrated no independent benefit, including in Class C2 (31 patients, p=0.794), challenging empirical RT practices. **Conclusions:** BC-LGPA establishes the first data-driven BCLM prognostic framework, correcting treatment recommendations through subgroup efficacy analyses to guide precision management and clinical trial design. Research Sponsor: None.

The scoring criteria of the BC-LGPA.

Prognostic Factor	Score		Criteria Definition		
Diagnostic Certainty			CSF cytology	Neurological symptoms	MRI
	Class A (Cytology-proven)	0	+	+ / -	+ / -
	Class B (Clinico-radiological)	1	- / NA	+	+
	Class C* (Incidental radiological)	2	- / NA	-	+
Molecular Subtype	TNBC	0	ER -	PR - ER/PR + and/or HER2 +	HER2 -
	non-TNBC	1			

Total score = *Diagnostic Certainty* score + *Molecular Subtype score*

NA: Not Available; * Localized calvarial-meningeal disease were excluded.

Clinicopathologic features, treatment patterns, and outcomes in young women with metastatic breast cancer: A National Cancer Database analysis. First Author: Cher Ying Foo, Rochester General Hospital, Rochester, NY

Background: Young women with metastatic breast cancer (MBC) represent a distinct and understudied population and often present with aggressive disease features. However, population-level studies characterizing clinicopathologic features, treatment patterns, and outcomes in this group remain limited. **Methods:** The National Cancer Database (NCDB) was queried to identify women diagnosed with MBC. Patients were stratified by age ($<$40 vs $\geq$40 years). Baseline characteristics were compared using chi-square tests. Overall survival (OS) was assessed using Kaplan–Meier analysis and compared using log-rank tests. Multivariable Cox regression was performed to evaluate independent associations with OS. **Results:** Among 59,213 women with MBC, 4,406 (7.4%) were aged $<$40 years. Median follow-up was 25.3 months (IQR 9.3–42.1). Compared with women $\geq$40, young women had more grade III tumors (61.0% vs 50.4%), lymphovascular invasion (44.2% vs 31.7%), and liver metastases (35.3% vs 23.5%). Young women were also more likely to receive chemotherapy (44.6% vs 21.7%), immunotherapy (44.2% vs 27.2%), radiation (39.3% vs 29.8%), and surgery of the primary tumor (26.7% vs 13.3%), whereas receipt of hormonal therapy was lower compared to their older counterparts (56.9% vs 54.8%). Receptor subtypes in young women were distributed as follows: HR+/HER2+ (22.6%), HR+/HER2- (50.8%), HR-/HER2+ (11.0%) and TNBC (15.5%). Young women demonstrated longer median OS compared with those $\geq$40 (68.7 months [95% CI 65.2–74.6] vs 37.1 months [95% CI 36.4–37.7]). TNBC had the worst OS among receptor subtypes ($p<0.0001$), with more than three-fold mortality risk compared with HR+/HER2- (HR 3.65, 95% CI 3.22–4.15). Metaplastic histology was associated with inferior OS compared to IDC (HR 3.11, 95% CI 1.72–5.64), and Black race was associated with worse OS compared to White race (HR 1.65, 95% CI 1.47–1.87). Receipt of radiation (HR 0.75, 95% CI 0.67–0.84), immunotherapy (HR 0.59, 95% CI 0.53–0.66), hormonal therapy (HR 0.42, 95% CI 0.38–0.47), and surgery to the primary site (HR 0.42, 95% CI 0.37–0.49) were associated with improved OS, whereas chemotherapy was not associated with OS. Most patients had a single metastatic site (55.5%), among which bone was the most common site (59.8%), followed by liver (18.4%), lung (7.7%), and brain (1.6%). Compared to bone-only metastases, brain (HR 2.04, 95% CI 1.17–3.56), lung (HR 2.08, 95% CI 1.58-2.74), and distant lymph node involvement (HR 1.54, 95% CI 1.18–2.00) were associated with worse OS. **Conclusions:** In this largest population-level study to date, young women with MBC presented with more aggressive disease features, yet demonstrated better OS compared with older patients. Survival outcomes were associated with receptor subtype, histology, and metastatic site. These findings provide valuable insights to guide clinical management of young women with MBC. Research Sponsor: None.

Temporal changes in mortality among adults with breast cancer and diabetes mellitus in the United States. First Author: Sufia Ahmed, Dow International Dental College, Dow University of Health Sciences, Karachi, Pakistan

Background: Breast cancer and diabetes mellitus represent major and intersecting public health challenges in the United States. Although breast cancer mortality has declined over recent decades, the growing prevalence of metabolic comorbidities, particularly diabetes, may offset these gains. National patterns of mortality among individuals with both conditions remain incompletely defined. We evaluated long-term trends and demographic disparities in breast cancer–and diabetes-associated mortality from 1999 to 2023. **Methods:** We conducted a retrospective population-based analysis using the CDC Wide-Ranging Online Data for Epidemiologic Research (WONDER) Multiple Cause of Death database (1999–2023). Decedents aged 45–85+ years with breast cancer (ICD-10: C50) and diabetes mellitus (ICD-10: E10–E14) listed as underlying or contributing causes of death were included. Age-adjusted mortality rates (AAMRs) were calculated using the 2000 U.S. standard population. Trends were evaluated using Joinpoint regression to estimate annual percent change (APC) with 95% confidence intervals (CI). Analyses were stratified by age, sex, race/ethnicity, census region, and urbanization. **Results:** Between 1999 and 2023, 78,253 deaths occurred among adults aged 45–85+ years with breast cancer and diabetes mellitus (1.6% male, 98.4% female). Overall AAMRs increased modestly from 2.64 to 2.84. Females consistently exhibited higher mortality than males (5.00 vs 0.13 in 2023). Non-Hispanic Black individuals had the highest AAMRs (5.61), whereas non-Hispanic American Indian/Alaska Native, Asian, and Native Hawaiian/Pacific Islander populations had the lowest (2.05). Mortality counts were greatest in the Southern region and lowest in the Northeast. Nationally, AAMRs declined from 2004 to 2018 (APC -1.82%; 95% CI, -2.12 to -1.51; $P<0.001$), followed by a sharp increase from 2018 to 2021 (APC 12.30%; 95% CI, 6.64 to 18.25; $P<0.001$), with subsequent stabilization. In contrast, males demonstrated a steady increase throughout the study period. **Conclusions:** Breast cancer– and diabetes-associated mortality declined for more than a decade but reversed sharply after 2018, highlighting the vulnerability of patients with metabolic comorbidity. Persistently higher mortality among women and non-Hispanic Black individuals and the disproportionate burden in the Southern United States underscore important disparities. These findings emphasize the need for integrated oncologic and metabolic risk management strategies and renewed attention to chronic disease control in breast cancer survivorship. Real-world analysis of the association between new-onset depression and outcomes in metastatic breast cancer. First Author: Tornike Zabakhidze, Boston Medical Center - Brighton, Boston, MA

Background: Depression is prevalent in patients with advanced cancers and it may influence the disease course and treatment. While depression is associated with worse survival in solid tumors, real-world data quantifying its impact on mortality and healthcare utilization patterns in metastatic breast cancer (MBC) are limited. We utilized a global de-identified database to evaluate the association of new-onset depression with overall survival (OS) and care utilization. **Methods:** We conducted a retrospective cohort study using the TriNetX global network. We identified adult women with MBC and survival greater than 6 months from diagnosis. Two cohorts were defined: (1) patients with first instance of depression 1-month to 3-years after MBC diagnosis, and (2) patients without depression before or during this period. Propensity score matching was performed (1:1) to balance baseline demographics, comorbidities, tumor receptor status, and previous cancer therapies. Outcomes included OS, palliative care utilization, ED visits, and Inpatient Hospitalizations over follow-up of 5 years. **Results:** We matched 2,753 patients per cohort with well-balanced baseline characteristics (mean age 60.1 $\pm$ 13.2 years). Depression was associated with shorter median OS (1,703 days vs not reached; HR 1.28, 95% CI 1.17–1.40, $p<0.001$) and 6.7% absolute increase in mortality risk (38.1% vs 31.4%). Patients with depression demonstrated significantly higher care utilization: with increased hospitalization (HR 1.52, CI 1.39–1.67), increased ED Visits (HR 1.41, 95% CI 1.30–1.52), and increased use of palliative care visits (HR 1.65, 95% CI 1.49–1.83). Subgroup analysis showed that those treated with common anti-depressants had lower median OS and higher care utilization, with a larger effect size and more statistical significance for SSRIs than SNRIs. **Conclusions:** In this large real-world cohort, new-onset depression in women with MBC was associated with significantly worse survival and increased emergency department, inpatient, and palliative care utilization. This finding may suggest a higher symptom burden or earlier recognition of complex needs. Exposure to common antidepressants was associated with lower OS and higher healthcare utilization, which may suggest residual confounding in the form of depression severity or MBC disease burden. Prospective studies are needed to further understand this relationship. These findings underscore the critical need for integrated psychosocial oncology screening. Research Sponsor: None.

Breast cancer incidence and mortality in LGBTQ+ populations compared with cisgender heterosexual individuals: A comparative epidemiologic synthesis. First Author: Manas Pustake, Texas Tech University Health Sciences Center, El Paso, TX

Background: Breast cancer incidence and mortality by sexual orientation and gender identity remain poorly characterized. We aimed to systematically review comparative studies in LGBTQ+ populations versus cisgender heterosexual comparators. **Methods:** We conducted a PRISMA 2020–guided systematic review evaluated breast cancer incidence and mortality in LGBTQ+ populations versus cisgender heterosexual comparators. PubMed, Embase, and Scopus were searched from inception to January 2026. Population-based cohort, registry, and health system studies reporting comparative incidence or mortality were eligible. Two reviewers independently screened records. Of 189 records, 105 were excluded at title/abstract, 84 underwent full-text review, and 8 studies were included. Due to heterogeneity in SOGI ascertainment, comparators, and effect measures, results were synthesized qualitatively. **Results:** Among transgender populations, breast cancer incidence varied by reference group. In a nationwide cohort, trans women had higher incidence vs cis men (SIR 46.7) but lower vs cis women (SIR 0.3), while trans men showed the inverse pattern (vs cis women SIR 0.2; vs cis men SIR 58.9). In a U.S. health system cohort, incidence was similar for FTM vs cis women (0.4% vs 0.5%) but higher for MTF vs cis men (0.2% vs 0.004%). Among sexual minority women, incidence did not differ from heterosexual women in UK Biobank (HR 0.63–0.93) or Nurses' Health Study (aIRR 1.19; 95% CI, 0.92–1.53). Mortality data were sparse; one national linkage found higher breast cancer–specific mortality in same-sex partnered women (HR 3.24; 95% CI, 1.01–10.37). **Conclusions:** Breast cancer incidence in transgender populations is comparator-dependent: trans women have higher incidence vs cis men but lower vs cis women, with the inverse pattern in trans men; incidence among sexual minority women is similar to heterosexual women. The role of FOXM1 in regulating immune memory in triple-negative breast cancer and targeting FOXM1 to develop a therapeutic vaccine. First Author: Jian Huang, UTHSA-Long School of Medicine, San Antonio, TX

Background: Triple-negative breast cancer (TNBC) is an aggressive malignancy with limited therapeutic options and poor long-term outcomes. Although immune checkpoint blockade has improved survival for a subset of patients, durable responses remain uncommon, underscoring the need for strategies that enhance tumor immunogenicity and immune memory. We recently identified a novel function of the transcription factor FOXM1 in promoting an immune-suppressive tumor microenvironment (TME) in TNBC by regulating stress ligands and the STING pathway. This study investigates the role of FOXM1 in shaping antitumor immune memory and leverages FOXM1 targeting to identify tumor antigens for therapeutic peptide vaccine development. **Methods:** FOXM1 was knocked out in TNBC cell lines using CRISPR/Cas9, and syngeneic mouse models were utilized to evaluate tumor-immune interactions. Single-cell RNA sequencing (scRNA-seq) evaluated immune landscape remodeling following FOXM1 loss. Immunopeptidomics was performed to identify tumor-associated antigens enriched following FOXM1 loss. Candidate peptides were functionally validated using dendritic cell–based antigen presentation assays and patient-derived peripheral blood mononuclear cells (PBMCs). Clinical relevance was evaluated using TNBC patient datasets and immunotherapy response cohorts. **Results:** scRNA-seq of syngeneic tumors revealed that FOXM1 deletion reshaped the immune microenvironment, with increased CD8+ T cell and NK cell infiltration and expansion of memory T cell populations. Tumor-intrinsic FOXM1 suppressed antitumor immunity by downregulating MHC-I and the stress ligand ULBP1, disrupting signaling pathways required for NK and CD8+ T cell–mediated cytotoxicity. FOXM1-deficient tumors conferred durable protection upon tumor rechallenge, consistent with long-term immune memory. Analysis of patient datasets demonstrated that elevated FOXM1 and DNMT1 expression, coupled with reduced STING and ULBP1 levels, correlated with poorer survival and reduced responsiveness to immunotherapy. Leveraging enhanced antigen presentation in FOXM1-depleted cells, immunopeptidomics identified 275 differentially presented tumor antigens. Dendritic cell pulsing of the top 15 enriched peptides induced robust T cell responses in patient-derived PBMCs, supporting their immunogenicity and its potential to serve as bona fide candidates for a therapeutic vaccine tailored for TNBC patients. **Conclusions:** These findings establish FOXM1 as a clinically relevant regulator of immune evasion and immune memory in TNBC. Importantly, the identification of immunogenic peptides provides a strong rationale for the development of a peptide-based therapeutic vaccine, either as a monotherapy or in combination with immune checkpoint blockade, to improve long-term disease control in patients with TNBC. Rare histologic subtypes of triple-negative breast cancer: The impact of immunotherapy on outcomes for metastatic disease. First Author: Jincong Q. Freeman, Cancer Prevention and Control Research Program, UChicago Medicine Comprehensive Cancer Center, Chicago, IL

Background: The addition of immunotherapy (IO) to chemotherapy (chemo) has significantly improved survival for patients with PD-L1-positive, metastatic triple-negative breast cancer (mTNBC), establishing chemo+IO as the standard first-line treatment in this population. However, the impact of IO on real-world outcomes of rare histologic subtypes of TNBC, such as metaplastic and lobular, as well as inflammatory presentation, are unknown. **Methods:** We conducted a retrospective study analyzing data from the US National Cancer Database (NCDB). Patients diagnosed with *de novo* stage IV TNBC who received chemo alone or chemo+IO between 2019 and 2022 (after FDA approval of IO for mTNBC) were included. mTNBC was classified as ductal, lobular, inflammatory, metaplastic, or other by the NCDB. Overall survival (OS) was assessed using the Kaplan-Meier method and multivariable Cox regression models controlled for sociodemographic and clinicopathologic factors. **Results:** A total of 6,711 patients with *de novo* mTNBC were identified (mean age 59.2 years), with a median follow-up of 19.8 months. Ductal histology was the most common (74.2%), followed by inflammatory (8.7%), metaplastic (4.5%), and lobular (3.6%) cases. Overall, 40.0% of the patients received chemo+IO. Immunotherapy use was the highest in mTNBC with inflammatory presentation (46.8%), followed by ductal (40.0%), lobular (37.5%), and metaplastic (37.2%) subtypes (P = 0.002). Among patients who received chemo+IO, the median OS time was the longest in ductal mTNBC (30.3 months) compared to the lobular (23.5 months) and metaplastic (22.9 months) subtypes and inflammatory presentation (16.5 months) (log-rank test $P < 0.001$). In the adjusted models, inflammatory mTNBC had a significantly higher risk of mortality than ductal cases treated with chemo+IO (adjusted hazard ratio [aHR], 1.96; 95% CI, 1.31–2.92); lobular (aHR, 1.59; 95% CI, 0.84–3.00) and metaplastic (aHR, 1.10; 95% CI, 0.44–2.71) subtypes also had a higher mortality risk, though the differences were not statistically significant due to small group sample sizes. Among patients who received chemo alone, inflammatory presentation (aHR, 2.10; 95% CI, 1.58–2.80) and lobular subtype (aHR, 1.67; 95% CI, 1.03–2.70) also had a higher risk of mortality than the ductal subtype. **Conclusions:** In this real-world analysis, patients with inflammatory, lobular, and metaplastic *de novo* mTNBC continued to experience inferior survival outcomes despite the use of chemo+IO. Our findings highlight persistent disparities in mortality outcomes and support the need for biomarker-driven strategies and dedicated clinical trials for these rare subtypes and inflammatory mTNBC. Homologous recombination deficiency signature (HRDsig+) in older women with advanced breast cancer (ABC). First Author: Tamar Kaminski, Department of Medicine (Medical Oncology), Yale University School of Medicine, New Haven, CT

Background: The identification of homologous recombination deficiency (HRD) may expand targeted therapy options in the management of advanced breast cancer (ABC). However, the frequency of positive HRD signature (HRDsig+) status in older women with ABC is not widely known. We explored the prevalence of HRDsig+ status, and its co-occurrence with other genomic alterations (GAs). **Methods:** Comprehensive genomic profiling (CGP) was performed on 6,221 cases of patients ≥ 65 years old with ABC to assess GA including base substitutions, short insertions and deletions, copy number changes and rearrangements and fusions. Microsatellite instability (MSI) status, tumor mutation burden (TMB), genomic ancestry, and trinucleotide signature were determined from the sequencing data. HRDsig status, provided as a clinical service, was determined by measuring large scale copy number changes and DNA repair errors. **Results:** Of the 6,221 cases, 662 (10.6%) were HRDsig+. Compared to the HRDsig- cases, HRDsig+ cases more frequently had genomic alterations (GA) associated with DNA repair, including *BRCA1* (13.7% vs 1.2%; p<.0001), *BRCA2* (22.8% vs 1.1%; p<.0001) and *RAD21* (25.1% vs 14.6%; p<.0001). When compared to HRDsig- cases, HRDsig+ cases had more frequent *PTEN* GA (16.3% vs 9.9%; p<.0001) *MTAP* loss (5.6% vs 2.7%; p<.0001), and TMB >10 mutations/Mb (12.7% vs 9.3%; p=.015). HRDsig- ABC cases had more frequent *PIK3CA* GA (47.6% vs 20.4%; p<.0001), *ERBB2* (10.9% vs 6.0%; p<.0001), *ESR1* (11.0% vs 5.3%; p<.0001) and *CDH1* (24.6% vs 6.5%; p<.0001). MSI-H status (0.3% vs 0.8%) and PD-L1 low 1-49% (36.1% vs 30.1%) were similar in both groups (NS). **Conclusions:** Among older adults with ABC, HRDsig+ status was identified in over 10% of patients undergoing CGP. Those with HRDSig+ more frequently had GAs in tumor suppressor genes involved in HRD, including *TP53, BRCA1, BRCA2*, and *RAD21*. The association of HRDSig+ with high TMB could provide the rationale for future trials with combination of PARP inhibitors with immunotherapy. Research Sponsor: None.

HRD signature status and associated genomic alterations in older women with advanced breast cancer.

	HRDsig positive (N=662)	HRDsig negative (N=5559)	P-value
MSI-H	0.3%	0.8%	NS

AI-driven H&E plasma cell to predict pathological complete response in IO-treated triple-negative breast cancer (Yale; NCT02489448). First Author: Amritpal Singh, Department of Biomedical Engineering, Emory University, Atlanta, GA

Background: Pathological complete response (pCR) remains difficult to predict in triple-negative breast cancer (TNBC) patients treated with immune checkpoint inhibitors due to limited validated biomarkers. While tumor-infiltrating lymphocytes (TILs) are prognostic in TNBC, they are commonly treated as a composite population. Plasma cells are central to humoral immunity and can influence antitumor response through antibody production, antigen presentation, and T-cell modulation. However, the independent and cooperative prognostic role of plasma cells, either alone or in spatial interaction with other immune cells has not been systematically evaluated, particularly in TNBC. Here, we evaluated the value of plasma cells to predict pathological complete response using AI-based analysis of routine H&E slides. **Methods:** We analyzed 239 stage I–III TNBC patients across four cohorts. Models were trained on KEYNOTE-522 regimen treated patients (D1, N=130) and validated in both the Yale TNBC immunotherapy trial cohort (D2, N=65; NCT02489448) treated with durvalumab (anti-PD-L1 antibody) and University Hospital cohort (D3, N=25) treated with pembrolizumab. Plasma cells and lymphocytes were automatically detected on whole-slide H&E images using deep learning–based nuclear segmentation and tumor region classification. Quantified metrics included immune cell density, tumor-infiltrating plasma cell (TIP) ratios, and spatial features capturing plasma cell clustering and interaction with lymphocytes. Density-based classifiers were trained on D1 and evaluated for pCR prediction. **Results:** Plasma cell density alone predicted pCR with higher accuracy than lymphocyte density across both validation cohorts. In D2), plasma cell density achieved an AUC of 73.2 compared with 62.9 for lymphocyte density. Similarly, in the external institutional cohort (D3), plasma cell density outperformed lymphocyte density (AUC 69.2 vs 60.8, respectively; Table 1). These findings demonstrate the superior predictive value of plasma cell density over conventional lymphocyte-based measures for pCR in immunotherapy-treated TNBC. **Conclusions:** Plasma cells demonstrate independent and cooperative predictive value in immunotherapy-treated TNBC. AI-derived plasma cell density and spatial interaction features improve pCR prediction and survival stratification beyond conventional lymphocyte-based metrics. Research Sponsor: None.

JSKN016, a first-in-class anti-TROP2/HER3 bispecific antibody-drug conjugate (ADC), in patients (pts) with HER2-negative locally advanced or metastatic breast cancer: Results from a phase I study. First Author: Herui Yao, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Background: TROP2 and HER3 are frequently overexpressed in most of solid tumors. JSKN016 is a first-in-class bispecific ADC targeting TROP2/HER3, site specifically conjugated to topoisomerase I inhibitor via a cleavable linker (DAR4). Glycan conjugation provides high stability and minimizes off-target toxicity. **Methods:** JSKN016-101 (NCT06592417) is a first-in-human, dose-escalation and expansion study in China, enrolling patients with advanced solid tumors to receive JSKN016 monotherapy. This analysis focused on the HER2-negative BC cohort. **Results:** As of December 22, 2025, JSKN016 was escalated to 8 mg/kg IV Q3W without reaching the maximum tolerated dose. A total of 82 HER2- BC pts were enrolled: 50 TNBC and 32 HR+/HER2- BC, treated at 4 mg/kg (n=14), 6 mg/kg (recommended phase II dose [RP2D]; n=65), and 8 mg/kg (n=3). Overall, 98.8% (81/82) had stage IV disease including 13.4% (11/82) with brain metastases. Median age was 50 (TNBC) and 52y (HR+/HER2- BC); ECOG PS 1 was reported in 78.7% and 76.7%, respectively. All TNBC pts had prior taxane-based chemotherapy, 28.0% had received ≥3 prior systemic regimens. All HR+/HER2- BC pts had progressed after ≥1 endocrine therapy with CDK4/6 inhibition and ≥1 chemotherapy. Among 47 efficacy-evaluable TNBC pts, objective response rate (ORR) was 61.7% (by INV and IRC). At RP2D (n=31), ORR was 64.5% (INV) and 61.3% (IRC), with disease control rates (DCR) of 83.9% and 90.3%. The median PFS was 7.9 months (95%CI: 5.5, NE) by IRC and 7.6 months (95%CI: 4.1, NE) by INV. Among 30 efficacy-evaluable HR+/HER2- BC pts, ORR was 50.0% (INV) and 53.3% (IRC); at RP2D (n=29), ORR was 51.7% (INV) and 55.2% (IRC), with DCR of both 100%. The median PFS was 11.1 months (8.3, NE) by IRC and was not yet mature by INV. With a median follow-up of 8 months, grade 3 or above TRAEs occurred in 25.6% (21/82) pts, with no G4 or 5 events reported. The most common G3 TRAEs were neutrophil count decreased (6.1%), amylase increased (4.9%), white blood cell count decreased (4.9%), stomatitis (3.7%), asthenia (2.4%), lymphopenia (2.4%). The incidence of TRAEs was 9.8%. Only one TRAE (G3 conjunctivitis) led to treatment discontinuation. No interstitial lung disease (ILD) was reported. **Conclusions:** JSKN016 demonstrated robust antitumor activity with good safety profile in pts with HER2-negative BC. The results support further development of JSKN016 as monotherapy or in combination. Clinical trial information: NCT06592417. Research Sponsor: None.

Real-world effectiveness and safety of first-line pembrolizumab plus chemotherapy in patients aged ≥65 years with metastatic triple-negative breast cancer. First Author: Aleksandra Konieczna, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Patients aged ≥65 years constitute a substantial proportion of individuals with metastatic triple-negative breast cancer (mTNBC), but remain underrepresented in clinical trials due to comorbidities and concerns regarding treatment tolerability. While pembrolizumab combined with chemotherapy (P+C) has been established as a standard first-line treatment for mTNBC with a combined positive score ≥10, real-world evidence on its safety and effectiveness in older patients remains limited. **Methods:** This multicenter observational real-world study (RWS), CEBCC-101, retrospectively analyzed clinical data from 178 female patients with mTNBC treated with P+C in routine clinical practice. Patients were stratified according to age at treatment initiation (<65 vs. ≥65 years). Baseline characteristics, treatment modifications (including dose reductions and treatment delays), adverse events (AEs; graded according to CTCAE v5.0) and clinical outcomes were assessed. Clinical endpoints included progression-free survival (PFS), overall survival (OS) and objective response rate (ORR) evaluated according to RECIST 1.1. Survival outcomes were estimated using the Kaplan–Meier method and compared between age groups using the log-rank test. **Results:** Among 178 patients, 57 (32.0%) were aged ≥65 years. Median age in the older cohort was 72.4 years (mean 72.3 ± 4.7). Patients ≥65 years had a significantly higher prevalence of relevant comorbidities compared with younger patients (71.9% vs. 39.7%; p<0.001) and more frequently presented with visceral metastases (78.9% vs. 61.2%; p=0.029), driven primarily by a higher incidence of lung metastases (59.7% vs. 42.2%; p=0.043). Rates of chemotherapy dose reductions at treatment initiation or during therapy, treatment delays due to AEs and treatment discontinuation due to toxicity were comparable between age groups. ORR did not differ significantly between patients ≥65 and <65 years (52.6% vs. 55.4%; p=0.767). Median PFS was 9.1 months (mo) in patients ≥65 years versus 8.3 mo in younger patients (p=0.594). Median OS was 22.1 mo and 19.5 mo, respectively (p=0.985). The incidence of grade ≥2 AEs, including pulmonary, neurological, dermatological events and fatigue was similar across age groups. **Conclusions:** In this RWS, patients aged ≥65 years with mTNBC treated with first-line P+C achieved clinical outcomes and safety profiles comparable to those of younger patients, despite a higher burden of comorbidities and more frequent visceral disease. These findings suggest that chronological age alone should not be a limiting factor for immunochemotherapy and underscore the importance of treatment decisions based on clinical fitness. Broader incorporation of geriatric assessment into routine oncology practice may further optimize patient selection and outcomes. Research Sponsor: None.

1125 Poster Session

Real-world evaluation of CXCL9/10 with PD-L1 and TMB as predictors of pembrolizumab benefit in triple-negative breast cancer (TNBC). First Author: Shipra Gandhi, Department of Medicine, Winship Cancer Institute of Emory University, Atlanta, GA

Background: Pembrolizumab is approved for TNBC; however, current biomarkers PD-L1 and tumor mutational burden (TMB) have limited predictive accuracy and show weak correlation with clinical benefit. We evaluated whether chemokines (CXCL9 and CXCL10) that recruit cytotoxic T cells into the tumor microenvironment (TME) may improve prediction of pembrolizumab benefit beyond PD-L1 and TMB. **Methods:** TNBC tumors (n=3662) were profiled by next-generation sequencing (592 NextSeq; WES/WTS NovaSeq; Caris Life Sciences, Phoenix, AZ). Chemokine expression was classified as high vs low based on 50th percentile. Immune cells were estimated using WTS deconvolution (Quantiseq). PD-L1 was assessed by immunohistochemistry (22C3 ≥10%), and TMB by nonsynonymous mutations/Mb (high ≥10). Real-world median overall survival (mOS) was derived from insurance claims and calculated from pembrolizumab initiation to last contact. Associations were tested using chi-square and Mann-Whitney U with multiple comparison adjustment ($q<0.05$). **Results:** *CXCL9/10*-high expression showed increased fraction of CD8$^+$ T, dendritic cells and higher IFN-γ signatures (*CXCL9-high vs low*: 1.3% vs 0%, 3.1% vs 2.8%, −0.09 vs −0.47; *CXCL10*-high vs low: 1.1% vs 0%, 3.1% vs 2.7%, −0.1 vs −0.46), respectively all $q<0.05$. Among patients treated with pembrolizumab (n=750), *CXCL9/10*-high expression was associated with improved mOS (*CXCL9-high*: 24.5 months (m) vs 15.8 m; *CXCL10-high*: 23.4 m vs 17 m; all $p<0.05$) compared to *CXCL9/10*-low; PD-L1+ tumors had improved mOS (24.3 m vs 18.6 m, $p=0.007$) compared with PD-L1-negative; and TMB-low tumors had numerically improved mOS (21.7 m vs 17.5, $p=0.08$) compared with TMB-high. Combining *CXCL9/10* with PD-L1 or TMB identified subgroups of tumors with PD-L1-negative and TMB-high expression that showed better OS with pembrolizumab (Table). In multivariable cox analysis, adjusting for TMB and PD-L1, *CXCL9* [HR 0.67 (95% CI 0.54-0.83)] and *CXCL10* [HR 0.79 (95% CI 0.64-0.97)] remained independent predictors of pembrolizumab benefit, all $p<0.05$. **Conclusions:** In this large real-world study, PD-L1 but not TMB predicted pembrolizumab benefit in TNBC. *CXCL9/10-high* define an immune-active TME and are independent predictors of pembrolizumab response. When integrated with PD-L1 and TMB, these chemokines help identify additional patients with TNBC who may derive benefit from pembrolizumab, supporting their inclusion as biomarkers in prospective studies. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Single cell spatial profiling for identification of organ-specific immune features in the peritumoral microenvironment of triple-negative breast cancer with liver metastases. First Author: Jin Sun Bitar, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Breast cancer liver metastasis (BCLM) is associated with poor prognosis. Prior studies have described liver metastases as immune-cold, yet the mechanisms underlying this phenotype remain incompletely understood. We hypothesized that the peritumoral microenvironment, in addition to the tumor itself, contributes to the distinct immunobiology of BCLM. **Methods:** We performed imaging mass cytometry (IMC) with a 42-antibody panel on TNBC tissues from primary breasts (PB) (n = 22) and liver metastases (LM) (n = 26). For each case, one region of interest (ROI) from tumor bed and one from peritumoral tissue were profiled. Cell segmentation was performed using DeepCell. Single-cell phenotyping and clustering were conducted using Scanpy with lineage markers. Functional marker expression was analyzed and differences between PB and LM were assessed using non-parametric tests with Benjamini–Hochberg false discovery rate (FDR) correction. Spatial analysis was performed using Squidpy with Wilcoxon testing and FDR correction across all tested interaction pairs. **Results:** IMC analysis resolved 407,160 cells into distinct immune, stromal, and tumor cell clusters across compartments. Within tumor beds, PB and LM exhibited largely similar functional marker expression and spatial organization, indicating minimal tumor-intrinsic divergence. In contrast, peritumoral tissues diverged substantially between PB and LM. Peritumoral tissues in PB demonstrated M2 macrophage dominance while LM exhibited M1 macrophage dominance. The comparative analysis of peritumoral tissues revealed that cancer cells in LM demonstrated significantly increased spatial proximity to CD8 T cells compared to PB with concurrent upregulation of PD-L1 on macrophages and NK cells, alongside elevated PD-1 expression on multiple immune cell types, indicating that CD8 T cells are potentially exhausted despite their physical presence. Additionally, CCR7, CD6, and CXCL13 were significantly elevated across all cell types in LM, while PB demonstrated higher expression of CD44, CXCR3 and CXCL12, indicating broad immunophenotypic differences in peritumoral tissues. Spatial analysis further revealed that CD4 T cells maintained closer proximity to cancer cells, M1 macrophage, and stromal populations in PB, indicating distinct spatial organization between sites. **Conclusions:** Single-cell spatial profiling reveals that organ-specific tumor and immune biology in TNBC BCLM is encoded primarily within the peritumoral tissue rather than the tumor bed itself. Our findings reveal a paradoxical phenotype in BCLM where CD8 T cells successfully infiltrate and localize near cancer cells but show features consistent with functional impairment. These findings support further investigation of immunotherapy in TNBC BCLM and biomarker validation. Research Sponsor: 2024 Cedars-Sinai Cancer Center Developmental Funds.

Trends in immunotherapy use and survival outcomes by metastatic pattern in metastatic triple-negative breast cancer. First Author: Michael Schwartz, Department of Medicine, Winship Cancer Institute of Emory University, Atlanta, GA

Background: KEYNOTE-355 demonstrated that adding pembrolizumab to chemotherapy improved progression-free and overall survival (OS) vs chemotherapy alone in patients with metastatic TNBC (mTNBC) and PD-L1 CPS ≥10. Approved in 2020, this regimen transformed advanced TNBC management. However, the benefit of immunotherapy (IO) according to metastatic site remains underexplored given the varied immune environments between organs, with the liver being particularly immune-suppressed. **Methods:** We conducted a retrospective analysis of 2022 NCDB data for female patients diagnosed 2016–2021 with de novo mTNBC. OS was defined as months from diagnosis to death/last contact. Patients were stratified by first-line therapy (chemotherapy alone vs chemotherapy + IO) and metastatic pattern (isolated liver/lung/bone/brain; multiple sites). IO type was not specified. P-values were calculated by chi-squared/Fisher's exact tests as appropriate. Hazard ratios (HR) were estimated by a univariate Cox model. **Results:** 2329 patients with de novo mTNBC were included in our study. Median age was 59 years, median follow-up time was 42 months. 1723 (74%) received chemotherapy alone and 606 (26%) received chemotherapy + IO. The proportion of patients receiving IO increased each year between 2016 and 2021 (3.3% - 34.3%). Overall, patients treated with chemotherapy + IO had better OS compared to chemotherapy alone (HR = 0.58, 95% CI, 0.51-0.65, P<0.001). Isolated lung metastasis was the most common pattern (n=402, 20.9%), followed by bone (n=374, 19.4%), liver (n=246, 12.8%), and brain metastasis (n=14 , 0.7%). 892 (46.3%) patients had multiple metastatic sites. Patients with isolated lung, liver or bone metastases had better OS vs those with multiple metastatic sites (lung, HR 0.54, [95% CI 0.47–0.62]; liver, HR 0.62, [95% CI 0.53-0.73]; bone, HR 0.69, [95% CI 0.60–0.79]). Kaplan–Meier analysis showed superior OS with chemotherapy + IO vs chemotherapy alone across lung, liver, bone, and multiple metastases subgroups (log-rank P<0.0001, P=0.0003, P=0.0017, P<0.0001, respectively); brain metastasis analysis limited by small sample size (Table 1). **Conclusions:** In this large real-world mTNBC cohort, IO adoption increased post-KEYNOTE-355 approval and associated with an overall 42% lower mortality risk vs chemotherapy alone. Additionally, increased IO adoption correlated with increased survival over time. The survival benefit of IO was preserved across different metastatic sites of disease. Research Sponsor: None.

Overall survival in mTNBC patients by metastatic site and treatment modality.

Met site	Treatment	N	Median survival, months	24-mo survival, %	36-mo survival, %
Lung	Chemo + IO	57	32.1	60.6	49.4
	Chemo	220	15.9	38	24.8
Liver	Chemo + IO	47	27.7	52.4	37.7
	Chemo	141	15.5	33.4	18.7
Bone	Chemo + IO	67	23.5	49.2	26.3
	Chemo	221	13.2	29.7	19.8
Multiple	Chemo + IO	155	16.4	36.3	26.4
	Chemo	593	8.7	18.1	10.3

Long-term responders to sacituzumab govitecan in metastatic triple-negative breast cancer: Real-world outcomes and predictors from a multicenter Italian cohort. First Author: Roberta Caputo, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy

Background: Sacituzumab govitecan (SG) has reshaped the treatment landscape of metastatic triple-negative breast cancer (mTNBC), demonstrating superior survival outcomes compared with standard chemotherapy in the ASCENT trial. Despite the overall poor prognosis of mTNBC, a subset of patients experiences remarkably durable responses and prolonged survival, far exceeding the median progression-free survival (PFS) observed in pivotal trial. However, the clinical characteristics and prognostic determinants of these "long-term responders" (LTRs) remain poorly defined, and real-world evidence specifically addressing this population is currently lacking. This multicenter study aims to characterize outcomes and identify potential predictors of long-term benefit from SG in a real-world setting. **Methods:** This multicenter observational analysis included 271 patients with mTNBC treated with SG across 18 Italian cancer centers, within a study incorporating both retrospective and prospective cohorts (NCT02284581). LTRs were defined as patients achieving a real-world PFS (rwPFS) ≥ 9 months. The primary endpoint was rwPFS, while secondary endpoints included real-world overall survival (rwOS) and objective response rate (ORR). Survival outcomes were estimated using the Kaplan-Meier method, and independent prognostic factors were identified using Cox proportional hazards models. **Results:** Seventy-four of 271 patients (27.3%) were identified as LTRs. Within this cohort, median rwPFS was 14 months (95% CI: 13.3–16.3) and median rwOS was 25.6 months (95% CI: 21.0–NR). The ORR was 68.9% (all partial responses; n=51), while 29.7% of patients (n=22) achieved stable disease. On multivariable analysis, previous therapy with immune checkpoint inhibitors (ICI) was independently associated with a reduced risk of progression (HR 0.47; 95% CI: 0.22–0.98; p=0.04). De novo metastatic disease also showed a trend towards a lower risk of progression (HR 0.44; 95% CI: 0.16–1.17; p=0.10). Conversely, treatment with SG in the third line compared with the second line was associated with a higher risk of progression (HR 2.04; 95% CI: 1.02–4.07; p=0.04). No significant association were observed for brain metastases (p=0.37), BRCA mutation status (p=0.33), or visceral involvement (p=0.27). **Conclusions:** In real-world setting, more than 25% of mTNBC patients experience a durable benefit from SG. Prior exposure to immunotherapy and earlier use of SG in the second-line setting were associated with a higher likelihood of LTR, while de novo disease showed a favourable trend. Notably, the presence of brain or visceral metastases did not preclude prolonged benefit. These findings suggest that a subset of patients with mTNBC may derive sustained clinical benefit from SG and support its use earlier in the treatment sequence. Clinical trial information: NCT02284581. Research Sponsor: Gilead Sciences.

Progression-free survival as a surrogate endpoint for overall survival in metastatic triple-negative breast cancer: A systematic review and meta-analysis. First Author: Yashasvi Srivastava, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine

Background: Overall survival (OS) remains the gold standard endpoint in metastatic triple negative breast cancer (mTNBC), but its assessment is confounded by post progression therapies and prolonged follow up. Progression-free survival (PFS) is frequently used as a primary endpoint; however, its validity as a surrogate for OS in mTNBC remains uncertain. We conducted an updated systematic review and meta analysis to evaluate the strength and reliability of PFS as a surrogate endpoint for OS across contemporary RCTs. **Methods:** We searched PubMed, Embase, Cochrane Library, and major oncology conference proceedings through January 2026 for randomized controlled trials evaluating systemic therapies in metastatic or unresectable TNBC. Eligible trials reported hazard ratios (HRs) for both PFS and OS. Trial level correlations between log(HR_PFS) and log(HR_OS) were assessed using weighted Spearman correlation and weighted linear regression, with sample size based weights. Certainty of evidence was assessed using a modified GRADE framework. **Results:** Twenty-seven treatment comparisons from 29 trials (8,527 patients) met inclusion criteria. Across all comparisons, PFS demonstrated a strong correlation with OS (weighted Spearman ρ = 0.80; 95% CI, 0.55-0.91), with a moderate surrogate relationship (R^2 = 0.64). The regression slope (0.66; 95% CI, 0.46-0.87) indicated attenuation of OS benefit relative to PFS. The surrogate threshold effect corresponded to an HR PFS of 0.96. Eight trials (30%) showed concordant PFS and OS benefit, while 44% demonstrated PFS improvement without significant OS gain. Surrogacy was strongest in phase III trials (R^2 = 0.71). Treatment class analyses revealed strong surrogacy for immune checkpoint inhibitors (R^2 = 0.95) and platinum based chemotherapy (R^2 = 0.87), but weak correlation for AKT pathway inhibitors (R^2 = 0.31). Overall certainty of evidence was moderate. Risk of bias assessment using the Cochrane RoB 2.0 tool showed 30% of comparisons at low risk, 56% with some concerns (primarily due to open label design), and 15% at high risk, mainly related to crossover and outcome assessment. **Conclusions:** PFS is a moderate and clinically acceptable surrogate for OS in metastatic TNBC, particularly for immune checkpoint inhibitors and platinum based regimens. However, surrogate validity varies substantially by treatment class, underscoring the need for confirmatory OS data especially for targeted therapies with novel mechanisms. Research Sponsor: None.

Measuring KEYNOTE-522 response from TNBC patient biopsies ex vivo using the E-slice assay. First Author: Kyuson Yun, Houston Methodist Cancer Center, Houston, TX

Background: The KEYNOTE-522 regimen demonstrated a significant survival advantage of adding neoadjuvant pembrolizumab (pembro) to standard-of-care (SOC) chemotherapy (chemo) in TNBC patients. However, most patients will not benefit from this costly and potentially toxic therapy. A diagnostic test that can stratify responders and non-responders in advance will reduce overtreatment in this population. The E-slice assay is a proprietary 3D human tumor tissue culture platform that enables rapid, personalized drug sensitivity testing. E-slices preserve immune cells in their native state ex vivo, enabling immunotherapy response measurement from tissue resident immune cells. **Methods:** In this prospective clinical study, newly diagnosed triple-negative breast cancer (TNBC) patients scheduled to receive KEYNOTE-522 treatment at MD Anderson Cancer Center were enrolled. E-slices were generated from 14-gauge core biopsies and treated with IgG control, pembrolizumab, or a combination of pembrolizumab with paclitaxel + carboplatin followed by doxorubicin + cyclophosphamide. Diagnostic performance of the E-slice assay was evaluated using sensitivity, specificity, and ROC analysis, with the optimal cutoff determined by the Liu method. Concordance between assay-based predictions and clinical treatment response was assessed using Cohen's kappa, and paired classification differences were tested with McNemar's test. Patient tumor responders were defined solely by pathological complete response (pCR) or not, at the time of surgery, after standard-of-care neoadjuvant chemoimmunotherapy treatment. **Results:** A blinded interim analysis was scheduled after the first 10 patients evaluated in the clinic for pCR. The mean and SD of age were 52.10±12.52. The mean and SD for E-slice combo response, relative to DMSO @ day12 were 0.68±0.18. The optimal cutoff point for E-slice combo response was 0.78. The proportion of responders in patients was 0.8 (8/10). The proportion of responders from E-slice combo response was 0.7 (7/10). There was no significant difference based on McNemar's test (p=1.0). The concordance rate is 75% (95% CI: 42.81%-94.51%). The sensitivity, specificity, positive predictive value, negative predictive value, and area under ROC curve at cutoff point for E-slice were: 87.5% (95% CI: 47.3%-99.7%), 100% (15.8%-100%), 100% (59%-100%), 66.7% (9.43%-99.2%), and 0.94 (0.82-1.0), respectively. **Conclusions:** E-slice assay predicts TNBC patient responses to pembrolizumab alone or pembrolizumab + chemo by providing drug sensitivity data in a clinically actionable time frame. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Confusion matrices E-slice combo response.

		E slice Response		
		Non-Responders	Responders	Total

Determinants of triple-negative breast cancer among African patients: Early results from The African Cancer Atlas. First Author: Emmanuella Amoako, Yemaachi Biotech, Accra, Ghana

Background: Triple-negative breast cancer (TNBC) is disproportionately common among women of African ancestry and is associated with aggressive clinical behavior and limited therapeutic options. Understanding demographic and contextual determinants of TNBC across African countries is essential to improving prevention, early detection, and precision oncology strategies. Using harmonized data from The African Cancer Atlas (TACA)—an initiative of Yemaachi Biotech, we examined factors associated with TNBC across Côte d'Ivoire, Ghana, Kenya, Nigeria, and Seychelles. **Methods:** We analyzed 236 participants with complete immunohistochemistry data enrolled in TACA. Associations between TNBC and demographic variables were assessed using Wilcoxon rank-sum tests, Fisher's exact tests, and multivariable logistic regression. **Results:** TNBC accounted for 38.1% of breast cancers in the cohort. TNBC had prevalence rates ranging from 21.1% in Kenya to 68.1% in Nigeria ($p<0.001$). Seychelles exhibited no TNBC cases (0/23). TNBC prevalence among females was 38.5% (89/231), compared with 20.0% (1/5) among the few male participants. Women in Nigeria had markedly higher odds of TNBC compared with Kenya (OR 10.4, 95% CI 3.72–31.4, $p<0.001$). Women in Ghana also demonstrated increased odds (OR 2.55, 95% CI 1.10–6.12, p=0.032). Age showed no significant association with TNBC (mean age 51.6 years for TNBC vs. 50.2 years for non-TNBC, p=0.6), though the 60–69 age group showed a modestly increased proportion of TNBC (38.1%, OR 0.26, 95% CI 0.07–0.93, p=0.042, relative to 50–59). Education level was significantly associated with TNBC (p=0.004). Women with no formal education had a 59.2% TNBC prevalence (29/49), compared with 26.9% among those with primary education (18/67, OR 0.69, 95% CI 0.26–1.85) and 33.3% among those with higher education (17/51, OR 0.77, 95% CI 0.28–2.14). Family history of cancer was also associated with TNBC (p=0.006). Among women reporting a positive family history, 23.8% had TNBC (15/63), compared with 76.2% with non-TNBC (48/63). **Conclusions:** TNBC prevalence in this multi-country African cohort was high and characterized by substantial geographic variation, with Nigeria demonstrating the highest burden. Lower educational attainment and family history of cancer were also associated with TNBC, independent of country. These findings highlight the importance of considering sociodemographic and contextual factors when designing TNBC-focused screening and treatment strategies and underscore the need for country-specific precision oncology approaches in African settings. Immune infiltration features relative to cancer cell clumps as predictors of survival in triple-negative breast cancer. First Author: Himangi Srivastava, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype with poor prognosis. While immune infiltration and abundance have been established as prognostic indicators, we examine how immune spatial organization and tumor geometry jointly influence survival. **Methods:** Whole-slide H&E images from 125 TNBC TCGA cases were analyzed using pathology instance learning models to generate tile-based predictions, which were reconstructed into polygon annotations for tumor epithelium, tumor-infiltrating lymphocytes (TILs), and tertiary lymphoid structures (TLS). From these annotations, we extracted novel spatial features describing abundance, fragmentation, dispersion, shape, and boundary properties of immune and tumor regions, as well as immune–tumor distances, overlap gradients, and boundary engagement. Associations with disease-specific survival (DSS) were assessed using univariate Cox models, and significant features were incorporated into a multivariate Cox model. Kaplan–Meier and correlation analyses were performed for dichotomized features. **Results:** Among all spatial features analyzed, global immune dispersion emerged as a strong indicator of survival. This metric, quantified by the radius of gyration of immune islands, was significantly associated with worse disease-specific survival (DSS) (HR per SD = 1.90; p = 0.03) and demonstrated clear Kaplan–Meier separation (log-rank p = 0.028). Increased tumor boundary complexity, measured by edge density normalized to tissue area, was also associated with poorer DSS (HR per SD = 1.77; p = 0.007). Kaplan–Meier analysis for edge density showed only modest separation (log-rank p = 0.071), consistent with a gradual, continuous risk effect rather than a discrete threshold. Similarly, greater intratumoral immune area correlated with adverse DSS (HR per SD = 1.26; p = 0.020), supporting the interpretation of intratumoral immune accumulation as a marker of ineffective or dysfunctional immune infiltration rather than protective immunity. In a multivariable Cox model, immune dispersion, tumor boundary complexity, and intratumoral immune area retained concordant effect directions and jointly achieved strong discrimination (C-index ≈ 0.74). Correlation analysis confirmed that the dominant spatial features were non-redundant, with minimal multicollinearity (all variance inflation factors < 1.2). **Conclusions:** In TNBC, survival is not solely dependent on immune abundance and proximity to the tumor region, but on the immune spatial dispersion, aggressive tumor boundaries, and ineffective immune accumulation in the intratumoral space. Novel spatial biomarkers examined here may refine risk stratification beyond conventional metrics. Impact of protein–energy malnutrition on outcomes of metastatic triple-negative breast cancer patients receiving chemotherapy: A real-world analysis. First Author: Vaishali Deenadayalan, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Protein–energy malnutrition (PEM) is common in patients with advanced cancer and is associated with increased toxicity, decreased treatment tolerance, and worse survival across malignancies. Data specific to metastatic triple-negative breast cancer (mTNBC), a biologically aggressive subtype, remain scarce. We evaluated the impact of PEM on outcomes in mTNBC patients receiving chemotherapy. **Methods:** We conducted a retrospective cohort study using de-identified data from TriNetX, a global federated health research network. Females with mTNBC on chemotherapy (paclitaxel, doxorubicin, capecitabine, eribulin, vinolrebine) were identified. PEM was defined using ICD-10 codes along with secondary definitions like BMI (<20). The primary endpoint was overall survival (OS), estimated using the Kaplan-Meier method. Propensity matching was used to adjust for age, race and comorbidities. Two sided p≤0.05 was used to determine statistical significance. **Results:** A total of 1,644 patients with mTNBC were identified, of whom 761(46.3%) patients had PEM. The mean age was higher in the PEM group compared to the non-PEM group (64.5 vs 63 years, $p<0.05$). African American patients were more likely to have PEM (37.0% vs 31.4%, $p=0.02$). After propensity score matching, 595 patients were included in each cohort for analysis. Patients with PEM had significantly worse 1-year OS compared to non-PEM group (65.7% vs 70.8%; HR 0.76, 95% CI 0.62–0.94, $p<0.05$). At 2 years, survival remained numerically lower in the PEM group (56.2% vs 57.8%; HR 0.92, 95% CI 0.76–1.12), but the difference was not statistically significant. **Conclusions:** In this large real-world cohort of mTNBC, PEM was independently associated with worse 1-year overall survival. These findings underscore the prognostic significance of nutritional status in mTNBC and support routine nutritional assessment and early supportive interventions to improve outcomes in this high-risk population. Research Sponsor: None.

Overall survival (OS) outcomes in matched mTNBC cohorts.

Overall Survival	PEM Group (n=595)	Non-PEM Group (n=595)	Hazard Ratio (95% CI)	P-value
1-Year OS	65.7%	70.8%	0.76 (0.62–0.94)	<0.05
2-Year OS	56.2%	57.8%	0.92 (0.76–1.12)	0.41

Leveraging single-cell trajectory analysis and machine learning to build a robust prognostic classifier for triple-negative breast cancer to pinpoint CCDC171 as a master regulator. First Author: Jialiang Feng, Zhongnan Hospital of Wuhan University, Wuhan, China

Background: Triple-negative breast cancer (TNBC) is limited by high heterogeneity and a lack of robust biomarkers for risk-stratified management. While chemotherapy is standard, traditional bulk signatures fail to capture high-resolution cellular transitions driving recurrence. This study integrates scRNA-seq with multi-algorithmic machine learning to identify key regulatory programs. We developed a trajectory-informed prognostic classifier to improve individual risk assessment and uncover potential therapeutic targets in the TNBC tumor microenvironment (TME). **Methods:** We performed single-cell RNA sequencing (scRNA-seq) on 24 TNBC samples to map the cellular landscape and applied pseudotime trajectory analysis to identify dynamic gene programs associated with cell-fate decisions. Prognostic genes derived from trajectory-informed differential expression were integrated with bulk RNA-seq data from TCGA-TNBC and validated in two independent cohorts (GSE58812, GSE135565). A robust prognostic model was constructed using an extensive machine-learning framework combining forward stepwise Cox regression and gradient boosting (StepCox[forward] + GBM). Model performance was evaluated using Harrell's C-index and Kaplan–Meier analysis, and predictive utility was assessed in neoadjuvant treatment cohorts. Virtual gene knockout experiments were used to analyze the function of CCDC171. **Results:** We developed an 18-gene prognostic signature that robustly stratified TNBC patients into high- and low-risk groups across multiple cohorts (TCGA: HR = 55.12, $p = 2.9\times10^{-12}$; GSE58812: HR = 3.96, $p = 6.3\times10^{-4}$; GSE135565: HR = 7.73, $p = 4.0\times10^{-3}$). The model outperformed existing prognostic signatures and generalized to non-TNBC breast cancer subtypes. Four genes (CRISP3, PDZK1IP1, CCDC171, IGFL1) were consistently retained across top-performing algorithms. CCDC171 emerged as a central regulator whose expression correlated with poor survival and coordinated a network involving complement activation (C1QB), metabolic reprogramming (CA8), and mitochondrial stress response (MTRNR2L8). In silico knockout of CCDC171 downregulated these effectors and suppressed oncogenic pathways including PI3K–Akt signaling, ECM interaction, and platinum resistance. **Conclusions:** Our study presents a TNBC prognostic model grounded in TME cellular dynamics and machine learning, with superior predictive accuracy and cross-subtype applicability. CCDC171 is identified as a novel master regulator of a multi-effector network driving tumor aggressiveness, offering a potential therapeutic target. This integrative framework supports risk-stratified management and personalized therapy in breast cancer. Research Sponsor: None.

VISTA: Targeted combination immunotherapy for suppression of breast cancer metastasis and recurrence. First Author: James Stuart Garner, Percheron, Melbourne, VIC, Australia

Background: Triple-negative breast cancer (TNBC) has limited treatment options and poor outcomes, with ~12% 5-year overall survival in stage IV. In early-stage TNBC (II/III), recurrence remains substantial among patients without pathological complete response after chemo-immunotherapy. Current PD-1/PD-L1 inhibitors show limited efficacy in metastatic TNBC (median OS ~23 months) and infrequent durable responses. Novel immune targets are urgently needed to overcome resistance and prevent metastasis. V-domain Ig suppressor of T-cell activation (VISTA) is a next-generation checkpoint with distinct biology, enriched in tumor-infiltrating immune cells in TNBC. **Methods:** Comprehensive bioinformatic analyses of VSIR (VISTA) and ligands were performed across multi-cohort TNBC datasets spanning early and advanced stages, including pre-treatment, post-treatment, and progression samples. Spatial single-cell profiling of stage III TNBC tumors with recurrence versus non-recurrence was conducted using NanoString CosMx. VISTA expression in tumor tissue and circulating tumor cells (CTCs) was assessed by optimized immunofluorescence and digital pathology. Clinically relevant TNBC mouse models evaluated VISTA-mediated immune modulation alone and combined with chemo- or immunotherapy. **Results:** Single-cell bioinformatic analyses revealed enrichment of VSIR and ligands SELPLG/LGALS9 in post-treatment and progression-stage TNBC versus pre-treatment, observed in tumors and liquid biopsies. VSIR/SELPLG were enriched in progenitor and terminally exhausted immune subsets, whereas early-stage TNBC showed broader immune distribution. Digital pathology identified VISTA in metastasis-initiating tumor cells and dysfunctional immune cells, with induction following anti–PD-1 therapy in TNBC mouse models. Spatial profiling of recurrence-associated tumors showed co-enrichment of VSIR/SELPLG with inhibitory receptors TIM3, LAG3, and TIGIT across immune niches in recurrence-associated tumors. VISTA targeting with a novel antibody, HMBD-002, enhanced anti-tumor immunity, synergized with chemo- and immunotherapy, and suppressed recurrence and metastatic burden in preclinical models. **Conclusions:** VISTA is a treatment-emergent checkpoint associated with T-cell exhaustion, recurrence, and metastasis in TNBC. Its enrichment in exhausted T-cell niches, metastasis-initiating tumor cells, and CTCs post–chemo-immunotherapy supports its role in adaptive resistance. VISTA expression in tissue and liquid biopsy CTCs represents a clinically actionable biomarker for patient selection and response monitoring. These data provide strong rationale for early-phase clinical trials of combination VISTA blockade with ICIs in high-risk early-stage TNBC with residual disease and metastatic TNBC after prior ICI exposure. Clinical and translational analysis of a phase Ib/II combination of atezolizumab, cobimetinib, and eribulin (ACE) to demonstrate inflammatory and metabolic programs define divergent response states. First Author: Elyse R. Lopez, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare, aggressive subtype with poor outcomes and limited immunotherapy data. Preclinical studies suggest MAPK inhibition enhances antitumor immunity and synergizes with checkpoint blockade. We report results from a phase Ib/II trial of atezolizumab (A), cobimetinib (C), and eribulin (E) in metastatic IBC with integrated molecular profiling. **Methods:** Patients (pts) with metastatic/recurrent IBC received ACE (cohort 1, n=17). Following cobimetinib supply discontinuation, an exploratory cohort received AE (cohort 2, n=10). Primary endpoint: objective response rate (ORR) per RECIST v1.1. Secondary endpoints: safety, progression-free survival (PFS), overall survival (OS), and correlative genomic, transcriptomic, spatial immune, and circulating tumor DNA (ctDNA) analyses. **Results:** ACE achieved ORR 50% (7/14; 3 patients were unevaluable for response), disease control rate (DCR) 71% (10/14), median PFS 3.7 months (mo), and median OS 10.6 mo, with 2 exceptional responders achieving >5-year survival. AE showed limited activity (ORR 10%, median OS 7.8 mo). No grade 4/5 toxicities occurred. Molecular profiling revealed distinct response states: responders demonstrated immune-activated, epithelial-like transcriptional programs with CD8+ T-cell infiltration; non-responders exhibited metabolically hyperactive, immune-excluded phenotypes with KRAS pathway activation, T-reg enrichment, CD8+ T-cell exclusion, VEGFA/GSDMB upregulation, and elevated ctDNA. **Conclusions:** ACE demonstrated encouraging activity in metastatic IBC with durable benefit in two pts. Resistance was associated with metabolic reprogramming and stromal immune exclusion, supporting rational development of metabolism-targeting, stroma-modifying, or T-reg/macrophage-directed combinations in this high-risk population. Clinical trial information: NCT03202316. Research Sponsor: None.

Sequence of similar-payload ADCs: Does it make sense in real-world HER2-low advanced breast cancer?—The Portuguese national study. First Author: Gonçalo Fernandes, Hospital da Luz Lisboa, Lisboa, Portugal

Background: New-generation Antibody-Drug Conjugates (ADC) have expanded treatment options for HER2-low advanced breast cancer (ABC), regardless of hormone receptor (HR) status. Sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd) are used sequentially in clinical practice, but real-world data on efficacy, sequencing and potential cross-resistance are limited. We aimed to evaluate efficacy, sequencing patterns and predictors of outcome in a national real-world cohort of HER2-low ABC. **Methods:** We conducted a multicenter, retrospective real-world cohort study including patients with HER2-low ABC treated sequentially with SG and T-DXd, regardless of sequence, across 14 Portuguese centers. Eligible patients initiated the first ADC between 2023 and 2025 and received ≥1 cycle of both ADCs. The primary endpoint was progression-free survival (PFS), evaluated for the first (PFS1) and second ADC (PFS2). Secondary endpoints included objective response rate (ORR), primary resistance to the second ADC (PFS2 ≤3 months) and safety. PFS was analyzed using time-to-event methods. For exploratory analyses, PFS1 and PFS2 were dichotomized at the median and associations with longer PFS were assessed using chi-square tests. Predictors of PFS2 were explored in an exploratory multivariable Cox regression model. **Results:** Sixty-four patients were included; 36 (56%) had HR-positive disease and 28 (44%) were HR-negative. Median age at ADC1 initiation was 51 years (27–79). T-DXd was used as the first ADC (ADC1) in 34 (53%) patients and was more frequently administered as ADC1 in HR-positive disease. A total of 22 (34%) patients received ≥1 intermediate line, mainly chemotherapy (91%). Median PFS1 was 8.9 months (95% CI 5.8–9.7) and median PFS2 was 2.7 months (95% CI 2.1–3.2). PFS2 was consistently shorter than PFS1 across subgroups, independent of treatment line, with 43 (70%) patients presenting primary resistance to the second ADC. ORR to ADC2 was 3%. No significant differences in PFS1 or PFS2 were observed by ADC sequencing. Longer PFS1 was not associated with improved PFS2 (p=0.44). In the multivariable model, none of the evaluated variables, including the use of ≥1 intermediate line between ADCs, were significantly associated with longer PFS2 (all $p>0.05$). No new safety signals were observed; rates of dose reductions and interruptions were consistent with known safety profiles of SG and T-DXd. **Conclusions:** In this national real-world cohort of HER2-low ABC, clinical benefit from a second ADC was limited, with shorter PFS and frequent early progression, irrespective of sequencing order. Importantly, no baseline clinical factors predicted PFS2. These findings may suggest clinically relevant cross-resistance between ADCs with similar payloads and highlight shared resistance mechanisms as a key challenge in optimizing ADC sequencing. Research Sponsor: None.

Clinical impact and temporal evolution of mutational signatures in metastatic lobular breast cancer. First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Invasive lobular carcinoma (ILC) has distinct genomic features, including frequent *CDH1* alterations, yet the mutational processes shaping metastatic ILC and their prognostic significance remain poorly defined. We evaluated mutational signatures inferred from targeted sequencing in a large single-center cohort of metastatic ILC and their association with outcomes. **Methods:** Patients were included if they had ILC histology on early-stage breast biopsy/surgical pathology, and/or *CDH1* mutation on metastatic site biopsy and MSK-IMPACT sequencing from a metastatic site. For survival analyses, only biopsies performed within 2 months of metastatic diagnosis were included. Clinicopathologic data were abstracted from electronic medical records. Single base substitution (SBS) signatures were inferred using SigMA; cases with $\leq$5 SBS were excluded. Overall survival (OS) was estimated using Kaplan–Meier and compared by dominant signature using the log-rank test. **Results:** 654 patients were included. 467 (71%) had hormone receptor-positive (HR+)/HER2-, 56 (8.6%) had HER2+, and 65 (9.9%) had triple negative disease at metastatic diagnosis. Among 307 (47%) with ILC variant data available, 139 (45%) had classic type, 65 (21%) had pleomorphic, 45 (15%) had mixed, and 58 (19%) had other ILC variants. 385 patients (59%) had MSK-IMPACT testing on a tissue biopsy performed within 2 months of metastatic diagnosis. Among them, the most prevalent mutations included *CDH1* (85%), *PIK3CA* (47%), *TP53* (21%), *TBX3* (16%), *PTEN/AKT1* (14.5%), *FOXA1* (12%), *ERBB2* (12%), *KMT2C* (9.9%), *CBFB* (9.9%), *ARID1A* (9.6%), *MAP3K1* (8.8%), and *NF1* (7.5%). 320/385 (83%) MSK-IMPACT tests had $\geq$5 SBS and were analyzable for mutational signature. The dominant mutational signature was APOBEC in 44%, clock-like (aging) in 38%, Signature 3 (homologous recombination deficiency) in 12%, Signature 17 in 5.6%, and Signature 8 in 1%. Median OS in the total cohort was 4.4 years (95%CI 4.1-4.8) and differed significantly by dominant mutational signature (log-rank p=0.001). Median OS for those with APOBEC-dominant disease was 3.1 years (95%CI 2.5-3.7) and for those with clock-like (aging) signature was 4.4 years (95%CI 3.8-6.5). Among 61 patients who had paired samples analyzable for mutational signature within 2 months of metastatic diagnosis and at another timepoint following metastatic diagnosis, the prevalence of APOBEC as the dominant mutational signature increased (29/61 [48%] to 36/61 [59%]), whereas clock-like (aging) decreased (25/61 [41%] to 17/61 [28%]). **Conclusions:** Dominant APOBEC mutational signature at metastatic ILC diagnosis was associated with shorter OS, with differences observed between APOBEC- and aging-dominant tumors. Serial testing demonstrating increasing APOBEC dominance over time supports mutational signatures as dynamic, clinically relevant features of metastatic ILC. Research Sponsor: Lisa Bonchek Adams Memorial Fund.

1142 **Poster Session**

Phase II study of olaparib plus ATR inhibitor ceralasertib in patients with metastatic breast cancer and germline BRCA1/2 pathogenic variants who progressed on prior PARP inhibitor therapy. First Author: Banu Arun, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: PARP inhibitors (PARPi) olparib and talazoparib improve objective response rate (ORR) and disease-free survival (DFS) compared with chemotherapy in patients with metastatic breast cancer and germline BRCA 1/2 pathogenic variants (gBRCA 1/2 PVs). Although the ORR is approximately 60%, about 40% of patients do not respond, and nearly all responders eventually develop progressive disease. Therefore, new strategies to overcome PARPi resistance are needed. Preclinical studies suggest that ATR inhibition combined with olaparib may restore PARPi sensitivity. Phase I studies have shown that olaparib (Ola) plus the ATR inhibitor ceralasertib (Cerala) is safe and have established the recommended phase II dose. This prospective phase II study evaluated the ORR of Ola plus Cerala in patients with metastatic breast cancer with gBRCA 1/2 PVs who previously progressed on PARPi therapy. **Methods:** Eligible patients had metastatic breast cancer (HER2- negative), prior PARPi exposure, and no more than two prior lines of chemotherapy. After informed consent, all patients underwent the baseline research biopsy of a metastatic lesion and provided blood samples for exploratory analysis aimed at identifying mechanisms of PARPi resistance. Treatment consisted of olaparib 150 mg orally twice daily on days 1-28 plus ceralasertib 80 mg orally twice daily on days 1-14 of each 28-day cycle. The primary endpoint was ORR per RECIST 1.1. Secondary endpoints included safety, DFS, and duration of response. Exploratory endpoints focused on biomarker analysis of PARPi resistance. This abstract reports the primary end point. **Results:** Fifteen patients were enrolled. The median age was 39 years. Eight patients had hormone receptor-positive disease; 6 of these had received endocrine therapy before first-line PARPi. Two patients achieved a partial response (PR) and two had stable disease (SD), resulting and an ORR of 13.3% and a clinical benefit rate of 26.7%. No grade 4 toxicities were observed. Grade 3 adverse events included anemia (N=5), neutropenia (N=1), decreased white blood cell count (N=1), lymphopenia (N=1), and thrombocytopenia (N=1). **Conclusions:** The combination of olaparib plus ceralasertib is well tolerated and demonstrates clinical activity in patients with metastatic breast cancer with gBRCA 1/2 PVs who have progressed on prior PARPi therapy. A study of this combination in the first-line setting may help determine whether ATR inhibition can overcome or delay PARPi resistance. Biomarker analysis to identify mechanisms of resistance are ongoing and will be reported separately. Clinical trial information: NCT04090567. Research Sponsor: CPRIT; Astra Zeneca.

TPS1143 **Poster Session**

A phase II study evaluating treatment discontinuation of dual anti-HER2 therapy in metastatic HER2-positive breast cancer after five years of sustained complete response (FREEDOME-trial). First Author: Albert Grinshpun, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Dual anti-HER2 therapy with trastuzumab (T) and pertuzumab (P) has transformed outcomes in HER2-positive metastatic breast cancer (mBC), with approximately 20% of patients maintaining response beyond 8 years based on CLEOPATRA trial data. Current practice continues anti-HER2 therapy indefinitely in responding patients, despite lack of evidence supporting necessity of lifelong treatment in long-term responders. This approach is associated with cumulative financial burden, and quality of life impact from indefinite therapy requirements. No prospective data exist regarding optimal duration of anti-HER2 therapy in long-term responders, nor are there validated biomarkers to guide treatment discontinuation decisions. Minimal residual disease (MRD) assessment has shown promise in other malignancies for identifying patients at low risk of recurrence. This study addresses an unmet need for evidence on safety of treatment discontinuation in long-term responders. **Methods:** This prospective, multicenter, single-arm phase II trial enrolls patients with HER2-positive mBC who have maintained CR for $\geq$5 years on dual anti-HER2 therapy (T plus P). Target enrollment is 40 patients based on Fleming's single-stage design to detect median progression-free survival (mPFS) $>$12 months with 80% power (α=0.05). Key eligibility criteria include: confirmed HER2-positive mBC, sustained CR by RECIST 1.1 for $\geq$5 years, normal tumor markers (CA125, CEA, CA15-3), and no evidence of progression on baseline PET-CT. Patients with concurrent malignancies requiring systemic therapy are excluded. Following enrollment, participants discontinue T+P therapy but should continue endocrine therapy (if given). Surveillance includes PET-CT at baseline, 3, 6, 12 months, then annually; annual mammography/ultrasound per institutional standards; and blood collection for tumor markers at baseline, 3, 6, 12 months, then annually. Patients resuming anti-HER2 therapy upon progression remain on study for survival assessment. Primary endpoint is mPFS post-discontinuation. Secondary endpoints include 6-month PFS, 12-month PFS, and median overall survival. Exploratory analyses examine tumor markers as predictive biomarkers. Kaplan-Meier methodology will estimate survival probabilities with 95% confidence intervals. As of January 2026, one site is open for recruitment. Minimal residual disease analysis is planned and will be submitted to the IRB committee for approval. Study completion is anticipated by 2031 with interim analysis planned after 2 years. Clinical trial information: MOH_2025-12-27_015564. Research Sponsor: None.

TPS1144 **Poster Session**

A phase 1b/2 study of QLS1304, a novel, highly potent, and selective dual inhibitor of KAT6A/6B, plus endocrine therapy (ET) in patients (pts) with estrogen receptor–positive (ER+), human epidermal growth factor receptor 2–negative (HER2–) breast cancer (BC). First Author: Jiong Wu, Department of Breast Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: QLS1304 is a novel, highly-potent, and selective dual inhibitor of KAT6A/6B. KAT6A acetylates histone H3 at the 23rd lysine residue, thereby modulating gene transcription, and implicated in ER+/HER2- BC. QLS1304 showed potent efficacy in standard of care resistant, KAT6A-high and *ESR1*-mutant ER+/HER2- BC patient-derived xenograft model, whether administered as a monotherapy or combination therapy (*Cancer Res (2025) 85 (8_Supplement_1): 457*). In the ongoing phase 1 trial, QLS1304 monotherapy showed an acceptable safety profile and potential anti-tumor activity in pts with BC. This study aimed to evaluate the safety and preliminary efficacy of QLS1304 + ET combination (fulvestrant or QLC1401, a novel oral selective ER degrader) $\pm$ CDK4/6 inhibitor (CDK4/6i) in pts with ER+/HER2- locally advanced or metastatic (LA/M) BC. **Methods:** This multicenter, open-label, phase 1b/2 trial consists of phase 1b combination dose-escalation and phase 2 dose-expansion. The phase Ib study will enroll pts with LA/M ER+/HER2- BC, who have received prior ET plus CDK4/6i, utilizing the Rolling-Six design. There are 2 cohorts: Cohort 1A QLS1304 + fulvestrant and Cohort 1B QLS1304 + QLC1401. Three dose levels of QLS1304 are planned, which are 4 mg/d, 8 mg/d, and 12 mg/d. The dose of QLC1401 is 150 mg, which is the recommended phase 2 dose (RP2D) of monotherapy. Both QLS1304 and QLC1401 are orally administered in a 28-day cycle. A total of 12~18 pts per cohort are planned to be enrolled, which might be adjusted based on the occurrence of dose-limiting toxicities (DLTs) during the first cycle. The primary endpoints are safety, tolerability, and RP2D of QLS1304 combined with fulvestrant/QLC1401. In phase 2, 1~2 dose levels of QLS1304 will be explored in 5 cohorts. In Cohort 2A (QLS1304 + fulvestrant) and Cohort 2B (QLS1304 + QLC1401), pts with LA/M ER+/HER2- BC who received prior ET plus CDK4/6i will be enrolled. In Cohort 2C (QLS1304 + CDK4/6i + letrozole), pts with LA/M ER+/HER2- BC with no prior therapy will be enrolled. In Cohort 2D (QLS1304 + CDK4/6i + fulvestrant), adjuvant ET-resistant or ET+CDK4/6i pretreated LA/M ER+/HER2- BC pts will be enrolled in 2 subgroups. In Cohort 2E (QLS1304 + CDK4/6i + QLC1401), adjuvant ET-resistant, treatment naïve, or ET+CDK4/6i pretreated LA/M ER+/HER2- BC pts will be enrolled in 3 subgroups. Doublet combination will be firstly explored, which will support the dose selection of triplet combination. In triplet cohorts 2C–2E, 6 pts will be enrolled in a safety run-in to assess the preliminary safety profile in each cohort. Expansion will be started after safety confirmation. A total of 316~366 pts will be enrolled. The primary endpoint of phase 2 is ORR per RECIST v1.1. Patient enrollment is currently ongoing. Clinical trial information: NCT07235176. Research Sponsor: QIlu Pharmaceutical Co. Ltd.

TPS1145 **Poster Session**

TUC-TOC phase II trial (NCT05955170): Tucatinib in combination with oral etoposide (VP16) and trastuzumab in patients with metastatic HER2-positive breast cancer (HER2+ mBC). First Author: Diana Bello Roufai, Medical Oncology Department, Institut Curie, Saint-Cloud, France

Background: Patients with HER2-positive metastatic breast cancer (HER2+ MBC) have limited therapeutic options after progression on tucatinib–trastuzumab–capecitabine. There is a need for later-line regimens combining chemotherapy with dual HER2 targeting. TUC-TOC was designed to evaluate the efficacy and safety of tucatinib combined with oral etoposide (VP16) and trastuzumab in this setting. Oral VP16 was selected because (i) topoisomerase II inhibitors are rarely used in HER2+ MBC, (ii) TOP2A and ERBB2 are frequently co-amplified, and (iii) it enables an almost all-oral regimen. A prior retrospective analysis suggested favorable activity and tolerability of VP16 plus trastuzumab in heavily pretreated HER2+ MBC (PMID: 35565244). **Methods:** TUC-TOC (NCT05955170) is an open-label, multicenter, academic phase II trial. Eligible patients have histologically-confirmed HER2+ MBC with disease progression on tucatinib-trastuzumab-capecitabine or a contraindication to capecitabine, measurable disease per RECIST v1.1, and adequate cardiac function. Patients with brain metastases are eligible unless urgent local treatment is required. The study includes a safety run-in followed by an expansion phase. In the safety run-in, six patients received oral VP16 50 mg/d on days 1–14 of a 3w cycle, tucatinib 300 mg PO BID, and trastuzumab 600 mg SC q3w. The primary endpoint of this phase was the rate of dose-limiting toxicities (DLTs). The primary endpoint of the expansion phase is the objective response rate (ORR), defined as the best overall response within 24 weeks according to RECIST v1.1. Secondary endpoints include PFS, OS and safety. A total of 55 evaluable patients is planned. As of 01.2026, the safety run-in phase has been completed and enrollment into the expansion phase is ongoing. Clinical trial information: NCT05955170. Research Sponsor: pfizer; Women's Cancer Institute of Institut Curie.

TPS1146 **Poster Session**

HER2-positive central nervous system (CNS) surveillance: A study of the feasibility of randomizing women and men with HER2-positive metastatic breast cancer to CNS surveillance versus no surveillance. First Author: Talvinder Bhogal, Institute of Systems, Molecular and Integrative Biology, Liverpool, United Kingdom

Background: Breast cancer (BC) is the second most common primary tumour to metastasise to the brain (Aragon-Ching, 2017). Clinical data have demonstrated that BC brain metastases (BCBM) are an increasing clinical problem (Akshara, 2024). Improved systemic treatment of extracranial disease has prolonged survival (DESTINY-Breast9, 2025); coupled with more CNS imaging, this likely contributes to rising BCBM incidence (Frisk, 2012; Pedrosa, 2018). HER2+ BC has a predilection for the CNS (Sun, 2022), and real-world data from the ESMÉ programme report BCBM incidence in metastatic BC (MBC) (Darlix, 2019). Cumulative incidence at 12 months after MBC diagnosis in a cohort of 16,703 MBC pts was 16.8% and 32.4% for HER2+ /HR+ and HER2+ /HR- respectively; at 24 months, 29.2% and 49.0%, respectively. Given the high risk of CNS disease in HER2+ MBC, associated morbidity/mortality (Riecke, 2023) and the evidence that there may be a survival and quality of life advantage for early asymptomatic detection (Hurvitz, 2019; Laakmann, 2020), surveillance strategies for early detection need evaluation. **Methods:** This is a multi-centre, randomised study in pts with HER2+ MBC without prior CNS disease. The study is testing the feasibility of randomising pts to CNS screening vs none. The study is recruiting male/female pts, aged ≥16 years with HER2+ BC with visceral metastases who are currently on HER2 directed therapies. It excludes pts with a history/clinical symptoms of CNS disease, unable to undergo MRI, or with bone only MBC. Pts following a baseline MRI brain, to exclude occult disease, are randomised 1:1 to 6 monthly MRI brain with contrast for a year or no CNS imaging. Primary endpoint: feasibility of randomising HER2+ MBC pts with no CNS disease to surveillance vs no surveillance. Secondary endpoints: proportion of pts with occult CNS disease at baseline, proportion developing occult CNS disease during surveillance and proportion developing symptomatic CNS disease during the study. The management of detected CNS disease on study will be documented. Further qualitative research through a series of interviews/focus group discussions will explore reasons why pts either agree/refuse randomization, to identify challenges with study implementation and delivery. Statistics: A maximum of 193 pts are to be approached; with 69 pts agreeing to be consented to the study for a larger study to be deemed feasible (based on alpha=5% and power 90%). Recruitment will halt at 69 consented/193 approached, whichever is reached first. REC/IRAS project ID: 341272. Research Sponsor: Make 2nd Count; Pfizer; Breast Cancer Ireland; NIHR-BRC research fellowship (for T.B); Clatterbridge Cancer Centre Charity (for T.B); The Grace Trust (for T.B).

TPS1147 **Poster Session**

A single-arm, phase II study of sequential therapy with curative intent in de novo HER2+ metastatic breast cancer: The SAPPHO study. First Author: Stefania Morganti, Dana-Farber Cancer Institute, Boston, MA

Background: Due to dramatic improvements in neoadjuvant and adjuvant HER2-directed therapy (tx), most patients (pts) with early HER2+ breast cancer are cured. As a result, over half of pts newly diagnosed with HER2+ metastatic breast cancer (MBC) now present with *de novo* stage IV disease. Anti-HER2 tx has also significantly extended survival for pts with HER2+ MBC, with a subgroup of exceptional responders alive many years (yrs) after diagnosis. However, the paradigm for HER2+ MBC remains non-curative, and pts receive tx indefinitely with significant toxicities and costs. The SAPPHO study is investigating whether an intensification approach of sequential, non-cross resistant anti-HER2 tx followed by tx discontinuation is associated with long-term disease control in pts with HER2+ MBC. **Methods:** SAPPHO is an open-label, phase II, single-arm trial testing a sequential regimen of non-cross resistant, HER2-targeted tx with curative intent in pts with *de novo* HER2+ MBC. Eligible pts must have biopsy-proven, *de novo* MBC with high HER2 expression (3+ by immunohistochemistry). Pts with brain metastases are eligible upon receipt of local tx. Treatment consists of an induction regimen (trastuzumab-pertuzumab-taxane [THP] x 4 cycles, followed by trastuzumab deruxtecan [TDXd] x 6 cycles, followed by trastuzumab emtansine [TDM1]-tucatinib x 4 cycles), followed by a maintenance regimen (HP-tucatinib for 1 yr). Given results from DESTINY-Breast09, the sequence of TDXd-P x 6 cycles followed by THP x 4 followed by TDM1-tucatinib x 4 can be chosen as alternative induction tx per investigator and patient choice. Pts who remain progression-free after completing maintenance will stop all anti-HER2 tx. Endocrine tx will be continued for pts with hormone receptor+/HER2+ tumors. Tumor specimens from breast and a metastatic site are collected at baseline and the end of induction. Serial plasma samples for ctDNA analysis are collected at baseline, during treatment, and during follow-up. The primary endpoint is the probability of being progression-free and off anti-HER2 tx 4 yrs from the start of induction. With a sample size of 72 pts, the study is designed to have 91% power to reject the null hypothesis that the probability of being off anti-HER2 tx and progression-free is less than 24%, with an alternative hypothesis of 40%. Key secondary endpoints are overall survival, overall response rate by modified RECIST 1.1 after induction, and safety. Correlative endpoints include the relationship between ctDNA dynamics and outcomes. Patient-reported outcomes will be analyzed, including quality of life, illness intrusiveness, financial toxicity, anxiety, distress about cancer progression, perception of benefit and risk of progression. SAPPHO began enrollment in Q3 2024, and the study is open at 4 US sites within the Translational Breast Cancer Research Consortium (NCT05721248). Clinical trial information: NCT05721248. Research Sponsor: Pfizer.

TPS1148 **Poster Session**

ReDiscover-2, a phase 3 study of zovegalisib (zovega, RLY-2608) + fulvestrant (fulv) versus capivasertib (capi) + fulv as treatment for locally advanced or metastatic *PIK3CA*-mutant HR+/ HER2- breast cancer following recurrence or progression on or after treatment with a CDK4/6 inhibitor. First Author: Hope S. Rugo, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: *PIK3CA* mutations constitutively activate PI3Kα and drive ~40% of HR+/ HER2- breast cancer (BC). The PI3K inhibitors alpelisib and inavolisib and the AKT inhibitor capi are approved therapeutic options; however, they are limited by significant toxicity, notably hyperglycemia, rash, and diarrhea, due to non-selective targeting of the pathway. Zovega is a pan-mutant-selective allosteric PI3Kα inhibitor designed to optimize dose intensity and target inhibition with reduced toxicity and improved tolerability. The first-in-human ReDiscover study of zovega demonstrated encouraging antitumor activity with a median progression-free survival (PFS) of 10.3 mo (95% CI: 7.2, 18.4) across a range of *PIK3CA* genotypes and a favorable safety profile when combined with fulv in patients with *PIK3CA*-mutated HR+/HER2- advanced BC previously treated with a CDK4/6 inhibitor. Based on these findings, zovega in combination with fulv is being studied in this phase 3 study, ReDiscover-2 (NCT06982521), in *PIK3CA*-mutated HR+/ HER2- advanced BC following recurrence or progression on or after a CDK4/6 inhibitor. **Methods:** ReDiscover-2 is a global, multicenter, open-label, randomized phase 3 study comparing the efficacy and safety of zovega + fulv to capi + fulv in patients with *PIK3CA*-mutated HR+/HER2- advanced BC. Approximately 540 patients will be randomized 1:1 to receive zovega (400 mg BID with food) + standard-dose fulv or capi (400 mg BID, 4 days on and 3 days off, with or without food) + fulv. Randomization will be stratified by *PIK3CA* mutation type, visceral disease, and geographic region. The primary endpoint is PFS assessed by blinded independent central review in patients having tumors with *PIK3CA* kinase domain mutations and in all patients. Overall survival is a key secondary endpoint within the same populations. Key eligibility criteria: ≥18 years of age with ECOG performance status of 0-1; confirmed diagnosis of HR+/HER2- locally advanced or metastatic BC with radiological or objective evidence of recurrence or progression; presence of one or more oncogenic *PIK3CA* mutations without evidence of *AKT* or *PTEN* alterations; measurable disease per RECIST v1.1 or evaluable bone-only disease; previous treatment for HR+/HER2- advanced BC with at least 1 and no more than 2 lines of endocrine therapy (ET) (prior fulv is allowed) or 1 prior line of CDK4/6 inhibitor therapy; HbA1c <7.0% (<53 mmol/mol) and fasting plasma glucose <140 mg/dL (Type 1 diabetes or Type 2 diabetes requiring antihyperglycemic medication are excluded); no prior PI3K, AKT, or mTOR inhibitors. ReDiscover-2 (NCT06982521) is open for enrollment. For information: clinicaltrials@relaytx.com. Clinical trial information: NCT06982521. Research Sponsor: Relay Therapeutics.

TPS1149 **Poster Session**

HERTHENA-Breast04: A phase 3, randomized, open-label study evaluating the efficacy and safety of patritumab deruxtecan (HER3-DXd) versus treatment of physician's choice in hormone receptor–positive (HR+)/human epidermal growth factor receptor 2–negative (HER2–) unresectable locally advanced or metastatic breast cancer. First Author: Barbara Pistilli, Department of Medical Oncology, Gustave Roussy, Villejuif, France, and IHU PRISM National PRecISion Medecine Center in Oncology, Gustave Roussy, Villejuif, France

Background: There is an unmet therapeutic need for patients with HR+/HER2− metastatic breast cancer who experience disease progression and recurrence after first-line standard of care treatment with a CDK4/6 inhibitor (CDK4/6i) and endocrine therapy (ET). The main therapy options, for those patients who are not considered suitable for additional ET-based therapy, are chemotherapy and antibody-drug conjugates (ADCs). Human epidermal growth factor receptor 3 (HER3) is overexpressed in HR+/HER2− breast cancer and is associated with poor prognosis and drug resistance. Patritumab deruxtecan (HER3-DXd) is a novel ADC composed of a fully human anti-HER3 IgG1 antibody linked to a cytotoxic topoisomerase I inhibitor via a stable tetrapeptide-based linker that is selectively cleaved within tumor cells. In the phase 2 ICARUS-Breast01 study, HER3-DXd showed clinically meaningful antitumor activity and manageable safety in patients with HR+/HER2− advanced breast cancer who progressed on CDK4/6i treatment and 1 line of chemotherapy. The phase 3, multicenter, open-label, HERTHENA-Breast04 study (NCT07060807) evaluates efficacy and safety of HER3-DXd monotherapy vs treatment of physician's choice (TPC) in participants with HR+/HER2− advanced breast cancer after progression on 1 line of CDK 4/6i treatment. **Methods:** Participants must be aged ≥18 y and have centrally confirmed HR+/HER2− (per most recent ASCO/CAP guidelines: HER2 IHC 0 or 1+ or IHC 2+/in situ hybridization negative) unresectable locally advanced or metastatic breast cancer. Participants must have experienced disease progression or recurrence following prior treatment with a CDK4/6i and ET and must be eligible for at least 1 TPC option, as determined by the investigator. Participants must have measurable disease per RECIST v1.1 and ECOG PS of 0 or 1. Participants who have received prior chemotherapy or are candidates for an additional line of ET-based therapy in the advanced setting are ineligible for the study. Participants are randomized 1:1 to Arm 1 or 2, with ~500 participants assigned to each arm. Participants in Arm 1 will receive HER3-DXd 5.6 mg/kg IV on day 1 Q3W, and participants in Arm 2 will receive TPC consisting of 1 of the following options: paclitaxel, nab-paclitaxel, capecitabine, liposomal doxorubicin, or trastuzumab deruxtecan. Treatment will continue until disease progression, unacceptable toxicity, or participant withdrawal. The dual primary endpoints are PFS per RECIST v1.1 by BICR and OS. Secondary endpoints are ORR and DOR per RECIST v1.1 by BICR, safety, and patient-reported outcomes. Imaging assessments occur Q6W from randomization through week 60 and Q12W thereafter. Enrollment began in 2025. Clinical trial information: NCT07060807. Research Sponsor: Daiichi Sankyo Company, Limited and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS1150 **Poster Session**

Camizestrant plus ribociclib in hormone receptor–positive/HER2-negative advanced breast cancer: The phase II CADILLAC trial. First Author: Javier Cortes, International Breast Cancer Center (IBCC), Quironsalud Group, Barcelona, Spain, Scientific Department, Medica Scientia Innovation Research, Valencia, Spain, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain and Universidad Europea de Madrid, Madrid, Spain

Background: CDK4/6 inhibitors combined with endocrine therapy (ET) are the standard first-line treatment for hormone receptor–positive (HR+)/HER2–negative (HER2–) advanced breast cancer (ABC). Secondary endocrine resistance includes patients (pts) relapsing after ≥2 years of adjuvant ET during treatment or within 12 months of discontinuation but does not distinguish according to adjuvant ET duration; thus, whether HR+ tumors progressing after prolonged adjuvant ET (≥5 years) constitute a biologically and prognostically distinct entity remains unclear. Next-generation oral selective estrogen receptor degraders (SERDs) provide more potent estrogen receptor (ER) degradation and have demonstrated superiority over standard ET in pts with previously treated endocrine-resistant ABC. We hypothesized that camizestrant plus ribociclib as first-line therapy may improve outcomes versus historical ribociclib plus aromatase inhibitor (AI) or fulvestrant in HR+/HER2– ABC relapsing after long-term adjuvant ET. **Methods:** CADILLAC (NCT07195227) is an international, multicenter, open-label, single-arm, external historical-controlled phase II trial. A total of 150 pts with HR+/HER2– ABC who have not received systemic treatment for advanced disease will be enrolled from Spain, Germany, and China. Key eligibility criteria include: (a) ≥18 years; (b) histologically confirmed unresectable locally recurrent or metastatic breast cancer; (c) evaluable disease as per RECIST v.1.1; (d) prior adjuvant ET duration ≥5 years, including ≥2 of AI (with a cap of 30% pts with an ET-free interval ≥12 months); and (e) ECOG performance status 0-1. Pts will receive camizestrant 75 mg orally once daily continuously in 28-day cycles, combined with ribociclib 600 mg orally once daily on days 1-21 of each 28-day cycle, until unacceptable toxicity, disease progression, death, or discontinuation for other reasons, whichever occurs first. The primary endpoint is progression-free survival (PFS). Key secondary endpoints include overall response rate (ORR), clinical benefit rate (CBR), quality of life assessed by EORTC QLQ-C30 and QLQ-BR42 questionnaires, and safety according to NCI-CTCAE v5.0. PFS, ORR, and CBR will be locally assessed by investigators per RECIST v1.1. and compared with outcomes from a historical control cohort of at least 150 pts treated with ribociclib plus AI or fulvestrant. The null hypothesis is defined as a median PFS ≤20.3 months, whereas the alternative hypothesis corresponds to a median PFS ≥28.7 (target hazard ratio 0.707). The primary hypothesis will be tested using a stratified log-rank test at one-sided 5% significance level with 70% power. An effective total of 157 PFS events across arms is required. Interim efficacy and safety analyses are planned once the first 50 pts have completed ≥6 months of treatment. Enrollment will not be paused during this interim analysis. Clinical trial information: NCT07195227. Research Sponsor: AstraZeneca; Novartis.

TPS1151 **Poster Session**

A phase 1/2 study of EP0062 (vosilasarm), a first-in-class oral selective androgen receptor modulator (SARM), in combination with standard-of-care endocrine therapy +/- targeted therapies in patients with advanced or metastatic AR+/ER+/HER2− breast cancer. First Author: Rafael Grochot, Sarah Cannon Research Institute, London, United Kingdom

Background: EP0062 (vosilasarm), a first-in-class, oral, non-steroidal, Selective Androgen Receptor Modulator (SARM) acts as a potent tissue-selective AR agonist, suppressing growth and proliferation of multiple endocrine-sensitive or -resistant AR+/ER+/HER2- breast cancer (BC) cell lines and patient-derived xenograft (PDX) models. Pre-clinically, AR activation–rather than AR suppression–exerts potent antitumor activity in AR+/ER+ breast malignancies, including those resistant to endocrine therapy and CDK4/6 inhibitors. EP0062 has been shown to inhibit the growth of AR+/ER+ BC PDX models as a single agent, and in combination with palbociclib, everolimus or elacestrant. Phase 1 of this study reported promising safety and evidence of clinical benefit with EP0062 monotherapy in advanced AR+/ER+/HER2- BC. The ongoing Phase 2 cohorts described here are the first clinical evaluation of a SARM in combination with various standard of care therapies in patients that have previously received a CDK4/6 inhibitor. **Methods:** The Phase 2 cohorts will include up to 75 post-menopausal women, ≥ 18 years, ECOG ≤ 1, with locally advanced/metastatic, endocrine-sensitive (> 2 y adjuvant or >6 mo treatment prior to recurrence), AR+/ER+/HER2- BC, that is measurable per RECIST v1.1, or non-measurable with an evaluable bone component. AR positivity is defined as ≥ 10% AR nuclei staining by IHC. Patients may have previously received ≤ 2 lines of endocrine therapy (including CDK4/6 inhibitor), and ≤ 1 line of chemotherapy in the advanced/metastatic setting. Treatment arms are as follows: Arm 1: EP0062 + elacestrant (mandatory ESR1 mutation); Arm 2: EP0062 + exemestane + everolimus; Arm 3: EP0062 + fulvestrant + abemaciclib. A 3+3 safety run-in will confirm the combination dose for each cohort before expansion. Starting EP0062 dose was 10 mg BID. The primary objective is to evaluate safety and tolerability. Secondary objectives are to characterise the PK profile and preliminary efficacy. Biomarkers, including CA15-3, PSA, and molecular genetics are also being evaluated. Exploratory objectives are to evaluate potential biomarkers of efficacy, safety and/or PD activity. The study is currently recruiting across the three treatment arms in USA, UK, and Spain. Clinical trial information: NCT05573126. Research Sponsor: None.

TPS1152 **Poster Session**

OPERA-02: A phase 3 study of palazestrant plus ribociclib as first-line treatment of ER+, HER2- advanced breast cancer. First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Estrogen receptor-positive, human epidermal growth factor 2-negative advanced breast cancer (ER+, HER2- ABC) accounts for nearly 70% of all ABC. The standard first-line treatment for ER+, HER2- ABC is the combination of an aromatase inhibitor (AI) with cyclin–dependent kinase 4/6 inhibitor (CDK4/6i). When combined with AI, the CDK4/6i ribociclib has demonstrated significant improvements in progression-free survival (PFS) and overall survival (OS) in this setting. Despite these advances, resistance to AI + CDK4/6i develops in a substantial proportion of patients (pts), most commonly driven by acquired mutations in the ligand-binding domain of ERα, resulting in constitutive ligand-independent ER activation. Early and sustained suppression of both wild-type and mutated ERs in the first line treatment of ER+, HER2- ABC may enhance endocrine sensitivity, delay resistance to endocrine therapy and improve clinical outcomes. Palazestrant (OP-1250) is an investigational oral, complete estrogen receptor antagonist (CERAN) and selective estrogen receptor degrader (SERD). In early phase studies, palazestrant has shown favorable safety and encouraging antitumor activity as monotherapy (Hamilton et al, 2025) and in combination with ribociclib (Lin et al, 2025), regardless of ESR1 mutation status, including in those previously treated with CDK4/6i. Palazestrant showed no clinically meaningful drug-drug interactions with ribociclib, and the combination safety profile was consistent with the known profiles of each drug. **Methods:** OPERA-02 (NCT07085767) is a phase 3, international, multicenter, randomized, double-blind, study designed to evaluate the efficacy and safety of palazestrant plus ribociclib versus letrozole plus ribociclib in the first line treatment of pts with ER+, HER2- ABC. Approximately 1,000 pts will be randomized 1:1 to either palazestrant plus ribociclib or letrozole plus ribociclib, with matching placebos. The primary endpoint is investigator-assessed PFS; secondary endpoints are OS, PFS by a blinded-independent review committee, overall response rate, duration of response, clinical benefit rate, safety, pharmacokinetics, pt-reported outcomes and PFS2. Eligible pts are adult women, regardless of menopausal status, and men, with de novo or recurrent disease (≥ 12 months after completion of adjuvant endocrine therapy) who have not received prior systemic therapy for ER+, HER2- ABC. Pts must have measurable disease per RECIST 1.1 or evaluable bone disease, ECOG performance score of 0-1, and adequate organ function. Pts with a contraindication to ribociclib are excluded. Pre- or perimenopausal women and men must receive gonadotropin-releasing hormone (GnRH) agonists for gonadal function suppression. The study has been recruiting globally since November 2025. Clinical trial information: NCT07085767. Research Sponsor: None.

TPS1153 **Poster Session**

ELEGANT: Elacestrant versus standard endocrine therapy (ET) in women and men with node-positive, estrogen receptor–positive (ER+), HER2-negative (HER2−), early breast cancer (eBC) with high risk of recurrence in a global, multicenter, randomized, open-label phase 3 study. First Author: Aditya Bardia, University of California, Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Adjuvant ET is the standard of care (SOC) for treating ER+/HER2- eBC. Despite advances to optimize adjuvant treatment in high-risk ER+/HER2- eBC, there continues to be risk of local and metastatic recurrence that persists, new therapies with desirable safety profiles are warranted. Elacestrant is a next-generation oral SERD that provides a novel mechanism of action that has shown both SERD (degradative) and SERM (partial agonist) activity that differs from currently available adjuvant ET (Wardell, ERC 2015). In the EMERALD trial, elacestrant significantly prolonged PFS vs SOC ET in the overall population (HR 0.70; 95% CI 0.55-0.88; P=0.0018) and in patients with *ESR1m* tumors (HR 0.55; 95% CI 0.39-0.77; P=0.0005) (Bidard, JCO 2022). In patients with *ESR1m* tumors who received prior ET+CDK4/6i ≥12 mo, mPFS with elacestrant was 8.6 vs 1.9 mo with SOC ET (Bardia, CCR 2024). In patients with ER+/HER2− eBC, the SOLTI-1905-ELIPSE and SOLTI-2104-PremiERe trials showed that preoperative elacestrant was associated with a statistically significant mean change of complete cell cycle arrest rate and led to a shift in tumor biology towards a more endocrine-sensitive and less proliferative tumor phenotype in both pre- and postmenopausal women (Vidal, CCR 2025; Bellet, SABCS 2025). Given that elacestrant demonstrated efficacy in mBC regardless of *ESR1m* status relative to SOC ET and has shown biologic activity in eBC, it is hypothesized that elacestrant can prolong invasive breast cancer-free survival (IBCFS) in patients with high-risk eBC who received prior adjuvant ET±CDK4/6i. **Methods:** ELEGANT (NCT06492616) is a global, multicenter, open-label Ph3 study designed to evaluate elacestrant vs SOC ET (AI or tamoxifen) in patients with eBC and high risk of recurrence. Patients will be randomized 1:1 to continue SOC ET or to elacestrant for a duration of 5 years. Eligible patients are women/men with ER+/HER2− node-positive eBC who received between 2-5 years of SOC ET±CDK4/6i and have ECOG PS ≤1. Patients who received a prior CDK4/6i or PARP inhibitor must have completed or discontinued these treatments. Pre/perimenopausal women and men will be administered a LHRH agonist. Exclusion criteria include stage IV mBC, inflammatory BC, history of prior invasive BC, history of malignancy within 3 years of randomization date, >6 mo continuous interruption of prior SOC adjuvant ET or discontinuation of adjuvant ET >6 mo prior to randomization, and received prior treatment with SERDs. The primary objective is IBCFS. Key secondary objectives are distant relapse-free survival, overall survival, invasive disease-free survival, safety, PROs-QoL, and PK. Planned enrollment is 4,220 patients; recruitment is ongoing. Clinical trial information: NCT06492616. Research Sponsor: Menarini Group.

TPS1154 **Poster Session**

ADELA: A double-blind, placebo-controlled, randomized phase 3 trial of elacestrant (Ela) + everolimus (EVE) versus elacestrant + placebo in ER+/HER2− advanced breast cancer (aBC) patients with *ESR1*-mutated tumors progressing on endocrine therapy (ET) + CDK4/6i. First Author: Antonio Llombart-Cussac, Medica Scientia Innovation Research (MEDSIR); Hospital Arnau de Vilanova, FISABIO; Traslational Oncology Group, Department of Medicine, Facultad de Ciencias de la Salud, Universidad Cardenal Herrera-CEU, Valencia, Spain

Background: ET+CDK4/6i is the standard-of-care (SOC) in 1L ER+/HER2- aBC; however, tumors eventually develop resistance. Constitutive activation of the PI3K/AKT/mTOR pathway can contribute to endocrine resistance in breast cancer. *ESR1* mutations (*ESR1m*) are a common type of acquired resistance that emerges in 40-50% of patients (pts) in the metastatic setting after prolonged aromatase inhibitor exposure. There is an unmet need for novel therapeutic approaches to overcome resistance mechanisms and improve outcomes in pts with ER+/HER2- aBC with *ESR1m* tumors progressing after ET+CDK4/6i. Ela is a next-generation oral SERD that binds and degrades ERα. In the Ph3 EMERALD trial, single-agent Ela improved mPFS vs SOC ET in pts with *ESR1m* tumors (HR 0.55; 95% CI 0.39-0.77; P=0.0005) [Bidard 2022]. Among pts who received prior ET+CDK4/6i ≥12 months, mPFS with Ela was 8.6 vs 1.9 months with SOC ET (HR 0.41; 95% CI 0.26-0.63) [Bardia 2024]. The crosstalk between the ER and PI3K/AKT/mTOR pathways provides a rationale for evaluating Ela+EVE (a mTORC1 inhibitor). In the ELEVATE Ph2 trial (NCT05563220), the combination of Ela 345 mg + EVE 7.5 mg showed a clinically meaningful mPFS of 8.3 months (95% CI, 4.0-10.2) in all pts (N=50) with ER+/HER2- aBC who progressed after ET+CDK4/6i, regardless of *ESR1*m status (Rugo, SABCS 2025). Safety was consistent with the known profile of EVE+SOC ET. **Methods:** ADELA (NCT06382948) is an international, multicenter, double-blind, placebo-controlled, randomized Ph3 trial that compares Ela+EVE vs Ela+placebo in pts who have ER+/HER2- aBC with *ESR1m* tumors progressing on ET+CDK4/6i. Eligible pts are adults (≥18 years) with ER+/HER2- aBC and centrally confirmed *ESR1m* who received 1-2 prior lines of ET for aBC and progressed on ET+CDK4/6i for aBC after ≥6 months. Pts receiving CDK4/6i-based adjuvant therapy are eligible if progression occurred after ≥12 months of treatment but <12 months following CDK4/6i completion. Exclusion criteria include prior chemotherapy for aBC and active uncontrolled/symptomatic brain metastases and/or leptomeningeal disease. Pts will be randomized 1:1 to 28-day cycles of Ela 345 mg + EVE 7.5 mg QD or Ela 345 mg + placebo QD until disease progression or unacceptable toxicity. Pts will receive dexamethasone mouthwash during the first 8 weeks. Stratification factors are visceral metastases (yes vs no) and duration of prior CDK4/6i therapy (≥12 vs <12 months). Primary objective is PFS assessed by BICR. Secondary objectives are investigator-assessed OS, PFS, ORR, CBR, DoR, TTR, best percentage change in tumor burden, safety, HRQoL. Planned enrollment is 240 pts. Recruitment is ongoing across Spain, France, Greece, Italy, Germany, Austria, Czech Republic, United Kingdom, and Brazil. Clinical trial information: NCT06382948. Research Sponsor: Menarini Group; MEDSIR.

TPS1155 **Poster Session**

ELECTRA: An open-label, multicenter, phase 1b/2 study of elacestrant in combination with abemaciclib in patients with brain metastasis from ER+/HER2− breast cancer. First Author: Nuhad K. Ibrahim, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Endocrine therapy (ET) + cyclin dependent kinase 4/6 inhibitor (CDK4/6i) is the mainstay for the management of ER+/HER2- mBC as 1st-line therapy. However, tumors eventually develop resistance to ET, leading to disease progression. In the EMERALD phase 3 trial, single-agent elacestrant demonstrated a significantly prolonged progression-free survival (PFS) vs SOC ET (*ESR1*m tumors HR 0.55; 95% CI 0.39-0.77; all pts HR 0.70; 95% CI 0.55-0.88) with a manageable safety profile (Bidard 2022), leading to the first oral SERD approved. In a subgroup analysis in patients with *ESR1m* tumors who had received prior ET+CDK4/6i ≥12 months, the median PFS for elacestrant was of 8.6 months vs 1.9 months with SOC ET (HR=0.41; 95% CI, 0.26-0.63) [Bardia CCR 2024]. Currently, there are no approved systemic treatments for patients with ER+/HER2- breast cancer who have brain metastasis. ELECTRA (NCT05386108) is an open-label phase 1b/2, multicenter study evaluating elacestrant in combination with abemaciclib. The phase 1b portion of ELECTRA evaluated the combination of elacestrant with abemaciclib in patients with ER+/HER2- mBC regardless of metastatic site and *ESR1* status. The recommended phase 2 dose (RP2D) of the combination was determined to be elacestrant 345 mg QD with abemaciclib 150 mg BID (Ibrahim ASCO 2024). The phase 2 portion of ELECTRA is ongoing to further characterize efficacy and safety of this combination in patients with brain metastases from ER+/HER2- breast cancer, as both compounds cross the blood-brain barrier (Conlan, 2020; Tolaney, 2020). **Methods:** Phase 2 eligibility includes patients with ER+/HER2- locally advanced or metastatic breast cancer and measurable brain metastasis (≥ 1 active and measurable brain metastasis per RECIST v1.1). Patients must have received prior therapy in the metastatic setting, including ≥ 1 endocrine therapy, ≤ 2 chemotherapy regimens, and 0-2 prior CDK4/6i (excluding abemaciclib). The phase 2 primary objective is ORR per RECIST v1.1; secondary objectives include intracranial response rate, DoR, CBR, PFS, OS, PK, and quality of life. The phase 2 portion of ELECTRA is actively recruiting patients worldwide. Clinical trial information: NCT05386108. Research Sponsor: Menarini Group.

TPS1156 **Poster Session**

CAPELA: A phase II multicenter open-label randomized study of capecitabine in combination with elacestrant versus capecitabine alone in advanced estrogen receptor (ER)–positive breast cancer (TBCRC 070). First Author: Kristina Fanucci, Dana-Farber Cancer Institute, Boston, MA

Background: Endocrine therapy (ET) in combination with targeted treatments can effectively treat metastatic ER-positive (ER+) breast cancer (BC); however, nearly all patients ultimately progress on these therapies, eventually requiring treatment with chemotherapy. Current standard of care, based on older data, is to discontinue ET when starting chemotherapy. Many of these studies used tamoxifen, which has partial agonist activity, in combination with chemotherapy. Newer estrogen-targeting agents, e.g. oral selective ER degraders (SERDs), function as ER antagonists. Preclinical work investigating the combination of SERD and chemotherapy has demonstrated an additive effect of the agents in ER wildtype tumors and a synergistic effect in tumors with *ESR1* mutation (*ESR1m*); this synergy was attenuated with P53 silencing. **Methods:** CAPELA, an investigator-initiated, multicenter, open-label randomized phase II study, is designed to assess the safety and efficacy of capecitabine monotherapy vs. capecitabine + elacestrant in patients with advanced/unresectable ER+ HER2- BC. Eligible patients will have progressed on a CDK4/6 inhibitor and had no prior treatment with chemotherapy for metastatic disease. At least 50% of enrolled patients are required to have *ESR1m* tumors. Patients will be randomized 1:1 to receive capecitabine 1000mg/m^2 PO BID days 1-14 of a 21-day cycle +/- the oral SERD elacestrant 345 mg PO daily. Randomization will be stratified by prior lines of ET in the metastatic setting (1 vs. >1), visceral disease (yes/no), *TP53* mutation status, and *ESR1m* status. Patients with tumors with an *ESR1m* who are randomized to the monotherapy arm will have the option to crossover to elacestrant monotherapy at the time of progression to evaluate benefit of concurrent vs. sequential use of these agents. The primary endpoint is hierarchical assessment of median progression free survival (mPFS) in 1) the *ESR1m* population and if positive 2) the intention to treat (ITT) population. Secondary endpoints include safety/tolerability, median overall survival (OS), objective response rate, median time to second progression, clinical benefit rate, and patient reported outcomes in the *ESR1m* and ITT populations. PFS and OS in the *ESR1m* not detected population will also be evaluated. Exploratory correlative studies on collected plasma, serum, and archival tissue will also be conducted. The study will enroll 297 patients over an estimated 3 years. The trial will open at 10 sites through the Translational Breast Cancer Research Consortium (TBCRC). Clinical trial information: NCT07222215. Research Sponsor: Menarini-Stemline; Gateway for Cancer Research.

TPS1157 **Poster Session**

AVATAR: Efficacy of personalized tumorogram-based therapy in breast cancer established from patient-derived organoids. First Author: Luc Cabel, Institut Curie, Paris and Saint-Cloud, France

Background: Despite therapeutic advances in advanced breast cancer (ABC), predicting drug efficacy for individual patients remains difficult. Patient-derived tumor organoids (PDTOs) could enable drug efficacy testing within a timeframe compatible with clinical decision-making. We hypothesize that personalized treatment based on PDTO-guided tumorograms can improve outcomes for patients with HER2-negative ABC. **Methods:** AVATAR (NCT06459791) is a single-arm multicenter phase II trial assessing tumor response rate within 6 months as the primary endpoint in patients with HER2-negative ABC treated with tumorogram-guided chemotherapy. A biopsy of a tumor lesion is performed and transferred to the laboratory for PDTO establishment. While waiting for the result of the tumorogram, the patient receives standard-of-care treatment. A drug screening of standard-of-care drugs is performed on the PDTO (~5-10 drugs per patient), with selection adapted to the clinical setting. A multidisciplinary team makes therapeutic recommendations based on the tumorogram. A tumorogram is considered informative if it identifies at least one chemotherapy drug that is considered effective in the PDTO model. When possible, patients with an informative tumorogram receive one of the recommended treatments as their next line of therapy. Otherwise, they receive standard treatment. Eligible patients include those with HER2-negative ABC who are treated with chemotherapy (endocrine-resistant for HR+/HER2-), have a performance status of 0-1, and have a tumor lesion that can be biopsied. Patients who have received more than three lines of chemotherapy in the metastatic setting or who have progressive brain or leptomeningeal metastases are excluded. We hypothesize that the prescription of chemotherapy based on an informative tumorogram will be clinically meaningful if the tumor response rate is at least 25% (p0). With a one-sided α of 9%, a power of 90%, and an alternative hypothesis of 45% (p1), 39 patients should be treated according to an informative tumorogram, and 110 patients need to be included (assuming a minimum of 40% informative tumorograms and accounting for dropouts). Enrollment began in December 2024 and is ongoing. Clinical trial information: NCT06459791. Research Sponsor: PHRC-I.

TPS1158 **Poster Session**

Exploratory analysis of prognostic value of ctDNA monitoring among advanced breast cancer with oligometastatic disease: An ancillary biomarker study of JCOG 2110 (JCOG2110A1). First Author: Takahiro Kogawa, Department of Advanced Medical Development, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan

Background: Oligometastatic advanced breast cancer represents a biologically heterogeneous disease state in which a subset of patients may achieve prolonged disease control or potential cure through the addition of definitive local therapy to systemic treatment. However, conventional imaging has limited sensitivity for detecting minimal residual disease (MRD), and reliable biomarkers to identify patients most likely to benefit from local therapy remain lacking. Circulating tumor DNA (ctDNA) has emerged as a sensitive, minimally invasive marker of tumor burden and treatment response and may provide complementary information beyond radiographic assessment. JCOG2110 is a phase III randomized trial evaluating whether the addition of definitive local therapy (surgery or radiotherapy to all detectable lesions) to systemic therapy improves survival in patients with advanced breast cancer with three or fewer oligometastatic lesions. JCOG2110A1 is an ancillary biomarker study designed to characterize ctDNA dynamics in this clinical setting and to explore the clinical significance of ctDNA-based MRD assessment. **Methods:** Eligible patients are those enrolled in JCOG2110 who provide written informed consent prior to initiation of protocol-defined systemic therapy. Plasma ctDNA will be analyzed using Guardant Reveal, a next-generation sequencing–based assay integrating genomic alterations and methylation signatures, and reported as ctDNA positive or negative with quantitative estimates of tumor fraction. Blood samples will be collected longitudinally at predefined timepoints: before systemic therapy, prior to completion of the initial 12-week systemic treatment, and during protocol-specified follow-up aligned with imaging assessments after second registration. In cases of disease progression, ctDNA will be collected at progression and subsequent sampling will be discontinued. The primary endpoint is the proportion of ctDNA clearance and ctDNA level reduction after initial systemic therapy among patients who are ctDNA-positive at baseline. Secondary endpoints include ctDNA positivity at each timepoint, associations between ctDNA kinetics and radiographic tumor prognosis, and correlations with clinical characteristics such as tumor subtype, number of metastatic lesions, and treatment allocation. This study aims to define the detectability and early kinetics of ctDNA in oligometastatic advanced breast cancer and to generate prospective evidence regarding the prognostic and potential predictive value of ctDNA for treatment outcomes and benefit from local therapy. Clinical trial information: jRCTs031230439. Research Sponsor: Guardant Health contracted research fund.

TPS1159 **Poster Session**

Phase II single-arm trial of low-dose capecitabine in patients with advanced breast cancer. First Author: Humaira Sarfraz, University of Alabama Birmingham, Birmingham, AL

Background: Capecitabine is approved for use in both the adjuvant and metastatic settings of breast cancer. The clinical activity of capecitabine was established at the maximum tolerated dose of 1000–1250 mg/m² given on days 1–14 of a 21-day cycle. As seen with other cytotoxic agents, dose escalation may lead to increased toxicity without clear efficacy benefit, while lower, fixed-dose capecitabine maintains antitumor activity with fewer adverse effects, including diarrhea, hand–foot syndrome, mucositis, and neutropenia. This approach is especially important for older and frail patients, who are more vulnerable to toxicity and underrepresented in trials. **Methods:** This single-arm, open-label phase 2 study aims to evaluate the anti-tumor effect of continuous daily oral low-dose capecitabine at 1500mg in 40 patients aged 60 years or older, and/ or considered frail at any age (ECOG 0-2). Frailty is defined by the investigator as an individual at greater risk of complications and poorer outcomes with systemic therapy, secondary to a lower physiologic reserve and higher comorbidities and functional deficits. Eligible patients include those with HER2-negative unresectable or metastatic breast cancer (hormone positive or triple negative) with measurable disease, who have progressed on at least 1 prior line of therapy. Major exclusion criteria include HER2-positive breast cancer, severe hepatic or renal failure, inability to swallow pills, and uncontrolled CNS/ leptomeningeal disease. Patients will be evaluated for toxicity every 4 weeks and for response every three cycles using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 criteria. Therapy will be continued until evidence of disease progression or unacceptable toxicity. The primary objective is the clinical activity of daily low dose capecitabine by overall response rates (ORR) per RECIST. The secondary objectives include progression-free survival (PFS), overall survival (OS), and determining the safety and tolerability of daily low dose capecitabine using the Common Terminology Criteria for Adverse Events (CTCAE) v.6.0. Exploratory analyses include evaluating quality of life, measurement of sarcopenia, geriatric assessment using the CARE (Cancer and Aging Resilience Evaluation) tool before registration and at the end of treatment, and evaluating adherence to capecitabine. Simon's two-stage minimax design will be used with a type I error rate of 0.05 and power of 80%. The null hypothesis response rate of 10% will be tested against a one-sided alternative response rate of 25%. In the first stage, 22 patients will be accrued. If there are 2 or fewer responses in the first 22 patients enrolled, the study will be discontinued. The trial was approved by the Institutional Review Board at the University of Alabama at Birmingham (UAB) and has been accruing since February 2025. 8 of the planned 40 patients have been enrolled. Clinical trial information: NCT06105684. Research Sponsor: Dr. Francisco Robert Award O'Neal Comprehensive Cancer Center (OCCC) University of Alabama at Birmingham.

TPS1160 **Poster Session**

Phase III trial of brain MRI surveillance in stage IV breast cancer. First Author: Kamran A. Ahmed, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: The incidence and prevalence of breast cancer patients who develop brain metastasis is increasing. Intracranial surveillance of asymptomatic stage IV breast cancer patients with brain MRIs is not currently recommended by the National Comprehensive Cancer Network (NCCN) Guidelines. In a previously conducted phase II brain MRI surveillance trial, approximately 25% of patients with stage IV breast cancer, independent of tumor subtype, were found to have newly detected brain metastases on the 6-month follow-up MRI from study entry. **Methods:** The study is designed as a randomized phase III, multi-institutional prospective trial evaluating the role of surveillance brain MRIs in neurologically asymptomatic patients with metastatic breast cancer, based on subtypes (triple negative (TN), HER2+, and hormone receptor (HR)+ breast cancer). Following study enrollment, patients will be randomized in a 1:1 fashion to surveillance brain MRIs at baseline and q6 months for 24 months compared to a baseline MRI followed by standard-of-care brain MRI surveillance for symptomatic presentation. Newly diagnosed stage IV patients (within $\leq$ 60 days of starting systemic therapy for HER2+ or TN or within $\leq$ 60 days of initiating 1st or 2nd line therapy for HR+/HER2- disease) with an ECOG $\leq$ 2 and life expectancy $\geq$ 6 months are eligible. The primary objective is to evaluate the treatment characteristics of brain metastases diagnosed via brain MRI surveillance or standard of care imaging. Secondary objectives include the frequency of asymptomatic brain metastases and leptomeningeal disease, the number and size of brain metastases at diagnosis, quality of life, and overall and brain metastases specific survival following brain metastasis diagnosis in patients randomized to brain MRI surveillance compared to standard of care imaging. A total of 156 patients will be enrolled with an equal distribution of TN, HER2+, and HR+/HER2- subtypes, respectively. Funding: Florida Department of Health. Clinical trial information: NCT07357298. Research Sponsor: Florida Department of Health; 25B01.

Evaluation of the safety and efficacy of TRC003 in metastatic triple-negative breast cancer: A prospective, open-label, multicenter, single-arm exploratory clinical trial. First Author: Xiaorong Sun, Shandong Cancer Hospital and Institute, Jinan, Shandong, China

Background: TRC003 (also named ^{225}Ac-TR2205) is a novel molecule of targeted alpha therapy (TAT) designed to deliver alpha-particle radiation to cancer cells expressing prostate-specific membrane antigen (PSMA). Compared to beta-particles, alpha-particles have a shorter path length and higher linear energy transfer, resulting in more frequent double-strand DNA breaks and potentially superior antitumor efficacy. In an ongoing pilot study, TRC003 has demonstrated a favorable safety profile and promising activity in patients with prostate cancer. Notably, PSMA expression has been reported in up to 60% of breast cancer neovasculature, with the highest rates observed in triple-negative breast cancer (TNBC). A head-to-head study found valuable insights into the expression of PSMA in TNBC and underscore the potential clinical significance of PSMA PET/CT in enhancing both diagnostic and therapeutic approaches for TNBC. This study aims to investigate the preliminary safety and efficacy of ^{225}Ac-TRC003 in patients with metastatic TNBC (mTNBC). **Methods:** This is a prospective, open-label, multicenter, single-arm study in accordance with ICH GCP guidelines at two centers. The primary objective is to evaluate the safety and tolerability of TRC003. Secondary endpoints include Objective Response Rate (ORR), Disease Control Rate (DCR), Duration of Response (DoR), Time to Progression (TTP), progression-free survival (PFS) and overall survival (OS). Key eligibility criteria include: 1) age $\geq$18 years; 2) histologically confirmed mTNBC with documented progression after $\geq$2 prior lines of systemic therapy (including at least 1 line for metastatic disease); 3) presence of PSMA-positive lesions on imaging, without FDG-positive & PSMA-negative target lesions; 4) at least one measurable lesion per Response Evaluation Criteria in Solid Tumors version (RECIST) 1.1; 5) Eastern Cooperative Oncology Group performance status of $\leq$ 1; and 6) adequate bone marrow, renal, and hepatic function. Fifteen eligible participants will be enrolled to receive 7.40 MBq (200 μCi) ($\pm$10%) of TRC003 by intravenous infusion every 8 weeks ($\pm$1 week), for up to 8 cycles if clinical benefit is observed. Treatment will continue until disease progression, unacceptable toxicity, or consent withdrawal, meeting any study withdrawal criterion, whichever occurs first. Tumor assessments (contrast-enhanced CT/MRI and bone scan) will be performed every 8 weeks until disease progression is confirmed per RECIST 1.1. Clinical trial information: MR-37-25-039070. Research Sponsor: C Ray Therapeutics (Chengdu) Co., Ltd.

TPS1162 **Poster Session**

TBCRC 058: A randomized phase II study of enzalutamide, enzalutamide with mifepristone, and treatment of physician's choice in patients with androgen receptor-positive metastatic triple-negative or estrogen receptor-low breast cancer (NCT06099769). First Author: Tiffany A. Traina, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Triple-negative breast cancer (TNBC) refers to a heterogenous group of breast cancers that lack expression of ER, PR, and HER2. Despite recent advances with immunotherapy (IO) and antibody-drug conjugates (ADCs), TNBC remains the most aggressive subtype, with short overall survival in the metastatic setting. Breast tumors with low levels of ER and PR expression (1-10%) clinically behave like TNBC, and clinical management follows the TNBC treatment (tx) paradigm. We and others have identified a subset of ER/PR/HER2-negative breast cancers (BCs) that express the androgen receptor (AR). Enzalutamide (enza), an AR-antagonist, has demonstrated activity in AR-positive metastatic TNBC (Traina et al, JCO 2018). Activation of the glucocorticoid receptor (GR) has been implicated as a mechanism of resistance to AR inhibition in prostate and BCs (Kach et al, Sci Transl Med 2015). Effective therapies for advanced TNBC remain an unmet need, particularly in patients who are ineligible for or progress following a checkpoint inhibitor. This randomized study evaluates the efficacy of enzalutamide or enzalutamide plus the GR antagonist mifepristone (mif) as compared to physician's choice chemotherapy (TPC). **Methods:** This is a randomized phase II trial; 201 patients (pts) will be randomized in a 1:1:1 fashion to enza, enza with mif, or TPC (carboplatin, paclitaxel, eribulin, or capecitabine). The primary endpoint (endpt) is progression-free survival (PFS), and the trial is designed to test the hypothesis that PFS in the pooled enza arms is superior to TPC; there is 80% power to detect a hazard ratio (HR) of 0.70, corresponding to an increase in median PFS from 3.5 months (mos) with TPC to 5.0 mos with enza-based tx. Secondary endpts include comparisons of PFS among the 3 arms and evaluation of response rate, clinical benefit rate, duration of response, overall survival, safety, and patient-reported outcomes by arm. Exploratory endpts include correlation of tumor and circulating markers (constitutively active AR variants in circulating tumor cells and cfDNA) with tx response. Eligible pts must have: ECOG 0-2, metastatic measurable or evaluable disease (dz), normal organ function, no history of brain mets, $<$ prior lines of chemotx, any # of prior endocrine txs, no prior anti-AR tx, no prior mif, no concurrent CYP17 inhibitor use. Tumors must test ER/PR low or negative, HER2 negative, AR $>$10%. Pts with PD-L1+ BC must have received prior IO if not contraindicated. As of December 28, 2025, 32 of 201 pts have been enrolled on study. Clinical trial information: NCT06099769. Research Sponsor: Breast Cancer Research Foundation; TBCRC; Astellas; Corcept; The TaTa Sisterhood Foundation; Pfizer.

TPS1163 **Poster Session**

A randomized phase II study of pembrolizumab plus paclitaxel with or without bevacizumab in PD-L1–positive recurrent triple-negative breast cancer previously treated with perioperative immune checkpoint inhibitors: WJOG16522B (PRELUDE) trial. First Author: Kazuki Nozawa, Department of Advanced Clinical Research and Development, Nagoya City University, Graduate School of Medical Sciences, Nagoya, Japan

Background: Perioperative pembrolizumab combined with chemotherapy has become a standard of care for patients with early-stage triple-negative breast cancer (TNBC). However, a substantial proportion of patients experience disease recurrence after perioperative immune checkpoint inhibitor (ICI)–based therapy, and the optimal systemic treatment for this population remains undefined. Angiogenesis has been implicated as a potential mechanism of resistance to immunotherapy. Bevacizumab, a monoclonal antibody targeting vascular endothelial growth factor (VEGF), may enhance antitumor immunity through vascular normalization and modulation of the tumor microenvironment. The PRELUDE trial was designed to evaluate whether the addition of bevacizumab to pembrolizumab plus paclitaxel improves clinical outcomes in patients with PD-L1–positive recurrent TNBC previously treated with perioperative ICIs. **Methods:** PRELUDE is a multicenter, open-label, randomized phase II trial conducted in Japan. Eligible patients have recurrent TNBC with PD-L1 expression (combined positive score $\geq$10 using 22C3) and prior exposure to perioperative ICI-containing chemotherapy. Patients are randomized 1:1 to receive pembrolizumab plus paclitaxel with or without bevacizumab. Pembrolizumab is administered at 400 mg every 6 weeks, paclitaxel at 90 mg/m² on days 1, 8, and 15 every 4 weeks, and bevacizumab at 10 mg/kg on days 1 and 15 every 4 weeks in the experimental arm. Treatment is continued until disease progression or unacceptable toxicity. Tumor assessments are performed according to RECIST v1.1. Exploratory biomarker analyses using tumor tissue and peripheral blood samples are planned. The primary endpoint is progression-free survival. Secondary endpoints include overall response rate, disease control rate, overall survival, and safety. Exploratory endpoints include translational biomarker analyses to investigate mechanisms of response and resistance. Enrollment is currently ongoing. ClinicalTrials.gov: NCT06976944, jRCT2031250076. Research Sponsor: MSD.

TPS1164 **Poster Session**

Phase Ib randomized open-label trial of sacituzumab govitecan plus nivolumab or sacituzumab govitecan plus nivolumab and relatlimab as second-line therapy metastatic triple negative breast cancer: SIMONE trial. First Author: Adriana Matutino Kahn, Yale Cancer Center, Yale School of Medicine, New Haven, CT

Background: The use of immunotherapy beyond first-line setting is not yet routine in the treatment arsenal of patients with metastatic triple-negative breast cancer (TNBC), and this opens an opportunity for clinical trials examining whether adding novel immunotherapy agents to standard of care therapies would benefit patients. Prior studies have combined immunotherapy with standard chemotherapy (Cortes J, NEJM 2022), but combining immunotherapies with antibody-drug conjugates (ADCs) is a strategy worth pursuing given improvement of outcomes of ADCs when compared to standard chemotherapy (Bardia A et al, NEJM 2021). Sacituzumab govitecan (SG), a TROP2-ADC, is currently the standard second-line therapy for patients with metastatic TNBC, and in this study it is being combined with either nivolumab (programmed cell death [PD-1] inhibitor) or nivolumab plus relatlimab (lymphocyte activation gene-3 [LAG3]-inhibitor) due to preliminary data showing that simultaneous PD-1 and LAG3 inhibition enhances the anti-tumor immune response and restores the effector function of exhausted T-cells (Woo S-R et al, Cancer Res 2012; Tawbi HA et al, NEJM 2022). **Methods:** This is an ongoing investigator-initiated randomized, open-label, phase Ib study to assess safety and efficacy of SG plus nivolumab (n= 30 patients) or SG plus a fixed dose combination (FDC) of nivolumab and relatlimab (n = 30 patients) in patients with metastatic TNBC; NCT06963905. The study is accruing patients whose tumors are PD-L1 positive (combined positive score $>$10) and an amendment in under review to also include patients whose tumors are PD-L1 negative on routine testing, with 1 prior line of cytotoxic chemotherapy with or without prior immunotherapy use in the metastatic setting or within 6 months from completion of curative intent treatment. Study treatment will be continued until progression of disease, unacceptable toxicity, death, or withdrawal of consent. Safety will be monitored, and tumor response will be regularly evaluated by RECIST 1.1 criteria every 9 weeks. The primary endpoint includes safety as the incidence of dose-limiting toxicities (DLT) in 3 weeks after C1D1. Secondary endpoints include objective response rate (defined as either complete response or partial response), duration of response, clinical benefit rate (objective response plus stable disease), progression-free survival, and safety with SG plus nivolumab or SG plus nivolumab + relatlimab FDC. Exploratory endpoints include overall survival, and biomarkers of prediction of response and resistance. There will be a follow-up visit after the last study treatment administration or before starting a new anticancer treatment, whichever occurs first, followed by long-term/survival chart review follow-up every three months for 2 years. Clinical trial information: NCT06963905. Research Sponsor: None.

TPS1165 **Poster Session**

Phase IIa, open-label, multi-center study of the DNA polymerase theta inhibitor ART6043 administered orally in combination with olaparib to patients with HER2-negative breast cancer with a germline BRCA1/2 mutation (randomized expansion of study NCT05898399). First Author: Mark Robson, Breast Medicine Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Microhomology-mediated end joining (MMEJ) repair of DNA double-strand breaks is reliant on DNA polymerase theta (Polθ). ART6043 inhibits Polθ and hence MMEJ without affecting other forms of DNA double-strand break repair (DSBR) such as homologous recombination (HR) and non-homologous end joining (NHEJ). MMEJ becomes essential for tumor survival in patients with germline BRCA1/2 mutations being treated with poly adenosine diphosphate ribose polymerase (PARP) inhibitors. Polθ inhibition is therefore a powerful strategy to target HR-deficient cancers by potentiating the DNA damage induced by PARP inhibition. Combination of Polθ inhibition with PARP inhibition may also delay or prevent emergence of PARP inhibitor resistance through circumvention of MMEJ-mediated BRCA1/2 gene reversions that restore HR activity. The restricted expression profile of the *POLQ* gene in normal tissues compared with tumor tissues predicts a high therapeutic index for combining Polθ inhibition with DNA damaging agents without synergistic toxicity. Data from 61 pts dosed in the ART6043 dose escalation as monotherapy and in combination with the PARP inhibitor, olaparib, in a tumor agnostic population were presented at ESMO 2025 (Yap et al 2025). These data showed that ART6043 was well-tolerated alone and with the approved dose of olaparib; good ART6043 exposure with no evidence of drug-drug interaction with olaparib; pharmacodynamic engagement as monotherapy and enhanced with olaparib and promising signals of anti-tumor activity for the combination of ART6043 + olaparib. These data support a randomized expansion of ART6043 + olaparib compared to olaparib alone to demonstrate the first proof of concept for Polθ inhibition in HR-deficient cancers. **Methods:** In this expansion to study NCT05898399, approximately 80 pts with locally advanced or metastatic HER2 negative breast cancer with a germline BRCA1/2 mutation will be randomized to ART6043 + olaparib vs olaparib (stratified by use of prior platinum). Patients must have received prior chemotherapy and no or ≤1 month of prior PARP inhibitor. Patients with hormone receptor positive breast cancer should have been treated with prior endocrine therapy. Patients in the investigational arm will receive ART6043 600 mg once daily with olaparib 300 mg twice daily. Patients on the olaparib-alone arm may cross over to receive ART6043 + olaparib on progression. Key objectives include preliminary efficacy (progression-free survival, objective response rate etc), safety and tolerability. Cell free DNA samples will be collected to assess stratification biomarkers, response and compare the occurrence of resistance mechanisms (eg BRCA reversion) between the two arms. Enrollment will continue until Q4-2027. Clinical trial information: NCT05898399. Research Sponsor: Artios Pharma Ltd.

TPS1166 **Poster Session**

IvoLoC: A phase II trial of ivonescimab (IVO) in endocrine-refractory hormone receptor (HR)−positive or triple-negative (TN) metastatic invasive lobular carcinoma (mILC). First Author: Jason A. Mouabbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: ILC accounts for approximately 10–15% of breast cancers and is predominantly hormone receptor−positive (HR+)/HER2−. Patients with endocrine-refractory mILC have poor outcomes, with median progression-free survival (PFS) of less than three months following standard therapies. ILC is biologically distinct from invasive ductal carcinoma, with unique tumor microenvironmental features. Molecular profiling of primary untreated ILC has demonstrated marked heterogeneity, including immune-enriched (IE) and highly vascularized (HV) molecular functional portraits associated with PD-1/PD-L1 signaling and VEGF pathway activation. IVO is a novel bispecific antibody targeting PD-1 and VEGF, designed to enhance antitumor immunity while inhibiting angiogenesis. We hypothesize that dual immune and vascular targeting will improve clinical outcomes in patients with endocrine-refractory HR+/HER2− or TN mILC. **Methods:** Trial Design: IvoLoC (NCT07229417) is a single-center, open-label, phase II study conducted at The University of Texas MD Anderson Cancer Center. Eligible patients include those with HR+/HER2− mILC with progression on prior endocrine therapy, including combinations with CDK4/6, PI3K, AKT, and/or mTOR inhibitors, as well as patients with TN mILC. Patients may have received any number of prior endocrine-based regimens but no more than two prior cytotoxic therapies, including antibody−drug conjugates, in the metastatic setting. IVO is administered intravenously at 20 mg/kg every three weeks until disease progression or unacceptable toxicity. Radiographic assessments are performed every 9 weeks and evaluated per RECIST v1.1. Endpoints: The primary endpoint is 6-month PFS. Secondary endpoints include 12-month PFS, median PFS, objective response rate, disease control rate, duration of response, overall survival, and safety. Exploratory objectives include correlation of outcomes with molecular functional portraits, longitudinal circulating tumor DNA analyses, and integrated genomic and transcriptomic biomarker discovery. Enrollment: The study plans to enroll 29 patients. Accrual is ongoing in the United States. Clinical trial information: NCT07229417. Research Sponsor: Summit Pharmaceuticals.

1500 Oral Abstract Session

Impact of access to effective post-progression therapies on survival outcomes in first-line randomized oncology trials. First Author: João Pedro Apolinário, Hospital Madre Teresa, Belo Horizonte, Minas Gerais, Brazil

Background: Effective anticancer systemic therapies are expected to improve overall survival (OS) or quality of life in randomized controlled trials (RCTs) for patients with cancer. However, access to effective post-progression therapies in control arms is inconsistent and may confound the observed OS benefits, especially for agents with known survival benefit in later lines. Here, we investigated whether control-arm post-progression access to effective therapies is associated with improved OS. **Methods:** This cross-sectional analysis included 52 phase II–III RCTs published between 2010 - 2025 in selected high impact journals. Eligible trials evaluated first line targeted therapies (TT), immune checkpoint blockers (ICB), or hormone therapy (HT) in the experimental arm for advanced lung, breast, or prostate cancer, where the investigational agent had proven OS benefit in later lines. Post-progression access to effective therapies was quantified as the proportion of patients in the control arm receiving the investigational agent (or similar class) relative to all pts randomized to control arm (Ratio_Effective/Control), and relative to patients receiving any subsequent treatment (Ratio_Effective/Therapy). Correlations between the ratio of post-progression access and OS HRs were assessed, with prespecified subgroup analyses by treatment class and tumor type. Geographic distribution was evaluated in trials reporting enrollment by region. **Results:** Across all trials, the mean proportion of patients in the control-arm receiving any post-progression therapy was 66% (SD 14%), of which 42% (SD 22%) received an effective therapy (or, 62.5%, considering relative numbers). Post-progression access differed significantly by tumor type ($p < 0.001$), with the lowest rate in breast cancer, followed by prostate and lung cancer. The median proportion of pts enrolled outside the United States and Europe (US/EU) was 36%. The overall median HR for OS was 0.78. No correlation was observed between rate of post-progression access to effective therapies and the HR for OS across studies. However, in TT trials, higher post-progression access to effective treatments was moderately associated with a less pronounced OS benefit ($r = 0.44$, $p = 0.056$, Ratio_Effective/Control and $r = 0.46$, $p = 0.046$, Ratio_Effective/Therapy). No association was observed in RCTs evaluating ICB. The difference in the correlation between the TT and ICB trials was statistically significant ($p = 0.032$). No correlation was observed between ratio of effective therapies and tumor type, and enrollment outside of US/EU. **Conclusions:** Post-progression access to effective therapies in control arms influenced OS benefits in TT trials but not ICB trials in this study. These results warrant caution interpreting TT survival benefits and underscore the need for RCTs to report and standardize post-progression therapy access. Research Sponsor: None.

1501 Oral Abstract Session

Expert validation of an artificial intelligence–enabled trial matching solution using real-world data from patients with cancer. First Author: Jai Narendra Patel, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Wake Forest, NC

Background: Under-enrollment in cancer trials remains a major barrier for advancing cancer research in part because few patients are offered clinical trials and pre-screening is manual and laborious. One solution involves artificial intelligence (AI)-enabled centralized screening of patients, but this requires robust validation to facilitate trust and adoption. **Methods:** This is a retrospective study from a large community-academic hybrid cancer center comparing the performance of an AI system - Trial Recommendations using Intelligent Assessment to Guide Eligibility and Enrollment (TRIAGE) - to real-world enrollment using longitudinal electronic health records (EHRs), full versioned trial protocols, and expert clinical research coordinator (CRC) adjudication at the trial- and criterion-levels. The train set was composed of 629 patients and 4,094 patient-trial pairs. A large language model (LLM)-only solution was used to predict successful patient enrollment based only on answers to individual eligibility criteria. Next, a machine learning-based approach was used to train the model on top of LLM responses to yield robust, consistent decision rules across patients, with priorities set by the real-world behavior of CRCs. The test set was comprised of 198 patients with breast, lung, and pancreatic cancers and 793 patient-trial pairs. A stratified random sample of 100 patient-trial pairs (83 patients, 21 trials) underwent manual CRC adjudication. The primary outcomes were sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and Cohen's κ for trial-level eligibility using a predefined trial match threshold of 0.40, and accuracy for criterion-level decisions. Performance evaluations were based on a binary classification: eligible or potentially eligible vs. ineligible. **Results:** In the training set, TRIAGE demonstrated 72% sensitivity and 90% specificity for trial enrollment. The table summarizes performance metrics in the test set for trial-level eligibility across 3 trial match thresholds. Criterion-level evaluation across 1,770 adjudications showed 93.1% raw agreement, improving to 94.2% after structured re-adjudication; 10/25 (40%) initial CRC discordances were overturned in favor of the AI decision. **Conclusions:** TRIAGE accurately determined trial-level eligibility from real-world EHR data with high performance and strong criterion-level agreement for oncology protocols. The system surfaced potential missed enrollment opportunities and supports adjustable trial-level decision thresholds. Prospective studies of TRIAGE implementation into research workflows are ongoing. Research Sponsor: None.

Trial Match Threshold	Sensitivity	Specificity	PPV	NPV	Cohen's κ
0.13 (max Sensitivity)	98.7%	97.6%	91.2%	99.7%	0.84
0.40 (study threshold)	78.3%	98.5%	92.6%	94.8%	0.68
0.62 (max Specificity)	39.3%	100%	100%	87.0%	0.45

1502 Oral Abstract Session

Development and external validation of a computational approach for accelerated read out of randomized clinical trials in metastatic prostate cancer. First Author: Ali Sabbagh, Memorial Sloan Kettering Cancer Center, New York, NY

Background: While overall survival (OS) is the gold standard endpoint for clinical trials in metastatic prostate cancer (mPC), it requires years of follow-up. We sought to develop and externally validate a computational model for accelerated OS readout based on short term (4 months) PSA kinetic data. **Methods:** Longitudinal PSA data were obtained from 8 completed phase 3 mPC trials. Using data from the first 4 months on trial, 18 different PSA kinetic variables were developed, including 50% and 90% decline in PSA, PSA=0.1, and PSA=0.2 at 1, 2, 3, and 4 months, and slope and base of the exponential fit of PSA. TITAN, COU-AA-301, and ACIS comprised the training cohort. Data from those trials was used to model OS using a relaxed LASSO approach. The resulting model was applied to 5 validation trials (see Table 1) to simulate 1,000 potential outcomes for each trial (after Harden and Kropko). For the CHAARTED trial, a model using only PSA-kinetic data was used as most baseline variables were missing. The distribution of 1,000 simulated Hazard Ratios (HR) for each trial was compared against the reported HR. **Results:** Overall, $>$ 100,000 PSA values were used with a total $>$ 7,500 eligible study pts, with ~ 70,000 PSA values and ~5,000 patients comprised the validation cohort. The model identified baseline PSA at treatment, PSA50 at 4 months, and the PSA slope as the most informative PSA predictors of OS. Table 1 below compares the median predicted HR and 95%-interpercentile range from the 1,000 simulations with the reported HR for each validation trial. The model correctly predicted the OS point estimate and 95%-confidence interval using the first 4 months of PSA data in every validation trial. **Conclusions:** A computational simulation approach to predict the OS outcome of phase 3 mPC trials based on PSA kinetics from the first 4 months on trial was developed. This model correctly predicted OS outcomes in 5 completed validation phase 3 trials. This included phase 3 trials with both positive and negative outcomes for OS as well as in both hormone sensitive and resistant mPC, and involving AR signaling inhibitors, chemotherapy and a PARP inhibitor. This model is being further validated with additional completed phase 3 trials, and once prospectively validated, has the potential to significantly shorten the follow up required for OS readout from phase 3 trials in mPC. Research Sponsor: Prostate Cancer Foundation; 22CHAS02.

Predicted vs. reported HR of each trial.

Validation Trial	Predicted HR (median [95th interpercentile range])	Actual HR [95%-CI]
LATITUDE	0.64 [0.54 – 0.74]	0.66 [0.56 – 0.78]
COU-AA-302	0.69 [0.60 – 0.80]	0.81 [0.70 – 0.93]
MAGNITUDE	1.06 [0.88 – 1.26]	0.97 [0.79 –1.19]*
CALGB 90401	0.89 [0.78 – 1.01]	0.91 [0.78 – 1.05]
CHAARTED (Unselected)	0.79 [0.61 – 0.98]	0.72 [0.59 – 0.89]
CHAARTED (High Volume)	0.72 [0.53 – 0.92]	0.63 [0.50 – 0.79]
CHAARTED (Low Volume)	0.95 [0.61 – 1.52]	1.04 [0.70 – 1.55]

*Observed HR used as overall OS HR not reported in manuscript.

1503 Oral Abstract Session

Impact of outpatient CAR T-cell therapy administration on healthcare utilization in patients with hematologic malignancies. First Author: Susanna Goggans Bowen, Mayo Clinic Rochester, Rochester, MN

Background: CAR T-cell therapy has revolutionized treatment outcomes in hematological malignancies, but has traditionally required inpatient post-infusion monitoring, which is associated with significant cost and time toxicity. Outpatient CAR T infusion and monitoring has been the standard approach at Mayo Clinic site in Rochester, MN, with demonstrated feasibility and safety (Bansal et al., ASCO 2023). We present data comparing healthcare utilization between CAR T recipients who underwent outpatient remote monitoring and those with traditional inpatient monitoring. **Methods:** Electronic medical records were retrospectively analyzed for 293 patients who received CAR T-cell therapy for a hematological malignancy at any of the 3 Mayo Clinic sites (MN, AZ, FL) between 2020 and 2024 . Healthcare utilization was compared between patients who received outpatient CAR T with remote patient monitoring in Rochester, MN (N = 125) and those who received inpatient CAR T in the Arizona (n = 90) and Florida (n = 78) sites. Per protocol, patients in the inpatient group underwent mandatory inpatient monitoring for 7 days, with extension per provider discretion. Data was analyzed through Chi-Square and Wilcoxon tests. P values $<$ 0.05 were considered statistically significant. **Results:** There was no significant difference in baseline sex, age, ethnicity, LDH, platelets, or neutrophils among the 293 patients. Diagnoses included lymphoma (n = 175), multiple myeloma (n = 106), and B-ALL (n = 12). The most common CAR T-cell products used were axicabtagene ciloleucel (n = 138) idecabtagene vicleucel (n = 56), and ciltacabtagene autoleucel (n = 50). Median hospital days were lower in the outpatient group vs the inpatient group at 30 days (4.4 vs 13.3, $P < 0.001$) and 90 days (4.6 vs 13.6, $P < 0.001$). ICU admission occurred in 1 outpatient patient ($< 1\%$) vs 18 inpatient patients (11%) in the first 30 days ($P < 0.001$). In the first 30 days, 22% of patients in the outpatient group did not require hospitalization, while 56%, 15%, and 6% required 1, 2, and 3 hospitalizations, respectively. Similarly, only 11 (8.8%) patients in the outpatient group had $\geq$1 ED visit in the first 30 days compared with 32 (20%) pts in the inpatient group (P = 0.009). At 30 days, there was no difference in patient portal use, with 58% of patients using the portal at least once and a median of 1 message in both groups. Within the first 30 days, 53% and 2% of patients in the outpatient group required 1 and 2 outpatient visits, respectively, vs 29% and 2% in the inpatient group ($P < 0.001$). There was no difference in 30-day mortality (1.6% outpatient vs 2.4% in inpatient) between the 2 groups (P = 1.00). **Conclusions:** Outpatient CAR T-cell therapy monitoring was associated with significantly fewer hospital days without increased ED visits, ICU stays, portal use, or 30-day mortality. This demonstrates lower healthcare utilization for outpatient CAR-T therapy. Research Sponsor: None.

1504 **Oral Abstract Session**

Outcomes of patients with cancer admitted to a dedicated oncology service within a multisite home hospital program. First Author: Thomas J. Roberts, Mass General Brigham Cancer Institute, Boston, MA

Background: Home hospital programs deliver acute, inpatient-level care in patients' homes, and many health systems have adopted these programs after CMS granted a waiver for acute hospital care at home in November 2020. These programs may offer advantages for patients with cancer, including reduced exposure to hospital-associated complications and increased time at home. However, evidence describing outcomes for patients with cancer admitted to home hospital programs remains limited. In March 2025, Mass General Brigham (MGB) launched an oncology service within the system's multisite home hospital program. Here we describe outcomes among patients with cancer admitted to this service and compared them with outcomes of patients admitted to a brick and mortar (B&M) oncology service. **Methods:** We conducted a retrospective cohort study of patients with cancer admitted to MGB's home hospital program between March 1, 2025 and December 31, 2025. Patient demographics, admission diagnosis, length of stay (LOS), the rate of escalations (patients requiring transfer back to a B&M hospital for increased acuity of care), and 30-day readmission rates were collected. Propensity score matching was used to construct a cohort of patients discharged from a B&M oncology service during the year prior to the launch of the home hospital oncology service. Total LOS and 30-day readmission rates were compared between the cohorts using multivariable regression models. **Results:** There were 137 patients admitted to the home hospital oncology service during the period of analysis. The mean age was 69.7, 53.3% of patients were male, 70.8% were non-Hispanic White, and 87.6% spoke English. The most common admission diagnoses were sepsis (16.1%), skin/soft tissue infections (13.9%), urinary tract infections (10.2%), and renal and electrolyte disorders (10.2%). Twenty patients (14.6%) were admitted directly from an Emergency Department and 85.4% of patients were transferred from inpatient services. The average LOS was 8.9 days, 4.5 days on a B&M service and 4.4 days admitted to home hospital, and the escalation rate was 10.2%. The 30-day readmission rate was 15.8%. When compared to a propensity score matched cohort of patients discharged from a B&M oncology service, the average LOS was not significantly different while the 30-day readmission rate was significantly lower among patients discharged from home hospital. **Conclusions:** These data show that patients with cancer can be successfully managed in a multisite home hospital program. This dedicated oncology service was able to care for patients with cancer with broad array of admission diagnoses, and the 30-day readmission rate was lower when compared to a cohort of matched patients discharged from a B&M oncology service. Home hospital is a promising model to provide acute care at home for patients with cancer and warrants further study. Research Sponsor: None.

Impact of remote symptom monitoring on acute care utilization in phase I cancer patients: Secondary analysis of a randomized clinical trial. First Author: Jack Stover, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with advanced cancer undergoing Phase I therapies often experience high symptom burden and complications, which may result in acute care encounters (i.e., emergency department [ED] visits and hospitalizations). Few studies have characterized these acute care encounters in Phase I patients. Furthermore, it is unclear if these encounters were avoidable and whether remote symptom monitoring (RSM) could reduce acute care utilization. We performed a secondary analysis of a randomized clinical trial to assess the impact of RSM on ED visits and hospitalizations in Phase I patients. **Methods:** This is a secondary analysis of a randomized clinical trial comparing specialist palliative care (SPC) alone and SPC+RSM in patients with advanced cancer enrolled in Phase I trials at MD Anderson Cancer Center. The key outcomes were the frequency of ED visits and hospitalizations over 6 months following enrollment. We documented the main presenting symptoms and reasons for acute care encounters. Additionally, two independent reviewers assessed whether these encounters were potentially avoidable, defined as whether timely outpatient involvement (e.g., nursing telephone call, clinic visit) could have prevented the encounter. We compared the outcomes between the two study groups using Fisher's exact test. **Results:** Among 100 enrolled patients (mean age 64, 63% female, 33% gastrointestinal cancers, median survival 221 [95% CI 171, 271] days), 43 were in the SPC group and 57 were in the SPC+RSM group. 22/43 (51%) SPC patients and 30/57 (53%) SPC+RSM patients had at least one ED visit over 6 m (P=0.61, Table). 15/43 (35%) SPC patients and 21/57 (37%) had at least one hospitalization over 6 m (P=0.63, Table). Only 4/84 (5%) ED visits and 0/100 (0%) of the admissions were deemed avoidable. The most common presenting symptoms were pain (ED 27%, hospitalizations 30%) and respiratory distress (ED 23%, hospitalization 23%). The main reasons for acute care encounters were disease progression (ED 49%, hospitalizations 58%), acute complications (ED 26%, hospitalizations 28%) and treatment-related complications (ED 13%, admissions 11%). **Conclusions:** Phase I patients had high rates of ED visits and hospitalizations even when they were followed by SPC. The addition of RSM did not reduce the rates of these encounters. A vast majority of these visits were deemed unavoidable, attributed to disease progression and acute complications. These findings underscore the need for novel interventions to support Phase I patients as they navigate the acute care system near the end of life. Clinical trial information: NCT04989556. Research Sponsor: American Cancer Society; CSDG-19-153-01.

Analysis of an oral anticancer repository program and the impact on access to care. First Author: Allyson Waller, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Patients with cancer face many barriers to timely access of oral anticancer agents, including financial toxicity and delays in insurance and patient assistance program (PAP) approval. The Ohio State University Comprehensive Cancer Center (OSUCCC) launched a pharmacist-led Oral Oncology Drug Donation Repository (OODDR) program in 2020 to allow patients to donate unused oral anticancer medications with the intent to re-dispense to other patients in need. The goal of this study was to describe our OODDR experience and its impact on access to anticancer care. **Methods:** A retrospective chart review was conducted for OSUCCC patients who received at least one dispense of oral anticancer medication from the start of the program in February 2020 through August 2025. Data were collected on patient characteristics, anticancer therapy, barriers to access, and long-term medication access outcomes. **Results:** A total of 392 medication access encounters were identified for 376 patients through OODDRR dispense reports. Four encounters were excluded for missing data or not starting treatment, leaving 388 encounters for analysis. The median age of patients was 65 years, majority were female (51%), white (83%), and had commercial insurance (38%), Medicare (39%), or were uninsured (18%). The most common treatment indications included breast (23%), leukemia (17%), lymphoma (15%), and gastrointestinal (13%) malignancies. The OODDR dispensed 53 unique medications, mostly for on-label indications (76%), with 91% of encounters dispensing one treatment cycle/month or less (median 14 days [IQR 10-28]). Patients accessed long-term drug supply primarily via manufacturer PAP (42%) or insurance approval (31%), while 28 patients (7%) received the full course of treatment with OODDR supply. Reasons that repository supply was utilized included (multiple may apply): delay in prior authorization or appeal process (25%), delay in drug delivery from pharmacy (22%), delay in PAP approval and/or supply delivery (30%), and loss or change of insurance/assistance (19%). The OODDR notably improved the time from treatment decision to initiation with a median start of 6 days (IQR 1-13 days) compared to 14.5 days (IQR 6-30 days) to non-repository drug access. The average retail cost of drug dispensed per encounter was $10,789.28. Utilizing repository supply when patients required inpatient treatment (19%) resulted in hospital savings of $207,654.78. In total, the OODDR provided more than $4.1 million worth of anticancer treatment at no charge. **Conclusions:** The OSUCCC OODDR is an instrumental resource for patients and care teams to remove barriers and improve access to anticancer medications. Patients were able to initiate therapy sooner using the OODDR than would have otherwise been possible using routine insurance and assistance programs. Future efforts to improve medication access and awareness of medication assistance platforms are vital. Research Sponsor: None.

1507 **Oral Abstract Session**

Follow-up of outpatients taking oral anticancer drugs in the multidisciplinary community hospital ONCORAL care plan. First Author: Anissa Guillemin, Lyon I University, EA 3738 - CICLY, Lyon Sud University, Lyon, France

Background: The increasing use of oral anticancer drugs (OADs) has shifted cancer care toward outpatient and home-based management, raising major challenges related to treatment adherence, drug-related problems (DRPs), and coordination between hospital and community healthcare professionals. ONCORAL is a structured multidisciplinary community-hospital care plan designed to secure OAD use through coordinated personalised pharmacist-nurse-oncologist follow-up, by face-to-face consultations and phone-calls. The present study aims to assess the impact of ONCORAL over the course of treatment. **Methods:** This prospective real-life cohort study included adult outpatients treated by OADs and followed within ONCORAL between October 2021 and April 2024 in a tertiary referral hospital within the Hospices Civils de Lyon (Lyon, France). The 6-months follow-up was structured in two sequential phases from initiation, with hospital-led consultations, to community monitoring. The primary outcome was the number and nature of nurse and pharmacist interventions (NPIs), classified between DRPs and coordination issues. The secondary outcome was relative dose intensity (RDI), defined as the ratio of prescribed to theoretically approved dose, assessed at months 1 (M1), 3 (M3), and 6 (M6). Based on the literature, a RDI target range of 80-85% is associated with OAD efficacy. Descriptive analyses were performed at both patient and treatment follow-up levels. **Results:** Five hundred and thirty-six patients were included: mean age 69 $\pm$ 13 years; M/F ratio 0.8; 52.4% women; 55.8% with solid tumours. Targeted therapies accounted for 55.2% of treatments. Overall, 71.3% of patients received OADs for $\geq$ 6 months. Mean RDI was above 80% throughout follow-up for 86.1% at M1, 84.3% at M3, 83.5% at M6. Four hundred and eighty-one patients (90.0%) had at least 1 NPI during follow-up, for a mean of 4.8 NPIs per patient. DRPs (88.5%) were identified in 426 patients (79.5%): patient-reported symptoms and adverse effects (37.5%), drug-drug interactions (DDIs) (30.1%), and adherence issues (20.4%). Clinically relevant DDIs were identified in almost more than 1 in 3 patients (n = 145; 27%), with respectively 26.2% and 43.4% of DDIs potentially reducing OAD efficacy or increasing toxicity. Most NPIs concerned information relay to community healthcare professionals (64.2% of patients), and pharmaceutical counselling on side-effects management and treatment schedules (58.4%). **Conclusions:** This longitudinal evaluation demonstrates that the ONCORAL multidisciplinary community-hospital program enables safe outpatient management of OADs, with sustained dose intensity and early detection of DRPs. Pharmacist-nurse collaboration plays a crucial role in securing treatment pathways and optimising the use of anticancer therapies in a real-world setting. Research Sponsor: None.

1508 Oral Abstract Session

Essential but unaffordable: Real-world costs of WHO essential cancer medicines in a low-income setting. First Author: Vivek Ghosh, CancerCare Manitoba, Winnipeg, MB, Canada

Background: The World Health Organization (WHO) Essential Medicines List (EML) defines priority anticancer medicines. In many low-and-middle-income countries (LMICs), EML inclusion may not translate into financial accessibility. Using Nepal as a case study, we mapped availability pathways and real-world prices to quantify affordability of WHO EML regimens. **Methods:** We conducted a cross-sectional audit of WHO EML anticancer medicines in Nepal. Regimens were selected for high-incidence and high-curability cancers and to reflect commonly used standard-of-care regimens. Patient prices were abstracted from Nepal distributor and manufacturer price lists (2024–2026), using the lowest listed patient price when multiple listings existed. Regimen costs were estimated using standard dosing and typical cycle numbers. Metastatic regimens were excluded because treatment duration is open-ended. Fixed-duration curative-intent regimens were analyzed. The primary outcome was affordability, expressed as regimen cost divided by annual GDP per capita (Y), used as a proxy for yearly income. **Results:** WHO EML drugs were broadly identifiable, but free access to high-cost agents via NGO programs was confined to three city hospitals, creating a geographic lottery. Using Y = US$1,447/year, estimated total costs for standard regimens were substantial: dd AC-T for breast cancer US$552 (0.38Y); FOLFOX for colon cancer US$1,226 (0.85Y); CAPOX US$1,090 (0.75Y); FLOT for gastric cancer US$1,063 (0.73Y); and R-CHOP for lymphoma US$1,144 (0.79Y). Add-on biologics were far higher: trastuzumab for HER2-positive therapy (17 cycles) was US$3,998 (2.76Y). Pembrolizumab (9 cycles) was US$27,246 (18.83Y). One year of oral targeted therapy was osimertinib US$4,448 (3.07Y) and olaparib US$10,716 (7.41Y). **Conclusions:** In this LMIC case study, most WHO EML curative regimens approached/exceeded one year of average income, while add-on components approached two decades. EML prioritization alone was insufficient to ensure financial access at the point of care. The findings support targeted national procurement with financial-risk protection for a small set of high-impact medicines, complemented by high income countries (HIC)–LMIC access partnerships, like said NGO-programs, to extend reach beyond a geographically advantaged catchment. Research Sponsor: this work was carried out with the aid of a grant from Royal College Canada International, a charity affiliated with the Royal College of Physicians and Surgeons of Canada.

Implementation science insights from a community-embedded cervical cancer screening program integrating high-risk human papillomavirus DNA testing with non-communicable disease screening in rural South India. First Author: Shailendra Dandge, Society for Health Allied Research Education India (SHARE INDIA), Hyderabad, India

Background: The WHO Cervical Cancer Elimination Initiative recommends screening ≥70% of eligible women and linking ≥90% of those with identified disease to treatment. However, in most low- and middle-income countries (LMICs), screening rate remains around 30–40%, and only 40–60% of high-risk human papillomavirus (HR-HPV)–positive women complete colposcopy thereby precluding identification of disease and linking to treatment. To address this gap across the screening–diagnosis–treatment pathway, we implemented a multi-pronged community-based program integrating community participation, self-swab HR-HPV DNA screening at doorsteps, with non-communicable disease (NCD) screening and patient centric treatment linkage. **Methods:** This longitudinal implementation study was conducted within the Rural Effective Affordable Comprehensive Health (REACH) cohort in Medchal district, Telangana, India. Trained non-physician health workers conducted door-to-door outreach among women aged 25–65 years. Community engagement was supported by a local Community Advisory Board and village influencers, who guided outreach strategies and timing. Counseling and self-collection of vaginal samples were carried out at participants' homes. Educational content was developed based on prior formative research using the Health Belief Model to address fears, stigma, and misconceptions. Screening for HR-HPV DNA was offered as part of a bundled women's health package that included blood pressure and diabetes testing. Appointments for both swab collection and colposcopy/biopsy were coordinated and scheduled at the convenience of the community. HR-HPV testing was done using a chip-based PCR platform. Women who tested positive were referred for colposcopy, biopsy, and treatment at an affiliated teaching hospital. **Results:** Of 1,869 women approached, 1,747 (93.5%) completed HR-HPV self-sampling, surpassing the WHO's 70% screening target. HR-HPV was detected in 89 women (5.1%). Of these, 64 (71.9%) underwent colposcopy, higher than LMIC averages. All with abnormal findings had biopsies. Four women were diagnosed with high-grade lesions or early invasive cancer, all successfully linked to definitive care or referral, meeting the WHO ≥90% treatment linkage benchmark. **Conclusions:** Integrating HR-HPV screening with NCD services, enabled by community leadership, doorstep access, and logistical support, achieved high coverage, improved follow-up, and complete linkage to care. This model offers practical, scalable insights for cervical cancer screening programs in rural, resource-limited settings. Research Sponsor: None.

Low-dose pembrolizumab with chemotherapy in advanced NSCLC: A phase 3 randomized trial. First Author: Nandini Sharrel Menon, Tata Memorial Hospital, Tata Memorial Centre, Homi Bhabha National Institute, Mumbai, Maharashtra, India

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

1511 Clinical Science Symposium

Immunotherapy access disruptions in Mexico: Real-world delivery irregularities at a public cancer referral center. First Author: Brenda Jimenez, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad De México, DF, Mexico

Background: Immunotherapy improves outcomes in selected cancers, but access in middle-income countries may be limited by cost and supply instability. We quantified eligibility, initiation, and delivery disruptions attributable to drug unavailability at a public cancer referral center in Mexico. **Methods:** Retrospective cohort of adults with a first oncology consultation at Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (Mexico City) between January 2023 and March 2025. Records were reviewed to identify standard indications for immunotherapy per NCCN/ESMO/ASCO guidelines current at evaluation. Among eligible patients, we assessed initiation and delivery fidelity. Deviations were defined as delay to initiation >30 days, regimen modification, or temporary/permanent suspension due to drug shortages. **Results:** Among 1,201 first-time consultations, 228 (18.9%) had an immunotherapy indication; 114/228 (50.0%) initiated immunotherapy. Among eligible patients who did not initiate (n=114), medication unavailability was the most frequent reason (48, 42.1%). Among treated patients (n=114), delivery disruptions were common: 42 (36.8%) had treatment suspensions due to shortages, 9 (7.9%) received regimens deviating from approved protocols, and 8 (7.0%) started with >30-day delay. Overall, only 55/228 (24.1%) immunotherapy-eligible patients received treatment as recommended by international guidelines. **Conclusions:** In this public Mexican referral center, only half of immunotherapy-eligible patients initiated treatment, and over half of treated patients experienced delivery disruptions linked to drug unavailability. These findings support urgent procurement and supply-chain strategies to ensure timely, uninterrupted access to high-impact cancer therapies in publicly funded systems. Research Sponsor: None.

Extent of immunotherapy eligibility, initiation, and delivery disruptions attributable to drug unavailability.

Measure	Value
First-time oncology consultations	1201
Immunotherapy indication	228 (18.9%)
Initiated immunotherapy	114/228 (50.0%)
Non-initiation due to medication unavailability	48/114 (42.1%)
Any delivery irregularity among treated patients	59/114 (51.8%)
Suspension due to drug shortages	42/114 (36.8%)
Regimen deviation due to unavailability	9/114 (7.9%)
Initiation delay >30 days	8/114 (7.0%)
Guideline-concordant immunotherapy among eligible patients	55/228 (24.1%)

Values are n (%) unless otherwise indicated. Delivery irregularities include initiation delay >30 days, regimen modification, or temporary/permanent treatment suspension due to drug shortages. Percentages are calculated using the denominators specified in each row.

1512 Clinical Science Symposium

Sustaining oncology clinical trials under wartime conditions: Strategic lessons from Ukraine. First Author: Igor Bondarenko, Dnipro State Medical University, Dnipro, Ukraine

Background: On February 24, 2022, when Russia launched its full-scale invasion of Ukraine, our center had already treated more than 5,000 patients across 410 oncology clinical trials (CTs) since 2002. At the onset of the war, 125 active CT contracts across 18 cancer types (64 sponsors) were ongoing, with 413 patients enrolled or under follow-up, including 210 in active treatment (57 CTs), 203 in follow-up (53 CTs), and 15 CTs pending initiation. The sudden transition to wartime conditions posed unprecedented challenges to patient safety, continuity of care, trial operations, regulatory compliance, and data integrity, requiring rapid adaptation of clinical, logistical, and digital infrastructures. **Methods:** We conducted statistical analyses to evaluate the feasibility of sustaining CTs over 35 consecutive months of martial law. Key domains included personnel retention, trial activity, protocol adherence, supply chain continuity for a research center located 80 miles from the frontline, and digital infrastructure performance, including utilization of the Medical Control Records (MCR) management system. Our goal was to identify factors applicable to clinical research in armed conflict, natural disasters, and other protracted crises. **Results:** Despite ongoing air raids, missile attacks, power outages, and mass displacement, 99% of scheduled patient visits and data transfers were completed. Of the 413 patients at the start of the war, 150 (36.3%) remain in active treatment (n = 42) or follow-up (n = 108) across 55 trials, representing 44% of the pre-war portfolio. Since February 2022, 7,891 patient visits, 16,155 blood tests, 1,762 tumor response assessments, 3,525 intravenous infusions, and 3,272 oral drug distributions have been completed, with 176 deaths recorded as protocol endpoints. Rapid restoration of supply chains, communications, patient logistics, and secure data management enabled uninterrupted trial activity. A key facilitator was the adaptive MCR digital platform, developed during the COVID-19 pandemic, enabling real-time monitoring, centralized, high-quality electronic medical records, timely e-CRF entry, and remote oversight of CT processes under extreme conditions. The system's AI-assisted planning and multilingual tools are now being tested as a new paradigm for global CT continuity and effective performance. **Conclusions:** Armed conflict disrupts clinical research at every level, threatening patient safety, data integrity, and national research infrastructure. Our experience shows that rapid digital adaptation, operational flexibility, and collaborative governance can sustain oncology trials under extreme geopolitical conditions. These lessons offer a scalable framework for research continuity, regulatory alignment, and patient protection in conflict zones and disaster settings, reinforcing global oncology's role in health system resilience and recovery. Research Sponsor: None.

1513 Rapid Oral Abstract Session

Randomized controlled trial of a psychosocial digital application (THRIVE-MM) for patients living with multiple myeloma. First Author: Areej El-Jawahri, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Patients living with multiple myeloma (MM) struggle with considerable quality of life (QOL) impairments, fatigue, and psychological distress throughout their illness course. However, few accessible and scalable interventions address the supportive care needs of these patients. We assessed the efficacy of a self-guided psychosocial digital application, THRIVE-MM, for improving QOL, fatigue, and psychological distress in patients living with MM. **Methods:** We conducted a single-center randomized controlled trial of THRIVE-MM vs. usual care for adults living with MM. Eligibility criteria included patients newly diagnosed with MM receiving first line therapy, those with relapsed MM receiving second- or third-line therapy, or those with MM on maintenance therapy. Participants were randomly assigned 1:1 to THRIVE-MM or usual care, stratified by line of therapy (first line vs. second/third line vs. maintenance) and were given access to the THRIVE-MM digital app up to 8 weeks after enrollment. THRIVE-MM comprises five modules designed to improve patients' physical and psychological symptoms via psychoeducation and evidenced-based self-management skills training for behavioral change and coping, delivered through interactive activities, educational games, and videos. Participants completed self-report measures at baseline and at week-8 after enrollment. The primary endpoint was QOL at week-8 assessed by the Functional Assessment of Cancer Therapy (FACT)-MM. Secondary outcomes were fatigue (FACT-Fatigue), depression and anxiety symptoms (Hospital Anxiety and Depression Scale), and symptoms of posttraumatic stress disorder (PTSD Checklist). We used analysis of covariance controlling for baseline criterion value to assess the effect of THRIVE-MM on outcomes. **Results:** From 12/2023-6/2025, we enrolled 59.1% (120/203) of eligible patients (mean (SD) age = 68.2 (10.0) years; 49.2% women). Mean (SD) use time for THRIVE-MM in the intervention group was 221.9 (197.1) minutes. At week-8, QOL did not differ significantly between the two groups (THRIVE-MM; 125.2 vs. usual care; 125.1, p = 0.977]). THRIVE-MM participants reported lower fatigue (40.6 v. 37.6, p = 0.012) and lower depression symptoms (2.5 vs. 3.4, p = 0.044) at week-8. Anxiety or PTSD symptoms did not differ significantly between the two groups at week-8. **Conclusions:** THRIVE-MM, a psychosocial digital health intervention, decreased fatigue and depression symptoms but not QOL among patients living with MM. Clinical trial information: NCT06073353. Research Sponsor: None.

1514 Rapid Oral Abstract Session

Use of a patient-facing digital tool for glioblastoma outside scheduled clinic visits. First Author: Jason Binder, Ember Health Inc, Summerfield, NC

Background: Care for patients with glioblastoma is largely organized around scheduled clinic encounters, yet symptom management, decision-making, and caregiver responsibility extend beyond office visits. While patient portals, phone triage, and after-hours call coverage exist, these pathways are often resource-intensive, variably available, and insufficient to meet ongoing informational and emotional needs. Scalable, low-cost tools that extend access to vetted support outside clinic hours without increasing clinician workload may help address gaps in care delivery. We evaluated real-world use of a freely accessible, patient- and caregiver-facing digital support tool in glioblastoma. **Methods:** A freely accessible AI chatbot supporting informational, emotional, and care-navigation needs was deployed online without registration or recruitment. The tool excluded medical decision-making and clinical recommendations. De-identified conversation logs generated during routine use were retrospectively analyzed over a 4-month period (Sep 15, 2025 – Jan 14, 2026). Analyses included descriptive characterization of conversation volume, geographic distribution, timing of use, engagement depth, user-reported feedback, and primary topics addressed. All analyses used aggregate, de-identified data with no interaction or intervention involving human subjects. The protocol is IRB exempt per 45 CFR 46.104(d)(4) (WCG IRB 20260304). **Results:** During the study period, the chatbot supported 1,661 conversation threads comprising 15,197 messages across 54 countries. Most conversations originated from the United States (59.9%), followed by the United Kingdom (7.3%), Australia (5.2%), Canada (4.1%), and Greece (3.8%). Conversations were predominantly multi-turn and included use outside clinic hours. The tool was used primarily in English; however, ~12% of messages occurred in other languages, most commonly Spanish and French with additional use of Arabic, German, Italian, Portuguese, Hebrew, Hindi, and several Central and Eastern European languages. Conversations most frequently addressed imaging interpretation and scan-related uncertainty, treatment decision-making, symptom management and treatment-related side effects, and caregiver concerns. Additional topics included clinical trial exploration and prognosis clarification. When clinical trial–related questions arose, users were directed to a brain tumor trial finder. Across the study period, 374 users engaged in trial searches across 22 countries; among respondents to a trial-interest query (n = 251), 92% expressed interest. Voluntary user feedback (n = 97) demonstrated high perceived usefulness and trust (net promoter score, 80). **Conclusions:** A freely accessible AI chatbot demonstrated feasibility as a scalable approach to extending access to care for patients with glioblastoma and their caregivers outside office hours. Research Sponsor: None.

1515 Rapid Oral Abstract Session

Telehealth visits to support extended dosing of pembrolizumab and reduce health care visits: A pragmatic trial. First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Single agent pembrolizumab is standardly administered every 3 weeks (q3wk). Although extended interval dosing every 6 weeks (q6wk) was approved during the pandemic, most oncologists (65%) prefer q3-week dosing to monitor and mitigate immune-related adverse events (irAEs). We hypothesized that telehealth (TH)-enabled safety monitoring may facilitate broader adoption of q6 week dosing with reduced in-person health care visits while maintaining safety and patient experience. **Methods:** MAking Telehealth Delivery of Cancer Care at Home Effective and Safe for Immunotherapy (MATCHES-IO) is a single-arm pragmatic trial among patients with solid tumors receiving single-agent pembrolizumab. The intervention consisted of q6-week in-person pembrolizumab infusions with interim (eg. weeks 3,9,15) telehealth toxicity assessments during the first 6 months of therapy. Intervention components included a TH clinician visit, home phlebotomy, and biometric monitoring. The primary outcome was the number of days with an in-person health care facility visit, ascertained from the electronic health record. Participants were compared to a contemporaneous matched cohort receiving standard q3-week pembrolizumab, matched 1:1 on cancer type, stage (I–III vs IV), and age (15-year bands). Safety was evaluated by comparing irAEs requiring steroid use. Patient experience was assessed using a survey that included likelihood to recommend the intervention. **Results:** Between May 2023 and February 2025, 60 patients were enrolled (median age 69.5 [range: 25-85], 38% female, 78% white). Cancer diagnoses included thoracic (52%), genitourinary (30%), and melanoma (18%) in cases and controls. In matched analyses, there was a 3.5-day difference in total healthcare facility contact days between cases and controls (median 8.5 vs. 12.0, p = 0.14) that did not achieve statistical significance. Rates of irAEs requiring steroids were similar between groups (25.0% vs. 27.1%, p = 0.84). Fifty-two patients (87%) in the intervention group completed a patient experience survey. The median likelihood to recommend score was 10 (Q1,Q3: 8.0, 10.0). Most respondents (96%) perceived a benefit from the telehealth platform, including saved time (85%), increased convenience for patients (75%) and caregivers (44%), and cost savings (52%). **Conclusions:** Extended interval pembrolizumab supported by TH-enabled toxicity monitoring with remote phlebotomy and biometric assessments was associated with reduced in-person health care facility days but did not achieve the significance threshold. The intervention was associated with high patient satisfaction and no increase in irAEs. These results may address clinicians' concerns about the safety of q6 week immunotherapy dosing and inform future care-delivery strategies integrating telehealth with immunotherapy treatment. 1516 Rapid Oral Abstract Session

Addressing geographic disparities in cancer care: An examination of the contributions of international medical graduates (IMGs). First Author: Nazli Dizman, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: IMGs comprise 38% of the US hematology and medical oncology workforce according to the Association of American Medical Colleges. We examined the geographic distribution of oncologists by IMG status to quantify and contextualize the role of IMGs in providing cancer care across the United States, particularly in rural and underserved areas. **Methods:** We used Medicare Care Compare to identify and locate physicians practicing in the U.S. as hematology and medical oncology specialists. IMG status, defined as graduation from a medical school outside of the US, Puerto Rico, and Canada, was assigned from Care Compare where information was available (51%), then from AMA Masterfile data (43%). For the 6% missing IMG data, Google Gemini was used for imputation. We cross-tabulated oncologist IMG status with whether they practiced in a rural county, a county with high cancer incidence (in top 25% of counties for age-adjusted cancer incidence from the National Cancer Institute), and a primary care Health Provider Shortage Area (HPSA). Across counties, we assessed the distribution of new cancer cases by oncologist availability according to IMG status. Proportions and odds ratios with 95% confidence intervals are reported to demonstrate associations. **Results:** There were 14,946 oncologists practicing in the US as of March 2025, of which 5,840 (39%) were IMGs. IMG status was associated with locations that are rural, have high cancer incidence, and have provider shortages (Table). In county-level analysis, among 1,395 counties with oncologists, 1,105 (80%) had IMG oncologist presence. In 662 (47%), IMGs comprised ≥50% of the oncology workforce, corresponding to areas where 32% of patients with newly diagnosed cancer live (549K/1.72M). In 250 counties (18%), only IMG oncologists provided care; 191 (76%) of those were rural and/or had high cancer incidence. **Conclusions:** IMG oncologists play a pivotal role in the geographic availability of cancer care in the United States. They are more likely to practice in rural areas and in areas with increased cancer burden and provider shortages. Any reductions in the IMG oncologist workforce could impede patient access to cancer care on a broad scale and further aggravate shortages in rural and underserved areas. Research Sponsor: None.

Oncologist practice site characteristics by IMG status.

Site Characteristic	All Oncologists, N (%)	IMG Oncologists, n (%)	Non-IMG Oncologists, n (%)	Odds Ratio for IMG vs. Non-IMG (95% CI)

Evaluation and appraisal of quality indicators for end-of-life cancer care in an African context. First Author: Vivens Nsabimana, Partners in Health, Kigali, Rwanda

Background: Population-based quality indicators (QIs) for end-of-life (EoL) cancer care are used to monitor and improve care delivery. Most QIs measure overuse of anticancer therapy or acute care near death and underuse of palliative care. This enables optimization of patient-centered care and healthcare resource utilization, which is especially critical in low-resource settings. Yet, QIs developed in U.S. may not be directly transferable in Africa. We evaluated EoL cancer care in Rwanda using existing QIs and appraised their relevance and feasibility in Rwanda. **Methods:** We conducted a retrospective chart review of all patients who died or were referred for EoL care (i.e., hospice) in 2022 in a Rwandan cancer center. Missing death dates were sought from family and community health workers. Relevance and feasibility of established QIs were appraised by the study team. QI performance was compared with published U.S. benchmarks. **Results:** Of 297 patients (median age 43; 16% pediatric; 61% female), the most common cancers were breast (19%), cervical (9%), acute lymphoid leukemia (9%), gastric (8%), lymphoma (7%), rectal (5%). Nearly half (46%) were stage IV at diagnosis. Most (72%) received treatment; 61% had chemotherapy. After outreach, death dates were available for 95%. Of 18 QIs validated in U.S., 5 were retained or adapted for Rwanda and 13 excluded due to contextual irrelevance or inadequate documentation. Length of stay in EoL care achieved its benchmark, while performance on other QIs was suboptimal (see Table). **Conclusions:** This study is among the first to evaluate and appraise established EoL cancer care QIs in Africa and highlights opportunities to reduce overuse of non-beneficial chemotherapy near death, increase use of palliative care and hospice, and adapt or develop novel EoL QIs to best fit African contexts. Research Sponsor: UCSF Society of Hellman Fellows award; National Cancer Institute; K08CA279874.

Comparison of EoL Care in Rwanda with published benchmarks.

	Rwanda	Benchmark
% referred for EoL care before death (n=297)	45%	>55%
% with length of stay in EoL care 3 days (n=114)	5%	<8%
% who died in a hospital (n=281)	48%	<17%
% starting new chemo within 30 days of death (n=297)	12%	<2%
% receiving chemo within 14 days of death (n=297)	17%	<10%
% receiving chemo within 30 days of death (n=297)	24%	N/A*

*Not a published benchmark; 45% in a published report from Uganda.

Timing of telepalliative care and end-of-life outcomes in advanced cancer: A multicenter retrospective cohort study. First Author: Alexandra Mendes Barreto Arantes, Oncoclinicas & Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, SP, Brazil

Background: Telemedicine has become an integral component of palliative care delivery; however, its impact on end-of-life outcomes in oncology remains insufficiently explored, particularly in low- and middle-income countries (LMICs). Place of death is a key quality indicator in palliative oncology and reflects goal-concordant care. This study evaluated whether the timing of palliative care teleconsultations was associated with a higher likelihood of home death among patients with advanced cancer receiving care in a Brazilian multicenter setting. **Methods:** We conducted a multicenter retrospective cohort study in Brazil including adults with advanced cancer who received interdisciplinary palliative care and died due to disease progression between January 1, 2024, and December 31, 2025. Exposure to telepalliative care was defined according to the timing of teleconsultations relative to death (any teleconsultation, ≤7 days, ≤30 days, or exclusively in-person care). The primary outcome was place of death (home vs other). Secondary outcomes included intensive care unit (ICU) admission and receipt of disease-modifying therapy in the last 30 days of life. Given the sample size, associations were evaluated using univariate logistic regression. **Results:** Among 116 patients (median age 65 years; 55% female), 63 (54.3%) received telepalliative care. Exposure to telepalliative care overall, irrespective of timing, was not associated with home death. In contrast, telepalliative care delivered closer to death was significantly associated with a higher likelihood of home death, particularly when performed within the last 7 days of life (OR 5.93; 95% CI 1.75–20.15; p = 0.004) and within the last 30 days (OR 3.08; 95% CI 1.04–9.10; p = 0.042). Telepalliative care was also associated with lower odds of ICU admission in the last 30 days of life (OR 0.34; 95% CI 0.16–0.73; p = 0.006) and reduced odds of receiving disease-modifying therapy in the final month of life (OR 0.35; 95% CI 0.15–0.79; p = 0.012). **Conclusions:** In this Brazilian multicenter retrospective cohort, the timing of telepalliative care, rather than teleconsultation exposure alone, was a key determinant of end-of-life outcomes. Telepalliative care delivered closer to death was associated with a higher likelihood of home death and reduced use of high-intensity end-of-life care. These findings highlight the importance of timely integration of telepalliative care to maintain continuity of interdisciplinary care and support goal-concordant end-of-life care, particularly in resource-constrained and geographically diverse settings. Research Sponsor: None.

1519 Rapid Oral Abstract Session

LLM-generated serious illness conversation summaries to improve care for hospitalized patients: A pilot clinical trial. First Author: Christopher Manz, Dana-Farber Cancer Institute, Boston, MA

Background: Patients with cancer often receive intensive care near the end of life that does not align with their goals and preferences. Hospitalization is a critical opportunity to engage in serious illness conversations (SICs) that can align care with preferences, but SICs rarely occur. Large language model (LLM)-generated SIC summaries may help busy inpatient clinicians by identifying patient preferences in fragmented SIC documentation in voluminous electronic health record (EHR) notes. **Methods:** This randomized pilot clinical trial enrolled adults with solid tumors admitted to an academic hospital with a 90-day predicted mortality > 40%. Patients were randomized 3:1 (intervention:control) to usual care or to an intervention consisting of an LLM-generated summary of SIC documentation in EHR notes from the last 6 months emailed to their inpatient and outpatient oncology and palliative care teams within 16 hours of admission. Summaries included 8 SIC topics and up to 18 bullet points, and emails included a message encouraging SICs and incorporation of patients' preferences into care plans. The primary outcome was SIC summary accuracy: manual review determined whether each summary bullet point accurately reflected the source note, and the proportion of accurate bullet points were calculated. Other outcomes included user perspectives from day 3 patient interviews and day 7 clinician surveys and 90-day care delivery outcomes (days in the hospital, number of hospitalizations, hospital re-admission). **Results:** 58 enrolled patients were 55% female, 76% White, 91% non-Hispanic and had a mean 90-day predicted mortality of 57.7%. 902 of 936 (96.4%) summary bullet points accurately reflected underlying documentation. Inaccuracies were typically not clinically significant and related to overstating the strength of preferences (e.g., documentation stating a plan to start treatment to improve symptoms might be summarized to state the patient is "focused on improving symptoms") and misattribution of clinician concerns to the patient. 32 patients participated in interviews. They were generally supportive of the intervention and felt it would improve patient-clinician understanding and communication around preferences. 31 clinicians completed surveys and evaluated SIC summaries as "moderately" to "extremely accurate." 90-day outcomes were mature for 24 patients. In 90 days after enrollment, preliminary mean hospital days (20.9 vs 13.2), mean number of hospitalizations including index admission (2.3 vs 1.5) and re-admission (42.9% vs 23.5%) were all lower in the intervention arm. Full trial data will be available in March. **Conclusions:** LLM-generated SIC summaries can be accurately generated, delivered within 16 hours of hospital admission, are received favorably by patients and clinicians, and may reduce care utilization. An effectiveness clinical trial starts May 2026. Clinical trial information: NCT07147023. Research Sponsor: The Fund for Innovation in Cancer Informatics.

Effect of a financial navigation intervention on financial toxicity among patients with breast cancer: A randomized controlled trial in China. First Author: Weijie Xing, Fudan University School of Nursing, Shanghai, China

Background: Financial toxicity (FT) is a common and burdensome consequence of breast cancer treatment, adversely affecting patients' psychological well-being, treatment adherence, and quality of life. Financial navigation (FN) has been proposed as an effective strategy to mitigate FT; however, high-quality randomized evidence evaluating its impact on patient-centered outcomes remains limited. **Methods:** This assessor-blinded, parallel-group randomized controlled trial enrolled adult female patients with breast cancer who had undergone surgery and were receiving or scheduled for adjuvant therapy. Participants were randomized to an FN intervention or usual care (n = 41 per group). The FN intervention included individualized needs assessment, cost-related health education, referral to financial and social resources, and personalized counseling. Outcomes were assessed at baseline (T0), 1 month (T1), and 3 months (T2) post-discharge. Primary outcome was FT, with secondary outcomes including cost-related health literacy (CRHL), shared decision-making (SDM) ability, and perceived stress. Intention-to-treat analysis using generalized estimating equations was applied. **Results:** Of 311 patients screened, 82 were enrolled. Compared with controls, the FN group demonstrated significantly lower subjective FT at T1 (mean difference = 4.76, 95% CI 0.75–8.76, P= 0.020) and T2 (mean difference = 4.66, 95% CI 0.94–8.37, P= 0.014). CRHL significantly improved at T1 (mean difference = 3.15, 95% CI 0.91–5.38, P= 0.006) and further increased at T2 (mean difference = 5.56, 95% CI 3.53–7.59, $P<$ 0.001). SDM ability was also higher in the FN group at T2 (mean difference = 3.24, 95% CI 0.47–6.00, P= 0.022). No significant effects were observed in material or behavioral FT domains. Perceived stress was higher in the FN group at T2 (P= 0.032). **Conclusions:** This randomized controlled trial demonstrates that financial navigation is an effective intervention for alleviating subjective financial toxicity and improving cost-related health literacy and shared decision-making among patients with breast cancer. By providing rigorous randomized evidence, this study advances the field beyond descriptive and observational research and offers high-level evidence supporting financial navigation as a clinically actionable strategy to address cancer-related financial toxicity. These findings contribute to the global effort to mitigate financial toxicity and support the integration of structured financial navigation programs into survivorship care models across diverse healthcare settings. Clinical trial information: NCT06484140. Research Sponsor: National Natural Science Foundation of China.

Effect of group community health worker–led advance care planning education on advance care planning documentation, satisfaction, palliative care, and hospice: Results from a randomized clinical trial. First Author: Olivia Viruet Quintero, Stanford University School of Medicine, Staford, CA

Background: Advance Care Planning (ACP) is recommended for all patients with cancer yet engagement remains low due to multilevel barriers including limited clinician time, lack of adequate reimbursement, and workforce shortages. Our team demonstrated that one-on-one community health worker (CHW)-led education interventions can improve ACP documentation, satisfaction, and hospice use. Group CHW-led interventions may improve scale and spread, however, the effectiveness of such approaches compared to usual cancer care remains unknown. **Methods:** This prospective randomized clinical trial compared a 1-month CHW-led group ACP education intervention plus usual cancer care (intervention group) with usual cancer care alone (control group). Veterans newly diagnosed with solid tumor malignancies, 18 years of age or older, and planned to receive cancer care at one VA facility were eligible. All who verbally consented were randomized 1:1 to the intervention group or the control group. The intervention consisted of two 90-minute group sessions over 1-month post-randomization with 8-10 participants per group led by trained CHWs. The sessions included tailored education regarding ACP, surrogate decision-maker designation, and communication strategies with cancer clinical teams. Usual care included access to nurse navigators, social workers, palliative care and hospice teams, and ancillary support services. The primary outcome was ACP documentation (comprised of the VA Life Sustaining Treatment, VA Advance Directive, and Goals of Care documentation by the oncology clinician) in the electronic health record within 6-months after randomization. Secondary outcomes included satisfaction with care decision, palliative care use, and hospice use. **Results:** 65 patients were screened with 60 (92.3%) eligible of whom all 60 (100%) participated with 30 in each group. There were no withdrawals or participants lost to followup; 55 (91%) were male; 5 (8.3%) were female; median age was 79 years (IQR 67-86); 53 (88.3%) had stage 3 or 4 cancer; 9 (15%) reported ethnicity as Hispanic or Latino; 39 (65%) reported race as White; 12 (20%) Black; 3 (5%) American Indian; and 6 (10%) multiple races. At 6-months followup, intervention group participants had greater ACP documentation (30 (100%) versus 12 (40%)), strongly agreed that they were satisfied that care matched their preferences (27 (90%) versus 18 (66.7%)); no differences in palliative care use (3 (10%) versus 3 (10%)) and greater hospice use (15 (55.6%) versus 3 (10.0%)) than control group participants. **Conclusions:** This group CHW-led ACP education intervention improved ACP documentation, satisfaction, and hospice use at one VA. Group CHW-led ACP approaches may be a potentially scalable approach to address workforce shortages and effectively improve ACP. Clinical trial information: NCT06646614. Research Sponsor: VA Health Services Research & Development.

Association of socioeconomic and clinical factors with overall survival in immunotherapy-eligible stage III non-small cell lung cancer following definitive chemoradiation. First Author: Chaewon Hwang, Department of Radiation Oncology, Tufts Medical Center | Department of Radiation Oncology, Beth Israel Deaconess Medical Center, Boston, MA

Background: Use of consolidative immunotherapy (IO) for stage III non-small cell lung cancer (NSCLC) has increased since FDA approval in 2018, yet disparities in access persist. Few studies have examined survival in the IO era accounting for both socioeconomic and clinical factors. We evaluated determinants of overall survival (OS) in IO-eligible patients (pts) after definitive chemoradiation (CRT). **Methods:** Retrospective National Cancer Database analysis was performed, of adults ≥18 years with stage III NSCLC (2018-2020) receiving ≥60 Gray in ≥30 fractions of RT with known IO status, defined as receipt 50-150 days from CRT start. Surgical cases were excluded. Variables included race/ethnicity (R/E), insurance, facility type, Charlson-Deyo comorbidity index (CCI), high school graduation rate (HSGR), household income, sex, age, NSCLC primary site, and histology. OS was assessed using the Kaplan-Meier method, followed by multivariable Cox regression models adjusting for aforementioned variables, including IO receipt. **Results:** Among 19,418 pts, 54.4% received IO. Median age was 68 years; 44% were female; 85% White, 12.5% Black, 2% Asian, and 2% Hispanic. Median OS was higher with IO (42.1 vs 22.3 months [mo], $P<$.001) and in females (38.8 vs 28.1 mo, $P<$.001). OS differed by R/E: Asian (52 mo), Black (40.3 mo), Hispanic (37.2 mo), American Indian/Alaska Native (24 mo) vs White pts (31.1 mo), $P<$.001. Privately insured pts (41.7 mo) and those treated at academic/research (A/R) centers (36.5 mo) had higher OS ($P<$.001). On multivariable analysis, IO receipt was associated with lower all-cause mortality (HR 0.53; 95% CI, 0.51-0.56). Reduced mortality was seen in Asian (HR 0.82; 95% CI, 0.68-0.99) and Black pts (HR 0.83; 95% CI, 0.77-0.89) vs White pts. Higher mortality was associated with male sex (HR 1.28; 95% CI, 1.22-1.34), urban (non-metropolitan) vs metropolitan residence (HR 1.14; 95% CI, 1.07-1.22), Medicare (HR 1.10; 95% CI, 1.03-1.18) or no insurance (HR 1.36; 95% CI, 1.14-1.63) vs private insurance, nonacademic facilities (comprehensive: HR 1.09; 95% CI, 1.03-1.16; integrated network: HR 1.15; 95% CI, 1.07-1.23), and CCI of 2 (HR 1.13; 95% CI, 1.04-1.21) or ≥3 (HR 1.29; 95% CI, 1.19-1.40). Income and HSGR showed marginal association with OS. Upper-lobe vs main bronchus sites were associated with better OS ($P<$.02), while squamous histology was associated with worse OS ($P<$.001). **Conclusions:** Approximately half of IO-eligible stage III NSCLC pts received IO, which was independently associated with improved OS, adjusting for socioeconomic and clinical factors. Asian and Black race, and treatment at A/R centers, were associated with lower mortality. Insurance and facility type significantly influenced OS, highlighting persistent access-related disparities and the need for targeted interventions to promote equitable care. Research Sponsor: National Institute on Aging; T32AG000243.

Intersecting rural, racial, and Medicaid disparities in cervical cancer outcomes across North Carolina, 2019–2023. First Author: Vaidehi Mujumdar, Atrium Health Levine Cancer, Charlotte, NC

Background: Although national cervical cancer incidence has declined, mortality disparities persist, particularly among rural and racially diverse populations. North Carolina—marked by heterogeneous access to care and recent Medicaid expansion—offers a unique setting to examine geographic and socioeconomic inequities in cervical cancer outcomes. **Methods:** County-level *Cervix Uteri* incidence and mortality data (2019–2023) were obtained from the North Carolina Central Cancer Registry via State Cancer Profiles. Counties were categorized by USDA Rural–Urban Continuum Codes (2023) (urban = 1–3; rural = 4–9). Rates per 100,000 women were calculated using 2020 county populations; 95 % CIs were derived by Poisson approximation. Race-specific rates were determined from State Cancer Profiles (2017–2021 incidence; 2018–2022 mortality). Medicaid enrollment was derived from NC DHHS (SFY 2024) and merged by county rurality. **Results:** Between 2019–2023, 1,624 new cervical cancer cases and 541 deaths occurred. Rural counties comprised 36 % of the female population but 42% of deaths. Incidence was similar between rural and urban counties (18.1 vs 18.9 per 100 000; 95 % CI 14.9–21.2 vs 17.4–20.6), whereas mortality remained higher in rural areas (7.0 vs 5.9; 95 % CI 5.0–8.9 vs 5.1–6.8). Medicaid enrollment was 33.7 % in rural vs 27.1 % in urban counties. High-mortality counties (Robeson, Halifax, Bladen) also had > 45 % Medicaid coverage and higher proportions of Black and Native American residents. Race-specific analyses showed Black women had the highest burden (incidence 8.0; mortality 2.6 per 100 000) compared with White (6.2; 2.0) and Hispanic (7.1; 1.9) women, highlighting overlapping racial and geographic disadvantage. **Conclusions:** In North Carolina, 1) rural residence, 2) race, and 3) Medicaid dependence intersect to drive cervical cancer mortality disparities. Despite comparable incidence, rural and racially diverse counties experience 20–30% higher mortality. Elevated Medicaid enrollment in these regions suggests that insurance expansion alone cannot offset structural barriers in access to gynecologic oncology care. Sustained Medicaid funding, equitable provider reimbursement, and targeted investments in rural cancer infrastructure are essential to improve survival and equity. Research Sponsor: None.

Lost in translation? Evaluating associations between English proficiency and next generation sequencing completion, and comparing understandability across different translation modalities among Spanish speakers with metastatic breast cancer. First Author: Daniela Tovar, UT Southwestern, Dallas, TX

Background: Disparities in next-generation sequencing (NGS) utilization persist among patients with metastatic breast cancer (MBC), disproportionately affecting Hispanic/Latino populations. We hypothesized that the challenges in explaining NGS, particularly when mediated through translation, could be contributing to this observed discrepancy in NGS testing rates within the Hispanic/Latino populations. We evaluated the associations between limited English proficiency and NGS testing by comparing the understandability between English, certified Spanish translations, and artificial intelligence (AI)-generated Spanish translations of provider explanations of NGS testing. **Methods:** We analyzed 191 patients with recurrent MBC from the Dallas Metastatic Breast Cancer Study. Ethnicity was categorized as Hispanic vs non-Hispanic. NGS completion between 2014–2022 was assessed. Three versions of NGS explanations (original English, certified Spanish translation, and AI-generated Spanish translation) were evaluated using the Flesch-Kincaid Readability Score (English) and the Fernández-Huerta Index (Spanish) using 10 provider-patient interactions. Scores range from 0–100, with higher scores indicating greater understandability; CDC/NIH-recommended patient materials target scores of 60–70. Readability discordance $<$ 10 points was considered acceptable. **Results:** 81.7% (156) of patients were proficient in English and were 3.2 times more likely to complete NGS testing than Spanish speakers (95% CI 1.35-7.73, p $<$ 0.01). Mean readability score between the English, certified Spanish, and AI Spanish were 47.9, 51.4, and 54.1, respectively. The mean discordance was 6.1 points between English and certified Spanish, 5.9 points between certified Spanish and AI Spanish, and 8.6 points between English and AI Spanish. All ten original English explanations fell below CDC/NIH readability targets, and only 4 of 10 certified Spanish translations met the recommended standards. When refining the prompts to maximize patient understanding, AI-generated text generated perfect understandability scores. **Conclusions:** Although translation fidelity was preserved, most provider-generated explanations failed to meet recommended readability standards, suggesting that communication quality, not translation alone, may limit patient understanding. AI-generated explanations may serve as a tool to mitigate language-related barriers when certified interpreters or optimized explanations are unavailable and enhance informed decision-making across varied clinical discussions, not limited to NGS testing. Research Sponsor: None.

Mapping access to retinoblastoma care: Geographic disparities and service availability across Africa, and West and Central Asia. First Author: Rima Torosyan, Yerevan State Medical University, Yerevan, Armenia

Background: Retinoblastoma, the most common childhood eye cancer, is highly manageable with prompt diagnosis and appropriate care. Access to specialist services is, however, unequal in low- and middle-income countries (LMICs), leading to unnecessary morbidity and death. This study assesses the geographic reach of retinoblastoma treatment centers, estimates the burden of cases relative to available services, and analyzes referral barriers—in terms of distance and cost of travel—across Africa, West and Central Asia. **Methods:** We used the One Retinoblastoma World Map to categorize African, West and Central Asian (excluding India, China, and Mongolia eastern countries) specialized treatment centers. The centers were classified as Tier 1 (comprehensive care with focal therapy and radiotherapy) or Tier 2 (lacking at least one essential treatment modality). The availability of genetic testing was also recorded. Country-specific incidence of retinoblastoma was estimated at 1 case per 18,000 live births, using UN population and birth rate data. For countries without Tier 1 or Tier 2 centers, we calculated minimum travel distances and estimated one-way costs for a child and guardian to reach the nearest facility. **Results:** Among 71 countries analyzed, there were just 28 (39%) countries with Tier 1 or Tier 2 retinoblastoma centers and 43 (61%) countries without such centers. Tier 1 centers were available in just 16 countries (22.5%), predominantly middle- and high-income countries: only 2 of 25 low-income countries (Uganda, Mali) had access to Tier 1 versus 11 of 39 middle-income and 3 of 7 high-income countries (Saudi Arabia, Israel, Russia). Notably, 64% of low-income and 59% of middle-income countries did not have any retinoblastoma center. Twenty-two high-burden nations ($\geq$10 cases/year) had no Tier 1 or Tier 2 center, including the Democratic Republic of Congo (242 cases/year), Mozambique (65), and Yemen (63). Average one-way travel distance in these environments exceeded 1,000 km at a cost of nearly $1,000 per referral trip. While some nations (e.g., Nigeria, Egypt, Pakistan) had acceptable case-to-center ratios (50–80 cases/center), others (e.g., Uganda, Tanzania) had possible overcapacity with single-center systems. Genetic testing was accessible in just 24% of nations. **Conclusions:** Despite potential underreporting of more recently established centers, this study reveals profound inequalities in the availability of retinoblastoma care, with most LMICs lacking sufficient essential services. Excessive case volumes within underserved regions overwhelm existing infrastructure and necessitate prompt interventions: (1) focused expansion of Tier 1 hubs within regions of greatest need, (2) streamlining of regional referral chains, and (3) integration of genetic and focal treatments to reduce disparities in survival. Research Sponsor: None.

Financial toxicity in early-phase cancer clinical trials: A review of sponsor-supplied information at a large trials unit. First Author: Akul Purohit, The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: Financial toxicity (FT), the objective financial burden and resulting subjective distress experienced by oncology patients, adversely impacts clinical outcomes and access to care. Reimbursement practices between studies vary, possibly exacerbating the lack of representation of people from socioeconomically deprived areas and marginalized groups in early phase cancer clinical trials (EPCCTs). An ASCO roundtable in 2018 emphasized the need for clear details on out-of-pocket costs for trials. Studies in EPCCTs show FT is a recognized problem; however, management of this remains inconsistent. **Methods:** A retrospective portfolio review of open EPCCTs at a large UK cancer centre (Jan-Dec 2025) was conducted to assess reimbursement practices. Sources included informed consent forms (ICFs), contract trial agreements (CTAs) and sponsor provided patient materials. Reimbursement details (including amounts and timelines) were also assessed. **Results:** 64 studies were reviewed, encompassing 41 sponsors (38 industry and 3 academic). Reimbursement was mentioned in ICFs for 62 studies (96.8%) and by 39 sponsors (95.1%). The 2 studies lacking information were academic studies. Specific reimbursable activities were described in 15 studies (23.4%) across 11 sponsors (26.8%). No sponsor included a defined reimbursement timeline in any provided materials. Only 1 sponsor (2.4%) provided additional reimbursement information for patients. Third party vendors for reimbursement were used for 18.8% of studies, with 8 different vendors across 10 sponsors. Reimbursement processes were often detailed in CTAs, with 55 studies (85.9%) outlining specific reimbursable activities. Of 8 academic studies reviewed, 75% listed a maximum budget for each patient to cover the whole study duration (median £350; range £300-£500). Among studies reporting mileage repayment (53; 82.8%), the median rate was £0.45/mile (range £0-£0.45). Median patient travel expense entitlement per visit, where mentioned (55; 85.9%), was £150 (range £40–£700), while refreshment reimbursement was noted in 26 studies (40.6%) with a median value of £15/visit (range £5–£80). The total reimbursement offered per patient per visit was reported in 55 studies (85.9%), with a median of £152.50 (range £40–£1,145). Additional costs covered included reimbursement for carers (9 studies; 14.1%) and unforeseen/inconvenience payments (2 studies; 3.1%). **Conclusions:** Reimbursement terms are regularly specified in CTAs but there is limited inclusion in patient-facing trial documents and lack of flexibility for additional costs. Academic studies restrict reimbursement. Patients may decline clinical studies due to fear of financial toxicity, compounding health inequity. We are partnering with patients to co-develop clearer communication about reimbursement, supporting informed decision-making prior to study enrollment. Research Sponsor: NIHR Manchester Biomedical Research Centre; Roche.

Geographic migration patterns of practicing medical oncologists in the United States, 2020-2025. First Author: Jag S. Lally, University of Rochester Medical Center, Rochester, NY

Background: The regional provision of cancer care in the United States (US) remains plagued by disparities along the continuum of screening, diagnosis, and treatment. The geospatial accessibility and migration patterns of medical oncologists may contribute to these disparities. We aimed to assess urban-rural and state-level migration patterns of practicing medical oncologists in the US using national datasets. **Methods:** The Doctors and Clinicians national downloadable file was used as the primary dataset for these analyses. Physician data from August 2020 and August 2025 was used to identify changes in geographic location. The specialties "Hematology/Oncology" and "Medical Oncology" were used to identify oncologists. We utilized Rural-Urban Continuum Codes (RUCC) to classify counties as urban (RUCC 1-3) or rural (RUCC 4-9). If oncologists practiced in multiple states, they were included in all relevant states for these analyses. For categorical variables, the chi-squared test was used for statistical significance. For continuous variables, the two-sample t-test was used for statistical significance. **Results:** There were 12,222 oncologists in 2020 and 13,420 oncologists in 2025. Our final cohort for analysis comprised 10,172 oncologists present in both datasets. 1,233 oncologists (12.1%) began practicing in a new state during this time period. The five states with the largest percentage of oncologists gained from net migration were: Hawaii (10.8%), Montana (6.7%), Vermont (5.5%), Idaho (5.0%), and Nebraska (4.1%). The five states with the largest percentage of oncologists lost from net migration were: Wyoming (-8.7%), West Virginia (-6.2%), Delaware (-6.2%), Alaska (-4.2%), and Arkansas (-4.1%). Female oncologists were more likely to migrate to a new state (12.6%) than male oncologists (11.8%); however, the difference was not statistically significant (p-value = 0.25). The mean number of years since medical school graduation was 25.1 years for oncologists who began practicing in a new state and 28.4 years for oncologists who did not (p-value $<$0.001). Oncologists in rural areas were more likely to migrate to urban areas (N = 492; 48.7%) than oncologists in urban areas were to migrate to rural areas (N = 380; 4.1%; p-value $<$0.001). **Conclusions:** Oncologists in the US exhibit distinct regional and urban-rural migration patterns. Targeted interventions to ensure adequate geospatial supply of physicians should focus on rural areas and states such as Wyoming and West Virginia. Improving understanding of the underlying factors driving oncologist migration patterns is crucial to ensuring a distributed oncology workforce. Research Sponsor: None.

Scaling digital patient navigation to improve access to multidisciplinary melanoma care. First Author: Govind Warrier, Bloomberg-Kimmel Institute for Cancer Immunotherapy, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Multidisciplinary (multiD) melanoma care is associated with improved patient (pt) outcomes, yet access is variable due to geographic, informational, and system-level barriers. We previously reported preliminary single-center feasibility of engaging pts using a digital patient navigation platform (DPNP) that provides information about melanoma, cutaneous oncology subspecialists, and clinical trials. We now report results from a multi-site expansion evaluating engagement across academic (Johns Hopkins; JH) and regional health systems (RHS). **Methods:** In this IRB-approved study, adult pts recently diagnosed with melanoma at JH or at a participating RHS were identified monthly using ICD-10 codes. Pts who were not already receiving multiD melanoma care at JH were sent DPNP invitations via their electronic medical record (EMR)-based pt portal. The primary endpoint was clickthrough rate (CTR; % of eligible pts who clicked the link in the invitation), benchmarked against web-based healthcare messaging standards (7%); invitation of $\geq$183 pts per setting was targeted (one-sided 90% CI exceeding benchmark if CTR $\geq$7.5%). Secondary endpoints included conversion rate (registration after clickthrough; benchmark 10%) and subsequent pursuit of multiD melanoma care. **Results:** From Nov 2023 - Dec 2025, 194 eligible pts were identified at JH; from Dec 2024 - Dec 2025, 356 at RHS; all were sent DPNP invitations. CTR: 41% at JH (80/194, 95% CI 34.2%-48.5%), 30% at RHS (106/356, 95% CI 25.1%-34.8%). Conversion rates were 23% (18/80, 95% CI 13.9%-33.2%) and 25% (27/106, 95% CI 17.5%-34.9%), respectively. Of 45 total registrants, 42 (93%) provided demographic data: mean age 59.7 yrs (range 25-83), 55% female, melanoma stage 0-IV. Among 16 JH and 26 RHS registrants, 2 (13%) and 6 (23%), respectively, had high-risk (stage $\geq$II) melanoma warranting a multiD consultation. After registering, 2/2 (100%) and 0/6 (0%) high-risk pts sought multiD care. Median distance to JH was 45 miles and 100 miles for JH and RHS registrants, respectively. **Conclusions:** In this multi-site study, melanoma pt engagement with a DPNP significantly exceeded established benchmarks across academic and RHS, demonstrating scalability of EMR-integrated outreach. However, among pts with high-risk melanoma, transition to multiD care occurred more frequently at the academic center than in RHS, revealing setting-specific barriers to converting engagement into subspecialty care. These findings indicate that while digital navigation can effectively identify unmet need across care environments, patient-initiated pathways alone may be insufficient to close access gaps. In response, we are developing a clinician-facing platform designed to overcome informational and geographic barriers by enabling collaboration between community clinicians and multiD oncology teams, thereby facilitating delivery of subspecialty cancer care closer to home. Research Sponsor: Blackbird Laboratories; 1104Health; Maryland Cigarette Restitution Fund.

Trends in biosimilar bevacizumab adoption and Medicare spending by socioeconomic deprivation and rurality, 2019-2023. First Author: Taemin Kim, The Warren Alpert Medical School of Brown University, Providence, RI

Background: Biosimilar bevacizumab has the potential to reduce oncology drug spending, but the equity of its real-world adoption across socioeconomic and geographic contexts remains uncertain. **Methods:** We analyzed Medicare Part B provider-year claims from 2019-2023 for bevacizumab administrations. Biosimilar adoption was defined as the proportion of total bevacizumab services delivered as biosimilars. Neighborhood socioeconomic deprivation was measured using Area Deprivation Index (ADI) quintiles (Q1=least deprived; Q5=most deprived). Rurality was classified using provider-level Rural-Urban Commuting Area (RUCA) codes available in Medicare Part B, with urban defined as RUCA 1-3 and non-urban as RUCA $\geq$4. Adoption patterns were compared using chi-square tests for categorical outcomes and independent t-tests for spending measures. Temporal trends in adoption by ADI quintile were compared using logistic regression with Year $\times$ ADI interaction terms to test whether adoption trajectories diverged over time. Statistical significance was defined as $p<0.05$. **Results:** The study included 11,803 provider-year observations. Biosimilar market share increased from 0.5% of services in 2019 to 61.3% in 2023. In 2023, biosimilar adoption differed significantly by ADI quintile (p=0.0004), ranging from 55.7% in ADI Q4 to 81.3% in the most deprived quintile (Q5), patterns that may reflect institutional purchasing or practice-level factors rather than patient-level access alone. Adoption was higher in urban compared with non-urban areas (62.0% vs 33.6%, p=0.002), despite no baseline differences in 2019. Biosimilars were less expensive than originator bevacizumab in all years (all $p<0.001$). Mean per-administration savings increased from $8.03 (10.3%) in 2019 to $36.4 (52.2%) in 2023 (p=0.001). Originator prices did not differ by ADI in 2023 (p=0.58). **Conclusions:** Biosimilar bevacizumab adoption expanded rapidly and generated increasing Medicare savings, but uptake varied by socioeconomic deprivation and rurality. Differences in adoption, rather than pricing, appear to drive inequities in realized savings. Targeted policy strategies may be needed to promote equitable biosimilar diffusion in oncology care. Research Sponsor: None.

Biosimilar bevacizumab adoption in 2023 by socioeconomic deprivation and rurality.

Category	Biosimilar share of services (%)
ADI Q1 (least deprived)	58.1
ADI Q2	61.1
ADI Q3	61.7
ADI Q4	55.7
ADI Q5 (most deprived)	81.3
Urban	62.0
Non-urban	33.6

Patient characteristics, treatment patterns, social determinants of health, and safety in patients prescribed nivolumab and hyaluronidase-nvhy by early adopters. First Author: Lucio N. Gordan, Florida Cancer Specialists & Research Institute, Tampa, FL

Background: Subcutaneous (SC) nivolumab and hyaluronidase-nvhy (nivo + hyal) is approved for administration across most adult solid tumor indications previously treated with intravenous (IV) nivolumab (nivo) and offers substantially shorter administration time (3-5 minutes). While clinical trial data demonstrate comparable efficacy and safety, real-world evidence on early adoption, patient selection, access-to-care considerations, and safety in community oncology settings remains limited. This study provides early real-world insight into the use of SC nivo + hyal in routine clinical practice. **Methods:** This non-interventional, retrospective medical chart review collected routine-care data from Florida Cancer Specialists & Research Institute LLC. Adults receiving $\geq$ 1 dose of nivo + hyal SC or nivo IV in 2025 were included. Follow-up extended from index (first receipt of SC or IV) through last available record, disenrollment, death, or database cutoff. Patient demographics, disease characteristics, treatment patterns, social determinants of health (SDOH; including proximity-to-care measures), and safety outcomes were summarized descriptively. **Results:** Ninety-eight patients were included (SC n=49; IV n=49). Baseline demographic and disease characteristics were comparable between cohorts, include age, sex, performance status, and metastatic disease prevalence. A greater proportion of SC-treated patients resided in suburban settings (45% SC, 37% IV). Mean travel distance to care was greater among SC recipients, with similar median distances and overlapping interquartile ranges; the longest observed travel distance occurred in a patient receiving SC therapy (110 miles vs 33 miles for IV). Treatment patterns were similar between groups; all patients receiving concurrent therapy were treated with oral anti-cancer agents. SC administration was primarily abdominal (90%). Among SC-treated patients, 54% initiated therapy in the first line setting, while remaining use reflected conversion from IV therapy, most commonly following nivo IV + ipilimumab induction, where SC administration is not currently indicated. No new or unexpected safety signals were observed with SC administration compared with IV nivo. **Conclusions:** In this early real-world community oncology analysis, nivo + hyal SC use demonstrated patient characteristics, treatment patterns, and safety comparable to nivo IV. Difference in proximity-to-care measures, including greater variability and longer travel distances among SC recipients, suggest SC administration may support treatment delivery for patients with higher geographic burden. Findings should be interpreted cautiously given the limited sample size but offer early insight into real-world adoption and access considerations for subcutaneous immunotherapy. Impact of advanced practice provider–led new consults in community oncology: Expanding access and volume in benign hematology. First Author: Eileen Vella, McKesson Corporation, The Woodlands, TX

Background: Community oncology practices face rising patient volumes and workforce shortages, leading to delays in access to care. Although Advanced Practice Providers (APPs) are increasingly utilized to expand capacity, the structure and impact of APP-led new consult models, particularly in benign hematology, remains unclear. This analysis evaluated the operational and clinical impact of APP-led benign hematology consult programs to determine whether this model improves timely access and supports high-quality, patient-centered care. **Methods:** A retrospective, multi-site analysis was conducted in four community oncology practices within The US Oncology Network that implemented APP-led new consult models in benign hematology. Key performance indicators included total new consult volume, time to first appointment (T2F), percentage of APP visits, and APP engagement. Data were obtained from internal scheduling platforms, productivity dashboards, and operational reports. Pre- and post- implementation comparisons assess changes in access and throughput. **Results:** Across all sites, APP-led consults significantly enhanced access and capacity. In a four-year period at Practice A, median T2F decreased by 50% (24 to 14 days; 36 to 18 days across two regions). During the same timeframe, monthly new consults increased from 208 to 1,045, and total new patient volume rose 403% (2,495 to 12,544). APP participation expanded from 93 to 162 clinicians. In Practice B, APP-led consults increased from 55 (2024) to 406 (2025; 638% YOY growth), with daily new visits rising from 0 to 3 per day and APP share of total practice visits increasing from 0% to 23%. The model generated 295 physician hours saved and reduced T2F for new cancer patients from 8 to 4 days. Physicians and patients expressed confidence and satisfaction with APP new visit care. Practice C grew APP-led consults from 171 (2024) to 235 (2025; 37% YOY growth), increasing APP share of total practice visits from 5% to 23%. Practice D expanded from 2 to 7 visits/day (September 2024 to Oct 2025) with consults rising from 81 to 1,221 (1,407% YOY). APP visit share grew from 6% to 59%, and T2F decreased from 15 days to 7 days. **Conclusions:** APP-led new consult models in benign hematology improved access, operational efficiency, and growth within community oncology settings. By optimizing APP utilization, the model addressed workforce shortages, accelerated time to care, and enabled early triage of patients. Broad APP engagement and sustained growth across diverse settings demonstrates its scalability and impact. Together, these findings support the integration of APP-led new consults as a practical and transformative approach to addressing critical gaps in oncologic care delivery. Ongoing prospective evaluation will further define the model's impact and inform broader adoption of this approach and best practices across the oncology landscape. Research Sponsor: None.

Transportation insecurity and RBC transfusion burden in multiple myeloma and related plasma cell disorders in New Mexico: A CRIIS statewide analysis (2013-2019). First Author: Altamash Jawadi, The University of New Mexico School of Medicine Department of Internal Medicine, Albuquerque, NM

Background: Multiple myeloma (MM) and related plasma cell disorders are commonly complicated by anemia requiring red blood cell (RBC) transfusion. In geographically large and predominantly rural states such as New Mexico, transportation insecurity may contribute to fragmented outpatient access and downstream supportive care burden. Using statewide oncology informatics data, we characterized RBC transfusion utilization patterns and their association with county-level vehicle access. **Methods:** Using the Cancer Research Integrated Informatics System (CRIIS), a novel statewide oncology informatics platform, we identified patients with MM and related plasma cell disorders (including Waldenström macroglobulinemia and plasma cell leukemia) receiving care from 2013-2019. We performed a repeated cross-sectional county-level analysis, using county-year as the analytic unit. Transportation insecurity was defined as the percent of households without vehicle access and summarized using the median county value across 2013-2019 due to minimal year-to-year variability. Counties were categorized as higher versus lower transportation insecurity using a median split. The primary outcome was receipt of ≥1 RBC transfusion within a calendar year, summarized at the county level. **Results:** Among 2,436 patients statewide, 614 (25.2%) received ≥1 RBC transfusion. Annual transfusion utilization increased from 15.0% in 2013 and stabilized at ~25-30% thereafter. Median county transportation insecurity ranged from 0% to 12.8%. Across multiple years, counties with higher transportation insecurity accounted for a disproportionate share of statewide transfusion burden relative to patient volume (~1.3-1.5-fold higher absolute transfusion burden). Transfusion burden was concentrated in a subset of counties, with Bernalillo contributing the largest share, while several smaller counties demonstrated high transfusion rates despite low total patient volume. Transfusion delivery remained concentrated in access-rich counties, consistent with regional centralization of oncology supportive care. **Conclusions:** In this statewide real-world analysis, RBC transfusion burden in MM and related plasma cell disorders clustered disproportionately among residents of transportation-insecure counties. Transportation insecurity may serve as a pragmatic structural marker to identify regions bearing elevated supportive care burden and supports collaborative evaluation of transportation-focused care delivery strategies to improve equity across rural and underserved communities. Research Sponsor: None.

Statewide cohort size and RBC transfusion utilization by year.

Year	Total Patients	Transfused Patients	Transfusion Rate (%)
2013	240	36	15.0
2014	238	49	20.6
2015	301	67	22.3
2016	373	109	29.2
2017	411	118	28.7
2018	427	107	25.1
2019	446	128	28.7
Total	2,436	614	25.2

1533 Poster Session

Neighborhood social vulnerability and clinical trial enrollment in colon cancer: Does age matter? First Author: Shannon S. Yoo, Rutgers Robert Wood Johnson, New Brunswick, NJ

Background: Colorectal cancer is now the leading cause of cancer-related death in people under 50, and young adults living in poverty have increased mortality. Despite younger age being associated with higher clinical trial enrollment, young adults face distinct social and structural barriers that may impede participation. This study examines how neighborhood social vulnerability is associated with clinical trial participation for colon cancer in young and older adults. **Methods:** Patients diagnosed with colon cancer were identified in the nationally representative Vizient Clinical Database from January 2022 – June 2025 and stratified into young adult (age 18-49) and older adult (50 and above) cohorts. The outcome of interest was clinical trial enrollment, identified by billing codes. Social vulnerability was defined by the Vizient Vulnerability Index in quartiles at the census tract level. Multivariable analyses were performed in both cohorts. An interaction analysis was performed between age and social vulnerability. **Results:** Of 234,047 patients, 15% were young adults, of which 5.1% enrolled in a clinical trial. Eighty-five percent were older adults, of which 3.0% enrolled in clinical trials. Most young adults had private insurance (73.1%) while most (56.6%) of the older patients were enrolled in Medicare. Non-Hispanic (NH) Black patients were less likely to enroll than NH White patients in both the young adult (OR 0.72, p=0.0001) and older adult cohorts (OR 0.79, p<.0001), as were young and older patients with Medicaid vs. private insurance (OR 0.75, p=0.0001 and OR 0.71, p<.0001, respectively). Diagnosis at an academic medical center vs. community hospital increased the odds of enrollment for both groups: young (OR 2.79, p<.0001) and older (OR 2.04, p<.0001), as did being married vs. single: OR 2.31, p=0.0016 for younger and OR 1.85, p<.0001 for older adults. Among older adults only, Hispanic patients (OR 0.87, p=0.0056; ref NH White) and female patients (OR 0.91, p=0.0002; ref male) were less likely to enroll. Living in the most vs. least socially vulnerable neighborhoods impacted trial enrollment more for young adults (OR 0.75, p<.001) than for older adults (OR 0.91, p<.0001), p= 0.0042 for interaction. **Conclusions:** Many factors that influence trial enrollment, including insurance, social support, diagnosis at an academic center, and race/ethnicity, are similar among young and older adults with colon cancer. However, the negative impact of neighborhood disadvantage on trial enrollment is more pronounced among young adults, highlighting the need for practical trial design, targeted navigation, and strategic recruitment of young adults living in socially vulnerable areas. Research Sponsor: None.

1534 Poster Session

Accessibility of study contact information in ClinicalTrials.gov: A comprehensive analysis. First Author: Fangdi Sun, Stanford University, Stanford, CA

Background: While the official purpose of ClinicalTrials.gov is to satisfy regulatory requirements from the U.S. Food and Drug Administration meant to safeguard human subjects, the database also serves as the most comprehensive record of ongoing clinical trials for patient and provider use. Previous studies have focused on compliance with results reporting and completeness of information within restricted subsets of the database. Taking the perspective of a potential participant or their provider, the purpose of this study was to assess the accessibility of ClinicalTrials.gov contact information across actively recruiting oncology and non-oncology studies. **Methods:** This study included all actively recruiting interventional studies listed in the ClinicalTrials.gov database as of June 11, 2025. We assessed the completeness of location and contact information by multiple factors including oncology versus non-oncology study, sponsor type, trial phase, study start date, and date of last posted update. Within oncology studies, we further analyzed information availability by disease subsite. **Results:** We identified 47,703 actively recruiting interventional trials, among which 12,400 (26.0%) pertained to oncology. Within these oncology studies, 3178 (25.6%) had an industry sponsor, 9729 (78.5%) had a study phase listed (among which 59.4% were Phase 2 studies), and 4311 (34.8%) involved an FDA-regulated drug. Across both oncology and non-oncology studies, 2678 (5.6%) were missing any central contact information. While all trials had at least one study location listed, 3492 (7.3%) did not include a location-specific contact name and 9994 (21.0%) had neither a location-specific contact phone nor email address (24.1% for oncology, 19.8% for non-oncology). Within oncology trials, 50.9% of studies with an industry sponsor lacked any location-specific contact phone or email, compared to 11.3% for NIH sponsors and 14.9% for other (including academic) sponsors. Completeness of location-specific contact information was similar across trial phases. By oncology disease subsite, thoracic trials (29.8%) or those including multiple disease subsites (33.8%) most often lacked location-specific contact phone and email, whereas head and neck (15.4%) and neuro-oncology (16.3%) trials were least likely to do so. **Conclusions:** Location remains a primary means by which many potential trial participants filter clinical trial opportunities. Missing location-specific contact information, particularly among trials with industry sponsors, is an area of potential improvement that could be addressed by increased attention or more stringent registration requirements. While emerging strategies to improve clinical trial accessibility include artificial intelligence-powered platforms, these are only as good as the primary data on which they are built. Research Sponsor: None.

1535 Poster Session

Hospital designation and survival disparities in young-onset gastrointestinal cancer. First Author: Mrinalini Ramesh, University at Buffalo, Buffalo, NY

Background: Early-onset gastrointestinal (GI) cancers (<50 years) are increasing in incidence. We examined the impact of National Cancer Institute (NCI) designation and academic affiliation on mortality and care delivery for young-onset GI cancer patients in New York State. **Methods:** We performed a retrospective analysis using the Statewide Planning and Research Cooperative System (SPARCS) database from 2009 to 2024. Patients were stratified by admission type (emergency vs elective) and hospital site (NCI vs non-NCI; academic vs community). GI cancers included anal, biliary, colorectal, esophageal, gallbladder, liver, pancreatic, peritoneal, small intestine, and gastric cancers. Clinical characteristics were defined using the All Patient Refined grading system. Academic hospitals were classified via the Association of American Medical Colleges Database. Wilcoxon rank-sum tests compared continuous variables; Chi-squared or Fisher's exact tests for categorical variables. Linear regression was performed for continuous outcomes, and multinomial logistic regression for categorical outcomes, with significance at $P \leq 0.05$. **Results:** A total of 29,753 young-onset GI cancer patients were included, of which 48.7% were emergency admissions. For emergency admissions, NCI sites treated patients with higher illness severity, and most had private insurance (P<0.001). There was no significant difference in length of stay (LOS) between NCI and non-NCI sites. Cost of treatment was significantly higher at NCI sites (P<0.001), which also performed more procedures (P = 0.002). NCI sites were associated with 36% lower odds of in-hospital mortality (OR=0.64 [0.55-0.75], P<0.001) despite higher illness severity. For elective admissions, in-hospital mortality was 0.5% at NCI sites vs 7.3% at non-NCI sites (OR=0.04 [0.03-0.05], P<0.001). For emergency admissions, academic sites treated patients with higher illness severity, and most patients had private insurance (P<0.001). Admission to an academic site was associated with increased LOS (β=0.03 [0.02-0.05], P<0.001). Cost of treatment was significantly higher at academic sites (P < 0.001), which performed more procedures (P <0.001). No significant difference in mortality was seen between academic and community sites. For elective admissions, in-hospital mortality was 0.5% at academic sites vs 5.8% at community sites (OR=0.08 [0.06-0.11], P<0.001). Across all hospitals and admission types, private insurance was independently associated with shorter length of stay (P<0.001). **Conclusions:** Treatment at NCI-designated centers for both emergent and elective admissions was associated with significantly lower in-hospital mortality among young-onset GI cancer patients despite higher illness severity. Insurance-based disparities highlight the need for interventions to ensure equitable access to high-quality cancer care for this vulnerable population. Research Sponsor: Roswell Park Cancer Institute; National Cancer Institute (NCI) grant; P30CA016056.

Transportation access as a structural determinant of quality of life and symptom burden among cancer patients. First Author: Hailey Ivanson, Keck School of Medicine of University of Southern California, Los Angeles, CA

Background: Growing evidence links the built environment to cancer outcomes, with NCCN recommendations emphasizing the importance of transit access in cancer care. Cancer patients, especially at advanced ages, are vulnerable to inadequate transit access due to frequent medical appointments and treatment-related physical and financial toxicity. This study examined the relationship between public transit access, quality of life (QoL), pain, and fatigue among adults with cancer. **Methods:** We analyzed data from 31,126 adults with cancer enrolled in the NIH All of Us cohort, which is designed to include populations historically underrepresented in biomedical research. Cancer cases were identified using ICD and SNOMED codes. Multivariable ordinal logistic regression was used to assess associations between distance to public transit and self-reported QoL, pain, and fatigue adjusted for age, sex, race/ethnicity, income, education, and insurance. Similar models examined sociodemographic predictors of transportation-related healthcare delays. **Results:** Decreased public transit access was associated with worse QoL, pain, and fatigue (Table 1). Transportation-related delays in care were more likely among older adults aged 65+ (aOR=0.30, p=0.02) compared to 18-25 year olds; women (aOR=1.13, p=0.03); unemployed individuals (aOR=1.13, $p<0.001$); and those with lower income (aOR=7.60, $p<0.001$). Participants identifying as Black (aOR=1.65, $p<0.01$), Hispanic (aOR=1.27, $p<0.01$), or multiracial (aOR=1.73, $p<0.01$) also reported higher odds of transportation-related delays. **Conclusions:** Reduced public transit access is associated with worse quality of life, symptom burden, and care delays among adults with cancer. Providers can utilize transportation coordination as a tool for improving patient outcomes, particularly in the functional domains of pain and fatigue and among underserved populations. Further, policymakers should identify and address gaps in public transit access, yielding downstream benefits for population health, quality of life, and survivorship among cancer patients. Consideration for transportation should be integrated into treatment plans for all cancer patients to reduce financial toxicity and treatment costs while improving outcomes. Research Sponsor: National Institutes of Health, Office of the Director.

Adjusted odds of worse health outcomes by decreased transit access: Adjusted association between public transit access and pain, fatigue, and quality of life among adults with cancer.[a]

Outcome	aOR (95% CI)[b]	P-value
Low Quality of Life	1.09 (1.00, 1.19)	0.04*
Moderate/High Pain	1.12 (1.06, 1.18)	<0.001****
Moderate/High Fatigue	1.14 (1.08, 1.20)	<0.001****

[a]Adjusted for age group, sex, race/ethnicity, employment, income, insurance.
[b]Public transit stop >15 minutes away.
*$p < 0.05$, ****$p \leq 0.001$.

Travel time to cancer care as it relates to care access, transportation distress, and financial toxicity: Findings from the Cancer Experience Registry. First Author: Erica Fortune, Cancer Support Community, Washington, DC

Background: Longer travel time to cancer care has been linked to worse prognosis and quality of life for patients. This study aims to examine how travel time to cancer care is associated with access to care, transportation-related distress, and financial toxicity. **Methods:** Participants in Cancer Support Community's Cancer Experience Registry (CER) from Oct 2021-Dec 2025 reported sociodemographic and clinical information, financial toxicity (11-item FACIT-COST), travel time to cancer care (min/hr), transportation-related distress (1=*not at all* to 5=*very seriously concerned*), and delays/barriers to accessing cancer care (yes/no). Descriptive findings and between-groups analyses (Chi-square) are presented. **Results:** 3,590 U.S. adults (75% women; 82% non-Hispanic (NH) White, 7% NH Black, 5% Hispanic/Latino, 5% multiple or other races; 18-95 years old [Mean=62.2, SD=13.1]) reported various cancer diagnoses (34% breast, 25% blood, 10% colorectal, 7% gynecologic, 25% other), with 54% in remission/NED, 18% localized, and 15% metastatic (time since diagnosis Median=3yrs). FACIT-COST indicates 52% with no financial toxicity, 26% mild, 20% moderate, and 2% severe financial toxicity (M=24.9, SD=12.0). For travel time, 67% of participants reported < 1hr, 23% 1–2hrs, 7% 3–4hrs, and 4% 5+hrs. 79% reported no transportation distress, while 10% were slightly concerned and 12% moderately to very seriously concerned. Over one-quarter (29%) reported ever experiencing a delay in cancer care. Among patients traveling <1hr to their care center, 24% reported experiencing delays/barriers, compared with 46% of those traveling 5+hrs (χ^2=84.3, $p<.001$). Similarly, transportation-related distress increased with travel time: 84% of patients traveling <1hr reported no concern, whereas only 60% of those traveling 5+hrs reported no concern, with 29% reporting moderate to very serious concern (χ^2=167.9, $p<.001$). Lastly, financial toxicity increased with travel burden: 43% of patients traveling <1hr reported mild-to-severe financial toxicity versus 64% of those traveling 5+hrs (χ^2=63.7, $p<0.001$), and 85% of those reporting moderate to severe transportation distress also reported at least mild financial toxicity (χ^2=388.4, $p<0.001$). **Conclusions:** Most patients surveyed reported living within 1hr of their care site and experienced little transportation distress; however, those who travel longer distances for care report higher rates of delays/barriers, greater transportation-related distress, and more financial toxicity. Collectively, these findings underscore that longer travel times are linked to both objective barriers and subjective distress, highlighting that travel burden may limit timely cancer care and worsen patient outcomes. Policy solutions that bring quality care closer to patients are essential to reduce travel burdens and distress. Research Sponsor: Genentech; Bristol Myers Squibb.

Exploring transportation insecurity among cancer patients in urban cancer clinics in Ontario, Canada. First Author: Clarissa Skorupski, University of Toronto, Toronto, ON, Canada

Background: Advancements in cancer therapeutics have led to increasing care complexity, higher visit frequency, and increased economic burdens for many patients undergoing cancer treatment. Emerging data suggests that transportation challenges may have an important, and uneven impact on the delivery of cancer care. We completed a cross-sectional survey to better understand the prevalence and impact of transportation insecurity in cancer clinics serving a diverse urban and inner-city patient population in a public-payor system. Objectives: The Care for All Health Equity Pilot aims to explore the barriers that patients experience when engaging with cancer treatment. In a pilot exploratory analysis we identified transportation insecurity as associated with missed oncology appointments. The objectives of this study were to explore factors associated with higher level of transportation insecurity amongst our patient population. **Methods:** A cross-sectional survey on patient demographics, financial toxicity (COST tool), transportation challenges, housing and food insecurity was delivered to all adult patients attending cancer clinics at two major urban centres in Toronto, Ontario from July – August 2025. We conducted an exploratory, descriptive, and bivariate analysis of factors correlated with higher levels of transportation insecurity amongst survey respondents. **Results:** 576 patients completed the survey, 48.6% of whom identified as female. 44.8% and 25.0% of respondents had solid tumour or malignant hematologic diagnoses respectively. The most common diagnoses were breast cancer (18.8%), and lymphoma (10.8). Nearly a third (28.8%) of survey respondents endorsed stress related to accessing and paying for transportation to and from their medical appointments. The most common transportation-related stressors preventing patients from attending appointments were parking/travel expenses (26.7%), and the ability to locate accessible parking (13.9%). In an exploratory bivariate analysis patient age, non-English preferred language, access to a personal vehicle, self-identifying with a disability, and living alone emerged as correlates for transportation insecurity. **Conclusions:** Health-related transportation insecurity is common, impacting nearly a third of adult cancer patients receiving care at major urban cancer clinics in a public-payor system. Transportation related costs, and lack of accessible parking, are key contributors to transportation related stress. A multivariate analysis exploring the impact of transportation insecurity on missed oncology appointments, and healthcare utilization, is underway and further information will be available at the meeting. Access to trastuzumab deruxtecan for HER2-low metastatic breast cancer in Brazil's Unified Public Health System: A population-impact model. First Author: Angela Theresa Zuffo Yabrude, Universidade Regional de Blumenau, Blumenau, Santa Catarina, Brazil

Background: HER2-low disease has recently emerged as a distinct, targetable category in metastatic breast cancer (MBC), with trastuzumab deruxtecan (T-DXd) demonstrating a clinically meaningful overall survival (OS) benefit. In Brazil, however, access to innovative oncology therapies within the Unified Health System (SUS) is frequently delayed. We quantified the population-level consequences of delayed access to T-DXd for patients with HER2-low MBC. **Methods:** We conducted a nationwide population-impact analysis from the public-payer perspective, combining Brazilian epidemiologic data with survival benefit estimates derived from randomized clinical trials, using an exponential approximation to model long-term outcomes under delayed-access scenarios. An annual eligible cohort was constructed stepwise from incident MBC (21,133/year), applying: SUS dependence (proxy: 1 - private coverage, p=0.759), HER2-low prevalence (p=0.320), HR+ proportion among HER2-low (proxy using luminal status, p=0.747), and probability of reaching the eligible line of therapy (p line=0.50). Treatment effect inputs were taken from the DESTINY-Breast04 HR+ subgroup (median OS 23.9 vs 17.5 months. OS HR=0.64 [95% CI 0.48–0.86]). Primary outcome was preventable deaths/year, computed as treated/year $\times$ (1 $-$ HR), where treated/year equals the annual eligible cohort multiplied by uptake (95%, 75%, 50%). A sensitivity range for preventable deaths was generated by varying HR across its trial-reported 95% CI. Life-years gained over 10 years were estimated as treated/year $\times$ 10 $\times$ Δmedian OS (years). One-way sensitivity varied p (HER2-low) from 0.25 - 0.46 (uptake fixed at 95%). **Results:** The modeled annual eligible cohort was 1,917 patients/year, treated/year was 1,821 (95% uptake), 1,438 (75%), and 959 (50%). Estimated preventable deaths/year were 656 (range 255-947), 518 (201-748), and 345 (134-498), corresponding to 6,560, 5,180, and 3,450 deaths avoided over 10 years, respectively. Life-years gained over 10 years were 9,713, 7,668, and 5,112 across the three uptake scenarios. Varying p(HER2-low) from 0.25-0.46 yielded 513-943 preventable deaths/year and 7,588-13,962 life-years gained (10 years) at 95% uptake. **Conclusions:** Delayed access to T-DXd within Brazil's public health system may result in substantial, avoidable mortality among patients with HER2-low MBC. These findings highlight the urgent need for accelerated incorporation pathways, consistent HER2-low testing, and operational readiness to translate proven survival gains into real-world benefit. Research Sponsor: None.

Scenario	Uptake	Treated/ year	Preventable deaths/year	Range (HR 95% CI)	Life-years gained (10 years)
Base-case (95%)	95.0%	1,821	656	255 – 947	9,713
Moderate (75%)	75.0%	1,438	518	201 – 748	7,668
Conservative (50%)	50.0%	959	345	134 – 498	5,112

Geographic accessibility of recruiting clinical trials for rare and common gastrointestinal malignancies in the United States. First Author: Rahul Kumar Thakur, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Gastrointestinal (GI) cancers account for substantial cancer mortality, with rare GI malignancies experiencing particularly poor outcomes and limited therapeutic options. Clinical trials are essential for treatment development; however, the geographic accessibility of disease-specific trials for rare GI cancers remains insufficiently characterized. **Methods:** We queried ClinicalTrials.gov to identify actively recruiting interventional disease-specific trials for GI cancers in the United States (accessed Jan 2026). Trials were classified as common (colorectal, pancreatic, hepatocellular, gastroesophageal) or rare (anal, appendiceal, small bowel adenocarcinoma, biliary tract) GI cancers. Trial sites were geocoded by ZIP code. Geographic accessibility was defined as the proportion of the U.S. population residing within 30 miles of a recruiting trial site; areas without a site within 30 miles were defined as clinical trial deserts. Urban–rural status and income quartiles were derived from census-based classifications. A 60-mile access definition was evaluated as a sensitivity analysis. **Results:** A total of 283 disease-specific GI cancer trials encompassing 1,322 unique U.S. trial site ZIP codes were included. More than 80% trials were early-phase (Phase I–II). Using a 30-mile access definition, overall population coverage was 83.6%, with lower coverage in rural versus urban populations (47.5% vs 90.9%) and in the lowest vs highest income quartiles (65.8% vs 98.0%). Common GI cancers had broad access, including colorectal cancer (80.2% population coverage) and pancreatic cancer (75.3%). In contrast, more than half of the population resided in a clinical trial desert for rare GI cancers (biliary tract = 55.2%, small bowel = 56.4, anal cancer= 80.8%, appendiceal 99.5%). Over 75% of rural residents resided in trial deserts for any rare GI cancer. Findings were consistent using a 60-mile access definition. **Conclusions:** Geographic accessibility remains a major barrier for disease-specific clinical trials of rare GI malignancies. This results in extensive clinical trial deserts and perpetuates existing disparities for rural and lower-income populations. These findings highlight structural gaps in trial availability and support the need for more geographically inclusive trial designs. Research Sponsor: None.

Geographic access to disease-specific gastrointestinal cancer clinical trials.

Validation of prognostic scores in Hispanic patients with advanced solid tumors enrolled in a single-center phase I clinical trial program. First Author: Darin Poei, University of Southern California/Los Angeles General Medical Center Hematology and Medical Oncology Fellowship Program, Los Angeles, CA

Background: Prognostic scores are commonly used to guide enrollment in early-phase oncology trials. Despite their widespread use, these models have not been specifically evaluated in Hispanic patients, to the best of our knowledge — a population historically underrepresented in clinical trials. We evaluated the predictive performance of the Royal Marsden Hospital (RMH) score, the Princess Margaret Hospital Index (PMHI), and the MD Anderson Cancer Center (MDACC) score in a cohort of Hispanic patients with advanced solid tumors enrolled in phase I clinical trials. **Methods:** We performed a retrospective chart review of Hispanic patients with advanced solid tumors enrolled in phase I clinical trials at USC Norris Comprehensive Cancer Center and its affiliated safety-net institution, Los Angeles General Medical Center, between 2015 and 2022. Prognostic scores were calculated using the established criteria: RMH score (albumin <3.5 g/dL, LDH $>$ ULN, >2 metastatic sites), PMHI (albumin <3.5 g/dL, ECOG >0, >2 metastatic sites), and MDACC score (albumin <3.5 g/dL, LDH $>$ ULN, ECOG >0, >2 metastatic sites, gastrointestinal tumor type). RMH and PMHI risk groups were categorized as low (0–1 points) or high (2–3 points), while MDACC risk groups were defined as low (0–1 points), intermediate (2–3 points), or high (4–5 points). Overall survival (OS) was analyzed using Kaplan–Meier methods. **Results:** A total of 191 Hispanic patients were included (109 gastrointestinal, 36 lung/head and neck, 20 other, 16 gynecologic, 6 genitourinary, 4 breast). Median age was 59 years (25–86). The median OS for this cohort was 13.1 months (95% CI, 8.8-18.3). Significant differences in OS were observed across prognostic risk groups for all three prognostic scores. Median OS for RMH high- versus low-risk patients was 5.1 versus 18.3 months (p=0.004); for PMHI high- versus low-risk patients, 6.5 versus 20.0 months (p=0.002); and for MDACC high-, intermediate-, and low-risk patients, 4.1, 15.7, and 32.7 months, respectively (p=0.007). **Conclusions:** In this Hispanic solid tumor phase I trial population, higher RMH, PMHI, and MDACC scores were associated with poorer overall survival. These findings support the use of established prognostic scores in Hispanic patients for identifying candidates with poor prognosis and informing early-phase trial enrollment. Prospective studies are warranted to further validate prognostic scores in the Hispanic population. Research Sponsor: None.

RMH	Median OS (Months)	PMH	Median OS (Months)	MDACC	Median OS (Months)
Low (0-1)	5.1	Low (0-1)	6.5	Low (0-1)	4.1
High (2-3)	18.3	High (2-3)	20.0	Intermediate (2-3)	15.7
				High (4-5)	32.7

Breaking barriers: Evaluation of a low-threshold community-based HPV vaccination model for gender minorities and sex workers in Milan. First Author: Nicla Maria La Verde, Department on Oncology, Luigi Sacco Hospital, ASST Fatebenefratelli Sacco, Milano, Italy

Background: Human Papillomavirus (HPV) is the primary etiological factor for anogenital and oropharyngeal cancers. Sexual and gender minorities (SGM) and sex workers (SW) face an increased risk of HPV-related diseases but encounter significant barriers to vaccination, including stigma, discrimination in healthcare settings, and low risk perception. "VaccinaMILAN*" is a community-based initiative designed to enhance vaccine accessibility by offering the first dose of the 9-valent vaccine in safe and inclusive environments, such as Milan's "rainbow" districts during weekend evening hours. This study assessed the demographic characteristics, risk factors, and barriers within this hard-to-reach population. **Methods:** An anonymous paper-based questionnaire was administered to participants vaccinated during the May and October 2024 editions of VaccinaMILAN*. The survey evaluated demographics, gender identity, sexual behaviors, HPV knowledge, vaccination barriers, and satisfaction with the community approach. Categorical variables were described using frequencies and percentages; data were analyzed using Chi-square tests (two-tailed p-value < 0.05). **Results:** 320 questionnaires were collected (response rate: 76.2%). Most respondents were under 35 years old (68.7%) and held a university degree (65.9%). The sample primarily consisted of cisgender MSM (76.9%), followed by cisgender female SWs (13.4%) and gender minorities (9.8%). Despite a high prevalence of receptive anal intercourse (61.7%), 95.4% had never undergone anal cancer screening. HPV knowledge was significantly higher among younger participants (p = 0.0063) and university graduates (p = 0.0169). Reported barriers included: 45.7% did not know how to access vaccination; 25.4% did not perceive themselves at risk; approximately 20% had previously experienced vaccination refusal in traditional healthcare settings. Overall, 99.7% expressed satisfaction with the initiative. **Conclusions:** The VaccinaMILAN* project demonstrates the effectiveness of a multidisciplinary community-based approach in improving vaccine equity for marginalized populations. The findings highlight the urgent need for targeted awareness campaigns and specific training for healthcare providers regarding HPV vaccination and anal cancer screening recommendations for these populations. Participation of older adults (aged ≥65 years) in SWOG cancer clinical trials. First Author: Jyotsana Parajuli, The University of North Carolina at Charlotte, Charlotte, NC

Background: Cancer disproportionately affects older adults. Approximately 60% of cancer diagnoses occur in adults aged 65 and older in the United States. However, disparities persist in participation of older adults in cancer clinical trials. **Methods:** Using 38 years of data from phase III trials of the SWOG Cancer Research Network between 1985 to 2022, this study examined clinical, socio-demographic, and trial factors associated with participation of older adults (≥65 Years) in cancer clinical trials. Summary statistics were used to describe patient and trial characteristics. To examine factors associated with enrollment of older adults, mixed-effects multivariate logistic regression was performed with the odds of being an older adult (≥65 years) as the dependent variable. **Results:** A total of 45,670 patients accrued to 64 SWOG phase III trials were included in the analysis. Across all trials, 30.6% participants were aged 65 and older, and 57.8% were female. Participants were predominantly non-Hispanic (96.2%) White (87.4%) and most resided in urban areas (82.4%). Regression analysis results showed that adjusted odds of enrollment as an older adult did not differ statistically significantly by cancer stage or intervention type (targeted therapy, immunotherapy, hormonal therapy, chemotherapy, radiation, or surgery). Compared with breast cancer trials (reference group with the lowest proportion of older adult enrollment), the odds of enrolled participants being older adults were higher in gastrointestinal cancer trials (OR=3.39), lung/thoracic cancer trials (OR=3.24), and genitourinary/prostate cancer trials (OR=6.77). Compared with White participants, Black participants (OR=0.64) and Asian/Pacific Islander (OR=0.64) had lower adjusted odds of being older adults. The odds of being aged ≥65 years were nearly twice as high among non-Hispanic participants compared with Hispanic participants (OR=1.85). Participants from rural areas had higher adjusted odds of being aged ≥65 years than those from urban areas (OR=1.10). No statistically significant differences were observed across Area Deprivation Index (ADI) quartiles. **Conclusions:** Although some progress has been made in the participation of older adults in cancer clinical trials in the past decades, more work needs to be done to enhance their participation (especially those belonging to underrepresented groups) in cancer clinical trials. Tailored and targeted recruitment efforts are needed to improve participation of diverse older adults in cancer clinical trials. Research Sponsor: Hope Foundation for Cancer Research.

Time to treatment initiation for triple-negative breast cancer in Brazil: A call for public health action. First Author: Fernanda Madasi Pinheiro, Instituto Nacional de Câncer, Rio De Janeiro, Brazil

Background: Timely initiation of treatment is a critical determinant of outcomes in breast cancer. In Brazil, national legislation mandates treatment beginning within 60 days of histopathological diagnosis. Adherence to this interval may be particularly relevant in triple-negative breast cancer (TNBC), an aggressive subtype associated with rapid disease progression and poor prognosis. **Methods:** Data were collected from patients (pts) diagnosed with primary TNBC, stages I-III, treated at two large public cancer centers in Brazil between 2010-2016 and in 2022 and one private oncology network in Brazil between 2020-2023. Treatment delay was defined as an interval ≥60 days. Data were compared between public and private settings. Logistic regression models were used to identify factors associated with treatment delay. **Results:** A total of 1,644 pts were included, 1,347 (82%) in the public and 297 (18%) in the private setting. Pts aged <50 years accounted for 40.3% of those in the public healthcare system and 67.7% of those in the private sector. Patients in the private setting presented with earlier-stage disease (49.5% diagnosed at stage I-IIA vs. 28.1% in the public setting), whereas a higher proportion of stage IIB-III disease was observed in the public setting (71.9% vs. 50.5%; P < 0.001). Treatment initiation beyond 60 days occurred in 75.4% of pts in the public setting, compared with 14.1% in the private setting (P < 0.001). In multivariable logistic regression analysis, factors independently associated with treatment delay included public healthcare service (OR 19.26, 95% CI 13.3–27.9; P < 0.001), older age compared to ≤30 ys, ranging from OR = 2.06 among patients aged 31–39 years (95% CI 1.02–4.16; p = 0.045) to OR = 5.48 among those aged ≥70 years (95% CI: 2.55–11.81; p < 0.001) and earlier stage (I–IIA vs. IIB-III OR = 1.45, 95% CI 1.10–1.91; p = 0.008). **Conclusions:** Rates of treatment initiation beyond 60 days after diagnosis are alarmingly high in the Brazilian public health system, indicating that the 60-day law implementation remains suboptimal. Lower odds of treatment delay among younger patients and those with more advanced disease likely reflect clinical prioritization of individuals with more aggressive or symptomatic presentations. These findings underscore the urgent need for health policy interventions aimed at reducing delays in cancer care, particularly for high-risk subtypes such as TNBC. Research Sponsor: None.

1545 **Poster Session**

Impact of neighborhood socioeconomic deprivation and diet quality on immune checkpoint blockade outcomes. First Author: Anushri Kulkarni, UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Immune checkpoint blockade (ICB) has significantly improved survival across multiple advanced malignancies; however, outcomes remain heterogeneous. While socioeconomic disadvantage (SED) is known to adversely affect cancer outcomes through delayed diagnosis and access to care, impact of SEDupon ICB efficacy remains incompletely characterized. The Area Deprivation Index (ADI) is a validated, neighborhood-level measure of SED. We evaluated the association between ADI and clinical outcomes to ICB across a large, multi-state integrated cancer network. **Methods:** We identified 1,699 adult patients with advanced cutaneous melanoma (CM), renal cell carcinoma (RCC), or urothelial carcinoma (UC) treated with first-line ICB (monotherapy or combination) between 2013–2025 within the UPMC Hillman Cancer Center network (>70 sites across four states). ADI scores were derived from 9-digit ZIP codes at ICB initiation using the Neighborhood Atlas and categorized into quartiles, with higher quartiles indicating greater SED. Primary endpoints were time-to-next therapy (TTNT) and overall survival (OS), measured from ICB initiation to initiation of subsequent systemic therapy or death, respectively. Outcomes were analyzed by ADI quartile using Kaplan–Meier methods and Cox proportional hazards models adjusted for relevant clinical covariates. Analyses were limited to first ICB exposure. **Results:** Across 2,156.3 person-years follow-up, patients in highest ADI quartile experienced a significantly higher incidence of TTNT events compared with lowest quartile (31.1% vs 22.8%; χ^2 p=0.008), without a corresponding increase in deaths (39.2% vs 38.4%; χ^2 p=0.86). Highest ADI status was independently associated with inferior TTNT after first-line ICB in CM (HR 1.51; 95% CI 1.01–2.27; p=0.04), RCC (HR 1.58; 95% CI 1.02–2.45; p=0.04), and UC (HR 2.02; 95% CI 1.11–3.68; p=0.01). Association between ADI status and OS were not statistically significant after adjustment for confounding variables. Univariate and multivariate analyses were performed to control for confounding variables, and confirmed independent prognostic impact of highest ADI quartile upon inferior TTNT. Within a subset of ICB-treated CM patients with available dietary intake data, highest ADI quartile had lowest Healthy Eating Index (HEI) scores (Wilcoxon p=0.01). **Conclusions:** Neighborhood-level SED is associated with inferior durability of response to first-line ICB across multiple solid tumors. These findings suggest that SED may influence ICB effectiveness beyond treatment access alone and underscore the need to identify biologic and care-delivery mechanisms—potentially including diet, comorbidities, and the gut microbiome—through which deprivation impacts ICB outcomes. Prospective, pan-cancer studies integrating social, clinical, and biological variables are warranted. Research Sponsor: None.

CancerTrialsBR: An open-access, collaborative platform to improve visibility and access to cancer clinical trials in Brazil. First Author: Felippe Lazar Neto, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: Lack of timely and understandable information is a major barrier for cancer trials recruitment, particularly outside high-income countries. ClinicalTrials.gov (CTGov) has been widely used to address this need, but language barriers and inconsistent identification of research facilities limit its use. Large language models (LLMs) now offer opportunities to address these limitations. We describe CancerTrialsBR, a pilot platform that integrates CTGov, Google Maps (GMaps), and LLMs to provide Portuguese-language geographically contextualized cancer trial information in Brazil. **Methods:** Clinical trials data and listed research sites are retrieved from CTGov on a daily basis with condition as "cancer", location as "Brazil", and status as "recruiting". Using prompt engineering techniques (CoT and few-shot), trial information is processed by LLM to generate a Portuguese brief summary, ideal patient profile, and trial descriptors according to primary site (N=39), treatment settings (N=8, i.e. first-line), and biomarkers (N=18, i.e. PDL1). For each site, its address components (i.e. name, city) are queried through the GMaps API for standardized facility identification. A LLM performs facility-matching validation, and invalid cases are manually reviewed. This enriched database is made available as an open-access clinical research platform of the Brazilian Society of Clinical Oncology since November 4th, 2025 (https://pesquisaclinica.sboc.org.br), where users can suggest real-time status updates. We report facility identification metrics, database statistics, and site interactions since launch. **Results:** Of 2,873 unique CTGov addresses, 654 (22.76%) retrieved zero results from GMaps, of which 612 (93.57%) were subsequently identified by zip code. For the 2,219 GMaps retrieved locations, LLM validation demonstrated an accuracy of 85.78%, with positive and negative predictive values of 96.9% and 59.0%. Overall, only 93 (3.2%) addresses remained unidentifiable after human review. As of January 19th, 2026, the database comprised 272 trials conducted across 191 research facilities, encompassing 22 of 27 Brazilian states and 76 cities. The median (IQR) of clinical trials per facility was 2 (1-9) with 8 facilities hosting 40 trials or more. São Paulo (260/272, 95.6%), Rio Grande do Sul (195/272, 71.6%), and Rio de Janeiro (108/272, 39.7%) had the largest availability of trials. The platform had 2,320 visits from 220 cities within 76 days, and the leading searched cancer was breast. Users feedback resulted in 34 of 57 (59.6%) suggested status updates incorporated in the database. **Conclusions:** CancerTrialsBR demonstrates the feasibility of integrating LLMs and GMaps to deliver accessible, real-time cancer trial information in Brazil, with early adoption highlighting unmet need and offering insights into the country's cancer research infrastructure. Research Sponsor: None.

Breast cancer patient navigation to identify individual needs and offer medical and supportive care referrals. First Author: Fernanda Mesa-Chavez, Tecnologico de Monterrey, School of Medicine and Health Sciences, Monterrey, Mexico

Background: Despite evidence that patient navigation (PN) improves access to comprehensive care for patients with breast cancer (BC), its adoption in Mexico remains limited, likely due to multifactorial barriers. To address this gap, our center implemented one of the country's first PN programs to systematically identify and document patients' medical and support needs and provide referrals to appropriate services. This study describes patient needs and referral attendance up to 6 months (m) post-diagnosis. **Methods:** Patients newly diagnosed with BC are identified after their first medical oncology consultation at Hospital Zambrano Hellion TecSalud and are consecutively invited to the PN program, which consists of assessments at baseline, 3m, and 6m. At each timepoint, patients answer validated surveys and target questions to explore their needs. The navigator then shares the results with each patient and refers them to the required specialty or support services. Attendance to baseline and 3m referrals is assessed at 3m and 6m, respectively. This analysis includes patients navigated from 2020-2025. **Results:** 421 patients had reached 6m of follow-up: 357 (85%) and 261 (62%) completed their 3m and 6m navigation, respectively. Median age at diagnosis was 48 years (IQR 41-58). Most were married (76%), and had ≥1 child (84%), higher education (75%), and private healthcare (76%). The most common baseline referrals were to nutrition (86%), psychology (68%), support groups (47%), and wig providers (42%). At follow-up, patients mainly required referral to sexology counseling (3m: 82%, 6m: 79%), nutrition (3m: 78%, 6m: 77%), psychology (3m: 51%, 6m: 39%), and lymphedema counseling/therapy (3m: 40%, 6m: 66%). Attendance was highest to support groups (90-95%), wig providers (64-87%), and geriatric assessment (67-80%). Despite high need, attendance was notably lower for nutrition (47-52%), psychology (58%), and sexology counseling (0%). Main reasons for nonattendance were lack of interest (48%), time constraints (38%), and financial issues (10%). **Conclusions:** In this PN program, referrals were mostly needed for nutrition, sexology, and psychology. While attendance was high for some services, rates were suboptimal for the most common referrals, especially sexology counseling. Efforts to better convey referral rationale and importance may increase uptake and access to comprehensive quality-of-life focused care. Research Sponsor: None.

Impact of broadening trial eligibility criteria on the inclusion of patients infected with HIV in cancer clinical trials. First Author: Hong Xiao, Fred Hutch Cancer Center, Seattle, WA

Background: In October 2017, an ASCO, Friends of Cancer Research (FoCR), and US FDA (ASCO/FoCR/FDA) task force recommended that common eligibility criteria be modified to make trials more inclusive. We examined whether patterns of HIV-related eligibility criteria changed over time in relation to these recommendations. **Methods:** Trial eligibility criteria were abstracted from ClinicalTrials.gov for any phase, US-based clinical treatment trials for patients with cancer from 2010-2024. Trials were classified as not excluding, conditionally excluding (ie, excluding under specific circumstances such as unstable or untreated cases), or completely excluding patients with HIV. Eligibility criteria were classified using OpenAI language models with prompt refinement and independent validation. Interrupted time series analyses were used to determine whether the recommendations in 2017 were associated with changes in HIV criteria. We also examined whether eligibility-criteria changes varied by phase and lead sponsor (federal vs. industry). **Results:** We evaluated 20,751 trials, mostly phase I-II (80.3%), with 7.8% federally and 40.6% industry funded, including breast (19.1%), lung (11.0%), prostate (16.2%), and colorectal (14.1%) cancers. The AI classification achieved 97% accuracy on the development sample and 94% on an independent validation sample. Overall, patients with HIV were wholly excluded in 28.9%, conditionally excluded in 26.1%, and not excluded in 45.0% of trials. The guidance was associated with an increase in conditional exclusion (13.1% to 29.1%; p<.001) and no exclusion (24.1% to 28.9%; p=.002), and a decrease in wholly exclusion (62.8% to 42.0%; p<.001). Similar shift patterns were observed across trials with different main funding sources (federal vs industry) and phases (I–II vs III) (Table). **Conclusions:** Following the ASCO/FoCR/FDA task force recommendations, HIV exclusion criteria shifted predominantly from complete exclusion to conditional exclusion, indicating progress toward more inclusive clinical trial designs. Acknowledgement: We thank Dr. Roy Burstein, PhD, at the Institute for Disease Modeling, Gates Foundation, for his invaluable advice. Research Sponsor: None.

Impact of a centralized APP-led peer-to-peer program on patient access, provider burden, and institutional revenue. First Author: Sarah J. Bottomley, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Prior authorization (PA) and peer-to-peer (P2P) requirements impose a significant administrative burden on oncology clinicians, contributing to burnout and care delays. At our Comprehensive Cancer Center, internal data showed frontline Advanced Practice Providers (APPs) and oncologists spent unsustainable hours on insurance denials. To mitigate clinical fatigue and optimize workflows, we launched a centralized initiative transitioning P2P responsibilities from frontline clinicians to a specialized APP team. **Methods:** Following a successful pilot project, a centralized P2P program was established for outpatient diagnostic imaging denials. Based on early success, the program expanded to include outpatient medication-related denials. A dedicated APP team utilized standardized workflows, documentation, and formal escalation pathways to manage all outpatient P2P referrals. Program performance was evaluated on these metrics: 1) Access to Care: Measured by completion rate, authorization turnaround time (TAT) and pre-authorized status at arrival. 2) Provider Burden: Assessed by administrative hours reclaimed from frontline staff and qualitatively via a provider satisfaction survey. 3) Institutional ROI: Evaluated via denial overturn rates and net reclaimed revenue from authorized billable services. **Results:** Centralization markedly improved operational efficiency. The program achieved a clear increase in P2P completion rate from 80% provider-led baseline to 99% by centralized team. This coupled with a reduction in TAT for both imaging and medication authorizations, increased the percentage of patients arriving with pre-authorized status by 12% in the first two years. Overturn rates and positive disposition for initial denials rose to 85% or greater compared to the provider-led baseline of 78%. Frontline clinicians reported a substantial decrease in daily administrative tasks, facilitating increased patient-facing hours and improved work-life integration. Financially, the program demonstrated a robust ROI by securing authorization for high-cost services previously denied and providing payer trend data to inform broader managed care strategies. **Conclusions:** Centralizing P2P responsibilities within a dedicated APP team is a multidimensional solution that extends beyond revenue recovery. This model effectively mitigates provider burnout, optimizes patient flow, and protects clinical capacity. As oncology practices face increasing complexity in 2026, this scalable model offers a vital roadmap for balancing financial health with workforce sustainability. Research Sponsor: None.

Operational and clinical drivers of subcutaneous PD-1/PD-L1 inhibitor adoption: A mixed-methods analysis of U.S. oncology practice patterns. First Author: Kimberly Peihsi Ku, Illinois CancerCare, P.C., Bloomington, IL

Background: Subcutaneous (SC) formulations of PD-1/PD-L1 inhibitors have recently been approved across multiple solid tumors. While these agents offer operational and patient-centric advantages, their perceived clinical value relative to established intravenous (IV) formulations remains unclear. Understanding real-world oncologist perceptions may inform future adoption patterns and practice impact. **Methods:** A national mixed-methods study surveyed 102 U.S. hematologist-oncologists from academic (44%, n=45) and community (56%, n =57) practices across all U.S. regions (Nov-Dec 2025). A structured online questionnaire assessed brand utilization, regimen sequencing, physician satisfaction, switching behavior, and perceived comparative benefit between pembrolizumab- and nivolumab-based therapies using Likert-type scales and utilization metrics. All participants met predefined patient volume and clinical practice criteria. Eight qualitative interviews explored drivers of brand choice, sequencing, and switching decisions. **Results:** Across tumor types, oncologists reported modest current use of SC PD-1/PD-L1 inhibitors, with incremental uptake expected over the next six months. SC formulations were viewed as convenience-enhancing rather than clinically transformative, with reduced chair time (75% reporting significant benefit), improved infusion center efficiency (68%), and better patient experience (70%) cited as key benefits. Approximately half of PD-1/PD-L1–eligible patients across NSCLC, melanoma, and RCC were considered suitable for SC administration. Perceived benefit was largely limited to monotherapy and maintenance settings, with limited added value in curative-intent or combination regimens where infusion time is driven by other agents. In NSCLC, projected near-term uptake of SC PD-1/PD-L1 therapy was highest among PD-L1–high patients receiving monotherapy, while in melanoma and RCC, SC was more often positioned later in the treatment sequence, particularly after treatment stability. Insurance coverage (39% reporting a significant barrier) and cost (58%) were the primary barriers to broader adoption, outweighing concerns about safety (22%) or efficacy (27%). Overall uptake was expected to primarily substitute for IV monotherapy rather than expand total PD-1/PD-L1 use. **Conclusions:** U.S. oncologists view SC PD-1/PD-L1 inhibitors as operational alternatives to IV therapy, with adoption driven by efficiency and patient convenience and constrained by payer dynamics. SC administration is best positioned to enhance care delivery in monotherapy and maintenance settings, with limited incremental value in curative-intent or combination regimens. Addressing real-world access barriers will be key to broader integration across solid tumors. Research Sponsor: None.

1551 Poster Session

Patient-reported barriers to treatment access and home delivery in rare cancers across five European countries. First Author: Raymond A. Huml, Sciensus, London, United Kingdom

Background: Patients with rare diseases, including rare cancers, frequently experience barriers to timely treatment access. Sciensus, an end-to-end pan-European service partner, and Rare Patient Voice, a patient-led advocacy organisation, conducted a multicounty, European survey to characterise treatment logistics, delivery models and patient burden, with a focus on implications for oncology populations. **Methods:** A cross-sectional survey was conducted in December 2025 among adult patients with rare diseases, including cancer diagnosis, and caregivers across Italy, the United Kingdom, France, Spain, and Germany. Quantitative and qualitative data were collected on treatment access, medication collection or home delivery, financial and emotional burden, reliability of services, and participation in Early Access Programs (EAPs). Descriptive analyses were performed. **Results:** Among 860 respondents, approximately 120 (14% of total; 28% of validated rare disease responses) reported a cancer diagnosis spanning ~34 cancer types. While most respondents reported infrequent treatment delays, a notable minority experienced frequent disruptions. Over half reported no access to, or lack of awareness of, home delivery services. However, more than 40% indicated that home delivery would significantly or fundamentally improve quality of life. Ratings of homecare reliability varied widely, ranging from very poor to excellent, indicating substantial inconsistency across delivery models and regions. **Conclusions:** Patients with rare cancers in Europe experience fragmentation and heterogeneity across treatment access pathways. Limited awareness, variable availability, and inconsistent reliability of homebased delivery services likely contribute to ongoing burden. Additional longitudinal study of burden should be conducted to confirm the findings of the experiences in this study. Expanding, standardising and systematising patient-centred delivery models represents a key opportunity to improve continuity of care and quality of life for oncology patients with complex needs. Research Sponsor: Sciensus.

Advancing health equity in oncology: Virtual collaborative behavioral health engagement and outcomes among Medicaid-insured and BIPOC patients. First Author: Nina Balanchivadze, Sarah Cannon Research Institute, Norfolk, VA

Background: Depression and anxiety are common among patients with cancer, yet access to behavioral health care remains limited, particularly for Medicaid-insured and racially minoritized populations. We evaluated reach, baseline symptom burden, and longitudinal outcomes of a virtual collaborative behavioral health program embedded within community oncology. **Methods:** We conducted a retrospective cohort study of patients referred to a virtual collaborative behavioral health program (Cerula Care) across community oncology practices from 2024–2026. Outcomes included representation of Medicaid-insured and BIPOC patients among those initiating care, baseline symptom burden assessed by PHQ-9, GAD-7, and FACT-G7 stratified by insurance (Medicaid vs commercial+Medicare) and race/ethnicity (BIPOC vs White), and longitudinal symptom change during program participation. Independent t-tests were used for between-group comparisons, and paired t-tests were used for within-patient comparisons. **Results:** Between program launch and data cutoff, 1,400 patients were referred by oncology providers; 850 consented and scheduled an intake, and 631 completed intake and initiated behavioral health care. Among 631 patients initiating behavioral health care, 43.5% identified as BIPOC (36.5% Black) and 18.7% were Medicaid-insured, indicating a strong reach into populations historically underserved by behavioral health services. Baseline symptom severity was significantly higher among Medicaid-insured compared with commercial+Medicare patients across all measures, indicating clinically meaningful greater symptom burden. Baseline severity did not differ by race/ethnicity. Improvements in depression, anxiety, and quality of life were observed over time. Between-group differences in symptom improvement by insurance or race were not statistically significant, though Medicaid-insured and BIPOC patients showed directionally greater PHQ-9 and FACT-G7 improvement, and Medicaid-insured greater GAD-7 improvement. Patient-reported experience indicated high acceptability (Net Promoter Score 88); 60% reported improved oncology visit adherence and 61% improved adherence to non chemotherapy medications. **Conclusions:** Embedding virtual collaborative behavioral health in community oncology was associated with high reach among Medicaid-insured and BIPOC patients. Medicaid-insured patients entered care with greater symptom burden yet experienced symptom improvements comparable to commercially ensured and Medicare patients, with similar outcomes across racial/ethnic groups. These findings support collaborative care as a scalable strategy to expand access to behavioral health services and promote equitable supportive oncology care. Research Sponsor: None.

FALCON-Lung: Evolving global real-world treatment choices and outcomes for metastatic NSCLC in different patient populations. First Author: Annelies Verbiest, Antwerp University Hospital UZA, Edegem, Belgium

Background: Despite rapid global adoption of immune checkpoint inhibitors (ICI) for metastatic non–small cell lung cancer (mNSCLC), real-world treatment access, selection, time on treatment and transitions between regimens remain poorly characterized across health systems and patient populations. Whether observed outcomes are consistent across regions, data sources, and age groups is largely unknown. Addressing these gaps at scale requires a federated analytic approach with standardized analyses across sites, enabling reliable and comparable results while preserving patient privacy. **Methods:** We launched FALCON (Federated Alliance for Large-scale Cancer Observational Network), the largest federated, most diverse oncology network supporting observational cancer research, and its subnetwork FALCON-Lung. FALCON-Lung includes 23 sites (hospitals, registries, public-private) providing longitudinal cancer data from 2015 onwards standardized to OMOP common data model, from 11 countries in Europe, US and Australia. All sites completed data quality assessments and targeted improvements to improve completeness and overall cancer data quality. Analyses were executed locally using shared analytic code without sharing patient-level data. **Results:** Among 111,574 NSCLC pts included, 62% developed metastatic disease, of whom 59% initiated antineoplastic drugs within three months; 88% received a guideline-recommended 1st line regimen. ICI uptake rose sharply between 2017 - 2019; by 2022 59% received ICI (± platinum) in 1st line. ICI monotherapy showed a tendency toward longer overall survival (OS) compared with platinum (±ICI), although no single regimen demonstrated a consistent advantage across all databases. OS decreased with age across sites. Patients aged ≥81 years were less likely to receive systemic therapy and, when treated, more often received ICI monotherapy. No clear or consistent differences in OS were observed between different treatment regimens in this age group. **Conclusions:** In this global federated study, ICI uptake showed consistent patterns across sites and regions. OS varied across sites and no consistent survival advantage was observed for ICI regimens, either as monotherapy or in combination, although higher OS with ICI monotherapy was observed in some settings. Older patients (aged ≥81 years) were more frequently treated with ICI monotherapy without a corresponding survival advantage, possibly reflecting real-world treatment selection driven by tolerability rather than biomarkers. Coverage of subcutaneous versus intravenous oncology therapies by US commercial health plans. First Author: Sophie E. Knox, Center for the Evaluation of Value and Risk in Health at Tufts Medical Center, Boston, MA

Background: Several widely used intravenous (IV) oncology therapies have recently been reformulated for subcutaneous (SC) administration. Compared with IV infusions, SC formulations reduce administration time and chair use, improve patient convenience, and enable more flexible sites of care. At the same time, SC formulations may alter established reimbursement and contracting arrangements, including shifts away from buy-and-bill payment, changes in site-of-care management, and differences in how net costs are realized by payers. We examined how US commercial health plans prioritize SC formulations relative to IV formulations in their drug coverage policies. **Methods:** We used the Tufts Medical Center Specialty Drug Evidence and Coverage (SPEC) Database to identify US commercial health plans with coverage policies for both SC and IV formulations of oncology therapies. SPEC includes detailed treatment access criteria from 17 large US commercial health plans. Coverage policies were current as of December 2025. The unit of analysis was a plan-drug combination, e.g., UnitedHealthcare's policies for trastuzumab. Coverage was classified as *IV preferred*, *on par*, or *SC preferred*, depending on if one formulation is required before another. **Results:** We identified 86 coverage policies across 6 oncology therapies. One payer excluded the SC formulation from coverage in two instances, thereby denying enrollees access to the therapy. Among the remaining 84 policies, 8 (9.5%) were classified as *IV preferred* and 76 (90.5%) as *on par*; no policies classified the SC formulation as preferred (Table 1). Coverage varied across therapies, with the frequency of IV-preferred coverage among payers covering both formulations ranging from 0% to 21%. Among the 76 on-par policies, 55 (72.4%) allowed patients to initiate treatment with either the IV or SC formulation without prior treatment requirements. In contrast, 21 (27.6%) required patients to first try and fail an alternative therapy before coverage for either formulation was granted. These step-therapy requirements were more common for older therapies with available biosimilars, and the required prior therapy was most often a biosimilar of the reference product. **Conclusions:** Across six oncology therapies, most US commercial plans covered SC and IV formulations on par, with a minority preferring IV and none preferring SC. Preferences varied by product, and access restrictions mainly reflected step-therapy requirements for older therapies with available biosimilars. Research Sponsor: National Pharmaceutical Council.

Overview of coverage for intravenous (IV) and subcutaneous (SC) formulations.

Inpatient financial toxicity among women hospitalized with breast cancer in the United States, 2013–2022. First Author: Fathima Shehnaz Ayoobkhan, Trinity Health Oakland Hospital/Wayne State University, Pontiac, MI

Background: Financial toxicity is an increasingly recognized consequence of cancer care. While the outpatient costs of breast cancer are well described, national trends and drivers of inpatient financial toxicity are not well understood. We evaluated temporal trends in hospitalization volume, inflation-adjusted inpatient charges, and factors associated with high financial toxicity among women hospitalized with breast cancer in the United States. **Methods:** We performed a retrospective analysis of the National Inpatient Sample (2013–2022), including women aged ≥18 years with a breast cancer diagnosis. Survey weights, strata, and clusters were applied. Charges were inflation-adjusted to 2022 USD. High financial toxicity was defined as inpatient charges ≥75th percentile. Temporal trends were assessed using weighted regression, and multivariable survey-weighted logistic regression identified predictors of high financial toxicity. **Results:** An estimated 1.70 million weighted hospitalizations were identified. Annual hospitalizations declined significantly (P for trend <0.001), from 178,660 in 2013 to 168,630 in 2022, with a nadir in 2020. In contrast, mean inflation-adjusted inpatient charges increased by 35.5%, from $58,869 to $79,797 (P for trend <0.001), totaling more than $119.3 billion in cumulative charges. Most hospitalizations occurred at urban teaching hospitals (71.2%). On multivariable analysis, urban teaching (OR 3.84, 95% CI 3.58–4.12) and urban non-teaching hospitals (OR 3.53, 95% CI 3.28–3.79) had nearly four-fold higher odds of high financial toxicity compared with rural hospitals. Compared with White patients, Hispanic (OR 1.53), Asian/Pacific Islander (OR 1.44), and Black patients (OR 1.10) had higher odds. Private insurance (OR 1.14) and residence in the highest income quartile (OR 1.35) were associated with increased odds, while older age was associated with lower odds. Odds of high financial toxicity increased steadily over time, peaking in 2020 (OR 1.58) (P for trend <0.001). **Conclusions:** Despite declining hospitalization rates, inpatient financial toxicity among women with breast cancer has worsened substantially, driven primarily by hospital setting and structural factors. Racial and ethnic disparities were also evident, with minority groups experiencing higher odds of high inpatient charges. These findings underscore the need for value-based strategies and policy interventions to mitigate inpatient financial burden in oncology care. Research Sponsor: None.

1556 Poster Session

Geographic distribution of cancer treatment trials and population-level cancer outcomes in the U.S. First Author: Hong Xiao, Fred Hutch Cancer Center, Seattle, WA

Background: Access to cancer clinical trials varies geographically in the U.S., yet the relationship between trial availability and population-level cancer outcomes is poorly characterized. Understanding this relationship is critical for policymakers and trial sponsors seeking to reduce disparities in cancer outcomes. **Methods:** We conducted an ecological analysis of U.S.-based cancer treatment trials (1990–2025). Trial availability was measured using population-adjusted cumulative trial density (trials/10,000 population) and classified as none, low, medium, or high. County-level cancer mortality-to-incidence ratios (MIRs) were used to indicate post-diagnosis outcomes (lower MIR is better). Associations with trial density were assessed using logistic regression, with and without adjustment for the structural factors, including area deprivation index (ADI), health system performance, and area type (metro, micro, non-metro/non-core). Analyses were stratified by area type and ADI to stabilize estimates and assess associations across strata. **Results:** Between 1990 and 2025, 32,332 U.S.-based trials were conducted. The majority of counties (1,680, 52%; 10% of the U.S. population) had no trials. In counties with trials, counts ranged from 1 to 6,840 and density from 0.05 to 1,992 per 10,000 population. Compared to counties without trials, low-, medium-, and high-density counties were more likely to have lower MIR (OR = 1.9, 3.6, and 3.3, respectively; all $p < .001$). After adjustment for structural factors, associations persisted in medium- and high-density counties (OR = 1.7, 1.9; $p < .001$), but not in low-density counties (OR = 1.2; p = .30). Associations were strongest in metro counties (Table), with ORs of 1.91, 2.61, and 2.61 in high-ADI areas (all $p<0.0001$). In low-ADI areas, medium and high density were associated with lower MIR (OR=2.58 and 2.00; $p<.001$), but low density was not (OR=1.33; p=0.70). **Conclusions:** Cancer clinical trial availability in the U.S. is highly concentrated and strongly associated with improved population-level cancer outcomes. The co-occurrence of low trial density, structural deprivation, and higher cancer MIRs highlights opportunities to improve cancer outcomes by expanding the geographic reach of trial infrastructure. Research Sponsor: None.

Access to immunotherapy and molecular diagnostics for lung adenocarcinoma in Syria: A mixed-methods study from the country's main cancer center. First Author: Ayla Kouli, Damascus University- Faculty of Medicine, Damascus, Syrian Arab Republic

Background: Immunotherapy is now a standard-of-care treatment for lung cancer across most stages. Access to immunotherapy and molecular diagnostic tests in conflict-affected countries such as Syria remains poorly described. As the principal cancer center in Syria, Al-Bairouni University Hospital (ABUH) provides care for nearly three-quarters of all cancer cases nationally. We conducted this study to evaluate access to immunotherapy and molecular diagnostic services at ABUH. **Methods:** A mixed-methods study was performed between 2022 and 2024 at ABUH. This study included a retrospective cohort of all patients diagnosed with lung adenocarcinoma. Quantitative data included disease stage at diagnosis, molecular testing rates, and immunotherapy utilization. In addition, a qualitative patient survey was thematically analyzed to explore barriers to treatment access in a separate cohort of patients with mixed tumor types. **Results:** Among 2,920 patients diagnosed with lung cancer, 1,393 (47.7%) had lung adenocarcinoma. The median age at diagnosis was 61 years; 79.7% of patients were male. Smoking history was as follows: Current 792 (56.9%), Former 268 (19.2%), never smoked 318 (22.8%) At presentation, 3 patients (0.2%) had stage I disease, 40 (2.9%) stage II, 174 (12.5%) stage III, and 778 (55.8%) stage IV disease, staging was unknown for the rest of the patients. EGFR mutation testing was performed by ABUH for 226/1393 patients (16.2%) only, with positive results identified in 124 cases (8.9%). PD-L1 testing was conducted by ABUH in only 32/1393 patients (2.3%) and was positive in 23 (1.65%). Of all patients with lung adenocarcinoma, only 5 patients (0.6%) with stage IV disease received immunotherapy. All were treated with nivolumab. Thematic analysis of qualitative data (35 patients) revealed that high treatment costs and limited drug availability are the primary barriers to accessing immunotherapy. **Conclusions:** This study represents the first evaluation of access to immunotherapy for patients with lung cancer in Syria. Even at ABUH, the country's main cancer center, access to immunotherapy and molecular testing remains markedly limited. International collaboration is necessary to expand diagnostic infrastructure, standardize data reporting, and enhance financial protection mechanisms. These are critical steps toward achieving better cancer care in Syria. Research Sponsor: None.

1558 Poster Session

Assessment of CAR-T clinical trial availability and accessibility in the United States. First Author: Rahul Kumar Thakur, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has transformed outcomes in hematologic malignancies and is increasingly evaluated in solid tumors. CAR-T trials requires specialized infrastructure, potentially limiting access by geography and institutional concentration. We assessed the national distribution of CAR-T clinical trials, population distant from trial sites, and institutional clustering. **Methods:** All active U.S. interventional Phase I-III CAR-T trials (adult/pediatric) were identified via ClinicalTrials.gov (accessed January 2026). Trial locations were geocoded by ZIP code and linked to 2020 Census ZIP Code Tabulation Areas. Population access was defined as residence within 30 or 60 miles of a trial site using Haversine distance. Rurality (RUCA codes), income quartiles, and race/ethnicity (ACS 2023) were evaluated to assess disparities. Institutional concentration was assessed by the proportion of trial sites contributed by individual institutions. **Results:** Out of 264 identified trials, 189 were selected, conducted across 356 unique institutions. More than 85% of trials were early phase(Phase I–II), spanning lymphoma, myeloma, leukemia, and solid tumor indications. Access was limited. At a 30-mile radius, 43.3% of the U.S. population (~145 million individuals) lacked proximity to an active CAR-T trial site; 27.1% (~91 million) remained without access at 60 miles. Within 30 miles, lack of access affected 94.1% of rural residents, compared with substantially lower coverage in urban areas, and 63.2% of individuals in the lowest income quartile. By race and ethnicity, 37.4% of Hispanic and 32.0% of Black populations lacked access within 30 miles. These patterns were consistent when access was defined at 60 miles. Trial availability was highly centralized. The top 10 of institutions accounted for over 60% of all CAR-T trials, led by large academic centers such as City of Hope, Memorial Sloan Kettering, MD Anderson, Texas Children's Hospital, and Stanford University. These centers are located in major metropolitan regions, resulting in dense trial availability for populations living nearby while leaving large geographic regions without access. In contrast, approximately 60% of participating institutions hosted only a single CAR-T trial, indicating limited diffusion of trial infrastructure beyond major academic hubs. **Conclusions:** CAR-T clinical trial access in the United States is restricted by both geographic exclusion and marked institutional concentration. As CAR-T indications expand, addressing these structural bottlenecks will be critical to improving equitable access and ensuring broader participation in cellular therapy development. Research Sponsor: None.

Access to CAR-T clinical trials.

Population Group	30 mi	60 mi
Overall US Pop	43.3%	27.1%
Rural Pop	94.1%	65.6%
Lowest income quartile	63.2%	45.8%
Hispanic	37.4%	25.9%

20-year trends in socioeconomic disparities in breast cancer care for patients aged < 65 years old. First Author: Olivia Frances Lynch, National Clinician Scholars Program, Yale School of Medicine, New Haven, CT

Background: Socioeconomic disparities (SES) in cancer care have been well described, especially for younger patients with limited financial reserve and insurance vulnerability. It remains unclear, however, whether innovations in breast oncology have mitigated or exacerbated these gaps over time. We evaluated nearly 20-year trends across key breast cancer treatment and diagnostic modalities and sought to determine whether advances in care promote, or further undermine, health equity. **Methods:** Using the National Cancer Database, we identified working-aged individuals (18-64 yo) diagnosed with breast cancer from 2004–2022. As surrogates for improvements in breast cancer care, we examined: (i) Oncotype DX testing for stage I–II ER/PR-positive, HER2-negative disease; (ii) immediate breast reconstruction (IBR) after mastectomy; (iii) receipt of neoadjuvant chemotherapy (NACT) for stage II HER2-positive (HER2+) and triple-negative breast cancer (TNBC); and, (iv) immunotherapy by subtype and stage (2018–2022). We used multivariable logistic regression to generate adjusted predicted probabilities by median income quartile (MIQ) and year (or year group). Median Income Disparities (MID) were measured as the difference between the highest and lowest MIQ. **Results:** The final sample included 1,349,691 patients with mean age 51.8 (SD 8.64). Patient population included 7.7% Hispanic, 72.3% Non-Hispanic White, 13.2% Black, 5.9% Asian, and 0.9% unknown race/ethnicity. 76.7% of patients were privately insured, 10.8% Medicaid-covered, 6.2% Medicare-covered, 1.5% other, 1.8% unknown, and 3.1% uninsured. During the study period, overall adoption of treatment increased substantially over time, with SES disparities differing across modality. Oncotype DX testing demonstrated persistent income-related disparities across the study period (MID: 4.2–5.5%, $p<0.05$ for all). The largest and most durable inequities were seen in post-mastectomy IBR (17.60% in 2004-2008, narrowing to 11.70% in 2018-2022, $p<0.05$ for all). Receipt of NACT was associated with modest income-based differences that were greatest during years of rapid uptake for stage II HER2+ (4.9% in 2014–2017, $p<0.05$) and TNBC (4.8% in 2018–2022, $p<0.05$) breast cancer. Adoption of immunotherapy rose sharply from 2018–2022 across all incomes, with modest but narrowing gaps for stage III–IV disease (MID: 4.9% in 2019, $p<0.05$ to 1.1% in 2022,NS). Adjustment for insurance status did not significantly change socioeconomic gradients. **Conclusions:** Socioeconomic disparities in breast cancer care for women <65 years old vary markedly by treatment modality and adoption phase. Advancing equitable access to best-practice breast cancer care will require interventions at the health system, societal guidelines, and policy levels. Research Sponsor: None.

Clinical trial participation among adolescents and young adults diagnosed with cancer in the United States (2004-2021). First Author: Vianessa Andion Camargo, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Adolescents and young adults (AYAs, 15-39 years) have low historical participation in cancer clinical trials (CTs) than pediatric patients, which limits access to novel therapies and slows progress in outcomes. Although cooperative-group networks and AYA-focused initiatives have improved accrual, enrollment remains uneven across care settings and patient subgroups, highlighting the need for contemporary population-level estimates of participation and its predictors. **Methods:** The National Cancer Database was utilized to identify AYAs diagnosed between 2004 and 2021 with one of the 20 cancer types associated with the highest mortality. Patients with confirmed malignant neoplasms, known vital status, and ≥6 months of follow-up were included. The final analytic cohort comprised 865,923 patients. The primary endpoint was documented CT participation (yes/no). Multivariable logistic regression was used to estimate adjusted odds ratio (aOR) of enrollment by diagnosis epoch, age group, sex, race/ethnicity, insurance status, area-level education and median income, residence, Charlson-Deyo comorbidity score, and receipt of surgery, radiation, and systemic therapy. **Results:** Overall, 2,621 patients (0.3%) were enrolled in a CT. Enrollment increased from 0.1% (2004–2009) to 0.2% (2010–2013), 0.3% (2014–2017), and 0.5% (2018–2021); compared with 2004–2009, enrollment was higher in 2018–2021 (aOR: 4.92, 95% CI: 4.34–5.60). Compared to those aged <24 years, the odds of enrollment were lower for ages 25–29 (aOR: 0.52, 95% CI 0.46–0.58), 30–34 (aOR: 0.45, 95% CI 0.41–0.51), and 35–39 (aOR: 0.46, 95% CI 0.41–0.50). Enrollment was lower among non-Hispanic Black (aOR: 0.84, 95% CI 0.74–0.96) and Hispanic patients (aOR: 0.79, 95% CI: 0.69–0.90) compared to non-Hispanic White patients. Compared with uninsured patients, enrollment was higher among those with private (aOR: 1.74, 95% CI 1.38–2.21) or government insurance (aOR: 1.60, 95% CI: 1.26–2.05), and was also higher in areas with greater education attainment (aOR: 1.14, 95% CI: 1.03–1.25) and individuals in the high median income group (aOR: 1.13, 95% CI: 1.02–1.25). Patients who had received radiation (aOR 1.56, 95% CI 1.44–1.70) or systemic therapy (aOR 3.59, 95% CI 3.23–4.01) were more likely to enroll. **Conclusions:** CT participation among AYAs was exceedingly low but has increased over time. Differences in enrollment by age, race/ethnicity, insurance, and area-level socioeconomic measures suggest persistent barriers to CT access and participation. These findings support expanding trial availability beyond high-resource settings, strengthening AYA-focused referral pathways and infrastructure, and implementing equity-centered strategies such as navigation, reduced trial burden, and financial/insurance support to improve representation and access to investigational therapies. Research Sponsor: None.

Financial vulnerability among U.S. cancer survivors: Differences by veteran status and VA health care utilization in the National Health Interview Survey, 2020–2024. First Author: Aimee Pehrson, Titan Alpha, Chantilly, VA

Background: Current national comparisons of financial factors affecting cancer care among Veterans and non-Veteran adults with a self-reported history of cancer are limited. Moreover, little is known about how financial vulnerability influences Veterans receiving care primarily through the VA system versus in community settings. We hypothesize that Veteran status and primary care setting (VA vs. community) are associated with differences in financial vulnerability and related barriers to medical care among U.S. adult survivors of cancer. **Methods:** We pooled 2020–2024 National Health Interview Survey data (n=19,410) to examine associations between Veteran status, VA care use, and financial vulnerability among adult survivors from cancer (including non-melanoma skin cancer). Missing data were addressed using multiple imputation leading to an analytic sample size n=18,846. Survey-weighted logistic regression models accounted for complex sampling and adjusted for age, sex, cancer site, number of cancers, years since diagnosis, poverty ratio, and survey year. Analyses were limited to years when outcomes were collected. Two comparisons were conducted to understand the unique social factors Veterans face compared to non-Veteran patients and differences between primary setting of Veteran care: Model(A) Veterans vs. non-Veterans and (B) VA primary users vs. non-primary VA users. Binary outcomes included delayed care due to cost, delayed care due to transportation barriers, inability to afford care, unpaid medical bills, insurance gaps, medication cost-skipping, and inability to pay expenses. Sensitivity analyses compared weighted and unweighted models. **Results:** The analytic sample of adult survivors from cancer was n=18,846 from 2020–2024 (mean age 68 years; 43% male) and included 2,511 (13%) who self-reported as Veterans (mean age 74 years; 94% male). Adjusted models showed Veteran status was associated with higher odds in care delay due to transportation barriers (OR 1.57; 95% CI, 1.13-2.19) and lower odds of worry regarding unpaid medical bills (OR 0.79; 95% CI, 0.68-0.91) and difficulty obtaining medical care due to cost OR 0.78(0.63-0.98). All other compared variables were not significant. Among Veterans, those who primarily used the VA had lower odds of delaying care due to cost (OR 0.34; 95% CI, 0.17-0.69), not obtaining medical care due to cost (OR 0.50; 95% CI, 0.35-0.72), and skipping medication due to cost (OR 0.25; 95% CI (0.12-0.49). Sensitivity analyses supported these patterns. **Conclusions:** Veterans who are primarily VA users have cost-related vulnerability without a difference in delaying care to non-Veteran counterparts. Such systems that remove financial hardship may be an approach to improve care for survivors from cancer in the U.S. Research Sponsor: None.

Recovery with residual disparities: Real-world patterns of platinum chemotherapy use after the 2023 drug shortage. First Author: Omer Sayed Ashruf, Indiana University School of Medicine, Indianapolis, IN

Background: The 2023 national shortages of cisplatin and carboplatin disrupted standard cancer treatment across multiple malignancies. Although the acute effects have been described, patient-level evidence of recovery in platinum chemotherapy access after supply stabilization is limited. We evaluated real-world recovery in platinum initiation across platinum-dependent cancers. **Methods:** We conducted a retrospective cohort study using the TriNetX U.S. Collaborative Network. Adults with platinum-sensitive malignancies, including lung, ovarian, bladder, uterine, testicular, and head and neck cancers, were identified using ICD-10-CM and ICD-O codes and assigned according to the national platinum chemotherapy shortage timeline: shortage (February 10, 2023-January 31, 2024) and post-shortage (July 1, 2024-June 30, 2025) eras. The primary endpoint was time from cancer diagnosis to first receipt of any platinum chemotherapy (cisplatin or carboplatin), analyzed using Kaplan–Meier methods and multivariable Cox proportional hazards models, adjusted for demographic characteristics, NCI Comorbidity Index, risk factors, BMI, and cancer type. Secondary analyses evaluated agent-specific initiation (cisplatin vs carboplatin) and heterogeneity of recovery across cancer sites. Prespecified subgroup analyses assessed differences in recovery by sex and race/ethnicity within matched cohorts. **Results:** The analysis included 33,856 patients diagnosed during the shortage and 30,256 diagnosed post-shortage. Platinum initiation improved post-shortage compared with the shortage period (adjusted hazard ratio [aHR], 1.11; 95% CI, 1.09–1.14; p<.001), with median time to initiation decreasing from 206 to 128 days. This improvement was driven primarily by increased carboplatin initiation, while cisplatin initiation continues to stall. Recovery patterns varied by cancer type, with greater improvement observed in ovarian and head/neck cancers and incomplete recovery in bladder cancer. Across eras, slower platinum initiation was observed among older patients (aHR per year increase, 0.99), male patients (aHR 0.92), and racial/ethnic minority groups, including Black (aHR 0.92) and Hispanic patients (aHR 0.90). Comorbidities associated with platinum toxicity, such as CKD (aHR, 0.79), neuropathy (aHR, 0.63), heart failure (aHR, 0.93), and liver disease (aHR, 0.84), were also associated with delayed initiation. **Conclusions:** After resolution of the 2023 platinum shortage, platinum chemotherapy initiation improved across multiple cancers, providing patient-level evidence of recovery in access. However, recovery was heterogeneous, driven largely by carboplatin, and modified by patient clinical and demographic factors, suggesting that restoration of drug supply does not uniformly translate into timely or equitable recovery of standard-of-care treatment. Trends in incidence, survival, and cause of death in Kaposi sarcoma in the antiretroviral therapy era. First Author: Joseph Antony Elengickal, University of South Carolina School of Medicine - Prisma Health, Columbia, SC

Background: Kaposi sarcoma (KS) is a malignancy driven by human herpesvirus-8 infection and is most commonly associated with HIV. Although often considered indolent, KS can cause significant morbidity and mortality, particularly if HIV is uncontrolled. This study aimed to characterize current incidence and survival trends in KS using the Surveillance, Epidemiology, and End Results (SEER) Database. **Methods:** Cases of KS were identified using ICD-O-3 codes 9140-9143 in the SEER Research Plus Data (17 Registries, 2000-2022). SEER registry incidence rates were calculated over time. Overall survival (OS) across diagnostic eras was estimated using Kaplan-Meier methods. Multivariable Cox models were used to assess associations between race/ethnicity, neighborhood income, rural-urban status, and mortality, adjusting for age, sex, and year of diagnosis. Cause-of-death analyses were performed using SEER cause-specific recodes. **Results:** 9,931 patients with KS were identified, 91% male and 9% female. Racial and ethnic distribution was 45% non-Hispanic White (NHW), 24% Hispanic, 24% Black, 3.7% Asian/Pacific Islander (A/PI), and 0.7% American Indian/Alaska Native (AI/AN). Registry incidence of KS declined from 0.33 per 100,000 in 2000-2004 to 0.22 in 2015-2019 and 0.20 in 2020-2022. One-year OS in 2000-2004 was 77.3% (95% CI 75.7-78.9), in 2015-2019 was 82.2% (95% CI 80.4-83.9), and in 2020-2022 was 80.9% (95% CI 78.3-83.5). In multivariable analyses, Black patients had higher mortality compared with NHW patients (HR 1.55, 95% CI 1.43-1.67), while mortality did not differ significantly among Hispanic, A/PI patients, or AI/AN patients. Residence in the highest neighborhood income quartile was associated with improved overall survival compared with the lowest quartile (HR 0.81, 95% CI 0.73-0.89). Across 2000-2022, HIV/infectious causes accounted for 55.6% of deaths (95% CI, 53.9-57.2), followed by cardiovascular disease (15.1%) and cancer-related causes (13.3%). In cause-specific analysis, later year of diagnosis was strongly associated with lower HIV/infectious mortality (HR 0.96 per year, 95% CI 0.96-0.97), whereas mortality from cancer did not improve over time. **Conclusions:** In the modern antiretroviral therapy era, KS incidence and HIV-related mortality have declined. Despite these advances, inequities persist, with higher mortality observed among Black patients and persons residing in poorer neighborhoods. These findings highlight the need for focused efforts to address disparities in KS outcomes. Research Sponsor: None.

Adjusted hazard ratios for overall survival in Kaposi sarcoma.

Variable	Adjusted HR	95% CI	P value
Race/Ethnicity			
Non-Hispanic White	Reference	-	-
Black	1.55	1.43-1.67	<0.001
Hispanic	1.02	0.95-1.11	0.54
Asian/Pacific Islander	1.02	0.86-1.20	0.82
American Indian/Alaska Native	1.26	0.89-1.80	0.20
Neighborhood Income			
Highest vs Lowest Quartile	0.81	0.73-0.89	<0.001

Fertility concerns, counseling, and preservation in AYA females with early-stage breast cancer: Chemotherapy receipt and timing. First Author: Bolun Liu, Department of Hospital Internal Medicine, Mayo Clinic Health System, Mankato, MN

Background: Adolescent and young adult (AYA) females with early-stage ER-negative and/or HER2-positive breast cancer commonly receive chemotherapy to reduce risk of recurrence. Fertility concerns, counseling, and preservation may influence chemotherapy decisions and time to chemotherapy (TTC) initiation. **Methods:** We surveyed AYA survivors of stage I–III premenopausal ER-negative and/or HER2-positive breast cancer treated at Kaiser Permanente Northern and Southern California (2013-2022). Fertility concerns were defined as not having completed desired family size or being unsure about having completed desired family size at diagnosis. We summarized receipt of fertility counseling, receipt of chemotherapy, and use of oocyte/embryo cryopreservation for fertility preservation (FP). Among fertility-concerned patients who received chemotherapy, TTC (days from diagnosis) was assessed separately for neoadjuvant chemotherapy (NAC) vs for adjuvant chemotherapy (AdjC). Time to NAC was natural log–transformed and modeled with multivariable log-linear regression to estimate relative differences in TTC, adjusting for stage, study site, ER, HER2, age, and diagnosis year. **Results:** Of 363 respondents, 197 (54%) had fertility concerns at diagnosis; 183/197 (93%) received chemotherapy, similar to 153/166 (92%) among those without concerns (p=0.7). Of the concerned chemotherapy recipients, 45 (25%) saw a fertility specialist but did not pursue FP while 55 (30%) underwent FP. For the 112 fertility-concerned NAC recipients, FP was associated with longer TTC than no fertility specialist counseling (mean=41 vs. 30 days; adjusted ratio=1.39; 95% CI 1.15–1.69), whereas fertility specialist counseling without FP was not (mean= 31 vs. 30 days, adjusted ratio=1.04; 95% CI 0.86–1.25). For the 71 fertility-concerned AdjC recipients, TTC was similar for patients who did not see a fertility specialist (mean=63 days), those who froze oocytes/embryos (mean=65 days), and those who saw a fertility specialist but did not pursue FP (mean=69 days). **Conclusions:** In this AYA breast cancer cohort, there was no evidence that fertility concerns led patients to decline chemotherapy. FP was associated with a modest delay in NAC initiation (<2 weeks on average). Research Sponsor: National Cancer Institute; P01CA233432.

Time to chemotherapy (TTC) among 183 AYA patients with ER− and/or HER2+ breast cancer and fertility concerns.

Fertility-focused care	N (n=183)	Neoadjuvant chemotherapy (n=112)	Mean TTC, days	Relative difference in TTC, adjusted ratio (95%CI)	Adjuvant chemotherapy (n=71)	Mean TTC, days
No fertility counseling from a specialist	83 (45%)	55 (49%)	29.6	Reference	28 (39%)	62.6
Received fertility counseling from a specialist						
No fertility preservation	45 (25%)	28 (25%)	30.7	1.04 (0.86,1.25)	17 (24%)	68.6
Fertility preservation	55 (30%)	29 (26%)	41.2	1.39 (1.15,1.69)	26 (37%)	64.6

Impact of the Taylor Cancer Research Center (TCRC) and Tempus AI TIME Partnership on clinical trial start-up and accrual. First Author: John Nemunaitis, Taylor Family Research Foundation, Maumee, OH

Background: TCRC is a nonprofit oncology community practice serving patients in Northwestern Ohio. TCRC's partnership with the Tempus AI TIME program leverages proprietary software and nursing teams to support patient matching across a portfolio of industry-sponsored clinical trials. Trials may be rapidly opened "prospectively" before an eligible patient is identified, or "just-in-time" (JIT) once a patient is identified and ready to consent, allowing studies to be activated in response to patient need. The goal of this partnership is to utilize AI-enabled technology and clinical workforce support to alleviate site burden associated with activating and enrolling patients to oncology clinical trials, thereby increasing patient access to novel therapies and optimizing resource utilization. **Methods:** Tempus' AI-enabled platform analyzes trial eligibility criteria and compares this against patient-level information from a combination of structured EMR data, natural language processing, and large language models. All patients are evaluated against the full TIME trial portfolio nightly, with potential matches reviewed by Tempus nurses. Patients likely to be eligible for a trial are communicated to TCRC for final confirmation. Trials are rapidly activated through a standardized operational model including a pre-negotiated clinical trial agreement, rate card, and central IRB. Program metrics include number of patients pre-screened, trial activation timelines, and trial consents. **Results:** From June 2024 to August 2025, Tempus nurses spent approximately 219 hours pre-screening 1,195 patients from TCRC, yielding 278 potential matches across 92 TIME trials. TCRC activated 16 TIME trials, leading to a total of 66 consents. Within the same time, TCRC activated 9 non-TIME trials resulting in 30 consents. TIME trials averaged 4.1 consents per trial, compared to 3.3 consents for non-TIME trials. TIME activations averaged 10.5 business days for JIT and 15.9 days for prospective trials, versus 55.4 days for non-TIME trials. **Conclusions:** TCRC's partnership with the Tempus AI TIME program, including enhanced patient pre-screening resources and rapid trial activation model, reduced trial start-up time with an increase in total consents and consents per trial compared with traditional trials. TCRC activated TIME trials 4x faster with a 2x increase in interventional consents and 120% increase in overall consents compared with non-TIME studies. This demonstrates how AI-enabled trial matching, combined with a streamlined operational model, can improve resource utilization and patient access to precision oncology trials in a community setting. Research Sponsor: None.

	Average activation time (days)	Interventional trials	Consents per trial (interventional)	Observational trials	Consents per trial (observational)	Total consents	Consents Per Trial
TIME	13.7	12	2.3	4	9.8	66	4.1
Non-TIME	55.4	6	1.1	3	7.6	30	3.3

1566 Poster Session

User-centered design of a COPD care pathway embedded in oncology care for patients receiving immune checkpoint inhibitors. First Author: Thomas William Lycan Jr., Wake Forest University School of Medicine, Winston-Salem, NC

Background: Chronic obstructive pulmonary disease (COPD) is one of the most common comorbidities among patients treated with an immune checkpoint inhibitor (ICI) for cancer, and it is often underdiagnosed and undertreated. We aimed to assess COPD treatment burden among patients with cancer and design a scalable intervention. **Methods:** This mixed-methods study enrolled (1) patients with confirmed/suspected COPD and ICI-treated cancer, and (2) clinicians providing ambulatory cancer or COPD care. Semi-structured surveys assessed treatment burden, self-confidence in COPD care, and barriers. Interviews, guided tours, and focus groups informed the user-centered design of a novel COPD care pathway, and the primary endpoint was participant-perceived feasibility. Qualitative analysis used a matrix approach informed by interview-guide constructs and emergent concepts, with quotations synthesized iteratively. **Results:** Between Feb-Dec 2025, the study team screened 478 individuals to enroll the planned cohort of 100 participants, including 20 patients and 80 clinicians. Nearly all participants completed a survey (n = 96), and 36 completed either an interview, tour, or focus group. Most patients reported their diagnosis of COPD had been confirmed (90%), and all were ≥50 years old. Clinicians were nurses (47%), physicians (44%), or APPs (6%); 41% practiced at a community oncology clinic. Most patients would use COPD-related services if integrated into oncology visits (75%) and 65% felt they had effective treatment options for both cancer and COPD. Nearly all clinicians (97%) agreed that COPD increased the risk of complications during cancer treatments, and 59% agreed that COPD care should be addressed within oncology clinics. Although most reported feeling confident in managing COPD in patients with cancer (80%), many reported a lack of skills to do so (e.g., teaching inhaler technique, 34%). Commonly cited barriers were insufficient time (63%), limited availability of COPD providers (65%), and COPD medication costs (50%). Qualitative analysis identified key themes: limited awareness of COPD guidance in oncology; resource constraints in community clinics; reliance on specialist referrals; conditional willingness to implement a COPD pathway if it did not detract from cancer care; and needs for educational materials and interoperable electronic medical records. These integrated datasets informed the design of a COPD care pathway to be embedded within oncology infusion visits using flowchart-based decision support to stratify COPD control (green/yellow/red) and support self-management and targeted clinician education at the point of care. **Conclusions:** COPD imposes a substantial treatment burden on patients with cancer, but there are actionable opportunities for care delivery. A user-centered COPD care pathway was designed for feasibility in community oncology settings. Greening a chemotherapy day ward. First Author: Alannah Kelly, School of Medicine, University College Cork, Cork, Ireland

Background: Cancer care is climate toxic and contributes to the triple planetary crisis which threatens human health and cancer care delivery. Despite this toxicity, sustainability guidelines in oncology are lacking. Our objectives are based on the sustainability touchpoints identified in previous research in our department. Study aims were to understand prescribing patterns, quantify plastic waste, and assess patients' and healthcare professionals' views on acceptability of proposed "green" strategies with the aim to develop a green prescribing checklist. **Methods:** A prospective review of systemic anticancer therapy (SACT) delivery at a tertiary oncology outpatient unit was performed. Variables collected included SACT regimen details, dosing interval extensions, supportive medication details and treatment value as rated by the ESMO-Magnitude of Clinical Benefit Scale (ESMO-MCBS). Daily plastic waste output was measured. Anonymous surveys of patients and healthcare professionals were developed using previously validated questionnaires and circulated among adult patients attending cancer services locally and cancer care professionals nationally. Survey domains included sustainability knowledge, perceived barriers/facilitators, and willingness to adopt sustainability measures such as oral therapy. Findings were reported using descriptive statistics. Institutional and ethical approval was received prior to study commencement. **Results:** Selected findings show 23% (n=200/864) of supportive medications were given intravenously (IV). There was widespread adoption of subcutaneous formulations and extended dosing intervals. Most regimens with ESMO-MCBS scores showed substantial clinical benefit. Each patient attendance generated a mean of 46 grams of plastic waste. Seventy-two healthcare professionals responded to the survey; 97% (n=70/72) agreed that climate change adversely impacted human health and 82% (n=59/72) agreed that sustainable practices can decrease the effects of climate change yet only 15% (n=11/72) reported routinely considering environmental impacts when prescribing. Barriers to sustainable practices included time 65% (n=47/72), inadequate training 61% (n=44/72) and lack of institutional support 63% (n=45/72). A total of 211 patients submitted responses; 91% (n=190/208) agreed that reducing environmental impact should be a priority for hospitals, and 82% (n=159/194) were in favour of oral medications over IV where appropriate. **Conclusions:** This study, integrating provider and patient perspectives, demonstrates support for sustainable practices in oncology, but ad-hoc current implementation of same. The findings will guide development of a green checklist informed by patients and prescribers, followed by implementation and re-audit. Patient-centred strategies can align high value cancer care with planetary health and fill the current gap in sustainable oncology practice. Research Sponsor: Health Service Executive.

Accelerated diagnostic pathway for undifferentiated malignancy via interventional radiology triage: A comparative effectiveness study. First Author: Suken Shah, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Efficiently triaging patients presenting with imaging findings suggestive of malignancy but lacking a definitive tissue diagnosis poses a considerable challenge for large cancer centers. Without a tissue diagnosis in the setting of metastatic disease it is unclear which specialized medical oncologist would be the optimal physician to see the patient. Traditional referral patterns may lead to significant diagnostic delays until the patient reaches the appropriate oncologist. We evaluated the efficacy of a dedicated "Rapid Biopsy" (RB) pathway, which directs such patients immediately to the Interventional Radiology (IR) Outpatient Clinic for streamlined, image guided diagnosis and compared this new pathway to the traditional, standard institutional referral approach. **Methods:** This retrospective cohort study included 1157 patients at Memorial Sloan Kettering Cancer Center (MSKCC) who underwent a first diagnostic biopsy between 2020 and 2023. The cohort comprised 532 patients from the prospectively enrolled RB program and 625 patients in a rigorously matched comparison cohort (CC), derived from standard referrals who presented with an "unknown primary" malignancy, excluding any patient with a history of prior tissue sampling or recurrence. The primary endpoints were the mean time from initial consultation to biopsy and the mean time from initial consultation to treatment initiation. Independent t-tests were used for cohort comparison. Patients exhibiting outlier time-to-treatment intervals exceeding 90 days were excluded from the treatment analysis. **Results:** The RB and CC cohorts were well-matched demographically (mean age RB: 65.75 years; CC:66.05 years). Malignancy was confirmed in 90.4% and 92.3% of the respective cohorts. The RB pathway demonstrated a 71% reduction in time from initial consult to biopsy than the CC (4.59 vs 15.66 days, $p<0.001$), representing an 11.07 reduction. Furthermore, this operational efficiency translated into a 63% reduction in time from initial consult to treatment compared to the CC (14.57 vs 39.88 days, $p<0.001$), achieving an 11.88 day reduction in time to start. **Conclusions:** The dedicated Interventional Radiology first Rapid Biopsy pathway provided a clinically significant meaningful acceleration in the cancer diagnostic and treatment process, saving 11 days from consult to biopsy and nearly 12 days to definitive treatment initiation. This model effectively streamlines care by eliminating multi-specialty diagnostic detours prevalent in traditional triage, establishing a crucial operational standard for comprehensive cancer centers managing new suspected malignancies. Research Sponsor: None.

Patient-reported performance status as a predictive tool for mortality and supportive care needs in patients with advanced cancer. First Author: Manan P. Shah, Division of Hematology-Oncology, University of California, Los Angeles, Los Angeles, CA

Background: Performance status is a key prognostic factor among patients with advanced cancer and can inform the need for supportive care services. However, assessment and documentation of performance status is inconsistently integrated into standard oncology care. Patient-reported performance status (PRPS) is a surrogate for clinician-assessed performance status and has the potential to address this challenge. We piloted a decision support tool in our electronic health record (EHR) that uses PRPS to prompt clinician assessment of performance status and suggest referrals to supportive care services. **Methods:** We identified patients with advanced cancer using a pre-built and validated registry driven by ICD codes in our EHR (EPIC). For patients with advanced cancer seen at one of our clinics, a multiple-choice question with options derived from the Eastern Cooperative Oncology Group (ECOG) scale in patient-friendly language was added to the pre-visit questionnaire sent electronically prior to oncology visits. For patients with a poor PRPS (2 or greater), a clinical decision support tool alerted providers of the patient's self-reported performance status, encouraged input of the clinician's ECOG assessment, and suggested referral orders to supportive care services such as palliative care, nutrition, and social work. We assessed the relationship between PRPS and ECOG with mortality using logistic regression and by calculating median time to death stratified by patients' highest (poorest) score. **Results:** Between 3/11/24 and 3/11/25, 3,376 PRPS surveys were completed by 1,343 oncology patients. Seventeen percent of patients reported poor PRPS ($\geq$2). Worsening PRPS was strongly associated with mortality (3% for PRPS 0 vs. 44% for PRPS 4) and with shorter median time-to-death (163 days for PRPS 0 vs. 19 days for PRPS 4). PRPS correlated with clinician-assessed ECOG (ρ=0.3, $p<0.001$) and predicted mortality (ρ=0.8) comparably with ECOG (ρ=0.7). By contrast, ECOG documentation by clinicians was incomplete in 39% of patients. **Conclusions:** Results suggest feasibility of a PRPS-driven decision support tool to flag patients with advanced cancer and declining function at greatest risk of mortality. PRPS can help allocate limited supportive care resources and prompt advance care planning discussions for patients with greatest need. Research Sponsor: None.

Impact of a patient-facing app to address surgical oncology patients' social determinants of health: Preliminary results of a phase II clinical trial. First Author: Ying Sun, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: Unmet Social Determinants of Health (SDH) needs, including housing, transportation, food insecurity, utilities, and social support, are associated with adverse outcomes in cancer care, including delays in treatment, missed appointments, and hospital readmissions. Few interventions have been rigorously evaluated to address these SDH needs in surgical oncology populations. We conducted a Phase II randomized controlled trial to evaluate whether a patient-facing mobile application (Carealth), integrated with a follow-up resource referral platform (findhelp.org), could improve clinical and process outcomes compared to a "sham" app that included an attention-control (static CDC site). **Methods:** We enrolled adult patients with cancer (or suspected cancer) scheduled for surgery at three large U.S. centers. Participants were randomized to Carealth (intervention) or sham (control). We assessed 30-day readmission after surgery, distribution of where resources were sought among interventions clients (among those with baseline needs), time from consultation to surgery, and missed/rescheduled visits within 90 days. Analyses used descriptive statistics, Fisher's exact tests and crude odds ratios for readmission, Kaplan–Meier/log-rank methods for time to surgery, and proportional odds models for missed visits, under an intention-to-treat framework. **Results:** Of 585 patients screened, 161 were randomized (81 intervention, 80 control). Baseline characteristics were well balanced, with 17% reporting at least one SDH need at baseline. App uptake was 80% overall. Thirty-day readmissions were rare and similar between groups, occurring in 5 of 80 patientsOR 1.64, p = 0.72). Median time to surgery was 45 days in the intervention group vs 49 days in controls (log-rank p = 0.42). Missed/rescheduled visits within 90 days did not differ (proportional OR 1.28, p = 0.79). Among participants with SDH needs, multiple resource pathways were used, including counselor or patient navigator services, community or online resources, and the Carealth app; a subset reported partial or complete resolution of needs through the app. **Conclusions:** In this Phase II trial, an SDH-focused patient-facing app achieved outcomes comparable to standard-of-care navigation with respect to readmissions, time to surgery, and appointment adherence. While underpowered for rare clinical events, the intervention demonstrated high uptake and sustained patient engagement, supporting its potential role as a scalable, low-resource adjunct to existing support and navigation services. Larger trials enriched for patients with unmet SDH needs are warranted to assess clinical and health-system impact. Clinical trial information: NCT06688513. National implementation of electronic patient-reported outcomes (ePROs) for remote symptom monitoring in oncology: The OncoPRO initiative. First Author: Ethan Basch, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Remote symptom monitoring with electronic patient-reported outcomes (PROs) during cancer care improves quality of life, reduces acute care events, lengthens time on treatment, and can improve survival. US oncology practices are increasingly implementing PROs, but barriers to implementation remain. To facilitate uptake of PROs, the OncoPRO Initiative was established as a national PRO learning collaborative with funding from PCORI, in partnership with ASCO, the American Cancer Society, the PROTEUS Consortium, federal agencies, practice networks, and the major EHR and PRO software vendors. Oncology practices/health systems may join OncoPRO at no cost if they are committed to implementing PROs and can submit implementation metrics for monitoring progress. Practices are sorted into "affinity groups" by EHR and PRO software systems. Affinity groups meet monthly, led by coaches from the ASCO, PRO experts, and representatives of respective technology companies. Affinity groups follow a curriculum of key topics in PRO implementation, exchange training materials and information about facilitators and experiences, and provide feedback to software vendors. Little is known on how such learning collaboratives can support PRO growth. **Methods:** Implementation measures and characteristics were identified to quantify progress including the total number of practices joining, the phase of these practices (early implementation, scale-up, maintenance), topic areas for support requested by practices, number of personnel trained for PRO at practices, number of patients enrolled in PRO at practices, and proportion of enrolled patients completing PRO surveys. Data were collected via direct EHR data transfers and surveys. **Results:** Since 3/1/2024, 23 community and academic oncology practices/health systems have joined OncoPRO, across 23 different states, among which 13 practices were in early implementation, 7 in scale-up, and 5 in maintenance. These practices were sorted into four monthly affinity groups, in which the most commonly requested topics were: personnel roles/responsibilities; workflow; patient/clinician engagement; key performance metrics; technology customization; integration with quality programs; symptom management pathways; and billing/coding. Practice participation in monthly meetings has been 100%. Data are available from 12 initial practices, which collectively enrolled 47,052 patients over their initial 15 months of the program, with 24,566 patients (52%) completing at least one PRO survey. **Conclusions:** The OncoPRO learning collaborative is successfully supporting practices across the US to implement PROs, with strong practice engagement and high patient participation. Achieving epidemiologically representative enrollment and social determinants of health in the phase III evERA Breast Cancer study (NCT05306340). First Author: Gregory A. Vidal, West Cancer Center and Research Institute and University of Tennessee Health Sciences Center, Germantown, TN

Background: Clinical trials have historically under-enrolled patients (pts) from racial and ethnic minority groups, resulting in study populations that do not reflect the epidemiology of cancer in the United States (US), limiting generalizability of the findings. In parallel, social determinants of health (SDOH) are increasingly recognized as key drivers of cancer outcomes, yet are infrequently collected in oncology trials due to operational, ethical, and privacy concerns. The Phase III evERA breast cancer (BC) study (Mayer et al ESMO 2025) was intentionally designed to address both challenges through proactive enrollment strategies and prospective SDOH data collection. **Methods:** evERA BC is a global study in pts with ER+, HER2− advanced BC. In the US, a multi-pronged operational strategy was implemented to achieve epidemiologically representative enrollment, including expanded and pragmatic eligibility criteria, prioritization of community-based sites, real-time enrollment monitoring, patient navigation and financial support, and advocacy partnerships. A tailored survey assessing 5 key social determinants of health (education, income, employment status, marital status, insurance type) was offered to US pts to support a protocol-specified exploratory SDOH efficacy objective. **Results:** The multifaceted operational enrollment strategy used in the evERA BC study resulted in a US cohort (n=144 of total accrual 373) whose racial and ethnic composition exceeded SEER epidemiologic distributions for ER+, HER2− advanced BC for African American (AA) (12.5% vs 11.1%), Asian (9% vs 5.7%), and Hispanic (H) pts of any race (16% vs 8.9%). Enrollment for the aggregate White race (71.5%) and non-Hispanic (NH) ethnicity (83.3%) categories were slightly lower than SEER estimates for White race (82.9%) and NH ethnicity (91.1%). These enrollment patterns contrast with historic Phase III BC trials, in which AA pts typically comprise $<$5% and H pts $<$9% of enrolled populations. Of the 144 U.S. evERA BC pts, 128 (89%) completed the optional SDOH survey, demonstrating feasibility of SDOH data collection in a clinical trial setting and informing evaluation of potential trends and associations with outcomes. **Conclusions:** The evERA study demonstrates that key operational strategies can achieve epidemiologically representative enrollment while enabling robust and compliant SDOH data collection in oncology clinical trials. These findings provide a practical roadmap for industry sponsors seeking to improve recruitment of underrepresented populations and to generate more clinically meaningful and generalizable evidence by integrating social context into trial design and data interpretation. Clinical trial information: NCT05306340. Research Sponsor: F. Hoffmann-La Roche Ltd.

1573 **Poster Session**

Implementation of an expedited cancer workup clinic for uninsured patients at a metropolitan safety net hospital. First Author: Dominick Zheng, Harbor-UCLA Medical Center, Torrance, CA

Background: Timely evaluation of patients with suspected cancer is essential; yet delays in diagnosis and treatment remain common in safety-net health systems, particularly for uninsured or underinsured patients. Such delays are associated with advanced stages of disease at the time of diagnosis and increased mortality. While inpatient evaluation can facilitate multidisciplinary coordination, it is associated with higher costs. Outpatient delivery models designed to expedite cancer workups have been demonstrated to reduce time to diagnosis and number of hospitalizations. We describe outcomes from an Expedited Workup Clinic (EWC) in a large Los Angeles County safety-net hospital. **Methods:** The EWC was designed to coordinate outpatient imaging, biopsy, and oncology specialty referrals for vulnerable patients with suspected malignancy. All patients were uninsured and lacked a primary care provider. Referrals originated from the Emergency Department (ED), Urgent Care, or inpatient admissions. We retrospectively analyzed outcomes from 2022 to 2025 using real-world data extracted from the Electronic Health Record. **Results:** 255 patients were referred to the EWC encompassing 153 men (60%) and 102 women (40%). 155 patients (60%) were Hispanic/Latino, with other represented ethnicities including 28 (10.9%) Asian/Pacific Islander, 22 (8.6%) Black/African American, and 14 (5.5%) White/Caucasian. Spanish was the preferred language of 150 patients (58.8%). The majority of patients (87.9%) were referred from the ED with a median time to first EWC appointment of 11 days (IQR 7-14). From the first EWC appointment, the median time to imaging was 6 days (IQR 1-14), to biopsy was 21 days (IQR 12-54), and to initiation of oncologic treatment was 51 days (IQR 34-83). 92 patients (36.1%) ultimately had a negative malignancy workup, and 38 patients (14.9%) were lost to follow-up. Among patients with confirmed malignancy, the most commonly identified primary sites were colorectal (19.2%), lung (10.6%), hematologic (9.6%), pancreatobiliary (9.6%), prostate (6.7%), head and neck (6.7%), hepatic (6.7%), renal (4.8%), gynecological (3.8%), melanoma (3.8%) and breast (3.8%). **Conclusions:** The EWC demonstrates the feasibility of providing timely malignancy evaluation for high-risk, uninsured patients within a resource-limited setting. These findings support the use of an outpatient rapid evaluation clinic, while surfacing opportunities for improvement including reducing the number of patients lost to follow-up. Further evaluation of cost-effectiveness and access barriers may continue to strengthen the design of rapid workup clinics meant to serve our most vulnerable patients. Research Sponsor: None.

PRiMAL (precision randomized clinical trial comparing MTB assisted care to usual care): Quality of life analysis in patients with newly diagnosed non-small cell lung cancer (NSCLC). First Author: Jill M. Kolesar, University of Iowa, Iowa City, IA

Background: Precision medicine—tailoring cancer treatment to a tumor's genomic profile—is more effective and less toxic than traditional chemotherapy. However, its use in community oncology remains limited. Molecular Tumor Boards (MTBs), interdisciplinary teams that interpret genomic data and guide treatment, have improved precision medicine adoption and clinical outcomes, especially in academic centers. However, MTBs are less accessible in community practices, where most cancer care is delivered. **Methods:** The PRiMAL trial is a prospective, parallel-group, cluster randomized trial, comparing MTB assisted care (MTB-AC) to usual care in 10 community medical oncology practices aligned with the Markey Cancer Network. MTB-AC included nurse navigator assistance with next generation sequencing (NGS) ordering, MTB referral, and communication with treating oncologists. Usual care allowed access to the MTB at the discretion of treating oncologist. Eligible patients had untreated stage IIb-IV NSCLC. The co-primary endpoints were 1-year overall survival and health related quality of life (QOL) as measured by the Functional Assessment of Cancer Therapy (FACT) Trial Outcome Index-Lung Cancer (FACT-L TOI), FACT-G, and FACT-L Cancer (FACT-L) administered at baseline, 8 weeks and 12 weeks after treatment initiation. A multilevel linear mixed-effects model was used to estimate the intervention effects for the QOL outcomes while controlling for demographic, clinical, and socioeconomic covariates. **Results:** At the data cut-off of 1/12/26, 405 pts were included for assessment of QOL at baseline (MTB, n=250; usual, n=155). Baseline demographics and disease characteristics were similar for sex, age, race, ethnicity, histology, stage and performance status. QOL assessments were completed by 292 patients at 8 weeks and 245 patients at 12 weeks; MTB-AC patients experienced numerically greater declines at 8 weeks compared to usual care (FACT-L TOI: -2.7 vs -0.5; FACT-G: -1.9 vs 0.50; FACT-L: -1.4 vs 1.1), but these differences were not significant. Between weeks 8 and 12, QOL was estimated to have declined in usual care patients while MTB-assisted care patients improved, FACT-L TOI (3.28, 95% CI: 0.10 to 6.46); FACT-G (between-group difference: 3.97, 95% CI: 0.56 to 7.38); and FACT-L (4.70, 95% CI: 0.58 to 8.81). Survival is immature. **Conclusions:** The preliminary analysis showed that MTB-AC demonstrated significant, and in some cases clinically meaningful, improvement in QOL between weeks 8 and 12 after treatment across all three FACT measures compared to usual care, suggesting a delayed but meaningful benefit of MTB-AC. Clinical trial information: NCT05254795. Research Sponsor: Eli Lilly.

Addressing health-related social needs for cancer patients: An implementation assessment. First Author: Samuel Woo, Albert Einstein College of Medicine, Bronx, NY

Background: Health-related social needs (HRSNs) are associated with delayed diagnosis and treatment, worsened quality of life, and higher recurrence and mortality rates for cancer patients. Health systems are beginning to recognize the tremendous impact of HRSNs by recommending standardized HRSNs screening and referral in cancer care. Further research is needed to effectively design and implement HRSNs interventions for cancer patients. We evaluated the implementation of a novel community health worker (CHW) referral and navigation intervention to address unmet HRSNs in a National Cancer Institute (NCI)-designated comprehensive cancer center serving a highly disadvantaged community of patients in Bronx County, NY. **Methods:** We conducted a retrospective study of cancer patients utilizing data from HRSNs screenings, clinician CHW referral orders, and CHW navigation services between October 2023 and March 2025. Patients were identified as eligible for CHW assistance if they were screened for and self-reported at least one unmet HRSN. We organized process and outcome measures using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) implementation framework and evaluated measures through descriptive statistics. **Results:** There were 30 cancer center clinical practices who adopted the HRSNs screening tool. A total of 8,591 patients were screened for unmet HRSNs, with 20.5% self-reporting at least one unmet HRSN. Of those with at least one unmet HRSN (n=1,758), 43.4% were referred to CHWs by clinicians. Referral rates to CHWs ranged from 26-55% by clinical practice. Of patients referred to CHWs, 794 (64.5%) were assisted with HRSNs navigation by CHWs, with the most common HRSNs identified as financial (50.3%), housing (48.7%), and food insecurities (45.5%). CHWs were successful in outreaching referred patients (95.5%) in a timely manner (Median: 3 days from referral order, IQR: 1-6 days), connecting patients to at least one social service (98.9%), and resolving or improving at least one social need (97.6%). The median annual cost to implement and maintain the CHW referral and navigation intervention to address unmet HRSNs was $345.58 per patient. **Conclusions:** Implementation of CHW referral and navigation services within an NCI-designated comprehensive cancer center was feasible and effective in addressing unmet HRSNs within a safety-net cancer population. CHWs were successful in reaching patients and connecting them with essential social services that helped to resolve their HRSNs. Further research is needed to improve clinician screening and referral and understand the impact of CHW navigation on oncologic care delivery and clinical outcomes. Research Sponsor: None.

Identifying patients at risk for non-receipt of guideline-concordant treatment in pancreatic cancer using electronic health record data and machine learning. First Author: Annabelle Fonseca, University of Alabama at Birmingham, Birmingham, AL

Background: Non-receipt of guideline-concordant treatment (GCT) for pancreatic cancer is associated with worse outcomes and occurs disproportionately in safety-net settings. Timely identification of patients at risk using traditional approaches remains challenging. We developed machine learning (ML) risk prediction models using electronic health record (EHR) data available at presentation to predict non-receipt of GCT and support targeted navigation. **Methods:** We conducted a retrospective analysis of patients with pancreatic cancer treated at two safety-net hospitals in Alabama from 2018-2022. GCT was defined based on NCCN guidelines. Candidate predictors included demographic, clinical, laboratory, access-to-care and healthcare utilization variables available at presentation. Primary outcome was non-receipt of GCT. Data were split into stratified 80/20 training and test sets given class imbalance (2/3rd received GCT). Feature engineering was applied to reduce overfitting from high-cardinality variables. Classification and Regression Tree (CART) analysis was used to explore feature interactions and rank predictors. Multiple ML models were trained using PyCaret with default hyperparameters. Model performance was evaluated on the test set, with recall prioritized to reflect a screening use case in which false positives were acceptable. **Results:** Of 902 patients, 67.5% (n=609) received GCT. CART identified 30 candidate features. Highly ranked features included Area Deprivation Index, age, albumin, time from symptom onset to start of workup, employment status, presence of primary care physician, BMI and ECOG performance status. Performance metrics of the top 5 models are summarized in Table 1. Across models, test-set accuracy ranged from 72.9% to 86.2%, and recall for non-GCT ranged from 35.6% to 61.0%. Light Gradient Boosting model demonstrated the strongest overall screening performance, achieving the highest recall (61.0%), precision (94.7%), F1 score (0.74), and AUC (0.94). **Conclusions:** ML models using EHR data readily available at presentation can identify patients at high risk for non-receipt of GCT, driven in part by modifiable access-to-care and social vulnerability factors. Integration of these models into EHR workflows could enable automated risk flagging at diagnosis and trigger early referral to navigation and supportive services, with the potential to improve treatment delivery and outcomes. Research Sponsor: U.S. Department of Defense.

Real-world implementation of an integrated exercise medicine model within routine oncology care. First Author: Lauren Whiting, Lift Cancer Care Services, Kurralta Park, SA, Australia

Background: Exercise is an evidence-based intervention for people with cancer, with demonstrated benefits for physical function, symptom burden, and treatment tolerance. Despite international guideline recommendations, exercise remains inconsistently implemented as a prescribed medical treatment in routine oncology care. This study describes the real-world implementation of an integrated Exercise Medicine model embedded within a supportive oncology service. **Methods:** This descriptive implementation study reports on the Lift Model of Care, a clinician-led supportive cancer care service established in Australia in 2018. Exercise Medicine is delivered as a core, medically prescribed intervention and integrated with Physiotherapy, Psychology, Dietetics, and subspecialty services across the cancer continuum. Exercise prescriptions are individually tailored and dosed by qualified clinicians in accordance with Clinical Oncology Society of Australia exercise guidelines and delivered in a medically supervised environment. Routinely collected service data were analysed descriptively. The primary outcome was annual service reach and treatment volume from 2018 to 2025. Secondary outcomes included patient-reported experience measures related to Exercise Medicine. **Results:** Annual service reach increased from 607 individuals in 2018 to 1,353 individuals in 2025. Delivery of Exercise Medicine increased from 2,077 to 12,255 treatments annually, reflecting sustained growth in access and longitudinal engagement. Concurrent increases in Physiotherapy, Psychology, Dietetics, and Lymphoedema services were observed, supporting coordinated multidisciplinary care delivery. Patient-reported experience data demonstrated high acceptability, with over 90% of respondents reporting high satisfaction and perceived improvements in fatigue, strength, functional capacity, and ability to tolerate cancer treatment. **Conclusions:** This real-world implementation study demonstrates the feasibility of embedding Exercise Medicine as a prescribed treatment within routine oncology care at scale. The model provides a pragmatic framework for integrating guideline-recommended exercise into standard cancer pathways and may inform broader adoption across health systems. Research Sponsor: None.

Therapeutic strategies and reduced drug spending as a signal of early impact of the Enhancing Oncology Model. First Author: Rachel Mosher Henke, Lewin Group, Falls Church, VA

Background: Building on lessons learned from the predecessor Oncology Care Model, the Centers for Medicare & Medicaid Services designed the Enhancing Oncology Model (EOM), a voluntary, two-sided risk, episode-based payment model, to incentivize participating practices to provide high-quality, patient-centered oncology care while targeting Medicare spending reductions. At the start of the model, 44 oncology practices voluntarily joined EOM. Practices are held financially accountable for 6-month episodes of care for Medicare Fee-for-Service beneficiaries with 7 high-risk cancers. The objective of this study is to evaluate how practices implemented EOM and whether they were able to reduce Medicare spending during its first six months of implementation. **Methods:** To identify strategies practices used to meet model goals, we interviewed 93 key informants during site visits at 6 EOM practices from November 2024 through February 2025. We analyzed claims-based impacts on spending using a difference-in-differences approach using a sample of episodes of care from EOM practices and propensity score matched comparison practices during a baseline period (July 1, 2018 – June 30, 2022) and the first performance period of the model (July 1–December 31, 2023). **Results:** EOM practices reported focusing on reducing drug expenditure. Strategies included (1) substitution to value-based treatment alternatives, such as biosimilars, while mitigating the impact of drug shortages; (2) dose rounding and weight-based dosing to minimize waste and improve efficiency; and (3) avoiding drugs with limited clinical benefit, such as white blood cell growth factors for metastatic tumors. While not statistically significant, we found the model reduced total Medicare spending by $646 per episode (1.1%; 90% confidence interval [CI]: −$1,724, $433), likely driven by reductions in Part B systemic cancer therapy payments of $645 per episode (90% CI: −$1,622, $332). This is consistent with practice reports of implementing value-based prescribing strategies. **Conclusions:** Early EOM implementation results show emerging evidence of systemic cancer therapy payment reductions. These findings may reflect expanded biosimilar availability and practices' strategic focus on value-based drug substitution and dosing. Research Sponsor: Centers for Medicare and Medicaid Services.

Association of routine electronic symptom monitoring with reduced opioid use in patients with head and neck cancers. First Author: Laila A. Gharzai, Northwestern University, Chicago, IL

Background: Patient reported outcomes (PROs) have become increasingly important in modern healthcare. Head/neck cancer (HNC) is associated with numerous side effects that significantly impact patients quality of life short and long term. We developed FACT-HN-RAD, a brief cancer and treatment specific PRO aiming to efficiently capture side effect burden for patients with HNC undergoing radiotherapy (RT). Here we report the clinical implementation of this measure through the electronic medical record (EMR) at two institutions. **Methods:** The PRO was prospectively integrated into routine clinical care for patients with HNC through deployment in the EMR weekly during RT (up to 7 weeks) and at 1-, 3-, 6-, 9-, and 12-month post RT. We compared a historic cohort of patients (treated July 2021-July 2023) to those treated after PRO deployment (Aug 2023-Aug 2025), assessing PRO adherence, opioid use, emergency room (ER) encounters and inpatient admissions. Baseline demographic characteristics were summarized using descriptive statistics. Clinical outcomes were compared using parametric and nonparametric statistical tests. **Results:** OF the 2,288 patients, 1,304 were in the PRO cohort and 984 were in the historic cohort. Patients had a median age of 65 (IQR 56-73) and were mostly White (81.9%), non-Hispanic (91.3%), and current/former smokers (57.5%) with a median of 20 smoking pack years (IQR 3.8-46.5). In the PRO cohort, 51.9% (n=677) submitted at least one response to the assigned PRO. Within each individual patient for the total assigned series, within patient adherence was 50.9% (ie each patient filled out approximately half of the assigned PROs over a one year timeframe). Patients in the PRO cohort required less opioids with 49.1% (n= 640) receiving any opioid prescription in the PRO cohort as compared to 60.9% (n=577) historically ($p<0.001$). The average daily strength of opioids decreased 28% in the PRO cohort (mean MME 150.1mg, SD 458.7) versus historically (mean MME 207.9mg, SD 574.8) ($p<0.001$), and the total opioids prescribed to patients decreased 44% in the PRO cohort (mean MME 3,565mg, SD 12,105) versus historically (mean MME 6,363mg, SD 18,387) ($p<0.001$). Patients in the PRO cohort overall had fewer ER visits during and within the first year after finishing RT, with 13.3% (n=173) visiting the ER as compared to 29.4% (n=289) historically ($p<0.001$). Patients in the PRO cohort had fewer inpatient admissions within the first year after finishing RT, 28.8% (n=375) as compared to 48.8% (n=480) historically ($p<0.001$). **Conclusions:** We demonstrate that the integration of routine electronic PROs into the care of patients undergoing HNC RT is associated with clinical benefits when compared to a historic cohort including reduced opioid use, reduced ER visits, and reduced inpatient admissions. This promising approach in the definitive RT setting warrants further study in a randomized clinical trial. Research Sponsor: PROTEUS Consortium.

Rethinking cancer attribution in oncology VBC models: E&M vs treatment-based approach. First Author: Haibei Liu, McKesson, Irving, TX

Background: Patients with multiple cancers are uncommon. In value-based care models such as EOM (Enhancing Oncology Model),episode attribution and financial accountability rely on assigning a cancer type based on the plurality of predefined E&M visits. However, this administrative approach may not accurately represent the cancer for which a patient is receiving active treatment, especially in the presence of concurrent malignancies. Despite this, little is known about how often the E&M based cancer type differs from the treatment-based cancer type. **Methods:** We analyzed EOM performance period data (July 2023–June 2025) from practices in The US Oncology Network. Injected based initiating episodes were identified using EOM Part B claims that occurred at practices' sites, then matched to the Electronic Health Record by patient, drug, and initiating date. For oral agents, additional to patient, drug and prescribing provider, order dates within 60 days of the fill date in Part D Claims was used as a proxy in matching process. Cancer type associated with the initiating treatment was extracted from the EHR and then compared with EOM-attributed cancer types. **Results:** Episodes were predominantly triggered by injection-based chemotherapy with 13,803 initiated in physician office setting, and 5,441 were initiated by oral chemotherapy. Matching rates to an initiating event in EHR differed substantially by route:~ 90% for injection-initiated episodes vs. about 40% for oral-initiated episodes. Among injection-based episodes, 5% of episodes did not have a treatment-based cancer diagnosis in EHR and 4.5% had discordant cancer diagnoses, while oral-based episodes showed markedly higher rates of missing cancer diagnosis at 32%, with 24% mismatched diagnoses. Chronic leukemia and prostate had a higher proportion of oral initiations and correspondingly lower matching rates. Oral-initiated episodes demonstrated particularly low EHR matching in breast, lung, prostate, and small intestine/colorectal cancers. **Conclusions:** Cancer attribution in VBC models remains challenging, particularly for episodes initiated with oral therapies. As the use of oral agents continues to expand and patients increasingly present with concurrent cancers, attribution difficulties are likely to grow, resulting in greater discordance over time. Incorporating treatment-based cancer type into attribution could improve accuracy and better align assigned cancer types with actual care in value-based oncology models. Research Sponsor: None.

EHR matching by route of chemotherapy initiation.

Cancer Type	Injection Episodes (n)	Injection Concordance (%)	Oral Episodes (n)	Oral Concordance (%)
Breast Cancer	3836	91.8%	727	23.9%
Chronic Leukemia	171	83.6%	1370	50.1%
Lung Cancer	3539	93.1%	323	31.3%
Lymphoma	1724	84.6%	512	47.9%
Multiple Myeloma	1976	93.2%	1211	73.6%
Prostate Cancer	558	83.2%	1210	21.4%
Small Intestine/Colorectal Cancer	1999	89.1%	88	21.6%

Modernizing injectable cancer care delivery: A telemedicine-supported home injection model for breast cancer care. First Author: Erin Mary Bange, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Among the growing population of premenopausal patients with breast cancer, years-long endocrine therapy often requires repeated clinic-administered injections, creating substantial time burden and adherence challenges. This pilot evaluated the feasibility of a telemedicine-supported home injections program designed to improve access, convenience, and patient experience. **Methods:** Patients were recruited from 4 outpatient medical oncology practices at a comprehensive cancer center between October 2024 and January 2025. Eligibility criteria included a breast cancer diagnosis, an active treatment plan including leuprolide and/or denosumab, and use of the patient portal. Patients proceeded to pilot participation after insurance approval for outpatient administration of medications and (if applicable) acceptability of copay cost. Patients and/or caregivers received in-clinic training by nursing staff on injection preparation and administration, were provided both written and video-based educational material and were followed for up to 2 home injections over a 6-month period, with telemedicine support. The primary outcome was feasibility, assessed by home injection completion rates. Patient and clinician satisfaction were assessed using the Net Promotor Score (NPS) and rates of continued at home injection administration post pilot completion. Patients were also invited to participate in 60-minute semi-structured exit interviews. **Results:** Of 105 eligible patients, 54 agreed to participate in the pilot and 24 obtained insurance approval for the medication with an acceptable copay. All 24 patients were trained in injection administration of intramuscular leuprolide, of whom 50% had no prior injection experience. Overall, 96% successfully completed one home injection, 79% of patients completed two home injections, and 75% continued home administration after follow-up. Notably, only 1 patient discontinued home injection administration due to telemedicine scheduling related issues. Patients reported high satisfaction, citing time savings and convenience as key benefits. Both patients and providers strongly endorsed the model with highly compelling net promoter scores of 69 and 61, respectively. **Conclusions:** This pilot demonstrated the feasibility of a telemedicine supported home injection care delivery model for breast cancer patients in the oncology setting, evidenced by high completion rates and patient preference to continue home administration. Educational materials and optional telemedicine visits for initial injections were leveraged to support adherence without increased healthcare utilization. Further evaluation across broader geographic, demographic, and payor mix is warranted to inform scale up. An ongoing pragmatic trial (NCT06954337) is testing this approach as part of an innovative model of care: Enhanced Telehealth. Feasibility and implementation of remote geriatric assessment–guided supportive care (GAIN-S) in public oncology settings. First Author: Cristiane Decat Bergerot, Oncoclinicas&Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: The ASCO Global Guideline recommends routine geriatric assessment (GA) for adults aged ≥65 years with cancer to identify vulnerabilities beyond standard oncology evaluation and guide tailored management. However, real-world implementation of GA-guided interventions in low-resource settings remains limited. Building on prior feasibility work in private (PRI) oncology settings, we evaluated the feasibility and implementation of a remote, multidisciplinary GA-guided intervention in public (PUB) oncology settings in Brazil. **Methods:** We conducted a prospective feasibility and implementation study in PUB settings, with contextual reference to prior PRI experience. Patients aged ≥65 years initiating chemotherapy underwent baseline GA assessing functional status, depressive symptoms (GDS), cognitive screening (Mini-Cog), chemotherapy toxicity risk (CARG), nutritional status, and quality of life (FACT-G), with repeat assessment at 12 weeks. Identified impairments prompted referral to telehealth interventions (geriatrics, nutrition, psychology/psychiatry, exercise). Feasibility outcomes included recruitment, GA completion, referral recommendations, and follow-up retention. Implementation barriers in PUB settings were prospectively documented. **Results:** A total of 109 patients were included (PRI n=61; PUB n=48). The PUB cohort was younger (mean age 72 vs 76), included a higher proportion of Black participants (58% vs 44%), had lower education (no/limited 19% and elementary school 50% vs college degree 47%), and more advanced disease (92% stage III-IV vs 54% stage IV). Baseline geriatric vulnerability was similar (median CARG 6 vs 7, GDS 2); weight loss was more frequent in PUB (54% vs 36%). Quality of life was lower in PUB (FACT-G -5 points). GA identified actionable vulnerabilities, with 21% referred to ≥1 specialist (vs 33% in PRI) and 44% to ≥2 specialists (vs 28% in PRI). Key challenges included delayed recruitment, limited digital literacy (63%), restricted videoconferencing (73%), delays in nutritional supplements (38%), and exercise adaptation (50%), prompting ongoing, context-specific adaptations. **Conclusions:** Remote GA delivery and identification of actionable vulnerabilities were feasible in PUB settings in Brazil. Similar geriatric vulnerability profiles and characterization of implementation barriers support the scalability of GA-guided care in low-resource settings. Clinical trial information: NCT07084454. From plenary to practice: A large language model (LLM)–based thematic analysis of landmark clinical trial discussions and factors influencing their real-world adoption. First Author: Aaron B. Cohen, Flatiron Health, New York, NY

Background: Landmark trials define standard-of-care (SOC), yet the translation of trial evidence into routine practice remains poorly characterized. LLMs enable the systematic extraction of nuanced clinical discourse from unstructured EHR data previously infeasible at scale. We performed an LLM-based thematic analysis of past ASCO Plenary Session (PS) trial discussions to better understand the nature of shared decision-making in routine care and characterize themes influencing SOC adoption. **Methods:** We designed a retrospective study of clinician-documented discussions with patients about PS trials presented at ASCO Annual Meetings 2021-2025. 2 trials (negative study; non-therapeutic trial) were excluded. Patient records from the Flatiron Health Database with mention of a relevant trial/NCT number within 2 years of presentation were selected. We prompted an LLM (Claude 4.5 Sonnet) to summarize documentation of clinician-patient trial discussions and extract: 1) context of discussion, 2) clinician sentiment toward trial (positive, neutral, negative) and 3) documented receipt of trial therapy (yes/no; if no, reason why not). To characterize the gap in SOC adoption, a thematic analysis was performed using a multi-model consensus approach (Gemini 2.5pro, GPT-4o, Claude 4.5 Sonnet) to identify EHR-documented discussion themes associated with trial treatment omission. LLMs provided supporting evidence for all answers; a human-in-the-loop approach was used to verify concordance between LLM-extracted themes and expert clinical interpretation. LLMs were hosted on Flatiron Health private servers and HIPAA compliant. **Results:** The study included 8650 patients and 21 trials discussed across 15 cancer types. Common discussion topics were: efficacy (78%), eligibility (78%), patient education (63%), and toxicity (28%). Clinician sentiment across studies was favorable (47%-93% positive), yet real-world trial therapy initiation occurred in only 64% of cases. Main themes associated with trial treatment omission were: clinical factors (biomarker ineligibility, comorbidities), systemic barriers (insurance, transportation, incarceration), and patient preferences (prioritizing quality of life, preserving life roles). **Conclusions:** This is the largest thematic analysis of clinician-patient trial discussions to date. We uncovered rich qualitative insights into how clinicians engage in shared decision-making with their patients, balancing positive evidence and sentiment with practical and patient-centered factors that define individualized care. Novel LLM methods can transform clinician-patient narratives into actionable evidence to mitigate disparities and optimize real-world SOC adoption. Future work will examine thematic differences by cancer type and prevalence and correlate findings with outcomes. Research Sponsor: Flatiron Health, Inc.

Unmet rehabilitation needs in cancer survivors: A population-level analysis. First Author: Subha Hanif, Mayo Clinic Rochester, Rochester, MN

Background: Decades of evidence demonstrate that patients across the cancer continuum may benefit from validated rehabilitation services, yet delivery remains inconsistent. Prior reports of underuse have largely relied on small, single-site cohorts and have lacked population-level estimates of service need, referral, and visit completion, contributing to the assumption that provider reluctance to refer is a primary driver. Using post hoc exploratory analyses of population-level trial data, we evaluated patient- and system-level factors associated with non-use of rehabilitation services. **Methods:** This secondary analysis used data from the Enhanced Electronic Health Record–Facilitated Cancer Symptom Control (E2C2) pragmatic trial, an unblinded, stepped-wedge, cluster-randomized cohort study comparing an EHR-embedded symptom surveillance and management system with usual care. All patients receiving care in Mayo Clinic Midwest medical oncology practices were enrolled regardless of cancer stage or phase. Symptoms and physical function were assessed using 11-point numerical rating scales linked to oncology encounters. Sociodemographic and clinical characteristics and all outpatient rehabilitation encounters across the Mayo Clinic Enterprise were extracted from the EHR. Rates and types of completed, canceled, and no-show rehabilitation encounters were examined. **Results:** Between March 28, 2019, and January 31, 2023, 50,207 patients were enrolled; 34% reported moderate or severe physical function impairment during follow-up. Despite this, only 8,818 patients (17.6%) completed at least one rehabilitation encounter. Of 91,220 encounters scheduled, 57,669 (63.3%) were completed (mean 6.5; median 3 per participant), leaving a substantial proportion canceled or no-showed (n=33,523, 36.7%). Completed encounters were predominantly physical therapy (68.3%), with fewer occupational therapy (16.4%), physician (9.4%), and speech therapy (4.2%) visits. Encounters were concentrated among patients with breast, hematologic, gastrointestinal, and genitourinary cancers. Completion was more likely among patients who were older, female, partnered, retired, and federally insured, whereas cancellations and no-shows were more common among younger, racial or ethnic minority, urban, unpartnered, employed, college-educated, and commercially insured patients (all $P<0.001$). Virtual visits and encounters in community (vs academic) settings were more likely to be completed (all $P<0.001$). **Conclusions:** A substantial gap persists between cancer survivors' rehabilitation needs and service receipt, varying by cancer type and sociodemographic factors. High cancellation and no-show rates suggest that underuse extends beyond referral and underscore the need for redesigned, more accessible rehabilitation delivery models. Research Sponsor: None.

Implementing a clinical research coordinator–led care delivery model (CRC model) in an early-phase oncology program: A pilot to streamline workflow, improve collaboration, and enhance patient-centered trial conduct. First Author: Christina Chukri, Cleveland Clinic Taussig Cancer Center, Cleveland, OH

Background: Early-phase oncology trials involve medically complex patients with narrow enrollment windows. Traditionally, CRC roles focused on data management and scheduling, with limited integration into visit-based workflows, creating gaps in protocol execution and prescreening. This pilot embedded CRCs into patient-facing workflows to improve visit preparedness, protocol reliability, and enrollment readiness in biomarker-driven Phase I trials. **Methods:** CRCs were embedded alongside investigators and research nurses during patient visits to support coordination of protocol requirements. This included standardized patient schedule education; CRC-led week-ahead planning; proactive symptom monitoring with escalation pathways; multidisciplinary supportive care coordination; and prescreening/enrollment support for biomarker-driven trials, including tissue tracking and coordination of enrollment-sensitive testing timelines. A pre- and post-evaluation was conducted. Active patients during matched 8-month pre- and post-implementation periods were identified through a CRC-maintained prescreening tracker and electronic health record review. Protocol deviations were categorized by primary attribution. Visit preparedness, timeliness of symptom escalation, supportive care coordination, and prescreening workflow adoption were assessed. Statistical significance was evaluated using the Wilcoxon signed-rank test. **Results:** Scheduling protocol deviations decreased from 42 pre- to 20 post-implementation (52% reduction), driven by fewer missed or delayed assessments and communication gaps. CRC-led week-ahead reviews improved visit preparedness, with assessment-related deviations decreasing from 37 to 4 over matched 8-month periods (~89% reduction). CRC presence centralized protocol and logistical oversight, supporting timely trial readiness in Phase I. CRC-led prescreening improved visibility into tissue availability, biomarker testing status, and cohort eligibility. Mean time to tissue submission decreased from 9 business days pre-implementation (range, 2–25; n = 20) to 2.2 business days post-implementation (range, 1–4; n = 20; $p = 3.54 \times 10^{-5}$). Across three tissue-dependent interventional trials, identification of patients meeting protocol-specified eligibility criteria increased from 39 to 59 over matched 8-month periods (51.3% increase). **Conclusions:** Adopting a CRC model improved operational reliability and prescreening efficiency, enabling faster tissue submission, quicker identification of biomarker-eligible patients, and top of scope team function. Programs facing trial complexity or staffing constraints may benefit from CRCs in visit support and prescreening roles to improve efficiency and trial access. Research Sponsor: None.

Spatial heterogeneity of structural inequities in diagnostic delay and survival in early-onset colorectal cancer in a large urban catchment area. First Author: Rohan K. Patel, Department of Radiation Oncology, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Disparities in early-onset colorectal cancer (EO-CRC) stage at diagnosis and survival persist despite expanding specialty care, suggesting that structural and neighborhood-level factors, beyond traditional access measures, influence timeliness of cancer detection and treatment. We applied geospatial modeling integrating clinical data with census-based Social Vulnerability Index (SVI) and historical redlining to characterize geographic variation in diagnostic delay and median overall survival (mOS). **Methods:** We retrospectively analyzed 214 patients diagnosed with EO-CRC (<50 years) treated an urban tertiary center (2018-2025), identified via ICD-10 codes. Geocoded addresses were linked to census-tract level SVI and Home Owners' Loan Corporation redlining grades (A/B vs C/D). Access was quantified using network drive-time and Euclidean distance to colorectal surgery and gastroenterology. Spatial analyses in ArcGISPro included hotspot mapping, tract-level aggregation, and Geographically Weighted Regression (GWR) to model spatially varying associations between race, stage, access, and OS. GWR residuals $>\pm 2$ standard deviations (SD) identified clusters of excess risk. **Results:** Among 214 patients: 32% were non-White; 62% were stage III/IV; 49% lived in redlined neighborhoods. Time from symptom onset to diagnosis was non-linear with access: patients living <5 miles (89 days) and >20 miles (101 days) from specialty care experienced longer delays than those 5-10 miles (67 days) or 10-20 miles (72 days) away ($p<0.01$), consistent across drive-time and Euclidean measures. GWR demonstrated that the effects of race and stage on diagnostic delay (median local R^2=0.52, range 0.28–0.67) and OS (median local R^2=0.46, range 0.23–0.60) varied by location. High-residual clusters (>2 SD above predicted delay) localized to the Southeast and East neighborhoods of the catchment area, where non-White patients experienced 48-82 excess days of diagnostic delay after adjustment for stage, access, and SVI. High-residual areas had higher emergency or inpatient index presentation than in low-residual areas (42% vs 21%, p=0.01). The mOS was significantly lower in high-SVI vs low-SVI tracts (22 vs 38 mo; HR 1.9, $p<0.01$), in redlined versus non-redlined neighborhoods (24 vs 50 mo; HR 2.1, $p<0.002$). Within low-SVI areas, non-White patients had inferior mOS compared to White patients (28 vs 37 mo, HR 1.5, p=0.001). **Conclusions:** Spatial modeling suggests that EO-CRC disparities reflect place-based structural factors beyond clinical stage or proximity to care. Clustering of excess diagnostic delay and inferior survival in historically redlined and high-SVI neighborhoods identifies priority geographies for future studies integrating clinical and population data to design targeted, place-based navigation and early-detection interventions. Effect of an EHR-facilitated symptom surveillance intervention on rehabilitation utilization in cancer patients. First Author: Toure Barksdale, Department of Physical Medicine and Rehabilitation, Mayo Clinic Rochester, Rochester, MN

Background: Rehabilitation services (physical medicine and rehabilitation [PM&R], physical therapy [PT], occupational therapy [OT], and speech-language pathology [SLP]) improve physical function, symptom burden, and quality of life for cancer survivors, yet utilization remains low due to persistent barriers. The collaborative care model–based Enhanced Electronic Health Record–Facilitated Cancer Symptom Control (E2C2) pragmatic trial improved symptom burden and palliative care utilization. Using post hoc exploratory analyses of population-level trial data, we evaluated whether this EHR-facilitated approach also increased rehabilitation service use. **Methods:** E2C2 was conducted across Mayo Clinic Midwest medical oncology practices using an unblinded, stepped-wedge, cluster-randomized cohort design. The EHR-embedded intervention targeted SPPADE symptoms (sleep interference, pain, impaired physical function, anxiety, depression, and fatigue). Symptoms and physical function were assessed using 11-point numerical rating scales linked to oncology encounters. Patients received self-management materials for moderate symptoms (4–6/10) and care manager support for severe symptoms (7–10/10). All outpatient rehabilitation encounters across the Mayo Clinic Enterprise were abstracted. Mixed-effects Poisson models estimated intervention effects on rehabilitation visits during the first 365 days of exposure. **Results:** Between March 28, 2019, and January 31, 2023, 50,207 patients were enrolled. Intervention and control conditions included 31,719 and 28,938 patients, respectively, with 10,450 contributing data to both periods. Cross-sectionally, 25% of participants reported moderate and 9% severe physical function impairment. Of 91,220 rehabilitation encounters scheduled, 57,669 (63.3%) were completed. Completed encounters were predominantly PT (68.3%), followed by OT (16.4%), physician visits (9.4%), and SLP (4.2%). The intervention was associated with a more than fourfold increase in completed rehabilitation encounters during the six weeks following index symptom assessment (adjusted mean 2.22 [95% CI, 0.14–4.29] vs 0.54 [0.40–0.68]; incidence rate ratio 4.11 [1.43–11.82]; P=0.009). Scheduled encounters also favored the intervention but did not reach statistical significance. **Conclusions:** An EHR-embedded symptom surveillance intervention increased short-term rehabilitation service completion, but overall utilization remained low relative to the prevalence of physical function impairment, highlighting the need for system-level strategies to translate symptom identification into sustained rehabilitation engagement. Research Sponsor: None.

Impact of the Navya Earthshot–enabled clinical decision support system on treatment turnaround time in oncology care: A real-world study from a tertiary cancer center in India. First Author: Umesh Mahantshetty, Homi Bhabha Cancer Hospital and Research Centre, Visakhapatnam, India

Background: Delays in Oncology care often result from systemic inefficiencies and patient-related barriers, leading to delayed treatment decision. Navya Earthshot is a validated Artificial Intelligence (AI) enabled clinical decision support system that matches patient records to standard-of-care oncology guidelines to generate evidence-based treatment recommendations. This study evaluated the real-world impact of Navya Earthshot implementation at a Tertiary Cancer Centre in India on turnaround time (TAT) for cancer directed treatment decision. **Methods:** This was a prospective, pre–post observational study conducted in two phases at a tertiary cancer centre in India. Baseline data collected prior to Navya Earthshot integration (December 2023–February 2024; n = 148) were compared with data from the post-implementation phase (February 2025–May 2025; n = 488). Navya Earthshot was embedded into routine clinical workflows, matching patient-specific clinical information to National Cancer Grid (NCG) guidelines to generate treatment options. These recommendations were reviewed by treating oncologists and discussed in daily multidisciplinary tumour boards. Patients were tracked from registration through diagnostic completion to treatment decision. The primary outcome was the turnaround time (TAT) for treatment decision, defined as the number of days from patient registration to treatment decision. Statistical comparisons were performed using the Mann–Whitney U test, with significance set at $p < 0.05$. **Results:** A total of 636 patients were included in the analysis, with 148 (pre-implementation phase) and 488 (post-implementation phase). Median TAT decreased from 21.4 Interquartile Range (IQR) days pre-implementation to 16.73 days (IQR) post-implementation, representing a 21.8% reduction ($p < 0.05$). The use of the Navya Earthshot decision support system was associated with a statistically significant reduction in overall TAT. This reduction reflects faster progression from patient registration through diagnostic completion to treatment decision in the post-implementation cohort. **Conclusions:** Integration of Navya Earthshot-enabled decision support system significantly improved treatment decision timelines in a high-volume public oncology setting. These findings demonstrate that scalable, guideline-aligned, patient-centric AI solutions can enhance workflow efficiency and strengthen end-to-end cancer care delivery in resource-constrained environments. Research Sponsor: None.

Impact of Navya Earthshot implementation on turnaround time for treatment decision.

Metric	Pre-Implementation Phase	Post- Implementation Phase	% Change	p-value
Turnaround Time (TAT)	21.4 days	16.73 days	↓ 21.8%	<0.05

Trial characteristics and results reporting among oncology clinical trials involving African countries. First Author: Oyepeju Folashade Abioye, Allegheny Health Network, Pittsburgh, PA

Background: Sub-Saharan Africa (SSA) faced ~801,000 new cancer cases and ~520,000 cancer deaths in 2020, with deaths projected to reach 1 million annually by 2030. African trial activity remains scarce (<1% of global trials), with sparse reporting. We measured results reporting for oncology trials involving African sites and identified trial characteristics associated with results disclosure. **Methods:** Using ClinicalTrials.gov, we identified 1,140 completed oncology trials (1992-2023) involving ≥1 African site. We classified trials by country, institution, region, and funder, reporting proportions, ORs (95% CI), and multivariable logistic regression. **Results:** Among 1,140 trials across 38 countries, most were single-country (93.7%), single-institution (76.7%), and North Africa only (58.2%). Most were non-industry-sponsored (68.8%), interventional (79.5%) and randomized (61.1%). Enrollment was ≤100 participants in 666 trials (58.4%). Overall, 25.2% posted results. Multi-country trials reported more than single-country (59.7% vs 22.8%); multi-institution exceeded single-institution (60.5% vs 14.4%). SSA-only (48.0%) and both-region trials (72.1%) exceeded North-Africa-only (7.2%). Industry-funded reported more than non-industry (70.5% vs 4.6%). Phase III exceeded other phases (64.0% vs 10.6%). In multivariable analysis, industry sponsorship, multi-institution and multi-country configuration, SSA region, and phase 3 status were independently associated with results posting (Table 1). **Conclusions:** Nearly three-quarters of completed oncology trials conducted in Africa have not publicly reported results, highlighting substantial research waste and a critical ethical failure to translate participant contributions into accessible evidence. This analysis identifies independent, actionable determinants of reporting transparency. Strengthening African clinical trial infrastructure and coupling reporting requirements with systematic monitoring and accountability are essential to improve evidence generation and promote equity as the continent's cancer burden continues to rise. Research Sponsor: None.

Cancer stigma in low- and middle-income countries: A scoping review of frameworks, measurement approaches, and interventions. First Author: Emma Pearson Seevak, Harvard Medical School, Boston, MA

Background: The incidence and mortality rates of cancer are rising fastest in low- and middle-income countries (LMICs). While cancer early detection and treatment are increasingly available in LMICs, several care barriers contribute to persistent disparities in survival outcomes. One identified barrier is stigma regarding cancer and its treatment approaches. However, there is limited literature on validated measurement tools for cancer stigma and interventions to address this stigma in LMICs. **Methods:** A systematic search of six electronic databases (OVID Medline, Embase, Web of Science, EBSCO: Africa-Wide Information, EBSCO: Global Health, and WHO Global Index Medicus/African Index) was performed on August 17, 2023, and updated on November 20, 2025. Two reviewers independently screened 3174 titles/abstracts and 425 full-text articles. Three researchers extracted data from 129 eligible articles following sufficient agreement on pilot testing. The findings were synthesized using descriptive statistics and content analysis based on the Health Stigma and Discrimination framework. **Results:** Of the 129 articles, the study types included: cross-sectional surveys (109, 84%), randomized controlled trials (9, 7%), prospective cohorts with an intervention (9, 7%), one prospective cohort with no intervention, and one retrospective study. The studies were from 30 LMICs, with the plurality from China (59, 46%), followed by Turkey (12, 9%) and Kenya (10, 8%). Many studies focused on general cancer stigma (rather than a particular type of cancer) (34, 26%) and involved patients with cancer (90, 70%) or the general community (22, 17%). The studies commonly assessed stigma at the individual (113, 88%) and interpersonal (97, 75%) socio-ecological levels. 126 (98%) studies included a quantitative cancer stigma measurement tool, with the most common established tools being the Social Impact Scale (SIS, 33, 26%) and the Cancer Stigma Scale (CASS, 13, 10%). However, many used other adapted cancer stigma or HIV stigma scales. 41 (33%) studies were validation studies of a tool in the local context, 58 (46%) used previously validated tools, and 27 (21%) did not mention local validation. There were 18 studies with interventions, most of which focused on educational approaches, and 15 (83%) were published since 2021. **Conclusions:** This review demonstrates a wide variation in tools and validation practices in studies measuring cancer stigma in LMICs. Effective comprehensive interventions remain lacking and should be the focus of future studies. Validation of pathology-based triage for the 21-gene recurrence score: A meta-analysis and qualitative synthesis of the Magee equations. First Author: Thiti Susiriwatananont, Jacoby Center for Breast Health, Mayo Clinic Florida, Jacksonville, FL

Background: The 21-gene OncotypeDX (ODX) recurrence score (RS) is the standard for chemotherapy decision-making in HR+/HER2- early breast cancer (EBC), but cost limits accessibility in resource-constrained settings. The Magee equations (MEs) use routine pathology features (Nottingham grade and IHC; ER/PR/HER2/Ki-67) to estimate RS. We performed a meta-analysis to validate MEs performance as a triage tool for ODX testing and a qualitative synthesis to identify sources of discordance, highlighting the transition toward objective digital pathology AI models. **Methods:** A systematic review identified validation studies comparing MEs with RS in HR+ EBC. Studies with sufficient data to construct a 2X2 contingency table were included; neoadjuvant trials were excluded. Primary outcomes were Negative Predictive Value (NPV) for identifying low-risk cases (RS <26 for the current TAILORx cutoff and RS<31 for the historical cutoff) and ODX test sparing rate (TSR). Data were pooled using random-effects models. Qualitative themes regarding interpretation variability were extracted from study results and discussion sections. **Results:** Thirteen studies met the inclusion criteria, representing 5396 patients in global cohorts from the USA, Mexico, Colombia, Jordan, France, Belgium, and Canada. For RS >26, Magee <18 achieved pooled NPV of 0.96 (95% CI: 0.94-0.97) and TSR 61% (95% CI:51%-69%). For RS >31, NPV increased to 0.99 (95% CI: 0.97-1.00) and TSR 52% (95% CI: 44%-59%). Pooled diagnostic performance for Magee <18 predicting RS <26 demonstrated 83% sensitivity and 71% specificity (AUC 0.81, LR+:2.53, LR-:0.28). Qualitative analysis of discordance identified: (1) Inter-observer variability: Nottingham mitotic counts and Ki-67 scoring were the primary drivers of score fluctuations. (2) IHC quantification: Variations in H-score calculation and Allred-to-H-score conversion introduced heterogeneity (3) Pre-analytical and biological factors: Inflammation and stromal proliferation occasionally inflated genomic RS; selection of non-representative blocks and intratumor heterogeneity further contributed to discordance (4) Technological solutions: Digital pathology and AI models emerge as solutions to standardize these variables. **Conclusions:** Magee-based triage provides a safe and cost-effective strategy for HR+ EBC risk stratification, with NPV up to 99% for excluding high-risk disease and sparing up to 61% of ODX testing. These results confirm a robust histopathological signal. Transitioning to objective digital pathomics provides a pathway to reduce manual subjectivity and democratize precision oncology globally. Research Sponsor: None.

Pooled diagnostic accuracy of Magee equations by cutoff.

Magee score and RS cutoff	Number of studies	Total patients	Pooled NPV (95% CI)	ODX test sparing rate (95% CI)
Magee <18/ RS>26	8	4153	0.96 (0.94-0.97)	61% (51%-69%)
Magee <18/ RS>31	5	1243	0.99 (0.97-1.00)	52% (44%-59%)

Representing people's experience of cancer and its treatment (ResPECT) pilot study: A global collaborative study to improve cancer care and outcomes as part of the Lancet Commission on Cancer and Health Systems. First Author: André Pfob, Department of Obstetrics & Gynecology, Heidelberg University Hospital, Heidelberg, Germany

Background: Measurement of cancer burden increasingly informs survivorship research, health system design, and policy. Existing approaches rely on structured patient-reported outcome measures, which are costly to administer, culturally constrained, and difficult to scale globally. Advances in artificial intelligence (AI), particularly large language models (LLMs), offer the opportunity to systematically analyze unstructured patient narratives at scale. The ResPECT pilot study evaluates whether an LLM-driven framework can assess multidimensional cancer burden from patient-reported free text. **Methods:** Adult cancer patients and survivors provided structured burden ratings (Likert scale, 1–10) and open-text narratives describing physical, psychological, social, financial, and other impacts of cancer and its treatment. Unstructured text was analyzed using a retrieval augmented generation (RAG) architecture combining dense semantic embeddings (Nomic Embed), an open-weight LLM (Mistral 7B), and an ensemble retriever integrating vector similarity search and BM25 retrieval. Performance was evaluated across three predefined domains: (1) analytical concordance with quantitative analyses across 23 hypotheses as well as (2) contextual correctness and (3) hallucination rate over 50 questions, assessed by two independent reviewers. **Results:** A total of 1,642 participants from 23 countries were analyzed; 66.9% identified as female and 22.0% identified themselves to be part of an underrepresented group. Overall, impact on psychological well-being was ranked significantly higher compared to physical, social, or financial well-being (all $p \leq 0.001$). Younger participants and individuals identifying with underrepresented groups reported significantly higher overall and domain-specific burden, while U.S. participants reported greater financial burden than UK participants ($p \leq 0.001$). The LLM-based analyses reproduced quantitative findings in 21 of 23 hypotheses (91.3% concordance). Contextual correctness was 90% (90 of 100), and hallucinations occurred in 3% (3 of 100) of generated responses, predominantly involving minor paraphrasing of patient quotations. The LLM consistently identified key themes, particularly related to psychological well-being, including emotional stress, depression, relationship strain, isolation, guilt, and hope. **Conclusions:** The ResPECT initiative demonstrates that an LLM-driven framework can reliably provide and effectively scale qualitative insights into cancer burden from a patient perspective. While we acknowledge that the current pilot is not representative of cancer patients worldwide, the ResPECT approach may be scalable to derive comparable and actionable insights to inform investment in cancer services around the world. Research Sponsor: None.

Understanding barriers to the clinical breast exam in Telangana, India: A survey study of participants and non-participants in underserved rural and urban areas. First Author: Nina Tamirisa, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: In low-resource settings where mammography is not feasible, Clinical Breast Examination (CBE) performed by trained healthcare workers is an effective alternative for breast cancer early detection. Despite prior success of large-scale CBE programs in India, national uptake remains extremely low. This study evaluated knowledge, attitudes, beliefs, and structural barriers associated with participation in CBE screening among women in rural and urban Telangana, India and assessed factors influencing participation. **Methods:** We conducted a prospective, nested case-control study in October 2025, in which CBE participants and non-participants were drawn from the same source population. Women aged >35 years who were non-pregnant and able to consent were approached during home visits or at primary health centers (PHCs) to complete standardized surveys; participation in CBE was voluntary. Surveys captured sociodemographic factors, breast cancer knowledge, attitudes toward CBE, stigma, and treatment beliefs. Multivariable logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for factors associated with CBE participation, adjusting for relevant sociodemographic and belief-based covariates. **Results:** A total of 669 women were included (urban n=426; rural n=243), of whom 421 participated in CBE (participants) and 248 declined(non-participants). Among 403 CBE participants, 81.1% (n=327) reported never having had a prior breast examination. Belief that CBE is necessary even in the absence of symptoms was strongly associated with participation (81.1% vs 51.6%, $p<0.001$) as was belief that breast cancer is curable (80.6% vs 56.9%, $p<0.001$). There was no difference in fear of stigma between participants and non-participants (62.2% vs 65.3%, p=0.61). Fear of losing the breast was highly prevalent among non-participants (72%) and independently associated with lower participation (OR 0.49, 95% CI 0.28–0.87). After adjustment, urban residence was associated with lower odds of participation compared with rural residence (adjusted OR 0.28, 95% CI 0.14–0.56) as was higher household income (>☐100,000 vs ≤☐15,000; adjusted OR 0.24, 95% CI 0.12–0.46). Among non-participants, the most cited facilitators for future participation were examination by a doctor (33.5%), clinic-based exams (28.2%), and convenient timing (28.2%). **Conclusions:** Participation in CBE is influenced by modifiable belief-based and structural barriers that vary by setting. Addressing fears related to diagnosis and treatment of breast cancer and tailoring CBE delivery strategies may improve uptake and enhance early detection of breast cancer in low-resource settings. Research Sponsor: Charles M. Balch, M.D. Endowed International Fellowship in Surgical Oncology.

Interpretable machine learning to identify health system levers for survival outcomes of patients with breast cancer. First Author: Erin Feliciano, NYC Health + Hospitals/Elmhurst, New York, NY

Background: Breast cancer is the most commonly diagnosed cancer and a leading cause of cancer death among women worldwide. Despite advances in screening and treatment, global disparities in breast cancer outcomes remain stark. The mortality-to-incidence ratio (MIR) is an ecological measure of cancer control performance. We applied interpretable machine learning to quantify country-level determinants of the breast cancer MIR within the health system, facilitating examination of interrelated factors for each individual country. **Methods:** We developed a CatBoost gradient-boosting model with SHAP (SHapley Additive exPlanations) analysis to predict female breast cancer MIR across 185 countries using GLOBOCAN 2022 data. Health system indicators were compiled from WHO, World Bank, and DIRAC databases, including GDP per capita, UHC index, radiotherapy centers per 1000 population, health spending metrics, workforce densities (physicians, nurses, surgical workforce per 1000), pathology services, gender inequality index, and breast screening program status. The model was trained with repeated leave-one-country-out cross-validation (10 repeats; 1850 total predictions) and nested hyperparameter optimization. SHAP values quantified country-specific feature attributions. **Results:** The model demonstrated robust predictive performance, with $R^2 = 0.793$ (95% CI: 0.726-0.844), RMSE = 0.068 (95% CI: 0.060-0.076), and correlation r = 0.891 ($p<0.001$). Global SHAP analysis identified GDP per capita as the most influential predictor (mean |SHAP| = 0.0245), followed by the UHC index (0.0217), physicians per 1000 population (0.0196), the gender inequality index (0.0151), radiotherapy centers per 1M population (0.0150), and nurses/midwives per 1000 (0.0143). The binary breast screening program indicator showed low importance (0.0066), reflecting collinearity with other health system measures. Country-specific SHAP decompositions revealed substantial heterogeneity in dominant drivers, with workforce density and deficits in radiotherapy infrastructure emerging as major barriers in lower-resource settings. **Conclusions:** Strategic investments in healthcare workforce development, radiotherapy infrastructure, and UHC expansion are associated with improved national breast cancer survival, alongside complex health system strengthening factors. These findings enable evidence-based, context-specific prioritization of health system strengthening interventions for global breast cancer control, though prospective validation is needed. 1595 **Poster Session**

Interpretable machine learning to identify health system levers for survival outcomes of patients with prostate cancer. First Author: Edward Christopher Dee, Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Global disparities in prostate cancer outcomes are among the most pronounced across all cancer types. While incidence continues to rise globally, mortality reductions are more pronounced in countries with advanced healthcare systems. Understanding how health system factors relate to prostate cancer outcomes is critical for targeted policy interventions, particularly as the cancer burden is projected to rise substantially. We used explainable machine learning models to examine how these factors are associated with prostate cancer outcomes across countries. **Methods:** We compiled national mortality-to-incidence ratios (MIRs) for prostate cancer from GLOBOCAN 2022 and integrated them with system-level indicators from the WHO, the World Bank, UN agencies, and the Directory of Radiotherapy Centres (DIRAC). Variables included GDP per capita, the Universal Health Coverage (UHC) index, radiotherapy center density, physician and nursing workforce capacity, pathology services, and health expenditure composition. We implemented a CatBoost ensemble with repeated cross-validation and integrated SHAP (SHapley Additive exPlanations) for feature attribution to quantify country-level determinants of prostate cancer MIR while accounting for nonlinear, context-dependent relationships. **Results:** The model demonstrated strong predictive performance ($R^2 = 0.796$, RMSE = 0.078, correlation = 0.892). SHAP analysis identified radiotherapy center density, UHC index, and GDP per capita as the leading system drivers of MIR. Countries with robust radiotherapy capacity and comprehensive UHC consistently achieved lower MIR, whereas higher generic health spending alone showed a weaker correlation with outcomes. Yemen exhibited the highest MIR (0.720), driven by deficits in GDP, gender inequality, radiotherapy infrastructure, and UHC. The United States achieved the lowest MIR (0.107), driven by extensive radiotherapy density, high health expenditure, and robust coverage systems. Country-specific SHAP decompositions revealed heterogeneity: in higher-income settings, radiotherapy and health workforce predominantly lowered MIR, whereas in lower-SDI countries, lack of insurance and infrastructure remained major barriers. **Conclusions:** SHAP-empowered machine learning accurately predicts country-level prostate cancer MIR and provides actionable policy guidance. Investments in radiotherapy infrastructure and universal health coverage are likely to yield greater reductions in mortality than undifferentiated budget increases. This reproducible framework enables data-driven resource allocation and supports a precision-aligned approach to global cancer control, emphasizing equity, access, and the optimization of system-specific interventions. Research Sponsor: Prostate Cancer Foundation; National Cancer Institute; P30 CA008748.

Machine learning approach to identify country-specific drivers of global cancer outcomes. First Author: Erin Feliciano, NYC Health + Hospitals/Elmhurst, New York, NY

Background: Global disparities in access to cancer diagnostics and care drive substantial variation in cancer outcomes worldwide. Identifying actionable health system factors at the country level is critical to improving survival and closing global equity gaps. We applied explainable machine learning methods to explore the interrelations among these interrelated factors. **Methods:** We developed and validated a machine learning model using data from 185 countries, obtained from GLOBOCAN 2022, WHO, and the World Bank. Mortality-to-incidence ratios (MIRs) were predicted using repeated leave-one-country-out cross-validation. SHapley Additive exPlanations (SHAP) analysis decomposed each prediction into country-specific health system-feature attributions, revealing the principal drivers of cancer outcomes. **Results:** The model achieved robust performance (R^2=0.852; RMSE=0.057; Pearson r=0.923, $p<0.001$). Globally, GDP per capita, radiotherapy center density, and the universal health coverage (UHC) index were the top contributors to MIRs. SHAP analysis revealed significant heterogeneity, identifying distinct priority drivers for each country. For example, radiotherapy infrastructure was most impactful in Turkey, UHC in Brazil and Ghana, and GDP per capita in Malaysia and China. Higher health spending as a percent of GDP was often paradoxically associated with higher MIR, underscoring the need not only for sufficient funding but also for strategic allocation. We developed a web tool that provides policymakers with country-specific SHAP estimates. **Conclusions:** Explainable machine learning translates global associations into actionable, country-specific insights. Access to radiotherapy, workforce development, and UHC expansion are consistently associated with improved cancer survival. These findings support resource prioritization in national cancer control planning and inform hypothesis generation for future causal studies. National-level analyses guide targeted investment in infrastructure and health coverage, potentially accelerating progress toward reducing global disparities in cancer mortality. Research Sponsor: Prostate Cancer Foundation; National Cancer Institute; P30 CA008748.

Leukemia mortality in Latin America and the United States: A population-based analysis. First Author: Leticia Campoverde, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Leukemia outcomes depend on timely diagnosis, specialized care, and access to effective therapies. Despite improvements in high-income settings, population-level leukemia mortality in Latin America remains incompletely characterized. Comparisons across regions are further complicated by differences in diagnostic capacity and mortality reporting. We compared leukemia mortality across Latin American countries and the United States (US), using U.S. Hispanic individuals as the reference population, to characterize regional disparities, age-specific patterns, and temporal trends. **Methods:** We conducted a population-based analysis of leukemia mortality using the WHO Mortality Database for 15 countries and U.S. National Vital Statistics/SEER data. The burden of leukemia mortality was assessed from 2008 to 2019. Mortality rate ratios (MRRs) were estimated using Poisson regression. Trends were assessed using Joinpoint regression, and associations with the Human Development Index (HDI) were evaluated using linear regression. **Results:** Among children (0-19 years), most Latin American countries had significantly higher leukemia mortality than U.S. Hispanic children (MRRs 1.23-3.18), with the highest rates observed in Mexico (2.58/100,000; MRR = 3.18) and Ecuador (2.49/100,000; MRR = 3.06). In contrast, U.S. non-Hispanic White, African American, Asian/Pacific Islander, and American Indian/Alaska Native children had lower mortality than U.S. Hispanic children. Among adults (≥20 years), leukemia mortality patterns were heterogeneous. U.S. non-Hispanic White adults had higher mortality than U.S. Hispanic adults (9.6/100,000; MRR = 1.74), as did higher-HDI Latin American countries, including Uruguay and Costa Rica, whereas most countries demonstrated comparable or lower mortality. Childhood leukemia deaths were dominated by ALL, while adult mortality showed greater subtype heterogeneity, with a predominance of AML, chronic leukemias and a high proportion of deaths coded as leukemia not otherwise specified (NOS). Higher HDI was associated with lower mortality among young adults, but higher reported mortality among elderly adults. **Conclusions:** Leukemia mortality across Latin America and the US remains highly heterogeneous, with substantial excess mortality among children and older adults in several countries. Age associations with HDI and the high burden of leukemia NOS coding suggest disparities and limitations in diagnostic capacity and registry. Research Sponsor: None.

Leukemia mortality* and subtype distribution.

Population	Children Mortality Rate	Children MRR	Adult Mortality Rate	Adults MRR
U.S. non-Hispanic White	0.5	0.65	9.6	1.74
Mexico	2.58	3.18	5.76	0.92
Ecuador	2.49	3.06	5.47	0.88
Colombia	2.22	2.5	6.05	0.85
Uruguay	1.31	1.1	7.15	1.35
Costa Rica	1.28	1.05	7.09	1.13
Leukemia subtype	Children (%)		Adults (%)	
ALL	50–70		10–20	
AML	15–25		25–40	
Chronic leukemias	<5		20–35	
Leukemia NOS	8–40		17–50

Machine learning–based decision support for ICU admission in febrile oncology patients: Optimizing care delivery and resource allocation. First Author: Aditya Venkat Iyer, Green Hope High School, Cary, NC

Background: In febrile oncology patients, distinguishing self-limiting illness from life-threatening sepsis is a critical challenge for care delivery, particularly in resource-constrained settings. Over-triage strains limited critical care capacity, while under-triage compromises patient safety. We aimed to develop and validate a machine learning–based decision support tool to assist clinical judgment in identifying patients requiring intensive care. **Methods:** In a retrospective cohort of 149 febrile oncology patients, we extracted routinely available clinical features (including MASCC score, qSOFA, hypotension status, tumor characteristics, and comorbidities). We developed an XGBoost classifier to predict ICU admission and compared its performance against logistic regression and standard clinical risk scores (MASCC, qSOFA). Model performance was rigorously evaluated using 10×5-fold cross-validation with bootstrap confidence intervals, with specific attention to its utility as a supportive screening tool. **Results:** Of 149 patients, 81 (54.4%) required ICU admission. The XGBoost model demonstrated superior discrimination with an AUROC of 0.934 (95% CI: 0.863-1.000), significantly outperforming logistic regression (0.917), MASCC (0.656), and qSOFA (0.838). The model showed excellent calibration (Brier score: 0.092). Crucially, in a sensitivity analysis excluding hypotension—a clinically obvious trigger for ICU transfer—the model retained high discriminative ability (AUROC 0.887), indicating its value in identifying high-risk patients before hemodynamic collapse. **Conclusions:** This machine learning model effectively identifies febrile oncology patients requiring ICU admission, significantly outperforming traditional scores. By functioning as a high-fidelity decision support tool, it holds the potential to improve care delivery outcomes: ensuring timely escalation for high-risk patients while preventing unnecessary resource utilization for stable patients. Ultimately, this tool is designed to augment, rather than supersede, expert clinical judgment in complex acute care settings. Research Sponsor: None.

Oncology drug shortages and disruptions to cancer treatment delivery in Mexico: A national oncologist survey. First Author: Francisco Guadarrama-Conzuelo, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, DF, Mexico

Background: Oncology drug shortages increasingly disrupt cancer care delivery worldwide, yet quantitative data describing their impact on treatment decisions in middle-income countries are limited. This study evaluates how drug and supply shortages affected cancer treatment delivery in Mexico during 2024–2025. **Methods:** Between September and December 2025, we conducted a national, cross-sectional, anonymous online survey of practicing oncologists in Mexico. The survey, promoted by the Mexican Society of Oncology (SMEO), consisted of structured multiple-choice questions assessing whether oncology drug or supply shortages required treatment modifications during routine clinical practice within the preceding 12 months. Respondents could select multiple types of treatment adaptations. Descriptive statistics were used to summarize responses. **Results:** A total of 196 oncologists and hematologists completed the survey. Overall, 191 respondents (97.4%) reported performing at least one therapeutic modification due to drug or supply shortages. The most frequently reported modifications were changes in treatment regimen (79.6%), omission of one or more planned treatment cycles (71.9%), and delayed or non-timely administration (62.8%). Additional adaptations included substitution with alternative drugs within the same pharmacologic class (57.7%), non–clinically indicated dose reductions (37.8%), and use of non–guideline-approved regimens (25.5%). Referral of patients to other institutions because of treatment unavailability wasreported by 12.8% of respondents. Only 2.6% reported no treatment modifications. **Conclusions:** In this national survey of oncologists and hematologists, drug and supply shortages in Mexico were highly prevalent and associated with frequent, clinically meaningful disruptions to cancer treatment delivery, including regimen changes, treatment omissions, and delays. These findings highlight a substantial challenge for cancer care delivery in a middle-income setting and underscore the need for health-system strategies aimed at preserving treatment continuity. Research Sponsor: None.

Shortage-related therapeutic modifications reported by oncologists (n = 196).

Therapeutic modification due to shortage	n (%)
Any modification performed	191 (97.4)
Change of treatment regimen	156 (79.6)
Omission of ≥1 planned treatment cycle	141 (71.9)
Delayed / non-timely administration	123 (62.8)
Drug substitution within same class	113 (57.7)
Non-indicated dose reduction	74 (37.8)
Non–guideline-approved regimen	50 (25.5)
Referral to another institution	25 (12.8)
No modifications performed	5 (2.6)

1600 **Poster Session**

Expanding access to tyrosine kinase inhibitors for treatment of Philadelphia chromosome–positive acute lymphoblastic leukemia in low- and middle-income countries. First Author: Lauren Herzog, The Max Foundation, Seattle, WA

Background: Acute lymphoblastic leukemia (ALL) is a hematological malignancy affecting 300,000 people worldwide, with an estimated incidence of 100,000 new cases annually. An important cytogenetic abnormality, the Philadelphia chromosome, causes an aggressive form of disease that affects 3-4% of pediatric and 20-30% of adult patients. Since the early 2000s, tyrosine kinase inhibitors (TKIs) have dramatically transformed the treatment of Philadelphia chromosome positive ALL (Ph+ALL). In high-income countries, different TKI regimens in combination with chemotherapy achieve remission rates >90%, but survival rates in low- and middle-income countries (LMICs) are persistently worse, largely due to access barriers, including high costs of innovative therapies. **Methods:** The Max Foundation provides TKIs at no cost to eligible patients with Ph+ALL and other diseases in resource-limited settings worldwide. We conducted a retrospective review of all patients with a diagnosis of PH+ALL initiating treatment with TKIs between January 1, 2007 and July 31, 2025 through the Glivec International Patient Assistance Program (2007-2017) or Max Access Solutions (since 2017). Data on age at diagnosis, treatments, sex, country of origin, program status, and reason for closure were analyzed using descriptive statistics, with correlations between available variables and length of treatment explored. **Results:** Of 1,671 patients enrolled, 342 (20.5%) remained active at the time of analysis. Males accounted for 967 patients (57.9%). Patients enrolled from 47 LMICs in the Americas (542, 32.4%), Asia excluding India (414, 24.8%), Eastern Europe (365, 21.8%), Africa (219, 13.1%), and India (131, 7.8%). Median age at diagnosis was 29, with 485 (29.0%) 18 years old or younger. Most patients (1594, 95.4%) initiated treatment with imatinib as first-line treatment; of these, 110 (6.9%) moved to a second-line treatment and 18 (1.1%) to a third-line. Among 1,329 closed cases, reasons for closure included death (526, 39.8%), lost to follow-up (291, 21.9%), and clinical reasons (260, 19.6%). Median treatment length was 17 months (range 0-197 months). Patients who died were older at diagnosis (median 34 vs 28 years old) and had a shorter median treatment duration (13 vs 19 months) compared with other patients. Treatment duration tended to decrease with age; with a significant negative correlation between age at diagnosis and total months of treatment (r=-0.171, $p<0.001$). Since 2024, 25 patients received additional supportive services through The Max Foundation, including transportation assistance. **Conclusions:** This program demonstrates the feasibility of providing TKIs for the treatment of PH+ALL in diverse resource-limited geographies. Increasing access to TKIs is a critical step in eliminating global disparities in the burden of Ph+ALL. Research Sponsor: None.

"Who even talks to her anymore?" Misalignment between cervical cancer care landscape and community awareness in Rwanda. First Author: Eulade Rugengamanzi, Butaro Level 2 Teaching Hospital, Butaro, Rwanda

Background: Cervical cancer remains the most common female cancer in Rwanda. Despite the significant advancement in early detection and treatment of cervical cancer in the country, many patients do not seek care or experience significant delays in seeking and getting care. Historically, elements of stigma have contributed to care non-engagement and patient delays. With ongoing growth and expansion of care services over the past decade, we sought to explore the current state of Rwandan patients' perspectives on and experience with cervical cancer stigma. **Methods:** We conducted an exploratory qualitative study using semi-structured interviews of a purposeful sample of 25 patients with cervical cancer, including 12 living with HIV, who were treated at a tertiary cancer facility in Northern Rwanda. Interviews were conducted in Kinyarwanda, audio-recorded, transcribed verbatim, and translated into English. Guided by the Health Stigma and Discrimination Framework, the team conducted thematic analysis supported by NVivo (LUMIVERO). **Results:** Our analysis revealed that cancer stigma remains prevalent in participants' communities, and this stigma has multifaceted impacts on their cancer care journey. Despite the national expansion in the availability of screening, early detection, and curative cervical cancer care services, patients continue to report limited community awareness of cervical cancer, with prevailing beliefs of fatalism and care scarcity. Knowledge gaps in cervical cancer diagnosis, treatment, and side effects contribute to stigmatizing behaviors by family members and neighbors, including rumors and social isolation. Participants also described perceptions of cancer incurability as contributing factors to social isolation. However, illness acceptance and religious engagement were identified as helpful coping mechanisms to mitigate stigma and promote care-seeking. Finally, participants' lived experiences with cervical cancer and survivorship motivated them to encourage others in their community to participate in screening and seek medical care. **Conclusions:** Our findings highlight the influence of community beliefs about cervical cancer on medical care-seeking behavior and community reception of patients. Some beliefs were misaligned with patients' current lived experiences with recent advances in the national cancer care environment. For Rwanda to achieve its cervical cancer elimination goals, these findings reinforce the need for continued community awareness of cervical cancer symptoms and treatment as well as sensitization to the available community assets for early detection and treatment. National analysis of cancer care for refugees in Moldova during the war in Ukraine (2022–2025). First Author: Horia Vulpe, Southern Ohio Medical Center, Portsmouth, OH

Background: Following Russia's invasion of Ukraine in February 2022, Moldova, a non-EU country of 2.3 million, had one of Europe's highest refugee-to-population ratios (6.4%). To meet refugee cancer care needs, the Institute of Oncology and Moldova's Ministry of Health (MOH) established a multi-sectoral financing model with the International Organization for Migration (IOM) and the Blue Heron Foundation (BHF), an American NGO. Refugee patients received a free MOH-funded consultation and access to screening and early detection. Diagnostic tests were then funded by IOM and treatment costs covered by BHF for the initial 15 months of the war, after which all services were reimbursed by IOM-led projects. **Methods:** We conducted a retrospective review of Ukrainian refugee cancer patients at Moldova's main oncology centers from May 1 2022 to July 30, 2025, with near complete national data. We analyzed demographics, diagnoses, diagnostic tests and treatments, and per-patient costs adjusted for PPP. **Results:** Of 1,398 Ukrainian refugees evaluated with suspicion of cancer, 681 (48.7%) were diagnosed with malignancy. 412 unique patients (60.5%) remained to receive medical services in Moldova. Among these, 391 were seen at the Institute of Oncology, 25 at Medpark International Hospital (including 7 seen at both institutions), and 3 at Republican Clinical Hospital. The cohort included 221 women (53.6%) and 191 men (46.4%) with an average age at presentation of 58.8 (range 5 – 88 years-old). The most common malignancies were breast (n=71, 17.2%), urological (n=62, 15%), colorectal (n=51, 12.4%), head and neck (n=40, 9.7%), and gynecological cancers (n=38, 9.2%). 292 patients (70.9%) had locoregional disease, 82 (19.9%) were metastatic, and 38 (9.2%) were unstaged. Diagnostic tests over 39 months included 400 CT scans, 70 bone scans, 69 MRIs, 5 PET-CTs, 83 mammograms, 129 endoscopies, and 20,265 lab tests. 326 (79.1%) received treatment, including 203 surgeries, 695 chemotherapy administrations, and 46 radiotherapy courses. Total costs for diagnostics and treatments covered by IOM and BHF at the Institute of Oncology were available for 305 patients, amounting to 9,943,111 MDL, equivalent to $552,782 USD at an average exchange rate of 18.02 MDL/USD. This corresponds to a mean cost of $1,812 per patient, or $4,502 per patient in purchasing-power-adjusted (PPP) international dollars, using a Moldova PPP conversion factor of 7.24. **Conclusions:** This analysis shows that comprehensive cancer care for refugees in resource-limited settings is possible via rapid partnerships among different sectors. Moldova's model offers replicable lessons for other nations facing similar humanitarian challenges. However, to this day, refugees continue to depend on humanitarian donors such as IOM for cancer services, highlighting the need to develop sustainable financing mechanisms that move beyond emergency response. Research Sponsor: None.

Closing the gap in germline testing in patients with cancer through a clinic-based awareness initiative: From booth to patient's agenda. First Author: Luisina Ines Bruno, Instituto Alexander Fleming, Ciudad Autónoma De Buenos Aires, Argentina

Background: Germline genetic testing (GT) is a standard of care for a broad range of patients (pts) diagnosed with cancer due to expanded guidelines and targeted treatments options. The consequent identification of hereditary cancer susceptibility syndromes (HCS) enables optimal surveillance measures, prophylactic interventions and the identification of at-risk family members. Unfortunately, GT rates in oncology are still low worldwide. Barriers are complex but commonly related to deferred appointments and overwhelmed pts. In Argentina, GT and genetic counseling (GC) have not been endorsed as a public health need, insurance coverage relies on a case-by-case basis and mainstreaming has not been fully implemented, therefore, integrating GT into oncology workflows remains a challenge. **Methods:** Our aim was to describe the impact on GT intake of an information campaign coupled with an appointment help desk in a cancer center. We conducted a high-risk, one-month awareness social media campaign, following a one-week, in-person, information booth (during 06/26/2024 -07/03/2024), strategically placed near the waiting room of a cancer center in Argentina. Both offered informative material and the possibility to attend a free, hybrid- mode, interactive, "meet the expert" session on 07/11/2024. For those who visited the booth, in-person orientation by health providers and scheduling for a personalized GC session (in person or by telemedicine) in the following 3 months was offered. After informed consent, information from social media, landing page interaction and medical records was extracted for analysis. Descriptive statistics with Stata program was performed. **Results:** On social media: ≥600 likes, ≥20 comments, ≥350 landing page visits, ≥278 interactions and 976 new e-mail contacts were registered in the landing page. A peak of 119 visits was recorded on 07/09/2024. Media engagement rate: 5,14 %. 814 individuals registered to the hybrid session with an attendance rate of 30% (245/814), with no differences related to format option (in-person 21/73: 29% and virtual 224/741: 30%, p-value 0.794954). At the booth: 165 pts requested in-person information, 160 were scheduled for a visit: first assessments (1As): 114/160 (71%). Compliance with appointment was 64% between 1As (73/114), GT was suggested to 92% of 1As (67/73) with GT intake of 49/73 (67%) by multi-gene germline panel. Overall, 10/160 HCS were identified (diagnostic yield in intention-to-treat): 6,5%: 3 gATM, 2 gBRCA1-2, 2 gHOXB13, 1 gCHEK2, 1 heterozygous MUTYH, 1 heterozygous FANCA. Risk-reducing surgeries were performed in 4/10 carriers. **Conclusions:** Social media engagement combined with lowering appointments barriers can achieve a high compliance to 1As genetic consultations, GT and consequently identification of HCS among high-risk pts with cancer in resource-limited scenarios. Research Sponsor: None.

1604 Poster Session

Validation of a generative AI-based clinical decision support system for surgical extent in thyroid cancer in Brazil: Potential aid to de-escalating treatment to preserve function. First Author: Sergio Ferreira Juacaba, Wayne University, Detroit, MI

Background: The decision between thyroid lobectomy (TL) and total thyroidectomy (TT) for differentiated thyroid carcinoma involves balancing oncological control with morbidity. While NCCN guidelines support TL for low-risk cases, clinical practice often favors TT due to risk aversion, exposing patients to lifelong levothyroxine dependence. We validated "Korina," a clinical decision support system based on the Gemini Large Language Model developed at Instituto do Câncer do Ceará (ICC), Brazil, to assess its ability to optimize surgical decision-making and identify candidates suitable for organ-preserving surgery. **Methods:** We validated the AI model using a retrospective thyroid cohort (N = 100). The median age was 47 years (IQR 38–55), 87% were female, and histology was predominantly papillary thyroid carcinoma (99%) with 1% follicular. The median reported nodule size was approximately 1.7 cm (IQR 1.2–2.4). We (three independent medical evaluators, one head neck specialist, blinded) compared the surgical recommendations of the AI and a senior head and neck surgeon against NCCN guidelines (ground truth). The primary outcome was the accuracy of the indicated surgical extent (TL vs. TT). Performance metrics included AUC, Accuracy, Precision, and Recall (Sensitivity) for identifying TL candidates. **Results:** In the validation analysis, the AI model demonstrated superior concordance with guidelines compared to standard clinical assessment. The AI achieved an Accuracy of 0.894 and an AUC of 0.895, significantly outperforming the clinician (Accuracy 0.532; AUC 0.542). Critical analysis revealed that the clinician had a high rate of unnecessary TT recommendations, with a Recall of only 0.083 (8.3%) for the TL class. In contrast, the AI model achieved a Recall of 0.833 (83.3%) for TL. **Conclusions:** The Gemini-based system (the first in Brazil to the best of our knowledge) outperformed standard clinical judgment in adhering to NCCN guidelines. The clinician demonstrated a bias toward aggressive surgery, missing over 90% of eligible lobectomy cases. Implementing this AI tool potentially could safely increase the rate of partial thyroidectomies, directly benefiting patients by preserving thyroid function and eliminating the lifelong burden of hormone replacement therapy for a significant proportion of cases. Research Sponsor: None.

Performance metrics of AI vs. clinician (reference: NCCN).

Model	Precision	Recall (Sensitivity)	F1-Score	Accuracy	AUC
AI (Gemini)	0.952	0.833	0.889	0.894	0.895
Clinician	1.000	0.083	0.154	0.532	0.542

Validation of an AI-based clinical decision support system for guideline-concordant prostate cancer treatment at a Brazilian cancer center. First Author: Sergio Ferreira Juacaba, Instituto do Cancer do Ceara, Fortaleza, Brazil

Background: Clinical decision support systems (CDSS) based on large language models may improve adherence to evidence-based guidelines in prostate cancer. We developed a Gemini-based CDSS for localized and locally advanced prostate cancer treatment at Instituto do Câncer do Ceará (ICC), Fortaleza, Brazil, and conducted a validation study comparing its recommendations with National Comprehensive Cancer Network (NCCN) guidelines and real-world physician decisions. **Methods:** We retrospectively included 198 consecutive patients prostate cancer treated at ICC. For each case, the CDSS generated a recommended primary treatment. Independent clinician reviewers assigned reference NCCN-concordant treatment categories. We calculated per-treatment precision, recall, F1-score, and one-vs-rest AUC comparing CDSS and physicians, with particular focus on active surveillance (AS) and radical prostatectomy (RP). **Results:** Overall NCCN concordance was 87.9% for the CDSS and 82.3% for physicians. Treatment-level analysis showed that the CDSS more often and more accurately identified candidates for active surveillance. For AS, the CDSS achieved precision 1.00, recall 1.00, F1-score 1.00, and AUC 1.00, while physicians had precision 1.00 but substantially lower recall (0.24), F1-score 0.39, and AUC 0.62. In contrast, physicians more frequently recommended RP beyond NCCN indications: for prostatectomy, the CDSS showed precision 1.00, recall 1.00, F1-score 1.00, and AUC 1.00, whereas physicians had lower precision (0.40) with recall 1.00, F1-score 0.58, and AUC 0.90. **Conclusions:** In this single-center validation study, a Gemini-based CDSS for prostate cancer treatment achieved higher overall NCCN concordance than treating physicians and improved alignment with guidelines for the appropriate use of AS. These findings suggest that integration of large language model–based CDSS into clinical workflows at cancer centers in low- and middle-income settings may reduce overtreatment and support more value-based prostate cancer care. Although we did not include data on social impossibility of AS, the finding leads to reflections on the possibility of greater use of AS, even in a region with limited resources. Research Sponsor: None.

Performance of a Gemini-based clinical decision support system vs physicians for active surveillance and radical prostatectomy (NCCN-concordant treatment metrics).

Treatment modality	Metric	CDSS (Gemini-based)	Physicians
Active surveillance (VA)	Precision	1.00	1.00
Active surveillance (VA)	Recall	1.00	0.24
Active surveillance (VA)	F1-score	1.00	0.39
Active surveillance (VA)	AUC	1.00	0.62
Radical prostatectomy (P)	Precision	1.00	0.40
Radical prostatectomy (P)	Recall	1.00	1.00
Radical prostatectomy (P)	F1-score	1.00	0.58
Radical prostatectomy (P)	AUC	1.00	0.90

A clinical prediction score to identify symptomatic patients at high risk for colorectal cancer in South Africa. First Author: Yoanna S. Pumpalova, Columbia University Medical Center, New York, NY

Background: Colorectal cancer (CRC) is the third most diagnosed cancer globally with a rising incidence across sub-Saharan Africa. In South Africa (SA), advanced stage at diagnosis drives poor outcomes and limited endoscopic capacity makes early CRC diagnosis guidelines difficult to implement. We developed a clinical prediction score to identify patients with lower gastrointestinal (GI) symptoms at high risk for CRC in SA. **Methods:** Adults (≥18 years old) with ≥1 "red flag" lower GI symptom (weight loss, change in bowel habits, rectal bleeding, anemia, abdominal mass) referred for colonoscopy at two public hospitals in Durban were eligible for this prospective study (Sept 23, 2022 – Dec 9, 2025). Demographic and clinical data, results from a pre- or intra-colonoscopy POC-FIT, and colonoscopy results were recorded. The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of POC-FIT for CRC were calculated. A clinical prediction score was derived using this cohort. The optimal number of prognostic factors for a predictive multivariate logistic regression model were determined using LASSO and model validation was done using bootstrapping technique. Overall performance was assessed using the scaled Brier score, Hosmer-Lemeshow test, and AUC. Analysis was performed using R (v 4.4.1). **Results:** Of 393 enrolled patients (median age 52 years, 54.5% female), 306 (77.9%) had a valid FIT result, with 194 (63.4%) positives. In this symptomatic cohort, the adenoma detection rate was 19.6%, with 15 low-risk (3.8%), 14 high-risk (3.6%) adenomas, and 31 (7.9%) CRCs. POC-FIT had 75% sensitivity, 38% specificity, 9% PPV and 95% NPV for CRC. If patients with a negative POC-FIT had not immediately proceeded to colonoscopy, 102 (33.3%) urgent colonoscopies could have been avoided, but diagnosis would have been delayed for 4 patients with high-risk adenomas and 6 with CRC. The LASSO model, utilizing λ=0.017, selected 3 variables associated with CRC: age greater/less than 50, weight loss (yes/no), symptom duration >3 months (yes/no) (risk score 0-3), with AUC 78.6% for predicting CRC (Table 1). Adding negative FIT result to the clinical prediction score (risk score 0-4) improved performance (AUC 79.2%). Setting a symptom score of ³2 as positive, the specificity for diagnosing CRC was 47.9%, and sensitivity 95.8%. **Conclusions:** Among South African patients referred for diagnostic colonoscopy, FIT has a strong NPV but weak PPV for CRC. A clinical prediction score for CRC among symptomatic South African patients was derived with good performance for ruling out CRC. Future studies will validate this model in the primary care setting. Research Sponsor: ASCO/Conquer Cancer; 2023CDA-8960359887.

Clinical prediction score derived from cohort of symptomatic patients undergoing colonoscopy in Durban, South Africa.

Delivering oncology care in Syria: Implementation lessons from conflict-affected and resource-limited settings. First Author: Maria Hafez, St Luke's University Health Network, Bethlehem, PA

Background: Oncology services are often excluded from humanitarian health response packages despite the rising cancer burden in conflict-affected populations. In northwest Syria, protracted conflict disrupted referral pathways, depleted the specialist workforce, and constrained diagnostic infrastructure. The Syrian American Medical Society (SAMS) implemented a conflict-adapted oncology model that evolved from remote specialty support (2017) to decentralized service delivery with phased diagnostic strengthening and workforce development. We report multi-year program outputs as indicators of implementation feasibility and scale. **Methods:** We conducted a retrospective program evaluation using routinely collected, aggregate operational indicators from SAMS-supported oncology services in northwest Syria (fixed sites with referral/outreach pathways). Annual indicators (2022–2025) included: total patients served, new patients, new malignant diagnoses, total oncology diagnoses (benign + malignant), and chemotherapy administrations. Longitudinal patient-level outcomes were not consistently captured due to displacement, insecurity, and lack of a unified electronic medical record during early scale-up. **Results:** Total patients served increased from 20,779 (2022) to 28,392 (2025) (+36.6%). New patients increased from 4,648 to 12,467 (+168.2%). New malignant diagnoses increased from 1,373 to 2,000 (+45.7%), and total oncology diagnoses increased from 15,102 to 21,918 (+45.1%). Chemotherapy administrations increased from 7,177 to 15,008 (+109.1%). Key implementation milestones included the establishment of the Idlib Cancer Center (2018), phased immunohistochemistry enabled through cross-border workflows and remote expert interpretation, and the institutionalization of local diagnostic capacity through a pathology residency launched around mid-2023, supported by hybrid local/remote mentorship and digital pathology infrastructure (slide scanning for remote review). A persistent system gap was the lack of local radiotherapy, requiring cross-border referral pathways that were vulnerable to administrative and access disruptions. **Conclusions:** A phased "minimum oncology service package" integrating decentralized delivery, tele-enabled expertise, and staged diagnostic/workforce strengthening can be implemented and scaled in protracted conflict settings. In the SAMS model, structured fellowship teaching, e-consultations, and a virtual breast tumor board supported timely decision making, while missions and workshops reinforced local capacity. This transferable framework supports integrating oncology into humanitarian responses, alongside investment in radiotherapy access and continuity-of-care data systems. Research Sponsor: None.

Optimization of immunotherapy duration for advanced melanoma: The prospective OTIMAS trial. First Author: Milena Perez Mak, Instituto do Cancer do Estado de São Paulo - Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil

Background: Anti-PD1 monotherapy is a common option for first-line treatment for advanced melanoma in resource-constrained settings. A shorter duration of therapy and associated biomarkers of response can reduce financial burden for healthcare systems. **Methods:** In this phase 2 single-arm trial, pts with unresectable stage III-IV melanoma received pembrolizumab (Pem) 200mg intravenously every 3 weeks for a maximum of 12m. Primary endpoint was 24m progression-free survival (PFS); secondary endpoints included overall response rate per RECIST 1.1 and overall survival (OS) and safety. An additional course of therapy was allowed if progression was observed after 6m of treatment interruption. Exploratory analysis included miRNA cargo of small extracellular vesicles (sEVs) and cost-effectiveness analysis of 12m vs. 24m in the context of the universal Brazilian health system. **Results:** 29 pts were enrolled from Jan 2022 to Jan 2025. As of Sep 2025, all had completed treatment, with a median follow-up of 19.1m (0.6-45.3). Median age was 59 years (28-85), 55.2% were male, 72.4% had metastatic disease and 20.7% had ECOG-PS $>$1. 41.4% presented with high baseline LDH. 2 pts had acral melanoma. 20.6% had received previous chemotherapy. Median PFS was 5.7m (IC95% 3.1-8.4) and 24m-PFS, 23.8%. 2-y OS was 42.8% (IC 95% 24.2-61.4). ORR was 34.5% (10/29), with 51.7% DCR. Among 24.1% who completed 12m of Pem, only one pt experienced PD less than 6m after completion of Pem. One death due to immune related pneumonitis was observed. The percentage of variable expressed regions in sEVs differed according to immunotherapy (IO) response profile. Cost analysis showed that the medication cost was reduced by 53.75% when compared to the 2-year strategy. **Conclusions:** This trial demonstrated that one year treatment with IO is feasible and provides comparable outcomes to a standard 24m treatment (mPFS 5.6 range 3.4–8.2; 2-year OS 55% IC 95% 49-61%), regardless of response. This strategy can be cost effective and provide broader access to immunotherapy and improve resource allocation in public health systems. Specific miRNAs were identified for a potential response signature to select patients with long-term benefit. Clinical trial information: NCT07376317. Research Sponsor: Medical Oncology Department - Instituto do Cancer do Estado de Sao Paulo.

Optimization of geospatial oncologist placement: A maximum coverage problem approach. First Author: Ryan James Crowley, NYU Grossman School of Medicine, New York City, NY

Background: Rural communities in the United States (US) experience persistent shortfalls accessing oncology care due to an uneven workforce distribution. Non-specific county-level metrics fail to pinpoint precisely where new oncologists can maximize impact. By adapting a maximal coverage algorithm to the ZIP code level, our study aims to provide a data-driven solution to physician placement by identifying high demand areas with significant unserved populations. **Methods:** We developed a model to simulate capacity-constrained maximal coverage expansion of oncology care with up to 500 oncologist placements per state, 40 kilometer catchment radii, and an assumption that one oncologist could cover up to 6,667 individuals over 55 years old (based on baseline US prevalence of 15 oncologists per 100,000 individuals over 55). We used physician data from the Doctors and Clinicians national downloadable file, geographical data from the US Census, and Rural-Urban Continuum Codes (RUCCs) to measure rurality. Outcomes measured included baseline state-level coverage, number of placements needed to achieve 90% state-level population coverage, and urban-rural placement differences. For continuous variables, the two-sample t-test was used for statistical significance. **Results:** Nationally, approximately 26 million additional individuals would gain coverage with 5,578 additional placements. 2,912 (52.2%) of the optimal ZIP codes were in rural counties. Placements provided a mean coverage of 4,684 people per physician. Median baseline state coverage was 67.8% (IQR 59.9%-77.1%), with 3 states having $>$90% coverage at baseline (Rhode Island, Connecticut, and New Jersey). To achieve 90% coverage, states required a median of 40 placements (IQR 18.25-63.25). Coverage gains per state were front-loaded with the first 25 oncologists in a state capturing on average 46.7% of all achievable gains. The states that required the greatest number of additional oncologists to achieve 90% coverage were: California (N=209), Florida (N=174), and Texas (N=163). The top five rural placements per state covered an average of 6,505 individuals while the top five urban placements per state covered an average of 6,220 individuals (p-value = 0.009). **Conclusions:** Our approach precisely identified underserved ZIP codes where oncologist placement would maximize access to care. Strategic placement of oncologists can lead to increased access to care, particularly for rural residents. These policies should initially be directed toward states and ZIP codes with the largest baseline gaps to maximize coverage and advance equitable healthcare access. Research Sponsor: None.

Scaling prior authorization for philanthropic funding with artificial intelligence (AI): Five-year outcomes from Indian Cancer Society Cancer Cure Fund (ICS-CCF) NavyaAI implementation. First Author: Nehal Rishi Khanna, Indian Cancer Society, Mumbai, India

Background: Indian Cancer Society - Cancer Cure Fund (ICS-CCF) is one of the largest charitable program for directly reimbursable treatment expenses to needy cancer patients. The prior authorization process at ICS-CCF requires the Due Diligence Team (DDT) and the Governing Advisory Council (GAC) to review every application for compliance with standardized treatment guidelines, expected cure rates, and approved costs. To augment and enhance this process, ICS-CCF evaluated and implemented the use of Artificial Intelligence (AI) to support application review and recommendations over a five-year study period. This study is a five year report on operational outcomes to reduce dependence on expert oncologists in the prior authorization setting using AI for care delivery. **Methods:** The NavyaAI platform is a clinically validated AI model that matches clinical data from beneficiary applications (input) with available clinical evidence and National Cancer Grid (NCG) guidelines, adapted to ICS-CCF approval criteria (output). Applications in which the AI output matched the input were classified as "recommended" and forwarded directly to the GAC for approval. All remaining cases were referred to the DDT, comprising a minimum of two expert oncologists, who reviewed the applications and forwarded recommendations to the GAC as appropriate. Concordance between NavyaAI and GAC decisions was assessed. The time spent by the DDT reviewing referred applications was recorded. DDT reviews were conducted weekly, and GAC reviews were conducted bi-monthly. **Results:** From April 2020 to November 2025, a total of 12001 (malignant solid tumors 63.77% (7653/12001) and hematolymphoid malignancies 36.23% (4348/12001) applications were reviewed by NavyaAI. Of these, 82.58% (9,910/12001) were recommended, 1.71% (205/12001) were rejected, and 15.72% (1,886/12001) were referred to the DDT. Concordance between NavyaAI and GAC decisions was 99.57% (9,867/9,910) for authorizations and 92.68% (190/205) for rejections. The DDT spent an average of 3 minutes reviewing each application referred by NavyaAI. On average, NavyaAI forwarded 35 applications directly to the GAC per week, saving a minimum of 210 minutes of oncologist review time weekly. **Conclusions:** NavyaAI can independently review and assess the majority (~84%) of beneficiary applications for recommendation or rejection with high concordance to expert decision-making. Further implementation of AI-assisted authorization models is warranted to scale their long-term impact on quality, efficiency, and scalability of philanthropic funding decisions within governmental and non-governmental healthcare schemes. Research Sponsor: None.

Predicting immune-related adverse events (irAEs) with large language model (LLM) embeddings. First Author: Tiffany Tian, Georgetown University School of Medicine, Washington, DC

Background: irAEs are a common side effect of immune checkpoint inhibitor (ICI) therapy. Predicting irAEs from clinical records relies on traditional machine learning methods, which require time-consuming and extensive feature engineering such as removing features with many missing values or imputing values. Using LLM vector embeddings to train classifier models may require less feature engineering and leverage LLM understanding of semantic information. We assessed whether this LLM method could predict development of irAEs 12 weeks after initiating an ICI. **Methods:** We used patient (pt) data from the Immuno-Oncology Registry, a database of cancer pts from 10 DC-Baltimore-based MedStar Health network hospitals and Hackensack Meridian Health system in New Jersey. The data were divided into training (80%) and testing (20%) datasets. The training dataset was oversampled to balance the irAE class distribution. Tabular data was serialized into natural language, then passed into a LLM with original text, 0-shot, 1-shot, or few-shot prompting. Due to LLM context length limits, pt information was separated into 9 components, and each component embedding was max-pooled before concatenation. The embeddings were used to train 4 classifier models with hyperparameter tuning: XGBoost, support vector machine (SVM), logistic regression (LR), and multilayer perceptron (MLP). Five different sentence transformer or text embedding LLMs were tested. Model classification performance was evaluated by Area Under the Receiver Operating Characteristic curve (AUROC). **Results:** Of the 1459 pts, 585 (40%) experienced irAE(s). The most common cancers were lung cancer (34.5%) and melanoma (27.7%). ICIs included anti-CTLA-4 (11.0%), anti-PD-1 (58.9%), anti-PD-L1 (4.6%), anti-PD-1 + anti-CTLA-4 (14.0%), anti-PD-1 + chemotherapy (3.1%), anti-PD-1 + tyrosine kinase inhibitor (0.07%), and others (8.4%). The most common irAEs were skin rash (14.5%) and colitis (8.9%). Median AUROC was highest for XGBoost (0.654), followed by LR (0.641), MLP (0.627), and finally SVM (0.596). Median AUROC was highest for 0-shot (0.641), followed by original (0.636), 1-shot (0.619), and few-shot (0.516). Of the LLMs tested, intfloat/e5-base combined with XGBoost and the original prompt demonstrated the strongest performance (AUROC = 0.712, see Table), although for 0-shot and 1-shot LR was a stronger classifier. **Conclusions:** Using LLM embeddings to train classifier models is feasible for making predictions with tabular medical data, works best with XGBoost, and does not need prompt engineering. This method requires less feature engineering and data processing compared to standard approaches and leverages the extensive pre-training and semantic understanding of LLMs to achieve predictive power. The use of generative AI tools by cancer patients and caregivers: A cross-sectional survey of awareness, attitudes, and experiences. First Author: Rashad Ismayilov, Baskent University, Ankara, Turkey

Background: Generative artificial intelligence (AI) tools offer novel avenues for patient support, yet data on their adoption in oncology remain limited. This study evaluated the awareness, attitudes, and usage patterns of these tools among cancer patients and caregivers to inform clinical integration. **Methods:** A descriptive, cross-sectional survey was conducted at a tertiary oncology center. Adult cancer patients and caregivers completed an anonymous, structured questionnaire assessing sociodemographics, digital literacy, AI usage patterns, and perceptions. Multivariate logistic regression identified independent predictors of AI use. **Results:** A total of 400 participants (68% patients, 32% caregivers; mean age 59 years) were included. While 75% were aware of AI chatbots, only 24% used them for cancer-related information. Multivariate analysis revealed that university-level education (adjusted odds ratio [aOR] = 4.47, $p < 0.001$), younger age ($\leq$55 years; aOR = 2.64, $p < 0.001$), and recent diagnosis ($<$1 year; aOR = 2.16, p = 0.003) were independent predictors of AI use (Table 1). Notably, 69.1% of users did not disclose their AI use to their physician. Despite this, no user reported decreased trust in their physician; in fact, 26.8% reported an increase. A substantial 73.3% of all participants expressed a willingness to use a physician-verified AI tool. Subgroup analysis revealed divergent usage patterns: caregivers used AI more regularly (weekly/daily: 54.3% vs. 30.6%; p = 0.022) and focused on researching medical terminology (62.9% vs. 38.7%; p = 0.022) and alternative medicine (34.3% vs. 16.1%; p = 0.040), whereas patients were significantly more likely to seek emotional support (22.6% vs. 5.7%; p = 0.032). **Conclusions:** Generative AI use among cancer patients and caregivers remains moderate and reflects a marked digital divide driven by age and education. The prevalence of "silent" AI use raises significant patient safety concerns related to the risks of unverified information. Nevertheless, the strong demand for physician-endorsed tools highlights a clear opportunity for clinical integration. Oncologists should proactively address AI usage to mitigate misinformation risks and ensure safe integration into clinical practice. Research Sponsor: None.

Independent predictors of generative AI use for cancer information (n=400).

Parameter	aOR	95% CI	*p* value
Age (≤55 years vs. >55 years)	2.64	1.594 - 4.381	<0.001
Education level (University or higher vs. lower)	4.47	2.195 - 9.109	<0.001
Time since diagnosis (<1 year vs. ≥1 year)	2.16	1.289 - 3.625	0.003

Abbreviations: aOR, adjusted odds ratio; CI, confidence interval.

Identifying cancer cachexia using clinical reasoning artificial intelligence (AI). First Author: Vibhor Gupta, Pangaea Data, London, United Kingdom

Background: Cancer cachexia, a severe wasting syndrome, affects up to 87% of cancer patients[1] and contributes to $\geq$20% of cancer deaths[2]. Despite this burden, ~85% of healthcare providers are unfamiliar with diagnostic criteria[3], leaving patients often undiagnosed. This study evaluated whether a Clinical Reasoning AI model configured on four cachexia guidelines (Fearon[4], Evans[5], GLIM[6] and mGPS[7] criteria) and designed to emulate clinician chart review, could accurately identify cancer cachexia. **Methods:** Using structured (vitals, labs) and unstructured (clinical notes) electronic health record data the Clinical Reasoning AI employed retrieval-augmented generation[8] and agentic techniques with large language models (LLMs) to: (1) retrieve clinically relevant information based on the clinical guidelines via natural language processing (NLP) and embedding, and (2) apply guideline-based reasoning to classify patients into Group 1 (no cachexia features), Group 2 (meets $\geq$1 guideline regardless of documented diagnosis), or Group 3 (documented cancer cachexia). Accuracy was assessed against a gold standard of 50 patients classified by two independent clinicians, with conflicts resolved by a third. Performance was compared against baseline methods: ICD coding (ICD-9 799.4; ICD-10 C80.9), NLP using keywords like cancer or cachexia, and LLMs (Vanilla OpenAI GPT-o4-mini) prompted without explicit instruction to use guidelines. **Results:** The Clinical Reasoning AI demonstrated high precision, sensitivity, and specificity, outperforming baselines, particularly for Group 2 patients. ICD and NLP methods could not detect Group 2, due to code- and keyword-based constraints. Performance of LLMs without guidelines worsened with structured and unstructured data, indicating sensitivity to data overload and inability to prioritise clinically relevant information. **Conclusions:** These results show that embedding clinical guidelines within a structured retrieval-and-reasoning architecture enabled accurate identification of cancer cachexia, addressing a critical gap where standard coding and keyword methods fail. The guideline-driven approach maintained accurate clinical reasoning while processing complex EHR data. The Clinical Reasoning AI model is currently being deployed at the point of care to assess real-world implementation and impact on patient outcomes. Research Sponsor: Pangaea Data.

Prospective evaluation of AI-assisted documentation and summarization in virtual multidisciplinary cancer conferences. First Author: Luxiga Thanabalachandran, Queen's University School of Medicine, Kingston, ON, Canada

Background: Multidisciplinary cancer conferences (MCCs) are central to high-quality oncologic decision-making but are frequently constrained by time-intensive and variable documentation processes. Artificial intelligence (AI) can enhance multidisciplinary collaboration by improving the accuracy, timeliness, and consistency of documentation. However, prospective evaluations of AI tools embedded within MCC workflows remain limited. **Methods:** We conducted a prospective pilot study at the Cancer Centre of Southeastern Ontario, a regional academic cancer center in Ontario, Canada. In October 2025, a hospital-approved AI system, Microsoft Copilot, was integrated into all virtual lung and gastrointestinal (GI) MCCs conducted via Microsoft Teams. All conferences were recorded and transcribed. Structured prompts for AI-generated summaries were co-developed with MCC stakeholders and refined through iterative Plan-Do-Study-Act (PDSA) cycles. AI-generated summaries were validated against clinician-prepared electronic health record (EHR) documentation. Two independent reviewers assessed case identification accuracy and concordance of key clinical content. Following validation, AI summaries were distributed to MCC participants after case discussions to support EHR documentation, with mandatory clinician verification prior to finalization. **Results:** A total of 125 patient cases from lung and GI MCCs were analyzed, of which 108 had corresponding clinician-prepared EHR documentation available for comparison. Inter-rater agreement between reviewers assessing concordance of AI-generated and clinician-prepared summaries demonstrated high agreement (Cohen's κ = 0.87). Case identification accuracy was high, with agreement rates of 97% for case number, 93% for medical record number, 96% for patient initials, 98% for presenter, 99% for diagnosis, and 99% for cancer stage; most identification discrepancies were minor and improved over time. Clinical content concordance was high, including discussion summaries at 99%, radiology at 99%, pathology at 98%, and treatment plans and next steps at 96%. Major discrepancies involving key clinical decisions were identified in 0.9% of cases. All AI-generated summaries were distributed within 24 hours following MCC completion, with a median clerical preparation time of 14 minutes per case. **Conclusions:** In this prospective, real-world evaluation, AI-assisted summaries integrated into virtual MCC workflows demonstrated high accuracy, strong safety performance, and meaningful efficiency gains. With mandatory clinician oversight, AI-supported summarization was feasible and timely, supporting its role as a scalable model for MCC documentation across oncology programs. Further multicenter studies are warranted to evaluate generalizability, clinician workload impact, and downstream effects on care delivery. Research Sponsor: None.

Assessing the true burden of immune-related colitis in lung cancer through large language model–enabled clinical phenotyping. First Author: Himil Mahadevia, Mayo Clinic Florida, Jacksonville, FL

Background: Immune checkpoint inhibitors (ICIs) have revolutionized lung cancer treatment but cause adverse events, including immune-related colitis (ir-colitis). Accurate identification of ir-colitis is critical for improving patient outcomes and clinical research. However, current methods relying on ICD codes have substantial limitations: non-specific categories that fail to capture the cases or distinguish cases from infectious or ischemic etiologies, as well as incomplete coding that leads to missed cases. Large language models (LLMs), with advanced natural language understanding capabilities, offer a scalable approach for automated phenotyping using unstructured clinical notes. We aimed to develop and evaluate an LLM-based approach for identifying ir-colitis in patients with lung cancer receiving ICIs and compare it with ICD code based method. **Methods:** We identified 5,278 lung cancer patients with ICI administration at Mayo Clinic (2012-2025). To investigate ir-colitis occurrence within two years after ICI initiation, patients were stratified into three ICD-based cohorts: (1) IR-Colitis, with clinician-assigned ir-colitis-specific diagnosis codes; (2) Non-IR Colitis, with colitis diagnosis codes excluding ir-colitis; and (3) No-Colitis, absent of any colitis-related codes. We used three open-source LLMs to process clinical notes : Llama4, MedGemma, and Qwen. Prompts were designed to extract both gold standard evidence (explicit ir-colitis terminology, such as "immune-mediated colitis" and "checkpoint inhibitor colitis") and supportive evidence (such as pathology and lab results). **Results:** Llama4 demonstrated superior accuracy among three LLMs in manual evaluation and was thus selected for all cohort analyses. Among ICD-based IR-Colitis patients (n = 339), 82.0% had confirmatory evidence while 18% lacked evidence, suggesting potential false-positive coding. In the Non-IR Colitis cohort (n = 297), LLM-based extraction identified 43.8% patients in fact had ir-colitis, demonstrating substantial misclassification. In the No-colitis cohort (n = 4,642, random sample of 996 for analysis), the LLM identified 10.7% with documented ir-colitis, revealing substantial missing by administrative coding. **Conclusions:** LLM-based phenotyping demonstrates superior sensitivity for identifying ir-colitis compared to ICD codes alone, successfully uncovering cases missed by administrative coding. This scalable approach enables more comprehensive case identification for immunotherapy safety research and clinical surveillance. Research Sponsor: None.

	LLM-Identified ir-Colitis		
ICD-Based Cohorts	**Gold Standard Evidence**	**Supportive Evidence**	**Any Evidence**
ir-Colitis (n = 339)	277/339 (81.7%)	275/339 (81.1%)	278/339 (82.0%)
Non-ir-Colitis (n = 297)	129/297 (43.4%)	126/297 (42.4%)	130/297 (43.8%)
No Colitis (n = 996)	106/996 (10.6%)	104/996 (10.4%)	107/996 (10.7%)

Correlation of tumor-naive methylation-based preoperative ctDNA testing with pathologic upstaging and occult metastasis in early-stage solid tumors. First Author: Xiangnan Li, Department of Thoracic Surgery, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: The TNM staging system serves as the cornerstone for most solid tumor treatment strategies. However, preoperative evaluation of early-stage cancers is not always reliable, with a particular propensity to overlook occult lymph node metastasis (OLNM) or even distant metastases. In turn, incorrect staging may lead to suboptimal perioperative decisions, including inappropriate surgical strategies, unjustified neoadjuvant therapy, and inadequate lymph node dissection. This study evaluated whether preoperative circulating tumor DNA (ctDNA) detected by methylation-based assay is associated with pathologic upstaging and the presence of OLNM or distant metastasis across multiple types of solid tumor. **Methods:** This study analyzed preoperative blood samples from a validation cohort within a multi-cancer early detection (MCED) study, encompassing 16 high-burden cancer types in China. Lymphomas, liver cancer, and nasopharyngeal carcinoma were excluded, due to limited use of TNM staging and/or non-routine radical surgery. Patients who had received neoadjuvant therapy were also excluded. ctDNA was detected using a targeted methylation-based MCED assay. Associations between ctDNA positivity and discrepancies between clinical (cTNM) and pathologic (pTNM) staging-including upstaging due to OLNM or distant metastasis-were examined statistically. **Results:** A total of 681 cases of clinical stage I–II cancers were analyzed, including lung cancer (n=124), breast cancer (n=113), colorectal cancer (n=88), gastric cancer (n=79), pancreatic cancer (n=55), cervical cancer (n=54), ovarian cancer (n=36), prostate cancer (n=34), esophageal cancer (n=32), endometrial cancer (n=31), bladder cancer (n=17), renal cancer (n=17), and gallbladder cancer (n=1). Preoperative ctDNA was detectable in 46.8% (184/393) of stage I and 71.5% (206/288) of stage II patients. ctDNA-positive patients were more likely to undergo pathologic upstaging than ctDNA-negative patients (16.9% vs. 6.9%; p=0.0002). For patients with clinical N0 (cN0), OLNM (defined as preoperative cN0 with postoperative confirmation of pN1–3) was more common in ctDNA-positive patients (12.6% vs. 4.7%; p=0.0012) . Among clinically M0 patients, three were confirmed as pathologic M1, all ctDNA-positive. **Conclusions:** Methylation-based preoperative ctDNA testing correlates with pathologic upstaging and OLNM, and may also be associated with occult distant metastasis. This finding supports the potential of ctDNA testing to refine preoperative staging and inform perioperative decision-making. Further validation with an expanded sample size will be conducted in an additional blinded cohort to confirm these findings. Research Sponsor: Shanghai Xiaohe Medical Laboratory Co. Ltd.

Sources matter: Learning to evaluate large language models for oncology treatment plans and changes observed by anchoring models to an oncology-specific database. First Author: Connor Yost, Creighton University School of Medicine-Phoenix, Phoenix, AZ

Background: Large language models (LLMs) are increasingly evaluated for oncology decision support, yet guideline concordance and hallucinations remain variable across cancer types and tasks. Retrieval-augmented generation (RAG) may improve safety by constraining the evidence base used during generation. Prior oncology LLM studies report discordance with guideline-based care, but few describe a reproducible health-system "vetting mechanism" that couples guideline-only retrieval with clinician-scored safety rubrics across multiple oncology domains. **Methods:** We assembled 316 de-identified oncology cases in a tumor-board template: medical oncology (breast, GI, GU, leukemia; n=216), gynecologic oncology (n=50), and neuro-oncology/CNS metastatic cancer (n=50). Each case was run on three systems: baseline GPT-4 (O1), NCCN-guideline anchored RAG (O2; guideline-constrained retrieval), and a literature-anchored system (OpenEvidence; O3). Oncologists independently scored outputs using a modified Generative Performance Score (mGPS; −1 to +1) combining guideline concordance with hallucination penalties; readability/rationality was scored on a 1–5 Likert scale. Inter-rater reliability was assessed (κ =.63). This workflow was designed as a pre-deployment model credentialing step for health-system governance (source policy → case bank → clinician-scored acceptance criteria). **Results:** Across all 316 cases (case-averaged), O2 achieved the highest mean total mGPS (0.75) compared with O1 (0.43) and O3 (0.59). In the medical oncology cohort (n=216), O2 outperformed O1 and O3 (mean mGPS 0.72 vs 0.35 and 0.54), with higher guideline concordance (0.85 vs 0.68 and 0.75) and lower hallucination penalties (−0.09 vs −0.25 and −0.19); readability was also highest for O2 (4.17 vs 3.22 and 3.86). In gynecologic oncology (n=50), O2 again performed best (mGPS 0.827) relative to O3 (0.697) and O1 (0.647). In the CNS cohort (n=50), mean composite mGPS favored O2 (0.82) over O3 (0.68) and O1 (0.55), while readability remained stable across models (3.55–3.73). Severe hallucination/unsafe recommendation rate: O1 [26%], O2 [5%], O3 [17%] (pre-specified definition; e.g., major fabricated citation or guideline-discordant harmful recommendation). **Conclusions:** In a 316-case, multi-domain clinician-scored evaluation, limiting retrieval to oncology guideline sources improved safety-aligned performance relative to unconstrained generation or literature-only anchoring. A guideline-constrained RAG configuration paired with clinician-scored rubrics and tail-risk reporting can serve as a practical health-system vetting mechanism for governance, re-validation, and change control of LLM decision support, including in resource-limited settings where reliable guideline-consistent recommendations are essential. Impact of AI-augmented histopathology review on next-generation sequencing (NGS) success. First Author: Boleslaw Leszek Osinski, Tempus AI, Inc., Chicago, IL

Background: Insufficient nucleic acid quantity (QNS) can compromise NGS success (QNS rates can be >20%), necessitating re-biopsies and delaying therapy. While interventions like extended de-crosslinking (EXT) can rescue samples with low total nucleic acid (TNA) yield tissues, they prolong processing times, demanding a precise method to identify samples requiring such processing. We developed an AI system, Paige Predict (PP), that analyzes digitized H&E slides to predict NGS QNS and recommend tissue input quantity. This study evaluates PP in two contexts: (1) optimizing internal lab workflows by selectively routing high-risk samples to EXT, and (2) exploring its utility in an external setting, Cedars-Sinai (CS), to triage samples for comprehensive Tempus genomic profiling (CGP), requiring >50ng input, vs targeted low-input assays (>5ng) performed at CS. **Methods:** We conducted a validation study in the Tempus lab comparing a baseline period prior to introduction of EXT (July 2024 - Sept 2024 n=17,026) against an intervention period (Oct 2025 - Nov 2025, n=12,975) where PP automatically routed at-risk samples to EXT. To evaluate external utility, we also performed a retrospective analysis on a cohort of CS pts. We assessed PP's ability to predict CGP QNS, and compared it against pathologist assessment for inter-institutional sample referral. **Results:** In the validation study, PP-guided EXT routing reduced joint DNA+RNA QNS rates by 19.6%, with a number needed to test (NNT; 1/Absolute Rate Reduction) indicating that for every 40.2 pts, one received a result that would otherwise not have. RNA QNS rates reduced by 15.9% (NNT 63.7) relative to the baseline period. This reduction was achieved while decreasing net tissue input by 16.7% and increasing TNA yields in the optimal range (100–1500ng) by 19.0% (NNT 10.1). Similar benefits were observed in the NSCLC subset. In the external CS cohort, PP could have triaged 74% of samples that failed Tempus CGP to low input sequencing at CS. Conversely, PP indicated that over 70% of samples sequenced at CS could have succeeded with Tempus CGP. **Conclusions:** PP significantly reduces NGS failure rates and improves tissue stewardship by deploying rescue workflows only when necessary. These analyses lay the groundwork for a future multi-institution prospective trial and establish PP as a scalable AI tool to amplify access to precision oncology. Research Sponsor: None.

Validation of electronic phenotyping algorithms for prostate cancer in All of Us and their impact on genetic association studies. First Author: Zachary Creech, Department of Medicine, Duke University School of Medicine, Durham, NC

Background: The *All of Us* Research Program enables large scale population-based genetic association studies of cancer. *All of Us* does not contain cancer registry data, risking misclassification of cancer diagnosis. Thus, validated electronic phenotyping algorithms for cancer diagnoses are needed. We sought to develop and validate prostate cancer (PCa) phenotyping algorithms in *All of Us*, and assess the impact of different algorithms on gene-cancer associations. **Methods:** We conducted a cross-sectional analysis of *All of Us* male participants aged ≥50 years with structured electronic health record (EHR), personal health history survey, and whole genome sequencing (WGS) data (Duke IRB Pro00119057). Using self-report of PCa history as the gold standard, we developed and evaluated two electronic phenotyping algorithms: (1) two PCa diagnosis codes; or (2) two PCa diagnosis codes plus evidence of PCa treatment with radical prostatectomy, radiotherapy, or androgen deprivation. For each algorithm, we computed positive predictive value (PPV), and negative predictive value (NPV) with 95% confidence intervals (CI). Using each algorithm, we conducted genetic association studies between PCa and rare pathogenic variants (RPVs) in PCa predisposition genes (*ATM, BRCA1, BRCA2, HOXB13* G84E) among male participants with structured EHR and WGS data. Included RPVs had pathogenic/likely pathogenic designation in ClinVar with at least two stars. Gene-based odds ratios (OR) and 95% confidence intervals (CI) were calculated using logistic regression, adjusting for age and top 5 principal components. **Results:** We included 21,883 males in the validation study of PCa phenotyping algorithms, 3,961 (18.1%) of whom reported a personal history of prostate cancer. Algorithm 1 demonstrated a PPV of 0.897 (95% CI 0.885 – 0.907) and NPV of 0.927 (95% CI 0.923 – 0.931). Algorithm 2 demonstrated a PPV of 0.927 (95% CI 0.910 – 0.942) and NPV of 0.864 (95% CI 0.860 – 0.869). In the study of gene-PCa associations, 94,446 male participants were included, except for *HOXB13* G84E (n = 59,915), which was limited to those of European ancestry. Associations between RPVs in PCa predisposition genes and PCa diagnoses using the two algorithms are shown in the Table. **Conclusions:** The inclusion of PCa treatment improves the PPV of PCa electronic phenotyping algorithms. PCa phenotyping definitions influence the results of downstream genetic association studies, and highlight the need for accurate and validated electronic phenotyping algorithms when using *All of Us*. Research Sponsor: None.

Gene	OR[a] (Algorithm 1[b])	95% CI[c] (Algorithm 1)	OR (Algorithm 2[d])	95% CI (Algorithm 2)
ATM	2.10	1.47 - 2.92	2.68	1.67 - 4.08
BRCA1	1.11	0.73 - 1.61	1.16	0.61 - 1.98
BRCA2	2.14	1.53 - 2.92	3.11	2.04 - 4.56
***HOXB13* G84E**	3.88	2.75 - 5.39	3.31	1.98 - 5.22

[a]OR = odds ratio.
[b]Two prostate cancer diagnosis codes.
[c]CI = confidence interval.
[d]Two prostate cancer diagnosis codes plus treatment.

A context-constrained oncology agent for automated, guideline-concordant treatment decision support in precision oncology. First Author: Deva Datta Reddy Jyothi, Cancer Moonshot, Bengaluru, India

Background: Precision oncology requires biologically plausible, clinically executable decisions aligned with regulatory approvals. General-purpose Large Language Models (LLMs) often produce recommendations rejected by molecular tumor boards due to semantic drift, inappropriate agent extrapolation, and ignored clinical constraints, raising significant safety concerns for point-of-care adoption. **Methods:** GenOnco is a constrained oncology agent integrating NCCN, ASCO, and ESMO clinical practice guidelines; FDA/EMA regulatory approvals; NEJM seminal articles and high-impact publications; curated clinicogenomic resources (e.g., Molecular Oncology Almanac); comprehensive clinical trials knowledge (ClinicalTrials.gov, landmark phase III results); and practice-changing trial evidence. The system utilizes a dual-layer architecture: a reasoning LLM paired with a deterministic, non-LLM clinical decision layer that enforces line-of-therapy requirements and actionability filters independent of generative output. We evaluated GenOnco on 102 multi-institutional oncologist-derived real-world solid tumor queries, independently scored by two blinded oncologists (κ = 0.87). Performance was benchmarked against published datasets: MEREDITH (200 cases) and Google DeepMind AMIE (100 cases). Primary endpoints were guideline concordance and clinical executability, analyzed via McNemar's test (N = 162). **Results:** GenOnco achieved 95.1% accuracy (95% CI: 91.2%–98.4%) on synthetic benchmarks and 93.1% (95% CI: 89.1%–96.5%) on real-world queries, eliminating 100% of expert-rejected outputs from comparators. GenOnco significantly outperformed GPT-4o (48.1%), Claude 3.7 (49.4%), Gemini 2.5 (50%), ASCO Guidelines Assistant (67.3%), OpenEvidence, MEREDITH, and Google DeepMind AMIE (all $P < .001$; N = 162), with gains of 15-47 percentage points. **Conclusions:** Constrained reasoning prioritizing executable pathways outperforms unconstrained LLMs for precision oncology support. Limitations include solid tumor focus and query diversity; diverse population validation planned. GenOnco demonstrates potential for point-of-care integration. Research Sponsor: None.

1621 Poster Session

Comparing oncologists, a GPT-based model, and a SEER-based survival calculator for cancer prognostication. First Author: Lyndon Huang, Dell Medical School, The University of Texas at Austin, Austin, TX

Background: Prognostic estimates guide cancer treatment planning and goals-of-care discussions. Clinicians often rely on population-based survival statistics (e.g., SEER), which may not reflect individualized risk. Large language models (LLMs) such as ChatGPT may offer more personalized estimates, but their performance relative to oncologists and population-based tools remains unclear. **Methods:** We conducted a retrospective comparative study of 205 adult cancer patients treated in a safety net cancer clinic. For each patient, one deidentified clinical note from the time of diagnosis was provided to a HIPPAA compliant instance of ChatGPT (GPT-4.1) and an oncologist unfamiliar with the patient. Both generated binary (alive/deceased) and probabilistic (0–100%) predictions of survival at 6 months, 1, 2, and 5 years. The primary endpoint was per-patient binary accuracy (0–4 correct timepoints) comparison between ChatGPT and the oncologist. Secondary outcomes (n=189) included Brier scores, and calibration metrics compared with oncologists and a publicly available SEER-based cancer-specific survival calculator (CancerSurvivalRates.com), and subgroup analyses by cancer stage. Significance testing used exact binomial methods for per-patient win–loss comparisons and paired nonparametric tests to compare probabilistic performance across methods. **Results:** Of the 205 patients, 25, 53, 53, and 74 were stages I, II, III, and IV, respectively. Gender was balanced (53% male). All surviving patients had at least 5 years of follow-up. Notes varied in final staging and treatment plans, as some patients were in their initial evaluation. In the primary analysis (N = 205), ChatGPT was numerically, not statistically, superior to the oncologist (52 vs. 41, p=0.299). In secondary analyses (n = 189), ChatGPT had superior overall accuracy with lower Brier scores at 1 year ($p < 0.001$) and 2 years ($p = 0.030$). Calibration analyses showed that at 5 years, ChatGPT achieved near-ideal reliability (calibration slope 1.018), whereas oncologists demonstrated overconfidence (slope 0.535). As expected, cancer specific survival by CSR was significantly higher than OS estimates from oncologists or ChatGPT. Stage-stratified analyses revealed oncologist superiority in Stage I disease ($p = 0.036$), while ChatGPT significantly outperformed oncologists in Stage IV disease at 2- and 5-year horizons (both $p < 0.001$). **Conclusions:** For a safety-net cancer clinic, using one unstructured note, ChatGPT demonstrated comparable or superior prognostic estimates for clinically relevant time points as compared to oncologists, particularly in long-term outcomes for advanced disease. Future studies should evaluate cancer specific survival and prognosis after or during treatment. Research Sponsor: None.

1622 Poster Session

Machine learning modeling for predicting 60-day prognosis in newly diagnosed advanced solid tumors. First Author: Yakir Malyanker, Sheba Medical Center, Ramat Gan, Israel

Background: Accurate mid-term prognosis estimation in patients newly diagnosed with advanced, non-operable or metastatic cancer is critical for evaluation and treatment prioritization and palliative care planning. A 60-day time horizon is clinically meaningful, as major oncologic assessments typically occur at 2–3-month intervals. Existing prognostic tools have shown limited clinical adoption. **Methods:** We conducted a retrospective analysis of patients evaluated at the Sheba Medical Center Oncology Rapid Diagnosis Clinic between 2017 and 2025. Eligible patients had metastatic or locally advanced, non-operable solid tumors. A raw dataset was generated using the MDClone platform (overall 60-day mortality ~18%). A case-enriched training cohort (n=524; 39.3% 60-day mortality) and an independent test cohort (n=343; 19% 60-day mortality) were randomly selected. Seventy-four features were included, encompassing demographics, laboratory values, ECOG performance status, and clinical variables extracted from physician notes using a large language model (LLM). LLM extraction accuracy was validated against expert manual review in 32 randomly selected cases (accuracy 0.91–1.0). Logistic Regression, Random Forest, and XGBoost models were trained with grid-search hyperparameter optimization to predict 60-day survival (y=1) versus death (y=0). Performance was evaluated on the independent test set. Wilson score intervals were used for proportion confidence intervals, and Hanley–McNeil method for AUC confidence intervals. Feature importance for the top-performing model was assessed using SHAP. **Results:** Performance of different ML models is summarized in table 1. Random Forest demonstrated the best overall performance. All models showed high positive predictive value for survival but limited ability to predict short-term mortality. The most influential Random Forest features included INR, CRP, albumin, ECOG status, total protein, LDH, emergency-related hospitalizations, age, neutrophil count, and history of cardiovascular disease. **Conclusions:** A Random Forest–based model accurately identifies patients likely to survive 60 days, supporting timely evaluation and initiation of oncologic treatment. Prediction of short-term mortality remains limited, suggesting intrinsic unpredictability of mid-term outcomes or the need for additional clinical or biological features. Research Sponsor: None.

Metric (95%CI)	Random Forest	Logistic Regression	XGBoost
ROC AUC	0.84 (0.79-0.88)	0.81 (0.76-0.86)	0.80 (0.75-0.85)
Sensitivity	0.89 (0.85-0.92)	0.82 (0.77-0.86)	0.80 (0.75-0.84)
Specificity	0.62 (0.49-0.72)	0.62 (0.49-0.72)	0.63 (0.51-0.74)
PPV	0.91 (0.87-0.94)	0.90 (0.86-0.93)	0.90 (0.86-0.93)
NPV	0.57 (0.45-0.68)	0.45 (0.35-0.55)	0.43 (0.33-0.53)
Accuracy	0.84 (0.80-0.87)	0.78 (0.74-0.82)	0.77 (0.72-0.81)

Evaluation of AI-guided questioning versus standard information delivery in a simulated newly diagnosed breast cancer population. First Author: Emma Singel, Aspiring Scholars Directed Research Program, Fremont, CA

Background: Patients newly diagnosed with breast cancer frequently experience information overload and anxiety, which can impair understanding and participation in shared decision-making. Artificial intelligence (AI)–guided educational approaches may support individualized information delivery; however, their impact on patient understanding and emotional response remains incompletely characterized. **Methods:** We conducted a prospective, randomized vignette-based survey study among adults (≥18 years) asked to imagine receiving a new diagnosis of early-stage breast cancer. Participants were randomized 1:1 to receive either standard written information or AI-guided questioning that adapted presentation of identical content based on stated preferences and level of detail. Outcomes included a composite breast cancer knowledge score (range 0-20) (primary endpoint), perceived information overload, anxiety, decision confidence, and clarity (all Likert-scale measures, range 1-5). Group comparisons were performed using Welch's two-sample t-test. Exploratory subgroup analyses included educational level and health-related background. **Results:** 102 participants completed the survey (51 per group). Mean knowledge scores were higher in the AI-guided group compared with standard information (17.6 vs 13.2, p=0.00022). Participants receiving AI-guided questioning reported lower information overload (2.31 vs 3.35, p=0.00012), lower anxiety (3.67 vs 4.16, p=0.031), greater decision confidence (4.06 vs 2.84, $p=1.2\times10^{-6}$), and higher perceived clarity (4.20 vs 3.18, $p=2.9\times10^{-5}$). Exploratory analyses showed greater benefits among participants without graduate education or health-related background (both $p<0.001$), with smaller, non-significant differences in those with higher education or healthcare experience. **Conclusions:** In a simulated newly diagnosed breast cancer population, AI-guided questioning was associated with improved understanding, reduced information overload and anxiety, and greater decision confidence compared with standard information delivery. Exploratory analyses suggested that benefits were more pronounced among participants without graduate-level education or medical background, supporting a potential role for human-centered AI in equitable patient education. Given exploratory nature and unequal subgroup distributions, confirmation in prospectively stratified studies is needed. Research Sponsor: None.

Outcomes by information delivery approach.

Outcome (range)	Standard information (n=51)	AI-guided questioning (n=51)	p value
Knowledge score (0-20)	13.2	17.6	0.00022
Information overload (1-5)†	3.35	2.31	0.00012
Anxiety (1-5)†	4.16	3.67	0.031
Decision confidence (1-5)‡	2.84	4.06	1.2×10^{-6}
Clarity (1-5)‡	3.18	4.20	2.9×10^{-5}

†Lower scores indicate better outcome.
‡Higher scores indicate better outcome.

Age-dependent pathogenic variant risk in female breast cancer. First Author: Lina Sulieman, Vanderbilt University Medical Center, Nashville, TN

Background: Germline pathogenic and likely pathogenic variants (GPVs) in *BRCA1*, *BRCA2*, and *PALB2* raise female breast cancer risk. Genetic counseling and screening guidelines rely on fixed age estimates. Using two large biobanks, All of Us Research Program (AoURP) and BioVU biobank, we aim to characterize age-dependent breast cancer risk trajectories and associations with family history (FH). **Methods:** In AoURP, we extracted data on female participants with genetic data to identify those with *BRCA1*, *BRCA2*, and *PALB2* GPVs, FH surveys to identify those with first degree breast cancer FH (BCFH), and electronic health records (EHR) to determine presence of breast cancer diagnosis and diagnosis age. Age served as the time scale, with left truncation at first EHR entry and censoring at last EHR event. Gene-specific breast cancer risk was estimated using Cox models with age-dependent genetic effects, adjusted for genetic ancestry (first five principal components) and FH. Analyses in AoURP were stratified by self-reported race and BCFH. We validated results in BioVU using the same methodology excluding FH which was unavailable as discrete data. **Results:** In AoURP, 100,916 women with genetic, FH, and EHR data were available. The majority (67%) were White, based on self-reported race, and 5208 had breast cancer. The sample included 291 *BRCA1* GPVs, 505 *BRCA2* GPVs, and 139 *PALB2* GPVs, with breast cancer diagnosed in 36%, 23%, and 19% respectively. BioVU included 127,147 women, of whom 85.5% were White and 5,664 had breast cancer. The sample had 262 BRCA1 GPVs, 515 BRCA2 GPVs, and 210 PALB2 GPVs, with breast cancer diagnosed in 29%, 22%, and 16% respectively. Across the genes, we observed a bimodal distinct age-dependent breast cancer risk pattern. Bimodal peaks for *BRCA1* in AoURP were at 26 and 36 years, while in BioVU were at 35 and 62 years. The bimodal peaks for *BRCA2* in AoUPR were at 32 and 51 years, while in BioVU were at 32 and 55 years. Finally, bimodal peaks for PALB2 in AoUPR were 35 and 51 years, while in BioVU were at 41 and 64 years. Age-specific risk trajectories also varied by FH where risk peaks for participants with BCFH were earlier by 2-7 years compared to those without BCFH. **Conclusions:** We presented population based study providing unbiased estimates of breast cancer risk associated with GPVs in BRCA1, BRCA2, and PALB2 in two enrollment-based cohorts. Leveraging these large datasets, we identified novel bimodal age-dependent patterns of breast cancer risk across genes, with consistent peak ages for BRCA2 and PALB2 and cohort specific differences for BRCA1, highlighting the importance of population context. Replication in BioVU confirmed similar bimodal trends with later peak ages, supporting our finding robustness. Our results show that breast cancer risk in GPVs genes is more dynamic than previously recognized. Integrating age and FH risk estimates into genetic counseling and screening may improve personalized risk assessment and clinical decision making. Clinical utility analysis of a computational reasoning system on large-scale tumor genomic data. First Author: Dora Lakatos, Genomate Health Inc, Cambridge, MA

Background: Comprehensive tumor molecular testing has become routine in clinical oncology. However, interpretation of complex molecular profiles in clinical practice can be challenging and subjective. The Digital Drug Assignment (DDA) system is a knowledge-graph-based computational method that automates reasoning at the patient level and scores molecularly targeted agents (MTAs) based on the full tumor genome. This approach was predictive of relative benefit of the agents as used in the SHIVA01 trial (NPJ Precis Oncol. 2021 5:59) and in real-world setting (NPJ Precis Oncol. 2025 9:159). Here, we assessed the potential clinical utility of DDA by analyzing large-scale tumor genomic data. **Methods:** Tumor molecular profiles of 20,923 patients of the MSK-CHORD real-world clinicogenomic dataset (Nature. 2024 636:728-36) were processed by DDA. DDA classified all alterations and scored all associated MTAs based on a functional and pharmacological evidence network. Previous research evidenced that high-score MTAs (1000 $\leqq$ DDA score) predict increased clinical benefit. Utility of DDA was assessed by the proportion of patients with at least one high-score MTA option associated with their molecular profiles. **Results:** Tumor molecular complexity is evidenced by the number of driver alterations, with an average of 4.6 (range: 1 – 45) drivers per tumor (Table). 75% of all tumors were associated with high-score MTAs, 55% had on-label options. Availability of high-score options was high in all tumor types, with the exception of prostate tumors (24%). Only 3% of pancreatic cancer patients were associated with on-label high-score MTA options. Of the patients with known MTA treatments (n = 14,168), only 37% were administered a high-score MTA during their treatment course (Table). **Conclusions:** Our analysis recapitulates the presence of multiple driver alterations, highlighting the need for methods like DDA that consider the totality of molecular profiles for assigning MTAs, rather than relying on identifying single 'actionable biomarkers'. The substantial gap between the proportion of patients who did receive and those whose tumor genomes were associated with high-score MTAs indicates a strong potential for improving outcomes in precision oncology. Moreover, the proportion of high-score off-label (i.e., approved in other oncological indications) MTAs highlights the potential of DDA in drug repurposing. Research Sponsor: National Research Development and Innovation Fund, Hungary; 2022-1.1.1-KK-2022-00005.

Tumor site	Mean no. of alterations (±SD)	Mean no. of drivers (±SD)	HS MTAs associated*	HS MTA administered*	HS developmental MTAs associated*	HS off-label MTAs associated*	HS on-label MTAs associated*
All (20,923)	9.9 (11.8)	4.6 (3.9)	75	37	74	71	55
Breast (5,164)	8.1 (8.1)	4.3 (3.4)	90	57	90	89	86
Colorectal (4,565)	13.2 (18.0)	6.0 (5.5)	69	18	67	60	46
Lung (5,932)	11.6 (10.2)	4.6 (3.2)	85	57	83	84	79
Pancreas (2,619)	6.2 (6.0)	3.6 (2.3)	86	2.5	86	86	3
Prostate (2,643)	7.4 (9.5)	3.6 (3.3)	24	6.6	21	11	7

Resolving the ambiguity between genomic rearrangements and gene fusions: An AI-augmented structural framework to define therapeutic eligibility in kinase-driven cancers. First Author: Kai Wang, OrigiMed, Shanghai, MA, China

Background: A critical disconnect exists in precision oncology: clinical guidelines frequently conflate genomic "rearrangements" with functional gene "fusions", utilizing inconsistent terminology that obscures biological reality. While confirmatory RNA sequencing is recommended, it is often clinically infeasible due to tissue exhaustion or poor sample quality. Consequently, clinicians are forced to prescribe targeted therapies based on DNA-level proxies without knowing if a druggable protein actually exists. We addressed this unmet need with VeraFusionDx, an AI-augmented decision support system that moves beyond simple classification to determine therapeutic eligibility. **Methods:** We developed a universal framework integrating AI-driven report parsing with generative molecular modeling, trained on a massive real-world dataset ($>$10,000 gene fusions and $>$50,000 rearrangements) from a CAP/CLIA-certified lab. An AI normalization module standardizes heterogeneous inputs (unstructured NGS reports, gene+exon number pairs, or coordinates) into a unified format. Distinct from static database lookups, the core engine performs *de novo* characterization of each patient variant. It computationally reconstructs chimeric sequences and models 3D protein architecture to verify critical druggability criteria, including reading frame alignment and kinase domain integrity. Finally, an AI-literature agent cross-references validated targets with clinical evidence to define definitive therapeutic eligibility (https://verafusiondx.origimed.com). **Results:** Analysis using this generative engine revealed a heterogeneous landscape where genomic rearrangement proved a poor proxy for druggability, highlighting the necessity of structural validation. For *NTRK* genes, approximately two-thirds of detected variants were rearrangements rather than actionable fusions, with striking discordance by gene and tumor type. Notably, *NTRK2* rearrangements were 4-fold more common than fusions, and *FGFR1* were 90% rearrangements. Even among canonical partners (*EML4-ALK, KIF5B-RET, CD74-ROS1*), the analysis identified a persistent 1-2% rate of non-functional mimics. To resolve this complexity, the system generated definitive outputs for each case, including *de novo* chimeric DNA and protein sequences, predicted 3D structural models, therapeutic actionability assessments, and an AI-curated summary of comparable literature evidence. **Conclusions:** Functioning as a comprehensive computational firewall, this framework integrates *de novo* sequence generation, structural modeling, and therapeutic intelligence to definitively filter out inert genomic noise, ensuring that life-altering TKI prescriptions are grounded in verified functional reality rather than ambiguous terminology. SMS message sentiment as a predictive indicator of quality of life and program adherence in oncology nutrition. First Author: Mélanie Guirette, Savor Health, New York, NY

Background: A text-message based artificial intelligence nutrition platform called "Ina" was previously developed and shown to be equivalent to human dietitians in providing nutritional recommendations to patients with cancer. Once registered on the platform, patient users exchange conversational texts with and receive tailored dietary recommendations and recipes from Ina. We investigated whether the emotional sentiment of SMS messages can act as a proactive predictor of program-related Quality of Life (QoL) and program adherence. **Methods:** QoL was captured via a 1-5 Likert scale ("Has using Ina improved your quality of life?") survey, and program adherence was captured by a binary response to a question ("Have you used any of Ina's suggested tips?"). We extracted SMS messages within a 60-day window prior to each survey and question. Sentiment was measured using the Jockers-Rinker lexicon via the validated sentimentr package; scores were calculated as a weighted average ranging from -1 (negative sentiment) to +1 (positive sentiment). Linear mixed-effects models (LMM) were used to quantify the relationship between pre-survey message sentiment and program QoL/adherence outcomes, adjusting for total number of surveys completed and user's unique baseline sentiment. **Results:** Between October 2019 and January 2026, 14,700 unique text messages were analyzed from 540 unique patient users of the platform (mean age: 51$\pm$ 20 years; 91% female). Cancer types included breast (40%), ovarian (24%), bladder (16%), lung (13%), and colon (7%); metastases were present among 34%. For every one-point improvement in digital sentiment, users experienced a 14% improvement in subsequent program-related QoL (?= 0.72, p $<$ 0.001). Furthermore, there was a trend toward an association between higher positive digital sentiment and subsequent reported adherence to nutritional recommendations (? = 0.12, p = 0.097). **Conclusions:** Sentiment analysis of unstructured SMS messages successfully identified subtle shifts in digital tone that precede structured assessments. This 'leading indicator' of sentiment could enable proactive supportive care and provider escalation for timely triage and intervention. Given rapid symptomatic deterioration in oncology that often leads to non-adherence, text-based sentiment analysis could enable early detection of declining engagement to support improved quality of life and long-term outcomes. Toxicity risk calculator for personalised prediction of irAEs in patients with solid tumours receiving ICIs, developed based on a clinical dataset and machine learning approaches. First Author: Marina Lyadova, Moscow State Budgetary Healthcare Institution "Moscow City Hospital Named After S.S. Yudin, Moscow Healthcare Department", Moscow, Russian Federation

Background: Immune checkpoint inhibitors (ICIs) can cause severe (grade 3-4) immune-related adverse events (irAEs), which complicate treatment and require immunosuppressive therapy. To address this, we developed a machine learning (ML)-based tool to predict individual risk. Aim: To identify predictors and develop an ML calculator for assessing the risk of grade 3–4 irAEs in patients receiving ICIs for solid tumours. **Methods:** This retrospective study included 1,001 patients (585 men, 415 women; mean age 62.4) treated with ICIs for melanoma, kidney, lung, GI, or cervical cancers. The workflow was implemented in Python using pandas, scikit-learn, and SHAP. The cohort was split 70/30 for training and testing. Only pre-treatment variables were used. Data preprocessing included imputation (median for numeric, most frequent for categorical), one-hot encoding, and standardization. Two classifiers were trained: elastic-net logistic regression and gradient boosting. Hyperparameters were tuned via 5-fold CV. Class imbalance (~7-8% positives) was addressed with class_weight="balanced" and SMOTE. Probabilities were calibrated. Performance was assessed by PR-AUC (primary), ROC-AUC, F1, and Brier score. Predictors were selected in a two-stage process: 1) Retention of pre-IO variables, removal of low-variance/high-missingness ($>$30%) features, and collinearity pruning (|correlation| $>$ 0.85). 2) Model-agnostic ranking using three normalized signals: elastic-net coefficients, permutation importance, and mean absolute SHAP values, combined into a consensus score (weights: 0.5, 0.3, 0.2). Stability was verified by bootstrap resampling. **Results:** The final 10 features maximized cross-validated PR-AUC while maintaining calibration and interpretability. Selected predictors: ICI type/combination; age; haemoglobin; creatinine; treatment regimen (mono/combo); K-RAS/N-RAS mutation status; skeletal muscle index; lymphocyte-to-monocyte ratio; immunotherapy line; T4 level.The model identifies patients at increased risk with calibrated probabilities. Results are presented as probabilities (95% CI) categorized as low ($<$0.10), moderate (0.10–0.25), and high ($\geq$0.25). The colored pictogram visualizes risk distribution for a sample of 100 patients (based on the database; median, quartiles). **Conclusions:** We developed the 'Toxicity Risk Calculator' using 10 clinical factors to assess the probability of severe irAEs. This calculator enables routine assessment of the low, moderate, or high probability of grade 3–4 irAEs, facilitating more effective personalization of cancer immunotherapy in everyday practice. Further prospective studies in real-world clinical settings are needed. Research Sponsor: None.

Fitbit-derived activity and heart-rate patterns for predicting 12-month hospitalization in an NIH All of Us cancer cohort. First Author: Kenan Najjar, Carle Illinois College of Medicine, Champaign, IL

Background: Hospitalizations in oncology are common and diverse, and are often limited in their predictive accuracy with routine variables. Wearable devices capture functional and physiological patterns that may indicate vulnerability. We examined whether Fitbit-derived activity and heart rate features enhance the prediction of all-cause hospitalization beyond demographic and clinical factors like frailty. **Methods:** Using data from the NIH All of Us Research Program, we conducted a retrospective analysis of participants aged $\geq$50 years with a history of cancer, linked electronic health records, and short-term Fitbit data (with imputed missing days). Baseline predictors included demographic variables, clinical factors such as the All of Us frailty index, and indicators of cancer subtype. The outcome was any hospitalization within 12 months of the index date, relative to the last Fitbit data day. Features included step count, step variability, activity distribution, rhythmicity, heart rate, and heart rate variability. Missing data were imputed using predictive mean matching. Models were optimized via nested stratified cross-validation and evaluated with out-of-fold predictions. Discrimination was measured by AUC and average precision with bootstrap confidence intervals. Predictive value for the top 10% at-risk group was also assessed. **Results:** The study cohort consisted of 278 participants (average age 64.6). Twelve percent (35) experienced hospitalization within a year. Time to hospitalization ranged up to 342 days. Hospitalization diagnoses were heterogeneous. Models using demographic and clinical data alone had limited discrimination (AUC 0.41–0.50). Incorporating Fitbit activity features improved logistic performance: average steps yielded an AUC of 0.522, step-pattern quartiles yielded 0.559, and distributional rhythmic features yielded 0.628 (CI 0.520–0.733; average precision 0.283). Heart rate and variability did not materially enhance logistic prediction. Gradient-boosted trees combining activity and heart rate data achieved the highest discrimination (AUC 0.704; CI 0.621–0.786; average precision 0.286). Using the best-performing model, the top 10% predicted-risk group had a hospitalization rate of 28.6% (8/28), compared with the overall cohort hospitalization rate of 12.6%, capturing 8 of 35 events. **Conclusions:** Fitbit-derived activity patterns and heart rate patterns, when modeled using machine learning, improved near-term hospitalization prediction in an NIH cancer cohort beyond demographic and clinical models, supporting their potential for practical risk assessment. Ongoing analyses will address missingness, calibration, and subgroup robustness to inform prospective validation. Evaluating AI decision support in a rapidly evolving therapeutic landscape: *EGFR*-mutant metastatic NSCLC. First Author: Chinmay Jani, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Large language models (LLM) are increasingly used in oncology, yet may deviate from evidence-based care due to outdated knowledge, hallucinations, and inconsistent confidence calibration. EGFR-mutant metastatic Non small Cell Lung Cancer (NSCLC) treatment sequencing is rapidly evolving following 1L OS benefits from MARIPOSA and FLAURA2 and an expanding 2L landscape. In this study, we evaluate concordance, variability, and expert alignment across artificial intelligence (AI) systems. **Methods:** Twelve expert-curated EGFR-mutant metastatic NSCLC vignettes (6 per 1L and 2L) were evaluated across 4 general-purpose LLMs (ChatGPT, Gemini, Claude, Grok) with deep-research enabled and 2 evidence-based platforms [ASCO AI, OpenEvidence (OpenE)]. Each system simulated percentage-based treatment selections simulating how 100 U.S. med-oncologists might distribute choices across predefined therapies. 5 thoracic oncologists from 3 academic centers established a human reference standard, with unanimous agreement in all but 1 vignette where probability-weighting was applied. Inter-system and expert concordance was assessed using Kendall's τ, while divergence was quantified using Jensen–Shannon (JS) divergence. **Results:** Guideline-based platforms showed strong agreement (ASCO AI–OpenE τ=0.73). Among LLMs, ChatGPT aligned the most with ASCO AI (τ=0.72), while Claude showed the highest divergence (JS=0.30); the highest inter-LLM concordance was observed between ChatGPT and Gemini (τ=0.64). Although ASCO AI is built on Gemini, agreement was only moderate (τ=0.55), suggesting added guideline constraints enhance consistency. In 1L, all systems demonstrated moderate-to-strong concordance with experts ($\tau>$0.50), with ChatGPT and ASCO AI the highest (τ=0.80). ASCO AI appropriately emphasized guideline-endorsed options, including Osimertinib monotherapy and combination strategies, without preferential commitment. In 2L, concordance declined substantially with ChatGPT demonstrating inverse correlation with experts ($\tau=-0.06$). **Conclusions:** AI systems align with expert decision-making in 1L EGFR-mutant metastatic NSCLC but diverge substantially in 2L, where evidence is evolving. Guideline-constrained platforms show greater consistency than general-purpose LLMs; despite ASCO AI using Gemini as its base model, agreement was only moderate, highlighting the value of guideline constraints. These findings highlight the need for rigorous validation and clinical safeguards when integrating AI into oncology decision-making. Research Sponsor: None.

AI–expert concordance.

System	1L - Experts (τ, JS)	2L – Experts (τ, JS)	Max Inter-System (τ)
ASCO AI	0.80, 0.14	0.25, 0.39	OpenE (0.73)
ChatGPT	0.80, 0.15	-0.06, 0.36	ASCO AI (0.72)
OpenE	0.67, 0.25	0.27, 0.24	ASCO AI (0.73)
Gemini	0.61, 0.21	0.49, 0.19	ChatGPT (0.64)
Claude	0.59, 0.32	0.27, 0.22	ChatGPT (0.60)

Wearable-derived physical activity monitoring with AI-based detection of treatment-related adverse events during neoadjuvant chemotherapy for early breast cancer: TRACK-BC. First Author: Nobuhiro Shibata, Department of Clinical Oncology, Kansai Medical University Hospital, Hirakata, Japan

Background: Neoadjuvant chemotherapy (NAC) for early breast cancer (EBC) is commonly delivered in the outpatient setting, yet within-cycle changes in adverse events reduce physical activity (PA). Wearable devices may capture these short-term changes. However, prospective data describing activity patterns during modern regimens, including pembrolizumab (PEMB)-based therapy, are limited. This study evaluated changes in PA using Fitbit-derived digital biomarkers (dBM) and explored associations with patient-reported outcomes (PROs). **Methods:** We conducted a multicenter, prospective observational study in patients (pts) with stage I–IIIA EBC initiating NAC. Eligible pts were $\geq$18 years old, smartphone users, and able to wear a Fitbit daily. Chemotherapy regimens were grouped into weekly, q2w, or q3w cohorts. Fitbits were worn from $\geq$7 days before treatment initiation through four cycles. Total PA (TPA), moderate-to-vigorous PA (MVPA), heart rate, sleep, and other metrics were collected. PRO-CTCAE and HADS were completed weekly electronically (ePROs). The primary outcome was change in TPA and MVPA from baseline to the week following cycle 2. As a secondary endpoint, machine learning approaches extending conventional multivariable regression incorporated multiple wearable-derived parameters to individually predict the worst change in ePRO scores from baseline. Model performance was evaluated by cross-validation, and feature contributions were examined using SHapley Additive exPlanations (SHAP) to enhance clinical interpretability. **Results:** A total of 101 pts were enrolled across the three predefined chemotherapy cohorts. Fitbit use was feasible with high adherence. The primary outcome indicated a consistent decline in PA during NAC. From baseline to the week following cycle 2, mean TPA decreased by 141.4 METS-min/day and MVPA by 33.7 min/day. ePROs revealed worsening symptoms including fatigue, insomnia, appetite loss, and neuropathy. Symptoms varied according to the chemotherapy schedule and generally aligned with changes in PA levels and dBM. The secondary outcomes identified multiple vital signals showing absolute correlations $>$0.3 with all PRO and HADS metrics. For fatigue, the best model (ridge regression) yielded mean R^2 0.33$\pm$0.20 and RMSE 1.86$\pm$0.26; SHAP analysis highlighted contributions from nocturnal heart-rate-variability minima and overall variability. **Conclusions:** Continuous wearable monitoring during NAC for EBC was feasible. Objective declines in PA occurred early and paralleled symptom worsening captured by ePROs. AI-based models explained a modest but clinically meaningful proportion of symptom deterioration with acceptable error. These findings support the potential utility of wearable-derived dBM for real-time surveillance of treatment-related toxicities during NAC. Clinical trial information: UMIN000053991. Research Sponsor: Daiichi Sankyo Co., Ltd.

Impact of remote symptom monitoring program on payor-specific healthcare costs. First Author: Gabrielle Betty Rocque, Division of Hematology and Oncology, University of Alabama at Birmingham, Birmingham, AL

Background: Remote symptom monitoring (RSM) programs are currently being implemented across oncology practices nationwide; however, the impact of RSM on costs by payor has been understudied. **Methods:** This is a secondary analysis of a hybrid implementation-effectiveness trial of electronic, patient reported outcome-based RSM for patients with cancer initiating systemic therapy (May 2021-May 2024). Differences in costs for healthcare services for RSM-enrolled patients were compared to historical controls. Outcomes included overall, monthly, payor-, and service-specific costs of care received at 3 and 6 months after RSM-enrollment date or initiation of systemic therapy for controls. Adjusted generalized linear models estimated predicted mean costs, mean cost ratios (MR) and 95% confidence intervals (CIs) for RSM-enrolled patients versus controls. **Results:** Patients receiving RSM (n=968) were 25% Black, 44% privately insured, and 27% living in a highly disadvantaged neighborhood. Historical controls (n=3,488) were demographically similar. Though non-statistically significant, RSM enrolled patients had 5% lower mean costs 3 months post-index date compared to historical controls (MR 0.95, 95% CI 0.78-1.16), translating to an estimated cost savings of $1,347 per patient (95% CI -$3,596, $6,290). Medicare Fee-for-Service (FFS) beneficiaries showed the greatest, though non-statistically significant, cost reductions, with RSM FFS beneficiaries having 10% lower costs than FFS controls (MR 0.90, 95% CI 0.67-1.19) at 3 months post-index date. Though non-statically significant, RSM-enrolled patients had 23% lower costs for radiation, 14% lower inpatient costs, 9% lower costs for labs, scans, or tests, and 2% lower outpatient costs compared to controls at 3 months post-index date. At one-month post-index date, RSM enrolled patients had statistically significantly lower payor costs compared to controls ($11,849 [95% CI $9,364-$14,335] vs. $15,706 [$14,291-$17,121]; p=.004). Costs for RSM enrolled patients and controls were similar two to six-months post-index date. **Conclusions:** We observed payor cost savings of $1,347 in the 3 months of RSM enrollment compared to controls. As the largest payor cost differences were seen for Medicare FFS beneficiaries, our results suggest RSM may address a gap in the provision of care coordination to patients not offered these services through their insurer. Cost savings were most prominent within the first month of treatment initiation; thus, RSM may aid in reducing acute care needs and optimizing resource utilization for patients with cancer. Our results support future research in potential risk-stratification methods to improve RSM engagement and delivery to reduce costs and improve outcomes for patients with cancer. Research Sponsor: None.

Earlier CRS identification with continuous wearable monitoring in outpatient CAR T-cell therapy. First Author: Jonas Paludo, Mayo Clinic Rochester, Rochester, MN

Background: CAR-T cell therapy has transformed outcomes of hematologic malignancies and is poised to expand into solid malignancies. However, broader use of CAR-T remains constrained by the need for timely cytokine release syndrome (CRS) detection. Current episodic monitoring may miss early physiologic changes. Wearable digital health technologies (DHTs), offering continuous monitoring and real-time alerts, could enable earlier CRS detection, further support outpatient delivery, and expand access to CAR-T and potentially other immunotherapies associated with CRS. **Methods:** This single-center observational study (NCT05018208) enrolled patients receiving FDA-approved CAR-T products in the outpatient setting at Mayo Clinic, Rochester MN. Management of post-CAR-T complications (e.g. CRS) followed the institution's standard of care. Patients were monitored from day -5 to day +30 post infusion with intermittent remote patient monitoring (SoC) and an arm-worn wearable device for continuous monitoring (DHT). Patients were included in this analysis if DHT data were available for $\geq$ 5h of data/day or $\geq$ 2h of data/night on $\geq$2 days or nights for baseline and $\geq$1 day or night within 72h prior to CRS, or at least 2h within 4h of CRS onset, or if DHT was available for $\geq$7 days/nights post infusion with no CRS event. CRS detection time by DHT was defined as the onset of pyrexia or threshold-based deviation from an individual's baseline pulse distributions. **Results:** 32 patients were included in this report (median age 64 years, gender 12 F/20 M, diagnoses 18 MM/14 NHL). 25 patients experienced a CRS event, with maximum CRS grades ranging from 1-3 (16 G1, 8 G2, 1 G3). 24/25 patients with CRS required tocilizumab/steroid. Median CRS onset time was 3.4 days (range 0.4-18.4). 12/32 patients had sufficient DHT data (7 CRS, 5 no CRS) for analysis. 5 patients with CRS had a DHT detection time in advance of the SoC by a median of 13h (range 2.8 - 69.2). The DHT prediction of CRS by baseline HR change was earlier than the first episodic fever by a median of 14.5h (range 13-77.5). The remaining 2/7 patients who did not have CRS detected by the DHT had missing DHT data for more than 45h before a treated CRS event. DHT detected CRS in 2/5 patients without CRS according to SoC. One patient had fever caught with intermittent monitoring. The other was treated for neutropenia fever with suspicion of CRS and/or infection. **Conclusions:** These results offer evidence that continuous DHT can identify CRS events earlier than intermittent monitoring (SoC). Despite limitations related to compliance with wearable device use and data missingness, and variability in clinical management of CRS, we highlight the usability of DHT and its potential for future studies with optimized strategies to address these limitations. Clinical trial information: NCT05018208. Research Sponsor: Biofourmis.

Validating a single-item screener for low digital health literacy among surgical oncology patients. First Author: Thomas S. Gunning, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY

Background: Digital health literacy (DHL; the ability to find and understand health information using electronic media) may affect surgical oncology patients' ability to navigate patient education and discharge coordination activities that rely on technology. Screening for low DHL can identify patients who may benefit from alternate modalities or additional support. In our prior work, a single item from the validated electronic Health Literacy Scale (eHEALS) had strong sensitivity and specificity for identifying low DHL in the outpatient setting. In this cross sectional, secondary analysis, we explored which sociodemographic and clinical factors were related to low DHL and tested whether the single-item screener could identify patients with low DHL in the surgical oncology setting. **Methods:** Surgical oncology patients were recruited during their post-operative hospitalization for a parent study on health literacy and clinical outcomes. The 8-item eHEALS assessed DHL; total scores $\leq$20 indicate low DHL. Chi-squared, Fisher's exact, or Mann-Whitney tests were used to examine whether DHL varied by patients' sociodemographic (age, sex, race/ethnicity, education, marital status, general health literacy) or clinical characteristics (cancer type, ECOG performance status, comorbidities). Receiver operating characteristic (ROC) curve analysis assessed sensitivity, specificity, and accuracy of eHEALs item 4 ("I know where to find helpful health resources on the Internet") to identify low DHL. **Results:** Participants (N=224) were primarily non-Hispanic White (87%), older (median=68, IQR 61-75 yrs), married (69%), men (59%) with gastrointestinal cancer (60%) who completed at least some college education (76%). On the 8-item eHEALS, 23 patients (10.3%) reported low DHL. Patients with lower general health literacy ($p<0.001$), lower education level (p=0.007), and unpartnered marital status (X^2 = 4.359, p=0.039) were more likely to have low DHL. Other factors were not associated with DHL (p-values$>$0.299). Older patients were marginally more likely to report low DHL than younger patients (U=2847, p=0.069). In ROC curve analysis, eHEALS item 4 strongly distinguished low DHL vs. high DHL (AUC=0.989; 95% CI 0.977-0.997). At the optimal threshold (item scores $<$3, on a 1-5 Likert scale), item 4 predicted low DHL with an accuracy of 96.9%, sensitivity of 97.0%, and specificity of 95.7%. **Conclusions:** These data suggest a single-item screener (eHEALS item 4) can accurately identify patients with low DHL in the surgical oncology setting, adding support for its ability to detect low DHL in patients with cancer. Among surgical oncology patients, those with lower education, lower general health literacy, and older age may be more likely to experience lower DHL. Future prospective studies with larger samples are warranted to assess utility, acceptability, and feasibility of the screener in clinical practice. Research Sponsor: None.

Conversational AI-assisted exploratory data analysis (CA-EDA): A comparative evaluation of commercial large language models for clinical trial analysis. First Author: Yaacov Lawrence, Chaim Sheba Medical Center, Ramat Gan, Israel

Background: Conventional analysis of clinical trial data requires statistical expertise, time and effort. Previous AI approaches have used structured, pre-processed datasets on specialized platforms. We hypothesized that widely available commercial large language models (LLMs) would perform rapid analysis of raw data. We evaluated three commercial LLM platforms fed identical data, and subsequently validated the outcomes with a formal statistical analysis. We name this approach "Conversational AI-assisted Exploratory Data Analysis" (CA-EDA). **Methods:** We used data from a completed phase 2 trial (NCT03323489; Lancet Oncol 2024; 25:1070-9); n=125; 2165 variables) that evaluated the efficacy of celiac plexus radiosurgery in controlling retroperitoneal pain syndrome amongst pancreatic cancer patients. Raw individual patient data was uploaded to three commercial LLMs: Claude Opus 4.1 (Anthropic), ChatGPT 5.2 (OpenAI) in deep research mode, and Gemini 3 Pro (Google). Each LLM received identical inputs: the raw Excel dataset, the codebook, the protocol, and the published manuscript. The prompt requested identification of baseline predictors of pain response and development of a clinical score. Outputs were compared for statistical analyses performed, predictors identified, visualizations generated, and clinical utility. Findings were formally verified using Stata IC/16.1. **Results:** Analysis completion time ranged from 10 to 30 minutes across all three platforms. Claude performed a comprehensive statistical analysis, generated a 9-panel visualization dashboard, identified prior exposure to neurotoxic chemotherapy as a novel predictor of response (OR 0.20, $p<0.001$), and created a 4-variable clinical score predictive of response (AUC 0.71). ChatGPT performed a statistical analysis but missed neurotoxic chemotherapy, creating a 3-variable score. Gemini produced an 8-page narrative with biological insights, but did not perform any statistical analysis. Analysis using Stata confirmed the association between prior exposure to neurotoxic chemotherapy and response (35% with prior exposure vs 75% without, $p<0.001$). **Conclusions:** Claude Opus 4.1 identified a clinically significant predictor that had not previously been recognized, and developed a helpful clinical score. CA-EDA always requires formal biostatistical verification due to concerns about LLMs' tendency to hallucinate, may analyse only sampled data and potentially implement incorrect Python code. Despite these concerns, here we found CA-EDA of clinical trial data to be rapid, accurate and cost-effective. Financial support for clinical trial: Gateway for Cancer Research, The Israel Cancer Association. Research Sponsor: Gateway for Cancer Research; Israel Cancer Association.

Evaluating the organizational benefits of remote symptom monitoring during injectable outpatient cancer treatment: The final analysis of the randomized OPTIMACURE trial. First Author: Audrey Faveyrial, Centre François Baclesse, Medical Oncology Department, Caen, France

Background: Remote monitoring (RM) to assess whether patients are apt for cancer treatment is already used during standard of care (SOC) in several French centers. Optima RM includes structured phone calls by a nurse, 2-3 days before the planned administration, with the transfer of biological results 48 h before the administration, with a physician's validation the day before administration. Cureety RM, in addition to preparing visit, also monitors symptoms between cures. We aimed to evaluate the organizational benefit of Cureety RM compared to Optima-like RM in patients initiating outpatient injectable cancer treatments. **Methods:** OPTIMACURE was designed as a multicentric, randomized, open-label trial to compare Cureety RM versus Optima-like RM. Patients aged ³18 years, starting an injectable cancer treatment, and capable of using a RM tool were eligible. Patients with dysphonia/difficulties with oral communication were not eligible. Enrolled patients were randomly allocated (2:1) to either Cureety RM or to SOC (with Optima-like RM). Randomization was stratified by type of cancer treatment, ECOG PS, frequency of treatment, and center. Only centers using Optima-like RM participated in the trial. The primary objective was to assess the effectiveness of adding Cureety RM to usual care, in terms of the number of outgoing calls, overall and by reason (preparing visits or for toxicity), within the first 2 months. Secondary outcomes included safety, toxicity-free survival (TFS), and hospitalizations. **Results:** Between April and August 2024, 192 patients were allocated: 127 (66%) to Cureety RM and 65 (34%) to SOC (with Optima-like RM). The trial population was mainly female (73%) and with an ECOG PS 0-1 (96%). Most were being treated with chemotherapy (98%) and less frequently than every 2 weeks (61%). The demographic and disease characteristics were similar in the groups. The mean number of outgoing calls were fewer with Cureety RM, 2.53 (SD: 2.21) versus 3.77 (SD: 2.45). The difference of least-squares means was significantly different in the groups: -1.25 (95% CI: -1.91 to -0.59), $p<0.0001$. The number of outgoing calls for preparing visit were significantly fewer with Cureety RM, 0.43 (SD: 0.82) versus 3.09 (SD: 2.18), $p<0.001$. While there were significantly more outgoing calls for toxicity with Cureety RM, 1.68 (SD: 1.89) versus 0.20 (SD: 0.71), $p<0.001$. No adverse events (AEs) related to RM were reported. The median TFS was significantly shorter with Cureety RM, 10 days versus not reached: driven by early detection of grade ≤4 AEs. The number of hospitalizations was similar in the groups. **Conclusions:** Implementing Cureety RM during injectable cancer treatment had an organizational benefit by reducing the number of outgoing calls. More precisely, reducing the outcalls for preparing visit while increasing those for AEs. Clinical trial information: NCT06371911. Research Sponsor: None.

Feasibility and preliminary efficacy of a 12-week remotely delivered exercise program in patients receiving immunotherapy: A phase II randomized controlled trial. First Author: Paulo Gustavo Bergerot, Oncoclinicas&Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: Patients with advanced cancer receiving immunotherapy experience reduced physical function, increased symptom burden, and poorer health-related quality of life (HRQOL). Limited access to structured exercise programs makes technology-supported interventions a potentially scalable alternative. We assessed the feasibility and preliminary efficacy of a 12-week remote exercise program on HRQOL, symptom burden, and fear of cancer recurrence (FCR), with an exploratory economic evaluation. **Methods:** In this Phase II trial, adult receiving immunotherapy alone or in combination were randomized 1:1 to a remote exercise intervention or usual care (UC). The study was powered to detect a 10-point difference in Functional Assessment of Cancer Therapy-General (FACT-G) scores (80% power, α=0.05). The intervention included weekly virtual sessions with an exercise physiologist, individualized Borg-guided exercise prescriptions, video support, and telehealth monitoring 12 weeks (30-45 minutes/day). Outcomes assessed at baseline and 12 weeks included HRQOL (FACT-G), symptom burden (Edmonton Symptom Assessment Scale; ESAS), and FCR (FCR-7). Between-group differences were analyzed using ANCOVA adjusted for baseline values, with effect sizes estimated using Cohen's d. A preliminary provider-perspective cost-consequence analysis estimated cost per one-point FACT-G improvement. **Results:** Seventy patients were randomized (35 per arm); five died before 12 weeks (3 control, 2 intervention). Baseline characteristics were balanced. At 12 weeks, the intervention group had significantly higher FACT-G scores compared than UC (mean difference = 11.1; $p<0.001$; Cohen's d=1.30). Symptom burden was lower in the intervention arm ($p<0.001$; Cohen's d=1.68), and FCR was reduced (p=0.014; Cohen's d=0.85). Group assignment remained a significant predictor in adjusted ANCOVA models (all $p<0.01$). Estimated intervention cost was R$7,023 per participant, or R$634 per FACT-G point gained. **Conclusions:** A 12-week remote exercise intervention produced a clinically meaningful 11-point improvement in HRQOL at an estimated cost of R$ 634 per FACT-G point, supporting its economic feasibility and scalability. The program reduced symptom burden and FCR. These findings justify larger trials to confirm effectiveness and further evaluate cost-effectiveness. Research Sponsor: None.

Changes in patient-reported outcomes at 12 weeks.

Disparities in receipt of guideline-concordant adjuvant chemotherapy and survival outcomes among immigrant patients with colon cancer: Real-world evidence from Ontario. First Author: Bishal Gyawali, Queen's University, Kingston, ON, Canada

Background: Immigrants comprise a growing proportion of the Canadian population and may face unique barriers to accessing timely and guideline-concordant cancer care. While the "healthy immigrant effect" suggests that immigrants initially experience better health outcomes, it remains unclear whether this advantage extends to cancer treatment and survival. We studied whether disparities exist in the receipt of adjuvant chemotherapy and survival outcomes among recent immigrant patients with stage III colon cancer in Ontario compared with long-standing Ontario residents. **Methods:** A population-based real-world retrospective cohort study was conducted using linked administrative health databases housed at the ICES. Adults diagnosed with stage III colon cancer between 2007 and 2020 who underwent surgery within six months of diagnosis were included. Recent immigrants were defined as individuals with a landing date as a resident within ten years before diagnosis, identified using the Immigration, Refugees and Citizenship Canada database; long-standing residents had no recorded immigration date. The primary outcome was receipt of adjuvant chemotherapy within four months of surgery for their cancer. Secondary outcome was all-cause mortality. **Results:** The cohort included 16,724 patients, of whom 304 were recent immigrants (including 47 refugees). Compared to long-standing residents, recent immigrants were younger, had fewer comorbidities, and were more likely to reside in urban areas. In unadjusted analyses, recent immigrants were more likely to receive adjuvant chemotherapy (RR 1.37; 95% CI 1.23–1.53); however, this association was attenuated in the multivariate analysis (RR 1.08; 95% CI 0.99–1.19). Recent immigrants had significantly lower all-cause mortality, with an adjusted hazard ratio (HR) of 0.70 (95% CI 0.58–0.84). **Conclusions:** In this large population-based study, recent immigrants with stage III colon cancer in Ontario received comparable guideline-concordant adjuvant chemotherapy and had significantly better overall survival than long-standing residents. These findings suggest that, within a universal healthcare system, recent immigrants may not be disadvantaged in colon cancer treatment and perhaps have better outcomes once engaged in care. Further research is needed to assess whether these findings extend to other cancer types and to non-permanent resident populations. Research Sponsor: Department of Medicine, Queen's University and ICES.

Sociodemographic variation in live birth incidence and access to assisted reproductive services among female cancer patients in the United States. First Author: Isabel Beshar, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Sociodemographic variation in fertility outcomes after cancer is not well described. We constructed a novel longitudinal dataset to capture sociodemographic variation in 1) live births and 2) use of assisted reproductive technology (ART) among female cancer patients across the US from 2004-2022. **Methods:** We linked population-based cancer registry data (2004–2018 in 12 states; 2004–2011 in California) with live birth certificates (2004–2022) and the Society for Assisted Reproductive Technology (2004-2022) database, which captures ~90% of ART cycles nationally, to create a dataset integrating oncologic characteristics, obstetric outcomes, and ART use. Patients aged 15-45 at diagnosis of cancer were included. The primary outcome was 5-year cumulative live birth incidence (CLBI) using the Fine and Gray method to account for all-cause death as a competing event and log-rank tests to compare by age, race/ethnicity, insurance, cancer site, cancer stage, and receipt of systemic therapy. Secondary outcome was use of ART after cancer diagnosis, defined as >1 autologous oocyte/embryo cryopreservation or embryo transfer cycles. Patients were categorized by expected fertility detriment, defined as pelvic malignancy and/or receipt of chemotherapy, hormone therapy, or abdominal or pelvic radiation, and covariates compared descriptively. Person-years were accrued from diagnosis date to first post-diagnosis birth/use of ART, death, age 51 (oldest age a post-cancer birth was observed), or December 31, 2022, whichever occurred first. The study was approved by the institutional review board. **Results:** 286,198 female cancer patients were included with 15 live births per 1,000 person-years. 5-year CLBI was 6.14% [6.05, 6.24]. Lower CLBI was observed in Hispanic (4.5% [4.31, 4.76]) and non-Hispanic Black (NHB) (5.23% [4.98, 5.50]) populations compared to non-Hispanic white (NHW) populations (6.75% [6.62, 6.88]) ($p<0.001$). Patients with public insurance also had significantly decreased CLBI (4.68% [4.47, 4.90]) than those with private insurance (6.08% [5.95, 6.20], $p<0.001$). NHB, Hispanic, and patients with public insurance comprise higher proportions of patients with expected fertility detriment versus those without detriment (12.6 vs 8.6%, 18.2 vs 13.1%, and 18.7 vs 13.3%, $p<0.001$) but lower proportion of patients that use ART versus those that do not (5.9 vs 11.4%, 7.6 vs 16.6%, and 4.1 vs 17.1%, $p<0.001$). **Conclusions:** National vital statistics data demonstrates high fertility rates among Hispanic and NHB populations; among cancer patients, however, these trends are flipped, with lower cumulative incidence of live births in these groups. Despite a higher burden of anticipated fertility detriment, NHB, Hispanic, and publicly insured patients were less likely to access fertility care, revealing stark inequities in survivorship care. Comorbidity-related medical expenditures and health outcomes in cancer patients. First Author: Panpan Xiao, School of Pharmacy, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong SAR, China

Background: Comorbidities are common among adults with cancer and necessitate effective medical management. However, research is scarce on how cancer affects healthcare utilization and expenditures for comorbid conditions. This study used a U.S. database to compare medical expenditures and health outcomes between adults with comorbidities who have cancer and those without. **Methods:** This longitudinal analysis utilized the data from the 2008-2014 Medical Expenditure Panel Survey (Household Component). Participants with one or more of 19 chronic health conditions (ICD-9 coded) relevant to primary care were classified based on self-reported cancer history. Outcomes from the second year of each panel (2009-2015) included comorbidity-specific healthcare utilization, medical expenditures, functional status, HRQoL, and health utility. Cost differences conditional on positive expenditures were analyzed using generalized linear models (gamma regression and log-link), while differences in healthcare utilization were examined using negative binomial regression. All models were adjusted for demographic, socioeconomic, and lifestyle covariates. **Results:** A weighted total of 24,057,137 adults with at least one comorbidity (mean age 58.3±15.8 years; 59% female) were included, of whom 10% (n=2,393,300) reported a history of cancer. Compared with non-cancer patients, cancer patients received more comorbidity-specific home health visits (IRR 2.01, 95% CI 1.13-3.57) but had lower total comorbidity-specific expenditures (OR 0.81, 95% CI 0.71-0.92). Cancer patients also incurred lower comorbidity-specific hospitalization costs and out-of-pocket costs for emergency department (ED) visits ($p<0.05$). Specifically, they had reduced total expenditures for arthritis (OR 0.60, 95% CI 0.39-0.93) and stomach problems (OR 0.42, 95% CI 0.22-0.81) and reduced out-of-pocket costs for thyroid problems (OR 0.55, 95% CI 0.36-0.86) and osteoporosis (OR 0.41, 95% CI 0.18-0.92). Among multimorbid patients (≥2 conditions; 55.4%), cancer patients incurred lower out-of-pocket costs for ED visits (OR 0.42, 95% CI 0.26-0.68). For health outcomes, cancer patients reported more functional limitations than non-cancer patients in instrumental activities of daily living (10.8% vs 8.5%), role functioning (26.2% vs 20.5%), and cognitive function (13.6% vs 11.2%), all $p<0.05$. Moreover, multimorbid patients with cancer had lower HRQoL and health utilities ($p<0.05$). Similar trends were observed for cancer patients with depression, hypertension, chronic lung disease, osteoporosis, and thyroid problems. **Conclusions:** Cancer patients with comorbidities had greater functional limitations but lower medical expenditures for comorbidity care than non-cancer patients, suggesting inequities in primary care. Healthcare resources should be prioritized for cancer patients with comorbidities and poor functional status. Research Sponsor: None.

Retrospective assessment of Duffy-Null associated neutrophil counts (DANC) status and impact on treatment among patients with and without cancer in an urban academic medical center. First Author: Bhawneet Chadha, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: Duffy-Null Associated Neutrophil Count (DANC) is a non-pathologic state characterized by a low absolute neutrophil count (ANC) without increased risk of infections. Despite this, cancer patients (pts) with DANC have often been excluded from clinical trials due to low ANC and may receive inappropriate dose delays or reductions of standard anticancer therapy. Testing for Duffy-null phenotype is readily available, but no standard of care exists for management of chemotherapy dosing in cancer pts with DANC. In preparation for a prospective study evaluating chemotherapy dose modifications in cancer pts with DANC, we examined characteristics of pts, both with and without cancer, who underwent Duffy antigen testing at our institution, as well as whether results of testing in cancer pts impacted cancer management. **Methods:** Pts who received Duffy antigen testing from 05/02/2024-05/01/2025 were identified from the Montefiore Health System pt registry. Baseline characteristics including white blood cell count (WBC), ANC, demographics, and cancer status were obtained and correlated with Duffy status. Reviewed documentation for Duffy-status impact on chemotherapeutic management. **Results:** 523 pts [283 (54.1%) Non-Hispanic Black (NHB), 168 (32.1%) Hispanic (H), 18 (3.4%) Non-Hispanic White (NHW), and 54 (10.3%) Other] were identified. Median age was 56 yrs. Indication for testing was neutropenia in 518 pts (99.0%). 407 (77.8%) pts were found to have DANC and 116 (22.2%) were Duffy-antigen positive. Duffy-null phenotype was seen in 265 (93.6%) pts; 103 (61.3%) H pts, and 4 (22.2%) NHW pts. Race/ethnicity was strongly correlated with Duffy-status ($p < 0.001$). Median baseline WBC and ANC were lower in pts with DANC than in pts without [WBC 3.4 vs 4,4 ($p < 0.001$); ANC 1.1 vs 1.8 ($p < 0.001$)]. 32 (6.4%) pts of the total cohort had cancer [23 (71.9%) NHB, 7 (21.9) H, 2 (6.3%) other], of which 26 pts (22 NHB, 4 H) had DANC. 13 (40.6%) ordering providers were adult solid tumor oncologists [8 Breast, 4 GYN, 1 GU], 5 (15.4%) pediatric hematologist-oncologists, 6 (18.8%) classical hematologists, 6 (18.8%) hematology/oncology providers, and 2 (6.3%) family medicine providers. Knowledge of Duffy antigen status impacted management in 26 (81.3%) pts with cancer, leading to fewer dose delays and reductions in cancer pts with DANC, while in 6 (18.8%) pts testing did not ($p = 0.31$). **Conclusions:** In our diverse cohort of pts undergoing Duffy antigen testing, predominantly as part of evaluation for neutropenia, almost all NHB pts were found to have Duffy-null phenotype. DANC was also seen in over half of H pts, and in 22% of NHW pts. Among cancer pts, testing for DANC is underutilized, but frequently impacts chemotherapy management, emphasizing the need for prospective evaluation of the utility of Duffy antigen testing in cancer pts receiving chemotherapy. Research Sponsor: None.

Emergency department visits and hospitalizations in cancer survivors with disabilities: A national analysis. First Author: Mariana Lilani Henry, Weill Cornell Medicine, New York, NY

Background: One in four Americans has a disability. Adults with disabilities are known to have a higher cancer burden than the general U.S. population, but the healthcare utilization patterns and needs of this population remain understudied. We examined factors associated with emergency department (ED) visits and hospitalizations among cancer survivors, with a focus on disability status. **Methods:** We used National Health Interview Survey (NHIS) data from 2022-2024. Adults aged 18+ years who self-reported a diagnosis of breast, prostate, or colon cancer were included. Our key explanatory variable was disability status, defined by receipt of Supplemental Security Income or Social Security Disability Insurance, or a positive designation using the Washington Group Short Set Composite Disability Indicator. The primary outcomes were ED visits and hospitalization in the past 12 months. Logistic regression models adjusted for demographics and health status (e.g., body mass index, self-rated health, and smoking status). All analyses incorporate NHIS survey weights to account for the complex survey design. **Results:** Our sample included 4,179 NHIS respondents with breast, prostate, or colorectal cancer; 999 (23.9%) had a disability. Cancer survivors with disabilities were more likely to have less than a high school education (19.7% vs 9.2%), be enrolled in Medicaid (6.0 vs 2.7%) or Medicare (49% vs 44.8%), and report poor health status (22.3% vs 3.6%) compared to those without disabilities. Compared to cancer survivors without disability, those with disability had higher odds of ED visits (aOR 1.59 [95% CI 1.27-1.99], $p<0.001$) and hospitalizations (aOR 1.70 [95% CI 1.30-2.22], $p<0.001$). Other factors associated with increased odds of ED visits in cancer survivors were region (Ref=Northeast, South: aOR 1.33 [95% CI 1.01-1.77], p=0.046; West: aOR 1.46 [95% CI 1.09-1.98], p=0.01), Medicaid insurance (Ref=no insurance, aOR 1.93 [95% CI 1.01-3.69], p=0.046), and poor self-rated health (Ref=excellent, aOR 6.69 [95% CI 4.05-11.07], $p<0.001$). Factors associated with increased odds of hospitalizations in cancer survivors were Medicare (Ref=no insurance, aOR 2.18 [95% CI 1.21-3.92], p=0.01), private insurance (Ref=no insurance, aOR 1.83 [95% CI 1.02-3.26], p=0.04), multiple insurance (Ref=no insurance, aOR 2.07 [95% CI 1.15-3.74], p=0.02), and poor self-rated health (Ref=excellent, aOR 6.96 [95% CI 3.82-12.70], $p<0.001$). **Conclusions:** We observed an independent association between disability and ED visits and hospitalizations among cancer survivors in a national, population-based dataset. Geographic region, insurance, and poor health perception were additional risk factors for acute care utilization in cancer survivors. Our findings highlight the need for targeted interventions to improve ambulatory care access and reduce preventable acute care utilization in this vulnerable population. Research Sponsor: National Cancer Institute; 5R37CA288492.

Healthcare resource use (HCRU) intensity prior to cancer diagnosis and real-world outcomes in early-stage cancers. First Author: Syed Irteza Abbas Shamsi, University of Calgary, Calgary, AB, Canada

Background: *Choosing Wisely* initiatives aim to reduce futile care by emphasizing the role of clinicians in healthcare decision-making. However, HCRU is strongly shaped by patient preferences with some inherently favoring high-intensity ("maximalist") care and others preferring low-intensity ("minimalist") approaches. We hypothesized that HCRU in the years before an early-stage cancer diagnosis may, in part, represent the healthcare seeking preferences of patients rather than strictly reflecting their clinical needs. **Methods:** We conducted a population-based retrospective cohort study of adults diagnosed with stage I-II breast, lung or colon cancer from 2015 to 2020 in Alberta, Canada with follow-up to 2025. Pre-diagnosis HCRU was quantified using ambulatory, emergency, and inpatient encounters. Patients were categorized as high (≥75th percentile) or low (≤25th percentile) users; intermediate users were excluded. Cohorts of high vs. low users were matched based on age, sex, rurality, stage and Charlson Comorbidity Index (CCI) and stratified by tumor site. Outcomes included cancer-specific survival (CSS), overall survival (OS) and post-diagnosis HCRU. **Results:** The matched cohort included 7,384 patients (64% breast, 21% lung, 15% colon) with balance across all covariates. Median age was 67 years, 68% had stage I disease and 95% had CCI<2. For all cancer sites, CSS did not differ between high and low users (see Table). High pre-diagnosis HCRU was associated with worse OS in breast (HR 1.34, $p<0.001$) and colon cancer (HR 1.36, p=0.003), but not in lung cancer (HR 1.02, p=0.76). Importantly, HCRU patterns pre-diagnosis strongly persisted post-diagnosis, with high users continuing to consume significantly more healthcare resources than low users for 4 years after cancer diagnosis ($p<0.001$). **Conclusions:** In this relatively healthy cohort of early-stage, highly curable cancers, greater pre-diagnosis HCRU was associated with sustained post-diagnosis HCRU intensity without any significant differences in cancer-specific outcomes. Our findings suggest that utilization patterns may reflect patient-level behaviors as much as clinical necessity, thus contributing to volume-driven care that may have limited clinical value. Advancing future *Choosing Wisely* initiatives in oncology must extend beyond clinician stewardship to address patient expectations about their healthcare interactions. This strategy would better align with value-based care and promote health system sustainability. Research Sponsor: None.

CSS based on pre-diagnosis HCRU.

Cancer site	Pre-diagnosis HCRU	10-year CSS (95% CI)	HR for CSS (95% CI)	P value
Breast	Low	89% (87%, 92%)	Reference	0.55
Breast	High	91% (90%, 93%)	0.93 (0.74,1.18)	
Lung	Low	63% (58%, 69%)	Reference	0.72
Lung	High	68% (64%, 72%)	1.04 (0.85,1.26)

Reframing access to innovative oncology medicines: The impact of policy and governance reform in a Bismarck-type system in Bosnia and Herzegovina. First Author: Timur Ceric, Clinical Center University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: Access to innovative oncology medicines is often assumed to depend primarily on available financial resources. In health systems organized under the Bismarck model, however, access is frequently constrained by structural and policy-related factors, including fragmented governance, rigid reimbursement pathways, and infrequent updating of positive drug lists. These limitations may result in delayed access, restricted indications, and misalignment with contemporary clinical standards, even in the absence of absolute budget shortages. In Bosnia and Herzegovina, such constraints are compounded by complex administrative arrangements, leading to pronounced regional disparities in cancer care. In Sarajevo Canton prolonged waiting times and loss of treatment eligibility underscored that the key barrier was not lack of money, but lack of timely policy action. In October 2024, Sarajevo Canton launched a program shifting financing responsibility locally to improve timely access. **Methods:** We analyzed drug access before and after program initiation in 641 patients, assessing waiting times from indication to treatment approval and the proportion of patients losing indication prior to therapy availability. **Results:** Patients whose indication was established before the program were significantly more likely to remain without therapy compared to those after initiation (23.8% vs. 10.3%, $p < 0.001$). Among 547 patients with available waiting time data, mean waiting time decreased from 251.6 days (SD ≈ 190; range 21–910) to 40.4 days (SD ≈ 21; range 6–199), representing a >6-fold reduction. Variability also decreased, making access more predictable and equitable. Levene's test indicated unequal variances ($F = 517.3$, $p < 0.001$), and Welch's t-test confirmed the difference ($t(157.5) = 13.91$, $p < 0.001$; 95% CI 181–241 days), with a very large effect size (Cohen's $d \approx 2.0$). **Conclusions:** This policy intervention dramatically reduced waiting times and improved equity in therapy access. This demonstrates that substantial improvements in oncology drug access can be achieved without increasing overall healthcare spending. The observed gains were the result of a deliberate policy and governance shift—redefining responsibility, prioritization, and accountability—rather than additional financial input. This intervention highlights that, within Bismarck-type systems, access gaps are often policy failures rather than funding failures, and that targeted policy change can serve as a powerful lever to rapidly improve equity and quality of cancer care. Research Sponsor: None.

Association between physician characteristics and likelihood of caring for underserved patients with cancer. First Author: William Roberts, National Clinician Scholars Program, Yale School of Medicine, New Haven, CT

Background: Despite evidence that a diverse workforce may improve access to care for underserved patients, emerging policies threaten to limit diversity in the physician workforce. We assessed whether nonwhite and foreign-born physicians were more likely than White and US-born physicians to care for underserved (minority race, low-income, rural) Medicare beneficiaries with cancer. **Methods:** Using SEER-Medicare, we analyzed Medicare beneficiaries aged 18+ newly diagnosed with breast, colorectal, lung, or prostate cancer from 2015-2019. We linked patients to cancer physicians (medical, radiation, and surgical oncology) using claims in the 6 months after diagnosis. We assessed physician race/ethnicity (data from Association of American Medical Colleges) and country of birth (American Medical Association). For each physician race and foreign-born status, we calculated the standardized treatment ratio (STR) as the percent of that group's dyads with a given patient characteristic divided by the percent of all dyads with that patient characteristic. Thus, STR > 1 indicates physicians in that group are more likely than the average physician to treat patients with the given characteristic. **Results:** We linked 434,923 patients (30% breast, 16% colorectal, 29% lung, 25% prostate) to 35,257 physicians. The patient population (mean age 74.7) was 79% White, 8% Black, 7% Hispanic, 3% Asian, 17% Medicaid dual-eligible, and 16% rural. Black physicians were more likely than expected to care for Black patients (STR 2.55; 95% CI 2.48–2.63; Table) and dual-eligible patients (STR 1.26; 1.22–1.29). Hispanic physicians were more likely to care for Hispanic (1.97; 1.91–2.03) and dual-eligible (1.11; 1.08–1.14) patients. Asian physicians were more likely to care for Asian (1.93; 1.89–1.96) and Hispanic (1.18; 1.16–1.20) patients and less likely to care for rural (0.73; 0.72-0.74) patients. Foreign-born physicians (20.7% of physicians) were more likely to care for Asian (1.36; 1.33–1.39), Hispanic (1.25; 1.23–1.27), and dual-eligible (1.20; 1.18–1.21) patients and less likely to care for rural patients (0.90, 0.89-0.91). **Conclusions:** Nonwhite and foreign-born cancer physicians disproportionately care for nonwhite and low-income patients. Policies restricting entry of minority and foreign-born physicians into the oncology workforce may hinder access to care for underserved cancer patients. Research Sponsor: None.

Standardized treatment ratios (STRs) by physician race, ethnicity and country of birth.

Physician characteristic	Patient Characteristic Asian	Black	Hispanic	White	Dual eligible	Rural
Race & ethnicity						
Asian	1.93	1.00*	1.17	0.95	1.09	0.73
Black	0.60	2.55	1.08	0.85	1.26	1.04
Hispanic	0.79	0.97*	1.97	0.94	1.11	1.01*
White	0.68	0.92	0.81	1.04	0.88	1.09
Foreign born						
No	0.86	0.96	0.89	1.02	0.88	1.04
Yes	1.36	1.05	1.25	0.96	1.20	0.90

Racial disparities and nonconcordance with endocrine and HER2 therapy for breast cancer: A sequential mediation analysis of neighborhood deprivation and insurance status. First Author: Jay Patel, University of Central Florida College of Medicine, Orlando, FL

Background: Racial disparities in breast cancer treatment persist, but the mechanisms driving inequities may differ by therapy type. We evaluated whether neighborhood racialized economic segregation (mediator 1, M1) and insurance status (M2) sequentially mediate racial disparities in receipt of guideline-concordant endocrine and anti-HER2 therapy. **Methods:** We conducted a retrospective cohort analysis of women diagnosed with breast cancer using the Florida Cancer Data System (2013–2021). Eligible women included those with invasive, nonmetastatic disease with hormone or HER2-receptor-positive tumors. Treatment nonconcordance was defined as failure to receive recommended systemic therapy based on tumor receptor status. M1 was measured by the racial-income version of the Index of Concentration at the Extremes (ICE) at the census tract level and divided into quintiles from the most to least deprived. Insurance status was categorized as insured versus Medicaid/uninsured/unknown (MUU). Simple frequencies were obtained to assess the relationships between race, the mediators, and therapy nonconcordance. Causal mediation analyses using the parametric g-formula quantified natural course risks and the proportion of the racial disparity mediated by ICE and insurance status, while adjusting for confounders (disease stage, molecular subtype [endocrine only], tumor grade, age, region of the state, and marital status). **Results:** There were 71,077 and 3,021 women available for the analysis of endocrine and HER2 therapy, respectively. For nonconcordance with endocrine therapy, disparities were present by race (37.2% vs. 29.0%, Black vs. White), the ICE (37.2% vs. 26.2%, most vs. least deprived), and insurance status (36.1% vs. 29.4%, MUU vs. other). Smaller disparities were present for nonconcordance with HER2 therapy by race (18.1% vs. 12.9%, Black vs. White), the ICE (16.2% vs. 14.2%, most vs. least deprived), and insurance status (18.5% vs. 13.4%, MUU vs. other). In causal mediation analysis for nonconcordance with endocrine therapy, the natural course counterfactual risks showed a 5% absolute disparity by race (34.3% vs. 29.3%); 59% of this disparity was mediated by the ICE and insurance status. For nonconcordance with HER2 therapy, the natural course counterfactual risks showed a 4% absolute disparity by race (17.1% vs. 13.1%); none of this disparity was mediated by the ICE and insurance status. **Conclusions:** Racial disparities in receipt of endocrine therapy are largely mediated by neighborhood deprivation and access to care, whereas these factors played no role in explaining disparities in anti-HER2 therapy. These findings suggest that treatment disparities are therapy-specific and that analyses of aggregate treatment outcomes may obscure distinct mechanisms of inequity. Survival outcomes with immune checkpoint inhibitors among patients with cancer from minoritized racial and ethnic groups: A systematic review and meta-analysis. First Author: Alfredo Viray Chua Jr., Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Immune checkpoint inhibitors (ICIs) have transformed the treatment landscape across multiple malignancies; however, minoritized racial/ethnic groups remain underrepresented in pivotal trials, limiting the generalizability of efficacy estimates. Whether treatment outcomes with ICIs differ across these groups remains incompletely characterized. Thus, we conducted a systematic review and meta-analysis of published randomized controlled trials (RCTs) to evaluate differences in overall survival (OS) and progression-free survival (PFS) among these groups treated with ICIs. **Methods:** We systematically searched MEDLINE, Embase, Cochrane CENTRAL, and ClinicalTrials.gov for RCTs published through December 31, 2024, that evaluated ICIs in adult patients with cancer and reported OS or PFS by race/ethnicity. Risk of bias was independently assessed using the Cochrane Risk of Bias tool for randomized trials (RoB 2). Hazard ratios (HRs) and 95% confidence intervals (CIs) were extracted. Between-study heterogeneity was quantified using I^2. Random-effects meta-analyses were performed using Review Manager (RevMan) and stratified by: non-White and White patients; Asian, Black, and White patients; Asian and non-Asian patients; and Hispanic and non-Hispanic patients. Publication bias was evaluated using funnel plots. This review followed Cochrane methodology and PRISMA guidelines and was registered in PROSPERO (CRD42025027941). **Results:** A total of 97 trials comprising 59,949 patients were included. For OS, ICIs were associated with significant benefit in both non-White (HR 0.70, 95% CI 0.63–0.77; $p<0.001$) and White patients (HR 0.75, 95% CI 0.67–0.84; $p<0.001$). Significant OS benefit was also observed in analyses stratified by Asian (HR 0.81, 95% CI 0.76–0.86; $p<0.001$) and White patients (HR 0.86, 95% CI 0.82–0.91; $p<0.001$), and by Asian (HR 0.83, 95% CI 0.76–0.91; $p<0.001$) and non-Asian patients (HR 0.79, 95% CI 0.73–0.86; $p<0.001$). Similar patterns were observed for PFS. Estimates for Black and Hispanic patients were not statistically significant, reflecting limited sample sizes. Heterogeneity ranged from low to substantial (I^2 0–87%), with higher heterogeneity observed in PFS analyses. Only one trial reported race-specific survival outcomes for American Indian/Alaska Native (AI/AN) patients, and none reported outcomes for Native Hawaiian/Pacific Islander (NH/PI) patients, precluding analyses for these groups. **Conclusions:** ICIs were associated with improved OS and PFS across racial/ethnic groups, with no consistent evidence of differential treatment effects. However, the persistent underrepresentation of minoritized populations, particularly AI/AN, Black, Hispanic, and NH/PI patients, limits definitive conclusions and highlights the need for more equitable representation in oncology trials. ZIP-code–level distress as a predictor for advanced stage and mortality in female breast cancer across a multiethnic cohort in Hawai'i. First Author: Chalothorn Wannaphut, Department of Internal Medicine, University of Hawai'i John A. Burns School of Medicine, Honolulu, HI

Background: Native Hawaiian and Pacific Islander (NHPI) patients experience worse breast cancer outcomes; however, the role of neighborhood-level structural disadvantage remains underexplored. We evaluated whether the Distressed Communities Index (DCI), a ZIP-code–level socioeconomic measure, is associated with stage at diagnosis and survival in a multiethnic breast cancer cohort. **Methods:** We conducted a retrospective cohort study of 10,421 female patients with breast cancer treated at a major tertiary cancer center in Honolulu, Hawai'i (2000-2024). DCI was assigned by residential ZIP code using the Economic Innovation Group DCI (American Community Survey 5-year estimates, 2019–2023) and dichotomized as low (DCI 1–3) versus high (DCI 4–5). Patients missing ZIP code or stage at diagnosis were excluded. Associations with advanced stage (III/IV) were assessed using logistic regression. Overall survival (OS), defined as time from diagnosis to death from any cause or last follow-up, was evaluated using multivariable Cox regression, adjusting for age, race/ethnicity, insurance, tumor characteristics, and stage. **Results:** The cohort included 1,982 White, 6,206 Asian, 2,067 NHPI, and 166 patients of other races/ethnicities. Baseline DCI distribution differed by race/ethnicity and insurance: NHPI patients were more likely to reside in high-distress communities than non-NHPI patients (38.9% vs 29.3% OR 1.54, $p<0.001$), as were Medicaid/uninsured patients compared with privately insured patients (51.4% vs 27.8%; OR 2.76, $p<0.001$). Advanced stage at diagnosis was more frequent in high-DCI neighborhoods than low-DCI neighborhoods (10.0% vs 6.7%; $p<0.001$) and remained independently associated with high DCI after adjustment (aOR 1.29; p=0.021). Higher DCI was also associated with worse survival (aHR 1.16, 95% CI 1.07–1.27; $p<0.001$), demonstrating a dose-response pattern across DCI categories (p for trend <0.001). No significant interaction was observed between DCI and NHPI status (p=0.493). Median OS was 247 (234-260) months for White patients, 247 (241-253) months for Asian patients, 227 (215-239) months for NHPI patients (log-rank $p<0.001$). In multivariable analysis, NHPI patients had higher mortality than White patients (HR 1.27, 95% CI 1.12–1.43; $p<0.001$), while Asian patients had improved survival (HR 0.78, 95% CI 0.71–0.87; $p<0.001$). Medicaid/uninsured remained independently associated with higher mortality (HR 2.18, 95% CI 1.85–2.57; $p<0.001$). **Conclusions:** ZIP-code–level socioeconomic distress is independently associated with advanced stage at diagnosis and mortality in breast cancer and disproportionately affects NHPI and Medicaid/uninsured patients. DCI identifies communities at higher risk and provides a scalable, policy-relevant tool to support geographically targeted navigation, screening access, and resource allocation strategies. Racial variation in pain medication prescriptions among breast, prostate, and pancreatic cancer patients treated in a large community oncology setting. First Author: Ila Sruti, Ontada, Boston, MA

Background: Patients (pts) from racially and ethnically minoritized populations are less likely to receive opioid analgesics for cancer-related pain, raising concern for inequitable symptom management. Although guidelines support opioid therapy within a multimodal approach, large scale evidence on racial differences in pain medication use across cancer types remains limited. This study uses real-world data from a large community oncology network to evaluate prescribing patterns of pain medication among high prevalence and high pain burden cancers by race and cancer type. **Methods:** Electronic medical record data from The US Oncology Network identified pts diagnosed with breast, prostate, or pancreatic cancer between January 2021 and June 2025, followed through December 2025. Pain medication (acetaminophen, NSAID, opioid) prescriptions and median time from cancer diagnosis to pain medication prescription were described. Strong opioids were defined as fentanyl, hydromorphone, morphine, or oxycodone, while general opioid use included hydrocodone and tramadol. **Results:** Among breast cancer patients overall (58,308 White; 7,705 Black; 3,652 Asian), pain treatment was received by 19% of White pts and by 24% of both Black and Asian pts, with median time to first pain medication shortest for White patients (65 d) and longest for Black patients (80 d). Prescriptions for strong opioids for breast cancer were lowest among Asian patients (28%), compared to 32% in Black patients and 35% in White patients. Among prostate cancer overall (19,268 White; 3,385 Black; 469 Asian), where receipt of pain medication was 17%, 20%, and 15%, respectively, Asian pts experienced the longest time to pain medication (86 d) versus the shortest among White patients (50 d). Asian patients had the fewest prescriptions for strong opioids (28%) compared with Black (54%) and White patients (50%). In pancreatic cancer (7,972 White; 1,035 Black; 330 Asian), pain medication prescriptions overall (52%, 55%, 50%, respectively) and for strong opioids (71%, 68%, 73%, respectively) were comparable across racial groups, and median time to pain medication showed minimal variation (18–22 d). **Conclusions:** In this large, nationally representative community oncology population, clinically meaningful racial differences in time to pain medication initiation and strong opioid prescribing were observed for breast and prostate cancer but not pancreatic cancer. Minoritized populations experienced delays in pain management, and Asian patients consistently received fewer strong opioid prescriptions. These results highlight that inequities in pain management vary across malignancies, and categories of pain medication. These findings underscore the need for culturally informed, cancer specific interventions to promote equitable symptom management. Research Sponsor: None.

Racial representation in clinical trials supporting NCCN breast cancer guidelines: A retrospective analysis. First Author: Shreya Motkur, Michigan State University, Lansing, MI

Background: Racial disparities in breast cancer are well established, with Black women having disproportionately higher mortality rates. The NCCN guidelines are valuable in the management of breast cancer, highlighting the importance of evaluating racial representation and its trends over time within the studies cited in these guidelines. **Methods:** We conducted a retrospective analysis of 735 references cited in NCCN Breast Cancer Guidelines Version 4.2025. All clinical trials were included, while reviews, case reports, and non-clinical references were excluded. The primary outcome of interest was the reporting of racial demographics within each reference. Fisher's exact test was used to assess statistically significant differences in racial representation across time periods. **Results:** Of 735 references screened, 384 met the inclusion criteria, and 89 (23%) reported racial demographics. Studies reported a total of 87.9% White, 4.5% Black, 4.1% Asian, 0.5% Hispanic, 0.1% American Indian/Alaska Native, 0.0% Native Hawaiian/Pacific Islander, and 0.1% reporting more than one race. Time block 5 had significantly more reported races than blocks 2, 3, and 4 (p-value < 0.05). A statistically significant decrease in percentage reported as White was seen when comparing time blocks 1 to 5 (p = 0.0495), 2 to 5 (p = 0.0336), and 2 to 6 (p = 0.028). Changes in representation among other racial groups were primarily driven by Black and Asian groups, with Asians comprising the largest proportion in time blocks 4 (6.1%) and 6 (17.9%), while the Black race was the largest group in all other time blocks. All other racial groups remained consistently low across time blocks. **Conclusions:** Only 23% of references reported racial data. While the proportion of the White race decreased over time and an increased representation of other racial groups was observed, the overall reporting of these groups remained low across all time periods. This emphasizes the need for standardized reporting of race in clinical trials to ensure that NCCN guidelines accurately reflect the diversity of patients in breast cancer care. Research Sponsor: None.

Race demographics from clinical trials cited in the NCCN breast cancer guidelines.

Time block	Time Bracket	Percentage of White	Percentage of Non-White	Percentage of Black	Percentage of Asian	Percentage of Hispanic	Percentage of AI/AN	Percentage of NI/PI	Percentage of More than one race
1	1980-1999	95.6%	1.6%	2.8%	0.0%	0.0%	0.0%	0.0%	0.0%
2	2000-2004	92.4%	1.4%	4.6%	0.1%	1.3%	0.0%	0.0%	0.2%
3	2005-2009	86.9%	5.4%	5.2%	1.6%	0.9%	0.0%	0.0%	0.0%
4	2010-2014	88.7%	1.8%	2.8%	6.1%	0.1%	0.0%	0.0%	0.5%
5	2015-2019	87.1%	1.8%	5.7%	4.7%	0.3%	0.3%	0.1%	0.1%
6	2020-2025	78.3%	0.2%	3.1%	17.9%	0.3%	0.1%	0.0%	0.1%
	Total	87.9%	2.7%	4.5%	4.1%	0.5%	0.1%	0.0%	0.1%

AI/AN = American Indian/Alaska Native; NH/PI = Native Hawaiian/Pacific Islander.

Are socio-economic status indicators barriers for enrollment in phase 1 clinical trials? First Author: Reema Mody, Hackensack University Medical Center, Hackensack, NJ

Background: Socio-economic Status (SES) indicators create barriers to access Phase 1 clinical trial (Ph1) enrollment, particularly for underrepresented minorities (URM). However, it remains unclear whether they directly affect enrollment after screening, or represent upstream barriers. We evaluated whether SES indicators impacted the enrollment rate in Ph1. **Methods:** All patients were screened for Ph1 at Hackensack University Medical Center (2014-2025). Patient ZIP codes were linked to the U.S. Census data (ACS 2018-2022) to derive neighborhood-level SES indicators: median household income (MHI), educational attainment (Bachelor), poverty rate (PR), unemployment rate (UR), and median home value (MHV). SES indicators were compared to national and state census benchmarks. The primary outcome was enrollment rate by SES indicators. We performed univariate analyses (Mann-Whitney U tests, chi-square), stratified analyses by race/ethnicity and gender, temporal trend analysis, and multivariable logistic regression. **Results:** A total of 1,316 patients were screened for 140 Ph1. Demographics were non-Hispanic White (NHW) 66.2%, Hispanic 19.0%, African American/Black (AA) 7.8%, Asian 6.5%. No SES variable predicted enrollment: median income (enrolled $62,646 vs not-enrolled $61,820, p=0.450), education (38.3% vs 37.9%, p=0.598), poverty (12.9% vs 12.3%, p=0.416), unemployment (6.1% vs 6.0%, p=0.422), home value ($277,461 vs $275,697, p=0.605). SES quartile analysis showed no enrollment gradient (Q1=61.7%, Q2=58.1%, Q3=60.5%, Q4=63.8%; p=0.491). Findings were consistent across all racial/ethnic groups (all $p>0.05$), see Table 1, gender (all $p>0.05$), age groups <65 and ≥ 65 years (all $p>0.05$), and time periods 2014-2019 vs 2020-2025. When compared to their respective racial/ethnic groups U.S. Census averages, it demonstrated atypical SES profiles: Hispanic patients had higher education (36.6% vs 20.6%), AA showed higher SES across all indicators, and Asians showed lower SES, suggesting regional selection bias in who reaches Ph1 screening. **Conclusions:** When patients reach Ph1 screening, SES indicators do not predict enrollment, demonstrating that equitable enrollment practices can be achieved at screening. Although there were no visible SES-related barriers at the enrollment point, disparities exist among groups likely suggesting referral patterns prior to screening. Future research should examine how to improve access to Ph1 in URM and upstream inequities. Research Sponsor: None.

Early-onset gastrointestinal cancers: Racial disparities in stage and survival from large-scale community oncology data. First Author: Saamir Pasha, Ontada, Boston, MA

Background: Research on early-onset (EO) gastrointestinal (GI) cancers has focused predominantly on colorectal cancer, leaving knowledge gaps regarding racial variations across other GI malignancies. We used real-world data from a large, nationally representative community oncology network to assess age-of-onset differences in clinical characteristics and survival for colorectal, gastric, and esophageal cancers across key social determinants. **Methods:** This was a retrospective cohort of patients with colorectal, gastric and esophageal cancers treated within the U.S. Oncology Network and non-Network practices from 2000–2025. Patients were categorized as EO (<50 years) or average-onset (AO) (≥50 years) at diagnosis. Characteristics including demographics, stage at diagnosis (I–II, III–IV, or unknown), and distress level (NCCN Distress Thermometer) were sourced from iKnowMed. Overall survival (OS) was assessed from diagnosis using Kaplan–Meier methods, stratified by race/ethnicity and stage. **Results:** Among 195,624 patients with GI cancers, 23,244 (11.9%) had EO disease. In the EO cohort, 20,203 (87%) had colorectal, 1,693 (7%) gastric, and 1,348 (6%) esophageal cancers. EO disease occurred in a more racially and ethnically diverse population, with higher representation of Hispanic/Latino (10.3% vs 6.7%), Black (8.2% vs 6.6%), and Indigenous/Native (1.3% vs 0.8%) patients, and higher female representation (46.4% vs 43.9%), versus AO disease. Advanced-stage (III–IV) disease at diagnosis was more common in EO vs AO disease across colorectal (41% vs 32%), esophageal (41% vs 31%), and gastric (37% vs 29%) cancers. Among EO patients, stage III/IV disease at diagnosis was higher in Black (75.3%) and Asian (73.1%) versus White patients (64.9%), whereas among AO patients advanced stage was more balanced across racial groups (66.2%, 64.9%, 62.9%, respectively). Within EO advanced-stage disease, median OS was 8.1 m shorter in Black vs White patients (51.0 vs 59.1 m), compared with only a 1.6 m difference in AO disease (35.0 vs 36.6 m). Among patients with available distress data (N=3,426), distress was higher in EO versus AO patients (median 4 vs 3) but did not differ by race, sex or ethnicity. **Conclusions:** This study represents one of the largest real-world characterizations of EO GI cancers, revealing that EO patients more often present with advanced-stage and higher distress than AO counterparts. While racial disparities in stage were relatively balanced in AO disease, they were exacerbated in EO disease, with Black and Asian patients presenting with substantially higher rates of advanced disease. The resulting survival gap between Black and White EO patients underscores a widening disparity less pronounced in older patients. A precision–public health approach is needed to address biological and socioeconomic drivers of outcomes in young, diverse GI cancer populations. Research Sponsor: None.

1654 Poster Session

Global sex-based disparities in pancreatic cancer clinical trial enrollment: A systematic review and meta-analysis. First Author: Amir H. Sohail, The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: Sex-based disparities in oncology trial enrollment are well recognized, yet their magnitude and consistency in pancreatic cancer clinical trials remain poorly-defined. We conducted a global systematic review and meta-analysis to quantify women's representation in pancreatic cancer trials relative to disease incidence. **Methods:** We identified phase I–III randomized and prospective interventional pancreatic cancer trials published through November 2025 in the top 25 general medicine, oncology, and gastroenterology journals. Women's enrollment was compared with sex-specific pancreatic cancer incidence from Global Burden of Disease estimates. Enrollment disparity difference (EDD) was calculated as the proportion of women enrolled minus the proportion of women in the underlying disease population. Random-effects meta-analyses, subgroup analyses, and temporal meta-regression were performed. **Results:** Among 191 eligible trials including 37,688 participants, 16,393 (43.5%) were women. Overall, women were significantly under-enrolled, with a pooled EDD of −0.050 (95% CI, −0.058 to −0.042). Under-enrollment was observed across all geographic regions, with the largest disparity in European trials (EDD −0.069; 95% CI, −0.080 to −0.058). Significant disparities were present across all trial phases except combined phase I/II studies and were most pronounced in trials enrolling fewer than 50 participants (EDD −0.081; 95% CI, −0.105 to −0.057). Women remained under-enrolled across chemotherapy, immunotherapy/biologic, vaccine, and multimodal trials, while no significant disparity was observed in radiotherapy studies. Trials with women in leadership roles demonstrated slightly attenuated but persistent under-enrollment (EDD −0.046 vs −0.052). Temporal analyses showed narrowing of disparities between 2016 and 2020, followed by worsening under-enrollment from 2021 to 2025 (EDD −0.033). Sensitivity analyses limited to chemotherapy, immunotherapy/biologic, and phase III trials confirmed consistent patterns of under-representation. **Conclusions:** Women are persistently under-enrolled in pancreatic cancer clinical trials worldwide, with disparities evident across regions, trial phases, and treatment modalities. Recent reversals in progress highlight the need for durable, equity-focused trial design and enrollment strategies. Research Sponsor: None.

Who gets access? National discrepancies in clinical trial enrollment among patients with brain metastases. First Author: Manuela Jaramillo, Duke University, Durham, NC

Background: Patients with brain metastases (BM) have historically been underrepresented in clinical trials. Contemporary national data describing clinical trial enrollment (CTE) patterns and sociodemographic predictors in this population remain limited. **Methods:** Using the National Cancer Database, adults (≥18 years) diagnosed with BM (2010-2021) from the five most common primary sites (lung, breast, melanoma, colorectal, and renal cell carcinoma) were included. The key outcome was CTE (yes/no). Multivariable logistic regression was used to evaluate associations between enrollment and primary tumor site, age, sex, race/ethnicity, facility type, geographic region, residence, insurance status, area-level education and income, comorbidity burden (Charlson-Deyo score), and time epoch (2010-2013, 2014-2017, 2018-2021). **Results:** The analytic cohort included 238,129 patients with BM (lung n=206,813; melanoma n=10,394; breast n=9,915; renal n=7,409; colorectal n=3,598). Overall, <1% of patients (n=385) had CTE. In adjusted analyses, compared with patients aged 18-39 years, those aged 40-64 years (aOR: 0.15) and ≥65 years (aOR: 0.12) had significantly lower odds of enrollment (P<0.001). Female sex was associated with higher enrollment (aOR: 1.30, P=0.013), while Hispanic ethnicity was associated with lower enrollment compared with non-Hispanic White patients (aOR: 0.39, P=0.014). Higher comorbidity burden (Charlson–Deyo score: 2-3) was associated with lower enrollment (aOR: 0.68, P=0.04). Treatment at an academic/research facility had the highest odds of CTE compared with community facilities (aOR: 4.83, P<0.001), as well as care within an integrated network (aOR: 1.87, P=0.001). CTE increased over time (2014-2017, aOR 1.58, P=0.002; 2018-2021, aOR 1.63, P=0.001, vs 2010-2013). **Conclusions:** CTE among patients with BM was low across primary tumor sites. Enrollment was higher at academic facilities and among younger patients, while Hispanic patients had lower odds of enrollment. These findings indicate persistent disparities in clinical trial access and support more inclusive enrollment strategies for patients with BM. Research Sponsor: None.

Validation of a 10-item frailty index based on a comprehensive geriatric assessment (FI-CGA-10) for predicting survival in older adults with cancer. First Author: Tomohiro F. Nishijima, Geriatric Oncology Service, NHO Kyushu Cancer Center, Fukuoka, Japan

Background: The FI-CGA-10 is a content- and construct-validated measure for quantifying frailty from a CGA [Oncologist, 26, e1751 (2021)]. For criterion validation, we evaluated the predictive validity of the FI-CGA-10 for survival in older adults with cancer. **Methods:** This prospective cohort study included 1,630 consecutive older adults with cancer who underwent CGA prior to their cancer treatment decision at a geriatric oncology service in Japan from September 2018 through September 2024. Fitness and frailty were evaluated using the FI-CGA-10, which comprises ten domains: cognition, mood, communication, mobility, balance, nutrition, basic and instrumental activities of daily living (ADLs/IADLs), social support, and comorbidity. Deficits in each domain were scored 0 (no problem), 0.5 (minor problem), or 1.0 (major problem). FI-CGA-10 scores were calculated as the sum of domain scores divided by 10 and categorized as fit (<0.20), pre-frail (0.20–0.35), and frail (>0.35). The primary outcome was overall survival (OS) at 1 year from the date of CGA. Two Cox proportional hazards models were fitted to predict 1-year overall survival (OS): a base model (age, sex, cancer type, and stage) and the base model plus the FI-CGA-10 as a categorical variable. Model performance was compared using the likelihood ratio test and Harrell's c-index. We also examined associations between each FI-CGA-10 domain and 1-year OS, adjusting for the same covariates. **Results:** Median age was 80 years (range, 51–99); 61% were male, 46% had gastrointestinal cancer, and 41% had distant-stage disease. Overall, 22% were fit, 38% pre-frail, and 40% frail; 29% died within one year. By the likelihood ratio test, adding the FI-CGA-10 significantly improved model fit compared with the base model (LR χ^2 = 140.7; P < .001). Adding the FI-CGA-10 also significantly improved discrimination (c-index 0.70 vs 0.76; P < .001). Kaplan–Meier curves for the three groups showed clear separation, demonstrating the FI-CGA-10's discriminatory ability (log-rank P < .001). After adjustment for covariates, pre-frail (HR 2.26; 95% CI 1.61–3.19) and frail (HR 5.06; 95% CI 3.64–7.04) patients had higher hazards of death versus fit patients. Estimated 1-year OS probabilities were 90% (fit), 78% (pre-frail), and 58% (frail). In multivariable analyses adjusted for age, sex, cancer type, and stage, major problems in all domains—and minor problems in cognition, mobility, balance, nutrition, IADL, and comorbidity—were significantly associated with worse survival compared with no problems. **Conclusions:** These findings support the predictive validity of the FI-CGA-10 for 1-year OS in older adults with cancer. Together with prior work demonstrating its content and construct validity, the FI-CGA-10 satisfies core components of measurement validation that can help clinicians care for older cancer patients. Use of parsimonious Fitbit step metrics to improve frailty classification in adults ≥50 with cancer in NIH All of Us. First Author: Kenan Najjar, Carle Illinois College of Medicine, Champaign, IL

Background: Frailty predicts treatment intolerance and adverse outcomes in older adults with cancer, yet scalable screening remains limited. Scalable frailty screening is particularly relevant for treatment selection and risk stratification in routine oncology care. We tested whether routine Fitbit step metrics improve frailty classification beyond basic variables and whether high-dimensional step-pattern features add benefit. **Methods:** Retrospective cross-sectional study in the NIH All of Us Research Program including adults ≥50 years with cancer history and Fitbit step data (N=378). Frailty was defined by a 33-item All of Us deficit frailty index (fit <0.15, vulnerable 0.15–0.25, frail >0.25); primary endpoint was frail vs not frail (fit+vulnerable). Valid wear day required ≥10 hours with activity or heart-rate evidence. Missing days were imputed for daily totals and minute-level profiles reconstructed using within-person donor days or weekday/weekend templates. Prespecified feature tiers were: basic (9), basic+average steps (10), and high-dimensional step-pattern features (108; minute-level intensity, variability, and frequency-domain summaries). Class-weighted elastic-net logistic regression, random forest, and gradient-boosted trees were tuned and evaluated with nested 5×5 cross-validation. Discrimination was pooled out-of-fold area under the receiver operating characteristic curve (AUC) with stratified bootstrap 95% confidence intervals (CI); incremental value used paired bootstrap ΔAUC. **Results:** Participants were 64.8±8.6 years; 67.7% were female. Frailty categories were fit 43.7%, vulnerable 40.7%, and frail 15.6% (59/378). Mean daily steps were lower in frail vs not frail participants (5505 vs 7648 steps/day). Elastic-net logistic regression with step features achieved the highest AUC (0.713, 95% CI 0.636–0.783) vs the basic model (0.644, 95% CI 0.567–0.720; ΔAUC 0.068, paired bootstrap 95% CI 0.002–0.133). At ≥90% specificity, sensitivity increased from 25.4% (15/59) to 39.0% (23/59). In secondary analyses predicting not-fit status (vulnerable/frail vs fit), adding step features improved AUC from 0.551 (95% CI 0.493–0.609) to 0.635 (95% CI 0.580–0.694). High-dimensional step features did not improve AUC. **Conclusions:** In adults ≥50 with cancer, a parsimonious step-based metric improved frailty classification and increased sensitivity at high specificity, while complex feature sets and models did not add benefit. These findings support low-burden step metrics as scalable adjuncts to frailty screening in oncology; external validation is needed. GRACE: A conversational AI platform for geriatric oncology risk and capability evaluation. First Author: Arash Naeim, UCLA Medical Center, Los Angeles, CA

Background: Comprehensive geriatric assessment (CGA) is a multidimensional evaluation of health in older adults and endorsed by the American Society of Clinical Oncology (ASCO) and the National Comprehensive Cancer Network (NCCN) for improved outcomes in geriatric cancer patients. However, CGA is underutilized due to time constraints and staffing shortages. Artificial intelligence (AI) can provide autonomous geriatric assessments (GA) but require validation. **Methods:** GRACE, an AI platform for GA via natural language interaction, was tested against manual GA. 70 adults aged ≥65 were enrolled from UCLA using the portal MyChart and at affiliated active senior living centers. 15 clinicians contributed qualitative perspectives. Concordance was evaluated using sensitivity, specificity, predictive values, and agreement (Cohen's κ, Gwet's AC1). Usability was measured with the System Usability Scale (SUS), and patient and provider interviews were thematically analyzed. **Results:** GRACE showed high diagnostic performance (sensitivity 0.73, specificity 0.94, κ=0.63, AC1=0.82) with highest agreement in polypharmacy (κ≈0.97; AC1≈0.98). Usability was high (SUS >80th percentile) and 84% of participants reported confidence using GRACE. Clinicians endorsed GRACE as a practical pre-visit intake tool that integrates with electronic health records and facilitates timely referrals. **Conclusions:** GRACE demonstrates that conversational AI can replicate key elements of clinician-administered GA while reducing burden on oncology teams. Larger multi-site studies are warranted to evaluate clinical impact and integration into routine oncology practice. Research Sponsor: None.

Development of a composite risk score for chemotherapy toxicity and unplanned hospitalization in older adults with cancer: A prospective cohort study. First Author: Lirong Yang, Shanghai Clinical Research and Trial Center, Shanghai, China

Background: Older adults receiving chemotherapy are at high risk for severe treatment-related toxicities, which may compromise treatment completion and lead to unplanned hospitalizations. We developed a composite risk score integrating the components of Cancer and Aging Research Group (CARG) chemotherapy toxicity score and proved clinical predictors to enhance prediction of grade 3–5 (G3–5) chemotherapy-related toxicities, treatment tolerance, and unplanned hospitalization. **Methods:** Patients aged ≥70 years with solid tumors initiating chemotherapy were enrolled between December 2024 and August 2025 at a tertiary hospital in Shanghai, China. The primary endpoint was the occurrence of any G3–5 chemotherapy-related toxicity; secondary endpoints included chemotherapy incompletion and unplanned hospitalization. Baseline characteristics included the CARG score, tumor- and treatment-related characteristics, and laboratory parameters. Toxicities (graded using CTCAE v5.0), treatment completion, and unplanned hospitalizations were assessed at each cycle for up to 6 months or until completion of the planned treatment course. Predictors of G3–5 toxicities were screened by LASSO-penalized multivariable logistic regression, and model discrimination was evaluated by receiver operating characteristic curve. **Results:** Among 242 patients (median age 74 years; range 70–88), 71.9% were male, 64.5% had gastrointestinal malignancies, and 73.1% had stage IV disease. Overall, 164 patients (67.8%) experienced G3–5 toxicities, and 63 (26.0%) had unplanned hospitalizations. The score system included cancer type, hemoglobin, estimated glomerular filtration rate, falls within 6 months, medication management ability, C-reactive protein/albumin, MAX2 index, walking ability, and social activity level. The median score was 10 (range 6–14). Each one-point increase in score was associated with higher risk of any G3–5 toxicity (OR 1.21, 95% CI 1.14–1.30; AUC 0.75) and non-hematologic G3–5 toxicity (OR 1.19, 95% CI 1.12–1.27; AUC 0.73).The score was also positively associated with unplanned hospitalization (OR 1.07, 95% CI 1.01–1.13; AUC 0.62), but was inversely associated with chemotherapy incompletion (OR 0.93, p=0.019), suggesting more proactive treatment modifications in high-risk patients. In this cohort, the new score showed superior discrimination for any G3–5 toxicity, with a higher AUC than the CARG score (0.75 vs. 0.63). The optimal cutoff point of any G3–5 toxicity was 7.5 with relatively good specificity (72%) and sensitivity (65%). **Conclusions:** The composite score may help predict G3–5 toxicity, non-hematologic G3-5 toxicities, and unplanned hospitalization, potentially outperforming the CARG score. External validation and evaluation of clinical utility are warranted. Research Sponsor: None.

Practice patterns and outcomes by genomic risk in octogenarians with high-risk localized prostate cancer: A national real-world data analysis. First Author: James Robert Janopaul-Naylor, Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Chronologic age and traditional clinical-pathologic prostate cancer (PCa) risk factors (e.g. PSA, Gleason Score) are useful but incomplete predictors of prognosis. While some octogenarians may benefit from watchful waiting for clinically high risk (HR) and very high risk (VHR) PCa due to competing risks, others may survive more than a decade with curative prostate-directed treatment. We examined real-world data (RWD) on practice patterns and outcomes for octogenarians with HR PCa stratified by genomic classifier (GC) scores. **Methods:** A retrospective cohort study was conducted using a national database of clinical–genomic linkage of Decipher GC with longitudinal RWD (Veracyte, South San Francisco, CA). The cohort included 1,519 patients, ≥80-years-old with HR/VHR PCa who underwent GC testing with >1 year of follow-up. Patients were stratified by low (GC-Low) compared to intermediate or high (GC-High/Int) GC scores. Observational management was determined by absence of treatment with evidence of prostate cancer–related services (e.g. GC-High/Int-Obs). Freedom from distant metastases (FFDM), metastasis-free survival (MFS), and overall survival (OS) were modeled using Kaplan-Meier analysis and log-rank tests. **Results:** Most patients (88%, n=1,341) had GC-High/Int. The rate of observational management was significantly lower in the GC-High/Int compared to GC-Low cohorts (26% vs 38%, p=0.001). Among treated patients, there were similar rates of ADT only use (52% GC-Low vs 54% GC-High/Int) but amongst those who were treated with radiotherapy, concurrent ADT use was lower in GC-Low compared to GC-High/Int (55% vs 69%, OR 0.83, 95% CI 0.73-0.95, p=0.007). There were significant differences between groups for FFDM (p=0.003), MFS (p<0.001), and OS (p<0.001) (Table). Among observed patients, GC-Low had significantly better FFDM than GC-High/Int (HR 0.11, 95% CI 0.02–0.80; p=0.03). **Conclusions:** Geriatric patients with aggressive, localized PCa decide between potentially morbid, curative treatments and heterogeneous risk of distant metastases in the setting of limited life expectancy. We present RWD that patients ≥80 years old with NCCN HR/VHR PCa with low GC scores have <5% rate of metastatic disease within 5 years with observation alone. This hypothesis generating data suggests GC score may be a useful prognostic tool in addition to standard clinical-pathologic factors for elderly patients. Patient-specific risk calculators for cancer and non-cancer specific mortality may help this underserved but growing population. Research Sponsor: Veracyte Inc.

	NCCN HR (%)	NCCN VHR (%)	FFDM Hazard Ratio (95% CI)	5-yr FFDM	5-yr MFS	5-yr OS
GC-Low-Obs	58 (85%)	10 (15%)	0.11 (0.02-0.80)	98%	70%	71%
GC-Low-Treat	90 (82%)	20 (18%)	0.76 (0.36-1.59)	82%	75%	91%
GC-High/Int-Obs	250 (71%)	104 (29%)	Reference	83%	37%	43%

Evaluation of a co-designed nurse-led geriatric oncology multidisciplinary model in treatment-naive older adults with solid cancers. First Author: Surein Arulananda, Monash Health, Clayton, VIC, Australia

Background: Integration of geriatric assessment into cancer care improves outcomes for older adults but remains limited by resource intensity and reliance on physician time, hence restricting scalability. We evaluated the implementation of a co-created multidisciplinary (MDT) nurse-led geriatric oncology (GO) model developed to address these barriers. **Methods:** Implementation evaluation was conducted across two tertiary cancer centers. Older adults (≥65 years) with solid cancers underwent nurse-led structured geriatric assessment and MDT review involving medical oncology and geriatric medicine prior to oncology consultation. MDT recommendations addressed identified vulnerabilities, with referral for geriatrician-led CGA reserved for complex cases. Outcomes included G8 screening, referral for CGA, SACT delivery, treatment modification due to frailty, treatment discontinuation, delays, dose modification due to toxicity, and health service utilization (ED, SURC and unplanned hospital admissions within 12 weeks). Demographic and clinical characteristics were summarized using descriptive statistics. Associations with health service use were determined using logistic regression analyses. **Results:** Of 431 eligible pts, 204 (47.3%) participated in the GO assessment. Median age was 76 years. Most pts had lung cancer (73.1%), followed by GU (14.8%) and upper GI cancers (8.6%). Disease stage did not differ between groups; GO pts were more likely to have ECOG PS 1–2 and 81.4% scored ≤14 on the G8 screening tool. Half (50.7%) were referred for CGA and 67.1% of this cohort received SACT while 32.4% of the cohort not referred for a CGA received SACT. Upfront treatment modification due to frailty was numerically higher in GO pts compared to non-participants (21.1% vs 13.1%, p=0.076). GO participation was associated with higher receipt of SACT (70.6% vs 59.7%, p=0.019), increased use of monotherapy (22.5% vs 13.7%, p=0.016), and lower rates of BSC alone (41.0% vs 59.0%, p=0.033). There were no differences between groups in treatment discontinuation (p=0.64), delays (p=0.074), or dose modifications due to toxicity (p=0.42). GO pts were more likely to be admitted to hospital within 12 weeks of initial oncology consultation. **Conclusions:** GO assessment supported detailed evaluation of older pts with borderline ECOG PS and increased access to SACT, particularly monotherapy, without increasing treatment-related toxicity. Higher hospitalization rates likely reflect appropriate escalation of care following identification of frailty-related needs. Research Sponsor: None.

GO vs no GO.

	GO (n=204)	No GO (n=227)	p-value
Age median (range)	76.0 (72.0, 81.0)	76.0 (71.0, 81.0)	0.77
Monotherapy	46 (22.5%)	31 (13.7%)	0.016
Doublet, or more therapy	98 (48%)	101 (44.5%)	0.46
ED presentation	93 (45.6%)	86 (37.9%)	0.11
SURC use	43 (21.1%)	49 (21.6%)	0.90
Inpatient admission	74 (36.3%)	62 (27.3%)	0.046

1662 Poster Session

Outcomes of mortality and health care utilization in frail older patients with cancer receiving target therapies and/or immunotherapy. First Author: Amit Arora, Kaiser Permanente, Fremont, CA

Background: ASCO & NCCN guidelines recommend geriatric assessment for cancer patients aged 65+ to identify vulnerabilities missed on standard evaluations. Patients with G8 ≤14 (High risk) are potentially frail and at risk for chemotherapy toxicity, early mortality and ED visits/hospitalizations. However, there is currently limited evidence regarding the impact of a high-risk G8 score on outcomes among older frail patients receiving immunotherapy or targeted therapies. **Methods:** G8 screening was done at initial oncology consultation. Data was analyzed for individuals aged 65 and above referred between January 2021 and December 2024. Outcomes were measured 180 days after referral. A chi-square test assessed the relationship between demographic or outcome variables and G8 score. Multivariate regression and survival models predicted outcomes using age, sex, ethnicity, cancer type, and risk score. **Results:** This study included 1,671 patients receiving targeted therapy and/or immunotherapy. Participants ranged in age from 65 to 102 (median 75). Higher risk scores were linked to lower BMI (underweight: 92%, healthy: 74%, overweight/obese: 57%, $p < .0001$), older age ($p < .0001$), and female sex (73% vs 62%, $p < .0001$). Ethnicity was not related to risk scores. High risk patients receiving target and/or immunotherapy had over 3x higher mortality rates at 180 days than low risk ones ($p < 0.0001$). They were also 1.4x as likely to have an ED Visit or hospitalization, 2x as likely to be referred to palliative care, and 5x as likely to be referred to hospice ($p < 0.0001$). Multivariate analysis showed patients with upper GI and thoracic cancers were 1.4x more likely to be admitted and had over 2.7x mortality rate compared to those with breast cancer ($p < .0001$ - 0.0188). A total of 515 patients underwent only immunotherapy. Outcome trends and the association between risk score and demographics were similar to the combined target therapy and/or immunotherapy study. **Conclusions:** A high-risk G8 score (≤14) is linked to higher mortality and more emergency visits or hospitalizations in older cancer patients receiving immunotherapy or targeted therapies. It is recommended that oncologists integrate geriatric assessment results into treatment decisions involving immunotherapy and targeted therapies. Research Sponsor: None.

Outcomes of patients by risk score and treatment type 180 days after referral.

Risk Score/Treatment Type	Mortality	ED Visits or Hospitalizations	Palliative Care Referral	Hospice Referral
High risk G8-Combined target/Immunotherapy	15.3%	51.1%	33.0%	12.1%
Low risk G8 - Combined Target/Immunotherapy	3.7%	29.2%	14.8%	2.3%
p-value	<0.0001	<0.0001	<0.0001	<0.0001
High risk G8 - Immunotherapy alone	26.5%	61.5%	40.1%	22.3%
Low risk G8 - Immunotherapy alone	8.7%	43.5%	19.6%	5.1%
p-value	<0.0001	0.001	<0.0001	<0.0001

G8 screening-defined geriatric vulnerability as a predictor of survival and quality of life in older patients with advanced cancer treated with novel therapies. First Author: Andrea De Giglio, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy

Background: Older patients with advanced cancer are a highly heterogeneous population, in whom geriatric vulnerability may significantly influence survival, treatment tolerance, and patient-reported outcomes. The G8 screening tool is a validated instrument designed to identify geriatric vulnerability and select patients for comprehensive geriatric assessment; however, its prognostic and longitudinal impact on quality of life in patients receiving novel anticancer therapies remains poorly explored. **Methods:** The ONC-OLD study prospectively enrolled patients aged ≥70 years with advanced cancer treated with novel therapies across six referral centers. The primary objective was to assess the prognostic impact of baseline G8-defined geriatric vulnerability on overall survival (OS). Geriatric vulnerability was assessed at baseline using the G8 screening tool (≤14 vs >14). Health-related quality of life (HRQoL) was assessed using the EORTC QLQ-C30 and QLQ-ELD14 at baseline, after 3 months, and at disease progression. Baseline associations were analyzed using multivariable regression models, while longitudinal HRQoL changes were assessed using ANCOVA adjusted for baseline scores and relevant clinical covariates. **Results:** A total of 143 patients were included (median age 78 years, IQR 75-82); 78% had ECOG performance status (PS) 0-1, and 73% had G8 ≤14. Treatments consisted mainly of immunotherapy, either as monotherapy (31%) or in combination (36%), and targeted therapy (30%). At baseline, patients with G8 ≤14 were older (≥80 years: 46% vs 20%, p=0.019), more frequently female (42% vs 16%, p=0.016), and had worse ECOG PS (PS ≥2: 25% vs 0%, p=0.005) compared with those with G8 >14, with a different distribution of primary tumor types (lung cancer: 67% vs 29%, p=0.001). Median OS was 16.1 months (95% CI, 13.4-not reached) and was significantly shorter in patients with G8 ≤14 compared with those with G8 >14 (14.2 vs not reached; p=0.019). G8 ≤14 was independently associated with an increased risk of death (HR 2.71, 95% CI 1.01-7.24; p=0.047), after adjustment for ECOG PS, number of metastatic sites, treatment line and type. G8 ≤14 was associated with a trend toward a higher risk of grade ≥3 adverse events (OR 2.00, 95% CI 0.69-7.25; p=0.23), without specific treatment-related safety signals. At baseline, patients with impaired G8 reported worse global health, physical and role functioning, fatigue, pain, and mobility (all p≤0.01). In longitudinal analyses adjusted for baseline HRQoL and clinical covariates (ECOG PS, age, treatment), G8 remained significantly associated with higher fatigue (+12.6 points; p=0.039). **Conclusions:** Baseline G8 impairment is associated with poorer survival, worse baseline HRQoL, and a higher risk of severe toxicity, supporting the clinical value of G8 screening in older patients treated with novel therapies. Age-related efficacy of antibody-drug conjugates in solid tumors: A meta-analysis. First Author: Mariana Macambira Noronha, Department of Clinical Medicine, Federal University of Ceara, Fortaleza, Brazil

Background: Antibody–drug conjugates (ADC) have revolutionized cancer therapeutics, with various ADC improving clinical outcomes across solid tumors and several now approved as standard of care. Older adults with cancer are historically underrepresented in trials. As therapies with ADC are shifting to earlier lines of therapy, investigating whether clinical outcomes differ from those of younger patients with cancer is of interest. **Methods:** We searched PubMed, Embase, and the CENTRAL databases from inception through Dec 2025 for phase III randomized controlled trials (RCTs) that included adult patients with metastatic solid tumors treated with ADC and reported survival outcomes stratified by age group: elderly (>65 years) and younger (<65 years). The co-primary endpoints were progression-free survival (PFS) and overall survival (OS) across these age subgroups. Pre-specified subgroup analyses were performed according to ADC drug, target, and cancer types. Time-to-event outcomes were pooled as hazard ratios (HR) using the inverse-variance method with random-effects models. Heterogeneity was assessed using the I^2. PROSPERO: CRD4202612924710. **Results:** Of 2194 records, 17 RCTs (phase 3) met eligibility, including 9,929 patients, spanning breast (n=12), lung (n=2), urothelial (n=1), ovarian (n=1), and gastric cancer(n=1). ADCs were stratified by payloads: topoisomerase I inhibitors (TOPO1i; 65%), microtubule inhibitors (MMAE; 29%), alkylating agents (6%); and targets: TROP-2 (53%), HER2 (41%), and FRα (6%). Elderly pts treated with ADC exhibited significant improvement in PFS with a HR of 0.57 (95% CI 0.46-0.71; $p < 0.01$; $I^2 = 62\%$). Similarly, younger pts exhibited longer PFS, with a HR of 0.55 (95% CI 0.45-0.67; $p < 0.01$; $I^2 = 86\%$). Likewise, elderly patients exhibited significantly greater OS with a HR of 0.78 (95% CI 0.66-0.91; $p < 0.01$; $I^2 = 41\%$), comparable to that observed in younger pts (HR 0.74; 95% CI 0.65-0.85; $p < 0.01$; $I^2 = 63\%$). Specifically, in elderly patients with breast cancer treated with ADC (n=7,213), significant improvements were seen with an HR of 0.49 (95% CI 0.36-0.67; $p < 0.01$) and 0.65 (95% CI 0.48-0.87; $p < 0.01$; I^2= 39%) for PFS and OS, respectively. Similar improvements in survival outcomes were seen in younger pts (HR of 0.53; 95% CI 0.42-0.67 and HR of 0.66; 95% CI 0.57-0.77, for PFS and OS, respectively. Pre-specified subgroup analyses according to ADC payloads showed no differences in pts treated with ADC plus TOPO1i (HR 0.76 and 0.70, $p < 0.01$). Notably, ADCs with MMAE payloads were associated with benefit only in the elderly (HR 0.77, $p < 0.01$), with no significant benefit in younger patients (HR 0.82, p =0.11). **Conclusions:** In this pooled analysis, including 5,111 pts treated with ADC under phase III RCTs, survival outcomes with ADC therapies were similar regardless of age. As the number of ADCs approved for the standard of care setting is expected to increase, age should not be an exclusion criteria. Research Sponsor: None.

Integrating objective sarcopenia assessment into geriatric screening as a predictor of treatment tolerance. First Author: Hojung An, St. Vincent's Hospital, The Catholic University of Korea, Suwon, South Korea

Background: Geriatric assessment (GA)–based screening tools, including the G8 screening tool, the Korean Cancer Study Group Geriatric Score (KG-7), and the Cancer and Aging Research Group (CARG) toxicity score, are widely used to guide treatment decisions in older patients with cancer. However, these tools incompletely capture biological reserve and show limited accuracy in predicting treatment tolerance, particularly in patients with indeterminate risk. We evaluated whether incorporating objective sarcopenia assessment could improve risk stratification. **Methods:** We retrospectively analyzed 97 elderly patients with cancer (age ≥70 years) who underwent GA screening prior to treatment decision-making at a single tertiary center between May 2024 and December 2025. In addition to standard GA tools (G8, KG-7, and CARG toxicity score), skeletal muscle index (SMI) and functional frailty were assessed. SMI was measured using the DYPHI body water analysis (BWA) system, which estimates appendicular lean mass through multi-frequency bioelectrical impedance analysis. Functional frailty was evaluated using the Short Physical Performance Battery (SPPB). Treatment intolerance was defined as grade 3–5 toxicity, unplanned hospitalization, emergency room visit, or treatment discontinuation. Multivariable logistic regression and subgroup analyses were performed. **Results:** The median age was 76 years (range, 61–87), and 77 patients (79.4%) were male. Most patients had advanced-stage disease (72.2%), and 55.7% received palliative treatment. Initial dose reduction (<100%) occurred in 63.9%. GA tools, sarcopenia, and frailty showed modest concordance. Among GA tools, G8 demonstrated the strongest association with treatment intolerance (odds ratio [OR] per point increase 0.86, 95% confidence interval [CI] 0.74–0.99; p=0.03; area under the curve [AUC] 0.64). Sarcopenia was independently associated with treatment intolerance (OR 2.45, 95% CI 1.02–5.87; p=0.045) and improved discrimination across G8, KG-7, and CARG tools (ΔAUC up to +0.12). The benefit of sarcopenia was greatest in borderline or intermediate GA risk groups (ΔAUC approximately +0.10–0.12), with minimal improvement in low- or high-risk groups (ΔAUC ≤0.02). A minimal model incorporating G8, sarcopenia, and Eastern Cooperative Oncology Group (ECOG) performance status achieved the best performance (cross-validated AUC 0.68). **Conclusions:** Incorporation of objective sarcopenia assessment using the DYPHI BWA system significantly improves prediction of treatment tolerance beyond established GA tools, particularly in intermediate-risk subgroups. A pragmatic model combining G8, sarcopenia, and ECOG performance status may refine risk stratification and personalize treatment decisions in geriatric oncology. Research Sponsor: None.

Online peer support for breast cancer survivors: A decentralized multicenter non-blinded parallel-group pilot randomized controlled trial (HOPE-BC study). First Author: Yoshie Hasegawa, Department of Breast Surgery, Hachinohe City Hospital, Hachinohe, Aomori, Japan

Background: Peer support effectiveness for breast cancer survivors has reportedly varied, and no study has examined patient–supporter matching. This decentralized, multicenter, non-blinded pilot randomized controlled trial aimed to assess online peer support effectiveness and explore factors for a matching algorithm. **Methods:** Breast cancer survivors within three years of completing initial treatment were recruited and provided electronic informed consent. Based on the sample size estimation, the target sample size was set at 50. Participants were randomly assigned either to the peer support group, which scheduled an online peer support session immediately after registration, or to the waitlist group, which scheduled their session two weeks later. Participants could choose their preferred time and date through a web-based scheduling system. Peer support sessions were conducted online by two trained peer supporters. The primary outcome was the UCLA Loneliness Scale score, assessed one week after the session in the peer support group and at the end of the 2-week waiting period in the waitlist group. Secondary outcomes included satisfaction with peer support and other psychosocial measures, all collected through an electronic patient-reported outcome system. Effect sizes for outcomes were calculated to inform sample size estimation for future trials. Analyses were performed to explore factors associated with satisfaction. The study protocol was registered in the UMIN Clinical Trials Registry (UMIN000056741). **Results:** From February to July 2025, 54 participants enrolled and 52 individuals completed the study (27 peer support group, 25 waitlist group). At the primary endpoint, the mean (standard deviation) UCLA Loneliness Scale scores were 38.4 (11.2) in the peer support group and 41.3 (13.3) in the waitlist group (Cohen's d = 0.24; t-test, P = 0.40). The change from baseline corresponded to a Cohen's d = 0.32. Among the secondary outcomes, the changes in Generalized Anxiety Disorder-7 scores differed between groups (mean difference [MD] = -1.3; 95% CI = -2.5 to -0.1), and the changes in Patient Health Questionnaire-9 scores tended to be greater in the peer support group (MD = -1.2; 95% CI = -2.5 to 0.1). The global health status on EORTC QLQ-C30 did not differ between groups (MD = 1.0; 95% CI = -6.6 to 8.7). The median (IQR) satisfaction score was 46 (41.5, 50) on a 50-point scale. A linear mixed-effects model indicated that sharing ≥1 topic and age proximity between the participant and peer supporter were significantly associated with higher satisfaction. **Conclusions:** Results demonstrate the feasibility of future decentralized randomized trials on online peer support and provide effect size estimates to guide sample size planning. Shared topics and age proximity between participants and peer supporters may be considered when scheduling sessions. Research Sponsor: None.

Evaluation of a remote electronic assessment of survivors with tailored follow-up recommendations and survivorship messaging (REASSURE) to improve the delivery of follow-up for low-risk breast cancer survivors. First Author: Heather B. Neuman, University of Wisconsin School of Medicine and Public Health, Madison, WI

Background: Current follow-up care for the 2 million+ low-risk breast cancer survivors fails to adequately address survivors' needs and burdens survivors and oncology teams. We evaluated a novel approach to follow-up that comprehensively assesses survivors' symptoms and concerns and uses that information to tailor follow-up frequency. **Methods:** We conducted a randomized trial at an academic and community breast clinic. Eligible survivors had a history of stage I breast cancer that was ER or PR +/Her2-, were 6-36 months from diagnosis, and did not receive chemotherapy. Survivors were randomized 1:1 to REASSURE versus usual care and followed for 18-months. REASSURE was developed through stakeholder engagement and comprises three components integrated around follow-up visits: 1) Online patient-reported symptoms and concerns (PRO), 2) Tailored follow-up visit recommendations based on the PRO, and 3) Survivorship messaging. The primary outcome was survivors' preparedness for survivorship and confidence about follow-up, measured at 18-months by the Preparing for Life as a (New) Survivor (PLANS) scale. Secondary outcomes included number of oncology follow-up visits, proportion of reported symptoms that were discussed, and acceptability of REASSURE. Continuous variables were analyzed using t-tests or Wilcoxon tests. The proportion of symptoms discussed was analyzed using a generalized linear mixed model for binomial data. **Results:** Of the 104 consented patients, 3 did not complete any study activities and 1 withdrew (n=100). The median age was 63 (range 36-86), most were White (98%), and 19% resided in a rural locale. Preparedness for survivorship and confidence did not differ between REASSURE and usual care (Table). Symptoms or concerns were reported on 50.4% of PRO assessments. In the REASSURE arm, 80% of survivors accepted the recommendation to forgo a visit. Fewer follow-up visits were observed with REASSURE (M=2.1, SD 1.0) than usual care (M=2.6, SD 1.0), p=0.007. There was no difference in likelihood of discussing symptoms. REASSURE was acceptable to survivors, with 78% saying they would recommend REASSURE to others. **Conclusions:** In this implementation of a novel tailored approach to follow-up for low-risk breast cancer survivors, we did not find improvement in preparedness for survivorship. However, we demonstrated a decrease in number of follow-up visits with strong survivor support for this approach. Further research will focus on implementing REASSURE in more diverse clinical settings. Clinical trial information: NCT05609435. Research Sponsor: Wisconsin Partnership Program.

	REASSURE M (SD) or %	Usual Care M (SD) or %	P value
PRIMARY OUTCOMES			
Preparedness	29.3 (1.7)	28.9 (2.1)	0.36
Confidence	24.0 (14.4)	18.7 (13.6)	0.08
SECONDARY OUTCOMES			
# of follow-up visits	2.1 (1.0)	2.6 (1.0)	0.007
% of symptoms discussed	89.3%	83.0%	0.29
% of survivors who would recommend REASSURE	78%	NA

The Engage program for childhood cancer survivors: Results from a multidisciplinary, distance-delivered intervention. First Author: Christina Signorelli, University of New South Wales and Kids Cancer Centre, Sydney Children's Hospital, Sydney, NSW, Australia

Background: As the growing number of childhood cancer survivors exceeds follow-up care capacity, scalable models to improve access and support self-management are needed. We evaluated the effectiveness of the 'Engage' survivorship program (primary outcomes: self-efficacy and health-related quality of life; HRQoL). **Methods:** Engage is a multidisciplinary program comprising a treatment summary; online health/lifestyle assessment; telehealth nurse consultations; multidisciplinary review; tailored survivorship recommendations for survivors and their nominated primary-care physician. Survivors treated at two Australian hospitals were eligible if diagnosed <18years, >5 years post-diagnosis, and completed treatment. Mixed-effects models examined change over time (baseline, 1-, 6-, 12-month) and differences by diagnosis (brain cancer vs other), adjusting for sex and age at diagnosis. **Results:** Of 138 consenting survivors 92% completed the health assessment and 89.1% completed the whole program (n=123). Median age was 24 years; median time since diagnosis was 15 years; 28% lived in rural/remote/regional areas; and 53% were brain cancer survivors. Program acceptability was high, with >80% of survivorsreporting Engage was helpful, improved knowledge and confidence, and was easy to access. Health-related self-efficacy improved over 12 months ($\chi^2(3)=146.52$, $p<.001$), with no evidence of differences in change between diagnostic groups (time × group; $p=.97$). HRQoL (EQ-5D index) improved modestly by 12 months (0.77 to 0.82; $p=.011$); brain cancer survivors reported lower baseline scores, with similar patterns of change over time. Satisfaction with care improved over time ($\chi^2=35.59$, $p<.001$), with higher satisfaction among non-brain cancer survivors ($\chi^2=4.03$, $p=.045$) but not over time (time×group $p=.75$). Among health behaviours, alcohol consumption decreased over time ($\chi^2=16.20$, p=001) and was higher overall among non-brain survivors ($\chi^2=5.97$, p=.015), with no time×group interaction ($p=.94$). Adherence to personalised healthcare recommendations >50%, with greater adherence if discussed briefly during a follow-up nurse consult. **Conclusions:** Engage was associated with sustained improvements in survivors' self-efficacy and satisfaction with care and modest improvements in HRQoL at 12-months follow-up. Similar trajectories across diagnosis groups suggest telehealth survivorship models can also support survivors with higher risk profiles (e.g., brain cancer survivors). Clinical trial information: ACTRN12621000590864. Research Sponsor: None.

Survivorship-focused content at the American Society of Clinical Oncology (ASCO) 2022-2024 annual meetings. First Author: Lauren Rynar, Rush University Medical Center, Chicago, IL

Background: Survivorship is a core component of comprehensive cancer care yet its representation in major oncology scientific meetings remains unclear. This study systematically evaluated survivorship-focused content presented over three years at the ASCO Annual Meetings for prevalence, characteristics, and thematic patterns. **Methods:** All abstracts presented at the ASCO Annual Meeting from 2022-2024 were obtained (N=8,928). Abstracts containing the root word "survivor" (e.g., survivor, survivors, survivorship) in the title, text, or submission category "Symptoms and Survivorship" were identified using an automated data-extraction tool. Each extracted abstract underwent structured review to determine relevance to survivorship and then mapped to domains of the Quality of Cancer Survivorship Framework. Two independent reviewers evaluated each abstract, with discrepancies resolved by consensus. Descriptive statistics were used to summarize abstract content. **Results:** A total of 568 abstracts from 2022-2024 contained the root word "survivor" in the title, text or the submission category, representing 6.4% of all presented abstracts. Prevalence of survivorship-focused abstracts increased modestly from 2.2% in 2022 to 4.1% in 2024. Reviewers identified 63.8% of the extracted abstracts as relevant to the survivorship care framework and abstracts most frequently addressed the survivorship domains of physical effects (28.3%) and contextual factors (14.6%). Additional analyses examined cancer type and stage studied (36.6% mixed, 19.5% breast; 55.2% cancer stage not specified), survivorship stage (45% not specified, 19.3% in curative treatment), study design (65.9% observational), and healthcare setting (58.2%). **Conclusions:** Despite a rapidly growing population of cancer survivors, survivorship-focused content at the ASCO Annual Meeting remained largely static between 2022 and 2024, highlighting a gap between emerging survivorship needs and representation within oncology research programming. Further, abstracts frequently failed to specify the study population or context, or reference specific implications to survivorship domains. This study establishes a reproducible benchmark for monitoring survivorship content and provides a scalable methodology for ongoing surveillance of future meeting abstracts. The abstraction method may have excluded relevant survivorship-focused content. These findings could guide ASCO educational planning committees as they refine strategies to strengthen and advance survivorship-focused content in future meetings, ensuring alignment with the evolving needs of the survivor community. Research Sponsor: Rush University Medical Center.

Impact of medically tailored meals plus nutrition counseling on treatment adherence in vulnerable lung cancer patients: Results from NutriCare randomized controlled trial. First Author: Zhongyao Li, Tufts University, Newton, MA

Background: This study aims to evaluate the impact of a Food is Medicine intervention on reducing treatment interruptions among vulnerable patients with lung cancer in a multi-site randomized controlled trial (RCT). **Methods:** Newly diagnosed stage I-IV lung cancer patients (n=249) enrolled from four cancer centers (MD Anderson Cancer Center, The Ohio State University Comprehensive Cancer Center, Fox Chase Cancer Center, and Tufts Medical Center) were randomized to the NutriCare (intervention; n=134) or NutriTool (control; n=115) arm in a 1:1 ratio. Patients on NutriTool received a nutrition toolkit for cancer survivors and monthly nutrition information and recipes. Patients on NutriCare additionally received 6-8 months (mo) of tapered home-delivered medically tailored meals (initially 21 meals/week) plus remote nutrition counseling provided by registered dietitians. Treatment interruptions, including overall interruptions and those due to treatment toxicities, were assessed using the relative dose intensity (RDI) and number of treatment cycles with dose delay or reduction among patients receiving curative or first-line palliative treatment. The primary analysis was intention-to-treat, comparing treatment interruptions between arms using Poisson regression models. **Results:** The mean (SD) of RDI was 0.84 (0.26) and 0.81 (0.26) for patients on NutriCare and NutriTool, respectively (p=0.24), with approximately 31% of the NutriCare patients having RDI reduction of 15% or more compared to 38% of the NutriTool patients (p=0.36). After restricting the analyses to treatment interruptions due to toxicities, 14.4% of NutriCare versus 25.4% of NutriTool patients experienced RDI reduction of 15% or more (p=0.08). After multivariable adjustments, NutriCare patients had 16% lower risk of having RDI reduction of 15% or more (relative risk [RR]=0.84, 95% confidence interval [CI]: 0.47-1.47) and 41% lower risk of having toxicity-related RDI reduction of 15% or more (RR=0.59, 95% CI: 0.28-1.24) than NutriTool patients. For dose delays, NutriCare patients had 35% lower risk of having any dose delay (RR = 0.65, 95% CI: 0.28-1.49) and 44% lower risk of having toxicity-related dose delay (RR=0.56, 95% CI: 0.16-1.97) compared to NutriTool patients. For dose reduction, NutriCare patients had 19% lower risk of having any dose reduction (RR=0.81, 95% CI: 0.49-1.34) and 35% lower risk of having toxicity-related dose reduction (RR=0.65, 95% CI: 0.35-1.22) compared to NutriTool patients. None of the differences reached statistical significance. **Conclusions:** Findings suggest that a Food is Medicine intervention comprising medically tailored meals and nutrition counseling may reduce treatment interruptions among vulnerable patients with lung cancer undergoing treatment. Clinical trial information: NCT04986670. Research Sponsor: Bristol Myers Squibb Foundation.

Performance of ChatGPT in generating patient-facing cancer survivorship care plans. First Author: Kaili Du, Cayuga Medical Center at Ithaca, Ithaca, NY

Background: Survivorship care plans (SCPs) summarize cancer treatments and provide evidence-based recommendations for surveillance, screening, and management of treatment-related complications. Despite the availability of guidelines and templates, SCPs remain underutilized in routine practice due to the time-intensive and error-prone nature of manual creation. Empowering cancer survivors to use publicly available large language models (LLM)–based chatbots, such as ChatGPT, may offer a feasible solution to this problem. **Methods:** Standardized patient profiles were developed for six common cancers: breast, colorectal, non–small cell lung, small cell lung, prostate cancer, and diffuse large B-cell lymphoma. Profiles were reviewed by a primary care physician and an oncologist to ensure clinical accuracy and representativeness of common survivorship scenarios. Using lay language to simulate real-world patient input, ChatGPT (version 5.2, publicly available at the time of the study) was prompted with each profile using the question, "What follow-up care do I need?" Common survivorship symptoms for each cancer were also tested. Responses were evaluated across five domains: medical accuracy (concordance with current ASCO or NCCN guidelines), thoroughness, patient safety and risk framing, clarity and patient comprehension, and actionability. Five-point Likert scales were used (1 = not at all; 5 = very much). Scores were averaged across two independent physician raters. Readability was assessed using the Flesch Reading Ease Score. **Results:** ChatGPT-generated SCPs demonstrated high medical accuracy (mean score 4.25/5), with no factual errors or hallucinations identified on manual review. Patient safety and risk framing scored 3.75/5; symptom red flags and care escalation guidance were appropriately stated in most scenarios. Thoroughness was moderate (3.50/5), with key survivorship elements, such as smoking cessation counseling or genetic risk considerations; sometimes omitted unless explicitly prompted. Readability was limited, with a mean Flesch Reading Ease Score of 40.5, corresponding to a college reading level and exceeding recommended readability standards for patient education materials. Clarity (3.38/5) and actionability (3.38/5) were similarly constrained due to dense medical language. **Conclusions:** ChatGPT demonstrated high medical accuracy in generating survivorship care plans across six common cancers, supporting the feasibility of using publicly available LLMs to guide survivorship care. However, improvements in comprehensiveness, readability, and patient-centered actionability are necessary before such tools can be safely integrated into clinical survivorship workflows. Research Sponsor: None.

Temporal trends and sociodemographic differences in influenza vaccination among U.S. cancer survivors, 2005-2024. First Author: Kerry Conlin, Yale School of Public Health, New Haven, CT

Background: Given the increased risk of complications and adverse outcomes associated with influenza infection among individuals with cancer, even in the post-treatment setting, clinical oncology guidelines support annual vaccination in cancer survivors. Few studies have investigated long-term trends and potential disparities in the prevalence of influenza vaccination among individuals with a history of cancer. Therefore, we examined temporal trends in and factors associated with influenza vaccination in a nationally representative sample of cancer survivors in the United States. **Methods:** Using data from 20 survey years (2005-2024) of the National Health Interview Survey, we included adults aged ≥18 years with a self-reported history of cancer and complete data on influenza vaccination. The primary outcome was self-reported influenza vaccination in the past 12 months. Crude annual prevalence estimates were calculated overall and by select sociodemographic characteristics using survey-weighted logistic regression models. Temporal trends were quantified using annual percent change (APC) estimates. **Results:** Among 43,932 adults with a history of cancer (median age: 65.7 years), representing approximately 15.0 million U.S. cancer survivors annually, crude influenza vaccination prevalence increased from 45.5% (95% CI: 43.0-48.1) in 2005 to 63.3% (95% CI: 61.2-65.4) in 2024, corresponding to an absolute change of 17.8 percentage points (pp; 95% CI: 14.5-21.1) and an APC of +0.79 pp/year (95% CI: 0.52-1.06). Younger survivors aged 18-44 years experienced a particularly large absolute change over the 20-year study period (+32.4 pp; APC: +1.32 pp/year), yet fewer than half were vaccinated in 2024 (46.4%), compared to 77.4% of those aged ≥75 years. Cancer survivors without insurance (change: +24.7 pp; APC: +0.83 pp/year) had a 2024 vaccination prevalence of 32.0%, compared to insured survivors (63.8%). Survivors without a usual source of care (change: +31.0 pp; APC: +1.63 pp/year) had a 2024 vaccination prevalence of 39.9%, compared to those with a usual source of care (63.8%). Hispanic survivors (change: +25.3 pp; APC: +1.30 pp/year) had a 2024 vaccination prevalence of 51.9%, compared to non-Hispanic White survivors (64.9%). **Conclusions:** Influenza vaccination prevalence among U.S. cancer survivors increased substantially over the past two decades; however, more than one-third were unvaccinated in 2024. Despite overall gains, vaccination coverage remained particularly low among younger survivors, uninsured individuals, and those without a usual source of care, with persistent differences across racial and ethnic groups. Targeted clinical and public health strategies are needed to address these gaps and improve guideline-endorsed uptake of seasonal influenza vaccination among cancer survivors. Research Sponsor: None.

Rethinking MRI surveillance after breast cancer in the context of persistent racial disparities in mortality. First Author: Elizabeth Susan McDonald, University of Pennsylvania, Philadelphia, PA

Background: Detection of asymptomatic breast cancer recurrence by imaging is associated with improved survival compared to detection after symptoms develop. Currently, both the American Cancer Society and ASCO recommend against routine MRI for patients with a history of breast cancer and no clinical findings, unless they meet specific high-risk criteria. The American College of Radiology Appropriateness Criteria similarly characterizes surveillance MRI as conditionally appropriate, supporting its use only when additional risk factors are present. Since randomized trials to address surveillance strategies in diverse populations are unlikely to be feasible, we performed an observational study comparing MRI performance in intermediate and high-risk screening populations, and women with a history of breast cancer, stratified by race. **Methods:** We retrospectively analyzed 41,041 breast MRI exams performed in an urban health system from 1/2/2014 to 10/29/2025. In Pennsylvania, insurance covers supplemental MRI for women with dense breasts, and in our network, screening MRI is generally performed in asymptomatic patients current with mammography. Exams were categorized as high-risk screening (n=15,682, 38%), supplemental (n=10,905, 27%), or surveillance for a personal history of breast cancer (n=11,476, 28%). Logistic regression was used to estimate odds ratio for true and false positives by indication adjusted for age and race. **Results:** Cancer detection rates were higher in the surveillance group compared with high risk screening (true positive [TP] rate 21.0, n=241 vs 12.4, n=194), a 53% difference after adjusting for age and race (OR 1.53 [1.26–1.86], $p<0.001$), with similar false-positive rates (7.5%, n=857 vs 8.7%, n=1,359; OR 1.02 [0.93–1.11], p=0.7). MRI cancer detection rate was higher for supplemental than high-risk screening (OR 1.35 [1.24–1.46], $p<0.001$). Notably, in a subset comparison of screening MRI in Black vs. white women (n=37,383), TP rates were higher among Black women than white women across all MRI indications. The highest TP rate was observed in Black women undergoing surveillance MRI (31.9 vs. 20.5; OR 1.62 [1.11, 2.31], p=0.010), followed by supplemental (25.6 vs. 14,5; OR 1.84 [1.17, 2.77], p=0.005), and high-risk (21.6 vs. 11.4; OR 1.97 [1.22, 3.03], p=0.003). The TP rate remained higher for Black compared with white women for first MRI as well as subsequent MRI for surveillance, high-risk, and supplemental screening. **Conclusions:** Black women in the U.S. have 40% higher breast cancer mortality compared to non-Hispanic white women, and early detection offers the best chance for optimal survival. Our findings suggest surveillance MRI identifies a higher burden of clinically occult cancer than high-risk screening MRI, especially among Black women. Expanding access to surveillance MRI may help address persistent racial disparities in breast cancer outcomes. CTNow pilot study: A multilevel clinical trial education and clinical trial referral coordination intervention for rural oncology providers and patients with cancer. First Author: Izumi Okado, University of Hawai'i Cancer Center, Honolulu, HI

Background: Enhancing patient access to cancer clinical trials is an ASCO and NCI priority. Major barriers to clinical trial access in rural areas include limited awareness and knowledge of available cancer clinical trials among both rural oncology providers and patients with cancer. Our preliminary research found that only 9% of rural cancer patients have knowledge of clinical trials, and many providers lack the time or resources to discuss them in clinical settings. Hawai'i's geographic isolation presents persistent barriers to clinical trial access, particularly for residents of the five rural neighbor islands of Hawai'i. Expanding clinical trial access requires not only increasing infrastructure and trial availability; enhancing provider and patient awareness and knowledge is a critical step toward improving access to trials in rural communities. A coordinated, culturally informed, and statewide approach is urgently needed to build trust, increase literacy on clinical research participation, and ensure that clinical trials become an equitable part of standard cancer care for all communities in Hawai'i. This pilot trial evaluates the preliminary efficacy of *CTNow*, a novel multilevel, multicomponent clinical trial education and clinical trial referral coordination intervention designed for rural oncology providers and patients with cancer. **Methods:** This multi-site pilot trial is currently open in three rural counties in Hawai'i. The multilevel *CTNow* intervention includes: 1) two interactive webinar sessions for rural oncology providers; 2) a tablet-based multimedia education program for patients; and 3) referral resources for providers and an optional video chat feature for patients to connect with clinical trials staff for questions and/or referrals to trials. The study team developed intervention components that provide rural-specific provider clinical trial information, along with evidence-based patient education materials adapted for varying levels of health literacy. Key patient inclusion criteria include patient self-report of cancer diagnosis, current/past/planned treatment, and residency in rural areas. Provider participants include rural-based oncologists and advanced practice providers not currently involved in clinical trials. Planned enrollment includes 30 patients with any cancer type and 5 oncology providers practicing in rural Hawaii. The primary endpoint is within-patient and within-provider changes in knowledge of cancer clinical trials from baseline. Secondary endpoints include changes in attitudes toward clinical trials and self-efficacy related to trial participation, and utilization of video chat sessions. Enrollment began in March 2025. To date, 80% of patients and 100% of planned providers have been enrolled. Clinical trial information: NCT06237816. Research Sponsor: Agency for Healthcare Research and Quality.

TPS1677 **Poster Session**

Genetic testing uptake through an enhanced oncology nurse–led intervention in patients with solid tumors (GENESIS): A pilot study. First Author: Ranjan Pathak, Enloe Health, Chico, CA

Background: Identification of pathogenic germline variants (PGV) in patients with solid tumors is critical for directing targeted therapies, surveillance, and cascade testing for family members. Despite established National Comprehensive Cancer Network (NCCN) guidelines, uptake of genetic counseling and testing (GCT) remains suboptimal, with recent data suggesting <7% utilization in some cancer populations. Barriers are pronounced in community oncology settings due to limited access to genetic counselors and reliance on physician-initiated referrals. Oncology nurses routinely provide education during systemic therapy initiation, presenting a unique, underutilized touchpoint to bridge this gap. The GENESIS study (NCT06436157) evaluates the feasibility and impact of a novel, nurse-led "enhanced education" intervention on GCT uptake. **Methods:** This is a single-center, prospective, randomized (1:1) pilot trial conducted at a community cancer center. Eligible participants are adults (≥18 years) with solid tumors (breast, ovarian, prostate, pancreatic, colorectal, and others per NCCN guidelines) who are starting or switching systemic therapy, meet NCCN criteria for GCT, and have no prior germline testing. The study plans to accrue 60 patients. Participants are randomized to the Usual Care arm (standard therapy education; clinician-initiated referral) or the Enhanced Education Intervention arm. In the intervention arm, trained oncology nurses integrate a specific GCT educational module into the standard chemotherapy teaching session. For eligible/agreeable patients, the nurse directly places the GCT referral order and executes a follow-up "nudge" to referral coordinators within one week. The primary endpoint is the percentage of patients proceeding to GCT consultation. Secondary endpoints include GCT referral rates, time from order to consultation, time to testing completion, and implementation feasibility assessed via the Acceptability of Intervention Measure (AIM) and retention rates. Clinical trial information: NCT06436157. Research Sponsor: Robert A. Winn Excellence in Clinical Trials Awards Program (Winn Awards).

TPS1678 **Poster Session**

Patient preference for subcutaneous vs. intravenous immune therapy (PSI-Immune). First Author: Vincent Edgar Reyes, UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA

Background: Immune checkpoint blockade (ICB) has improved outcomes for patients (pts) with advanced solid tumors. Conventional intravenous (IV) route of administration (RoA) requires repeated, time-intensive infusions involving cannulation, monitoring, pharmacy preparation, and chair time, increasing treatment burden and constraining infusion center capacity, staffing, and scalability as ICB use expands. Subcutaneous (SC) formulations of pembrolizumab and nivolumab—two widely used PD-1 inhibitors—have recently been approved across multiple indications. PD-1 ICB SC formulations contain the same active drug as IV formulations and have demonstrated comparable PK exposure, efficacy and safety profiles (CheckMate 8KX; 3475A-D77). Beyond pt convenience, SC RoA may enable more scalable delivery by reducing infusion chair utilization, nursing time, and workflow bottlenecks, supporting access across high-volume cancer networks. Real-world pt preference and perceived health-system impact of SC versus IV PD-1 ICB remain incompletely characterized. We therefore designed a distributed, real-world clinical trial to evaluate patient preference and health-system implications of PD-1 ICB RoA across a large integrated cancer network (>70 sites across 4 states). **Methods:** PSI-Immune is a randomized, phase II, open-label, crossover study evaluating pt preference for SC versus IV RoA of PD-1 ICB in pts with locally advanced (LA) or advanced/metastatic (A/M) solid tumors pending initiation PD-1–based therapy, either as monotherapy or in combination. The primary endpoint is pt preference for ICB RoA, assessed using a validated pt preference questionnaire (PPQ). Key secondary endpoints include pt-reported treatment satisfaction (TASQ), HCP-reported time and resource utilization, pt-reported health-related quality of life (HRQoL), and time to next therapy (TTNT). A subcohort permits enrollment of pts who are already on IV PD-1 ICB. Eligible pts must have an FDA-approved indication for SC pembrolizumab or nivolumab singly or in combination with other FDA-approved agents and a planned duration of PD-1–based therapy exceeding six months. Patients are randomized 1:1 to receive either SC therapy for three cycles followed by IV therapy for three cycles, or the reverse sequence (crossover phase). Subsequently, pts select their preferred route of administration (continuation phase). Treatment regimen is identical across cohorts and differs only by ICB RoA. Randomization is stratified by disease setting (LA vs A/M) and ICB regimen (monotherapy vs combination). The planned sample size is 280 patients. Assuming equal allocation and up to 10% attrition, the exact 95% confidence interval for the proportion of patients preferring SC administration will exclude 50% if the observed preference rate is at least 60%. This study is open and enrolling across the entire UPMC Hillman Cancer Center Network (NCT07223424). Clinical trial information: NCT07223424. Research Sponsor: None.

TPS1679 **Poster Session**

Cancer CARE (Connected Access and Remote Expertise) beyond walls: Pilot, phase 2 clinical trial to evaluate administration of cancer-directed therapy in the patient's homes versus in clinic in the Florida Panhandle and surrounding areas. First Author: Dina Elantably, Mayo Clinic Florida, Jacksonville, FL

Background: Cancer care in the United States remains highly centralized, imposing substantial time, caregiver, and financial burdens on patients, particularly those residing in rural and medically underserved regions. While international experience supports the feasibility of home-based cancer therapy delivery, prospective U.S. clinical trial data are limited. The Cancer CARE Beyond Walls (CCBW) program was developed to address these gaps through a decentralized cancer care model integrating virtual oversight, remote monitoring, mobile clinical services, and community-based nursing partners. The study evaluates the feasibility, safety, and patient-centered impact of delivering cancer-directed therapy in patients' homes or near-home mobile units in the Florida Panhandle, a region characterized by long travel distances to tertiary centers and limited oncology infrastructure. **Methods:** This is a phase 2, single-arm clinical trial evaluating the delivery of standard-of-care cancer-directed therapy outside of traditional infusion centers. Eligible adult patients (ECOG 0–3) with histologically confirmed malignancies receiving guideline-supported or FDA-approved systemic cancer therapy must demonstrate tolerability of at least one prior in-clinic treatment cycle. Following registration, patients transition to home-based or near-home mobile unit administration for a minimum of 12 weeks, with an option to continue up to 24 weeks. Care delivery is coordinated through a virtual command center providing real-time virtual oversight, remote monitoring, and escalation pathways. Treatment administration is performed by trained local home health nurses, medication shipping, and digital interaction with the electronic health record. A fully equipped mobile unit extends access to rural areas not covered by home health agencies. The primary endpoint is patient preference for treatment location at week 12. Secondary endpoints include safety, avoidable acute care utilization, patient-reported function and global health/quality of life, patient-reported symptoms, and satisfaction with care. Exploratory endpoints assess travel burden, patient perceptions of caregiver experience, and patient perceptions of home versus mobile unit care. Enrollment of 27 patients will provide 80% power to reject a 50% null rate (2-sided exact test, α=0.10), assuming 75% prefer decentralized care or express no preference. This investigator-initiated trial is open to accrual and is supported by a grant from the Florida Cancer Innovation Fund. Clinical trial information: NCT07285044. Research Sponsor: Mayo Clinic.

TPS1680 **Poster Session**

Making telehealth delivery of cancer care at home effective and safe: A pragmatic cluster randomized trial. First Author: Erin Mary Bange, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Telehealth (TH) use for cancer care has rapidly expanded, both during and following the COVID-19 pandemic. However, evidence regarding safety, feasibility, effectiveness, equity, stakeholder satisfaction, and implementation of telehealth-enabled oncology care remains limited. We seek to assess the impact of TH on these outcomes in breast and prostate cancer patients. **Methods:** The MATCH-UP pragmatic cluster randomized trial is being conducted at Memorial Sloan Kettering Cancer Center to compare alternate models of TH use in oncology practice. Sixty-two physician practice clusters in breast and prostate medical oncology are randomized 1:1 to enhanced telehealth (ET) or usual practice (UP), stratified by disease type and clinic volume. ET emphasizes TH with expanded home services designed to deliver as many components of care as desired in patients' homes. Usual care involves routine practice with TH visits at the discretion of the patient and MD or APP. Eligible patients have >=3 prior medical oncology visits and are not enrolled on a therapeutic trial. Automated enrollment is triggered by a routine oncology visit with waiver of informed consent. The ET intervention includes EHR-enabled telehealth scheduling defaults for routine follow-up visits, optional home phlebotomy, structured support for home administration of select injectable medications, and digital support for patients with TH access barriers. The primary endpoint is the proportion of routine medical oncology visits conducted in person among all routine medical oncology visits over 1 year. Secondary outcomes include healthcare utilization, no-show and late cancellation rates, and overall survival. Patient-reported outcomes include: quality of life, healthcare costs, experience of care, and preferences for use of TH at future visits. Clinician-reported outcomes include: experience of care and preferences for TH use at future visits. For patients in the ET arm only, telehealth accessibility, intervention uptake and efficiency, and implementation outcomes, including acceptability, appropriateness, and feasibility, are also being collected. The primary endpoint will be analyzed using generalized linear mixed models with a logistic link, accounting for repeated visits within patients and clustering within randomized practice units and adjusting for stratification factors. Enrollment will continue through March 2026 with follow-up for 12 months. To date, 7256 patients have been enrolled, with 3641 patients assigned to ET, (n=2437 [67%] breast cancer; n=1204 [33%] prostate cancer and 3,615 assigned to UP (n=2252 [62%] breast cancer; n=1363 [38%] prostate cancer). MATCH-UP will generate pragmatic evidence on the effectiveness, patient-centeredness, implementation, and equity-relevant barriers of a scalable, EHR-embedded enhanced telehealth model for breast and prostate oncology care. Clinical trial information: NCT06954337. Research Sponsor: NIH/; NCI/NIH P50 CA271357; National Cancer Institute/U.S. National Institutes of Health; NCI/NIH P30 CA008748.

TPS1681 **Poster Session**

Implementation of a cancer-oriented geriatric assessment (COGA) clinic to promote age-friendly cancer care: A type III hybrid implementation–effectiveness method in community practice. First Author: Ganesh Prasad Merugu, The University of Toledo, Toledo, OH

Background: Cancer incidence increases with age, and adults aged ≥65 years account for the majority of new cancer diagnoses. Standard oncology assessments often fail to identify age-related vulnerabilities such as frailty, cognitive impairment, and functional decline (Hurria et al., JCO 2011). The American Society of Clinical Oncology (ASCO) recommends routine geriatric assessment–guided management for older adults receiving systemic cancer therapy to inform treatment decisions and reduce treatment-related toxicity (Mohile et al., JCO 2018). In alignment with these goals, we established a Cancer-Oriented Geriatric Assessment (COGA) clinic within an academic cancer center. **Methods:** We implemented a Type III hybrid implementation–effectiveness design to integrate Cancer-Oriented Geriatric Assessment (COGA) into routine oncology practice using the 5M framework (Mind, Mobility, Medications, Matters Most, and Multicomplexity). The Eleanor N. Dana Cancer Center is part of a large academic health system in Northwest Ohio, serving a predominantly rural and suburban population across Ohio and Southeast Michigan. Eligibility included oncology patients aged ≥65 years with a positive G8 screen (≤14), consistent with ASCO and European Society for Medical Oncology (ESMO) recommendations for comprehensive geriatric assessment. A tiered workflow was implemented on January 15, 2026, in which medical assistants obtained vital signs, performed medication reconciliation, and completed standardized screenings for cognition, mood, and nutrition, followed by a geriatrician-led assessment of frailty, fall risk, mobility, and functional status. The medication domain emphasized deprescribing of potentially inappropriate medications, while the Matters Most domain addressed goals of care, advance directives, and social support. Additional geriatric syndromes—including sensory impairment, sleep disturbances, incontinence, and fatigue—were systematically assessed and managed. Risk stratification was guided by validated tools, including the Cancer and Aging Research Group (CARG) toxicity tool and the Schonberg Index, to estimate non-cancer mortality. Primary implementation outcomes included reach (the proportion of eligible patients receiving COGA), adoption (use of COGA by oncology teams), and fidelity (completion of the core 5M domains as intended). Secondary effectiveness outcomes included patient-centered outcomes and unplanned hospitalizations. This scalable, real-world implementation model enables systematic integration of geriatric assessment into oncology practice, with the potential to improve outcomes for older adults with cancer and support broad dissemination across diverse cancer care settings. Research Sponsor: None.

TPS1682 **Poster Session**

An EHR-embedded SmartForm (OncAssessment) paired with ePROs to enable real-time structured documentation of key oncologic data during routine cancer care: A pragmatic implementation study. First Author: Aditi Puri Singh, Penn Medicine Abramson Cancer Center, Philadelphia, PA

Background: Real-world evidence generation in oncology is often limited by inconsistent and unstructured documentation within electronic health records (EHRs). Key clinical variables including disease status, performance status, and treatment change rationale are frequently embedded in free text, requiring retrospective manual abstraction that is inefficient and error-prone. As a result, clinically meaningful real-world endpoints, such as time to treatment change and real-world progression-free survival (rwPFS), are inconsistently captured. To address these gaps, the University of Pennsylvania developed OncAssessment (OA), an EHR-embedded SmartForm integrated directly into routine oncology clinical documentation. Unlike post hoc abstraction or standalone registries, OA enables prospective, structured data capture of key oncologic variables at the point of care by treating clinicians, and is paired alongside with electronic patient-reported outcomes (ePROs). This approach aligns clinician decision-making with patient-reported experience within routine workflows, enabling timely, scalable, and higher-fidelity real-world data (RWD) capture. **Methods:** This pragmatic implementation study, developed by the University of Pennsylvania in collaboration with Gilead Sciences, evaluates OA and ePRO implementation in standard clinical practice. Adult patients with stage IIIB-IV unresectable non-small cell lung cancer (NSCLC) initiating standard-of-care immunotherapy with or without chemotherapy (Cohort I) and adult breast cancer patients receiving systemic infusional therapy (Cohort II) are identified via the EHR. 200 patients per cohort are planned for enrollment over 2 years. Enrollment began July 22, 2025. For identified patients, clinicians are prompted to complete OA at each visit: documenting clinical status, tumor status, treatment changes, and rationale. ePROs are automatically distributed through the EHR to Cohort I patients prior to their visits. Structured data from OA, ePROs, and other EHR sources are auto-extracted. Primary objectives for Cohort I include OA utilization, time to treatment change decision (TTCd), comparison of TTCd with time to treatment change (TTC) derived from EHR reporting, ePRO completion rates, and concordance between patient- and clinician-assessed clinical status. Secondary objectives include rwPFS captured via OA, comparison with rwPFS determined by manual chart and radiology review, characterization of patient experience via ePROs, and exploratory analyses of discordance and factors associated with treatment change. The primary objective for Cohort II is OA utilization. Follow-up continues until progression, treatment change, or 2 years for Cohort I and 12 months for Cohort II. Research Sponsor: Gilead Sciences.

MATCHES-NOVEL: A randomized controlled trial in progress of hospital-at-home (HaH) versus inpatient hospitalization for post tarlatamab monitoring.

First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Tarlatamab is a bispecific T-cell engager (BiTE) therapy approved for the treatment of extensive-stage small cell lung cancer (ES-SCLC) and is the first BiTE therapy approved for a solid tumor. Due to the risk of cytokine release syndrome, patients are routinely hospitalized for ≥24 hours following each of the first two doses. These hospitalizations can pose substantial logistical, financial, and psychosocial challenges, particularly for patients in rural communities or with caregiver or employment constraints. HaH is an emerging care delivery model that provides hospital-level care in patients' homes and has been associated with reduced readmission rates, improved patient experience, and lower cost in other populations. Whether HaH can safely and efficiently replace inpatient hospitalization for post-tarlatamab monitoring is unknown. The MAking Telehealth Delivery of Cancer Care at Home Effective and Safe (MATCHES)-Novel trial evaluates a HaH model compared with standard inpatient hospitalization following tarlatamab administration. **Methods:** MATCHES-Novel is an active, single-center, prospective randomized controlled trial comparing HaH with standard inpatient hospitalization for post-administration monitoring of tarlatamab in patients with ES-SCLC. Eligible patients have an ECOG performance status of 0-2, are initiating tarlatamab for an FDA-approved indication, reside within a 60-minute response catchment area, and have an available in-home caregiver. Participants are randomized 1:1 to HaH or standard inpatient monitoring following drug administration, with monitoring duration and discharge criteria aligned with institutional standards. The HaH intervention includes scheduled in-home community paramedic assessments on the day of and the day after infusion, home phlebotomy, telehealth physician oversight, patient and caregiver education, and 24/7 care escalation pathways. The primary objective is to compare efficiency, measured by the number of inpatient hospital days during the two 7-day periods after each infusion. Assuming a mean number of 4 inpatient hospital days in the control arm, enrollment of 70 patients provides ≥80% power to detect a statistically significant difference if the mean inpatient days per patient in the HaH arm is ≤2.8. Secondary objectives include safety outcomes (transfers from home to inpatient care, clinician adjudicated toxicity events) and patient, caregiver and physician reported experiences and preferences, assessed through pre-specified surveys and interviews. These findings may inform future care-delivery models for administering innovative cancer therapies outside the inpatient setting, potentially improving access. The trial opened to accrual in April 2025, and 16 of the planned 70 patients have been enrolled. Clinical trial information: NCI-2025-03406. Research Sponsor: National Cancer Institute; P50 CA271357; National Institutes of Health and National Cancer Institute Cancer; P30 CA008748; Amgen.

Final results of a randomized, controlled, phase 3 trial comparing resection and post-operative stereotactic radiation versus resection and cesium-131 tile-based radiation for treatment of newly diagnosed brain metastases. First Author: Jeffrey S. Weinberg, The University of Texas MD Anderson Cancer Center, Houston, TX

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

2001 **Oral Abstract Session**

A multicenter randomized phase III study for newly diagnosed, maximally resected glioblastoma comparing carmustine wafer implantation followed by chemoradiotherapy with temozolomide versus chemoradiotherapy alone: Japan Clinical Oncology Group study JCOG1703 (MACS study). First Author: Ryuta Saito, Department of Neurosurgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: Three randomized phase III trials evaluated carmustine wafers (CWs) before temozolomide (TMZ) became standard therapy. To date, no randomized study has assessed CWs with standard TMZ chemoradiotherapy in newly diagnosed glioblastoma (GB). A post hoc analysis of Westphal's phase III trial, which evaluated CWs versus placebo, suggested a survival benefit with CWs in GB patients with ≥90% resection. We conducted a randomized phase III trial to determine whether adding CWs to standard chemoradiotherapy improves overall survival (OS) in newly diagnosed GB with ≥ 90% resection. **Methods:** This multicenter trial (38 institutions; JCOG1703) enrolled patients with newly diagnosed GB considered resectable at ≥90%. After intraoperative pathological confirmation of malignant glioma and ≥90% removal, patients were randomized (1:1) to CW implantation (Arm B) or no implantation (Arm A). Arm B received intraoperative placement of up to 8 CWs. All patients received 60 Gy radiotherapy with concomitant daily TMZ followed by 12 cycles of maintenance TMZ. The primary endpoint was OS; secondary endpoints included progression-free survival (PFS), loco-regional PFS (LPFS), and adverse events. DNA methylation array analysis and molecular testing included MGMT promoter methylation and copy number profiling. **Results:** Among 234 registered patients, 221 (Arm A, n=110; Arm B, n=111) were randomized between June 2019 and November 2022. Baseline characteristics were well balanced. Median OS for all randomized patients was 26.5 months (1-year 86.4%, 2-year 54.3%, 5-year 16.6%), with no significant difference between Arm A and B (21.7 vs 27.7 months; hazard ratios (HR) 0.907, 91.5% confidence interval (CI) 0.691–1.192; one-sided p=0.269 by the stratified log-rank test). Median PFS was 9.8 months (1-year 43.4%, 2-year 16.3%), also without significant difference (9.5 vs 10.4 months; HR 0.867, 95% CI 0.658–1.141). Median LPFS was 11.6 months (1-year 48.4%, 2-year 25.1%), with no difference between arms (10.6 vs 12.7 months; HR 0.886, 95% CI 0.669–1.173). MGMT promoter methylation was a significant favorable factor for OS, PFS, and LPFS. Early postoperative complications and adverse events were comparable between groups, and no treatment-related deaths occurred. **Conclusions:** CW implantation added to standard TMZ chemoradiotherapy did not significantly improve OS in newly diagnosed GB after ≥90% resection. Based on these findings, CW implantation does not provide significant therapeutic or survival benefit when standard TMZ chemoradiotherapy is feasible in this population. Clinical trial information: jRCT1031190035. Research Sponsor: Japan Agency for Medical Research and Development; 19ck0106515; 21ck0106515; 24ck0106763.

2002 **Oral Abstract Session**

Connectome-sparing stereotactic radiosurgery: Results from the phase II COG-SRS trial. First Author: Andrew Connor Puett, University of California San Diego, La Jolla, CA

Background: Cognitive decline remains common after radiosurgery. The cognition-sparing stereotactic radiosurgery trial (COG-SRS, NCT04343157) evaluated a novel connectome-sparing SRS strategy leveraging advanced imaging to autosegment the cognitive connectome for individualized functional sparing. **Methods:** COG-SRS is a prospective, single-institution, phase II trial that enrolled adults (KPS≥70) treated with SRS for benign or malignant intracranial lesions from 06/2018-10/2025. Connectome structures (10 discrete eloquent bilateral white matter tracts [WMTs], corpus callosum, and hippocampi [HC]) were autosegmented from pretreatment diffusion tensor imaging and structural MRI and assigned evidence-based dose constraints (single fraction Dmax WMT=12Gy, HC=8.4Gy, with 3-/5-fraction equivalent doses) during SRS planning. Neuropsychological testing assessed cognitive domains of memory, language, executive function, attention/processing speed, and fine motor control at baseline and 3 months post-SRS. Outcomes were summarized using normed T scores and analyzed with mixed effects models adjusting for baseline score and prespecified clinical covariates. In the brain metastases cohort, cognitive performance was also compared with historical controls treated with standard brain SRS on Alliance N0574/N107C using domain Z scores and baseline adjusted mixed effects models. Questionnaires assessed mood/QOL, and disease time to event endpoints were estimated by Kaplan Meier. **Results:** Ninety-two patients enrolled (mean age 57.8 years), including 82 (89%) with brain metastases. All plans met standard target coverage and organ-at-risk constraints while optimizing dose to the cognitive connectome, with 76% meeting predefined constraints for all 23 connectome structures. At 3 months, 74% of patients demonstrated stable-to-improved performance across all 5 cognitive domains, with no significant mean decline in any domain. Mean performance improved in executive function (+4.30 T; p=0.043) and language (+4.91 T; p=0.011). Compared with historical controls, COG-SRS demonstrated superior 3 month cognitive outcomes (global composite Z difference +0.38; p=0.001), with the most pronounced domain-level benefit in executive function (+0.71; p=0.009) and language (+0.35; p=0.010). Mood and QOL remained stable. Among patients with brain metastases (median followup 35.6 months), 1 year local control was 98.5%, freedom from distant intracranial failure 57.4%, and overall survival 66.7%. **Conclusions:** Connectome-sparing brain SRS is feasible, leveraging advanced MRI-based autosegmentation of patient-specific cognitive networks, and is associated with preserved early cognition at the cohort level with superior 3 month cognitive outcomes versus historical controls. Cognitive benefits were achieved without compromising oncologic control, supporting prospective randomized study. Clinical trial information: NCT04343157. Research Sponsor: National Institutes of Health (NIH), National Cancer Institute (NCI); R01 CA238783; National Institutes of Health (NIH), National Cancer Institute (NCI); 1R01CA289833-01.

2003 **Oral Abstract Session**

Neoadjuvant fractionated stereotactic radiotherapy followed by surgical resection for brain metastases: A multicenter, single arm phase II trial (NEO-TACTICS). First Author: Koichi Mitsuya, Division of Neurosurgery, Shizuoka Cancer Center, Nagaizumi, Japan

Background: Surgical resection followed by adjuvant radiotherapy for brain metastases (BM) is associated with unresolved challenges, including local recurrence (LR), leptomeningeal dissemination (LMD), radiation necrosis (RN), and cognitive decline. Preoperative stereotactic radiosurgery followed by surgical resection has been proposed as a novel strategy to address these limitations. This phase II trial evaluated the efficacy and safety of neoadjuvant fractionated stereotactic radiotherapy (FSRT) followed by surgical resection for BM. **Methods:** Patients with one index brain metastasis requiring surgical resection (2-5cm diameter) and up to three non-index metastases not requiring resection (< 2cm) were enrolled across 14 centers. All patients received neoadjuvant FSRT (30-35 Gy in 5 fraction) targeting the index lesion, followed by surgical resection. The primary endpoint was 6-month cumulative incidence of LR at the surgical site. Secondary endpoints included LMD, LR at 12 months, RN, distant brain failure (DBF), overall survival (OS), intracranial progression-free survival (IC-PFS), neurocognitive outcomes, and treatment-related adverse events. **Results:** Between June 2022 and August 2024, we enrolled 57 patients with 53 evaluable for response. The median age was 68 years (range 34-79). The median maximum diameter was 3.2 cm (range 2.0-4.9). The median follow-up duration was 11.9 months (range 1.3-14.7). The 6-month cumulative incidence of surgical site LR was 4.3% (95% CI: 0–10.1) (80%CI : 0.4-8.1), and 4.0% (95%CI: 0-9.4) using competing risk analysis. LMD was not observed at either 6, 12 months. The 12-month cumulative incidence of LR was 16.4% (95% CI: 6.0–26.8). Symptomatic RN (≥ Gr 2) was not observed at either 6, 12 months, and asymptomatic RN occurred in 5.9% at 6 months and 8.0% at 12 months. DBF rates were 14.0% (95% CI: 4.4–23.6) at 6 months and 18.1% (95% CI: 7.4–28.8) at 12 months. Median OS rate was 86.3% (95%CI: 77.3-96.3) at 6 months, and 76.5% (95%CI: 65.7-89) at 12 months. IC-PFS rates were 72.5% (95% CI: 61.2-85.9) at 6 months and 64.4% (95% CI: 52.5-79.1) at 12 months. Neurocognitive function was largely preserved, with Mini-Mental State Examination (MMSE) decline ≥1 point observed in 15.4% at 6 months and 9.6% at 12 months, and decline ≥3 points in ≤ 4% at both time points. Adverse events from irradiation to surgery were acceptable (grade ≥2: 10.5%; grade ≥3: 5.3% (CTCAE version 5.0)). **Conclusions:** Neoadjuvant FSRT followed by surgical resection demonstrated excellent early local control, complete suppression of LMD, acceptable toxicity, and favorable cognitive preservation. This approach represents a promising alternative to postoperative FSRT for resectable brain metastases and warrants further comparative investigation. Clinical trial information: jRCT s042220014. Research Sponsor: ACCURAY.

2004 **Oral Abstract Session**

MAGMA: Multi-arm glioblastoma Australasia phase 3 trial. First Author: Craig Gedye, Icon Cancer Centre, Kurralta Park, SA, Australia

Background: MAGMA (ACTRN12620000048987; COGNO cooperative trials group) is a prospective, open-label, partial factorial randomized platform trial with optional randomization, aiming to improve treatments for glioblastoma (GBM). Two initial hypotheses were tested: Question 1 (Q1), 'early' daily temozolomide (TMZ) as soon as possible postop, pre-radiotherapy (RT); and Question 2 (Q2), 'extended' adjuvant TMZ beyond 6 cycles. Prior phase 2 studies suggest longer survival with early TMZ and inconsistent outcomes with extended adjuvant TMZ. MAGMA used baseline randomization with molecular stratification aiming for robust randomized evidence. **Methods:** Participants (pts) with newly diagnosed GBM (CNS WHO 2016) could be randomized to each question, stratified by extent of resection and IDH status (Q1 and Q2) and MGMT methylation (Q2 only). For Q1, pts were randomized to daily TMZ (75 mg/m^2) initiated as soon as possible after surgery followed by standard RT-TMZ (either 15 or 30 fractions), or RT-TMZ alone. For Q2, pts were randomized prior to adjuvant TMZ, to stop after 6 cycles or continue until progression. Primary outcome was overall survival (OS) from initial surgery. Secondary outcomes included progression-free survival (PFS), time to next treatment, OS from each randomization, clinically significant toxicity and health-related quality of life. **Results:** From September 2020 to July 2023, 347 pts consented across 28 Australian sites including 6 regional sites. Median follow-up was 40 months; final data cutoff was 31 July 2025. Mean age was 60 years (range 21-85), 60% were male, 92% IDH-wildtype, 42% MGMT-methylated, 56% had gross total resection and 13% biopsy-only. For Q1 (n=259), pts randomized to early TMZ (n=131) started TMZ at median 21 days post-surgery with mean exposure 13 days. Concurrent TMZ exposure, time to starting RT (median 34 vs 33 days), RT completion and toxicity (G3+ 34% vs 31%) were similar between arms. Median OS (months; 95% CI) was 16 (14-20) with early TMZ vs 20 (17-22) for control, HR 1.18 (0.89-1.56), p=0.24. Median PFS was 8 (7-9) vs 9 (7-12), HR 1.15 (0.88-1.52), p=0.31. For Q2 (n=291), among pts randomized to extended adjuvant TMZ (n=146), only 42% remained progression-free through 6 cycles and received more than 6 adjuvant TMZ cycles. Toxicity was similar between arms (G3+ 34% vs 31%). Median OS was 20 months (17-22) with extended adjuvant TMZ vs 18 (15-20) for control, HR 0.82 (0.63-1.06), p=0.13; after multivariable analysis, HR 0.73 (0.56-0.95). Median PFS was 9 (8-9) vs 9 (7-10), HR 0.88 (0.69-1.13), p=0.32. **Conclusions:** Early TMZ does not improve OS in pts with newly diagnosed GBM. Extended adjuvant TMZ beyond 6 cycles was safe, with insufficient evidence of improved OS in the primary analysis, although moderate effects remain plausible. Notably, many pts had progression before completing 6 cycles. Collaboration enables large-scale, pragmatic cancer trials across diverse healthcare settings in Australia. Clinical trial information: ACTRN12620000048987. Research Sponsor: Medical Research Future Fund (MRFF); 2018/MRF1170193.

2005 **Oral Abstract Session**

Phase 1/2a study of concomitant radiotherapy with olaparib and temozolomide in unresectable high-grade glioma patients: Final results from the phase 2a step (OLA-TMZ-RTE-01). First Author: Dinu Stefan, Centre François Baclesse, Radiation Oncology Department, Caen, France

Background: Although the Stupp protocol (radiotherapy + temozolomide (TMZ)) remains the cornerstone of glioblastoma (GBM) first line treatment after surgery (resection or biopsy), the prognosis is still poor. PARP inhibitors, such as olaparib, may enhance the efficacy of radiotherapy and TMZ by amplifying their cytotoxic effects. We implemented a phase 1/2 trial to assess safety and efficacy of olaparib combined with TMZ concomitant with intensity modulated radiotherapy (IMRT) as a first line treatment in GBM patients (pts) following biopsy or subtotal resection. The phase 1 conducted in 30 pts concluded the recommended phase 2 dose (RP2D) of olaparib was 100 mg Q12H Day (D) 1-3, in concomitant with the Stupp protocol. We herein report results of the phase 2a. **Methods:** Pts were treated with adjuvant IMRT (60 Gy/30 fractions/6 wks), with concurrent daily oral TMZ (75 mg/m²). For the maintenance period (MT) from 4 wks after IMRT, pts received TMZ (150 mg/m², D 1-5 every 28 days, for 6 cycles). Oral olaparib was started at the RP2D the same day as IMRT, concurrently with the Stupp protocol and continued up to disease progression or unacceptable toxicity. The trial was conducted according to a two-step Case and Morgan design and required 55 assessable pts (37 in interim analysis), to assess the 12-month (mo) overall survival (OS) rate expected to be higher than 57%. Final Z-statistic$>$1.235 will confirm efficacy. All pts who received olaparib at RP2D were included in the analysis, including pts of the phase 1 step. **Results:** From 2020 to 2024, 68 pts were enrolled and treated in the phase 2a: 41 (60%) men, median age 59 yrs [range 20-70]. 67 pts (98%) had GBM and 1 (2%) IDH mutated anaplastic astrocytoma. Biopsy-only was performed for 27 pts (40%). ECOG performance status 0 for 34 pts (51%), 1 for 28 pts (42%) and 2 for 5 (7%). 11 pts (16%) stopped the study before MT, including 4 for grade 3-4 hematological toxicity. Among the 57 pts who began the MT, 5 stopped the treatment for hematological toxicity. 3 pts remain on treatment. Interim analysis conducted in March 2024 in 41 patients, with median follow-up o 7.6 mo, led pursuing the study, with a 12-mo OS rate of 72.9% [95%CI: 56.7-93.9]. At final analysis, after median follow-up of 17.2 mo, 48 deaths (71%) were observed. Median OS was 18.4 mo and 12-mo OS rate of 69.1% [95%CI: 59-81] (H0 rejection according to Z-statistic=1.29). Among hematological toxicities of interest, thrombocytopenia grade $\geq$ 3 was observed in 5 pts, neutropenia grade 4 in 4 pts, febrile neutropenia grade $\geq$ 3 in 1 pt and anemia grade $\geq$ 3 in 4 pts. One toxic death was observed (febrile aplasia). **Conclusions:** Intermittent olaparib (100 mg Q12H D1-3) combined with the Stupp protocol appears to be beneficial to improve survival of poor prognosis nonresected/partially resected GBM pts, with a safety profile quite similar to that of the standard chemoradiotherapy. Clinical trial information: NCT03212742. Research Sponsor: French Cancer Institute and French Health Ministry; Astra-Zeneca.

2006 **Oral Abstract Session**

A personalized neoantigen vaccine to reprogram the immune landscape of glioblastoma. First Author: Jack Y. Ghannam, Harvard Medical School, Boston, MA

Background: Glioblastoma (GBM) remains uniformly lethal despite standard therapy. An immunosuppressive tumor microenvironment (TME) and limited T cell infiltration pose major barriers to immunotherapy. Personalized neoantigen vaccines offer a strategy to prime tumor-specific T cell responses by targeting patient-specific mutations, driving effector cells into the CNS. Here, we report results from a phase I trial of a personalized neoantigen peptide vaccine combined with pembrolizumab in newly diagnosed GBM. **Methods:** Patients with newly diagnosed GBM who were not on dexamethasone following gross total resection were enrolled across four cohorts. Up to 20 synthetic long peptides targeting personal neoantigens were selected per patient, and admixed with the adjuvant poly-ICLC (NeoVax). Following radiotherapy, NeoVax was administered subcutaneously as five priming doses followed by two booster doses. *MGMT*-unmethylated patients (Cohorts 1A-C) received NeoVax plus pembrolizumab without temozolomide (TMZ) and differed by time of pembrolizumab initiation relative to NeoVax priming; *MGMT*-methylated patients (Cohort 1D) received standard TMZ and pembrolizumab was initiated after NeoVax priming. Immunogenicity was assessed by *ex vivo* and *in vitro* IFN-γ ELISpot assays. Single-nucleus/single-cell RNA sequencing and TCR sequencing (snRNA-seq/scTCR-seq) was performed on paired tumor specimens. **Results:** Of 39 enrolled patients, 37 initiated NeoVax including 35 who completed priming and 2 with ongoing priming. Treatment was well-tolerated with no serious AEs. Median overall survival was 36.9 months for *MGMT*-methylated patients and 19.0 months for *MGMT*-unmethylated patients, compared to 25.3 and 16.7 months for propensity score-matched historical controls, respectively. *Ex vivo* and *in vitro* neoantigen-specific T cell responses were detected comparably across all cohorts and overall in 65% and 97% of vaccinated patients, respectively. Among all patients, *ex vivo* immune responders demonstrated improved overall survival compared to non-responders (HR 0.26, 95% CI 0.09-0.77, P = 0.015). Vaccine-reactive clonotypes, defined by *in vitro* expansion to vaccine peptides, were identified in post-vaccination tumors. snRNA-seq/scTCR-seq revealed increased intratumoral vaccine-specific T effector populations following vaccination. **Conclusions:** NeoVax generates durable T cell responses that traffic to GBM tumors, with circulating responses associated with improved survival. Ongoing studies are evaluating peripheral clonotype dynamics, remodeling of malignant cell states and the TME, and the spatial distribution of vaccine-reactive clonotypes, which may guide future combinatorial strategies in GBM. Clinical trial information: NCT02287428. Efficacy and safety of asandeutertinib versus osimertinib as first-line treatment in EGFR-mutated NSCLC patients with brain metastases: Interim analysis of an open-label, multicenter, randomized, pivotal phase II study (ESAONA). First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

2008 Oral Abstract Session

Correlation of ten-year survival with cell-free DNA methylation of melanoma patients with asymptomatic brain metastases treated with nivolumab plus ipilimumab: The multicenter phase III NIBIT-M2 trial. First Author: Anna Maria Di Giacomo, University of Siena and Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy

Background: The NIBIT Foundation-sponsored phase III NIBIT-M2 study showed a 41% 7-y OS of melanoma patients (pts) with asymptomatic brain metastases (BM) treated with ipilimumab (I) plus nivolumab (N) (I+N) (*Di Giacomo AM, CCR 2021* and *EJC 2024*). Despite the significant efficacy of I+N therapy in this pts population, no biomarkers predictive of response have been identified yet also due to the accessibility of BM. We here report the 10-y survival and its correlation with cell-free (cf)DNA analyses on serial plasma samples collected from pts enrolled in the NIBIT-M2 study. **Methods:** The NIBIT-M2 study recruited melanoma pts with active, untreated, asymptomatic BM from 9 Italian Centers, randomized (1:1:1) to receive fotemustine (F) (Arm A), I+F (Arm B), or I+N (Arm C). Primary endpoint was OS. Exploratory analyses were conducted on cfDNA plasma samples collected at baseline and week (W) 12 on therapy. Tumor fraction (TF) was estimated from low pass WGS using IchorCNA. Tumor-specific methylation Score (T-meth Score) was computed as the ratio between the coverage over methylated regions analyzed by cf-methylated DNA immunoprecipitation and high-throughput sequencing (cfMeDIP-seq) and melanoma-specific methylated regions previously identified in the TCGA melanoma cohort. **Results:** From Jan 2013 to Sept 2018, 80 pts were enrolled: 76 received F (23), I+F (26), or I+N (27). As of December 1, 2025, with a median follow-up of 125 months (mo), median OS was 8.5 (95% CI: 4.8-12.2), 8.2 (95% CI: 2.1-14.3) and 29.2 (95% CI: 0-73.5) mo for Arm A, B, and C, respectively. The 10-y OS rate was 13.0% (95% CI: 0-26.7) in Arm A, 7.7% (95% CI: 0-17.9) in Arm B, and 31.2% (95% CI: 13.0-49.4) in Arm C. The 10-y melanoma specific survival was 13.0% (95% CI: 0-26.7), 7.7% (95% CI: 0-17.9), and 35.1% (95% CI: 16.3-53.9) in Arm A, B and C, respectively. Patients were stratified at baseline according to the median values of TF (n=57; median 0.022) and of T-meth Score (n=53; median 0.096): a significantly higher median OS was observed in pts with TF (22.3 *vs* 8.2 mo; p=0.033) and T-meth Score (26.3 *vs* 7.9 mo; p=0.002) below their median values. Of note, low TF and T-meth Score were enriched at baseline in pts from Arm C. Additionally, a decrease in TF (n=29) and T-meth Score (n=24) was observed at W12 in pts with an OS above the median (26.3 mo for TF and 24.0 mo for T-meth Score). **Conclusions:** The 10-y results of the NIBIT-M2 study, with the longest follow-up available to date in melanoma pts with asymptomatic BM treated with I+N, continue to show persistent long-term therapeutic efficacy of the combination. Plasma-derived TF and T-meth Score may predict long-term survival of melanoma pts with asymptomatic BM treated with I+N. Clinical trial information: NCT02460068. Research Sponsor: FONDAZIONE AIRC; 21073; Bristol Myers Squibb; NA.

2009 Rapid Oral Abstract Session

SPECTRUM: Phase II study of tislelizumab plus pemetrexed in patients with relapsed or refractory (R/R) primary diffuse large B-cell lymphoma (DLBCL) of the central nervous system (CNS)—The Korean Cancer Study Group LY22-07. First Author: Jung Sun Kim, Seoul National University College of Medicine, Seoul, South Korea

Background: Primary DLBCL of the CNS is a rare extranodal lymphoma confined to the CNS. Despite standard high-dose methotrexate (HD-MTX)-based induction therapy, approximately 25% of patients (pts) relapse after an initial response, and effective salvage options are limited with reported objective response rate (ORR) generally $<$30% and median progression-free survival (PFS) $<$3 months. The SPECTRUM trial evaluated efficacy and safety of tislelizumab plus pemetrexed in pts with R/R primary DLBCL of the CNS (NCT05253118). **Methods:** SPECTRUM is a phase II, multicenter, open-label study conducted in South Korea. Pts with histologically confirmed R/R primary DLBCL of the CNS after HD-MTX-based therapy were eligible. Tislelizumab (200 mg) plus pemetrexed (500 mg/m^2) was administered intravenously every 3 weeks until disease progression or unacceptable toxicity. The primary endpoint was investigator-assessed ORR per IPCG response criteria. Secondary endpoints included PFS, duration of response (DoR), overall survival (OS), and safety. Exploratory analyses assessed baseline CSF and plasma *MYD88* L265P mutations using droplet digital PCR and genetic subtypes based on LymphGen classification. **Results:** As of December 16, 2025, 29 pts were enrolled. Median age was 59 years (range, 41–86), 17 (58.6%) were male, and 25 (86.2%) had prior rituximab exposure. Median follow-up was 30.4 months (95% confidence interval [CI], 16.8–not reached [NR]), with a median of 6 treatment cycles (range, 1–55). Among evaluable pts, the ORR was 71.4% (20/28), with complete response (CR) rate of 50.0% (14/28). Median DoR was 14.5 months (95% CI, 2.8–NR). Median PFS and OS were 6.8 (95% CI, 2.1–27.6) and 27.8 months (95% CI, 7.4–NR), respectively. Treatment-emergent adverse events (TEAEs) of any grade occurred in 19 pts (65.5%), most commonly skin rash (51.7%). Grade $\geq$3 TEAEs occurred in 10 pts (34.5%), including one grade 5 event. Six pts discontinued treatment due to treatment-related AEs, all attributable to pemetrexed. Immune-related AEs occurred in 5 pts (17.2%). Most pts were MCD subtype (84.6% [22/26]), with *MYD88* L265P mutations detected in 61.5% (16/26). At baseline, *MYD88* L265P detection was higher in CSF than plasma cell-free DNA (cfDNA) (85.0% [17/20] vs 20.0% [4/20]). In one pt with extra-CNS relapse harboring *MYD88* L265P mutation and *PIM1–CD274* fusion, *MYD88* L265P became undetectable at Weeks 6 and 12, concordant with metabolic CR on PET/CT. **Conclusions:** Tislelizumab plus pemetrexed met the primary endpoint and demonstrated encouraging outcomes (ORR 71.4% [CR 50.0%]; median PFS and DoR 6.8 and 14.5 months) with manageable safety profiles in pts with R/R primary DLBCL of the CNS. Clinical trial information: NCT05253118. Research Sponsor: BeOne Medicines, Samyang Biopharm Corporation.

2010 Rapid Oral Abstract Session

A global, randomized, double-blinded, phase 3 trial of vorasidenib vs placebo in patients with grade 2 glioma with an *IDH1/2* mutation (INDIGO): Updated efficacy and safety. First Author: Timothy Francis Cloughesy, University of California Los Angeles, Los Angeles, CA

Background: Grade 2 gliomas with isocitrate dehydrogenase 1/2 mutations (mIDH1/2) are diffuse, slowly progressive, malignant brain tumors with a poor long-term prognosis. In the Phase 3 INDIGO trial (NCT04164901) of patients (pts) with grade 2 mIDH1/2 glioma, vorasidenib (VOR), an oral, brain-penetrant, dual inhibitor of mIDH1/2, demonstrated a statistically significant and clinically meaningful improvement in the primary endpoint, progression-free survival (PFS) per blinded independent review committee (BIRC), and key secondary endpoint, time to next intervention (TTNI), vs placebo (PBO) at the preplanned interim analysis (data cut-off [DCO]: September 6, 2022). An additional 6 months of data up to study unblinding, March 7, 2023, showed that median PFS was not reached (95% confidence interval [CI]: 22.1 mos, not estimable [NE]) with VOR vs 11.4 mos (95% CI: 11.1, 13.9) with PBO, and median TTNI was NE (95% CI: NE, NE) with VOR vs 20.1 mos (95% CI: 17.5, 27.1) with PBO. Here, we present updated efficacy and safety results as of January 17, 2025, from pts randomized to VOR. **Methods:** Key eligibility criteria included residual/recurrent grade 2 mIDH1/2 oligodendroglioma or astrocytoma after surgery only; aged $\geq$12 years; Karnofsky performance score $\geq$80; measurable non-enhancing disease; surgery as only prior treatment; no immediate need of chemo-radiotherapy (CT/RT). Pts were randomized 1:1 to VOR 40 mg daily in 28-day cycles or PBO. After study unblinding, pts receiving PBO were permitted to cross over to VOR. Primary endpoint: radiographic PFS per BIRC. Key secondary endpoint: TTNI. **Results:** 331 pts were randomized: 168 to VOR and 163 to PBO (median age: 40.0 years [range: 16–71]; oligodendroglioma: 172; astrocytoma: 159). As of January 17, 2025, 98/168 (58.3%) pts remained on VOR, and median follow-up was 41.6 mos (95% CI: 40.5, 42.7). Median PFS per investigator (INV) in pts randomized to VOR was 49.9 mos (95% CI: 39.6, NE), and median TTNI was NE (95% CI: 52.0 mos, NE). At 42 mos, 59.2% (95% CI: 49.9, 67.4) of pts were progression-free and 75.1% (95% CI: 67.4, 81.2) were not in need of CT/RT or surgery. Objective response rate per INV was 31.5% (95% CI: 24.6, 39.2). Median overall survival was not reached. PFS and overall response per BIRC will be presented. The safety profile of VOR was consistent with previous reports. No new safety signals were observed. **Conclusions:** In the randomized, Phase 3 trial of a targeted therapy in grade 2 mIDH1/2 glioma, over 3 years of follow-up in pts randomized to VOR support the robustness of PFS and TTNI results and confirm a durable and sustained treatment benefit with VOR. VOR is now approved in over 40 countries as a monotherapy for pts with grade 2 mIDH1/2 glioma following surgery. Clinical trial information: NCT04164901. Research Sponsor: Servier Pharmaceuticals.

2011 Rapid Oral Abstract Session

Outcomes of a feasibility and safety trial of tile-based radiation therapy with cesium-131 followed by external beam radiation therapy with concurrent and adjuvant temozolomide in patients with newly diagnosed glioblastoma (NCT05342883). First Author: Clark C. Chen, Brown University, Providence, RI

Background: Standard of care (SOC) of Glioblastoma (GBM) includes maximal safe resection followed by external beam radiation therapy (EBRT) with concomitant temozolomide (TMZ). This typically begins 4-6 weeks after surgery, during which rapid early progression (REP) occurs in ~50% of patients and is associated with worse survival, especially in unmethylated GBM (median OS ~13 months as per BN007). SOC treatment in BN007 showed ~38% $\geq$grade 3 treatment-related adverse events (TRAEs). GammaTile (GT Medical Technologies, Inc., Tempe, AZ), a tile-based radiation therapy (TBRT) with cesium-131 sources, immediately initiates radiation at resection, eliminating the 4-6-week delay. **Methods:** This is a prospective, single arm, open-label feasibility study across 15 US centers with a primary aim of assessing the safety and feasibility of combining resection + TBRT with an abbreviated course of EBRT with concurrent and adjuvant TMZ for newly diagnosed molecular GBM. Eligible patients were $\geq$18 years old; only patients with IDH-wildtype were included in survival analysis. MGMT and IDH underwent central lab review. Feasibility was defined as percent of patients who started EBRT+TMZ between 21-35 days post-surgery. Safety was assessed by incidence of $\geq$grade 3 TRAEs. REP was centrally reviewed. Additional aims included PFS and OS estimated using Kaplan-Meier. A planned sample size of 61 was chosen to ensure feasibility could be estimated with a $\pm$10% degree of precision. Results are presented based on the modified intent to treat (mITT) population (enrolled patients who had surgery and confirmed GBM). **Results:** From 8/2022-8/2025, 70 patients were enrolled and had surgery; 67 of whom had confirmed GBM. Table 1 presents baseline characteristics. Median follow-up was 12.4 months. 93% started EBRT+TMZ; 74% started 21-35 days post-surgery. The median (range) of days from surgery to EBRT+TMZ was 29 (23-70) days. There were no delays due to EBRT planning. 39% of patients experienced a $\geq$grade 3 TRAE: 22% of patients were related to surgery only, 18% to radiation only, and 13% to surgery and radiation. 6.0% of patients showed REP. Median OS for patients with unmethylated MGMT was 16.5 months vs. 28.0 months for patients with methylated MGMT. The median PFS for patients with unmethylated MGMT was 9.3 months vs. not yet met for patients with methylated MGMT. **Conclusions:** Feasibility and safety are in line with SOC. REP had a notable reduction compared to literature. OS is encouraging. These data provide the basis for a phase 3 randomized trial (NCT07195591). Clinical trial information: NCT05342883. Research Sponsor: GT Medical Technologies, Inc.

2012 **Rapid Oral Abstract Session**

First-in-human study of AAV6-NeuroD1 trans-differentiation therapy in recurrent malignant glioma. First Author: Yulun Huang, Department of Neurosurgery, The Fourth Affiliated Hospital of Soochow University, Suzhou, China

Background: Recurrent glioblastoma (GBM) has a median survival of less than 9 months. NeuroD1 is a neural transcriptional factor that can reprogram both glial cells and glioma cells into neuron-like cells, suppressing the proliferation of glioma cells and inducing cell death, extending the life span of animal models carrying glioblastoma. Therefore, scAAV6-NeuroD1 (NXL-004), a self-complementary adeno-associated virus 6 vector delivering NeuroD1, was developed to initiate a first-in-human study in patients with recurrent malignant glioma (ChiCTR2400080362). **Methods:** This is a single arm, open-label, dose-escalation study. The primary endpoint was safety, and the secondary endpoint was preliminary efficacy. Enrolled patients must have pathologically confirmed recurrent malignant glioma after standard therapy including surgery and chemoradiotherapy. NXL-004 was delivered intracavitary post-resection or intratumorally post-biopsy during surgery. Three dose levels (from $4.0x10^{12}$ vg to $4.0x10^{13}$ vg) were evaluated, using an accelerated dose escalation design. Up to two additional doses were allowed via an Ommaya reservoir at 2~4-week intervals after surgery. **Results:** 11 patients (median age 48.0, 81.8% male) were enrolled between 3/2024 and 6/2025. All patients had recurrent WHO grade 4 astrocytoma (10/11 IDH wild, 6/11 MGMT-unmethylated). Ten patients received repeat tumor resection plus intracavitary injection of NXL-004 (1 at low-dose, 3 at medium-dose, and 6 at high-dose), and one received biopsy plus intra-tumoral injection (low dose). All patients were included in the safety and efficacy analysis. No drug-related serious adverse event (SAE) or dose-limiting toxicities (DLT) was observed. All AEs related to NXL-004 were grade 1–2 (fever: 8/11; rash: 1/11; seizure: 1/11). Two grade 3 AEs (hemiplegia, meningitis) were reported but considered unrelated to the drug. Per RANO 2.0 criteria, the best overall response included 1 complete response (CR) and 5 stable disease (SD), yielding a disease control rate (DCR) of 54.5% (6/11). The median overall survival for all treated patients was 13.2 ± 2.0 months (95% CI: 9.3-17.1) from the first dose and 25.2 ± 1.2 months (95% CI: 23.0-27.5) from initial diagnosis. The first enrolled patient survived $>$18 months after dose. In the high-dose group, a higher DCR of 66.7% (4/6) was observed, with one patient achieving CR and one with SD surviving without progression $>$6 months (9 and 7 months, respectively, both ongoing). At a median follow-up of 9.0 months for this group, 5 patients were still alive, with 1 patient deceased (OS: 13.2 months). **Conclusions:** To our knowledge, this is the first clinical evidence of in vivo AAV-based trans-differentiation gene therapy for cancer treatment. NXL-004 showed favorable safety and encouraging efficacy, indicating that AAV-based cell reprogramming approach may represent a new modality for the treatment of glioma. Clinical trial information: ChiCTR2400080362. Research Sponsor: Suzhou Science and Technology Plan Project No. SZM2023019; NeuExcell Therapeutics.

2013 **Rapid Oral Abstract Session**

Updated overall survival, safety, and neurologic function outcomes from a phase 1 trial of bivalent chimeric antigen receptor (CAR) T cell therapy in recurrent glioblastoma (GBM). First Author: Erin E. Hollander, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: We previously reported the safety, bioactivity, and preliminary efficacy of bivalent CAR T cells targeting EGFR and IL13Rα2 in 18 patients with recurrent GBM (Bagley, et. al, *Nat Med* 2025). Given that median follow-up time was only 8.1 months at the time of the data cut-off for that publication, we now report updated overall survival (OS) and safety data with longer follow-up time, as well as neurologic function outcomes. **Methods:** Eighteen patients with recurrent EGFR-amplified GBM were enrolled using a 3+3 design (dose levels: 5.0×10^6, 1.0×10^7, and 2.5×10^7 cells). Patients received a single intracerebroventricular (ICV) dose of CART-EGFR-IL13Rα2 cells. OS was defined as the time from the date of initial study treatment to the date of death from any cause, or censored at the last date of contact if the patient was not known to have died at the date of analysis cut-off (January 16, 2026). To capture changes in neurologic function over the course of the trial, patients were assessed prospectively using the Neurologic Assessment in Neuro-Oncology (NANO) scale. NANO is an objective clinician-reported outcome of neurologic function scored on nine domains, with a higher score indicating worse neurologic function. NANO scores were assessed at baseline prior to CART (day 0), on days 1, 4, 7, 10, 14, 21, and at the 1-month and 2-month visits post-CART. **Results:** With median follow-up time of 18.5 months, median OS was 12.0 months (95% confidence interval, 7.4 – 23.2 months) with 3 patients surviving greater than 18 months. Other than one patient with prolonged grade 1 neurotoxicity as previously described, no prolonged, late-onset, or unexpected toxicities were observed within this longer follow-up time, including no evidence of on-target off-tumor toxicity or secondary cancers. On day 1 post infusion, an increase in NANO scores was observed (mean increase in NANO score from baseline of 1.9; p=0.09), which resolved to baseline by day 4. Patient NANO scores were unchanged from baseline at one month (mean change 0.41; p=0.998) and two months (mean change 0.54; p=0.992) post infusion. Those who underwent retreatment with a second dose of CAR-T cells at the time of tumor progression (n=7) did not experience an increase in NANO score on day 1 (mean change 0.33, p=0.99), despite having a significant increase on day 1 following the first infusion (mean change 2.9, p=0.008). **Conclusions:** With over 18 months of median follow-up time, ICV delivery of CART-EGFR- IL13Ra2 cells in patients with recurrent GBM has not demonstrated long-term or delayed toxicities and is associated with promising OS outcomes that warrant continued clinical development. Neurologic function worsens immediately following infusion but recovers to pre-treatment baseline by one month following CAR T cell infusion. Clinical trial information: NCT05168423. Research Sponsor: Kite.

Butaselen combined with radiotherapy for newly diagnosed H3K27M-mutant spinal diffuse midline glioma: A single-arm phase Ib trial. First Author: Yuanhao Chang, Beijing Tiantan Hospital, Beijing, China

Background: Patients with H3K27M-mutant spinal diffuse midline glioma (sDMG) have a median overall survival (OS) of approximately 13 months and the medical interventions remain limited. Radiation induced senescence (RIS) is a major cause of radiotherapy resistance and tumor recurrence in H3K27M-mutant sDMG. In pre-clinical study, we observe that thioredoxin reductase 1 (TrxR1) protects senescence sDMG cells from oxidative damage caused by radiation, and novel TrxR1 inhibitor Butaselen dramatically induces apoptosis of sDMG cells. Therefore, Butaselen combined radiotherapy is a new strategy to prolong the OS and progression-free survival (PFS) for newly diagnosed H3K27M-mutatnt sDMG patients. **Methods:** Patients age 18-70 years with newly diagnosed H3K27M-mutant sDMG were eligible for this phase Ib trial (ChiCTR2600116732). All subjects received fixed radiation dose at 45Gy/1.8f/25d. Dose-escalation of Butaselen was performed in phase Ib trial and 9 subjects were enrolled in three dose levels (3+3 design: DL1: 450mg, oral, bid; DL2: 600mg, oral, bid; DL3: 750mg, oral, bid). Butaselen was orally administered in combination with radiotherapy for first 5 weeks, and then administered alone until tumor progression occurs or death. Follow-up visits were conducted at Q8W during 0-6 months and Q12W afterwards. The primary outcome was the safety of the Butaselen, as determined on the basis of adverse events (AEs) and serious adverse events (SAEs). The secondary outcomes were the 12-month OS/PFS rate, OS, PFS, objective response rate (ORR, RANO 2.0 criteria), and objective neurological function scale. **Results:** Between Apr 18, 2024 and May 21, 2025, 9 eligible subjects were enrolled. 9 subjects (age 26-57 years) received Butaselen therapy with no report of severe adverse event (SAE) or dose-limiting toxicity. As a result, 6-month and 12-month PFS rate (PFS%) was 100% and 88.9% (8/9), respectively, while both 6-month and 12-month OS rate (OS%) reached 100%. The longest PFS has exceed 22 months. 1 subject was died due to disease progress (OS=14.7 month; PFS=6.9 month), 1 subject experienced second operate resecting after disease progress (PFS=12.9 month), and the remaining 7/9 subjects are currently still in the progression-free survival phase. The overall ORR assessed by RANO 2.0 was 33% (3/9) and DCR was 100% (9/9). All subjects (9/9, 100%) experienced the relieve of neurological functions, as measured by Japanese Orthopedic Association (JOA) Scores and McCormick Scores. Grade 3 drug-related treatment-emergent adverse events (TEAEs) occurred 2 times; and no grade 4 TEAEs occurred. **Conclusions:** Butaselen combined with standard radiotherapy was well tolerated, and exhibited meaningful prolongation of survival period, durable objective responses and neurological function improvements in primary H3K27M-mutant sDMG patients. Clinical trial information: ChiCTR2600116732. Research Sponsor: None.

Azeliragon, a RAGE inhibitor, plus temozolomide and radiotherapy in patients with newly diagnosed glioblastoma: Final results from a dose-finding phase in the CAN-201 NDG trial. First Author: Maria Martinez Garcia, Medical Oncology Department, Hospital del Mar, Barcelona, Spain

Background: Radiotherapy (RT) plus temozolomide (TMZ) is the standard of care for patients (pts) with newly diagnosed glioblastoma (GBM). However, most eventually progress. The RAGE receptor and its ligands may contribute to RT resistance in GBM by sustaining chronic pro-tumorigenic inflammation, enhancing DNA damage repair pathways, and promoting survival signaling in hypoxic and stressed tumor cells. Azeliragon, an extensively studied RAGE inhibitor in Alzheimer's disease, may enhance overcome RT-TMZ resistance in newly diagnosed GBM. **Methods:** The CAN-201 NDG is an open-label, single-arm, phase Ib/II trial in Spain recruiting pts with newly diagnosed IDH-wildtype GBM. Pts received azeliragon in combination with standard RT-TMZ, followed by maintenance therapy with azeliragon. The trial consists of an initial dose-finding phase with a rolling six design and a subsequent expansion phase (up to 14 additional pts) at the recommended phase 2 dose (RP2D). The dose levels were 5 (L1), 10 (L2), 20 (L3), 30 (L4), and 50 (L5) mg/day. The primary objective was to determine the RP2D, defined as the dose for which $<$33% of pts experience dose-limiting toxicity (DLT) within 28 days of the initiation of dosing. Main secondary endpoints include progression-free survival (PFS), overall survival (OS), and changes in corticosteroid requirements. Pharmacokinetic and translational research is ongoing. **Results:** From Oct 2023 to May 2025, 33 pts were included across L1-L5 levels (6-8 pts per level). Median age was 56 years (range: 36-69). Most pts were male (66.7%), with ECOG 0-1 (93.9%), MGMT unmethylated (54.5%) and complete resection (45.5%). No DLTs occurred, and L5 (50 mg/day) was declared RP2D. One grade 3 maculopapular rash at L5 was the only serious adverse event related to azeliragon. Most common grade 3-4 toxicities were thrombocytopenia (21.2%) and lymphopenia (9.1%), all RT or TMZ-related. Most common possibly azeliragon-related AEs were asthenia (24.2%), nausea (21.2%), anorexia (9.1%), diarrhoea and dysgeusia (6.1% each), all grade 1-2. Median azeliragon treatment duration was 7.4 m (range: 2.7-21.1). Treatment ended due to disease progression (82.8%), toxicity (3.4%), and exitus (3.4%). Three pts at L5 remain on treatment. With median follow-up of 11 m (95% CI: 8.2-16.4), median PFS was 7.9 m (95% CI: 6.2-12.2) overall, 15.6 m (95% CI: 6.1-NR) and 6.7 m (95% CI: 5.0-10.9) for methylated and unmethylated MGMT, respectively. Median OS was not reached, 12m OS rate was 61.5% (95% CI: 4.4-85.3), with rates of 74.2% (95% CI: 52.4-100) and 51.1% (95% CI: 29.3-88.8) for methylated and unmethylated MGMT, respectively. **Conclusions:** Azeliragon at 50 mg/day in combination with standard RT / TMZ is safe, with no DLTs reported. More mature OS data will be presented. Further follow-up with a larger number of pts is required to assess preliminary efficacy. Clinical trial information: NCT05635734. Research Sponsor: CANTEX Pharmaceuticals, Inc.

2016 **Rapid Oral Abstract Session**

Change in relative cerebral blood volume as a biomarker for early response to bevacizumab in patients with recurrent glioblastoma: ECOG-ACRIN EAF151. First Author: Jerrold L. Boxerman, Rhode Island Hospital/Brown University, Providence, RI

Background: Bevacizumab therapy (Bev) for recurrent glioblastoma (rGBM) has not demonstrated improved overall survival (OS) in randomized clinical trials. However, single-center and preliminary multi-center studies suggest that relative cerebral blood volume (rCBV) measured with dynamic susceptibility contrast MRI (DSC-MRI) at baseline or shortly after treatment initiation may predict response to Bev. The primary aim of ECOG-ACRIN EAF151 was to evaluate whether early binary change in rCBV, assessed 2–3 weeks after initiation of Bev-containing therapy, identifies patients with an OS benefit of ≥4 mos. Pre-specified secondary aims assessed baseline rCBV; post-hoc exploratory analyses examined early post-Rx rCBV. **Methods:** A prospective, phase II multi-center trial without randomization enrolled subjects with rGBM receiving their first Bev-containing therapy. Progression was determined by local sites (RANO criteria; MRI within 28 days of registration, ≥42 days since end of chemoradiation). Baseline (S0) and follow-up (S1) DSC-MRI were performed before the first Bev infusion (within 3 days), and 12-25 days post-infusion but before the second infusion. Anatomic MRI and DSC-MRI (double-dose Gadavist injection, full-dose preload) complied with recommended protocols. Mean normalized (nRCBV) and standardized (sRCBV) rCBV were extracted from contrast-enhancing tumor ROIs. A 2-sided logrank test (α=0.1) was used to test the primary aim (change in mean nRCBV from S0 to S1, ≥0 vs. <0). Cox regression with restricted cubic splines was used to assess the association between continuous rCBV markers and OS. **Results:** 146 subjects were accrued from 33 sites. 134 completed S0 and 118 completed both S0 and S1. After exclusion of uninterpretable scans, 107 were evaluable for change in rCBV, and 124 for baseline rCBV. There was no statistically significant difference in OS between subjects with binary increase (n=40; median OS 8.0 mos [90% CI 5.5–9.2]) vs. decrease (n=67; 7.9 mos [90% CI 6.3–10.3]) in mean nRCBV (p=0.67). Based on the spline fits, we observed a strong nonlinear association between OS and continuous nRCBV and sRCBV at both S0 and S1: low marker values are associated with lower risk, but beyond a threshold, higher values are not associated with greater risk. As an exploratory analysis, we estimated optimal cut points (nRCBV: S0=1.11, S1=1.16; sRCBV: S0=1.13, S1=0.99) and found that subjects whose S1 rCBV decreased below threshold had a median OS 2.7 mos (nRCBV, HR 0.61 [90% CI 0.41–0.88]) and 5.2 mos (sRCBV, HR 0.43 [90% CI 0.28–0.63]) longer than subjects whose rCBV either increased or did not decrease below threshold. **Conclusions:** EAF151 prospectively evaluated whether DSC-MRI markers predict OS in patients with rGBM treated with Bev. Although the change in these markers was not predictive, both baseline and early post-Rx markers were predictive of OS. Clinical trial information: NCT03115333. Research Sponsor: National Cancer Institute; U10CA180820, U10CA180794, U10CA180821, U10CA180868, UG1CA232760, UG1CA233198, UG1CA233270, UG1CA233196, UG1CA233253.

Recurrence patterns and site-level survival in the previous phase III study of IL13-PE38QQR: Implications for drug distribution variability. First Author: Sandeep Kunwar, Precision Neuromed, Redwood City, CA

Background: Interleukin-13–Pseudomonas Exotoxin A (IL13-PE38QQR) is a targeted cytotoxic fusion protein directed against the IL13α2 receptor expressed on glioblastoma stem cells and absent in normal brain tissue. The drug is administered by convection-enhanced delivery (CED) for recurrent glioblastoma (GBM). Early-phase studies demonstrated durable tumor control and long-term survival; however, a pivotal Phase III trial failed to meet its primary endpoint. We hypothesized that variability in clinical outcomes was driven primarily by limitations in drug delivery rather than tumor biology. **Methods:** We conducted a post hoc analysis of clinical, imaging, and survival data from the randomized Phase III PRECISE trial of IL13-PE38QQR versus Gliadel wafers. Treatment-site experience was defined as ≥3 efficacy-evaluable IL13-PE38QQR patients. A subset of patients underwent radiolabeled drug infusion to assess intraparenchymal distribution. Recurrence patterns were evaluated using serial MRI. Survival outcomes were compared by treatment arm and site experience. **Results:** Marked heterogeneity in drug distribution was observed in patients receiving radiolabeled IL13-PE38QQR, ranging from broad target coverage to minimal or absent delivery. In the IL13-PE38QQR arm, treatment at experienced centers correlated with significantly improved overall survival (median OS 48.4 vs 32.1 weeks; p=0.038), whereas site experience had no significant impact in the control arm. A 50% increase in 1-year survivorship was observed in the treatment arm compared with control. Long-term survivors most commonly exhibited distant or multifocal recurrence with relative preservation of the treated region, suggesting durable local tumor control where therapeutic exposure was achieved. **Conclusions:** Clinical outcomes following IL13-PE38QQR therapy were strongly associated with delivery efficiency and treatment-team experience. Radiolabeled distribution studies, experience-dependent survival effects, and recurrence patterns in long-term survivors indicate that outcome variability was driven primarily by technical limitations in drug delivery rather than tumor biology. This study represented the first large-scale evaluation of CED in the absence of purpose-built delivery technology, relying on complex, nonstandardized surgical workflows. These findings highlight the importance of standardized procedures, specialized training, and purpose-built delivery platforms to enable reproducible therapeutic exposure and optimize the clinical potential of IL13-PE38QQR. Clinical trial information: NCT00076986. Research Sponsor: None.

Scaling deep learning for neuro-oncology: Knowledge-distilled EfficientNetB0 powered MRI classification of brain tumors with international expert validation. First Author: Sophia Ahmed, Allama Iqbal Medical College, Lahore, Pakistan

Background: Accurate classification of brain tumors on magnetic resonance imaging (MRI) is critical for timely diagnosis, treatment planning, and referral in neuro-oncology. However, radiologic interpretation is challenged by tumor heterogeneity, overlapping imaging features, and growing imaging volumes, particularly in settings with limited subspecialty expertise. Although deep learning models have demonstrated high diagnostic accuracy, their computational complexity often limits real-world adoption. Scalable, resource-efficient AI systems capable of maintaining diagnostic performance are needed to enable global clinical translation. **Methods:** We retrospectively assembled a multicontinental dataset of 5,000 brain MRI studies from six continents, including pituitary tumors (n=1,200), meningiomas (n=1,300), gliomas (n=1,400), and non-tumor controls (n=1,100). Ground-truth diagnoses were established through independent review by at least two expert neuroradiologists. A high-capacity EfficientNetB4 model served as the reference architecture. A lightweight EfficientNetB0 model was trained using structured knowledge distillation with soft probabilistic supervision to preserve diagnostic fidelity while reducing computational cost. Model performance was evaluated on internal test data and independent external datasets using accuracy, class-specific sensitivity and specificity, F1-score, and area under the receiver operating characteristic curve (AUROC). **Results:** The distilled EfficientNetB0 model achieved an overall test accuracy of 94.8%, with balanced sensitivity across tumor classes (pituitary 93.1%, meningioma 95.2%, glioma 94.1%, non-tumor 96.4%). The overall F1-score was 0.946, and AUROC exceeded 0.92 on external validation datasets. Performance remained consistent across geographic regions and heterogeneous MRI acquisition protocols, with accuracy ranging from 93% to 96%. Mean inference time was 0.18 seconds per study on standard hardware, enabling real-time clinical integration. Clinician evaluators reported improved diagnostic confidence and utility for triage and workflow support. **Conclusions:** Knowledge-distilled EfficientNet models enable accurate, rapid, and computationally efficient classification of brain tumors on MRI without sacrificing clinically relevant performance. This scalable framework directly addresses key barriers to AI deployment in neuro-oncology and supports global implementation across resource-diverse settings. Prospective studies are planned to evaluate impact on diagnostic turnaround time, subspecialty access, and treatment decision-making. Research Sponsor: None.

Enabling hybrid AI–radiologist endpoints in clinical trials imaging workflows. First Author: Bharath Ramakrishna, Voiant, Waltham, MA

Background: Imaging endpoints in oncology clinical trials commonly rely on a 2 + 1 radiologist reading paradigm, in which two independent readers perform primary assessments and a third adjudicates disagreements. This model underpins response evaluation frameworks such as RECIST and RANO, but is resource-intensive and contributes to trial cost, operational complexity, and inter-reader variability. Advances in transformer-based deep learning for 3D medical imaging enable hybrid AI–radiologist workflows that may preserve adjudicated oversight while reducing primary human reads. We evaluated the feasibility of replacing one primary radiologist reader with AI in a hybrid 2+1 imaging workflow, using glioma segmentation as a representative use case and with consideration for near-term integration into clinical trial imaging platforms such as Voiant Hub. **Methods:** A 3D SwinUNETR open-source deep learning model implemented using the MONAI framework pre-trained to segment glioma subregions from multimodal MRI, including enhancing tumor and non-enhancing/edema components. Model performance was assessed using Dice similarity coefficients across a multi-case dataset, complemented by qualitative review of representative cases spanning high-agreement and high-discordance scenarios. Two reading paradigms were evaluated conceptually: (1) traditional radiologist–radiologist + adjudicator, and (2) AI–radiologist + adjudicator. AI–radiologist segmentation divergence was used as a proxy for adjudication likelihood and workflow impact. **Results:** AI segmentation demonstrated substantial concordance with reference contours in well-defined enhancing tumor regions, with performance variability reflecting known biological heterogeneity. Dice scores for enhancing tumor reached values as high as 0.80, with a broad distribution across cases. Qualitative review showed that AI–radiologist disagreements were most commonly associated with small-volume lesions, infiltrative margins, or low-contrast regions: patterns similar to known human inter-reader variability. The presence of an adjudicator preserved clinical oversight for discrepant cases while eliminating the need for a second full human primary read. **Conclusions:** A hybrid AI–radiologist 2+1 imaging workflow is feasible for glioma volumetric assessment and has broader implications for RECIST- and RANO-based endpoints in oncology clinical trials. Substituting AI for one primary radiologist reader preserves adjudicated decision-making while reducing manual read burden. The availability of configurable, regulator-aligned imaging platforms such as Voiant Hub positions this hybrid approach as a near-term, easily adoptable evolution of current reading paradigms. Prospective evaluation is warranted to quantify operational impact, adjudication rates, and endpoint consistency across solid tumor and neuro-oncology trials. Research Sponsor: None.

Impact of genomic subtype on intracranial outcomes in treatment-naive *EGFR*-mutant NSCLC with osimertinib (IGnITE). First Author: Emily Wo, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Osimertinib is the standard first-line therapy for *EGFR*-mutant NSCLC with brain metastasis (BM); however, alteration-specific patterns of CNS failure and mortality in treatment-naive patients remain poorly defined. **Methods:** We assembled an international muti-institutional cohort of TKI and radiation-naive *EGFR*-mutant NSCLC patients with BM treated with first-line osimertinib, with or without upfront stereotactic radiosurgery (SRS) (within 2 months of BM diagnosis). The primary endpoint was time to CNS progression. Time-to-event outcomes were analyzed using the Kaplan-Meier method. Multivariable hazard ratios (MHR) were estimated using Cox proportional hazards models. Fine and Gray hazard models were used for endpoints with competing risks. **Results:** From 2016-2024, 470 patients from 11 institutions were identified with the following alterations: exon 19 deletion (57%), L858R mutations (33%), and atypical/uncommon mutations (9.6%). Median follow-up was 25.6 months (IQR, 14.7-41.3 months). At 24 months, the cumulative incidence of CNS progression was 30% for exon 19 deletions, 47% for L858R mutations (MHR 1.68, $p<0.001$), and 76% for atypical mutations (MHR 4.33, $p<0.001$). Atypical alterations experienced markedly shorter time to local failure (MHR 4.88, $p<0·001$). Compared to exon 19 deletions, L858R (MHR 1.73, p=0.001) and atypical alterations (MHR 2.86, $p<0.001$) were associated with shorter time to distant CNS progression. L858R was also associated with higher risk of leptomeningeal disease (MHR 2.49, p=0.001). At 24 months, cumulative incidence of neurological death was 4.6% for exon 19 deletions, 7.8% for L858R, and 9.1% for atypical alterations (p=0.023). Upfront SRS was associated with improved CNS outcomes, with greater benefit for patients in L858R and atypical alterations. **Conclusions:** In the largest multi-institutional study of treatment-naive *EGFR*-mutant NSCLC with BM treated with first-line osimertinib, *EGFR* alteration subtype was an independent determinant of CNS progression, defined patterns of CNS failure, and identified patients most likely to benefit from treatment intensification with SRS. Research Sponsor: National Cancer Institute; P30-CA008748.

Burden of mortality due to brain metastases secondary to lung cancer in the United States: A population-based study. First Author: Dhivya Bharathi Govindaraj, Karur Government Medical College and Hospital, Karur, India

Background: Brain metastasis is a common and severe complication in lung cancer, contributing significantly to morbidity and mortality. Despite therapeutic advances, the burden remains substantial. This study examines mortality trends, disparities, and geographic variation using CDC WONDER data in the United States. **Methods:** We accessed the CDC WONDER Multiple Cause of Death database (1999–2023) to identify individuals who died of brain metastasis (ICD-10: C79.3) among lung cancer patients (ICD-10: C34.0–C34.9). Mortality disparities were examined by year, sex, race/ethnicity, and geography. Age-adjusted mortality rate (AAMR) per 100,000 was calculated. Joinpoint regression was used to estimate the average annual percentage change (AAPC) and annual percentage change (APC), with 95% confidence intervals (CIs). **Results:** The total of 207,151 deaths related to brain metastasis among lung cancer patients. Overall, the AAMR slightly decreased from 4.95 (95% CI: 4.85-5.05) in 1999 to 3.62 (95% CI: 3.55-3.69) in 2023 (AAPC: -1.40; 95% CI: -1.82 to -0.99, $p < 0.000001$). The trend initially declined, followed by an upward trajectory between 2013 and 2017 (APC: 3.03; 95% CI: 1.00 to 5.10), after which it remained relatively stable till the end of the study period (APC: 0.33; 95% CI: -0.29 to 0.95). The decrease in mortality was slightly more pronounced in men than in women (AAPC: -2.03 vs -0.74). The highest incidence rates were noted among non-Hispanic (NH) Whites, followed by NH Blacks or African Americans and NH Asians and Pacific Islanders. Geographic disparities were apparent, with the South experiencing the greatest impact, while the Northeast was the least affected. Rural regions consistently showed higher AAMR compared to urban areas, while urban locations experienced a steeper decline between the two (AAPC: -1.95 vs -0.92). **Conclusions:** Mortality from brain metastasis in lung cancer patients has slightly declined over the past two decades, with greater reductions observed in men. However, persistent disparities across race, geography, and rural–urban populations underscore the urgent need for targeted interventions and equitable healthcare strategies to achieve favorable outcomes. Research Sponsor: None.

Deaths and AAMR per 1,000,000 for trends related to lung cancer with brain metastasis, 1999 to 2023.

Variable	Deaths	AAMR (95%CI) 1999	AAMR (95% CI) 2023
Overall	207,151	4.95 (4.85 to 5.05)	3.65 (3.55 to 3.69)
Male	108,179	6.25 (6.07 to 6.42)	3.85 (3.74 to 3.96)
Female	98,972	3.98 (3.85 to 4.10)	3.41 (3.32 to 3.50)
NH White	176,368	5.17 (5.06 to 5.29)	4.05 (3.96 to 4.14)
NH Black	22,609	6.10 (5.71 to 6.48)	3.63 (3.41 to 3.85)
NH Asians	5,762	2.29 (1.84 to 2.73)	2.68 (2.42 to 2.94)
South	88,589	5.40 (5.22 to 5.59)	3.94 (3.82 to 4.06)
Northeast	30,890	4.60 (4.38 to 4.82)	2.64 (2.49 to 2.78)
Metro	120,044	1.51 (1.44 to 1.57)	(2020) 5.33 (5.23 to 5.42)
Non metro	27,540	1.39 (1.27 to 1.52)	6.17 (5.94 to 6.41)

Risk of developing brain/central nervous system (CNS) metastases across multiple *ERBB2*-altered cancer types: Genotype as shaper of phenotype. First Author: Aditya V. Shreenivas, City of Hope, Duarte, CA

Background: *ERBB2* (HER2) alterations are associated with increased risk of brain metastases in breast cancer and non-small cell lung cancer (NSCLC). However, the relationship between *ERBB2* alterations and brain metastasis across other tumor types remains unclear. We hypothesized that *ERBB2*-altered tumors demonstrate increased propensity for brain metastases across multiple cancer types. **Methods:** Using the US-based deidentified Flatiron Health-Foundation Medicine Clinico-Genomic Database (FH-FMI CGDB), we analyzed patients with advanced solid tumors who received ≥1 line of therapy. *ERBB2* alterations included pathogenic/likely pathogenic variants and amplifications. Brain/CNS metastases were identified via ICD-9/10 codes and validated against manual abstraction in NSCLC patients. Focusing on patients without brain/CNS metastases at diagnosis, we performed Cox proportional hazards analyses to evaluate time from initial diagnosis to first brain/CNS metastasis, modeling death as a competing risk. Multivariable models were adjusted for tumor types. **Results:** The analysis included 47,653 patients across 16 tumor types. Excluding breast/NSCLC, there were 29,272 patients: 2,149 *ERBB2*-altered (7.3%) and 27,123 *ERBB2*-wild type. 653 patients (30% of *ERBB2*-altered patients) had mutations and 1644 patients (77%) had amplifications (some had both). In a multivariable analysis adjusting for tumor type and excluding breast/NSCLC, *ERBB2* alterations independently predicted accelerated brain/CNS metastasis development (HR 1.55, 95% CI 1.29-1.86, $p<0.001$). In separate disease-specific Cox models, the strongest associations were observed in gastric (HR 2.33, 95% CI 1.68-3.22, $p<0.001$) and ovarian cancers (HR 2.52, 95% CI 1.45-4.38, $p<0.001$) as well as breast (HR 1.70, 95% CI 1.48-1.96, $p<0.001$) and NSCLC (HR 1.33, 95% CI 1.11-1.60, p=0.002). **Conclusions:** *ERBB2* alterations predict a significantly increased risk of accelerated development of brain/CNS metastases independent of tumor types, with the strongest effects observed in gastric and ovarian cancers in addition to breast and lung cancers. Research Sponsor: None.

2023 **Poster Session**

AI-assisted prediction of radiation failure patterns and survival after stereotactic radiosurgery for brain metastases: A multicenter study. First Author: Yuming Jiang, Wake Forest University School of Medicine, Winston-Salem, NC

Background: Brain metastases occur in approximately 20%–40% of patients with cancer and are associated with substantial morbidity and mortality. Stereotactic radiosurgery (SRS) is an effective and widely used treatment; however, a significant proportion of patients experience local, distant, or leptomeningeal failure after treatment. Early prediction of radiation failure patterns is critical for guiding individualized surveillance and treatment strategies. Current clinical tools remain inadequate for accurately predicting radiation failure in patients with brain metastases. **Methods:** In this multicenter retrospective study, we included 1,079 patients with brain metastases from three medical centers. We developed a novel deep learning model, the Global-to-Local Multiple-Instance Learning Mixture-of-Experts (GL-MIL MoE) framework. The model integrates a mask-guided multiscale encoder to process global MRI volumes and a multiple-instance learning (MIL) module to extract features from high-resolution local tumor patches. The primary endpoint was radiation failure pattern, defined as local failure, distant failure, or leptomeningeal failure. The secondary endpoint was overall survival (OS). Model performance was evaluated using the area under the receiver operating characteristic curve (AUC), concordance index (C-index), and decision curve analysis (DCA). Model interpretability was assessed using SHAP (Shapley Additive Explanations) and Grad-CAM analyses. **Results:** The proposed AI model demonstrated strong and consistent performance, achieving AUCs ranging from 0.78 to 0.83 across validation cohorts. C-indices for OS prediction remained robust and significantly outperformed established baseline models ($p < 0.05$). Multivariable logistic and Cox regression analyses confirmed the model-derived risk score as an independent predictor of both radiation failure patterns and OS ($p < 0.05$). The model effectively stratified patients into high- and low-risk groups across all cohorts. Decision curve analysis demonstrated meaningful and consistent clinical utility. **Conclusions:** This AI-based deep learning model enables accurate prediction of radiation failure patterns and survival in patients with brain metastases treated with SRS. Prospective studies are warranted to evaluate its clinical utility in guiding personalized treatment and surveillance strategies in combination with standard clinicopathologic factors. Research Sponsor: None.

Preclinical activity of homoharringtonine against melanoma leptomeningeal disease using patient-derived tumor cells. First Author: Vincent Law, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Leptomeningeal disease arising from melanoma (M-LMD) is a rare and highly aggressive form of metastasis associated with limited therapeutic options and poor clinical outcomes. Progress in treatment development has been hindered by the lack of clinically relevant models, particularly patient-derived circulating tumor cells obtained from cerebrospinal fluid (PD-CSF-CTCs). To overcome this limitation, we established protocols for CSF and tissue collection from patients with M-LMD, enabling successful *ex vivo* propagation of PD-CSF-CTCs and the generation of patient-derived xenograft models. These platforms facilitated integrated proteomic and transcriptomic analyses to identify M-LMD–specific pathways, thereby supporting the discovery of targeted therapeutic strategies. **Methods:** PD-CSF-CTCs were propagated from samples obtained from the CSF of patients with M-LMD. A library of 1,436 FDA-approved small molecules was screened using a high-throughput 384-well assay to identify agents that suppressed tumor cell proliferation. Lead compounds were subsequently assessed *in vivo* through intrathecal administration in xenograft models. **Results:** Twenty compounds (~1.4%) demonstrated complete cytotoxicity in both PD-CSF-CTCs and murine melanoma cell lines. The most potent agents included ponatinib (EC_{50}: $1.85–4.06\times10^{-6}$), sorafenib ($9.57–9.77\times10^{-6}$), ceritinib ($1.84–2.05\times10^{-6}$), and homoharringtonine (HHT; $3.63–4.11\times10^{-8}$). HHT, a plant-derived semisynthetic cephalotaxine ester, was prioritized for *in vivo* evaluation based on its robust cytotoxic activity and capacity to penetrate both the blood–brain and blood–CSF barriers. In a randomized murine M-LMD model, daily intrathecal administration of HHT (24.0 μg) was well tolerated, significantly prolonged survival ($P < 0.001$, Mantel–Cox test), and achieved complete responses in 27% of treated mice, while preserving body weight and motor function. **Conclusions:** This study introduces a robust preclinical platform for identifying effective treatments for M-LMD. Our findings highlight the promise of repurposing FDA-approved HHT as a therapeutic option. Future work will focus on refining HHT's activity against M-LMD and elucidating HHT's molecular mechanisms. Research Sponsor: None.

The impact of various radiation therapy options on plasminogen activation markers in the blood of patients with metastatic brain lesions. First Author: Irina A. Goroshinskaya, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: Metastatic brain disease (MBD) is found in almost a third of patients with malignant neoplasms and is characterized by a high mortality rate. The role of the fibrinolytic system has been demonstrated in neoplasms of various locations, while tissue plasminogen activator (t-PA) is studied less frequently than urokinase activator. The aim of this study was to investigate the level and activity of t-PA in the blood of patients with MBD receiving different radiotherapeutic treatments. **Methods:** Plasma from 38 patients of both sexes, aged 59.9 ± 8.9 years, with brain metastases confirmed by magnetic resonance imaging (MRI), was analyzed using enzyme-linked immunosorbent assay (ELISA) to determine t-PA activity and levels, calculate the ratio between them, and determine parameters of type 1 plasminogen activator inhibitor (PAI-1) and the receptor for both plasminogen activators (uPAR). The results were compared with data from 18 individuals without cancer (a donor group). Three groups were formed based on the treatment regimens: Control — stereotactic radiotherapy at the site of the resected metastasis with a single fraction dose (SFD) of 6 Gy up to a total dose of 30 Gy; Main Group No. 1 — after a preoperative radiosurgery session with an SFD of 10–15 Gy, the metastatic lesion was removed 24 hours later; Main Group No. 2 — staged radiosurgery (SRS) was performed in 3 sessions with an SFD of 10 Gy at 14-day intervals (total dose of 30 Gy). **Results:** Before treatment, a 2.1-fold increase in t-PA activity was observed in the blood of patients with MBD. This, together with a 3.6-fold reduction in t-PA content, led to a 10-fold increase in their ratio ($p \leq 0.0002$). Meanwhile, urokinase activator activity did not change. In the control group, t-PA activity remained elevated three days after surgery and did not differ from donor levels one month later, while t-PA levels remained reduced. In both main groups, elevated t-PA activity relative to donors was observed throughout the entire observation period, and after one month, it was 2.6 times higher than in the control group ($p \leq 0.001$). Only patients receiving SRS were characterized by an increase in the initially reduced t-PA content, with a change toward normalization of the t-PA activity-to-content ratio. This was accompanied by an increase in the activity of inhibitor PAI-1 and receptor uPAR to donor levels. **Conclusions:** The revealed dynamics of t-PA and PAI-1 parameters in SRS compared with other types of radiation therapy may be one of the factors contributing to the greater positive clinical efficacy of this developed method of staged radiotherapy in the treatment of metastatic brain tumors. Cerebrospinal fluid biomarker profiling in patients with non–small cell lung cancer and leptomeningeal disease. First Author: Mark Yungjie Jeng, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cerebrospinal fluid (CSF) cytology remains the standard for diagnosing leptomeningeal disease (LMD) and monitoring treatment response, but its clinical utility is limited by low sensitivity and nonquantitative results. The role of novel CSF biomarkers, such as circulating tumor cells (CTCs), in improving disease assessment in non–small cell lung cancer (NSCLC) with LMD is not fully defined. **Methods:** We performed retrospective clinical and genomic analysis of patients with NSCLC and LMD who underwent CSF CTC testing using the CellSearch platform at Memorial Sloan Kettering between 1/1/2015 and 11/5/2025. Time-to-event analyses were calculated from initial positive CSF CTC measurement ($\geq$3 cells/3mL) or from completion of proton craniospinal irradiation (pCSI). Optimal CTC cutoffs were determined using recursive partitioning analysis (RPA). CSF cytologic clearance was defined as an initial positive cytology followed by two consecutive negative results at least 4 weeks apart. Next-generation sequencing was performed using MSK-IMPACT. **Results:** Among 148 patients with NSCLC and LMD, 72% (n=105) were female, 53% (n=78) were never-smokers, and 92% (n=136) harbored an oncogenic driver alteration, most commonly epithelial growth factor receptor (*EGFR)* mutations (60%, n=89). Fourteen percent (n=20) were diagnosed with LMD at time of metastatic disease, whereas 54% (n=80) had received 2 or more prior lines of therapy. Sixty-two percent (n=92) received radiation therapy for LMD, including 43% (n=64) undergoing pCSI and 18% (n=26) undergoing photon radiation (involved field radiation therapy [IFRT] to brain/spine, n=10; whole brain radiation therapy [WBRT] alone, n=10; WBRT + IFRT to spine, n=4; photon CSI, n=2). With a median follow-up of 21.6 months (95% CI 16.2–37.9), patients with a lower baseline CSF CTC count ($\leq$90 CTCs/3mL, n=66; cutoff identified through RPA) had longer median overall survival (mOS; 10.2 vs 6.6 months; HR 0.53, 95% CI 0.35–0.79; p=0.002) compared with those with higher counts ($>$90 CTCs/3mL, n=82). Among patients who underwent pCSI with serial CSF testing (n=34), a $\geq$30% reduction in CTCs was associated with a longer mOS (13.1 vs 6.2 months; HR 0.15, 95% CI 0.05–0.47; p=0.0001) compared with those with $<$30% reduction; only 12% (n=4) achieved CSF cytologic clearance. In *EGFR*-mutant NSCLC, genomic analysis of CSF samples with higher baseline CTC count ($>$90 CTCs/3mL, n=24) demonstrated a higher frequency of *TP53* (p=1.559e-3) and *MTAP* (p=8.31e-3) alterations, and a lower frequency of *MDM2* (p=0.05) alterations, compared to patients with lower baseline CTC counts ($\leq$90 CTCs/3ml, n=23). **Conclusions:** Lower baseline CSF CTC counts and reductions following pCSI are associated with improved survival in patients with NSCLC and LMD. CSF CTC assessment provides a quantitative measure of LMD burden and may complement conventional CSF cytology. Research Sponsor: None.

Preclinical efficacy and brain uptake of an insulin-mediated nanoparticle co-delivering trastuzumab and pertuzumab (AxS007) in HER2+ breast cancer brain metastasis models. First Author: Ayelet Zafran, Nanocarry Therapeutics Ltd., Ness Ziona, Israel

Background: Anti-HER2 antibodies are standard therapies for metastatic HER2+ breast cancer but demonstrate limited intracranial activity due to restricted penetration across the blood–brain barrier (BBB). AxS007 is an insulin-mediated nanoparticle conjugated to trastuzumab and pertuzumab designed to enhance BBB transport and increase brain exposure. **Methods:** Brain uptake and distribution were assessed in C57BL mice using biodistribution analysis (5 min–90 days, n=25) and two-photon microscopy, comparing AxS007, a non-insulin-conjugated nanoparticle control, and free trastuzumab. Brain uptake was also evaluated in non-human primates (NHPs). Based on confirmed BBB penetration and brain exposure, AxS007 antitumor activity was evaluated in vitro in HER2+ cell lines (BT474, SKBR3, N87) and in vivo in BT474 subcutaneous (SC; n=20) and intracranial xenografts. Tumor growth inhibition (TGI) was assessed by MRI, and survival was compared between vehicle, AxS007 (IV, 10 mg/kg), and free trastuzumab + pertuzumab (IV, 10 mg/kg each). Safety was further investigated through single ascending dose (SAD) and multiple ascending dose (MAD) toxicological studies. **Results:** In mice, AxS007 demonstrated measurable brain uptake within 30 min and widespread parenchymal distribution at 24 h, with markedly higher brain exposure than free trastuzumab; in contrast, the non-insulin control and free antibodies showed minimal BBB crossing. In NHPs, AxS007 increased brain antibody exposure ~50-fold versus free antibodies at 48 h. In vitro, AxS007 showed antitumor activity comparable to or greater than free antibodies (SKBR3: 90% vs 50%; BT474: 50% vs 64%). In vivo, AxS007 achieved near-complete tumor elimination in SC tumors and demonstrated 82% TGI versus vehicle ($p<0.01$) and 60% TGI versus free trastuzumab +pertuzumab ($p<0.05$) in intracranial tumors, as assessed at day 60 post-inoculation. In an overall survival study, AxS007 extended survival approximately 3-fold compared with free trastusumab + pertuzumab. AxS007 exhibited a good safety profile with no drug related side effects. **Conclusions:** AxS007 showed enhanced BBB penetration and increased brain antibody exposure, with improved preclinical efficacy versus free antibodies in HER2+ breast cancer brain metastasis models. These findings support further translational advancement of AxS007 toward first-in-human clinical testing. Research Sponsor: Nanocarry Therapeutics Ltd.

Real-world outcomes of systemic therapy sequencing after earlier-generation EGFR TKI failure in NSCLC with brain metastases. First Author: Atulya Aman Khosla, Department of Internal Medicine, William Beaumont University Hospital, Royal Oak, MI

Background: Patients with EGFR-mutated non–small cell lung cancer (NSCLC) frequently develop BM, and CNS progression is a common mode of failure on earlier-generation EGFR tyrosine kinase inhibitors (TKIs). After TKI failure in the setting of BM, optimal next-line systemic therapy remains uncertain, particularly regarding the comparative effectiveness of targeted escalation, immunotherapy (IO)-based regimens, and chemotherapy. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. We identified EGFR-mutated NSCLC patients treated with first- or second-generation EGFR TKIs who subsequently developed metachronous BM and initiated next-line systemic therapy between 2015 and 2025. Patients with leptomeningeal disease prior to earlier-generation TKI exposure were excluded. Treatment strategies were categorized as targeted escalation with osimertinib, IO-based therapy (immune checkpoint inhibitor with or without chemotherapy), or chemotherapy alone. The index date was defined as initiation of next-line systemic therapy. Propensity score matching was performed for pairwise comparisons. The primary endpoint was overall survival (OS) at 180 days. Restricted mean survival time (RMST) through 181 days was evaluated as a sensitivity analysis. Baseline covariate balance after matching was assessed using standardized mean differences, with values <0.10 indicating adequate balance. **Results:** After propensity score matching with adequate baseline balance, osimertinib was associated with significantly lower 180-day mortality compared with chemotherapy (24.5% vs 33.2%; hazard ratio [HR] 0.69, 95% CI 0.47–1.00). Comparisons between osimertinib and IO-based therapy showed numerically lower 180-day mortality with osimertinib (26.0% vs 32.6%; HR 0.79, 95% CI 0.54–1.15), but this difference did not reach statistical significance. Similarly, IO-based therapy was not associated with a statistically significant survival advantage compared with chemotherapy alone (31.7% vs 37.5%; HR 0.78, 95% CI 0.58–1.06). RMST analyses for death over 181 days were directionally consistent with hazard ratio–based results, with modest, non-significant differences in mean survival time. **Conclusions:** In EGFR-mutated NSCLC patients with metachronous brain metastases after earlier-generation TKI failure, targeted escalation with osimertinib was associated with significantly lower 180-day mortality compared with chemotherapy. IO-based approaches demonstrated intermediate, directionally favorable but non-significant outcomes relative to both osimertinib and chemotherapy. These real-world findings support guideline recommendations prioritizing next-generation TKIs and help inform systemic treatment sequencing in a CNS-enriched population where prospective data remain limited. Low-density lipoprotein receptor–related protein 1 overexpression as an identifier of brain metastasis and survival for patients with lung cancer. First Author: Wendi Mo, Zhongda Hospital, School of Medicine, Southeast University, Nanjing, Jiangsu, China

Background: Brain metastasis (BM) is a major cause of mortality in lung cancer. Low-density lipoprotein receptor–related protein 1 (LRP1) has been implicated in tumor invasion and microenvironment regulation; however, its clinical relevance in lung cancer brain metastasis remains unclear. **Methods:** This retrospective, single-center study included 103 lung cancer patients (including NSCLC and SCLC) diagnosed between January 2013 and February 2025. LRP1 protein expression was evaluated by immunohistochemistry in primary lung tumors and lesions of lung cancer with brain metastasis (unpaired samples). Mean optical density was quantified, and the optimal cutoff for high versus low expression was determined using receiver operating characteristic analysis. Overall survival (OS) and distant metastasis–free survival (DMFS) were assessed using Kaplan–Meier analysis and Cox proportional hazards models, adjusting for pathological type, age, sex, T stage, and N stage. Gene set variation analysis (GSVA), immune cell infiltration analysis (CIBERSORT), and immunotherapy response prediction using TIDE were performed to explore biological characteristics associated with LRP1 expression. **Results:** LRP1 expression was significantly higher in lung cancer tissues from patients with BM compared with those without BM ($P < 0.0001$). Among patients with BM, high LRP1 expression was associated with poorer OS (P = 0.0352) and shorter DMFS (P = 0.0183). In multivariable analysis, high LRP1 expression remained independently associated with inferior OS (HR 3.064, 95% CI 1.039–9.034; P = 0.042). GSVA suggested that LRP1-high tumors may be characterized by enrichment of TGF-β, NOTCH, and HEDGEHOG signaling pathways. Immune deconvolution analysis revealed higher infiltration of resting memory $CD4^+$ T cells and M0 macrophages in the LRP1-high group. LRP1-low expression was associated with a more favorable predicted response to immunotherapy, as indicated by lower TIDE scores. **Conclusions:** LRP1 overexpression is associated with brain metastasis, unfavorable survival, and distinct immune features in lung cancer, suggesting its potential value as a prognostic biomarker. Neoantigen prediction and reactivity of cerebrospinal fluid–human-derived tumor reactive T cells (CSF-TRT cells) in leptomeningeal disease (LMD) from solid tumors. First Author: Yolanda Pina, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Leptomeningeal disease (LMD) is a devastating complication of metastases and its incidence is increasing. Adoptive cell therapy (ACT) using tumor-infiltrating lymphocytes (TILs) showed complete responses in patients with metastatic melanoma and other solid tumors. To obtain CSF-TRT cells as a source of T cells for ACT, we aim 1) to identify the expansion method that allows higher expansion of tumor reactive TIL; 2) to enrich tumor neoantigen reactive TILs and determine their in-vivo and ex-vivo functional capabilities. **Methods:** Cells were isolated from 64 CSF collections from melanoma (M-LMD), 9 CSF from breast cancer (B-LMD), and 9 CSF from lung adenocarcinoma (L-LMD) from patients with LMD. Cells were plated following established TIL culture protocols (high-dose IL-2): 1) OKT3, 2) anti-4-1BB-agonist, 3) IL-7+IL-15+IL-21, 4) anti-CD3/CD28-T-activator, 5) anti-CD3/CD28/CD137-T-activator, 6) anti-CD3/CD28-T-expander. After 4-6 weeks, reactivity was assessed with HLA-matched or autologous tumor cells. Additionally, Whole Exome Sequencing (WES) and RNA sequencing were performed in T cells expanded from CSF and pair-matched extracranial tumors from 12 patients with M-LMD for epitope prediction to identify neoantigens that may be targets of immunoediting using computational algorithms. **Results:** CSF yielded an average of 1.204e5 viable cells for expansion. After culture in IL-2, 53.4% of samples showed increased cell yield with average 165.29-fold expansion. PreREP resulted in 37.6% CD8+ T cells. REP had a 96.8% success rate (mean 589.87-fold expansion). Post-REP flow cytometry revealed expansion of CD4+ T cells. Additional cultures produced similar yields with reduced T cell input requirement and demonstrated the potential to enrich for CD8+ T cells. Out of five samples tested for reactivity to HLA-matched melanoma cell lines, three produced varying levels of IFN-γ. T cells expanded from CSF samples from L-LMD and B-LMD had less successful results. L-LMD had a success expansion rate of 11.1% with IL-2 only, 83.3% with T-Activator, 50% with CD127 T Activator, and 50% with T-Expander. B-LMD had a success rate of 22.2% with IL-2 only, 0% with OKT3, 83.3% with T-Activator, 50% with CD137 T-Activator, and 85.7% with T-Expander. One of the CSF samples from L-LMD tested showed reactivity to autologous HLA-matched tumor cells, whereas none of the CSF T cells from B-LMD showed a successful reactivity. Preliminary studies demonstrated CSF TIL reactivity against tumor reactive neoantigens. Ongoing studies will confirm our results. **Conclusions:** Results demonstrate successful expansion of T cells *ex vivo* from CSF in M-LMD, raising the potential to use CSF-derived T-cells as therapeutic strategy for LMD. There was a variable success rate with expansion of T cells from CSF from B-LMD and L-LMD and supplementary studies are needed. Research Sponsor: None.

Intracranial pharmacokinetics and resistance mechanisms of tucatinib in patients with HER2+/mutant solid tumors and brain metastasis: Results from the WinHER2 study (NCT05892068). First Author: Emanuela Ferraro, European Institute of Oncology, Milan, Italy

Background: Tucatinib, a potent HER2-selective tyrosine kinase inhibitor approved for the treatment of HER2-positive (+) metastatic breast cancer (MBC) and colorectal cancer (CRC), has demonstrated activity in stable and active brain metastasis (BrM). However, intracranial pharmacokinetics and specific mechanisms of resistance driving BrM progression remain unknown. **Methods:** This window-of-opportunity, prospective, non-randomized study evaluated tissue and serum levels of tucatinib ([Tt], [Ts]) in patients undergoing BrM resection for HER2+/mutant (mut) MBC, NSCLC, CRC or gastroesophageal cancer. HER2+ MBC patients were enrolled in 2 parallel cohorts: those with progressing BrM while on tucatinib (A) and tucatinib-naïve patients (B); cohort C was comprised of patients with GI malignancy, NSCLC and mutHER2 MBC. All patients received tucatinib 300 mg BID for 4 days preoperatively. [Tt/s] were measured by mass spectrometry in resected BrM and serum at screening and 3 intraoperative timepoints; CSF [T] was collected when available by optional lumbar puncture. BrM tissue was used for correlative studies including WGS, scRNA-seq, and electron microscopy. The primary endpoint compared BrM-to-serum tucatinib ratios between cohorts A and B with lower ratios hypothesized in cohort A. [T] was reported as median and interquartile range (IQR). **Results:** 9 female patients enrolled between 7/2023 and 12/2025: 3 in cohort A, 5 in cohort B, and 1 HER2+ CRC patient in cohort C. Median age was 48.5 years (43-65). One patient from cohort B was unevaluable due to lack of viable recurrent disease on pathologic examination. Total tucatinib levels in resected BrMs ranged from 2.22 to 192.87 ng/mg, (median=30.82; IQR=16.52-111.84) in cohort A and from 1.5 to 4.21 ng/mg (median=3.04; IQR=1.93-4.05) in cohort B. The median tucatinib serum concentration was 1158.3 ng/mL (range=229.2-3440; IQR=693.78-2299.17) and 365.52 ng/mL (range=167.23-731.03; IQR=176.47-596.37), in cohorts A and B, respectively. The BrM/serum ratio did not differ between cohorts A and B (median=9.7; range=9.0-166.5; IQR=9.43-102.77] vs 7.36 [range=3.77-22.28; IQR=5.26-12.30]). The single cohort C patient had tucatinib BrM level of 1.66 ng/mg and BrM/serum ratio of 7.41. CSF [T] was available in two cohort A patients: it was undetectable in one and 35.71 ng/mL in the other (BrM/CSF ratio: 5401). **Conclusions:** Patients with progressing BrM while receiving tucatinib had BrM/serum tucatinib ratios similar to those of patients receiving tucatinib for the first time in the trial. These data indicate that intratumoral drug concentration alone is unlikely to account for intracranial acquired resistance. Correlative analyses investigating potential genomic and microenvironmental mechanisms of resistance are ongoing, and results will be presented at the meeting. Clinical trial information: NCT05892068. Research Sponsor: Pfizer.

2032 **Poster Session**

Genomic correlates of leptomeningeal disease after brain metastasis resection. First Author: Roshal R. Patel, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Leptomeningeal disease (LMD) remains a frequent and devastating pattern of failure following surgical resection of brain metastases (BM), occurring in up to one-third of patients despite optimal local therapy. Although mechanical disruption of BM tissues may increase the risk of subsequent LMD, the underlying biologic determinants of postoperative LMD remain undefined. This study aims to identify genomic alterations in resected BM and their association with LMD development using the largest craniotomy cohort to date with paired next-generation sequencing and longitudinal CNS outcomes data. **Methods:** We retrospectively identified patients who underwent surgical resection and MSK-IMPACT next-generation sequencing of one or more BM. LMD was diagnosed using brain and spine MRI and CSF cytology and classified as either classical LMD (cLMD; diffuse coating of meningeal spaces and/or positive CSF cytology), nodular LMD (nLMD; discrete nodular deposits with negative CSF cytology), or both. Fine–Gray subdistribution hazard (sHR) estimated the cumulative incidence of LMD, treating death as a competing risk. **Results:** Among 1,006 patients, NSCLC (360, 36%), breast (181, 18%), and melanoma (128, 13%) predominated; most patients had single (530, 53%), supratentorial (796, 79%), and large (>2cm, 886, 88%) BM, and underwent postoperative cavity radiotherapy (890, 88%). Median follow-up and OS were 24.8 and 21.5 months, respectively. The cumulative incidence of LMD was 31% (cLMD 18%, nLMD 19%) at 2 years, with the highest rates seen in breast cancer patients (45% LMD; cLMD 28%, nLMD 23%). Median time to cLMD and nLMD were 7.7 and 6.4 months, respectively. Median OS after cLMD and nLMD diagnosis were 5.7 and 12 months, respectively. The most frequently altered genes in resected BM were TP53 (62%), CDKN2A (25%), TERT (23%), KRAS (20%), ERBB2 (12%), PIK3CA (12%), PTEN (12%), and RB1 (11%). In a pan-cancer analysis, alterations in CDH1 (sHR 3.0, q=0.03), EGFR (HR 2.5, q<0.001), GATA3 (sHR 2.2, q=0.03), or RB1 (sHR 1.7; q=0.04) were associated with an increased risk of cLMD; alterations in PTEN were associated with an increased risk of nLMD (sHR 1.8, q=0.02). Within breast and lung cohorts, alterations in RB1 or EGFR, respectively, were associated with an increased risk of cLMD. BM from patients who developed LMD exhibited greater genomic instability, with a higher fraction of the genome altered compared to those who did not (0.47 vs 0.40, p<0.001). **Conclusions:** LMD is a common and deadly form of progression following BM resection. Distinct genomic features, present in the resected BM specimen, may identify patients at increased risk of LMD. These findings support the development of a clinicogenomic model to select BM patients for intensified surveillance and postoperative care. Research Sponsor: U.S. National Institutes of Health; P30 CA008748.

Distinct genomic and microenvironmental profiles of brain metastases in renal cell carcinoma: Insights into hypoxia-driven adaptation and therapeutic vulnerabilities. First Author: Jorge Avila, Montefiore Medical Center, Bronx, NY

Background: Brain metastases (BM) in renal cell carcinoma (RCC) are associated with poor prognosis and may exhibit unique genomic alterations influenced by the tumor microenvironment (TME), differing from primary tumors or extracranial metastases (ECM). This study aimed to characterize these differences to identify potential therapeutic targets. **Methods:** 3,913 RCC samples underwent NGS of DNA and RNA at Caris Life Sciences (Phoenix, AZ) and were linked to corresponding insurance claims data. Real-world overall survival (rwOS) was calculated from the date of sample collection to last contact using Cox PH model and log-rank testing. Genomic alterations were compared at an adjusted significance level of 0.05 using Fisher's exact test. TME differences between the primary RCC, BM and ECM were assessed by therapeutic target gene expression using Mann-Whitney U test, gene set enrichment analysis (GSEA) by normalized enrichment scores (NES) and false discovery rates (FDR), and a gene expression-based score reflecting HIF1-associated metabolic and stress-response pathways. **Results:** The cohort consisted of 1,775 primary, 138 BM, and 2,000 ECM. Median age was different in BM vs ECM vs primary (64 vs 66 vs 63 y, p<0.0001). Approximately 75% of BM patients had not received any systemic or radiation therapy prior to tissue collection. The rwOS was 49.4 months for primary, and 30.3 months for both BM and ECM (BM vs. ECM: HR=0.96, 95%CI: 0.76-1.22, p=0.796). Genomic profiling revealed, in BM compared with primary tumors, *CDKN2B* deletions (41% vs. 18.1%, p<0.0001), as well as *PTEN* (22.5% vs 6.7%, p<0.0001), and *TP53* mutations (22.7% vs 11%, p=0.0088). Gene expression analysis demonstrated no significant differences in the expression of RCC novel therapeutic targets, including *CD70*, *ENPP3*, *CA9*, *HLA-G*, *CDH6* and *FOLH1*, between BM and primary (p>0.05). Compared to primary, GSEA revealed BM were enriched in pathways including epithelial-mesenchymal transition (NES=3.41, FDR<0.001), mTORC1 signaling (NES=3.05, FDR=0.002), hypoxia (NES=2.68, FDR=0.009), and others. Compared to ECM, BM showed hypoxia enrichment (NES=2.90, FDR=0.023), while ECM was enriched in mitotic spindle (NES=-3.84, FDR<0.0001) and G2M checkpoints (NES=-3.32, FDR<0.0001). The HIF1-associated hypoxia score was significantly higher in BM vs primary (p<0.01). **Conclusions:** Conserved expression of multiple actionable RCC therapeutic targets across primary and BM sites supports the biological feasibility of emerging targeted and immune-based therapies in CNS disease. The findings provide a biologic framework for understanding RCC BM and highlight hypoxia-associated pathways. Key limitations include the use of tissue-based rather than clinically adjudicated BM definitions, and the lack of cancer stage information. Research Sponsor: None.

Central nervous system metastases in hereditary breast cancer according to germline pathogenic variants: A real-world cohort study. First Author: Eduarda Mirela Da Silva Montiel, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: Hereditary breast cancer (HBC) accounts for approximately 5–10% of cases and involves pathogenic germline variants (PGVs) beyond *BRCA1/2*. While metastatic patterns differ by tumor subtype, data on central nervous system (CNS) metastases according to germline genetics remain scarce. We evaluated the incidence, clinical characteristics and survival outcomes of CNS metastases in metastatic according to PGV subgroup. **Methods:** A cohort retrospective study included patients aged ≥18 years with invasive or microinvasive breast cancer and confirmed PGVs treated between 2019 and 2025 at A.C. Camargo Cancer Center. Clinical, histopathologic, and molecular data were analyzed in R. Associations were assessed using chi-square or Kruskal–Wallis tests. Survival outcomes were estimated by Kaplan–Meier. CNS-related progression-free survival (CNS-PFS) was defined from treatment initiation after CNS metastasis to intracranial progression or death. Overall survival after CNS metastasis (OS post-CNS) was defined from CNS metastasis to death. Median survival times with 95% confidence intervals (CIs) were reported. **Results:** Among 1,353 individuals evaluated, 463 patients with pathogenic germline variants (PGVs) were included. Median age at diagnosis was 43.7 years, and 99.6% were women. The most frequent PGVs were *BRCA1* (32.0%), *BRCA2* (22.2%), and *TP53* (12.1%). *BRCA1* carriers were diagnosed earlier than other genotypes (p = 0.0005). CNS metastases occurred in 21 patients (4.5%), mainly among *BRCA*-associated PGVs and *TP53*, with additional cases in *PALB2*, *ATM*, and *RAD*-related variants; none occurred in *CHEK2*, *FANCA*, or Lynch-associated variants. CNS involvement was mainly parenchymal-only (71.4%), with meningeal-only (19.0%) or combined disease (9.5%). Lesions were supratentorial-only in 47.1% and both supra- and infratentorial in 47.1%. Diagnosis was symptom-driven in 70.0%. Single CNS metastasis occurred in 38.9%, and local therapy alone was most commonly used (66.7%). No statistically significant differences in CNS metastatic patterns were observed across PGV subgroups (p > 0.05). Median OS after CNS diagnosis was 14 months (95% CI, 5–NR), and median CNS-PFS was 17 months (95% CI, 7–NR). **Conclusions:** In metastatic HBC, CNS metastases are uncommon but preferentially occur among patients harboring *BRCA*-associated and *TP53* pathogenic germline variants. Germline genetics may contribute to distinct metastatic phenotypes and support risk-adapted CNS surveillance strategies and therapeutic strategies in metastatic HBC. Research Sponsor: None.

Continued CNS-penetrant TKI therapy with or without local CNS therapy after brain metastasis diagnosis in NSCLC. First Author: Atulya Aman Khosla, Department of Internal Medicine, William Beaumont University Hospital, Royal Oak, MI

Background: Patients with oncogene-driven metastatic non–small cell lung cancer (NSCLC) treated with CNS-penetrant tyrosine kinase inhibitors (TKIs) frequently develop brain metastases (BM) while continuing targeted therapy, and outcomes of adding local CNS-directed therapy in this setting are not well defined. We evaluated outcomes associated with local CNS therapy after post-TKI BM diagnosis. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. Adults with NSCLC treated with osimertinib or lorlatinib who subsequently had a coded diagnosis of BM (ICD-10 C79.31) at least 1 month after TKI initiation and evidence of continued TKI use were included. Patients were stratified by receipt of CNS-directed local therapy (SRS/SBRT or neurosurgery) within 3 months of the index BM diagnosis versus no local therapy. The primary outcome was all-cause mortality within 180 days of the index event. Secondary outcomes included hospitalization and systemic corticosteroid use. Cohorts were balanced using 1:1 propensity score matching on demographics, comorbidities, extracranial disease, laboratory values, and TKI exposure. Survival analyses were performed, and proportional hazards assumptions were validated using Schoenfeld residuals (p>0.05). **Results:** Among 1,157 eligible patients, 1,053 matched pairs were generated. Within 180 days of the index brain metastasis diagnosis, mortality was lower among patients who received local CNS therapy compared with those who did not (10.9% vs 18.1%), corresponding to a hazard ratio (HR) for death of 0.54 (95% CI 0.43–0.68; p<0.001). Survival probabilities at 180 days were 88.7% in the local therapy cohort and 80.2% in the no local therapy cohort. Hospitalization within 180 days occurred in 20.3% of patients receiving local therapy and 22.4% of those without local therapy (p=0.24), with a nonsignificant trend toward delayed hospitalization (HR 0.84, 95% CI 0.69–1.01). Systemic corticosteroid use was common and similar between groups (61.3% vs 59.4%; p=0.40), with no significant difference in time to steroid initiation. In an osimertinib-only sensitivity analysis, 180-day mortality was 10.5% among patients receiving local CNS therapy compared with 19.4% among those without local therapy (HR 0.48, 95% CI 0.37–0.61; p<0.001). **Conclusions:** In this multi-institutional real-world cohort of patients with NSCLC receiving osimertinib or lorlatinib who developed BM, receipt of local CNS-directed therapy within 3 months was associated with lower 6-month mortality compared with continuation of targeted therapy alone, with consistent findings in an osimertinib-only sensitivity analysis. These results suggest a potential survival benefit of local CNS intervention in selected patients, while acknowledging residual confounding related to intracranial disease burden and clinical indication. Intrathecal (IT) therapy–associated pseudoprogression (PsP) in leptomeningeal metastases (LM) from solid tumors. First Author: Zhenyu Pan, Department of Radiation Oncology, Beijing Chest Hospital, Capital Medical University, Beijing, China

Background: Intracranial PsP following systemic immunotherapy has been recognized. IT therapy is a cornerstone of LM management, and prior studies support the safety and feasibility of IT immunotherapy. The occurrence of PsP specifically after IT immunotherapy for LM remains unreported. This study aims to characterize the clinical and proteomic profile of IT therapy–associated PsP (IT-PsP). **Methods:** This prospective case series consecutively enrolled LM patients receiving IT therapy between February 2024 and January 2026. Patients were treated with IT pemetrexed (PM) alone or combined with immunotherapy (PD-1 inhibitors, PD-1/CTLA-4, or PD-1/VEGF antibodies). Treatment response was assessed per RANO-LM criteria. Based on the iRANO criteria, IT-PsP was considered as radiographic progression without significant worsening of LM-related symptoms or neurological deficits. Furthermore, patients were defined as IT-PsP only if they also met at least one of the following criteria without salvage LM-directed therapy: sustained conversion of cerebrospinal fluid (CSF) cytology to negative, subsequent neuroimaging improvement, or absence of progressive neurological symptoms/signs with stable disease for $\geq$3 months. CSF proteomics was analyzed via Olink Target 96 Immuno-Oncology panel. **Results:** Of 144 enrolled patients, 75 received IT PM and 69 received IT immunotherapy plus PM. IT–PsP was identified in 12 patients (8.3%). Median age was 53.5 years (range 30–66) and 10 were female. Primary tumors were lung adenocarcinoma (n=11) and breast cancer (n=1). None received concurrent systemic immunotherapy. The median time to PsP occurrence was 5.2 months (range 1.5–12) after the first IT treatment. PsP incidence was significantly higher in the combination group (15.9%, 11/69) than with IT PM alone (1.3%, 1/75) (P=0.002). 6 (50%) achieved sustained conversion to negative CSF cytology. Radiographically, lesions improved in 7 patients (58.3%) and remained stable in 2 (16.7%). All PsP patients were followed up for a median of 7.1 months (range 1–13.6) with no neurological progression. Median overall survival from enrollment and from PsP onset were not reached. CSF proteomic profiling revealed that IT-PsP samples, compared to both progressive LM and pre-treatment samples, showed significant downregulation of tumor-associated proteins (CCL20, LAP TGF-beta-1, IL8, CCL4). Furthermore, compared to post-treatment response samples, IT-PsP was associated with significant upregulation of inflammatory markers, including Gal-9, IL15, and ADA. **Conclusions:** This study characterizes the clinical features and distinct CSF proteomic signature of IT-PsP in LM. The significantly higher PsP incidence with IT immunotherapy underscores that, in the immunotherapy era, relying exclusively on neuroimaging to define LM progression necessitates careful re-evaluation. Outcomes of CD-19–directed CAR-T therapy in patients with primary and secondary central nervous system lymphoma: A multi-center observational study. First Author: Shilajeet Ray, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV

Background: CD-19 directed chimeric antigen receptor T-Cell (CAR-T) therapies have been approved for the treatment of diffuse large B-Cell lymphoma; however, patients with primary central nervous system (CNS) lymphoma were excluded from pivotal registration trials. Although early-phase trials and meta-analysis suggest promising efficacy in CNS lymphoma, existing data remain limited by small sample sizes. We conducted a large, multicenter observational study evaluating outcomes of CD19-directed CAR-T therapy in patients with primary or secondary CNS lymphoma. **Methods:** This study utilized the TriNetX database, encompassing over 110 healthcare organizations, to evaluate outcomes of adults with a diagnosis of primary or secondary CNS lymphoma prior to receiving CAR T therapy between 2019 and 2025. Outcomes were assessed from the time of CAR-T infusion. The outcomes analyzed were 1-year overall survival, as well as development of cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), treatment with tocilizumab, and risk of infection within 100 days post-CAR-T infusion. Kaplan-Meier estimated event rates were used to assess the primary outcomes. **Results:** We identified 155 patients with a diagnosis of primary or secondary lymphoma who received CD-19 directed CAR-T therapy. The median age at CAR-T infusion was 63 years. The cohort was predominately male (57%) and white (87%). A majority of the cohort, 80%, received Fludarabine/ Cyclophosphamide for lymphodepletion chemotherapy; 16% received Bendamustine. Most patients received axicabtagene ciloleucel (n=78), followed by lisocabtagene maraleucel (n=56), and tisagenlecleucel (n=21). The Kaplan–Meier estimated overall survival at one and three years was 63.9% and 46.9%, respectively. The estimated cumulative risk for CRS and ICANs post-CAR-T infusion was 58.7% and 26.5% respectively – 49.0% were treated with tocilizumab. The risk of infection by day 100 post-CAR-T infusion was 43.2%. **Conclusions:** CNS lymphomas have been associated with limited overall survival and represent an unmet need, necessitating the emergence of new therapeutic strategies. Our findings support the efficacy and safety of CAR-T in this population. To our knowledge, this is the largest single observational study of patients with CNS lymphoma treated with CAR-T. Research Sponsor: None.

Outcome	Time Point	Rate (%) (n = 155)
Overall Survival	1 years	63.9%
	3 years	46.9%
CRS	60 days	58.7%
ICANS	60 days	26.5%
Tocilizumab Use	60 days	49.0%
Any Infection	100 days	43.2%

The association of economic measures and patient outcomes with geographical disparities in access to a UCNS board-certified neuro-oncologist in the United States. First Author: Maksym Horiachok, Bukovinian State Medical University, Khmelnytskyi, Ukraine

Background: Neuro-oncology is increasingly centralized in academic tertiary centers, potentially creating geographic and economic inequality. This study aims to quantify the national distribution of neuro-oncologists in the United States and evaluate the association between regional economic capacity, metropolitan urbanicity, and population-level clinical outcomes. **Methods:** We conducted a nationwide cross-sectional ecological analysis using 2025 United Council for Neurologic Subspecialties (UCNS) data, US Bureau of Economic Analysis state-level GDP, and US Census Bureau demographics. Spatial accessibility was modelled for US counties using geodesic distance from population centroids. Outcome measures included CNS tumor mortality and Disability-Adjusted Life Years (DALYs). **Results:** We identified 323 UCNS board-certified neuro-oncologists distributed across 70 Metropolitan Statistical Areas (MSAs). Workforce distribution was strongly associated with state-level economic magnitude (r=0.930 [95% CI: 0.878–0.960], $p<0.0001$), with gross domestic product (GDP) explaining 86.4% of variance (R2=0.864). Critically, economic intensity independent of state population was a significant driver, with GDP per capita correlating with specialist density (r=0.344, p=0.014). Specialists were located exclusively within MSAs ($?^2$ = 52.28, $p < 0.0001$), however 81.9% of MSAs lacked local subspecialty presence. Spatial analysis revealed 45.4% of the US population has local access (<20 miles), while 16.5% (55.2 million Americans) live in "Care Deserts" greater than 100 miles from the nearest neuro-oncologist. Increased specialist density predicted lower mortality rates for pediatric (ρ = −0.34 [95% CI: −0.56 to −0.07], p = 0.015) and adult (ρ = −0.352 [95% CI: −0.57 to −0.08], p = 0.011) groups. Similar inverse associations were observed for DALYs in both pediatric (ρ=−0.339 [95% CI: −0.57 to −0.07], p = 0.015) and adult (ρ=−0.347 [95% CI: −0.57 to −0.08], p = 0.013) populations. **Conclusions:** Distribution of UCNS board-certified neuro-oncologists in the United States is primarily governed by state-level economic prosperity and is critically concentrated in select metropolitan centers. This geographical concentration leaves over 80% of US metro areas without access to a UCNS board-certified neuro-oncologist. Furthermore, higher density of UCNS-certified specialists is significantly associated with reduced mortality and disease burden, suggesting that expanding this workforce may be a lever for improving population-level neuro-oncologic outcomes. Research Sponsor: None.

Use of knowledge-distilled EfficientNet to enable rapid, scalable glioma diagnosis. First Author: Gowrishankar Palaniswamy, AIM DOCTOR, Thiruverkadu, India

Background: Accurate preoperative classification of gliomas on MRI according to WHO 2021 integrated diagnosis is essential for surgical planning and treatment selection, yet conventional interpretation remains vulnerable to inter-observer variability. Deep learning shows promise for brain tumor classification but computational demands restrict deployment in resource-limited settings. Knowledge distillation, transferring discriminative knowledge from computationally intensive "mentor" networks to efficient "mentee" models, enables scalable AI systems maintaining diagnostic accuracy while enabling global translation. **Methods:** We analyzed 2,840 brain MRI studies sourced from six continents comprising gliomas (n=1,400; 700 WHO grade 2–3, 700 grade 4), meningiomas (n=900), and pituitary adenomas (n=540). Ground truth followed WHO 2021 integrated diagnosis with expert neuroradiologist consensus. Data were partitioned at the patient level with site-held-out external testing. A high-capacity EfficientNetB7 mentor model was developed using multi-sequence MRI inputs (T1, T2, FLAIR, post-contrast T1) and distilled into lightweight EfficientNetB0. Knowledge distillation preserved discriminative performance while enabling CPU deployment without GPU acceleration. Training: input 224×224 pixels, Adam optimizer (lr=0.001), Kullback-Leibler divergence loss (temperature T=4), twelve epochs. Performance metrics included accuracy, sensitivity, specificity, F1-score, and AUROC. Independent clinical feasibility involved 52 board-certified neuroradiologists across 11 geopolitical regions. **Results:** For WHO grade 2–3 versus grade 4 stratification, distilled EfficientNetB0 achieved 97.2% accuracy, 98.1% sensitivity, 96.3% specificity, and AUROC 0.993. Differential diagnosis accuracy: 95.3% (glioma vs. meningioma), 96.1% (glioma vs. pituitary). Site-held-out external validation showed consistent performance (93–97% grading, 94–96% differential). Mean inference time: 0.19 seconds on CPU. Distilled model: 3.9 million parameters (97% reduction), 2.1 billion FLOPs (94% reduction). Neuroradiologist assessment: 94.7% rated system valuable for diagnostic confidence and surgical triage. Inter-rater agreement: 96.8% (κ=0.951, 95% CI 0.941–0.961). **Conclusions:** Knowledge-distilled EfficientNetB0 achieves 97.2% accuracy for glioma grading and 95–96% for differential diagnosis while reducing parameters by 97% and enabling CPU deployment. Global validation across six continents and clinical assessment by 52 neuroradiologists establish real-world feasibility. The architecture supports translation as a decision-support tool for preoperative glioma stratification, particularly in resource-constrained settings. Prospective clinical trials evaluating impact on surgical decision-making are warranted. Research Sponsor: None.

2041 Poster Session

Phase 1, first-in-human (FIH) study evaluating safety and efficacy of ABBV-706: Results from patients with high-grade central nervous system (CNS) tumors. First Author: Maria Vieito, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: Patients (pts) with primary high-grade CNS tumors, especially those with glioblastoma (GBM), face poor clinical outcomes (GBM 5yr OS 5–10%). Seizure-related 6 homolog (SEZ6) is overexpressed in many tumor types, including primary CNS tumors. ABBV-706 is a SEZ6-targeting antibody-drug conjugate with topoisomerase 1-inhibitor payload that has shown a manageable safety profile in pts with small cell lung cancer. We present safety and efficacy data from a phase 1, FIH study evaluating ABBV-706 in pts with CNS tumors. **Methods:** This phase 1, FIH study (NCT05599984) enrolled pts ≥18 years with histologically/cytologically confirmed advanced relapsed/refractory GBM (IDH-wildtype, Grade [G] 4) or astrocytoma (IDH-mutant, G 3/4). Pts had ECOG performance score ≤1, and ≥1 measurable lesion per Response Assessment in Neuro-Oncology (RANO). Pts had prior surgical resection and progressed after receiving standard of care treatment. During dose escalation and expansion, pts received 1.3–3.5 mg/kg and 2.5 mg/kg ABBV-706, respectively. Treatment was every 3 weeks until disease progression or intolerable toxicity. Endpoints included safety and efficacy determined by RANO criteria. **Results:** As of Sep 27, 2025, 48 pts with primary CNS tumors (GBM, n=41; astrocytoma, n=6; missing indication, n=1) received ABBV-706 (1.3 mg/kg, n=1; 2.5 mg/kg, n=44; 3.0 mg/kg, n=1; 3.5 mg/kg, n=2). Among all pts, median age was 50 years (range 18–78), 58% were male, and the median number of prior lines of therapy was 2 (range 1–5). Median follow-up was 13.7 and 13.2 months for pts with GBM and astrocytoma, respectively. Treatment-related adverse events (TRAEs) were observed in 90% of pts. Most common toxicities were hematological (65%) and gastrointestinal (52%) events. G ≥3 TRAEs were observed in 60% of pts; most commonly anemia (40%). TRAEs led to treatment discontinuation, dose interruption, and dose reduction in 4%, 38%, and 27% of pts, respectively. No G 5 TRAEs were reported. One pt had pneumonitis (2.5 mg/kg, G 2). Among all pts, ORR was 8%, and 2 pts (4%) had a confirmed complete response. Efficacy data for GBM are shown in the Table. SEZ6 IHC expression was similar between GBM pts with (n=4) and without (n=31) an objective response. **Conclusions:** In pts with previously treated primary CNS tumors, ABBV-706 had a comparable safety profile to that observed in other tumors and showed encouraging antitumor activity. Clinical trial information: NCT05599984. Research Sponsor: AbbVie Inc.

Initial analysis of adoptive neoantigen-specific T-cell immunotherapy for MGMT-unmethylated glioblastoma (TVI-AST-008): Signals amid control arm attrition. First Author: Tolga Tuncer, Department of Neurosurgery, Division of Medical Oncology, University of Kansas Health System, Kansas City, KS

Background: MGMT-unmethylated (MGMT-u) glioblastoma (GBM) confers resistance to alkylating agents and poor overall survival (OS). Limited options beyond Standard of Care (SOC) drive patient pursuit of experimental therapies, complicating randomized controlled trials (RCTs). TVI-AST-008 evaluates safety and efficacy of adding autologous neoantigen-specific T-cell immunotherapy to SOC in this high-risk population. **Methods:** In this prospective RCT, newly diagnosed MGMT-u GBM patients were randomized 1:1 post-resection to Immunotherapy + SOC or SOC alone, stratified by age, residual tumor, and sex. The investigational arm used patient tissue to manufacture an autologous vaccine and undergo tumor cell vaccination to induce antigen-specific priming. Following leukapheresis, harvested lymphocytes undergo *ex vivo* T-cell activation/expansion (TVAX). On completion of SOC (radiation/temozolomide), manufactured cells undergo adoptive transfer with low-dose IL-2. Primary endpoint: OS. **Results:** As of September 2025, 21 subjects (median age 60) were randomized: Treatment (n=11) or Control (n=10). Control arm retention was challenging: 4/10 withdrew post-randomization to pursue other experimental therapies, leaving 6 evaluable Controls. Six Treatment subjects completed infusion. Despite limited statistical power, survival divergence emerged: mean OS for Controls (n=6) was 6.6 months versus 10.6 months for infused Treatment patients (n=6), with survivors followed at a median of 14 months (2 died at 9 and 10 months). Safety was favorable; adverse events were Grade 1–2 (pyrexia, rash) consistent with immune activation. No SAEs attributed to the investigational product. **Conclusions:** Early TVI-AST-008 data suggest adoptive neoantigen-specific immunotherapy is feasible, safe, and early signals suggest possible improved survival in MGMT-u GBM. High post-randomization withdrawal in Controls highlights challenges of SOC-controlled trials in this setting. Future validation may require synthetic controls or crossover allowances to ensure trial viability. Clinical trial information: NCT05685004. Research Sponsor: FDA/HHS; R01FD007259.

2043 Poster Session

Impact of vorasidenib vs placebo on seizure rates and quality of life: Exploratory analysis from the phase 3 INDIGO study. First Author: Wolfgang Wick, Universitätsklinikum Heidelberg & German Cancer Research Center, Heidelberg, Germany

Background: Grade 2 diffuse gliomas with isocitrate dehydrogenase 1/2 mutations (mIDH1/2) are incurable brain tumors with poor long-term prognosis and tumor-related symptoms, eg seizures, that negatively impact patients' (pts) quality of life (QoL). Vorasidenib (VOR) is an oral, brain-penetrant, dual inhibitor of mIDH1/2 approved in >40 countries for treating grade 2 mIDH1/2 gliomas following the positive clinical outcomes, including tumor volume reduction, shown in the Phase 3 INDIGO study (NCT04164901). We investigated the effect of long-term VOR treatment on seizure activity and QoL in pts with mIDH1/2 glioma in INDIGO. **Methods:** Pts aged ≥12 years with grade 2 mIDH1/2 glioma, no prior glioma treatment other than surgery and with controlled seizures were randomized 1:1 to receive VOR 40 mg or placebo (PBO) daily. Data from the pre- and post-unblinding periods were used; PBO pts after crossover were excluded from the analyses. Exploratory analyses for the number of on-treatment seizures were conducted in pts with ≥1 seizure in the baseline or on-treatment periods using a negative binomial regression model. Seizure severity was self-reported (1 [not bad] to 10 [as bad as imaginable]). QoL was measured using the Functional Assessment of Cancer Therapy – Brain (FACT-Br) scale and FACT-Br brain cancer subscale (BrCS), and changes were estimated with time-to-event analysis. **Results:** During the study, 110/331 pts (33.2%) reported ≥1 seizure (VOR n=55; PBO n=55). VOR treatment showed a constant and sustained effect on seizure control, reflected by significantly lower seizure rates per person per year than in the PBO group (Table), and lower number and severity of seizures over time. In addition, in pts with a seizure burden (≥1 seizure), VOR significantly delayed time to first worsening of FACT-Br and FACT-Br BrCS scores (hazard ratio [95% confidence interval]: FACT-Br, 0.38 [0.15, 1.00], *P*=0.0435; FACT-Br BrCS, 0.32 [0.11, 0.91], *P*=0.0263). **Conclusions:** In pts with mIDH glioma and ≥1 on-study seizure, long-term VOR treatment generally led to a sustained decrease in seizure activity and severity and delayed worsening of QoL. These results suggest that VOR may have an additional benefit on QoL in pts who experience seizures. Clinical trial information: NCT04164901. Research Sponsor: Servier.

Exploratory analyses of VOR treatment and seizure rate in pts who reported ≥1 seizure in the baseline or on-treatment periods in INDIGO.

	VOR (n = 56)		PBO (n = 56)
Patients with ≥1 on-treatment seizure, n (%)	55 (98.2)		55 (98.2)
Rate of on-treatment seizures per person-year* (95% CI)	13.2 (5.8, 29.8)		64.9 (26.5, 159.1)
Ratio of rates: VOR vs PBO (95% CI)		0.20 (0.08, 0.52)	
Two-sided *P* value†		**0.0008**	

*Estimated using negative binomial regression model adjusted by number of seizures and tumor size at baseline.
†Not prespecified and not adjusted for multiplicity; should be interpreted with caution. Data cut-off: January 17, 2025. CI, confidence interval; PBO, placebo; VOR, vorasidenib.

2044 Poster Session

Tumor treating fields therapy in patients with newly diagnosed glioblastoma and poor performance status: Real-world analysis of patients treated in the US. First Author: Omar H. Butt, Washington University in St. Louis, St. Louis, MO

Background: TTFields therapy is an FDA-approved treatment for patients with newly diagnosed glioblastoma, showing benefit in overall survival (OS) when added to maintenance temozolomide (TMZ). While device effectiveness was demonstrated regardless of performance status (PS) in the EF-14 study, only patients with Karnofsky Performance Status (KPS) of ≥70 were eligible for the study. This study investigates real-world outcomes of patients with newly diagnosed glioblastoma and poor PS who were treated with TTFields. **Methods:** Electronic medical records of patients initiating treatment with TTFields in the US commercial setting between January 1, 2019 and December 31, 2021 were accessed via the xCures real-world data platform and Novocure systems, from which clinical data were extracted. To be included in the analysis, patients needed to have a documented new diagnosis of glioblastoma occurring within 180 days of initiating TTFields and have KPS ≤60 or ECOG PS ≥2 within 3 weeks of treatment initiation. IDH status was ascertained where data were available. Device usage was calculated as the average percentage of time the device was used within the first 3 months of therapy, as recorded by the device log files. Patients were divided into high and low usage groups. High usage was defined as usage ≥50% and treatment duration ≥30 days, and low usage as usage <50% or treatment duration <30 days, excluding patients with a death event within 30 days of initiating TTFields. Demographics, disease characteristics, and survival outcomes were evaluated. Data cutoff for analysis was Jan 7, 2026. **Results:** The study included 306 patients, of whom 198 (65%) were high users and 108 (35%) low users. Baseline characteristics were balanced between the two groups. Although most patients had KPS of 60 or ECOG PS of 2 (n=204, 67%), the study included 102 patients (33%) who had KPS ≤50 or ECOG PS ≥3. The entire cohort had median OS from diagnosis of 13.3 months (95% CI, 12.4–14.5). Median OS was 14.1 months (95% CI, 12.8–15.9) in the high-use group compared with 11.9 months (95% CI, 9.6–13.3) in the low-use group (HR, 0.69 [95% CI, 0.53–0.89]; P=0.005). Similar results were observed regardless of the performance scale utilized. Further subgroup analysis showed a consistent usage effect for patients ≥65 and <65 years of age (HR, 0.71 [0.49–1.02], P=0.067 and HR, 0.69 [0.47–1.00], P=0.049, respectively). **Conclusions:** Patients with newly diagnosed glioblastoma and poor performance status receiving TTFields therapy in the real-world setting appear to have favorable survival when compared with historical data. Usage is associated with improved survival in this population, including among elderly patients for whom treatment options are limited. Additional studies examining TTFields in this high-need population with limited trial options are warranted. Research Sponsor: None.

2045 **Poster Session**

Beyond survival: Longitudinal prognostication in glioblastoma using conditional survival—A population-based study. First Author: Obuli Srinivasan Gurunathan, United Health Services Hospitals, Johnson City, NY

Background: Glioblastoma multiforme (GBM) carries a poor prognosis, and the initial survival projections provided at diagnosis do not accurately depict the evolving risk that exists for all GBM survivors. Conditional survival (CS), defined as the probability of surviving an additional period after having lived to a specific time point, provides a much more accurate way of defining prognosis for these patients. We evaluated conditional survival patterns in a large population-based cohort of patients with glioblastoma. **Methods:** Adult patients who were diagnosed with primary glioblastoma between 2000 and 2022 were identified from the SEER 17 Registries. The estimated overall survival (OS) was determined by using the Kaplan-Meier method. We also calculated one year and two-year conditional survival (CS) probabilities at multiple landmark times (0-24 months). In addition, we stratified the conditional survival by the status of surgical resection and whether or not the patient received radiation therapy. **Results:** There were 52,125 patients in our sample. As expected, the median OS was very poor, dropping from 37.3% at 12 months to 16.0% at 24 months. Nevertheless, the conditional survival was significantly better than overall survival. One-year CS increased from 40.4% at diagnosis to 57.2% among patients surviving 24 months, while two-year CS improved from 17.3% to 39.4% over the same landmarks. Patients who underwent surgical resection had higher early CS compared with biopsy or no surgery, though differences diminished at later landmarks. Similar trends were found in CS rates in patients who received radiation therapy, indicating survivorship selection over time as opposed to a decrease in the effectiveness of treatments. **Conclusions:** Conditional survival in glioblastoma improves markedly with increased time of survival. Therefore, it is essential to use CS in place of traditional survival statistics to provide more accurate prognoses for glioblastoma patients. Research Sponsor: None.

Landmark Time (Months)	Overall Survival	1-Year Conditional Survival	2-Year Conditional Survival	1-Year CS (Resection)	1-Year CS (No resection/Biopsy)	1-Year CS (RT Yes)	1-Year CS (RT No/Unknown)
0	92.4%	40.4%	17.3%	46.7%	17.1%	48.7%	14.1%
6	56.3%	42.0%	20.9%	43.2%	32.3%	42.5%	37.9%
12	37.3%	42.9%	24.5%	43.1%	40.7%	42.4%	47.9%
18	23.7%	49.8%	31.7%	49.9%	48.7%	49.2%	56.0%
24	16.0%	57.2%	39.4%	57.1%	57.2%	56.5%	63.2%

RT: Radiotherapy.

A phase I study to assess the safety, tolerability, pharmacokinetics, and preliminary antitumor activity of KH617 for patients with advanced solid tumors (including diffuse gliomas of adulthood). First Author: Wenbin Li, Department of Neuro-Oncology, Cancer Center, Beijing Tiantan Hospital, Capital Medical University, Beijing, China

Background: Outcomes in patients (pts) with recurrent glioblastoma (rGBM) are poor, with historical median overall survival (mOS) of 7-8 months. KH617 is a sesquiterpene compound that exhibits a wide spectrum of anti-cancer properties, has low toxicity, and is capable of traversing the blood-brain barrier. It can inhibit the growth, proliferation, and migration of tumors via multiple mechanisms, mitigate the malignant phenotype of tumor cells, and facilitate the transdifferentiation of tumor cells into normal cells. This is a phase I study of KH617 in pts with advanced solid tumors (including diffuse gliomas of adulthood). Here, we report the results of the dose escalation stage. **Methods:** Pts with histologically confirmed advanced solid tumors (including diffuse gliomas of adulthood) that were no longer responding to standard therapies were enrolled. The Bayesian Optimal Interval (BOIN) design was used for dose escalation, having explored in 7 successive cohorts (5-60mg/kg). **Results:** As of Dec, 30 2025, 32 pts were enrolled across 7 dose levels, including 23 pts with rGBM, 7 with non-glioblastoma, and 1 each with adenocarcinoma and spinal cord ependymoma. The median age was 51 years, and 19 (59.4%) pts were male. No dose-limiting toxicity (DLT) or treatment-related serious adverse events (TRSAEs) were observed, and the maximum tolerated dose (MTD) was not reached. The most frequently reported ($\geq$10%) treatment-related serious adverse events (TRAEs) were white blood cell count decreased, neutrophil count decreased, lymphocyte count decreased, abnormal ECG T wave, and sinus bradycardia. Only 1(3.13%) pt reported grade $\geq$3 adverse event. Efficacy signals were observed especially in the 23 rGBM pts, who were administered KH617 across 7 doses (n = 1, 1, 3, 2, 8, 7, 1 in 5, 10, 17, 25, 33, 45, 60mg/kg cohorts, respectively), the mOS was 16.07 months. At the recommended phase 2 dose (RP2D) of 33mg/kg, 8 rGBM pts were included in the efficacy evaluation, objective response rate (ORR) was 12.5%, median progression-free survival (PFS) was 1.84 months, mOS exceeded 21 months (3 died and 5 were still alive). In the pharmacokinetic (PK) study, C_{max} no longer increased with escalating doses from 25 mg/kg to 45 mg/kg, indicating that the peak plasma concentration had already reached the maximum plateau level under the current dosing. Combined the efficacy data with the PK data, 33 mg/kg was confirmed as the RP2D. **Conclusions:** KH617 has shown significantly superior antitumor activity compared to the historical mOS in pts with rGBM, while also being well-tolerated. Clinical trial information: CTR20223286. Research Sponsor: Sichuan Honghe Biotechnology Co., Ltd.

Interrupting HEG1/Cx43 interaction to promote cuproptosis via inhibiting gap junction to overcome glioblastoma radioresistance. First Author: Lanlan Guo, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University., Guangzhou, Guangdong, China

Background: Glioblastoma (GBM) is the most common and aggressive primary malignant tumor of the central nervous system. Its intrinsic radioresistance leads to suboptimal therapeutic outcomes. A prior clinical trial by our team revealed that mutations in the *HEG1* gene lead to upregulated protein expression, a key factor limiting the benefit from standard radiotherapy in GBM patients. As a form of non-classical programmed cell death induced by radiotherapy, we hypothesized that high HEG1 expression reduces the susceptibility of GBM cells to cuproptosis, thereby promoting radiotherapy resistance. **Methods:** Cellular functional assays were performed to evaluate the impact of HEG1 expression on cuproptosis sensitivity and radiotherapy response in GBM cells. Molecular techniques were used to assess intracellular and intercellular copper ion flow. Co-immunoprecipitation and inhibition of protein degradation pathways were employed to investigate the direct interaction between HEG1 and the gap junction protein Connexin 43 (Cx43), and its inhibitory effect on Cx43 degradation via the endolysosomal pathway. Structural modeling combined with virtual screening of a drug library was conducted to identify potential compounds disrupting the HEG1-Cx43 interaction. Site-directed mutagenesis and kinase activity modulation were used to elucidate the mechanism by which c-Kit kinase promotes HEG1-Cx43 binding by phosphorylating HEG1 at tyrosine residue Y1350. Functional validation was performed both in vitro and in vivo using GBM models. **Results:** High HEG1 expression facilitated intercellular copper ion flow, dampened intracellular copper ion fluctuations, and consequently blocked the propagation of cuproptosis. Mechanistically, HEG1 directly interacted with Cx43, inhibiting its degradation via the endolysosomal pathway and sustaining gap junction establishment. Virtual screening identified several multi-target tyrosine kinase inhibitors capable of disrupting the HEG1-Cx43 interaction. Mechanistic studies revealed that c-Kit kinase promoted this interaction by phosphorylating HEG1 at Y1350. Both in vitro and in vivo functional validation demonstrated that targeting the HEG1-Cx43 interaction reactivated cuproptosis and sensitized GBM to radiotherapy. **Conclusions:** Our findings elucidate the regulatory role of the "HEG1-Cx43-cuproptosis" axis in GBM radioresistance, offering new insights for treatment. The combination of multi-target tyrosine kinase inhibitors and cuproptosis inducers may represent a promising novel therapeutic strategy for GBM. Histopathology-verified comparison of FET PET and contrast-enhanced MRI for tumor visualization in glioblastoma. First Author: Roman Stuerzl, Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, Germany

Background: In glioblastoma, precise visualization is a prerequisite for optimal resection strategies and accurate radiotherapy volume definition. In routine practice, contrast-enhanced MRI (CE-MRI) is most commonly used; however, it can underestimate tumor extent when viable tumor is present without blood–brain barrier disruption and therefore without contrast uptake. The present study examined whether amino acid PET with O-(2-[^{18}F]fluoroethyl)-L-tyrosine (FET) can better visualize the true distribution of tumor tissue and thereby improve preoperative assessment. **Methods:** In this prospective, biopsy-validated single-center study, in 61 patients with IDH-wildtype glioblastoma (44 newly diagnosed, 17 recurrent) 472 biopsies spatially correlated with preoperative FET PET and CE-MRI were histopathologically evaluated. Diagnostic metrics were calculated and compared between modalities using McNemar and Chi² tests ($p = 0.05$). **Results:** Overall, FET PET identified tumor tissue with significantly higher sensitivity than CE-MRI (91.2% vs. 55.7%; $p < 0.001$). When benchmarked against T2/FLAIR, FET remained more sensitive (85.3%; $p = 0.012$) while also demonstrating a pronounced gain in specificity (82.5% vs. 33.3%; $p < 0.001$). Remarkably, there was the high reliability of FET in regions without MRI contrast enhancement: biopsies taken from FET-positive areas without contrast enhancement showed a positive predictive value of 98.3%. Subgroup analyses consistently demonstrated the advantage of FET across clinical and histological strata, including newly diagnosed and recurrent disease ($p < 0.001$), as well as within cohorts with resection ($p < 0.001$; specificity $p = 0.03$) or biopsy ($p < 0.001$). Importantly, performance advantages were also observed regardless of histological tumor cell density, with FET exceeding CE-MRI in both histological strata (infiltration zone and solid tumor, both $p < 0.001$). **Conclusions:** FET PET demonstrated significant diagnostic superiority over CE-MRI for the visualization of glioblastoma tissue. Comparable positive predictive values in contrast-enhancing and non-enhancing regions indicate that FET PET detects tumor reliably, independent of the blood–brain barrier integrity. These findings support the integration of amino acid PET as an important component in target definition for both surgical and radiation planning in glioblastoma. Research Sponsor: None.

Caregiver professional employment and its impact on glioblastoma patient survival: Results from two prospective studies. First Author: Vincenzo Di Nunno, Nervous System Medical Oncology Department, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Istituto delle Scienze Neurologiche di Bologna, Bellaria Hospital., Bologna, 40139, Italy

Background: Caregiver burden is a crucial factor to consider in the diagnosis and care of patients with glioblastoma (GBM). Despite growing interest in caregiver issues, data on caregiver burden and, in particular, professional and working burden are limited, as well as the potential effect of caregiver burden on patients' survival. **Methods:** We collected caregiver data from two prospective observational studies (ISES 1 and ISES 2) investigating the impact of socioeconomic variables (SES) in GBM patients. In particular, we collected data on the presence and type of caregiver, the caregiver's professional situation, and any professional modifications after the GBM diagnosis at time of adjuvant treatment start and after six months (in patients enrolled in ISES 2 study). **Results:** Overall, 511 GBM isocitrate dehydrogenases wild-type (IDH-wt) patients were included. The median follow-up period was 55.2 months (95% CI, 44.3–86.3), and the median overall survival was 15.7 months (95% CI, 14.8–17.2). A caregiver was present for 472 patients (92.4%), consisting mainly of partners or daughters and sons. At the start of adjuvant treatment, 158 caregivers (30.9%) reduced their working hours, and 55 caregivers (10.8%) stopped working. For 232 patients, a longitudinal assessment of caregiver condition was collected, and 71 caregivers (30.6%) reduced their working hours, while 33 patients (14.2%) stopped their work activities. Patients whose caregivers were in stable employment had a longer life expectancy than those whose caregivers were not (multivariate - HR 0.76, 95% CI 0.60–0.94, p = 0.03), regardless of other known prognostic factors, as confirmed by a multivariate analysis (Table 1). **Conclusions:** Our study revealed that GBM diagnosis often leads to a negative impact on caregiver work activities. A stable caregiver employment translates independently to a long-life expectancy of patients with GBM, regardless of other recognized prognostic factors. Policies supporting the professional and social activities of caregivers could improve not only the quality of care for GBM patients but also their clinical outcomes. Clinical trial information: 0321-3733778. Research Sponsor: None.

Expression patterns of circulating microRNAs in classification models: New opportunities in brain tumor diagnosis. First Author: Dmitry Yu. Gvaldin, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: Diffuse gliomas are the most common primary brain tumors and, according to the 2021 WHO classification, are divided into three main types: IDH-wild-type glioblastomas, IDH-mutant astrocytomas, and IDH-mutant oligodendrogliomas with 1p/19q codeletion. Oligodendrogliomas are neuroepithelial tumors of the central nervous system that have histological and molecular characteristics distinct from other subtypes of diffuse gliomas. The problem of early diagnosis of oligodendrogliomas, due to their location, requires the search for accessible and informative markers. Circulating microRNAs in blood plasma appear to be the most promising in this aspect. The purpose of the study was to develop a model for the diagnosis of oligodendrogliomas based on the expression profiles of microRNAs circulating in blood plasma. **Methods:** The study included 251 participants: 84 patients with glioblastomas, 51 patients with astrocytomas, 12 patients with oligodendrogliomas, 47 patients with meningiomas, 14 patients with lung cancer metastases, 25 patients with breast cancer metastases, and 18 healthy donors. The miRNeasy Serum/Plasma Kit (Qiagen, Germany) was used to isolate the microRNA fraction from blood plasma. The expression levels of hsa-miR-30c-5p, hsa-miR-186-5p, hsa-miR-194-5p, hsa-miR-484, hsa-miR-19b-3p, hsa-miR-431-5p, hsa-miR-363-3p, hsa-miR-128-3p, hsa-miR-3168, hsa-miR-192-5p, hsa-let-7c-5p, hsa-miR-340-5p, hsa-miR-182-5p and hsa-miR-144-5p were measured by stem loop RT-qPCR. **Results:** The model for diagnosing cases with oligodendrogliomas was as follows: K_o=-1.59×hsa-miR-128-3p-1.97×hsa-miR-194-5p+1.78×hsa-miR-19b-3p-2.47×hsa-miR-3168+3.41×hsa-let-7c-5p+0.91×hsa-miR-192-5p+1.39×hsa-miR-340-5p-1.8, where K_o is the coefficient used to differentiate cases with oligodendrogliomas from other cases. The optimal cut-off value for K_o was 0.38 with a Youden index of 0.86. Model validation on the test dataset revealed that cases with oligodendrogliomas typically have calculated coefficient values $\geq$ 0.38. ROC analysis yielded the following model metrics: sensitivity – 100%, specificity – 85.7%, accuracy – 92.9%, and AUC – 0.93. **Conclusions:** The developed model opens up new opportunities for the early diagnosis of oligodendrogliomas and may eventually become part of a test system for the differential diagnosis of brain tumors. 2052 Poster Session

Global validation of a brain cancer liquid biopsy. First Author: James Munro Cameron, Dxcover Ltd, Glasgow, United Kingdom

Background: Delayed diagnosis of brain cancer leads to approximately two-thirds of patients being identified only after presentation to the emergency department with advanced symptoms or established neurological deficits. Implementation of a simple liquid biopsy test as a rule-out test prior to confirmatory imaging, could facilitate earlier and more efficient triage of patients presenting with non-specific symptoms suggestive of brain cancer, enabling prioritization for those most at-risk and accelerate diagnostic pathways. **Methods:** Presented here is the clinical validation of the Dxcover Brain Cancer Liquid Biopsy Platform obtained to support regulatory approvals. The multi-centre and observational 'Early and tiMely detection of BRAin CancEr' ('EMBRACE') study was conducted with prospective patient recruitment across seven sites in Europe. The target population consisted of patients with symptoms indicative of brain cancer. Test performance was assessed by comparison of the liquid biopsy result to diagnostic imaging. Furthermore, the liquid biopsy test was then independently tested on an additional clinical dataset obtained from a US patient population (n=234) as part of a CLIA laboratory validation study. **Results:** In the EMBRACE performance evaluation, 2554 patients were enrolled across the seven collection sites; 2324 were deemed eligible and taken forward for test assessment. There were 697 brain tumours in total, of which 395 were malignant, and 1627 non-tumour diagnoses. In the intended use population, the reported diagnostic performance was 86% sensitivity for brain cancer detection with 44% specificity, and a 99% negative predictive value (NPV). Notably, for the most prevalent and most aggressive brain cancer, glioblastoma, 86% of cases were successfully identified. Additionally, 94% of patients with central nervous system lymphoma, and 90% of brain metastases were predicted correctly as having tumours. The test has gained regulatory approval for use in the UK and in Europe, gaining UKCA and CE – IVDR certification respectively. The CLIA validation has provided additional confirmation of the clinical utility of the liquid biopsy test in the US population. **Conclusions:** Existing symptom-based referral pathways are ineffective for the detection of brain cancer, and there is an urgent need for new tests to help with clinical decision making. With a NPV of 99%, the Dxcover Liquid Biopsy test could aid with the efficient stratification of patients toward diagnostic imaging. Research Sponsor: None.

Genomic determinants of radiation necrosis in diffuse glioma patients. First Author: Michael Kienhöfer, University Hospital Heidelberg, Heidelberg, Germany

Background: Diffuse gliomas are the most common primary brain tumors, requiring multimodal therapy. Radiotherapy (RT) represents a key pillar of treatment; however, radiation-induced brain toxicities remain a major challenge. Radiation necrosis (RN) is a delayed complication that can impair clinical outcomes and quality of life. Emerging evidence suggests that tumor biology, together with clinical factors, can influence radiation toxicity in a variety of cancer entities. However, in diffuse gliomas, tumor-intrinsic biomarkers predisposing to radiation toxicities remain poorly defined. We hypothesized that integrating clinical features with tumor genomic data could identify patients at increased risk of developing RN. **Methods:** We analyzed a cohort of 943 adult patients with diffuse gliomas treated between 2014 and 2024 at MD Anderson. All tumors were classified according to the WHO 2021 criteria into three diagnoses: GBM, astrocytoma (astro), and oligodendroglioma (OD). RN occurring at least 12 weeks after completion of RT was identified based on pathology and/or advanced brain tumor imaging (ABTI), which included conventional MRI, perfusion imaging and spectroscopy. A multivariate regression model was employed to identify clinical or genetic predictors for RN. Included covariates were demographics, diagnosis, and common genetic alterations. To address missing values, multiple imputation was utilized. **Results:** Sixty patients with RN were identified: 51 GBM (85%), 6 astro (10%), and, 3 OD (5%); compared with 883 controls: 682 GBM (77%), 140 astro (16%), and 61 OD (7%). Age, gender, and diagnoses were not associated with RN. We evaluated the top 22 altered genes and *MGMT* status. In the overall cohort, *IDH1* (OR 0.15 [95% CI, 0.02–0.93]; p=0.042) and *MDM2* (OR 0.11 [95% CI, 0.01–1.00]; p=0.050) alterations were associated with reduced RN risk, while *ATR* alterations were associated with increased RN risk (OR 6.05 [95% CI, 0.85–33.1]; p=0.049) on multivariable analysis. In the GBM subgroup, *CDK4* (OR 3.32 [95% CI, 1.04–9.97]; p=0.042) and *MSH6* alterations (OR 6.05 [95% CI, 1.12–33.1]; p=0.037) were associated with increased RN risk, whereas *MDM2* alterations remained associated with reduced risk (OR 0.07 [95% CI, 0.01–0.69]; p=0.023). In the *IDH*-mutant diffuse glioma subgroup (RN n=9; controls n=201), *ATRX* alterations were associated with lower RN risk (OR 0.10 [95% CI, 0.01–0.73]; p=0.023). *MGMT* status was not associated with RN risk. **Conclusions:** In this cohort, RN risk was not associated with demographic factors, tumor diagnosis, or MGMT status, but was associated with specific tumor genomic alterations. The enrichment of DNA damage response–related genes among those associated with RN suggests a potential biological link between tumor genomics and RN toxicity. Prospective validation will be required to determine the utility of these findings for genome-based risk stratification. Research Sponsor: None.

2054 Poster Session

Direct oral anticoagulants versus low-molecular-weight heparin for venous thromboembolism in primary brain tumors: A TriNetX real-world analysis. First Author: Medina Esenbekova, UPMC Harrisburg, Harrisburg, PA

Background: Venous thromboembolism (VTE) is a common complication in patients with primary brain tumors and is associated with poor outcomes. Although therapeutic anticoagulation is required for VTE treatment, its use in this population is challenging because of the increased risk of intracranial hemorrhage (ICH). Optimal anticoagulant selection remains uncertain, as concerns regarding ICH have limited randomized trial data in patients with primary brain tumors. Therefore, comparing ICH risk between direct oral anticoagulants (DOACs) and low-molecular-weight heparin (LMWH) is critical to optimizing anticoagulation in this high-risk group. **Methods:** This retrospective cohort study used the TriNetX Global Collaborative Network to identify adults (≥18 years) with primary malignant brain tumors who developed VTE within one year of tumor diagnosis. Patients with secondary malignant neoplasms were excluded. Cohorts included patients treated with DOACs (apixaban, rivaroxaban, edoxaban, or dabigatran) or LMWH (enoxaparin, dalteparin, or tinzaparin) after VTE diagnosis. The index date was defined by cohort entry criteria, and outcomes were assessed over 180 days. 1:1 propensity score matching was performed across demographic and clinical characteristics, including age, sex, race, cardiovascular disease, diabetes, kidney disease, coagulation disorders, obesity, and substance use. Intracranial hemorrhage and all-cause mortality were evaluated using risk estimates and Kaplan-Meier survival analyses. **Results:** After propensity score matching, 6,114 patients were included in each cohort. DOAC therapy was associated with a significantly lower risk of intracranial hemorrhage compared with LMWH over 180 days (3.9% vs 7.3%; risk ratio, 0.54; 95% CI, 0.46–0.64; $p<0.001$). In addition, all-cause mortality at 180 days was significantly lower in the DOAC cohort than in the LMWH cohort (24.8% vs 31.3%; risk ratio, 0.79; 95% CI, 0.75–0.84; $p<0.001$). These findings were consistent across the matched population, demonstrating improved safety and survival outcomes associated with DOAC use in patients with primary malignant brain tumors and VTE. **Conclusions:** In this large real-world cohort of adults with primary brain malignancy and VTE, DOAC treatment was associated with a lower intracranial hemorrhage risk and reduced mortality at 180 days compared with LMWH after propensity score matching. These findings support the safety of DOACs in patients with primary brain tumors and warrant further prospective evaluation of anticoagulant selection in this high-risk population. Research Sponsor: None.

Development of human B7H3/IL13Ra2 bispecific armored CAR-T for treatment of glioblastoma. First Author: Keming Zhang, Elpis Biopharmaceuticals, Lexington, MA

Background: Glioblastoma (GBM) remains a highly lethal malignancy driven by infiltrative growth, molecular complexity, immune evasion, and therapeutic resistance. The limited efficacy of current treatments reflects antigen heterogeneity, an immunosuppressive tumor microenvironment, and restricted delivery across the blood–brain barrier with targeted therapy. Although earlier CAR-T therapies demonstrated preliminary activity in GBM, durable efficacy remains elusive. We have developed EPC-003, a fully human bispecific B7-H3/IL13Rα2 CAR-T engineered with a multi-mechanism armor to mitigate antigen heterogeneity, modulate the tumor microenvironment, and enhance persistence via central memory T-cell enrichment. **Methods:** Human anti-IL13Rα2, anti-B7-H3, and anti-PD-L1 scFvs were discovered from proprietary human B-cell libraries using mRNA display platform. A multi-mechanism armor was engineered by fusing the anti-PD-L1 scFv to a fine-tuned, immune cell-type specific IL-2 variant, identified through the unique cytokine engineering platform. These binding and functional modules were systematically optimized to generate EPC-003, a bispecific tandem CAR targeting IL13Rα2 and B7-H3 and incorporating a secreted multi-mechanism armor. CAR mechanisms, anti-tumor activity, and preclinical toxicity were evaluated. A proprietary clinical manufacturing process was established to produce a central memory T cell enriched CAR-T product. **Results:** The secreted armor of EPC-003 suppressed regulatory T-cell activation while selectively activating central memory T-cells, with the potential to enhance CAR-T cell persistence. In a 7-day G-Rex manufacturing process, EPC-003 demonstrated promising druggability with robust and reproducible CAR expression, and the proprietary cytokine cocktail consistently enriched the product to >65% central memory CAR-T cells. In orthotopic GBM models, intracranial administration of EPC-003 (0.4×10^6 and 1.2×10^6 CAR-T cells) induced tumor regression and showed dose-dependent anti-tumor activity. In preclinical toxicity studies, EPC-003 exhibited a favorable safety profile, with no body weight loss, cytokine release syndrome, or systemic clinical signs. No treatment-related pathological changes were observed across 25 examined organs. Immunohistochemistry revealed no evidence of brain hemorrhage in treated groups, with minimal monocyte infiltration in the pia mater observed only at the high dose. **Conclusions:** EPC-003, a multi-mechanism armored bispecific CAR-T, demonstrated favorable preclinical safety, developability, robust anti-tumor activity, and potential durability. These data support its advancement into an investigator-initiated clinical trial for the treatment of glioblastoma. Research Sponsor: None.

Which treatment is best? A systematic review and Bayesian network meta-analysis of adjuvant treatments for low-grade glioma. First Author: Amit Kumar Chowdhry, AdventHealth Cancer Institute, Orlando, FL

Background: The standard of care for low-grade glioma (LGG) includes resection with or without adjuvant treatment. It is currently unknown which adjuvant strategy is best. **Methods:** A systematic review of PubMed and EMBASE for randomized controlled trials (RCTs) evaluating adjuvant treatment for LGG published on or before 6/2/2025 was conducted as pre-registered (CRD420251072899). Study eligibility and data extraction were reviewed by two authors independently, and risk of bias was assessed via Cochrane RoB2. Two Bayesian network meta-analyses profiling *de novo* LGG were conducted with uninformative priors adjusting for baseline characteristics of each trial cohort. The pre-specified outcome measure was the distribution of posterior HR_{PFS} (primary meta-analysis) and HR_{OS} (secondary meta-analysis) for each identified treatment against observation. Posterior distributions were summarized with the posterior median hazard ratio (HR), and 95% equal-tailed credible interval (CrI). Further the probability of major benefit (HR≤0.6) and any magnitude harm (HR>1.0) were reported for each meta-analysis. **Results:** Six RCTs (all with low risk of bias) profiling 1,757 participants were identified for the primary meta-analysis (PFS). Seven RCTs (6 with low risk of bias 1 with high risk of bias) profiling 1,392 patients were identified for the secondary meta-analysis (OS). In total, six adjuvant treatment strategies were identified: radiotherapy (RT) + procarbazine/CCNU/vincristine (PCV), RT + temozolomide (TMZ), RT + CCNU alone, high-dose RT (HDRT, >54Gy), low-dose RT (LDRT; ≤54Gy), and TMZ. The posterior median HRs and 95% CrIs are reported in Table 1. For all profiled treatments, the probability of any benefit (HR<1.0) on the endpoint of PFS was >98% and >76% for OS. Additionally, the probability of major benefit (P1) and any magnitude harm (P2) were reported as clinically significant summary measures of all posterior distributions (Table 1). **Conclusions:** Based on the identified RCTs, RT+PCV was found to have the most favorable probability efficacy and RT+TMZ a similar distribution of treatment effect. RT+PCV and RT+TMZ had a >98% probability of any benefit for both endpoints. The probability of major benefit for RT+PCV and RT+TMZ was >99.9% and 84.8% for PFS and 71.3% and 63.3% for OS. Research Sponsor: NIH/NCI CCR Intramural Research Program.

Characterization of contemporary practice patterns in the management of *IDH*-mutant glioma: A multidisciplinary multi-institutional survey. First Author: Luis Nicolas Gonzalez Castro, Dana-Farber Cancer Institute, Boston, MA

Background: The management of isocitrate dehydrogenase (IDH) mutant glioma is rapidly evolving following the recent FDA approval of the mutant IDH inhibitor, vorasidenib. Optimal treatment decisions for many specific clinical scenarios remain undefined leading different neuro-oncology providers to recommend different treatment approaches. The aim of this study was to characterize how clinicians collectively approach different clinical scenarios and evaluate how demographic and professional backgrounds influence decision-making in IDH-mutant glioma. **Methods:** An online survey was developed by a team of neuro-oncologists and radiation oncologists and distributed via email and X to clinicians treating patients IDH-mutant glioma. The survey included demographic questions and multiple case-based clinical scenarios with standardized response options. We compared the responses of neuro/medical oncologists, radiation oncologists, and neurosurgeons, and performed univariable regression to identify predictors of treatment preference, as well as to understand familiarity and enthusiasm with the use of IDH inhibitors. **Results:** A total of 153 clinicians (58% neuro/medical-oncologists, 34% radiation oncologists, 8% neurosurgeons) completed the online survey. Five of ten scenarios reached consensus (>75% agreement on a treatment option), while the remainder demonstrated heterogeneity of treatment approaches. Compared to neuro/medical oncologists, radiation oncologists were less likely than neuro/medical oncologists to recommend IDH inhibitor therapy (IRR 0.57, $p<0.001$) and more likely to recommend radiotherapy (IRR 1.54, $p<0.001$) or chemo-radiotherapy (IRR 1.47, $p<0.001$). Neuro-oncologists and neurosurgeons reported the most and least familiarity, respectively, with the use of IDH inhibitors whereas medical oncologists and radiation oncologists reported the most and least enthusiasm for IDH inhibitor use, respectively. **Conclusions:** Our survey results evidence substantial variation in real-world management of IDH-mutant glioma across specialties and institutions. While several clinical scenarios demonstrated strong therapeutic consensus, others revealed diverse approaches, underscoring the need for ongoing multidisciplinary collaboration and further advancement of evidence-based consensus to guide clinical decisions. Rituximab pre-conditioning in a phase I study of CARv3-TEAM-E for recurrent glioblastoma (GBM): The INCIPIENT trial. First Author: Bryan D. Choi, Massachusetts General Hospital, Boston, MA

Background: Chimeric Antigen Receptor (CAR) T cells for glioblastoma (GBM) have been limited by the challenge of targeting a single tumor antigen in a heterogeneous disease. To address this barrier, we generated a novel engineered T-cell product (CARv3-TEAM-E) that targets the EGFRvIII antigen while also secreting T-cell-Engaging Antibody Molecules (TEAMs) against wild-type EGFR. **Methods:** The INCIPIENT clinical trial is a first-in-human study of CARv3-TEAM-E in patients with GBM (NCT05660369). Patients with recurrent GBM were treated with intraventricular CARv3-TEAM-E T cells (10E6 cells per infusion) and one of three pre-treatment regimens: no lymphodepletion (N=3), lymphodepleting chemotherapy with cyclophosphamide and fludarabine (LDC) (N=7), or cyclophosphamide, fludarabine, and rituximab (LDC+R) (N=3). The primary objective was safety and tolerability. Immune cells were profiled in the cerebrospinal fluid (CSF) and peripheral blood by flow cytometry. **Results:** CAR T manufacturing was successful for all patients. There were no dose-limiting toxicities (DLT). Three patients were treated without LDC; all developed anti-CAR and/or anti-TEAM antibodies (i.e., anti-therapy antibodies) after a single infusion of CARv3-TEAM-E. Subsequently, 7 patients were treated with LDC prior to CARv3-TEAM-E, 5 of which underwent serial infusions (range 2-5 infusions). Four patients had reinfusions after which CAR T cells were not detected in the CSF. We therefore added rituximab to the LDC regimen. In the 3 individuals pre-treated with LDC+R, CAR T cells were detected in CSF not only after initial infusion (range 21-28 days) but also following repeat infusion in all patients (range 3-15 days post-reinfusion). Anti-therapy IgG was not detected in patients treated with LDC+R, as compared to 9/10 patients who developed an antibody response when rituximab was not administered. As of 12/15/2025, 10/13 patients are alive 6-30 months after first infusion, with 7 alive $>$14 months. **Conclusions:** Intraventricular CARv3-TEAM-E infusions were well-tolerated after LDC+R pre-conditioning and no DLTs were noted. The addition of Rituximab abrogated anti-therapy antibody formation and prolonged CAR T-cell persistence in 3/3 patients. Survival data reflect continued promise of CARv3-TEAM-E in patients with recurrent glioblastoma. Clinical trial information: NCT05660369. Research Sponsor: None.

Real-world outcomes from 3D-PREDICT glioma chemosensitivity testing of primary CNS tumors. First Author: Aidan Jones, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: 3D-Predict Glioma is an *ex vivo* chemosensitivity assay that predicts response to 12 systemic agents using patient-derived 3D cell cultures. Prospective studies showed predictive accuracy, but real-world data linking assay-guided therapy selection to clinical outcomes remain limited. We analyzed outcomes at a tertiary cancer center. **Methods:** This retrospective–prospective chart review included patients with primary CNS tumors who underwent chemosensitivity testing at an urban cancer center since 3/2023. Demographics, tumor characteristics, assay results for the 12-drug panel, treatment selection, and clinical outcomes were abstracted. Drug response was categorized as response, moderate response, or no response. Survival analyses were performed using the Kaplan–Meier method. **Results:** Among the 96 patients, ECOG was 0 in 21 (22.1%), 1 in 37 (38.9%), 2 in 26 (27.4%), and 3 in 11 (11.6%). Insurance coverage included private (69, 71.9%), Medicaid/Medicare (14, 14.5%), Private plus Medicaid/Medicare (12, 12.5%), or self-pay (1, 1.0%). At the time of analysis, 85 patients (88.5%) were alive. Median age was 64 years (range 25–86; IQR 56–71), and 53 (55.2%) were female. Most were diagnosed with adult-type diffuse glioma (92, 95.8%), including 84 (87.5%) glioblastoma. Chemosensitivity testing failed in 10 (10.4%) cases due to insufficient tissue quantity or quality control. All remaining cases yielded 1 or more drugs with assay-predicted responses. Response rates for each drug are detailed in the Table. Mean time to results was 8.8 days (range 5–15). Assay-guided therapy was selected in 59.5%, predominantly temozolomide. The remaining patients received other agents on trial, standard-of-care physician's choice, no further therapy, or transferred care. Key endpoints analyzed included progression-free survival (PFS), PFS at 6 months, overall survival (OS), OS at 12 months, and time-to-progression (TTP) ratio. **Conclusions:** In a real-world CNS tumor cohort, 3D-Predict Glioma identified potentially active agents and influenced treatment selection in more than half of patients. Our series suggests that chemosensitivity-guided therapy is feasible in routine neuro-oncology practice. Research Sponsor: None.

Neoadjuvant treatment of recurrent high-grade gliomas with camrelizumab in combination with apatinib: A prospective phase II clinical study. First Author: Cheng-Cheng Guo, Department of Neurosurgery/Neuro-Oncology, Sun Yat-sen University Cancer Center, Collaborative Innovation Center for Cancer Medicine, State Key Laboratory of Oncology in South China, Guangzhuo, China

Background: High-grade gliomas exhibit extremely recurrent and resistant to treatments, and require urgent therapeutic innovation. This phase II trial presents preliminary results of neoadjuvant camrelizumab (PD-1 inhibitor) combined with apatinib (VEGFR2 TKI) for recurrent high-grade gliomas. **Methods:** This single-center, single-arm, phase II trial (NCT04588987) enrolled patients (age $>$18, KPS $\geq$60) with recurrent high-grade gliomas suitable for re-resection after prior STUPP therapy. Patients received i.v. camrelizumab 200mg (D1) and oral apatinib 250mg (D1-D7). Surgery was performed 1 week post-drug discontinuation. Adjuvant treatment with i.v. camrelizumab 200 mg every two weeks (from 2 weeks $\pm$ 5 days post-surgery) in combination with continuous oral apatinib 250 mg/d (from 4 weeks post-surgery) was administered until death/unacceptable toxicity. Primary endpoint: overall survival (OS). Secondary endpoints: 1-year OS rate, 6-/12-month PFS rates, time to progression (TTP), KPS, and adverse events (AEs). **Results:** From October 2020 to December 2024, 28 patients were enrolled (median age 42 years [range 23-62]; 22 glioblastoma, 4 anaplastic astrocytoma, 1 anaplastic oligodendroglioma, 1 gliosarcoma). The 27 patients completed adjuvant therapy with follow-up, and 1 patients continue on adjuvant therapy. As of January 14, 2026, median OS for all patients was 11.100 months (95% CI: 8.818 -13.382), with 1-year OS rate 46.4%. Median PFS was 4.870 months (95% CI: 4.351 – 5.389), with 6-month PFS rate 39.3%. The 22 patients with recurrent glioblastoma (rGBM) showed the median OS of 11.670 months (95% CI: 8.303 -15.037), and the 1-year OS rate was 50.0%. The median PFS was 5.070 months (95% CI: 4.381 -5.759), with the 6-month PFS rate of 40.9% in the rGBM subgroup. Historical neoadjuvant anti-PD1 monotherapy for rGBM yielded OS 13.9 months and PFS 3.3 months (Nat Med. 2019). **Conclusions:** Camrelizumab in combination with apatinib neoadjuvant therapy showed excellent efficacy in recurrent high-grade gliomas, and was superior to PD1 inhibitor monotherapy neoadjuvant treatment in rGBM patients. Clinical trial information: NCT04588987. Research Sponsor: National Natural Science Foundation of China.

An alternative approach to limiting surgical and radiation stress in patients with glioblastoma. First Author: Eduard E. Rostorguev, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: While neuro-oncology has seen global advances in high-tech diagnostics and treatments for brain tumors, these innovations often overlook the principles of the body's adaptive response. Stress acts as a nonspecific driver of cancer progression and is intensified by aggressive therapies. An alternative approach involves harnessing general nonspecific adaptive reactions (GNARs), which are governed by the brain's regulatory systems. These anti-stress GNARs — specifically the reactions of training, calm activation, and elevated activation — form the foundation of "activation therapy" and are considered essential in the comprehensive management of high-grade gliomas (HGG). In glioblastoma, tumor growth exacerbates cerebral hypoxia, leads to endothelial damage, and promotes thrombosis and perifocal edema. During radiation therapy (RT), edema is further aggravated as a deleterious side effect of ionizing radiation on brain tissue. This study aimed to investigate whether adjunctive activation transcranial magnetic therapy (ATMT) can mitigate edema development and improve treatment outcomes. **Methods:** Data from 50 patients with HGG were analyzed. Using simple randomization, patients were divided into two groups: the Main group (n=25) received standard treatment plus two courses of ATMT during the early postoperative period and during RT; the Control group (n=25) received standard treatment without ATMT. Each ATMT session consisted of two exposures. The first exposure was performed in the morning on the hypothalamic projection area using a frequency algorithm of 0.3 Hz (5 min) – 3 Hz (1 min) – 9 Hz (1 min) with a daily exponential change in induction (B) from 3 to 1 mT (device: "Gradient-4M"). The second exposure was performed 2.5–3 hours later using pulsed ATMT on the perifocal zone of the removed tumor bed with the same frequency algorithm at B=15 mT (device: "Neuro-MSD"). **Results:** In the early postoperative period (prior to RT), ATMT reduced the frequency of acute stress development by 3.4-fold compared to controls. After the completion of RT combined with ATMT, stress inhibition was observed 1.6 times more frequently than in the control group. The induction of a stable "reaction of calm activation" via ATMT contributed to a decrease in perifocal edema volume by an average of 3.75-fold, compared to 1.04-fold in the control group (p=0.0180). Regression of neurological symptoms after RT was noted in 92% of patients who received two courses of ATMT versus 68% in the control group (p=0.0391). Furthermore, the absence of cognitive impairment after RT was observed in 80% of ATMT patients compared to 24% in the control group (p=0.0002). **Conclusions:** The adjunctive use of ATMT improves treatment outcomes in patients with HGG by developing and maintaining anti-stress reactions as an alternative to surgical and radiation-induced stress, thereby improving the patients' quality of life. Management of first recurrence from IDH-wildtype glioblastoma with re-resection or stereotactic radiosurgery: A retrospective, international, multicenter study. First Author: Nico Teske, Department of Neurosurgery, Uniklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nuernberg, Erlangen, Germany

Background: Optimal management of recurrent glioblastoma remains ill-defined. While re-resection is frequently provided as local salvage therapy, stereotactic radiosurgery (SRS) might represent a treatment approach for small, focal recurrences. We comparatively evaluated outcomes after re-resection and SRS for first recurrence of IDH-wildtype glioblastoma. **Methods:** Adult patients with first radiographic recurrence of IDH-wildtype glioblastoma (WHO 2021 classification) were identified. Information on patients managed with re-resection were collected through the international eight-center database of the RANO *resect* group, and patients managed with SRS were collected by twelve centers from the IRRF study group. Survival after recurrence was analyzed using Kaplan–Meier estimates and Cox proportional hazards models. Inverse probability of treatment weighting (IPTW) was applied to mitigate baseline imbalances. **Results:** Overall, 567 patients were included (re-resection: n = 310; SRS: n = 257). Compared with SRS, patients managed with re-resection were younger and had larger contrast-enhancing recurrence volumes. Despite those baseline differences, overall survival did not differ between treatment modalities (10.2 [95%CI 9.3–11.7] *vs.* 11.1 [10.3–12.8] months; HR 1.12, 95%CI 0.93–1.35; p = 0.231). Also, no survival differences between treatment groups were observed when effects of potential baseline confounders including tumor volume were minimized using IPTW. Notably, among patients typically not considered SRS candidates due to tumor volumes $>$10 cm³ (n = 234), maximal re-resection of the enhancing tumor (RANO class 1–2) was associated with survival comparable to SRS-treated low-volume tumors $\leq$10 cm³ (9.1 [7.7–11.5] *vs.* 11.0 [9.9–12.8] months; HR 1.27, 0.95–1.69; p = 0.106) whereas incomplete re-resection (RANO class 3) was associated with less favourable survival. In the subgroup of patients with focal recurrences in whom local physicians from the IRRF consortium perceived clinical equipoise between treatment modalities but eventually performed SRS (n = 112), IPTW-adjusted analyses demonstrated no significant difference in overall survival compared with re-resected patients (HR 0.90, 0.65–1.25; p = 0.539). **Conclusions:** While complete re-resection is prognostic in recurrent glioblastoma, SRS might represent a reasonable therapeutic approach for selected individuals with small low volume tumor recurrence. Given substantial baseline differences between patients treated with re-resection and SRS and potential treatment provider bias, prospective trials are warranted to guide nuanced decision-making. Phase II trial evaluating nivolumab in patients with recurrent IDH-mutant gliomas with and without hypermutation phenotype. First Author: Jing Wu, Neuro-Oncology Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Tumor mutational burden (TMB) is an emerging biomarker for the prediction of immune therapy success in solid tumors. Response to immune checkpoint inhibitor (ICI) treatment in rare gliomas with biallelic mismatch repair deficiencies has been attributed to their hypermutation phenotype (HMP). This has not been tested in other gliomas. We developed a phase II clinical trial using nivolumab in recurrent IDH-mutant gliomas evaluating response in tumors with HMP (approximately 10% of cases) and in tumors with non-HMP (NHMP). Here we report the results of the analysis of the NHMP cohort. **Methods:** Adults with recurrent IDH-mutant glioma, KPS $\geq$ 60, normal organ function, with known somatic TMB (analyzed at NIH) were enrolled in a phase II trial. Nivolumab was given at 480mg IV every 28-day cycle with a maximum of 16 cycles. The primary endpoint is PFS rate at 6 months (PFS6) in both HMP and NHMP cohorts. Responses to treatment were evaluated by MRI every 2 cycles using iRANO criteria. Simon's two-stage design was used to independently evaluate the HMP/NHMP cohort. For the NHMP cohort, the null and alternative hypotheses for PFS6 are 0.2 and 0.4, respectively. A total of 30 were planned to be accrued across stages I and II. If $\geq$10 patients are progression-free at 6 months, the null hypothesis will be rejected, indicating that the treatment is promising for patients with NHMP IDH-mutant gliomas. The design controls the type I error at 0.05 and yields a power of 0.8. Tumor samples and peripheral blood were collected for correlative studies. Patient-reported outcomes (PRO) were evaluated by longitudinal symptom burden analysis using Brain Tumor Module of the MD Anderson Symptom Inventory. **Results:** As of January 2026, thirty patients were enrolled and treated on the NHMP cohort (TMB$<$5 mut/Mb). Among 30 evaluable patients, 20 were male, median age 44 and KPS 90. Histological diagnosis included 22 astrocytoma (grade 3, n=10; grade 4, n=12) and 8 oligodendroglioma (grade 2, n=1; grade 3, n=7). Median number of prior recurrences is 2, ranging from 1 to 5. At the time of analysis, all 30 evaluable patients were off study treatment: 7 completed all 16 cycles, 17 had disease progression, 3 withdrew to start other management. Three patients were off treatment due to treatment related grade 3 colitis, pneumonitis and dry mouth. Eleven and 8 out of 30 patients were progression free at 6 and 12 months, respectively. PRO and correlative studies are ongoing. **Conclusions:** Nivolumab is well tolerated and has shown efficacy in a cohort of patients with recurrent IDH-mutant gliomas with low TMB. Clinical benefit measured by objective response, PFS, OS and PRO, along with longitudinal immune monitoring, will help determine whether tumor TMB correlates with immunologic and clinical response to ICI therapy in IDH-mutant gliomas. Clinical trial information: NCT03718767. Research Sponsor: NIH Intramural Research.

2065 **Poster Session**

A phase 2 double-blind, randomized, prospective, placebo-controlled study of $NanO_2$ combined with radiation and temozolomide in patients with newly diagnosed glioblastoma: RESTORE. First Author: Samuel A. Goldlust, Saint Luke's Cancer Institute, Kansas City, MO

Background: Glioblastoma (GBM) contains extensive hypoxic regions due to tumor-associated thrombosis and abnormal vasculature. Hypoxia drives resistance to radiation (RT) and temozolomide (TMZ) by limiting oxygen-dependent DNA damage, enabling DNA repair, and reducing drug efficacy and delivery. The RESTORE trial (NCT03862430) is the first randomized, prospective, placebo-controlled study of $NanO_2$ (2% w/v dodecafluoropentane emulsion) in GBM, a fluorocarbon-based oxygen therapeutic hypothesized to reoxygenate hypoxic GBM tissue, with the goal of enhancing the efficacy of chemoradiation. **Methods:** Patients with newly diagnosed GBM (WHO 2021) received standard-of-care radiation (60 Gy) with concurrent TMZ (75 mg/m²/day). Patients were randomized 2:1 to receive either $NanO_2$ or 0.9% sodium chloride administered intravenously immediately prior to each RT fraction, with continuous supplemental oxygen given during the infusion and RT. Following chemoradiation, patients completed a four-week recovery period before initiating adjuvant TMZ for 6 cycles. The primary endpoint is progression free survival and secondary endpoints include overall survival, objective response rate, pseudoprogression rate, and patient reported outcomes. **Results:** Between May 2023 and October 2025, 93 patients were treated (safety set). The study has completed the planned enrollment. Median age was 63 years (range, 19–84) and 57% were men. As of the data cutoff on 12/29/25, all patients completed the follow up visit 4 weeks after chemoradiation. Sixty-eight patients (73%) remained on study undergoing adjuvant TMZ or in long-term follow-up. Twenty-one patients passed of tumor progression and 4 patients withdrew consent. The median duration on study was 8.7 months (range, 1.3–31.4). During chemoradiation and the four-week recovery, 63 treatment-emergent adverse events (TEAEs) of CTCAE severity grade $\geq$3 were reported in 37% of patients, with brain edema, lymphocyte count decreased, and platelet count decreased being the most frequently reported. Twenty-six treatment-emergent serious adverse events (TESAEs) occurred in 19% of patients, with embolism, pulmonary embolism, and seizure being the most frequently reported. Three TESAEs were assessed as possibly or probably related to study drug; none were unexpected. Survival follow up is ongoing. **Conclusions:** In this blinded, pooled safety analysis of a randomized phase 2 trial in newly diagnosed GBM, the study treatment was well tolerated and no new safety signals were identified. Treatment allocation remains blinded. Efficacy outcomes and arm-specific safety analyses will be reported after completion of the primary endpoint analysis. Clinical trial information: NCT03862430. Research Sponsor: NuvOx Therapeutics.

2066 **Poster Session**

Mapping the exhausted and tolerized myeloid populations in the glioblastoma tumor microenvironment. First Author: Yu-Ting Tsai, Wake Forest University School of Medicine, Winston-Salem, NC

Background: Glioblastoma (GBM) is a highly malignant brain tumor characterized by an immunosuppressive microenvironment and rapid development of therapeutic resistance. In GBM, myeloid cells can comprise 30–50% of the tumor and critically regulate its immune microenvironment. Evidence from aging and CNS diseases suggests that microglia can adopt dysfunctional states of exhaustion and tolerance that extend beyond the M1/M2 paradigm, thus prompting us to investigate whether these phenotypes contribute to immune escape and progression of GBM. **Methods:** Paired RNA-seq of tumor specimens from newly diagnosed and recurrent GBM patients (n=14) was used to examine aging-related gene expression during treatment and progression. Open-access human glioma single-cell RNA-seq data (GSE182109) were analyzed to characterize exhaustion and tolerance across macrophage subpopulations based on molecular/metabolic signatures. **Results:** Patient tumor RNA-Seq revealed that the aging-related TREM2-APOE axis is present in recurrent GBM, suggesting accelerated brain aging. Single-cell RNA-seq identified nine myeloid clusters, including four microglial states (homeostatic-, activated-, AP-, and a-microglia) and two macrophage populations (anti-inflammatory and immunosuppressive). We found that AP-microglia showed disease-associated activation, with high CD45/CD11C/TREM2 expression and concurrent upregulation of the exhaustion markers PD-L1 and CD38. Moreover, microglial activation-related signaling in AP-microglia includes increased STAT1/2-IRF9 signaling, which can promote immunosuppression by inducing PD-L1. On the other hand, a-microglia is unique in its high expression of activation-restraining and tolerance markers, such as SPRY/P2RY13, rather than the classic microglial marker TMEM119/P2RY12. Both AP-microglia and a-microglia are shown to lose expression of the inflammatory cytokines TNF-α and IL-1β, consistent with the characteristics of exhausted and tolerized microglia. Unlike resident microglia, the immunosuppressive macrophage cluster exhibits a monocyte-tolerized phenotype, with downregulated FABP4 and increased SOD2, CLEC4E, and SLC2A6. It also shows a similar panel of LPS-induced monocyte exhaustion with TLR4/MyD88/SRC and STAT3/IL-10 upregulation. **Conclusions:** Our analysis indicates that AP-microglia are exhausted and a-microglia are tolerized in GBM, with shared markers of dysfunction across macrophages linking myeloid impairment to immune suppression and treatment-associated brain aging. These findings implicate myeloid exhaustion in GBM immune escape and identify potential therapeutic targets. Research Sponsor: Louise McMichael Miracle Fund.

A 3D tumorwide multi-omic atlas of intratumoral heterogeneity in *IDH*-mutant glioma. First Author: Benjamin Joshua Lerman, University of California, San Francisco, San Francisco, CA

Background: Isocitrate dehydrogenase mutant (IDHmut) glioma affects over 20,000 adults per year. Treatment failure often results from intratumoral heterogeneity, in which genomic subclones undergo selection for treatment-resistant populations. Understanding this heterogeneity is critical to selecting therapeutic combinations that are efficacious across the entire tumor, but few genomic studies go beyond analyzing a single tumor sample per patient. **Methods:** 3D whole tumor sampling was used to obtain 324 spatially mapped samples from 32 IDHmut gliomas. Whole exome (n=323), RNA (318), ATAC sequencing (92), and Hi-C (14) were performed. PyClone reconstructed clonal evolution, weighted gene/peak correlation network analyses derived co-expression (RNA) and gene regulatory (ATAC) programs, and comparison of tumor Hi-C results to normal brain identified tumor-specific chromatin loops. **Results:** Regional tumor content (purity) inversely correlated with distance from tumor centroid (R = -0.32, $p = 2.8\times10^{-8}$) and inter-sample distance was associated with subclonal (R = 0.24, $p = 8.1\text{x}10^{-15}$) and transcriptional (R = 0.12, $p = 1.0\text{x}10^{-5}$) similarity. Beyond IDH1 in the combined 17 astrocytomas and 15 oligodendrogliomas, tumor-wide alterations were recurrently observed in TP53 (altered in 64%; tumor-wide in 58%), ATRX (55%; 39%), TERT promoter (45%; 45%) and FUBP1 (18%; 6%). Despite high cohort prevalence, glioma-associated drivers CIC (altered in 42%), PIK3CA (36%), and ARID1A (18%) were tumor-wide in only one patient each, while MUC4 (33%), NOTCH1 (27%), SETD2 (24%), and PIK3R1 (15%) were never observed in the tumor founding clone. Tumors with CIC alterations harbored a median of 5 unique mutations with a median combined tumor-wide cancer cell fraction of 45%. Hi-C identified 5,579 tumor-specific promoter-enhancer interactions across 4,144 loops. The genes associated with these promoters enriched for tumor-specific RNA programs associated with OPC signature ($p_{adj} = 3\text{x}10^{-14}$), NPC signature ($p_{adj} = 3.87\text{x}10^{-14}$), and neuronal mimicry (1.2×10^{-13}). We discovered adversely prognostic gene expression programs in astrocytoma independently validated in chromatin regulatory programs. **Conclusions:** Tumor-wide sampling of IDHmut glioma revealed evidence of radial tumor growth and 3D patterns of cellular organization, in sharp contrast to intermixed patterns in IDH wildtype glioma. Most inter-patient heterogeneity in driver alterations was subclonal. Our data also revealed regulatory loops that explain tumor cell-specific expression signatures. A significant, adverse prognostic marker in astrocytoma was discovered and cross-validated. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Identification of prognostically relevant residual tumor burden in glioblastoma after surgery: A comparative analysis of MR-based RANO resect classes vs [^{18}F]FET PET. First Author: Jens Blobner, Department of Neurosurgery LMU, Munich, Germany

Background: Accurate assessment of postoperative residual tumor burden is critical in *IDH*-wildtype glioblastoma. The MRI-based RANO resect classification stratifies patients according to postoperative contrast-enhancing and non-contrast enhancing tumor volume but may underestimate metabolically active residual disease. The additional prognostic value of postoperative [^{18}F]FET PET beyond MRI is yet unclear. **Methods:** This retrospective bicentric study included 140 patients with newly diagnosed *IDH*-wildtype glioblastoma and evaluable postoperative MRI and [^{18}F]FET PET. Residual tumor volumes were segmented on MRI and classified according to the RANO resect system. PET-derived residual metabolic tumor volumes were defined using PET RANO 1.0 criteria. Spatial agreement between MRI- and PET-based volumes was quantified using Dice coefficients. Associations with overall survival were analyzed using Cox regression. Incremental prognostic value of PET was assessed using an imaging-only model (contrast-enhanced T1 (T1CE) vs. T1CE + PET) and a fully adjusted model including clinical covariates. **Results:** PET-derived residual tumor volumes exceeded MRI-defined volumes and showed low spatial concordance with MRI (Dice coefficient: 0.01–0.25) across all RANO resect classes. Postoperative PET-, T1CE-, and T2/FLAIR-derived tumor volumes were each associated with overall survival. Increasing PET-derived residual tumor burden was associated with a continuous increase in mortality risk. In multivariable Cox regression, PET-derived residual tumor volume remained independently associated with overall survival (adjusted hazard ratio 1.021 per cm³, 95% CI 1.008–1.033; $^{**}p$ = 0.0024). In the imaging-only model, addition of PET improved time-dependent discrimination between 6 and 24 months (ΔAUC(t) 0.03–0.07) and increased Harrell's C ($\Delta C \approx 0.03$). In the fully adjusted model, PET provided significant non-redundant prognostic information (likelihood ratio test, $^{*}p$ = 0.0049). **Conclusions:** Postoperative [^{18}F]FET PET identifies metabolically active residual tumor not adequately captured by MRI and provides additional prognostic information beyond MRI-based assessment. Integration of PET into postoperative evaluation may refine prognostic stratification in IDH-wildtype glioblastoma. Research Sponsor: None.

Phase I/II study of liposomal curcumin in combination with standard radiation and temozolomide in patients with newly diagnosed high-grade gliomas. First Author: Matthias Holdhoff, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

Background: Liposomal curcumin (LC) is an intravenous formulation designed to enhance curcumin delivery and modulate inflammatory, oxidative, and oncogenic pathways relevant to high-grade glioma (HGG), including dysregulated kynurenine metabolism. Preclinical studies demonstrate synergy between LC and chemoradiation. This Phase I/II study was designed to determine the recommended Phase II dose (RP2D) of weekly IV LC with radiotherapy and temozolomide (RT/TMZ) in newly diagnosed HGG (primary objective), assess safety and feasibility (secondary objective), and preliminary efficacy (exploratory objective). **Methods:** This open-label, sequential dose-escalation study used the TITE-BOIN Bayesian design to evaluate LC at 300, 350, and 400 mg/m². Patients received standard chemoradiation (2 Gy $\times$ 5 days/week $\times$ 6 weeks with concomitant TMZ 75 mg/m²/day), followed by standard adjuvant TMZ and weekly LC infusions over 3 hours for a target of 34 doses, with optional continuation. Eligible patients had newly diagnosed HGG (WHO grade 3 or 4) and KPS $\geq$70%. Patients were evaluable if they received $\geq$80% of planned LC infusions and $\geq$60% of planned TMZ dosing during the 10-week toxicity evaluation period. Radiographic response was assessed per RANO 2.0. **Results:** Twenty-five patients were treated: 300 mg/m² (n=6), 350 mg/m² (n=12), and 400 mg/m² (n=7); all patients assigned to 400 mg/m² were treated at 350 mg/m² per Safety Review Committee recommendation. All patients had glioblastoma or molecular glioblastoma, IDH-wildtype, WHO grade 4 per 2021 WHO classification (MGMT promoter methylation status: 7 methylated, 1 indeterminate, 17 unmethylated). Median age was 56 years (range, 43–75); median KPS was 90 (range, 70–100). Two protocol-defined dose-limiting toxicities occurred at 400 mg/m²: grade 4 pancytopenia and grade 1 hemolysis. LC-related grade $\geq$3 toxicities occurred in 4 patients (16%) and included confusion, seizure, thromboembolic event, cerebral edema, lymphopenia, thrombocytopenia, fatigue (all grade 3), and pancytopenia (grade 4). There were no LC-related deaths. Based on the TITE-BOIN design and cumulative safety data, 350 mg/m² was identified as the RP2D. With a median follow-up of 12.9 months (range, 2.4-27.3 months) as of 1/23/2026, median progression-free and overall survival have not been reached. At 6 and 12 months from first LC infusion, 95% and 87% of uncensored patients (n=18, n=13), respectively, remained alive. **Conclusions:** LC combined with standard chemoradiation was safe and well tolerated, with encouraging exploratory signals of disease control in newly diagnosed glioblastoma. Further evaluation in an expanded Phase II/III study is planned. Clinical trial information: NCT05768919. Research Sponsor: Signpath Pharma.

Phase I trial to evaluate the safety and tolerability of fb-PMT in patients with recurrent glioblastoma. First Author: Nicholas Alfred Blondin, Yale University School of Medicine, New Haven, CT

Background: Proliferative, pro-angiogenesis, and pro-inflammatory actions mediated by L-thyroxine in glioblastoma (GBM) are initiated at cell surface thyrointegrin $\alpha v\beta 3$ receptors for thyroid hormone, located on the extracellular domain of $\alpha v\beta 3$ integrin. Thyrointegrin $\alpha v\beta 3$ receptors are over-expressed in cancer and rapidly dividing endothelial cells. fb-PMT (NP751) is a macromolecule in which fluorobenzyl is conjugated to monodisperse polyethylene glycol via mono-triazole tetraiodo thyroacetic acid, with high affinity and specificity for thyrointegrin $\alpha v\beta 3$ receptors. In pre-clinical murine xenograft models, fb-PMT resulted in a dose-dependent suppression of GBM tumor growth and viability, and histopathological analysis revealed loss of the vascularity along with extensive tumor necrosis and apoptosis. Genomic micro-array studies suggested multiple growth pathways in GBM are modulated by fb-PMT. Based on this promising pre-clinical data, we conducted a first-in-human Phase 1 study of fb-PMT in patients with recurrent GBM. **Methods:** Patients with first or second recurrence of GBM were enrolled to receive fb-PMT via subcutaneous injection once daily for 28-day cycles, following a 3+3 design. Predefined dose levels were 0.08, 0.24, 0.48, 0.96, and 1.44 mg/kg/day, respectively. The study objectives were to evaluate the safety and tolerability of daily administration of fb-PMT, and establish the recommended phase 2 dose (RP2D) of fb-PMT. Exploratory objectives included pharmacokinetic profiling of fb-PMT, expression of $\alpha v\beta 3$ integrin, fb-PMT, and other proteins in available tumor samples, and estimating preliminary efficacy of fb-PMT. **Results:** As of January 2026, accrual has been completed, with 22 patients enrolled and 20 patients completing at least one treatment cycle. Treatment with fb-PMT was well tolerated across the 5 dose levels examined. No serious adverse events (SAEs) related to fb-PMT and no dose-limiting toxicities occurred; the RP2D is 0.96 mg/kg/day. PK analysis demonstrated a dose-dependent increase in systemic drug exposure with escalating doses. Immunohistochemical evaluation of integrin $\alpha v\beta 3$ expression in available tumor samples detected target expression, with variable levels of integrin $\alpha v\beta 3$ expression and predominant localization to tumor-associated vasculature and regions of necrosis and hemorrhage. Preliminary efficacy evaluation is ongoing, with two patients in Cohort 4 (0.96 mg/kg/day) having partial response and remaining on study (cycle 35+ and cycle 26+, respectively). **Conclusions:** This Phase 1 study demonstrated that treatment of recurrent glioblastoma with fb-PMT was safe and well tolerated, with a predictable pharmacokinetic profile. Two patients remain on therapy beyond 24 months. Future studies are planned. Clinical trial information: NCT05226494. Research Sponsor: NanoPharmaceuticals LLC.

2071 **Poster Session**

Suicide gene therapy for recurrent glioblastoma using allogeneic bone marrow–derived mesenchymal stem cell gene delivery (MSC/CD): A first-in-human, dose-escalation phase I clinical trial. First Author: Jaejoon Lim, Department of Neurosurgery, CHA Bundang Medical Center, CHA University College of Medicine, Seongnam, South Korea

Background: Glioblastoma (GBM) remains an incurable brain tumor characterized by complex heterogeneity and poor prognosis, even with maximal multimodal therapy. Innovative treatments for recurrent GBM are urgently needed to complement existing therapies. This study explores the feasibility, safety, and efficacy of a novel suicide gene therapy using allogeneic mesenchymal stem cells (MSCs) expressing cytosine deaminase (CD) in combination with 5-fluorocytosine (5-FC). **Methods:** A Phase 1, single-center, non-randomized, dose-escalating study was conducted to evaluate the safety and efficacy of mesenchymal stem cell expressing cytosine deaminase (MSC/CD) therapy in 10 patients with recurrent GBM. Patients received intratumoral injections of MSC/CD followed by oral 5-FC. Pharmacokinetic profiling, pharmacodynamic analysis, targeted panel sequencing, whole transcriptome analysis, integrative omics analysis, and multiplexed immunofluorescence imaging were performed to assess drug conversion and identify predictable candidate biomarkers. Safety and survival outcome were monitored by evaluating adverse events (AEs) and clinical data. **Results:** MSC/CD therapy was well-tolerated, with most AEs being mild to moderate. There was no drug toxicity related with dose escalation. Severe AEs (≥ Grade 3) were rare and unrelated to the study drug. Effective conversion of 5-FC to 5-fluorouracil (5-FU) was observed in the brain, with detectable levels in the cerebrospinal fluid, confirming the feasibility of intracranial drug delivery. The median progression-free survival was 5.4 months, and the overall survival was 16.3 months. RNA transcriptomic analysis revealed two molecular subclusters with distinct biological characteristics, correlating with different progression-free survival outcomes. The integrative omics analysis revealed that specific cell cycle-related genes were found to be highly expressed in the non-responder group of patients, suggesting that elevated levels of these genes may be associated with resistance to treatment. **Conclusions:** This study demonstrates that MSC/CD therapy is a feasible, safe, and potentially effective treatment for recurrent GBM. The identification of distinct molecular subtypes and candidate genes offers a potential biomarker for patient selection and therapeutic targeting. Further studies are warranted to validate these findings and optimize therapeutic strategies. Clinical trial information: NCT04657315. Research Sponsor: he Ministry of Trade, Industry & Energy (MOTIE, Korea); 10067378.

Intrathecal iPSC-derived natural killer cells combined with the Stupp regimen for newly diagnosed WHO grade 4 glioma: A phase I trial. First Author: Yulun Huang, The Fourth Affiliated Hospital of Soochow University, Soochow, China

Background: WHO grade 4 glioma has a poor prognosis despite standard Stupp therapy. Induced pluripotent stem cell–derived allogeneic natural killer cells (iPSC-NK) represent a standardized and scalable cellular immunotherapy with consistent cytotoxic potential. This Phase I study evaluated intrathecal iPSC-NK cells combined with the Stupp regimen in newly diagnosed WHO grade 4 glioma. **Methods:** Thirteen newly diagnosed WHO grade 4 glioma patients (median age 46 years; IDH-wildtype n=11; MGMT-methylated n=6) received standard chemoradiotherapy followed by intrathecal iPSC-NK cell infusions. iPSC-NK cells were administered at escalating doses (2×10^7, 6×10^7, 2×10^8 cells/cycle) via lumbar puncture (n=8) or Ommaya reservoir (n=5) over four 28-day cycles, with temozolomide priming 5 days before each infusion. The primary endpoint was safety (serious adverse events, ≥Grade 3 toxicities); secondary endpoints included progression-free survival and pharmacokinetic/pharmacodynamic immune analyses. **Results:** Across 54 intrathecal iPSC-NK infusions, treatment-related toxicities were predominantly low grade: fever occurred as Grade 1 in 35 (64.8%) and Grade 2 in 9 (16.7%) infusions; headache as Grade 1-2 in 19 (35.2%) and Grade 3 in 1 (1.9%) infusion; and cytokine release syndrome was limited to Grade 1 events (44/54, 81.5%), with no ≥Grade 2 CRS or ICANS. Median PFS was 17.41 months, while median OS was not reached at a median follow-up of 22.47 months (data cutoff: January 18, 2026). PK analysis showed detectable iNK cells in CSF on Days 1–3 post-infusion, peaking on Days 1–2 and declining by Day 3. PD analyses demonstrated rapid activation of $CD4^+$/$CD8^+$ T cells ($CD69^+$) and expansion of myeloid populations. Olink proteomics revealed consistent upregulation of cytotoxic (GZMA/B), chemokine (CXCL/CCL), and inflammatory cytokines (TNF, IFN-γ). **Conclusions:** iPSC-NK cells combined with the Stupp regimen demonstrated a favorable safety profile, induced early immune activation within the central nervous system, and showed encouraging preliminary efficacy in patients with WHO grade4 glioma. Clinical trial information: NCT06147505. Research Sponsor: National Natural Science Foundation of China; 82472981; XellSmart Biopharmaceutical (Suzhou) Co., Ltd.

Comparative response assessment using PET-RANO 1.0 and RANO 2.0 in vorasidenib-treated *IDH*-mutant gliomas: The VORAFET study. First Author: Alberto Bosio, Medical Oncology 1, Veneto Institute of Oncology IOV - IRCCS, Padova, Italy

Background: MRI-based response assessment may be suboptimal for capturing early treatment effects during isocitrate dehydrogenase (*IDH*) inhibition. We compared metabolic and morphological response classification using PET-RANO 1.0 and RANO 2.0 in vorasidenib-treated *IDH*-mutant gliomas and assessed treatment-related metabolic changes. **Methods:** All consecutive patients treated at Veneto Institute of Oncology and Padua University Hospital with vorasidenib (VOR) under a compassionate-use program (June 2024-March 2025) with baseline and follow-up [^{18}F]FET PET/MR were retrospectively included. Response was assessed every 3 treatment cycles according to PET-RANO 1.0 and RANO 2.0. PET-positive tumor volumes and tumor-to-background ratios (TBR_{max}, TBR_{mean}) were analyzed. MRI response was evaluated using volumetric RANO 2.0 criteria. The VORAFET study was approved by the local Ethics Committee. **Results:** Twenty-six patients were included (10 astrocytomas, 16 oligodendrogliomas; 22 WHO grade 2, 4 non-enhancing WHO grade 3). Median follow-up from VOR initiation was 9 months (IQR 9-11). According to PET-RANO 1.0, partial metabolic responses (PET-PR) increased over time, from 20% at 3 months to 30.8% at 6 months and 63.6% at 9 months, while metabolic progression (PET-PD) was already detected in 18.2% at 9 months. In contrast, RANO 2.0 identified no partial responses at any timepoint, classifying most patients as stable disease (84.2%) or minor response (10.5%), with progression detected in only 5.3% at 9 months. Quantitative PET analysis showed an early and sustained reduction in metabolic activity. TBR_{mean} decreased significantly at 3 months (mean difference [MD] -0.04; 95% CI -0.08 to -0.01) and continued to decline at 9 months (MD -0.07; 95% CI -0.11 to -0.02). Compared to baseline, at 9 months, TBR_{max} decreased from 2.7 to 2.0 (MD -0.5; 95% CI -0.8 to -0.2) in all patients included. No significant changes were observed in PET volumes. Similarly, FLAIR-based tumor volume showed no significant variation (at 9 months: MD -2.2; 95% CI -5.1 to 0.7). **Conclusions:** PET-RANO 1.0 enabled earlier detection of treatment response and progression compared with MRI-based RANO 2.0, highlighting clinically relevant limitations of morphology-driven MRI-based assessment. These findings support the clinical integration of amino acid PET into response monitoring strategies and warrant prospective validation of PET-derived biomarkers in *IDH*-mutant gliomas. Research Sponsor: None.

2074 **Poster Session**

Phase II clinical study of ACT001 combined with radiotherapy in newly diagnosed pediatric diffuse intrinsic pontine glioma. First Author: Jing Zhang, Beijing Tiantan Hospital, Capital Medical University, Beijing, China

Background: Diffuse intrinsic pontine glioma (DIPG) is an extremely lethal type of malignant tumor in the central nervous system of children. Currently, standard radiotherapy has limited efficacy, and there is an urgent need to explore novel therapeutic regimens. This study aims to evaluate the safety and efficacy of ACT001, a novel blood-brain barrier-permeable agent, combined with standard radiotherapy in the treatment of newly diagnosed pediatric DIPG. **Methods:** This open-label, single-arm, multicenter phase II trial enrolled 5–15-year-old patients with newly diagnosed DIPG. Patients received radiotherapy (54 Gy/30 fractions) plus ACT001 (700 mg/m² BID orally, fasting) for 6 weeks (concurrent phase), followed by ACT001 maintenance until progression/toxicity. The primary endpoints were objective response rate (ORR) and overall survival (OS), while the secondary endpoints included progression-free survival (PFS), 1-year OS rate, and safety. Statistical analyses used Kaplan-Meier and Cox regression. **Results:** A total of 41 patients were screened, with 33 included in the full analysis set (FAS). Thirty-one patients completed the concurrent phase and were included in the per-protocol (PP) set. The median age was 8 years; 18.2% (6 cases) were biopsy-confirmed (83.3% harboring the H3K27M mutation) and 81.8% (27 cases) were radiologically diagnosed. In the FAS, ORR was 30.3% (10 partial responses [PR]), and the disease control rate was 75.8%; 21.2% (7 cases) in the PP set achieved >50% tumor reduction in pontine lesions. Median OS was 12.7 months (95% CI: 8.7–NA) with a 1-year OS rate of 50.1%; median PFS was 5.9 months (95% CI: 4.3–7.8) with a 6-month PFS rate of 45.3%. Multivariate analysis showed a higher baseline Lansky score was a favorable prognostic factor for OS (HR=0.899, P=0.0069), and achieving PR was favorable for PFS (HR=0.232, P=0.0162). Nineteen patients received salvage therapy post-progression; those undergoing re-irradiation had a median OS of 17.9 months, significantly better than non-re-irradiated patients (P=0.031). Ninety-six point nine percent (32/33) of patients experienced treatment-related AEs (mostly grade 1–2). The incidence of grade ≥3 AEs was 18.2%, with the most common being lymphopenia, weight loss, and upper respiratory tract infection (each 6%). No treatment-related deaths occurred, and no patients discontinued ACT001 due to toxicity. Additionally, 96.9% (31/32) of patients had improved or stable Lansky scores post-treatment. **Conclusions:** ACT001 combined with standard radiotherapy exhibits certain antitumor activity in the treatment of newly diagnosed pediatric DIPG, with improved OS compared to historical data, as well as a manageable safety profile and good tolerability. This regimen provides a new treatment option for pediatric DIPG and warrants further verification in larger-scale randomized controlled trials. Clinical trial information: ChiCTR2300074598. Research Sponsor: None.

Application of PET RANO 1.0 criteria and associations with outcome in *IDH*-mutant gliomas: A retrospective cohort study. First Author: Maximilian Mair, Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: Amino acid PET is increasingly used to guide clinical decisions in glioma. For standardized response assessment, PET RANO 1.0 criteria have been formulated, but are primarily consensus-based and lack validation in molecular subgroups of diffuse gliomas. **Methods:** In this retrospective cohort study, patients with newly diagnosed or recurrent *IDH*-mutant glioma and at least two O-(2-[^{18}F]-fluoroethyl)-L-tyrosine ([^{18}F]FET) PET scans in 02/2013 - 08/2025 were included. PET was evaluated using PET RANO 1.0 criteria based on maximum and mean tumor-to-background ratios (TBR_{max}/TBR_{mean}) and PET volume. Intervention-free survival (IFS) was used as endpoint. **Results:** Overall, 219 patients (110 [50.2%] oligodendroglioma, 106 [48.4%] astrocytoma, 3 with unknown 1p/19q status; 115 [52.5%] CNS WHO 2, 80 [36.5%] CNS WHO 3, 23 [10.5%] CNS WHO 4, 1 grading inconclusive) with 251 lesions were included. Median age at first PET was 45 years (range: 21-75), and 117 (53.4%) patients were male. In total, 220 treatment lines (173 [78.6%] first line treatment; 47 [21.4%] recurrence/progression) were followed, of which 135 (61.4%) involved radiotherapy and/or systemic treatment, and 85 (38.6%) observation. Median time between PET scans was 6.7 months (2.4-11.8). In first-line treatment at baseline, PET-based measurable disease was seen in 126/173 (72.8%), non-measurable in 38/173 (22.0%) and no measurable disease in 9/173 (5.2%). PET-based complete remission (PET-CR) was observed in 7/173 (4.0%), partial remission (PET-PR) in 32/173 (18.5%), stable disease (PET-SD) in 74/173 (42.8%), and progressive disease (PET-PD) in 60/173 (34.7%) patients. The primary driver of PET-PD was an increase in PET volume alone (27/60, 45.0%) or in combination with an increase in TBR_{max}/TBR_{mean} (19/60, 31.7%), followed by new measurable disease in 14/60 (23.3%) patients. In astrocytoma, IFS was shorter in patients with PET-PD (median: 10.0 months; 95%CI: 8.3-32.6) compared to PET-SD/-PR/-CR (33.0 months; 95%CI: 22.0-52.1; p = 0.043). Similar differences were seen in oligodendroglioma (PET-PD: 16.0 months; 95%CI: 11.7-63.3; vs. PET-SD/-PR/-CR: 34.5 months; 95%CI: 24.3-57.0; p = 0.036). At treatment for recurrence, baseline PET showed measurable disease in 37/47 (78.7%) and non-measurable disease in 10/47 (21.3%) patients. PET-CR was seen in 3/47 (6.4%), PET-PR in 16/47 (34.0%), PET-SD in 24/47 (51.1%) and PET-PD in 4/47 (8.5%) patients, with numerical differences in IFS (p = 0.16) according to PET response in recurrent disease. In both first-line treatment and recurrence, measurable disease at baseline was not associated with PET response ($p > 0.05$). **Conclusions:** Response assessment based on PET RANO 1.0 criteria is associated with outcome in *IDH*-mutant glioma. Further analyses considering MRI-based response assessment are ongoing for further validation of PET-based clinical trial endpoints. Research Sponsor: European Society for Medical Oncology (ESMO); (awarded to MJM).

Pooled analysis of phase I and expanded access study cohorts of DOC1021 (dubodencel) in combination with chemoradiation for glioblastoma. First Author: Jay-Jiguang Zhu, The University of Texas Health Science Center, Neurosurgery, Houston, TX

Background: Glioblastoma (GBM) is a poor-prognosis brain malignancy with median overall survival (mOS) of ~12-18 months despite aggressive standard of care (SOC) treatment. DOC1021 is an autologous dendritic cell (DC)-based immunotherapy generated by tandem loading with autologous tumor-derived mRNA and lysate, enabling broad antigen presentation. DOC1021 leverages p38MAPK and mTORC1 signaling cascades to initiate cDC1-like skewing of monocyte-derived DC, leading to potent downstream development of $CD8^+$ tissue-homing, cytolytic effector memory cells. **Methods:** This pooled analysis includes newly diagnosed and recurrent IDH-wt patients from two clinical trials (Phase I Study 8148 [NCT04552886] and Expanded Access Protocol EAP0001), treated with DOC1021 after resection and SOC chemoradiation. DOC1021, prepared from mobilized peripheral blood mononuclear cells (PBMC) loaded consecutively with autologous amplified tumor mRNA and tumor lysate, was administered bilaterally near deep cervical lymph node chains every other week for 3 administrations with weekly pegylated-IFN. Study 8148 (n=18) evaluated 4 dose levels (3.5×10^6 to 36×10^6 cells), while Study EAP0001 (n=7) administered only the highest dose level (36×10^6 cells). Patients with subtotal resection or pre-treatment progression were not excluded. Blood was collected before and after DOC1021 to assess peripheral immune responses. **Results:** Among the pooled population (N=25), median age was 58 years (range 47-75), 88% MGMT unmethylated, 24% partially resected, and 16% recurrent disease. There were no dose-limiting toxicities, and a similar safety profile between studies. Common AEs included mild, flu-like symptoms and injection-site reactions. One patient in the EAP study experienced grade 3 cerebral edema after the first DOC1021 dose that fully resolved and subsequent DOC1021 doses were completed per protocol. At the time of analysis, 7 of 21 newly diagnosed patients remain alive ~9-30 months post-surgery. Among recurrent patients (n=4), 2 patients remain alive ~16-20 months after second resection. Pseudo-progression within ~6 months of vaccination was commonly observed. Analysis of post-vaccination PBMC indicated expansion of $CD4^+$ (17/20 patients, mean +28.6%, p=0.0006) and $CD8^+$ (15/20 patients, mean +26.8%, p=0.001) central memory T-cell (T_{CM}) compartments as well as substantial upregulation of CD127 expression on circulating $CD8^+$ T cells (18/20; mean MFI +72.2%, p=0.03). **Conclusions:** Collectively, the data show that DOC1021 plus SOC is well-tolerated, feasible, and potentially efficacious in a challenging population that included subtotal resections, pre-treatment progression, and majority MGMT unmethylated. A multicenter, randomized, open-label Phase 2 trial (NCT06805305) in newly diagnosed GBM is now enrolling to compare DOC1021+SOC vs SOC treatment alone. Clinical trial information: NCT04552886. Research Sponsor: Diakonos Oncology; Cancer Cures 4 Kids.

2077 **Poster Session**

INB-200: Phase I study and characterization of gene-modified autologous gamma delta (γδ) T cells in newly diagnosed glioblastoma multiforme (GBM). First Author: Louis B. Nabors, University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL

Background: Cell therapy for glioblastoma (GBM) holds promise but previous studies have not demonstrated durable responses or improved progression free survival (PFS). We provide updated findings from our assessment of any patients who completed treatment with drug-resistant immunotherapy (DRI) in newly diagnosed GBM. **Methods:** DRI combines the polyclonal upregulation of stress-antigens with concurrent local delivery of MGMT-modified γδ T cells, engineered to resist temozolomide (TMZ) driven lymphodepletion. The standard-of-care (SOC) chemotherapy TMZ induces transient upregulation of tumor-associated NKG2D-L stress antigens enabling the functional γδ T cells to identify and eradicate residual cancer cells during the period of maximum tumor vulnerability. Patients received 1×10^7 DRI cells/dose into the resection cavity with 150 mg/m^2 of IV TMZ on Day 1 of each maintenance cycle.17 patients received treatment, including 3 who received only a single dose (Cohort 1). 14 patients received repeated doses (3 to 6), (median age 64 (range: 33-75); 93% IDH-WT, 50% MGMT-unmethylated, 57% subtotal resection, KPS 80). 10 contemporaneously enrolled patients treated with SOC only (median age 67 (range: 49-77); 100% IDH-WT, 60% MGMT-unmethylated, 20% subtotal resection, KPS 80) were examined as a control cohort. **Results:** No DLTs, CRS, ICANS or treatment related deaths were reported. As of December 31, 2025, the median PFS for DRI repeat dose patients (N=14) is 13.0 months (m), vs. SOC control (N=10) of 6.6m (+97%) demonstrating prolonged disease control in newly diagnosed GBM. The median overall survival (OS) for repeat dose patients will be updated, as it is still climbing at 17.2m+ vs. SOC control of 13.2m. Notably, 8/14 (57%) of the repeat dose patients had PFS that exceeded their expected OS based on age and MGMT-status, compared to only 1/10 (10%) of SOC control patients. One patient with a grade-4, IDH-mutant tumor remains progression free for 4.6 years with no additional maintenance therapies. Gene expression profiling of pre- and post-manufactured cell products revealed upregulation of cytotoxicity-associated markers of activation and immune cell trafficking (e.g., *IFN-g, GZMB, PRF1*). Patient correlate analysis showed that CRS associated serum cytokines *IL-6, IL-1B*, *CCL2*, and *TNF-a* were not increased over baseline during DRI + maintenance-phase TMZ. Peripheral γδ and total T cell levels, however, improved incrementally with each dose frequency cohort, suggesting an influence on systemic immune reconstitution through local DRI delivery. T cell persistence was demonstrated in recurrent GBM biopsies from patients that revealed significant γδ T cell infiltration and necrosis well beyond the final dose of TMZ and DRI γδ T cells. **Conclusions:** These findings demonstrate a manageable safety profile and a positive trend in PFS and OS from treatment with DRI cells. Clinical trial information: NCT04165941. Research Sponsor: IN8Bio, Inc.

Regorafenib in recurrent glioblastoma: Real-world outcomes from a Colombian cohort (REGOMA-COL). First Author: Javier Jacobo, Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center - CTIC, Bogotá, Colombia

Background: Therapeutic options for recurrent glioblastoma (GBM) remain limited, with historically poor outcomes following first progression. The phase II REGOMA trial demonstrated an overall survival benefit of regorafenib compared with lomustine, prompting its adoption in selected patients. However, real-world data from Latin America are scarce, where differences in patient characteristics, access to molecular testing, and treatment patterns may influence outcomes. We evaluated the effectiveness and safety of regorafenib in a Colombian cohort of patients with recurrent high-grade gliomas (HGG - WHO 4). **Methods:** REGOMA-COL is a retrospective, single-center cohort study including adult patients with histologically confirmed HGG treated at a tertiary referral center in Bogotá, Colombia. All patients received standard first-line therapy consisting of maximal safe resection followed by IMRT/VMAT with concomitant and adjuvant temozolomide, and subsequently progressed. Regorafenib was administered in the second- or third-line setting at a starting dose of 160 mg daily (3 weeks on, 1 week off), with dose modifications permitted for toxicity. Survival outcomes were estimated using the Kaplan–Meier method. Adverse events were graded according to CTCAE v5.0. Subgroup analyses examined progression-free survival (PFS) by molecular and clinical characteristics. **Results:** Twenty-six patients were included. The median age at diagnosis was 49.3 years, and 80.8% had an ECOG performance status of 1. Most tumors were IDH–wild type (84.6%), and MGMT promoter methylation was present in 38.5%. Regorafenib was administered as second-line therapy in 53.8% of patients and as third-line therapy in 57.7%. Median PFS from regorafenib initiation was 4.9 months (95% CI 3.9–5.7), and median OS from regorafenib was 11.3 months (95% CI 9.3–13.2) (Figure 1). Disease control rate (DCR) with regorafenib was achieved in 69.2% of patients. Toxicity was predominantly low-grade, with fatigue, mucositis, and diarrhea as the most common adverse events. **Conclusions:** In this real-world cohort, regorafenib demonstrated meaningful clinical activity and a favorable safety profile in patients with recurrent HGG. Survival outcomes compared favorably with those reported in pivotal and observational studies, particularly in a relatively young population with preserved performance status. These findings support regorafenib as an important therapeutic option in selected HGG cases and highlight the need for broader Latin American real-world data. Research Sponsor: None.

2079 Poster Session

Lucicebtide (ST101) plus chemoradiation in newly diagnosed GBM patients: Efficacy, pharmacodynamics, and safety from phase 2 window-of-opportunity study. First Author: Fabio M. Iwamoto, Columbia University Irving Medical Center, New York, NY

Background: Glioblastoma (GBM) is a lethal brain malignancy with no cure. Recurrent GBM (rGBM) is enriched in a mesenchymal-like state, and the tumor microenvironment (TME) is enriched in immune-suppressive tumor-associated myeloid cells (TAMs). C/EBPß is a master regulator of the mesenchymal GBM state and in sustaining immunosuppressive TAMs. Lucicebtide (ST101) is a first-in-class peptide antagonist of C/EBPß with demonstrated anti-tumor activity and TAM reprogramming in preclinical models. **Methods:** The WoO study enrolled 2 cohorts; 9 pts with rGBM that received 2-4 doses of lucicebtide 500mg QW prior to surgery and resumed lucicebtide after surgery to progression and 9 ndGBM pts that received 2-3 doses of lucicebtide 500mg QW prior to surgery and resumed lucicebtide + chemoradiation after surgery until progression. Endpoints include efficacy parameters of PFS and OS, safety as a single agent and in combination with chemoradiation, and pharmacodynamic (PD) analyses including spatial transcriptomics and TME characterization. **Results:** Lucicebtide was well-tolerated alone and in combination with chemoradiation. Tissue analysis indicates BBB penetration, tumor uptake, and C/EBPß target engagement. Lucicebtide + chemoradiation in ndGBM extended PFS beyond historic benchmarks, with the majority of patients remaining on study without progression beyond 21 months. As of January 27, 2026, mOS could not be evaluated; 18- and 24-months OS of 67% and 44% respectively exceeded the historic 39-45% and 26-31% respectively from Stupp 2005 and 2017. In rGBM, lucicebtide improved mPFS of 4.0 months and mOS to 12.3 months, exceeding historical data with chemotherapy (historic mPFS ~ 2 months and mOS 5.6-9.8 months). Spatial transcriptomics revealed significant reductions in C/EBPß regulon activity in tumor cells and macrophages, resulting in a dramatic reduction in the mesenchymal signature in tumor cells. Importantly, lucicebtide altered the infiltration patterns and phenotypes of the TME, including increased effector $CD8^+$ infiltration and an increase in the M1/M2 ratio that were associated with disease control. **Conclusions:** Lucicebtide is well-tolerated as monotherapy and in combination with SoC. Improvements in PFS and OS have been seen in GBM patients following lucicebtide exposure. Analysis of tumor resections demonstrate penetration across the BBB and target engagement, and on-target pharmacodynamic activity, including a dramatic reduction in mesenchymal gene signature in tumor cells and a remodeling towards a more permissive immune TME. These data provide the safety, efficacy and mechanistic rationale for continued clinical evaluation of lucicebtide as a novel approach for patients with GBM. Clinical trial information: NCT04478279. Research Sponsor: Ivy Foundation.

Tumor recurrence or treatment effect? Large multi-institutional evaluation of an AI risk assessment model in glioma and brain metastases. First Author: Dheerendranath Battalapalli, University of Wisconsin Madison, Madison, WI

Background: Distinguishing true tumor recurrence (TuR) from radiation necrosis (RN) on post-treatment MRI scans remains a major neuro-oncology challenge. We hypothesized that an integrated Spatial, Morphologic, and Textural radiomics risk (SMART-risk) model that comprehensively captures local and spatial organization of lesion heterogeneity, can unravel distinct biology across TuR and RN, on clinical MRI; and improve distinction over a data-driven ResNet50 deep learning model. **Methods:** We retrospectively collected multi-institutional post-treatment MRI cohorts: brain metastases (233 studies; from Cleveland Clinic (CCF), University Hospitals Cleveland (UH), University of Wisconsin (UW); and glioma (340 studies from Indiana University (IU), Dana-Farber Cancer Center, Thomas Jefferson University (TJU), and CCF). Over 80% of the studies were pathologically confirmed as TuR or RN. Institution-held-out external testing was performed (metastases: train CCF+UH, test UW; glioma: train IU+TJU+Dana-Farber Cancer Center, test CCF). Following segmentation, 944 radiomic features/lesion were extracted including graph-based spatial organization of tumor heterogeneity (GrRAiL), local gradient texture heterogeneity (COLLAGE), Haralick, and morphology. LASSO-selected features were integrated in a Random Forest classifier. Performance metrics included cross validation accuracy (CV), test accuracy, F1 score, and AUC; interpretability used SHAP. Comparison was performed with a ResNet50 baseline model. **Results:** SMART-Risk demonstrated consistent discrimination on the institution-held-out external test set (Table 1) with ~80% accuracy; ~10-15% improvement over a ResNet50 model. SHAP analysis indicated that features corresponding to spatial organization and local heterogeneity, i.e. average path length, node count and entropy measures, were dominant contributors (Mann–Whitney U test, $p \leq 0.001$). Recurrent tumors showed higher spatial complexity and greater heterogeneity than RN. **Conclusions:** SMART-Risk may provide a noninvasive approach to distinguish TuR from RN on routine post-contrast T1-weighted MRI. By integrating spatial-organization (GrRAiL), texture (COLLAGE/Haralick), and morphology features, SMART-Risk captures complementary signatures and may improve discrimination compared with any single feature family. An AI-based SMART-Risk approach may reduce diagnostic ambiguity, support earlier treatment decisions, and avoid unnecessary invasive procedures. Decision support for treatment of patients with glioblastoma: A systems biology approach enabled by explainable AI. First Author: Thomas D. Brown, Institute of Systems Biology, Seattle, WA

Background: Glioblastoma (GBM) patients (pts) have median survival of 15 months and 5-year survival <7% with standard therapy. Current clinical decision-making relies on IDH mutation and MGMT methylation status, which provide limited guidance for most pts. We developed SATGBM (SYGNAL Analytics Test for GBM), a systems biology-based test that integrates tumor mutations and gene expression to identify causally dysregulated gene networks and predict treatment response. **Methods:** SATGBM uses Systems Genetics Network AnaLysis (SYGNAL) to mine pts' molecular profiles (RNASeq, WES and NGS) and build disease network maps to single out an individual pt's molecular tumor profile and identify unique causal mechanisms that drive the progression of disease. Treatment predictions integrate network activity scores, deep learning scores, and historical objective response rates from clinical trials. We validated SATGBM in two independent cohorts: (1) 43 pt-derived glioma stem-like cells (PDGSC) screened against 28 anticancer drugs; (2) 83 GBM pts from XCELSIOR open registry observational study with documented treatment outcomes including progression-free survival (PFS) and time on treatment (TOT). **Results:** In PDGSC high throughput screening, SATGBM successfully predicted treatments with greatest drug sensitivity in each of the cell cultures. SATGBM predictions separated responders vs non-responders: median IC50 2.70×10^{-7} vs 1.00×10^{-3}, Mann–Whitney $p=2.1\times10^{-41}$, Pearson r = -0.38, AUC = 0.79. In the XCELSIOR cohort (n=31 drug courses), SATGBM correctly predicted the effective response of individual pts to 6 second-line therapies (including off-label drugs). Pts who stayed on SATGBM-recommended treatments remained on therapy 5-times longer compared to predicted non-responders, demonstrating real-world clinical validity and improved outcomes. SATGBM predictions yielded median TOT of 260 vs 50.5 days, p=0.0021; sensitivity/specificity were 60.0% / 95.2% and AUC = 0.79 (benefit = ToT ≥120 days). **Conclusions:** SATGBM demonstrated statistically significant prediction of treatment outcomes in independent preclinical and clinical validation cohorts. Network-based analysis provided superior predictive accuracy compared to mutation-only or expression-only approaches and provided insights beyond standard GBM biomarkers. These findings support clinical utility of mechanistic network analysis for personalizing GBM treatment decisions and warrant prospective validation in clinical trials. Germline HLA class II diversity as a predictor of survival selectively in MHC-silenced gliomas. First Author: Om H. Gandhi, Centre for Immuno-Oncology, University of Oxford, Oxford, United Kingdom

Background: $CD4^+$ T cell help is central to durable anti-tumour immunity and predicts response to neoantigen vaccination. Antigen presentation to $CD4^+$ T cells is governed by HLA class II molecules, yet the class II landscape in glioma remains poorly defined. Germline HLA diversity can influence immunity only if tumours retain antigen-presentation capacity. We hypothesised that the prognostic impact of HLA class II heterozygosity in glioma is conditional on tumour MHC-II expression. **Methods:** We performed germline HLA class II typing (DRB1, DQB1, DPB1) in 893 TCGA gliomas (388 glioblastoma, 505 lower-grade glioma) using a weighted consensus of four algorithms (HLA-HD, hla-genotyper, SOAP-HLA, Kourami). Tumour MHC-II expression was quantified using a nine-gene antigen-presentation signature. The primary analysis tested the interaction between germline heterozygosity and tumour MHC-II status on overall survival using multivariable Cox regression. Allele-level survival analyses were exploratory. **Results:** Gliomas showed extensive class II polymorphism (54 DRB1, 28 DQB1, 47 DPB1 alleles), with 35.9% of patients homozygous at one or more loci. The most frequent alleles were DRB107:01 (12.7%), DQB103:01 (20.7%), and DPB1*04:01 (38.7%). Germline heterozygosity was not prognostic in unstratified analyses (HR 1.04, 95% CI 0.83–1.32, p = 0.72). However, a significant interaction with tumour MHC-II expression was observed (p-interaction = 0.044). In MHC-II–low tumours, germline heterozygosity independently predicted improved survival (HR 0.71, 95% CI 0.52–0.97, p = 0.031), whereas no effect was seen in MHC-II–high tumours (p = 0.89). Tumour MHC-II expression itself was independently prognostic (p = 0.004). Exploratory allele-level analysis identified DRB1*03:01 (10.2%) as nominally associated with worse survival (median 23.7 vs 34.9 months, uncorrected p = 0.041). **Conclusions:** Germline HLA class II diversity influences survival in glioma only when tumour antigen presentation is impaired. Combined tumour MHC-II loss and limited germline diversity identify a biologically and clinically high-risk group with compounded antigen-presentation deficits. These findings have direct implications for neoantigen vaccine design and patient stratification, suggesting that restoration of antigen presentation may be required prior to immunotherapy in selected patients. The adverse association with DRB1*03:01 merits mechanistic investigation. Independent validation in 322 glioblastoma patients is ongoing. Research Sponsor: None.

Knowledge distillation for glioma diagnosis: ResNet-based deep learning for WHO grade stratification with real-world deployment optimization. First Author: Sravani Bhavanam, Brookdale University Hospital and Medical Center, New York, NY

Background: Gliomas are the most common primary CNS malignancies. WHO 2021 classification stratifies diffuse gliomas into molecularly-defined grades with vastly different treatment pathways: grades 2–3 (median survival 7–10 years) versus grade 4 glioblastoma (median survival 15 months untreated). Accurate preoperative grading is critical for surgical planning and treatment intensity. However, 5–8% of gliomas are initially misdiagnosed as meningiomas or pituitary adenomas, delaying definitive treatment by 3–6 months. Automated systems achieving high accuracy while remaining deployable in resource-limited settings could substantially reduce diagnostic error. **Methods:** Retrospective cohort: 2,840 brain MRI studies (1,400 gliomas: 700 grade 2–3, 700 grade 4; 900 meningiomas; 540 pituitary adenomas) from six continents. Ground truth used WHO 2021 classification; expert neuroradiologist consensus confirmed diagnoses. ResNet152 (60.2M parameters; 224×224 input; 28.6 GFLOPs) optimized for multi-sequence fusion (T1, T2, FLAIR, post-contrast) served as reference. ResNet18 (11.7M parameters; 224×224 input; 1.8 GFLOPs; 81% parameter reduction) underwent structured knowledge distillation—soft probability targets from ResNet152 with temperature-scaled softmax and regularized cross-entropy loss. Model performance evaluated on accuracy, sensitivity, specificity, F1-score, AUROC. Differential diagnostic accuracy assessed. Deployed globally; 52 neuroradiologists evaluated across six continents. **Results:** Glioma grading: ResNet18 achieved 96.9% accuracy for grade 2–3 vs. grade 4 (sensitivity 97.8%, specificity 96.0%, AUROC 0.991). Differential diagnosis: 95.1% for glioma vs. meningioma; 96.0% for glioma vs. pituitary. External validation confirmed consistent performance (93–97% grading; 94–96% differential diagnosis). Deployment advantage: ResNet18 inference time 38ms/image (ResNet152: 320ms), enabling real-time clinical integration on standard hospital GPU servers. Global deployment: 94.6% of neuroradiologists rated the system clinically valuable. Knowledge distillation preserved 99.2% of teacher diagnostic accuracy while reducing computational cost by 93.7%. **Conclusions:** Knowledge distillation enables ResNet18 to achieve ResNet152-comparable diagnostic accuracy for glioma grading and differential diagnosis while reducing parameters by 81% and computational cost by 94%. This framework solves critical deployment barriers in resource-limited healthcare systems. ResNet18's efficiency enables real-time inference on standard hardware, rapid diagnostic turnaround, and scalable global implementation. This system merits prospective evaluation to reduce time-to-diagnosis and eliminate glioma misclassification worldwide. Research Sponsor: None.

Transcriptomic signature of temozolomide treatment-effect heterogeneity in IDH-wildtype glioblastoma. First Author: Amirhossein Zare, Tehran University of Medical Sciences, Tehran, Iran

Background: Adjuvant temozolomide (TMZ) is standard of care for IDH-wildtype glioblastoma (GBM), yet clinical benefit is heterogeneous and not fully explained by MGMT promoter methylation. We developed a transcriptomic signature specifically predicting TMZ benefit rather than overall prognosis using a causal inference framework. **Methods:** Transcriptomic and clinical data from 448 patients with histologic grade 4 IDH-wildtype GBM treated with radiotherapy alone or radiotherapy plus TMZ across six cohorts were analyzed. A training set (N=322; TCGA, CGGA-325/693, GLASS) and an independent validation set (N=126; GSE7696, CGGA-301) were used. Data were normalized, batch-corrected, and screened for outliers. To address non-random treatment assignment, inverse probability of treatment weighting (IPTW) based on propensity scores from age, sex, and MGMT status was applied. A 15-gene Temozolomide Sensitivity Score (TSS) was derived using univariate prognostic filtering followed by LASSO modeling of gene-by-treatment interactions. Final gene weights were obtained from a doubly adjusted multivariable Cox model incorporating IPTW and clinical covariates. Performance was assessed by comparing adjusted hazard ratios (HRs) for TMZ benefit across TSS-defined subgroups. **Results:** Five genes emerged as significant independent modulators of TMZ response: C2CD4A, SLC35E3, and DNASE1L3 predicted sensitivity, whereas APOBEC3B and PMAIP1 predicted resistance. In the training cohort, TSS-sensitive patients derived significant benefit from TMZ (median overall survival, 21.0 vs 7.7 months; adjusted HR, 0.20; 95% CI, 0.10–0.39; P<0.001), whereas TSS-resistant patients did not (14.4 vs 13.1 months; adjusted HR, 0.89; 95% CI, 0.53–1.51; P=0.674), with a significant difference in treatment effect (P<0.001). Validation confirmed these findings: TSS-sensitive patients benefited (21.9 vs 12.8 months; adjusted HR, 0.32; 95% CI, 0.16–0.62; P<0.001), while TSS-resistant patients did not (13.7 vs 15.1 months; adjusted HR, 1.25; 95% CI, 0.70–2.23; P=0.453), showing differential efficacy (P=0.003). Age, sex, and MGMT status were balanced between groups. **Conclusions:** A 15-gene transcriptomic signature developed through causal inference and interaction modeling is associated with differential temozolomide benefit in IDH-wildtype glioblastoma independent of MGMT status. This signature may identify patients less likely to benefit from temozolomide, offering a promising tool for de-escalation strategies and enrollment in precision clinical trials. Research Sponsor: None.

Gene–treatment interaction modeling to identify temozolomide-sensitive *IDH*-mutant diffuse gliomas. First Author: Seyed Reza Salarikia, Tufts University School of Medicine, Boston, MA

Background: IDH-mutant diffuse gliomas are biologically heterogeneous. While radiotherapy is standard, temozolomide (TMZ) is variably used in a risk-adapted manner and preferentially administered to patients with adverse features, introducing substantial indication bias in observational cohorts. Existing molecular markers are largely diagnostic or prognostic rather than predictive of chemotherapy benefit. We aimed to develop a transcriptomic signature identifying differential TMZ benefit while correcting for treatment-selection bias using causal inference. **Methods:** IDH-mutant, histologic grade 2–3 glioma patients treated with radiotherapy or radiotherapy + TMZ were analyzed in a training cohort (N=438; TCGA, CGGA325/693) and an independent validation cohort (N=62; CGGA301). To mitigate non-random treatment allocation, inverse probability of treatment weighting (IPTW) was applied using propensity scores from age, sex, histologic grade, 1p/19q codeletion, and MGMT promoter status. A 10-gene temozolomide sensitivity score was derived using univariate filtering followed by LASSO modeling of gene–treatment interactions. Final weights were estimated from a doubly adjusted multivariable Cox model incorporating IPTW and clinical and molecular covariates. Performance was assessed by comparing adjusted hazard ratios (HRs) for TMZ benefit across score-defined subgroups. **Results:** Clinical and molecular baseline characteristics were well balanced between treatment groups. In the training cohort, TMZ-sensitive patients derived significant benefit from TMZ (median overall survival 114.0 vs 85.7 months; adjusted HR 0.58, 95% CI 0.35–0.96; P=0.035). In contrast, TMZ-resistant patients demonstrated an elevated adjusted HR (2.98, 95% CI 1.63–5.45; P<0.001), consistent with residual confounding from preferential TMZ use in patients with poorer prognosis rather than evidence of treatment harm. A significant difference in treatment effect was observed between subgroups (P<0.001). External validation confirmed differential treatment effects: TMZ-sensitive patients showed a concordant trend toward benefit (HR 0.51, 95% CI 0.13–1.94; P=0.323), with lack of significance attributable to limited sample size, while TMZ-resistant patients exhibited a resistant trajectory (HR 6.04, 95% CI 1.56–23.38; P=0.009), with the difference in treatment effect remaining significant (P=0.011). **Conclusions:** Using causal inference and gene–treatment interaction modeling, we developed and validated a 10-gene signature that predicts heterogeneity of TMZ benefit in IDH-mutant, histologic grade 2–3 gliomas. This approach distinguishes patients likely to derive substantial benefit from TMZ from those with limited benefit and provides a robust methodological framework for predictive biomarker discovery in non-randomized oncologic datasets. Preclinical evaluation of intrathecal TRP1-targeted CAR T cells: Effects on durable antitumor immunity in melanoma leptomeningeal disease. First Author: Peter A.J. Forsyth, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Melanoma leptomeningeal disease (LMD) is fatal, with median survival under 3 months and no effective immune-based therapies. Direct cellular immunotherapy of the cerebrospinal compartment has not been systematically explored. Tyrosinase-related protein 1 (TRP1) is a conserved melanocytic lineage antigen expressed across mouse and human melanoma, including CNS involvement. We evaluated the efficacy, durability, and safety of intrathecal TRP1-directed CAR T cell therapy in aggressive melanoma models. **Methods:** TRP1 CAR T cells were generated and evaluated in vitro and in vivo using syngeneic B16 melanoma model, including a leptomeningeal disease setting. CAR T cells were administered intrathecally. Antitumor activity was assessed by bioluminescent tumor burden and survival. Durability of response was evaluated by secondary tumor rechallenge. Toxicity was assessed by longitudinal neurologic monitoring and body weight. Human TRP1 CAR T constructs were evaluated in vitro using real-time cell adhesion (RTCA) assays across multiple donors using TRP1-positive melanoma cell lines to assess antigen-dependent functional activity. scRNAseq data from CSF of melanoma patients were analyzed to determine TYRP1 expression. **Results:** Intrathecal administration of TRP1 CAR T cells resulted in significant tumor control and prolonged survival in aggressive M-LMD models compared with controls (+CTX OS=18%, median survival:18 days; +1x-PBS OS=15%, median survival:17 days). Approximately 40% of treated animals achieved durable remission following intrathecal infusion of CAR Ts (OS=40%, median survival: 32 days, P<0.0001). Long-term survivors (eg. more than 60 days) demonstrated functional immune memory, with approximately 36% rejecting secondary tumor rechallenge (OS=36%, median survival: 41 days vs. naïve control OS=17%, median survival: 15 days, P<0.0001). Treatment was well tolerated, with no detectable neurologic toxicity or weight loss. RTCA data showed that human TRP1-CAR T cells across donors recognize TYRP1 antigen in target melanoma cells inducing killing. scRNAseq data revealed that 50% of 12 patient samples expressed TYRP1(33,3% were M-LMD, 8.3% were primary intradural spinal melanoma, and 8.3% from 1 autopsy). Surface expression of TYRP1 is being determined using our Rapid Tissue Donation in LMD Core. Together, our data supports translational relevance. **Conclusions:** Intrathecal TRP1-targetedCAR T cell therapy induces potent and durable antitumor immunity in aggressive disease-LMD with a favorable safety profile. These findings represent the first clear demonstration of intrathecal CAR T cell therapy in melanoma LMD and establish proof of concept for CNS-directed CAR T strategies targeting a melanocytic lineage antigen. This work provides a rational foundation for systematic optimization and IND-enabling development. Research Sponsor: None.

Efficacy of high-dose chemotherapy in adult patients with relapsed or refractory medulloblastoma. First Author: Nurlan Mammadzada, Ankara Gülhane Eğitim ve Araştirma Hastanesi, Ankara, Turkey

Background: Adult medulloblastoma (MB) is rare, and there is no standard salvage approach for relapsed or refractory cases. High-dose chemotherapy (HDC) with autologous stem cell transplantation (ASCT) has shown potential, but evidence in adults remains limited. This study evaluated the response rate, survival and toxicity after HDC with ICE regimen followed by ASCT in MB, with further focusing on post-ASCT response and pretransplant intracranial residual disease (ICRD). **Methods:** We retrospectively analyzed adult patients with relapsed/refractory MB who underwent HDC with the ICE regimen followed by ASCT. Baseline features, treatment response, progression-free survival (PFS), overall survival (OS), and treatment-related toxicity were evaluated. Subgroup analyses focused on post-ASCT response and pretransplant intracranial residual disease (ICRD). **Results:** The study included 23 patients (median age: 24 years; male: 52%, with 43% classic subtype and 61% pretransplant ICRD). The overall and complete response (CR) rates to HDC was 73.9% and 48%, respectively. The median PFS was 12.8 months, and OS was 45.1 months, with 2-year PFS and OS rates of 31% and 63%, respectively. Patients achieving CR after ASCT had significantly longer OS (NR vs 16.4 months; HR, 0.15; 95% CI, 0.03–0.72; P=.02), corresponding to an 85% reduction in mortality risk compared with non-CR patients. OS was markedly shorter in patients with pretransplant intracranial residual disease compared with those without (22.5 vs. 74.0 months; HR, 7.08; 95% CI, 1.3–36.3; p = 0.008).The large cell/anaplastic subtype remained the poorest prognostic group despite ICE induction. Toxicity was dominated by universal grade 4 myelosuppression and febrile neutropenia, but no transplantation-related mortality occurred. **Conclusions:** This study showed that HDC with ICE followed by ASCT is feasible in adults with relapsed/refractory MB, with encouraging survival and manageable toxicity. Pretransplant ICRD clearance and achievement of CR were major prognostic determinants, while non-CR patients remained at high risk, highlighting the need for treatment intensification in this subgroup. Research Sponsor: None.

Molecular characterization of WHO grade II atypical meningioma using the AACR Project GENIE database. First Author: Aden V. Chudziak, Arizona State University, Tempe, AZ

Background: Atypical meningioma (AM) is a WHO grade II neoplasm arising from meningeal arachnoid cap cells and is distinguished from WHO grade I meningiomas by parenchymal invasion and rapid proliferation. AM demonstrates recurrence rates up to 52% following gross total resection and >90% after subtotal resection. The absence of FDA-approved systemic treatments for AM underscores the need to define oncogenic drivers for targeted therapies. This study leverages the American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) database to characterize the genomic landscape of AM and identify key genetic drivers for therapeutic targets. **Methods:** The AACR GENIE database was accessed from cBioPortal (v18.0-public) on December 12, 2025 to identify all AM patient samples. Fisher's exact test and non-parametric tests (Mann-Whitney U) were used with Benjamini-Hochberg False Discovery Rate correction to analyze most common genetic mutations, demographic correlations, and mutual exclusivities. Unknown values were excluded from analysis. **Results:** The cohort identified 402 AM samples from 394 patients. The cohort was slightly female-predominant (52.8%) and largely adult (94.0%). Most patients were White (47.2%), followed by Asian (7.4%) and Black (3.6%). Most samples (n=307, 76.4%) were primary tumors and 48 (11.9%) were metastatic. *NF2* was the most prevalent mutation (n=228; 56.7%), followed by *TERT* promoter mutations (n=52; 12.9%). Chromatin-modifying genes, including *KMT2D* (n=24; 6.0%), *KMT2A* (n=19; 4.7%), and *KMT2C* (n=16; 4.0%), were frequently altered. Additional recurrent mutations were observed in *SPTA1* (n=21; 5.2%), *MT-ND5* (n=20; 5.0%), *FAT1* (n=20; 5.0%), *PRKDC* (n=18; 4.5%). Sex-stratified analysis revealed male-exclusive mutations in *DAXX* (n=9), *IL6ST* (n=4), *TMPRSS2* (n=4), *SMARCE1* (n=4), and *COL2A1* (n=5) that reached statistical significance (all $p<0.05$). *TSC2* and *DNMT3A* mutations were significantly more frequent in males, whereas *BRCA1* mutations were uniquely observed in females ($p<0.05$). *NF2* mutations were enriched in Asian patients ($p<0.001$), while *TERT*, *KDR*, *PTPRB*, *SPEN*, and *KMT2C* were enriched in Black patients (all $p<0.05$). *NF2* and *TERT* demonstrated significant mutual exclusivity ($p<0.05$). Co-occurrence was observed between *ROS1*/*ATM* and *KMT2D*/*TSC2* ($p<0.05$). Metastatic tumors were enriched for *BRCA1*, *IKBKE*, and *PALB2*, with *MDM4* exclusive to metastatic disease ($p<0.001$). **Conclusions:** To our knowledge, this is the first GENIE study to identify *NF2* and *TERT* as central genomic drivers of AM, with their observed mutual exclusivity suggestive of divergent oncogenic pathways. Race-associated mutations, such as enrichment of *NF2* in Asian patients and *TERT* in Black patients, emphasize demographic consideration in targeted therapies. These findings prioritize *NF2* and *TERT* as targets for precision therapeutics in AM. Research Sponsor: None.

Long term outcomes of central neurocytoma in a multi-institutional cohort: The role of radiotherapy and Ki-67. First Author: Yufan Yang, University of Michigan, Ann Arbor, MI

Background: Central neurocytomas (CNs) are rare, WHO grade 2 brain tumors that can have relatively high recurrence rates following surgical resection. Owing to the rarity of CNs and limited robust data, the optimal use and timing of radiotherapy (RT) remain undefined, particularly in young adults with low mortality. Tumor proliferation index (Ki-67) may also predict CN recurrence rates, but there is no consensus on its utility in clinical practice. The present collaboration between Northwestern University and the Mayo Clinic describes long-term outcomes of CN as it relates to RT timing and Ki-67 level. **Methods:** Patients established between 1990-2025 with a tissue diagnosis of CN at Northwestern University and the Mayo Clinic were reviewed. Demographic, treatment, and tumor characteristics (histologic/molecular) were recorded. Recurrence free survival (RFS) and overall survival (OS) were calculated according to the Kaplan Meier-method. **Results:** Fifty-one patients with CN (51% male, 49% female)—with a median age of 26 years and 9.7 years median follow-up—were included. RFS at 2, 5, and 10 years for the cohort was 79%, 65%, and 59% respectively; OS at 10 years for the cohort was 94%, and no deaths were attributed to uncontrolled CN. Subtotal resection (STR) yielded 2- and 5-year RFS of 74% and 65%, while gross total resection (GTR) yielded 2- and 5-year RFS of 90% and 66%. Median Ki-67 of the cohort was 3%; RFS at 2 and 5 years for Ki-67 <3% was 82% and 76%, compared to 76% and 43% for Ki-67 ≥3% ($p<0.02$). In patients who underwent resection without adjuvant RT (n=35), those with STR had a 2- and 5-year RFS of 61% and 45%, and those with GTR had a 2- and 5- year RFS of 88% and 61%. Additionally, without adjuvant RT, RFS at 2 and 5 years for Ki-67 <3% was 73% and 64% versus 71% and 24% for Ki-67 ≥3%. Among patients without adjuvant RT and Ki-67 ≥3% (n=14), 2-year RFS was 60% after STR and 78% after GTR. Salvage RT after first recurrence (n=16) had a 5-year RFS of 81%, with a median follow-up of 4.1 years. **Conclusions:** We report one of the largest cohorts of CN with long-term follow-up. STR and/or Ki-67 ≥3% were associated with shorter RFS. Salvage RT at recurrence achieved durable long-term tumor control, and long-term (~10-year) mortality was low. In appropriately selected patients, observation after resection may be a reasonable initial strategy, with RT reserved for salvage. Research Sponsor: None.

General cohort characteristics (n=51) with Ki-67 (n=39).

Variable	Number (%)
Median Age (years)	26 (range: 5-57)
Gender, Male:Female (M/F)	26:25 (51/49)
Subtotal Resection	29 (57)
Gross Total Resection	22 (43)
Adjuvant Radiotherapy	16 (31)
Salvage Radiotherapy	16 (31)
No Radiotherapy	19 (38)
Ki-67 ≥3	21 (56)
Ki-67 <3	18 (44)

2090 **Poster Session**

Final results of a single-arm, open-label, multicenter phase 2 study of the radiopharmaceutical [^{177}Lu]Lu-DOTA-TATE and [^{68}Ga]Ga-DOTA-TATE in adults with advanced intracranial meningioma. First Author: Sylvia Christine Kurz, Yale University School of Medicine, New Haven, CT

Background: A subset of meningiomas has an aggressive clinical course requiring multimodal therapies. Yet, treatment options beyond surgery and radiation are limited. Somatostatin receptor 2 (SSTR2) is uniformly expressed in meningiomas and can be targeted by the radiopharmaceutical agent [^{177}Lu]Lu-DOTA-TATE (^{177}Lu-Dotatate). [^{68}Ga]Ga-DOTA-TATE (^{68}Ga-Dotatate) PET is emerging as a promising imaging modality to assess treatment response in SSTR2-expressing tumors. However, prospective clinical data supporting the use of ^{177}Lu-Dotatate and ^{68}Ga-Dotatate in treatment-refractory meningiomas is limited. **Methods:** In this multicenter, open-label, phase 2 clinical study (NCT03971461), adult patients with progressive intracranial meningiomas received ^{177}Lu-Dotatate at 7.4 GBq (200 mCi) every 8 weeks for 4 doses. The primary endpoint was 6-month progression-free survival (PFS-6). Up to 5 meningioma lesions per patient were assessed by gadolinium-enhanced T1 MRI every 12 weeks. ^{68}Ga-Dotatate PET was obtained before/after ^{177}Lu-Dotatate treatments. Lesional ^{68}Ga-Dotatate PET activity was assessed relative to liver/spleen or superior sagittal sinus (SSS). **Results:** 32 patients (female = 21, male = 11) with progressive meningiomas (WHO grade 1 = 7, grade 2 = 24, grade 3 = 1) were enrolled. Median age was 65.5 (range 41-78) years. All patients had at least one prior tumor surgery and at least one course of radiation. Overall, ^{177}Lu-Dotatate was well tolerated and the most common grade 3/4 adverse events were transient cytopenia in 15 patients (47%). One patient (3%) discontinued treatment due to grade 4 thrombocytopenia. PFS-6 was reached in 22 patients (69%), which includes 5 of 7 (71%) with grade 1 and 17 of 24 (71%) with grade 2 meningiomas. Best radiographic response by MRI was partial response (PR) in 5 (16%) and stable disease (SD) in 20 (63%) patients. Eight patients (16 lesions) were evaluable by paired MRI and ^{68}Ga-Dotatate PET pre- and post-treatment. Referenced to SSS, ^{68}Ga-Dotatate avidity reduced by ≥50% in 2 lesions (PR), 25-49% (minor response, MR) in 3 lesions and remained stable (< 25% reduction and < 25% increase) in 11 lesions. Using liver/spleen as a reference (6 patients, 14 lesions), ^{68}Ga-Dotatate uptake was reduced in 9 lesions and stable in 5 lesions. ^{68}Ga-Dotatate PET assessments were generally concordant with MRI-based treatment response assessments. **Conclusions:** The primary endpoint (PFS-6) was met in this phase 2 study with 69% of patients achieving PFS-6, thereby surpassing established historical benchmarks. ^{177}Lu-Dotatate was generally well tolerated and deserves further study in patients with advanced meningiomas. Exploratory ^{68}Ga-DOTATATE PET studies showed decreased uptake in a subset of lesions and bears promise as an imaging biomarker to assess treatment response. Clinical trial information: NCT03971461. Research Sponsor: None.

2091 **Poster Session**

Long-term outcomes of CNS lymphoma patients treated with glucarpidase. First Author: Lauren Webb, Memorial Sloan Kettering Cancer Center, New York, NY

Background: High-dose methotrexate (HD-MTX) is the backbone of potentially curative therapy for central nervous system lymphoma (CNSL) but requires inpatient admission for hydration and monitoring to minimize toxicity. Glucarpidase is a recombinant bacterial enzyme that rapidly clears systemic MTX without crossing the blood-brain barrier. It is FDA-approved as a rescue agent in the setting of MTX toxicity. Exploration of use beyond this indication has been limited, in part, due to concerns about immunogenicity and effect on MTX efficacy. We previously demonstrated the safety of repeated low-dose glucarpidase. Here, we report long-term outcomes of CNSL patients treated with MTX and glucarpidase on clinical trial NCT03684980. **Methods:** NCT03684980 is a multicenter, open-label trial that prospectively enrolled primary (PCNSL) or secondary (SCNSL) lymphoma patients across different cohorts to receive repeated doses of MTX (3-8 g/m²) and glucarpidase (1000-2000u). Patients who received ≥ 6 of 8 planned doses were included. Patients had indication for MTX for newly diagnosed (ND) or relapsed/refractory (r/r) disease. There were no restrictions on post-MTX therapy or consolidation. Objective response rate (ORR), progression-free survival (PFS) and overall survival (OS) were assessed. **Results:** Twenty-two enrolled patients met inclusion criteria; 10 (45%) were women. Median age was 70 years, and median Karnofsky Performance Status was 80. PCNSL accounted for 20/22 (91%) of cases; 5/22 (23%) were treated for r/r disease. Following MTX-based induction, patients achieved complete response (CR) (n=10, 45%), CR unconfirmed (n=2, 9%), partial response (n=6, 27%), stable disease (n=2, 9%), or progressive disease (n=2, 9%) for an ORR of 18/22 (82%). Responding patients received consolidation with cytarabine (n=10), autologous stem cell transplant (ASCT) (n=5), ibrutinib maintenance (n=1), or unknown (n=2). Median follow-up was 55.5 months. Median PFS and OS were not reached overall. PFS and OS were not reached for PCNSL, versus 7.3 and 21.0 months for SCNSL. PFS was not reached for ND patients versus 12.4 months for patients with r/r disease; OS was not reached for either group. **Conclusions:** Repeated low-dose glucarpidase does not appear to adversely impact long-term outcomes in CNSL. Outcomes were superior in PCNSL and ND disease compared to SCNSL and r/r disease. These findings support further exploration into the use of glucarpidase to facilitate MTX clearance without compromising efficacy. Clinical trial information: NCT03684980. Research Sponsor: None.

TPS2093 **Poster Session**

Phase I trial of trastuzumab deruxtecan in combination with stereotactic radiosurgery for brain metastases from HER2-positive breast cancer. First Author: Zouina Sarfraz, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Brain metastases (BM) develop in nearly 40-50% of patients with HER2-positive breast cancer. Stereotactic radiosurgery (SRS) provides effective local control of treated lesions but does not prevent the development of new BM, while whole-brain radiation therapy is associated with significant neurocognitive toxicity. Trastuzumab deruxtecan (T-DXd) is a HER2-targeted antibody-drug conjugate (ADC) that has demonstrated significant systemic and intracranial activity in patients with HER2-positive breast cancer. Preclinical and clinical data suggest that combining HER2-directed therapy with radiation may enhance intracranial disease control. However, there is conflicting information about the rate of radiation necrosis in patients treated with T-DXd and SRS. We hypothesize that the combination of T-DXd and stereotactic radiosurgery may be safe and provide effective intracranial disease control in patients with HER2-positive breast cancer BM. **Methods:** This is a prospective, single-arm, multicenter, open-label, ongoing phase I clinical trial evaluating the safety, tolerability, and maximum tolerated dose of T-DXd in combination with SRS in patients with BM from HER2-positive breast cancer. Eligible participants are adults (≥18 years) with histologically confirmed HER2-positive breast cancer, Eastern Cooperative Oncology Group performance status of 0–2, adequate organ function, and 1–10 newly diagnosed BM who are candidates for SRS. Any number of prior systemic therapies is permitted, except prior exposure to T-DXd. Key exclusion criteria include leptomeningeal metastases, clinically significant intra- or peri-tumoral hemorrhage, prior cranial radiation therapy, active or prior interstitial lung disease or pneumonitis, and BM within 5 mm of the optic apparatus. Participants receive SRS to all eligible lesions with concurrent intravenous T-DXd every 3 weeks. A standard 3+3 dose de-escalation design is used, starting at 5.4 mg/kg with planned de-escalation to 4.4 mg/kg and 3.2 mg/kg. Dose-limiting toxicities are assessed during a 3-week post–SRS evaluation period. The primary endpoint is safety, tolerability, and determination of the maximum tolerated dose. Secondary endpoints include intracranial and extracranial progression-free survival, overall survival, and objective response rate assessed by RECIST v1.1. Exploratory endpoints include intracranial response assessed using RANO-BM criteria and longitudinal changes in neurocognitive function. Upon determination of the maximum tolerated dose, an expansion cohort will enroll up to 20 participants. The trial has been approved by the Institutional Review Board and is currently enrolling participants. Research Sponsor: None.

TPS2094 **Poster Session**

Randomized phase 2 trial of ruxolitinib in combination with radiation and temozolomide compared to radiation and temozolomide for newly diagnosed glioblastoma. First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Glioblastoma is the associated with poor outcomes despite treatment with radiation and temozolomide. Therapeutic resistance and disease recurrence are driven in part by glioma stem cell populations and activation of oncogenic signaling pathways, including the Janus kinase/signal transducer and activator of transcription (JAK/STAT) pathway. Aberrant JAK/STAT signaling has been implicated in tumor proliferation, stem cell maintenance, immune modulation, and resistance to radiation and alkylating chemotherapy in glioblastoma in preclinical models. Ruxolitinib is an oral JAK1/2 inhibitor with established clinical use in myeloproliferative neoplasms. Preliminary activity has also been reported in high-grade glioma; in the phase 1, non-randomized CRUX study. **Methods:** This is a randomized, multicenter, open-label, ongoing phase II clinical trial enrolling adults (≥18 years) with newly diagnosed, histologically confirmed IDH-wildtype glioblastoma and Karnofsky performance status ≥70. Eligible patients must have adequate organ function and available tumor tissue for molecular characterization. Participants are randomized 1:1 and stratified by MGMT promoter methylation status, performance status, sex, and extent of resection. Patients assigned to the experimental arm receive oral ruxolitinib 20 mg administered twice daily in combination with standard radiation therapy (60 Gy delivered in 30 fractions) and concurrent temozolomide at 75 mg/m², followed by adjuvant temozolomide at 150-200 mg/m² with continuous ruxolitinib at 20 mg bid. Patients in the control arm receive radiation therapy with concurrent and adjuvant temozolomide per standard of care. Treatment continues until disease progression, unacceptable toxicity, withdrawal of consent, or completion of protocol-defined therapy. The primary endpoint is overall survival (OS). Secondary endpoints include progression-free survival (PFS), objective response rate (ORR), duration of response (DOR), and safety. Tumor response is assessed using modified Radiologic Assessment in Neuro-Oncology (mRANO) criteria. Exploratory objectives include correlative analyses evaluating tumor tissue biomarkers associated with treatment response or resistance. The planned sample size is 190 participants across multiple institutions in the United States. The statistical analysis is a sequential design with one interim look at 50% events on one-sided log rank test, an overall sample size of 172 participants (86 in the control group and 86 in the treatment group) needed to achieve 80 % power at a 0.1 significance level to detect a hazard ratio of 0.68182 when the control group median survival time is 15 months. The trial has been approved by the Institutional Review Board (IRB) and is currently enrolling patients. Clinical trial information: NCT06991101. Research Sponsor: None.

TPS2095 **Poster Session**

CLARITY-GBM: A phase II, multi-centered, open-label, single-arm study to evaluate the safety and efficacy of cetuximab and lomustine (CCNU) in adult patients with recurrent high-grade glioblastoma. First Author: Zoya Peelay, SunAct Cancer Institute Private Limited, Mumbai, India

Background: Recurrent glioblastoma (GBM) has a poor prognosis with no universally accepted systemic standard of care. Lomustine (CCNU) remains a commonly used benchmark, achieving 6-month progression-free survival (PFS-6) rates of approximately 20%. Epidermal growth factor receptor (EGFR) amplification is present in a substantial proportion of GBMs and represents a biologically relevant therapeutic target. Cetuximab, an anti-EGFR monoclonal antibody, has demonstrated preclinical activity and limited clinical efficacy in EGFR-driven high-grade gliomas. CLARITY-GBM evaluates the safety and preliminary efficacy of combining cetuximab with lomustine in adults with recurrent high-grade glioblastoma. **Methods:** CLARITY-GBM is a prospective, open-label, multicenter, single-arm Phase II study conducted at four tertiary cancer centres in India. Eligible patients are adults (≥18 yrs) with histologically confirmed WHO grade 4 glioblastoma at first or second recurrence following standard chemoradiation, ECOG performance status 0–2, and measurable disease per RANO criteria. Participants will receive cetuximab intravenously 500 mg/m² every 2 weeks in combination with oral lomustine 110 mg/m² every 6 weeks. Treatment continues until disease progression, unacceptable toxicity, withdrawal of consent, or investigator decision. Tumour assessments are performed every 6 weeks using MRI and evaluated according to RANO criteria. The study uses an exact single-stage Phase II design testing the null hypothesis that PFS-6 ≤20% versus the alternative hypothesis that PFS-6 ≥40%, with a one-sided alpha of 0.10 and 80% power. A total sample size of 25 patients is planned to ensure 24 evaluable patients for the primary analysis. The regimen will be considered promising if at least 8 patients are progression-free at 6 months. A single interim futility analysis is planned after 15 evaluable patients. The primary endpoint is PFS-6. Secondary endpoints include progression-free survival, overall survival, objective response rate, duration of response, safety and tolerability (CTCAE v5.0), corticosteroid-sparing effect, and health-related quality of life (EORTC QLQ-C30 and BN20). Exploratory analyses evaluate correlations with EGFR amplification, EGFRvIII status, and MGMT promoter methylation. Clinical trial information: CTRI/2026/01/100794. Research Sponsor: None.

Design and key methodological features of the CLARITY-GBM trial.

Characteristic	Description
Study Design	Phase II, open-label, single-arm
Population	Adults with recurrent WHO grade 4 GBM
Sample Size	25 planned (24 evaluable)
Treatment	Cetuximab q2w + Lomustine q6w
Primary Endpoint	PFS-6
Statistical Design	One-sample exact binomial
Null/Alternative	PFS-6 ≤20% vs ≥40%
Power/Alpha	80%, one-sided 0.10
Interim Analysis	After 15 evaluable patients
Exploratory Biomarkers	EGFR, EGFRvIII, MGMT

TPS2096 **Poster Session**

TTFields with maintenance temozolomide (TMZ) and pembrolizumab versus TTFields with maintenance TMZ and placebo for newly diagnosed glioblastoma: The phase 3 EF-41/KEYNOTE D58 trial. First Author: David D. Tran, Department of Neurological Surgery, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA

Background: Glioblastoma remains a lethal disease with limited treatment options. With current standard-of-care, consisting of maximal safe resection followed by radiotherapy with concurrent TMZ, then maintenance TMZ plus TTFields, median overall survival (OS) is 20.9 months, as reported in the pivotal EF-14 trial completed more than a decade ago. While immune checkpoint inhibitors (ICIs) have improved outcomes in multiple malignancies, they have not demonstrated meaningful clinical benefit in glioblastoma, in part because the tumor microenvironment (TME) is typically profoundly immunosuppressive. Strategies that reprogram the TME toward immune activation may therefore enable ICIs to elicit more effective anti-tumor immunity. Beyond antimitotic effects, TTFields have shown preclinical evidence of inducing immunogenic cell death and activating type 1 interferon signaling via DNA sensor inflammasomes, with downstream increases in dendritic cell activation and cytotoxic T cell infiltration. In a single-arm phase 2 study (NCT03405792), TTFields plus TMZ and pembrolizumab was associated with improved progression-free survival (PFS) and OS compared to historical controls in newly diagnosed glioblastoma. Here, we describe the design of a randomized phase 3 trial evaluating this regimen. **Methods:** EF-41/KEYNOTE D58 is a randomized, double-blind, placebo-controlled, phase 3 study (NCT06556563). Eligible patients have newly diagnosed glioblastoma (WHO 2021 Classification), have completed concurrent chemoradiotherapy, and can initiate treatment 4–7 weeks thereafter. Additional criteria include ECOG performance status 0–1 and availability of tumor tissue for central MGMT methylation analysis. Key exclusion criteria include prior anti-PD(L)1 or anti-PDL2 therapy and ongoing dexamethasone $>$2 mg/day. Patients are randomized 2:1 to TTFields (200 kHz for $\geq$18 hours/day) plus maintenance TMZ (150–200 mg/m^2/day PO, days 1-5 of each 28 day cycle for 6-12 cycles) with either pembrolizumab 200 mg IV Q3W (up to 35 cycles) or matching placebo. TTFields is continued until second progression. At first progression, TTFields therapy is maintained and patients may receive standard salvage therapy, including re-resection and/or radiotherapy as well as systemic therapy. The target enrollment is 741 patients, providing 85% power to detect an OS improvement at a two-sided alpha of 0.05 using a 2-sided log-rank test. The primary endpoint is OS. Secondary endpoints include PFS per RANO 2.0 and RANO, PFS6 and PFS12 rates (RANO 2.0), PFS2 (RANO 2.0), 1- and 2-year survival rates, EORTC QLQ-C30 with BN20 module score, and safety. MRI assessments are performed every 9 weeks and evaluated per RANO 2.0. Adverse events are monitored throughout the study. Enrollment is ongoing. Clinical trial information: NCT03405792. Research Sponsor: None.

Key inclusion criteria.

Surgically resected and histologically proven ND-GBM
Tumor EGFR status by local test using commercially available or CLIA certified assay
Part 1: any pathogenic EGFR alteration
Part 2: EGFRvIII-positive by NGS
Unmethylated MGMT tumor status (Part 2 only)
No treatment for ND-GBM other than surgery followed by chemoradiation
≥4 weeks after chemoradiation therapy with post-radiation MRI showing no progression

TPS2097 **Poster Session**

Resection and intracranial implant of (Z)-*n*-butylidenephthalide wafer followed by temozolomide as treatment for recurrent glioblastoma: A randomized phase IIb/III trial. First Author: Clark C. Chen, Legorreta Cancer Center Warren Alpert Medical School of Brown University, Providence, RI

Background: Glioblastoma, an isocitrate dehydrogenase (IDH)–wildtype diffuse glioma, remains highly lethal despite standard therapy, and the absence of an effective treatment at recurrence highlights a critical unmet clinical need. (Z)-*n*-butylidenephthalide ((Z)-BP) is a multimodal anti-glioblastoma agent that inhibits key mechanisms mediating oncogenic signaling including epidermal growth factor receptor (EGFR), AXL-1 receptor, and c-mesenchymal epithelial transition factor (c-Met) receptor, as well as DNA repair (MGMT) and immune suppression (programmed death-ligand 1, PD-L1). To enable sustained local delivery of (Z)-BP, an interstitial controlled-release polymer wafer was developed and advanced through Phase I and Phase IIa evaluation, demonstrating feasibility, a favorable safety profile, and early indications of survival signals. Building on these findings, a randomized Phase IIb/III study has been initiated to further evaluate intracranial (Z)-BP implantation using this controlled-release platform. **Methods:** The trial (NCT07349693) is an open-label, randomized study that aims to determine the efficacy of tumor resection with implantation of the (Z)-BP wafer, followed by temozolomide treatment in the setting of recurrent glioblastoma. With a sample size of 175, the study is designed to observe 116 overall survival events to achieve 80% power. Eligible adults must have histologically confirmed glioblastoma at first or second recurrence following standard first-line therapy and maintain a Karnofsky Performance Status $\geq$ 70. Furthermore, candidates require measurable disease per response assessment in neuro-oncology (RANO) 2.0 criteria (lesion $\geq$ 1 cm) that is deemed suitable for gross total resection. Subjects are excluded if they present with oligodendroglioma, mixed glioma, specific genetic markers (IDH or H3K27M mutations, 1p19q co-deletion), or prior bevacizumab treatment with uncontrollable progression. Patients with MRI findings showing multi-focal disease, diffuse dissemination, lesions $>$ 6 cm, or tumor locations deemed unsuitable for safe resection and wafer implantation will also be excluded. Subjects are randomized in a 2:1 ratio to either resection with 6 (Z)-BP wafers implantation or resection only (control arm). All enrolled patients subsequently receive six cycles of temozolomide. The primary endpoint is median overall survival (OS). Secondary endpoints include progression-free survival (PFS), OS and PFS rates at 6, 9, 12, 18, and 24 months, and objective response rate (ORR, based on RANO 2.0). Exploratory objectives include assessing plasma concentrations of (Z)-BP and its metabolite, quality of life (EORTC QLQ-C30), and survival analyses stratified by molecular subgroups (EGFR, AXL, c-Met, MGMT, and PD-L1 expression). The enrollment is expected in Q2 2026. Clinical trial information: NCT07349693. Research Sponsor: Everfront Biotech.

TPS2098 **Poster Session**

Randomized phase 2 study to evaluate the efficacy and safety of silevertinib in combination with temozolomide in newly diagnosed patients with EGFRvIII-positive IDHwt MGMT unmethylated glioblastoma. First Author: Patrick Y. Wen, Dana-Farber Cancer Institute, Boston, MA

Background: Targeted therapy for patients with newly diagnosed glioblastoma (ND-GBM) has made little progress. First-line therapy remains surgery, adjuvant radiotherapy with temozolomide (TMZ), and maintenance TMZ. This treatment paradigm is even less effective for the ~60% of patients with MGMT unmethylated status. Oncogenic epidermal growth factor receptor (EGFR) alterations are identified in ~ 50% of ND-GBM tumors irrespective of MGMT status. EGFRvIII is present in ~30% of ND-GBM and is nearly always expressed with other EGFR mutations and/or EGFR amplification. Prior clinical trials of EGFR targeting drugs have shown limited benefit primarily due to poor CNS penetrance and/or lack of potency across EGFR variants and EGFR amplification. Silevertinib (BDTX-1535) is a 4th generation covalent EGFR tyrosine kinase inhibitor (TKI) with high CNS penetrance targeting the full spectrum of oncogenic EGFR alterations in GBM, including variants (EGFRvIII, vII, vVI), mutations, and amplification. Silevertinib has shown additive antitumor effects with TMZ in an intracranial GBM tumor model expressing EGFRvIII with EGFR amplification. A phase 0/1 window-of-opportunity study in patients with recurrent GBM showed that silevertinib reached therapeutic levels in infiltrative GBM tissue with associated biomarker suppression (NCT06072586). Silevertinib was well tolerated and demonstrated promising clinical activity in a phase 1 study in patients with recurrent GBM (ASCO 2024). This randomized phase 2 study will evaluate efficacy and safety of silevertinib in combination with TMZ in adults with EGFRvIII-positive (EGFRvIII) unmethylated MGMT ND-GBM. **Methods:** This multicenter study (NCT05256290) will be conducted in the US and consists of 2 sequential parts. Part 1 (Safety Run-in) will enroll up to 12 patients to evaluate the safety of two doses of silevertinib (150mg QD, 200mg QD) in combination with TMZ and will inform the selected dose for Part 2. In Part 2 (Efficacy Evaluation), patients will be randomized 1:1 to receive adjuvant silevertinib in combination with TMZ or TMZ alone. Patients with EGFRvIII ND-GBM who have completed surgery and adjuvant chemoradiation are eligible (Table). The primary endpoint for Part 2 is progression free survival by blinded independent central review using Response Assessment in Neuro-Oncology (RANO2.0) criteria. Clinical trial information: NCT05256290. Research Sponsor: Black Diamond Therapeutics.

TPS2099 **Poster Session**

Targeting macrophage migration inhibitory factor: A phase 2 and pharmacodynamic study of sitagliptin in patients with progressive grade 4 gliomas. First Author: David M. Peereboom, Cleveland Clinic Brain Tumor and Neuro-Oncology Center, Cleveland, OH

Background: One mechanism of immunosuppression in the glioblastoma (GBM) microenvironment involves systemic and local accumulation of myeloid-derived suppressor cells (MDSCs) that inhibit cytotoxic immune cell populations and contribute to immune suppression. GBM patients have increased circulating MDSCs compared to lower grade glioma patients, and GBM patients with a better prognosis have reduced MDSCs in their tumors as well as in their peripheral circulation. A trial (NCT02669173) performed at the Cleveland Clinic demonstrated that pre-surgical anti-MDSC therapy (capecitabine) was associated with reduced circulating MDSCs and increased cytotoxic immune infiltration in tumor tissue. This proof-of-principle pilot study demonstrated that targeting MDSCs in patients can attenuate tumor-induced immunosuppression. Subsequent work at the Cleveland Clinic demonstrated that MDSCs require dipeptidyl peptidase 4 (DPP-4) for entry into the brain and overall MDSC function. Screening for a DPP-4 inhibitor identified sitagliptin as a good inhibitor with limited toxicity with efficacy in pre-clinical models. Hypothesis: Treat of GBM patients with sitagliptin will deplete circulating MDSCs and reduce their entry into the brain, reversing systemic and intratumoral immunosuppression. To test this hypothesis, we plan a "window of opportunity" clinical trial to evaluate the safety and biological impact of sitagliptin treatment in patients with recurrent grade 4 glioma undergoing clinically indicated surgical resection. **Methods:** For this trial, we will randomize 48 patients: 36 will receive pre- and post-operative treatment with sitagliptin and 12 will receive post-operative sitagliptin alone. All patients will receive post-operative sitagliptin and chemotherapy until disease progression. Primary endpoint: Difference in tumor CD8+ T cell count between the participants randomized to pre-surgical sitagliptin versus the participants randomized to no pre-surgical treatment. Secondary endpoints: PFS_6, OS_{12}, and safety. Exploratory endpoints: peripheral and intratumoral immune profiling for assessment of TAMs, MDSCs, and CD8+ T cells; tumor radiomic features on MRI brain pre-surgery that might predict intratumoral and peripheral CD8+ T cell count and peripheral MDSC levels; peripheral blood cytokine and immune gene expression profiling for increase in immune activation signatures. This is a window-of-opportunity trial of sitagliptin for patients with grade 4 gliomas to test the hypothesis that sitagliptin, a DPP-4 inhibitor, can reduce MDSC activity, enhance immune activation, and thereby increase the quantity of tumor infiltrated CD8+ T cells. These improvements in immune suppression, combined with chemotherapy will hopefully increase PFS and OS for patients. Clinical trial information: NCT07003542. Research Sponsor: None.

TPS2100 **Poster Session**

A trial to evaluate CSF ctDNA and safety of plixorafenib alone or with retifanlimab in patients with BRAF-altered glioma. First Author: Karisa C. Schreck, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

Background: BRAF V600E mutant gliomas are difficult to treat in the recurrent setting due to adaptive resistance to FDA-approved targeted therapies. Emerging therapeutic approaches include novel BRAF inhibitors or combination therapies, but evaluating treatment response is limited by radiographic techniques and the infeasibility of serial tissue sampling. This two-arm study will evaluate the feasibility of using CSF and plasma circulating tumor DNA (ctDNA) as biomarkers for response to a novel-BRAF inhibitor, plixorafenib alone or in combination with PD-1 inhibitor, retifanlimab. Plixorafenib is a small-molecule selective inhibitor of BRAF-V600E and BRAF-fusion alterations without inducing paradoxical reactivation of MAPK signaling. **Methods:** This single institution trial of plixorafenib alone (Arm A) or combined with retifanlimab (Arm B) is enrolling patients (18+ years of age) with BRAF-V600E mutant glioma following progression on prior BRAF-targeted therapy who are recommended for a clinically-indicated diagnostic or debulking surgery. Eligible patients have recurrent BRAF-V600E mutant glioma (any grade) with measurable disease (by RANO 2.0), and a Karnofsky performance status $\geq$ 70. Leptomeningeal disease is allowed. All enrolled patients will undergo clinically-indicated resection or biopsy for confirmation of disease progression and characterization of putative resistance alterations with a ventricular reservoir placed at time of surgery for CSF sampling. In both arms, patients will initiate oral plixorafenib once clinically recovered from surgery. Patients will take the plixorafenib daily with food. In Arm B, enrolled patients will receive one dose of retifanlimab three weeks prior to surgery, then resume monthly retifanlimab infusions after surgery in combination with oral plixorafenib. MRI, CSF, and plasma assessments will occur approximately every two months to evaluate disease status. The primary trial endpoint is detectable ctDNA at baseline and after one month of treatment with plixorafenib. Secondary endpoints include safety of plixorafenib alone or in combination with retifanlimab, response rate in each arm, and the correlation of ctDNA with disease status over time. The trial is IRB approved and enrollment is ongoing (10 patients per arm). Clinical trial identifier NCT06610682. Clinical trial information: NCT06610682. Research Sponsor: Ivy Brain Tumor Foundation; Fore Biotherapeutics.

TPS2101 **Poster Session**

Progress report of a phase 2 study of BPM31510 (a lipid nano dispersion of oxidized CoQ10) with vitamin K in combination with standard of care (SOC) RT and TMZ in glioblastoma multiforme (GBM) patients without prior therapy. First Author: Seema Nagpal, Stanford University, Stanford, CA

Background: BPM31510 is an investigational, drug-lipid conjugate nanodispersion. Preclinical studies demonstrate that intravenous infusion can achieve plasma concentrations of oxidized CoQ10 approximately 10,000 times higher than baseline physiological levels with its accumulation in organs, including brain. Preclinical studies show that supraphysiological concentrations of CoQ10 induce metabolic shifts in a variety of cancer cells and generate Reactive Oxygen Species (ROS) leading to apoptosis. In Phase 1, the main adverse events were related to mild hepatotoxicity and coagulopathy. All coagulation related issues were alleviated by coadministration of Vitamin K. The Phase 2 trial in newly diagnosed patients with glioblastoma tests whether treatment with BPM31510 results in improved efficacy of standard of care temozolomide (TMZ) and radiotherapy (RT). **Methods:** BPM31510IV-11; NCT04752813 is a single-arm, non-randomized, open-label, phase 2 study of intravenous (IV) BPM31510 + prophylactic subcutaneous (SC) Vitamin K1 with standard chemoradiation and temozolomide (TMZ) in newly diagnosed GBM patients. The primary endpoint is Progression Free Survival at 6 months (PFS6) and 12 months (PFS12) while the secondary endpoints are Overall S (OS) survival and safety. Patients with recent hemorrhage, coagulopathy, or requiring anticoagulants are excluded. SC Vit K and IV BPM31510 are initiated 2-4 weeks after biopsy or tumor resection. After two weeks, standard of care chemoradiation and TMZ are started in combination with weekly IV BPM31510 for 8 weeks, after which IV BPM31510 treatment and standard RT are discontinued with subjects continuing to receive maintenance TMZ treatment for up to 12 cycles as per standard of care. Of the approximately 50 patients enrolled and treated upon the recommendation of an independent safety monitoring committee, 25 will be available for PFS6 efficacy endpoint analysis and these data will be presented. Clinical trial information: NCT04752813. Research Sponsor: BPGbio.

TPS2102 **Poster Session**

Gliofocus: A global, open-label, randomized phase 3 study comparing niraparib with temozolomide in newly diagnosed MGMT-unmethylated glioblastoma. First Author: Nader Sanai, Ivy Brain Tumor Center at Barrow Neurological Institute, Phoenix, AZ

Background: Glioblastoma (GBM) remains a fatal malignancy despite multimodality therapy. Approximately 60% of GBMs lack O6-methylguanine-DNA methyltransferase (MGMT) promoter methylation, thus associated with resistance to alkylating chemotherapy and poor survival with median OS of 12.7 months. Poly(ADP-ribose) polymerase (PARP) is a central regulator of DNA damage repair and genomic stability in GBM and represents a rational therapeutic target, particularly in the setting of radiotherapy-induced DNA damage. Niraparib is a selective PARP1/2 inhibitor that has demonstrated excellent central nervous system penetration and favorable tumor pharmacokinetic and pharmacodynamic properties in previously reported early-phase GBM studies. These findings provided the scientific rationale for Gliofocus, a global phase 3 trial designed to evaluate whether replacing temozolomide with niraparib during and after radiotherapy improves outcomes in patients with newly diagnosed, MGMT-unmethylated GBM. **Methods:** Gliofocus is a phase 3, open-label, randomized, two-arm study enrolling total 450 adults with newly diagnosed, MGMT-unmethylated GBM. Eligibility requires histologic diagnosis of GBM per 2021 WHO classification, Karnofsky performance status $\geq$70, documented MGMT promoter unmethylated status by validated local testing, and no prior GBM-directed therapy other than biopsy or resection. Patients are randomized 1:1 to receive niraparib or temozolomide concurrently with external-beam radiotherapy (60 Gy in 30 fractions using the ESTRO-EANO single-target volume approach), followed by adjuvant monotherapy of niraparib or temozolomide. Treatment continues until centrally reviewed disease progression per RANO 2.0 guidelines or completion of six cycles of temozolomide in the control arm. The primary endpoint is overall survival (HR = 0.698, 88% power). Secondary endpoints include progression-free survival, objective response rate, health-related quality of life, neurocognitive outcomes, and safety. Integrated correlative assessments include centralized imaging review, longitudinal neurocognitive testing, and patient-reported outcomes. Enrollment began in June 2024. The independent data monitoring committee last reviewed the study in January 2026, and recommended continuation as planned. The trial is sponsored by the Ivy Brain Tumor Center with funding/product support from GSK (NCT06388733). GSK was provided the opportunity to provide a courtesy review of the abstract; however, the authors are solely responsible for final content. Gliofocus study is being conducted across a minimum of 80 sites across 12 countries. Clinical trial information: NCT06388733. Research Sponsor: GSK.

TPS2103 **Poster Session**

Alliance A072301: A phase III trial of radiotherapy followed by adjuvant temozolomide in combination with vorasidenib vs placebo in *IDH*-mutated newly diagnosed grade 3 astrocytoma (VORTEX). First Author: Ugonma Nnenna Chukwueke, Dana-Farber Cancer Institute, Boston, MA

Background: Treatment for newly diagnosed IDH-mutant astrocytoma, WHO grade 3, is based on the results of the CATNON study, demonstrating benefit of radiotherapy followed by 12 months of adjuvant temozolomide. While temozolomide and radiotherapy significantly improved survival, the prognosis for these patients remains limited and more effective therapies are required. This trial will evaluate the benefit of the addition of the IDH1 and IDH-2 inhibitor vorasidenib to adjuvant temozolomide versus placebo following standard radiotherapy to evaluate possible improvement in outcomes. **Methods:** Alliance A072301 (NCT07215910) is a multicenter, double-blinded phase 3 randomized study to determine if the addition of vorasidenib to adjuvant temozolomide significantly improves progression-free survival (PFS), based on blinded central review in patients with newly diagnosed, IDH-mutant astrocytoma, WHO grade 3. Key inclusion criteria include age $\geq$ 12 years old, histological confirmation of astrocytoma (absence of 1p/19q codeletion), WHO grade 3, presence of any IDH mutation, plan for radiation and chemotherapy and surgery within 6 months. The presence of CDKN2A/B homozygous deletion, spinal or leptomeningeal disease, as well as prior chemotherapy, cranial irradiation or IDH inhibitor therapy, is exclusionary. 408 patients will be randomized 1:1 to receive vorasidenib 40 mg or placebo daily with 12 cycles of temozolomide following radiotherapy and then continued as monotherapy until disease progression or unacceptable toxicity. Stratification factors include age ($<$ 40 years old vs $\geq$ 40 years old) and residual disease ($<$ 2 cm vs $\geq$ 2 cm). Tumor assessments with MRI will be every three months for the first two years, every four months for the next two years and then every six months thereafter as per blinded independent central review using the Response Assessment in Neuro-Oncology (RANO) 2.0 criteria. Key secondary endpoints include PFS by local review, time to next treatment, safety and tolerability, quality of life measures. Exploratory measures will include seizure frequency. The trial will have 85% power to detect a hazard ratio of 0.625 with one-sided type I error rate of 0.025. Enrollment for the trial commenced February 2026. Support: U10CA180821, U10CA180882, U24CA196171. https://acknowledgments.alliancefound.org. Research Sponsor: National Cancer Institute; Servier Pharmaceuticals.

TPS2104 **Poster Session**

A phase 3 randomized trial comparing temozolomide with PCV as adjuvant chemotherapy in grade 2 and 3 diffuse gliomas in adults. First Author: Nandini Sharrel Menon, Tata Memorial Hospital, Tata Memorial Centre, Homi Bhabha National Institute, Mumbai, Maharashtra, India

Background: Both Temozolomide (TMZ) and PCV are standard adjuvant chemotherapy regimens used in treatment of grade 2 gliomas with high risk features and grade 3 gliomas. The PCV regimen has a complex schedule, higher rate of adverse events (esp myelosuppression), and is difficult to administer, but has long-term data with an overall survival benefit. On the other hand,TMZ is an oral drug, with a simple dosing schedule, and fewer adverse events. Currently, there is lack of data directly comparing PCV to TMZ, there is emerging evidence to suggest that PCV may be the regimen of choice for oligodendrogliomas (ODGs). There is often debate on the choice of adjuvant chemotherapy. Hence we are conducting this study to compare TMZ with PCV in this setting. **Methods:** This is an ongoing phase 3, parallel-arm, non-inferiority trial. Adults with high-risk grade 2 (age $\geq$40 years and/or the presence of residual disease $\geq$1 cm after maximal safe resection) or grade 3 gliomas, are randomized 2:1 to receive TMZ or PCV after adjuvant radiation (RT). Patients receive adjuvant focal conformal radiation, with doses between 54 to 59.4 Gy at 1.8-2 Gy/fraction with conventional fractionation. In the TMZ arm, patients receive RT with concurrent TMZ 75 mg/m^2/day (max. 49 days) followed by adjuvant TMZ 150-200 mg/m^2 for 5 of 28 days (max. 12 cycles). In the PCV arm, patients receive Procarbazine 60 mg/m^2 on days 8-21, CCNU 110 mg/m^2 on day 1 and Vincristine 1.4 mg/m^2 on days 8, 29 of a 56-day cycle (maximum 6 cycles). Adjuvant chemotherapy is started within 8 weeks of completing RT. Adverse events are recorded as per CTCAE v4.03. EORTC QLQ C-30 & QLQ BN-20 is used for quality of life (QoL) assessment. Follow up evaluation will be conducted every 3 months in the 1st year, every 4 months in the 2nd year, and every 6 months from the 3 rd to 5 th year, then annually. The primary endpoint of the study is Progression-Free Survival (PFS). Secondary endpoints are Overall Survival (OS), safety,compliance & QoL. Sample Size: Assuming a 3-year PFS of 70% in the PCV arm, with type 1 error of 5% (1-sided), type 2 error of 20%, with 2:1 ratio of accrual (in favor of the TMZ arm) for 10 years, with a study duration of 15 years, to show a non-inferiority by 12% for the upper limit of 95% confidence interval of the PFS with one interim analysis; the sample size estimated by group sequential design for time-to-event outcome was 216. Statistical analysis: Kaplan Meir analysis will be used to estimate the PFS & OS and log rank test will be used for comparison between two arms.Cox proportional hazard model will be constructed for calculation of hazard ratio with its 95%CI. An interim analysis will be performed at 82 events of progression. If the log rank p value for the difference in the estimated PFS of the 2 arms is $\leq$ 0.006 then the trial will be terminated. Otherwise the trial will continue and undergo a final analysis at 163 events of progression. Clinical trial information: CTRI/2018/07/015056. Research Sponsor: Indian Cooperative Oncology Network (ICON).

TPS2105 **Poster Session**

BRIDGES: A phase 3 randomized trial of immediate postoperative cesium-131 tile-based radiation therapy followed by abbreviated chemoradiation for newly diagnosed glioblastoma (NCT07195591). First Author: Clark C. Chen, Brown University, Providence, RI

Background: Glioblastoma remains a lethal primary brain tumor with limited therapeutic progress and a persistent unmet clinical need. Standard management requires maximal safe resection followed by external beam radiation therapy (EBRT) with concurrent temozolomide (TMZ); however, the required 4–6-week postoperative healing interval before initiating EBRT creates a vulnerable window for rapid early progression (REP), defined as radiographic tumor progression occurring between surgery and the start of chemoradiation. REP is detected in more than half of patients and is associated with inferior survival. Tile-based radiation therapy (TBRT) with cesium-131 brachytherapy sources (GammaTile, GT Medical Technologies, Tempe, AZ, USA), offers a strategy to eliminate this treatment gap by immediately initialing localized radiation at the time of resection. A feasibility and safety study (NCT05342883) evaluating TBRT implantation following EBRT has been fully accrued and supports randomized evaluation. The BRIDGES study (NCT07195591) builds on this foundation. **Methods:** NCT07195591 is a prospective, randomized, open-label, multicenter, phase 3 trial to evaluate whether immediate postoperative TBRT followed by abbreviated EBRT with concurrent and adjuvant TMZ improves outcomes compared with standard postoperative EBRT with concurrent and adjuvant TMZ. Eligible adults must have newly diagnosed, radiographic suspicion of glioblastoma, can undergo maximal safe resection, possess a Karnofsky Performance Status score $\geq$70, and be candidates for standard chemoradiation. Key exclusion criteria include multifocal or disseminated disease, prior cranial radiation or chemotherapy, inability to receive TMZ, and medical comorbidities that would interfere with protocol treatment or follow-up. Patients are randomized 2:1 to receive either TBRT implantation followed by a shortened EBRT course with concurrent and adjuvant TMZ or standard postoperative EBRT with concurrent and adjuvant TMZ. Randomization is stratified by age, sex, prior sub-maximal safe resection, and size of pre-operative tumor. A stratified log-rank test using Kaplan–Meier methods will be done using the stratification factors will be implemented for the primary endpoint. Additional time-to-event endpoints will be analyzed using Kaplan–Meier methods and Cox proportional hazards models, and the analyses will follow the intent-to-treat principle. The trial has two pre-planned interim analyses. A Data and Safety Monitoring Board will oversee the trial and conduct periodic safety reviews. Four of the 766 planned patients have enrolled. Clinical trial information: NCT07195591. Research Sponsor: GT Medical Technologies, Inc.

TPS2106 **Poster Session**

Prospective, randomized, placebo-controlled phase 2b trial of SurVaxM plus adjuvant temozolomide in newly diagnosed glioblastoma (SURVIVE). First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Survivin is widely expressed in glioblastoma (GBM) and is implicated in tumor cell survival and treatment resistance, supporting survivin-targeted immunotherapy in newly diagnosed disease. The survivin long-peptide conjugate vaccine SVN53-67/M57-KLH (SurVaxM) has shown feasibility, immunogenicity, an acceptable safety profile and promising efficacy, in phase 1 and 2 trials in newly diagnosed GBM. We hypothesize that SurVaxM combined with standard adjuvant temozolomide (TMZ) post chemo radiation will improve outcomes in newly diagnosed GBM and that correlative biomarkers will define patient selection. **Methods:** SURVIVE is a prospective, randomized, double-blind, placebo-controlled, multicenter phase 2b trial evaluating SVN53-67/M57-KLH plus standard adjuvant TMZ versus placebo plus standard adjuvant TMZ in adults with newly diagnosed GBM. Patients are randomized 3:2 to investigational vaccine (Arm A) or placebo (Arm B), with stratification by Karnofsky performance status, MGMT promoter methylation status, and IDH status. Study intervention consists of four priming SurVaxM injections administered every 2 weeks followed by maintenance dosing every 8 weeks, administered alongside standard adjuvant TMZ (5 days every 28-day cycle; typically, 6-12 cycles per standard practice). The vaccine regimen is delivered as a survivin peptide conjugate with immunologic adjuvants; blinding is maintained via matched placebo injections. MRI surveillance is performed per protocol to support response assessment and the planned imaging correlatives. Key eligibility criteria include age $\geq$18 years; Karnofsky performance status $\geq$70; pathologically confirmed cerebral GBM meeting 2021 WHO criteria with available MGMT and IDH status; gross-total or near-total resection with minimal residual enhancement on immediate post-operative MRI ($\leq$72 hours); completion of chemoradiation with $\geq$75% of planned concurrent temozolomide; no evidence of progression on post-chemoradiation MRI; randomization within approximately 16–18 weeks of resection; and dexamethasone $\leq$4 mg/day at enrollment. The planned evaluable sample size is 228 patients (n=137 Arm A; n=91 Arm B). The primary analysis will be conducted in the intention-to-treat population using a two-sided alpha of 0.05, with stratified time-to-event comparisons to account for key baseline factors. The alternate hypothesis assumes a 1-year survival rate of 75% in the SurVaxM group (Arm A; comparable to a median overall survival (mOS) of 29 months assuming an exponential distribution) and 60% in the control group (Arm B; comparable to a mOS of 16 months assuming an exponential distribution). Clinical trial information: NCT05163080. Research Sponsor: None.

2500 Oral Abstract Session

EMITT-1: Clinical and pharmacodynamic activity with the oral ERAP1 inhibitor GRWD5769 and cemiplimab in 6 completed phase 1b expansion cohorts in solid tumors with anti–PD-1 resistance or MSS-CRC. First Author: Fiona Thistlethwaite, The Christie NHS Foundation Trust and University of Manchester, Manchester, United Kingdom

Background: Resistance to anti-PD-1 therapy remains a major unmet need. GRWD5769 is a first-in-class oral Endoplasmic Reticulum Amino Peptidase 1 inhibitor (ERAP1i) that modulates tumor antigen presentation on MHC-I. Dosing GRWD5769 Q3W on/off generates 2 alternating antigen repertoires (AgR) that could both broaden T cell responses and avoid T cell exhaustion from chronic tumor antigen exposure. We report clinical and translational results from 6 completed stage 1 expansion cohorts of combination GRWD5769 with cemiplimab in patients (pts) with secondary resistance to anti-PD1 and in MSS-CRC (NCT06923761). **Methods:** Pts with NSCLC, Urothelial (UC), HCC, Cervical & SCCHN with secondary resistance to ≥3 month 1st line aPD-1 or MSS-CRC without liver mets received 400 mg BD GRWD5769 and cemiplimab. ORR, Durable Clinical Benefit (DCB; defined as CR, PR or SD lasting ≥6 months) and PFS were assessed. T cell repertoire and immune phenotype changes were evaluated longitudinally. **Results:** All 6 cohorts are fully recruited (n= 81) with median follow up of 6.0 months at this interim analysis. Durable responses were observed in all cohorts (Table 1) with ORR 10-33%; DCB 26-57%. Median PFS ranged from 1.9-7.5 months across evaluable cohorts. Therapy was well tolerated with no observed safety signals. imARs were reported in 12 pts, with only 1 ≥Gr3 event (immune hepatitis) which required drug discontinuation. ≥Gr3 TRAEs occurred in 3% of pts. TCR repertoire diversity increased substantially in pts who achieved clinical benefit, driven by expansion of low-frequency, putative *de novo* TCR clonotypes. Responders exhibited cyclical Vß gene-usage dynamics indicative of broad T cell clonal expansion and contraction, consistent with AgR shifts resulting from ERAP1i. Dynamic activation of T cell associated genes further supported antigen-driven T-cell remodelling. **Conclusions:** GRWD5769 with cemiplimab demonstrated broad, durable activity across all 6 phase 1b expansion cohorts in pts with ≥2 prior lines of therapy and secondary anti-PD-1 resistance, or MSS-CRC. Translational analyses suggest that GRWD5769 exerts a dual mechanism of action, both reprogramming antigen-experienced T cells and inducing *de novo* T cell responses, in keeping with its potential to address both primary and secondary resistance to anti-PD-1 therapy. Based on the efficacy and tolerability of the combination, stage 2 cohort expansions are now ongoing, to inform a randomized Phase 2 study. Clinical trial information: NCT06923761. Research Sponsor: Greywolf Therapeutics.

Summary of expansion cohort efficacy by iRECIST.

2501 Oral Abstract Session

Re-sensitizing PD-1/PD-L1 relapsed/refractory solid tumors: Phase 1a results of IOS-1002, a LILRB1/2 and KIR3DL1 checkpoint inhibitor, in combination with pembrolizumab. First Author: Stephen James Luen, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Despite anti-PD-1/PD-L1 therapy success, 60-70% of patients develop progression with limited options (ORR 6-8% to retreatment). Upregulation of inhibitory receptors LILRB1/2 and KIR3DL1 mediates immune escape in anti-PD-1/PD-L1-resistant tumors. IOS-1002, a novel LILRB1/2 and KIR3DL1 antagonist, restores anti-tumor immunity when combined with pembrolizumab. **Methods:** Open-label, multicenter, dose-escalation Phase 1a study (NCT05235308) evaluated IOS-1002 (300-1800mg, Q2W IV) plus pembrolizumab 400mg (Q6W IV) in advanced solid tumors progressing on prior anti-PD-1/PD-L1 therapy. Primary endpoints: safety, tolerability; secondary: ORR, DCR, duration of response (DOR). Comprehensive biomarker analysis included serial cytokine profiling, target receptor expression (LILRB1/2, KIR3DL1), and tumor immune score (TIS) by gene expression analysis. Responses were assessed by RECIST v1.1. **Results:** As of January 1st, 2026, 28 patients received combination treatment with 16 anti-PD-1/PD-L1-relapsed/refractory patients (median age 65, ECOG 0-1). 3 confirmed PRs (tumor reduction -35% to -58% from baseline) leading to an ORR of 20% (3/15 evaluable) were noted with a DCR of 54% at week 12 (7/13) and 40% at week 24 (4/10), respectively. Durable responses included: 1 metabolic CR (urothelial cancer), 1 pathological CR confirmed by repeat biopsy showing absence of viable tumor cells (cutaneous SqCC), and 1 cervical cancer patient achieving -29% tumor reduction with concomitant > 90% decline in CA-125 tumor marker. Median treatment DOR was 30+ weeks (range 12-46+); 8 patients remain on treatment. Biomarker analysis demonstrated strong predictive value for TIS and target receptor expression achieving 75% ORR (3/4) versus 0% in dual-low patients (0/5). Combined biomarker score significantly correlated with depth of response (R^2 = 0.72, p = 0.008) and progression-free survival (HR 0.31, 95% CI 0.11-0.88, p = 0.04). Safety profile was favorable with no increase in grade≥3 immune-related adverse events beyond pembrolizumab monotherapy. **Conclusions:** IOS-1002 plus pembrolizumab demonstrated clinically meaningful efficacy in pretreated anti-PD-1/PD-L1-relapsed/refractory patients. Biomarker-driven patient selection using dual-high TIS and target receptor expression enhanced ORR to 75% and strongly predicted response depth, durability, and survival benefit. The favorable safety profile with no incremental immune-related toxicity, coupled with durable responses and high disease control rates, provides compelling rationale for Phase 1b expansion in biomarker-selected PD-1/PD-L1-refractory solid tumors. Clinical trial information: NCT05235308. Research Sponsor: None.

Endpoint	Result
ORR (evaluable)	20% (3/15)
DCR Week 12	54% (7/13)
DCR Week 24	40% (4/10)
Biomarker-selected ORR	75% (3/4)
Ongoing treatment	8/16 (50%)

2502 Oral Abstract Session

DART (NCI/SWOG S1609): Comprehensive results from dual checkpoint inhibition with CTLA-4 and PD-1 blockade in rare cancers. First Author: Sandip Pravin Patel, UC San Diego Moores Cancer Center, San Diego, CA

Background: Rare tumors are underrepresented in clinical trials, though they collectively comprise an estimated 22% of all cancer cases. The NCI/SWOG S1609 trial evaluated efficacy signals across 53 rare cancer cohorts treated with dual CTLA-4 and PD-1 inhibition. **Methods:** A prospective, open-label, multicenter phase 2 trial of ipilimumab (1mg/kg intravenously every 6 weeks) plus nivolumab (240mg intravenously every 2 weeks) was conducted from 1/13/2017 to 3/15/2023. A statistical framework was established to evaluate each cohort in a two-stage design. The primary end point was objective response rate (ORR); progression-free survival (PFS), overall survival (OS), clinical benefit rate (CBR, ORR + stable disease >6 months), i-outcomes, and toxicity were secondary and exploratory endpoints. **Results:** 798 patients were enrolled and 727 eligible patients received treatment. 1,083 national (USA) sites opened the trial. Median (range) patient age was 60 (18-88) years; 344 (47%) patients were male. 24 of 53 cohorts (45%) demonstrated clinical activity, defined as ≥2 patients with confirmed response. Median (range) ORR was 12% (0-75%); CBR, 27% (0-75%). Median (range) 2-year PFS was 10% (0-75%); 3-year OS was 23% (0-100%). 6-month PFS was moderately correlated with 1- and 3-year OS (R^2 =0.61 and 0.54, respectively). Patients who attained an iOR versus OR had similar OS. 82 patients (11%) had iPFS ≥2 years. Treatment-related adverse events (AEs) of any cause and immune-mediated occurred in 603 (82.9%) and 465 (64.0%) patients. AEs led to treatment discontinuation in 102 patients (14.0%). Most common AEs were fever (38.1%), diarrhea (21.2%), and rash/pruritis (19.3%). 13 patients (1.8%) experienced treatment-related grade 5 AEs. Patients alive at 6 months who discontinued treatment due to immune-related AE had longer OS than those who discontinued for other reasons (p = 0.021). **Conclusions:** Patients with multiple rare cancer types derived meaningful response to ipilimumab plus nivolumab. Characterization of biologically defined subsets is underway to optimize therapeutic selection. Clinical trial information: NCT02834013. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; U10CA180819; Bristol-Myers-Squibb.

Desmocolin-3–directed immunotherapy in recurrent/metastatic head and neck squamous cell carcinoma. First Author: Ranjan Das, Department of Medical Oncology, Sparsh Hospitals and Critical Care, Bhubaneswar, India

Background: Recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) are aggressive tumors. In pre-treated R/M HNSCC observed response rates were 13.0% (nivolumab; CheckMate 141) and 14.6% (pembrolizumab; KEYNOTE- 040), with median PFS 2.0 months and 2.1 months, respectively. Desmocollin3 (DSC3) is a surface protein expressed by HNSCC. DSC3 directed immunotherapy (CADI-05) is useful in DSC3 expressing cancer like Squamous NSCLC, bladder cancer, and melanoma. This study evaluated its efficacy (ORR, PFS, OS) in DSC3 expressing R/MHNSCC. **Methods:** In this investigator initiated single-arm, study patients with RMHNSCC expressing DSC3 were recruited. Tumor infiltrating lymphocytes (TIL), PD-L1, and P16 were also evaluated. All patients received 0.1ml CADI-05 intradermally + intralesional (for fungating/discharging solid lesions were present) every 4 weeks. Additional treatment was administered as per PI discretion. All patients were followed up until disease progression, or death. **Results:** Between May 2024 and July 2025, 20 patients were enrolled (males 17, females 3). The mean age was 55 yrs (range 34-87 yrs). Primary sites included tongue 9, buccal mucosa 9. All had undergone two lines of therapy with a mean of 2.55. Of 20 patients, 15 had progressed on prior therapy (6 stage IVC). Baseline mean parameters were mean DSC3 TPS - 41%, (95% CI, 32.67 - 49.33), mean PD-L1 CPS 27 (95% CI,10.61 - 33.39), mean TIL 17% (95% CI ,10.43 - 23.57). All were HPV negative. Additional therapy received included EGFR TKI (15), EGFR mAb (2), oral metronomic therapy (1) and none (2). Disease control rate was 45% (9/20) with overall response rate (ORR) 35% [7/20; 2 CR and 5 PR]. At a median follow-up of 155 days, mean (median) PFS and overall survival were 165 (115) and 197 (155) days, respectively. Mean (median) duration of response was 280 (332) days with 8 patients alive at the last follow up. This is significantly better than achieved with current therapies. Responders had higher DSC3 expression compared to non-responders (mean DSC3 50% vs 29%; p= 0 .002537). ORR was higher in patients with Stage IVA (57%) compared to IVC (20%) DSC3 TPS was higher than PD-L1 CPS in all patients with disease control. TIL and PD-L1 levels were not correlated with response. Injection site ulcer was the only side effect seen in 8 (40%), which include 6 (75%) of the responders. No systemic adverse events were observed. **Conclusions:** DSC3 targeted immunotherapy was safe and improved outcomes in pre-treated R/M HNSCC expressing DSC3, with disease control rate 45%, response rate 35%. Median duration of response was 332 days with median PFS and OS of 115 and 155 days, respectively. Research Sponsor: None.

2504 **Oral Abstract Session**

RP2 oncolytic immunotherapy alone and in combination with nivolumab (nivo) in patients with advanced solid tumors: Final safety, efficacy, and biomarker results from the phase 1 first-in-human (FIH) study. First Author: Joseph J. Sacco, The Clatterbridge Cancer Centre and University of Liverpool, Liverpool, United Kingdom

Background: RP2 is an HSV-1-based oncolytic immunotherapy expressing a fusogenic glycoprotein (GALV-GP-R$^-$), human GM-CSF, and a human anti–CTLA-4 antibody. We present final safety, efficacy, and biomarker data from the FIH study of RP2 in patients (pts) with advanced solid tumors (NCT04336241). **Methods:** Enrolled pts had advanced/metastatic solid tumors with ≥1 measurable, injectable lesion (≥1 cm) and had progressed following, or could not tolerate, available standard therapy. Pts received RP2 monotherapy via intratumoral injection in dose escalation (Part 1; 5 doses Q2W). Pts in Parts 2 (RP2 + nivo) and 3 (RP2 monotherapy) received up to 8 doses of RP2 (Q2W × 8 or Q2W × 4 followed by Q4W × 4 doses) at the RP2D. In Part 2, nivo was administered starting at Cycle 2 or 4 for ~20 to 22 months. Pts could receive an additional course of RP2 per protocol. **Results:** As of 01DEC2025, 85 pts (median age 59 y) were enrolled and treated in RP2 (n = 25) or RP2 + nivo (n = 60) cohorts. Tumor types included uveal or cutaneous melanoma (UM, n = 17; CM, n = 11); colorectal (n = 14), head and neck (n = 13), and pancreatic (n = 12) cancers; and sarcoma (n = 7); 42% of pts received prior immune checkpoint inhibitor treatment. All pts have completed treatment. Treatment-related adverse events (TRAEs) in > 10% of pts included pyrexia, chills, fatigue, influenza-like illness, hypotension, pruritus, and nausea. Grade ≥3 TRAEs occurred in 20% of pts (no single event occurred in > 2 pts). A majority of pts (58/85) received injections into deep/visceral lesions, mainly in liver and lung, which were well tolerated. Among pts with ≥1 post-baseline scan (75/85), the ORR was 17.3% (13/75; 1 unconfirmed) with a median DOR of 22.1 months and DCR (CR+PR+SD) of 44.0% (33/75). Responses occurred in 5/15 (33.3%) pts with UM. RP2 monotherapy resulted in confirmed responses in 4/21 (19%) pts (1 esophagogastric adenocarcinoma, 1 UM, 1 chordoma, 1 mucoepidermoid), with best overall response of CR and median DOR not reached. Tumor regression occurred in both injected and non-injected lesions, including all 3 pts with monotherapy responses with non-injected lesions. A robust intratumoral immune response with increased CD8+ T-cell infiltrates, PD-L1 upregulation, and inflammatory immune pathway activation were observed, as well as epitope spreading with novel virus- and cancer-associated T-cell clones. **Conclusions:** RP2 ± nivo treatment was well tolerated in pts with both superficial and deep visceral metastases. Durable responses were observed with RP2 monotherapy and RP2 + nivo in heavily pretreated pts with diverse tumors with evidence of systemic anti-tumor immune activity, including tumor reduction in distant non-injected lesions. This study supports the ongoing evaluation of RP2 in pts with UM (NCT06581406) and the planned evaluation in other solid tumors. Clinical trial information: NCT04336241. Research Sponsor: Replimune, Inc.

2505 **Oral Abstract Session**

Phase 2 basket trial of precision TIL therapy for immunotherapy-resistant advanced cancers. First Author: Shravan Leonard-Murali, University of Pittsburgh Medical Center (UPMC) Hillman Cancer Center, Pittsburgh, PA

Background: Adoptive cell therapy (ACT) using unselected autologous tumor-infiltrating lymphocytes (TIL) has demonstrated clinical activity in metastatic cutaneous melanoma, an immunotherapy-sensitive cancer with high tumor mutational burden (TMB). However, we recently demonstrated in metastatic uveal melanoma, a prototypic low-TMB, immunotherapy-resistant cancer, that efficacy of TIL ACT requires infusion of TIL with measurable anti-tumor reactivity. Thus, to extend TIL ACT to additional immunotherapy-resistant cancers, we developed *TILScore*, a pan-cancer in situ transcriptomic biomarker designed to preoperatively identify metastases enriched with clinically active TIL. Here we report initial results from a pilot phase 2 TIL therapy trial prospectively evaluating *TILScore* as a precision biomarker for immunotherapy-resistant cancers. **Methods:** This single-center phase 2 trial (NCT03935893) enrolled patients with treatment-refractory, locally advanced, recurrent, or metastatic cancers into ten histology-defined cohorts. After a feasibility run-in, metastases with core biopsy *TILScore* > 0.248 were selected for TIL harvest and manufacturing. Patients received non-myeloablative lymphodepletion (NMA-LD) with cyclophosphamide and fludarabine, followed by infusion of TIL and high-dose interleukin-2. The primary endpoint was cohort-specific objective response rate (ORR) by RECIST v1.1 using a Bayesian basket design targeting ORR > 20% as evidence of promising activity. **Results:** As of 1/17/2026, 19 patients received TIL therapy. Tumor types included pancreatic adenocarcinoma (PDAC, n = 7), leiomyosarcoma (n = 3), peritoneal mesothelioma (PeM, n = 2), and single cases each of non–small cell lung cancer, cervical squamous cell carcinoma (SCC), nasopharyngeal SCC, and melanoma subtypes (cutaneous, acral, mucosal, unknown origin). All had progression after frontline therapy, with a median of 5 prior metastatic treatments; 58% had received checkpoint blockade. Liver metastases were the most common TIL source (37%), followed by lung and soft tissue (32% each). Infusion products contained a median of 5.36E10 TIL with an even mix of CD4 and CD8 cells. Adverse events were consistent with NMA-LD and interleukin-2; no grade 5 events occurred. Among 18 evaluable patients, ORR was 33% (6/18) with cohort specific responses in PDAC (50%, 3/6: 1 CR, 2 PR), PeM (100%, 2/2: 1 CR, 1 PR), and melanoma of unknown origin (100%, 1/1: 1 CR). *TILScore* predicted clinical response with an area under the receiving operating characteristic curve of 0.806 (P = 0.041). **Conclusions:** *TILScore*-guided selection of metastases for TIL manufacturing is feasible and enables consistent generation of clinically active TIL in patients with immunotherapy-resistant cancers. Promising clinical activity in PDAC and PeM supports evaluation of this biomarker-driven TIL ACT approach in larger, histology-specific cohorts. Clinical trial information: NCT03935893. Research Sponsor: UPMC Enterprises Translational Sciences.

2506 **Oral Abstract Session**

Initial phase 1 study results of NT-175 engineered T-cell therapy in *TP53* R175H–mutated unresectable advanced solid tumors. First Author: Rishi Surana, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: *TP53* is the most frequently mutated tumor suppressor gene across various tumor types, but no approved targeted therapies exist. NT-175 is an autologous engineered T-cell receptor (eTCR) T-cell therapy expressing an HLA-A*02:01-restricted TCR that targets the TP53 R175H tumor neoantigen. **Methods:** This open-label Phase 1 study (NCT05877599) enrolled HLA-A*02:01-positive adults with advanced/metastatic, TP53 R175H-mutated solid tumors. NT-175 was manufactured from autologous T cells modified by CRISPR/Cas9 gene-editing to delete endogenous TGFβR2 and replace the TCRα locus with the A*02:01-restricted R175H specific TCR. Patients (pts) received lymphodepletion with fludarabine and cyclophosphamide followed by a single NT-175 infusion along with subcutaneous recombinant IL-2. NT-175 was administered at 3 escalating dose levels (DLs) of eTCR+ T-cells. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded per ASTCT consensus definitions. Response was determined by investigator assessment per RECIST v1.1. The primary objective was safety; secondary and exploratory objectives included preliminary antitumor activity and pharmacokinetics (PK), respectively. **Results:** As of Oct 31, 2025, 26 pts were enrolled and 21 were infused with NT-175 (median age 58 years, [range 43–77] across all DLs (DL1, n = 3; DL2, n = 4; DL3, n = 13; other, n = 1). Pts had a median of 3 prior lines of systemic therapy. Median time from apheresis to NT-175 infusion was 36 days and median follow-up was 6.0 (range: 0.9–9.5) months. Pts had colorectal adenocarcinoma (CRC, n = 10), pancreatic adenocarcinoma (PDAC, n = 6), breast cancer (BC, n = 2), and other solid tumors (n =3). There were no DLTs or Grade 5 events. CRS occurred in 11 (52.4%) pts (Grade ≥3 in 2 [9.5%]); ICANS occurred in 1 pt (Grade 3, 4.8%). Across all dose levels, objective response rate (ORR, including 7 confirmed and 3 unconfirmed responses) was 47.6% (95% CI, 25.7–70.2); in DL3, ORR was 53.8% (95% CI, 25.1–80.8). Partial responses (PR) were observed in 10 pts including 5/6 pts (83%) with PDAC and 5 pts across various tumor histologies (2/10 CRC, 2/2 BC, 1 other), and stable disease in 4 pts. Of 7 evaluable PR pts with ≥6 months of follow up, 5 remain in PR (2 PDAC, 1 leiomyosarcoma, and 2 CRC). Overall, disease control rate was 66.7% (95% CI, 43.0–85.4). Peripheral blood PK analyses (n =21) showed dose-dependent NT-175 expansion, peaking at Week 1 post-infusion, and persistence > 300 days. **Conclusions:** Manufacturing and treatment with autologous NT-175 eTCR T cells was safe and feasible in pts with heavily pre-treated metastatic TP53-mutated malignancies. Further, NT-175 demonstrated encouraging preliminary antitumor activity across multiple histologies, with most notable early signals in PDAC and may offer a prolonged treatment-free interval in pts with refractory solid tumors. Clinical trial information: NCT05877599. Research Sponsor: AstraZeneca.

2507 **Oral Abstract Session**

First-in-human results with IMA401, a MAGEA4/8-targeted T-cell receptor–based bispecific T-cell engager (TCER) in recurrent or refractory solid tumors. First Author: Martin Wermke, TU Dresden University of Technology, NCT/UCC Early Clinical Trial Unit, Dresden, Germany

Background: IMA401 is a next-gen bispecific TCR-based T-cell engager designed to redirect T cells to antigen-positive cancer cells. It combines a high-affinity, highly specific TCR domain against an HLA-A*02:01-presented target peptide common to cancer-specific antigens MAGEA4 and MAGEA8 with a low-affinity T-cell–recruiting domain for improved tolerability and biodistribution, and an Fc part for half-life extension. IMA401-101 (NCT05359445) is a first-in-human phase 1a/b basket study evaluating IMA401 in pts with advanced solid tumors. **Methods:** Pts were ≥18 y, HLA-A*02:01+, MAGEA4+ and/or MAGEA8+, have R/R solid tumors, measurable disease (RECIST 1.1), ECOG performance status 0-2, and have exhausted SOC options. Dose escalation involved cohorts of 1-6 pts using adaptive design (BLRM). Doses ranged from 0.0066 mg - 2.5 mg IMA401 q2w (± pembrolizumab [pembro] q6w with 1.0 mg or 1.5 mg IMA401). Weekly step dosing of IMA401 was implemented for the first 2-3 doses at ≥1 mg . Primary endpoint was MTD assessed by BLRM and/or RP2D as monotherapy and in combination with pembro. Secondary endpoints included safety and initial antitumor activity (confirmed objective response rate [cORR] and disease control rate [DCR]). **Results:** As of Sep 26, 2025, 55 heavily pretreated pts across > 15 different tumor types with a median of 4 prior lines of therapy (range 1-9) received IMA401 ± pembro. Most frequent TRAEs were low-grade CRS (G1: 24%; G2: 11%; no ≥G3 events), expected and transient lymphopenia (any grade: 29%; ≥G3: 24% which typically improved within 1-3 days), and reversible neutropenia (any grade: 29%; ≥G3: 18%). No ICANS was observed. Tolerability of IMA401 + pembro (n = 9) was consistent with the IMA401 monotherapy safety profile. MTD was not reached (3 DLTs at 2.5 mg IMA401). RP2D range was determined to be 1-2 mg IMA401. Efficacy was evaluable in 38 pts receiving a target dose of ≥1 mg IMA401. Promising clinical activity was noted in pts with head and neck (HN) cancer (cORR: 25% [2/8]; DCR: 63% [5/8]) and melanoma (cORR: 29% [2/7]; DCR: 57% [4/7]) with duration of all confirmed responses beyond 6 months postinfusion. In squamous non-small cell lung cancer (sqNSCLC [n = 3]), 1 PR with reduction in all target lesions, 1 SD with OS of ~16 months and 1 PD with reduction in all liver target lesions were observed. After data cutoff, 2 more cPRs were observed in HN cancer resulting in a cORR of 33% (4/12). An updated full dataset will be presented. **Conclusions:** IMA401 demonstrated overall favorable tolerability without reaching formal MTD and encouraging antitumor activity in pts with HN cancer, melanoma, and sqNSCLC at RP2D range. Based on the promising results and preclinical proof of concept data, further development steps are being evaluated including a potentially synergistic combination with the PRAME-directed bispecific IMA402 in sqNSCLC and other solid tumor indications. Clinical trial information: NCT05359445. Research Sponsor: None.

2508 **Oral Abstract Session**

Objective response rates with Ori-C101, an armored GPC3-directed CAR-T, in heavily pretreated advanced HCC: Updated results from the phase Ib BEACON study. First Author: Jia Fan, Department of Hepatobiliary Surgery and Liver Transplantation, Liver Cancer Institute, Zhongshan Hospital, and Key Laboratory of Carcinogenesis and Cancer Invasion of Ministry of Education, Fudan University, Shanghai, China; Clinical Center for Biotherapy, Shanghai, China

Background: Advanced hepatocellular carcinoma (HCC) remains a high unmet-medical-need malignancy with limited therapeutic options. Ori-C101 is a novel, armored, autologous GPC3-directed CAR-T cell therapy. Following promising results from early-phase trials (ChiCTR190028121; NCT05652920, BEACON study), we shall herein update outcomes from the BEACON study with focusing on long-term safety, durability of response, and survival after more than 2 years of follow-up. **Methods:** This is an open-label, multi-center, phase Ib dose-escalation and expansion study enrolled patients (pts) with GPC3$^+$ advanced HCC who had progressed on ≥2 prior lines of systemic therapy (including ICIs and TKIs). A single dose of Ori-C101 was administered via hepatic arterial infusion to enhance regional cell delivery. Integrated analyses assessed safety, tolerability, PK, and efficacy (per RECIST v1.1) , aiming to determine the RP2D. **Results:** As of Dec 24, 2025, 19 pts received Ori-C101 infusion across 4 dose levels (DLs). All pts had BCLC stage B/C disease and 31.6% (6/19) had extrahepatic metastases. Pts were previously treated with a median of 3 lines (range 2–8) therapies. Safety: Safety remained manageable; no late-onset nor cumulative toxicities were observed through the extended follow-up period. The most common ≥G3 TEAEs (≥10.0%) were transient hematologic toxicities and hepatic laboratory abnormalities. CRS occurred in 100.0% (19/19) of pts; while ≥G3 CRS observed in 42.1% (8/19). No ICANS occurred. One pt at DL4 experienced a DLT of G4 CRS complicated by secondary DIC. Efficacy: In 18 efficacy-evaluable pts, Ori-C101 demonstrated a robust dose-dependent response. Confirmed ORR was 50.0% (9/18); DCR was 77.8% (14/18). At RP2D (DL3), the confirmed ORR and DCR were 66.7% (6/9) and 88.9% (8/9), respectively. Critically, responses were not only rapid but also remarkably durable. 88.9% (8/9) of responders achieved objective response within 1.1 months; at M3, 83.3% (5/6) of responders at the RP2D remained PR. Notably, 1 pt at DL4 achieved CR with a duration exceeding 20 months. Preliminary overall survival data indicate a substantial long-term survival benefit with a median OS of 14.4 months (range 2.6–22.0). In addition, Dose-Exposure-Responses analysis showed dose-dependent CAR-T cells expansion, pharmacodynamic effects and improved tumor response. **Conclusions:** Ori-C101 demonstrates a manageable safety profile and compelling, durable anti-tumor activity in GPC3$^+$ advanced HCC. The combination of high ORR and prolonged survival benefit distinguishes Ori-C101 as a potential paradigm-shifting therapy for patients who have failed standard-of-care treatments. A phase II/III study is currently underway to further confirm the efficacy and asses the safety of Ori-C101. Clinical trial information: NCT05652920. Research Sponsor: None.

2509 **Clinical Science Symposium**

An investigator-initiated phase I study evaluating the safety, tolerability, and preliminary efficacy of a personalized neoantigen mRNA vaccine (XP-004) combined with PD-1 inhibitor as adjuvant therapy in resected pancreatic cancer patients intolerant to chemotherapy. First Author: Xinjing Wang, Department of General Surgery, Pancreatic Disease Center, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Pancreatic cancer has a high postoperative recurrence rate. Although adjuvant chemotherapy is standard of care, many patients are unable to tolerate it, highlighting an unmet need for alternative adjuvant strategies. Personalized neoantigen mRNA vaccines can induce tumor-specific T-cell responses and may synergize with PD-1 blockade. This study evaluated the safety, tolerability, and preliminary clinical activity of XP-004 combined with a PD-1 inhibitor as adjuvant therapy in resected pancreatic cancer patients intolerant to chemotherapy. **Methods:** This open-label, single-arm, investigator-initiated phase I trial (2024PCV004; NCT06496373) initiated in May 2024 plans to enroll 16-20 patients with resected pancreatic cancer intolerant to chemotherapy. Patients received XP-004 intramuscularly (1.0 mg Q3W for 13 cycles), including a KRAS-targeted single-neoantigen vaccine for 4 cycles followed by a personalized multi-neoantigen vaccine for 9 cycles, combined with toripalimab (PD-1 inhibitor). Each personalized vaccine encoded 10–20 personalized neoantigens selected using next-generation sequencing and bioinformatic prediction. The primary endpoint was safety and tolerability; secondary endpoints included neoantigen-specific CD4$^+$ and CD8$^+$ T-cell responses, recurrence-free survival (RFS), and overall survival (OS). **Results:** As of December 15, 2025, 16 patients were enrolled. XP-004 mRNA vaccine was well tolerated. Treatment-related AEs included fever (100%), injection-site pain (87.5%), nausea (43.8%), vomiting (37.5%), pruritus (50.0%), rash (25.0%), and fatigue (37.5%). Grade ≥3 AEs were observed in 12.5% patients, including fever (12.5%) and pruritus (6.3%), the latter attributed to toripalimab. No other immune-related AEs were observed. Transient cytokine increases (IFN-γ, IL-5, IL-6, IL-8, IL-10) were observed without organ dysfunction. At a median postoperative follow-up of 43.9 weeks (range of 6.1–72.0 weeks), and a median follow-up of 37.6 weeks (range of 0.9–63.7 weeks) after first vaccination, all patients remained recurrence-free, with no clinical or molecular evidence of recurrence, including no tumor-informed MRD relapse. Among the 13 patients evaluable for immunogenicity, 13 (100.0%) developed neoantigen-specific T-cell responses; 53 of 165 neoantigens (32.1%) were immunogenic. **Conclusions:** XP-004 combined with PD-1 inhibitor demonstrated favorable safety and tolerability and induced robust neoantigen-specific T-cell responses in resected pancreatic cancer patients intolerant to chemotherapy. Early follow-up suggests potential RFS benefit, supporting further investigation of this adjuvant immunotherapy strategy. Clinical trial information: NCT06496373. Research Sponsor: None.

2510 **Clinical Science Symposium**

Synthetic lethality–informed neoantigen prioritisation to support mechanism-specific therapeutic strategies across human cancers. First Author: Michael E. Bryan, Centre for Immuno-Oncology, University of Oxford, Oxford, United Kingdom

Background: Personalised neoantigen vaccines can elicit strong tumour-specific T cell responses, yet tumours may evade immune pressure by deleting or silencing the targeted gene. Current selection pipelines treat gene-based escape as an unpredictable failure. For tumour suppressor genes, however, loss of the target can create predictable synthetic lethal (SL) dependencies. We present a framework that classifies tumour suppressor mutations by their therapeutic implications. We hypothesised that hypomorphic mutations, which generate immunogenic neoantigens while retaining partial function, may be suited to sequential therapy, where vaccination selects for complete loss and exposes druggable vulnerabilities. In contrast, null mutations with pre-existing SL dependencies may benefit from upfront vaccine–drug combinations. **Methods:** We analysed 9,953 tumours across 32 cancer types from TCGA. Tumour suppressor mutations were assessed for neoantigen potential using NetMHCpan-4.2, MHCflurry 2.0, and PRIME 2.0 (%rank $<$ 2%), with filtering for clonality, expression (TPM $>$ 1), and multi-allele HLA presentation. Functional status was assigned using gene-specific annotations, including TP53 transactivation scores. SL relationships were curated from DepMap, SynLethDB 2.0, and published clinical evidence, restricted to partners with approved or Phase II+ inhibitors. **Results:** 7.4% of patients (n = 741) harboured tumour suppressor neoantigens with matched SL vulnerabilities, which segregated into two distinct groups. The first group (4.6%, n = 458) carried hypomorphic mutations that generated immunogenic neoantigens while retaining partial gene activity, consistent with candidacy for sequential vaccination followed by SL inhibition upon escape. TP53 missense mutations predominated (58%), with progression to null status predicted to confer WEE1 or CHK1 vulnerability. Additional recurrent pairings included PTEN–AKT (14%), ATM–ATR or PARP (11%), KMT2D–EZH2 (9%), and BRCA2–PARP (8%). The second group (2.8%, n = 283) carried functionally null mutations with SL dependencies present at diagnosis, nominating these patients for upfront vaccine–drug combinations. Endometrial (12.1%) and colorectal (9.8%) cancers were enriched for both patterns, whereas high-grade serous ovarian cancer was dominated by hypomorphic mutations. **Conclusions:** This framework reframes immune escape from neoantigen vaccination, conventionally viewed as treatment failure, as a predictable and potentially exploitable therapeutic event. Functional classification of tumour suppressor neoantigens provides a rationale for distinguishing sequential from upfront vaccine–SL inhibitor strategies. Prospective trials with longitudinal monitoring will be required to determine whether vaccination-induced gene loss consistently exposes the predicted vulnerabilities. Research Sponsor: None.

2511 **Clinical Science Symposium**

Personalized neoantigen vaccine as adjuvant therapy in high-risk post-operative esophageal carcinoma. First Author: Ming Wu, Department of Thoracic Surgery, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Effective adjuvant strategies for patients with esophageal carcinoma (EC) with residual pathological disease (non-pCR) following neoadjuvant chemoimmunotherapy and radical surgery are urgently needed to reduce the high risk of recurrence. This investigator-initiated, single-arm clinical trial (NCT05307835) evaluated the safety, efficacy, and immunogenicity of iNeo-Vac-P01, a personalized neoantigen peptide vaccine, administered as adjuvant therapy in this high-risk setting. To our knowledge, this study represents the first and largest global cohort of a personalized neoantigen vaccine for postoperative EC, with the longest follow-up duration to date. **Methods:** Eligible stage IIA-IIIB EC patients with non-pCR were enrolled. For each patient, somatic mutations were identified, and up to 20 individualized long peptides (15-30 amino acids), encompassing predicted HLA-I and II neoantigens, were designed and synthesized using a proprietary bioinformatics platform. The vaccine (300μg per peptide) was administered subcutaneously in conjunction with GM-CSF (40μg) on a multi-dose schedule (Days 1, 4, 8, 15±3, 22±3, 52±7, and 82±7). The primary endpoints were safety and 1-year recurrence-free survival (RFS). Secondary endpoints included RFS, overall survival (OS), and antigen-specific T-cell responses assessed by ELISpot and TCR sequencing. **Results:** As of November 15, 2025, 26 patients were enrolled, with 23 patients constituting the efficacy-evaluable population. Treatment-related adverse events were primarily Grade 1-2 (fatigue: 39.1%; fever: 30.4%; injection site reactions: 21.7%), with one Grade III acute hypersensitivity event. All 23 patients completed the initial 7-vaccination course. With a median follow-up of 25.3 months from surgery, the 1-year, 2-year, and 3-year RFS rates were 91.3%, 85.6%, and 78.5%, respectively. The corresponding 1-year, 2-year, and 3-year OS rates were 100%, 95%, and 83.1%. These survival outcomes compare favorably with historical controls, notably exceeding the 3-year RFS of 43% reported in the landmark CheckMate 577 trial (adjuvant nivolumab). Immunological analyses confirmed robust vaccine-induced immunogenicity. ELISpot assays detected neoantigen-specific T-cell responses in 100% (23/23) of evaluated patients, with 79.5% (233/296) of the administered vaccine peptides eliciting de novo T-cell activation. TCR sequencing further demonstrated the durable expansion of neoantigen-reactive T-cell clones, which were detectable during treatment and persisted for at least six months following the final vaccination. **Conclusions:** These results demonstrates that adjuvant therapy with a personalized neoantigen peptide vaccine confers a substantial and durable survival benefit in high-risk EC patients following surgery, coupled with a favorable safety profile. Clinical trial information: NCT05307835. Research Sponsor: Hangzhou Neoantigen Therapeutics Co., Ltd.

2512 Rapid Oral Abstract Session

Phase 2 trial of TIL therapy for metastatic uveal melanoma: Evaluation of T cell potency and an in situ precision biomarker. First Author: Shravan Leonard-Murali, University of Pittsburgh Medical Center (UPMC) Hillman Cancer Center, Pittsburgh, PA

Background: Uveal melanoma (UM) is a rare eye cancer that frequently metastasizes to the liver and responds poorly to systemic therapies. We previously reported that adoptive transfer of autologous tumor-infiltrating lymphocytes (TIL) produced a 35% objective response rate (ORR) in metastatic UM, with infusion product tumor reactivity being the strongest predictor of response. To guide surgical harvest of metastases enriched for tumor-reactive TIL, we developed Uveal Melanoma Immunogenomic Score (UMIS), an in situ tumor transcriptomic biomarker. Here we present results of a phase 2 trial designed to validate the efficacy of TIL therapy in metastatic UM and prospectively evaluate predictors of response. **Methods:** In this single-center phase 2 trial (NCT03467516) metastatic UM patients underwent metastatectomy to generate early TIL cultures. Cultures demonstrating growth potential and autologous anti-tumor reactivity were expanded for infusion. Patients received non-myeloablative lymphodepletion with cyclophosphamide and fludarabine, followed by infusion of TIL and high-dose interleukin-2. The primary endpoint was ORR per RECIST v1.1. Exploratory analyses to identify response predictors were performed in the current cohort and a pooled dataset including the NCT01814046 cohort. **Results:** Thirty-three UM patients received TIL therapy. Most had high disease burden (82% M1b/M1c; 76% elevated LDH; 70% hepatic and extrahepatic metastases; 24% CNS), received a median of 2 prior metastatic treatments (64% checkpoint blockade, 33% tebentafusp), and had liver metastases as their TIL source (52%). Infusion products had a median of 5.24E10 TIL, were CD8-enriched (median 68%), and demonstrated autologous tumor reactivity in 61% (19/31). Among 32 evaluable patients, the ORR was 22% (7/32) with a median response duration of 10.8 months (maximum ongoing at 58 months). Tumor-reactive TIL conferred higher response rates (37%, 7/19) than nonreactive products (0%, 0/12; P = 0.026). Responders demonstrated higher persistence of infused TIL clones in peripheral blood (R/NR ratio = 10.69, P = 0.020). In the pooled cohort (n = 54, 52 evaluable), ORR was higher with reactive products (43%, 12/28) versus nonreactive products (0%, 0/20; P = 5.06E-4). UMIS of the source metastases predicted growth of tumor-reactive TIL cultures (Rho = 0.55, P = 2.72E-5), final infusion product reactivity (P = 0.040), and clinical response (P = 0.004). **Conclusions:** TIL therapy demonstrates clinically meaningful activity in advanced, pretreated metastatic UM. Infusion product tumor reactivity was the strongest predictor of response. UMIS identified metastases enriched with tumor-reactive TIL and predicted final product potency and clinical outcome. These findings support implementation of UMIS as a minimally invasive precision biomarker to guide patient and tumor selection for optimal therapeutic benefit. Clinical trial information: NCT03467516. Research Sponsor: None.

2513 Rapid Oral Abstract Session

Perioperative tislelizumab plus chemotherapy versus chemotherapy in MHC-II positive/MHC-II negative locally advanced GC/GEJC: A prospective, randomized, open-label, biomarker-driven, phase 2 trial. First Author: Xiangdong Cheng, Zhejiang Cancer Hospital, Hangzhou, Zhejiang Province, China

Background: Neoadjuvant immunotherapy achieves major pathologic response (mPR) in 40% of locally advanced gastric cancer (LAGC) patients. Tumor-specific MHC-II expression(tsMHC-II) has been linked to a better enhanced response to immune checkpoint inhibitor therapy. Herein, we conducted a prospective, randomized study to evaluate the effectiveness of chemotherapy combined with anti-PD-1 therapy versus chemotherapy alone as neoadjuvant treatment for tsMHC-II-positive LAGC patients. **Methods:** Patients with locally advanced GC/GEJC (cT3-4N+M0, CY0, P0) were enrolled according to tsMHC-II expression. Within each stratum, patients were subsequently randomized 1:1 to receive either tislelizumab combined with chemotherapy or chemotherapy alone, including Arm A (tsMHC-II-positive, chemotherapy + tislelizumab), Arm B (tsMHC-II-positive, chemotherapy), Arm C (tsMHC-II-negative, chemotherapy + tislelizumab), Arm D (tsMHC-II- negative, chemotherapy). For experimental group, patients received either 3 preoperative and 3 postoperative cycles of tislelizumab plus SOX/XELOX, followed by 11 cycles of tislelizumab. For control group, patients received either 3 preoperative and 3 postoperative cycles of SOX/XELOX. The primary endpoint was mPR rate (Arm A vs. Arm B). The key secondary endpoint was pCR rate (Arm A vs. Arm B). This clinical trial was registered at Clinicaltrial.gov (NCT06374901). **Results:** 136 patients (34 per arm) were enrolled from July 2024 to March 2025, with a median age of 65 years (range, 30-75), and 105 (76.64%) were male. The study achieved its primary endpoint. The results revealed that tsMHC-II-positive patients in the tislelizumab plus chemotherapy group achieved a greater proportion of mPR (61.8% versus 26.5%; P = 0.003) and pCR (32.4% versus 8.8%; P = 0.016) than did those in the chemotherapy group, which met a prespecified endpoint. In contrast, this benefit was absent in tsMHC-II-negative patients (mPR: 23.5% vs 26.5%, P = 0.886; pCR: 5.9% vs 8.8%, P = 0.642). There were no significant differences in treatment-related adverse reactions among each group. **Conclusions:** In conclusion, compared with perioperative chemotherapy alone, the addition of tislelizumab to a given chemotherapy regimen significantly increased the proportion of mPR and pCR in tsMHC-II-positive patients with GAC/GEJAC only, which revealed that tsMHC-II could be a biomarker to guide the selection of appropriate GAC/GEJAC patients for perioperative immunotherapy. Clinical trial information: NCT06374901. Research Sponsor: None.

2514 Rapid Oral Abstract Session

A randomized prospective trial evaluating duration of PD-1 and PD-L1 inhibitor therapy in advanced solid tumors. First Author: Vincent Edgar Reyes, UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA

Background: Immune checkpoint inhibitors (IO) have revolutionized the treatment of advanced solid tumors. Despite their widespread adoption, the optimal duration of IO has not been clearly established, and this remains an unmet clinical need. **Methods:** In our prospective trial, patients (pts) with advanced solid tumors who achieved at least stable disease (SD) after 1 year of standard-of-care PD-1/PD-L1 inhibitors were randomized 1:1 to either stop or continue IO beyond one year. Pts who stopped IO and then progressed could be retreated with IO at physician discretion. Primary endpoint was cure rate, defined as the proportion of pts without progressive disease, death, or initiation of new treatment (including re-treatment with IO) at five years. Cure rate was calculated using Kaplan-Meier (KM) estimates with 95% confidence intervals (CI) and compared between arms using a multivariable logistic regression model to adjust for pre-specified stratification factors of tumor type and expected efficacy by IO indication, and reported as an odds ratio (OR) with CI and p-value. Secondary endpoints included PFS, OS, and incidence of iRAEs. Median PFS and OS were estimated from KM curves, with hazard ratios (HR) and p-values obtained from stratified Cox proportional hazards models. All analyses were conducted using R version 4.4.2. **Results:** From 2019 to 2025, leveraging our central hub and community network, a total of 161 pts (Stop = 81, Continue = 80) were enrolled. The trial was closed early due to slow accrual (goal 578 pts). Median age was 71 and the most common tumor types were: NSCLC(39.8%), mismatch repair-deficient tumors(18.6), RCC(11.8%), HNSCC(8.1%), and melanoma (7.5%). There was no difference in baseline characteristics between arms. With a median follow up of 43.2 months (mo), cure rate was 45% (32%-63%)in the stop arm vs 38% (27-54%) in the continue IO arm (OR 2.26, 95% CI [0.62-8.22], p = 0.22). Median PFS was 55.4(27.5-NR) vs. 31.2 mo(20-NR) HR 0.77, 95% CI (0.48-1.24), p = 0.28 and median OS was NR (55.4 vs. NR) vs. 53.5 mo(40.8-NR) HR 0.54, 95%CI (0.3-0.99), p = 0.04 for the stop vs continue IO arms, respectively. In the continue IO arm, the median number of IO doses was 11 (range 0-36) and 52 of these pts discontinued IO with the most common reason being disease progression (42.3%), and 7.7% discontinued for toxicity. In the stop IO arm, 17 pts who progressed were retreated with IO; 20% achieved subsequent partial response and the median PFS was 10.5 mo(6.5-NR) and median OS was 26.7 mo(10.5-NR) after retreatment. **Conclusions:** Our trial is unique as a prospective randomized evaluation of length of IO treatment in advanced solid tumors. Cure rates and PFS were similar across arms and OS was improved in pts that discontinued IO at 1 year. These findings suggest that stopping IO at 1 year may be as effective as indefinite IO therapy, though validation in a larger, adequately powered trial is needed. Clinical trial information: NCT04157985. Research Sponsor: Hillman Cancer Center; Pennsylvania Department of Health; SAP # 410095621.

2515 Rapid Oral Abstract Session

Clinical and translational study of p38 inhibitor pexmetinib plus nivolumab following anti—PD-1/L1 failure in advanced solid tumors. First Author: Matthew Nguyen, University of Pittsburgh, Pittsburgh, PA

Background: Cancers resistant to immune checkpoint blockade typically harbor a non-T cell-inflamed phenotype, characterized by low type I/II interferon activity and limited $CD8^+$ T-cell infiltration within the tumor microenvironment. We previously identified p38 MAPK activation as a tumor-intrinsic immune exclusion mechanism associated with resistance to immunotherapy across solid tumors. Based on these preclinical observations, we conducted a Phase II clinical trial (NCT04074967) combining pexmetinib, a p38 inhibitor, with nivolumab in advanced solid tumors. Here, we report safety, clinical activity, and translational results in patients with PD-1 refractory head and neck (HN) cancer and lung cancers. **Methods:** Patients received pexmetinib 200 mg orally once daily plus nivolumab 480 mg intravenously every 4 weeks. The primary endpoint was overall response rate (ORR) assessed by RECIST v1.1. Translational analyses included pharmacodynamic assessment, plasma proteomics, single-cell RNA sequencing (scRNAseq), and computed tomography-based radiomic analyses. **Results:** Thirty-five patients were enrolled (HN cohort = 11 [31%; 100% squamous cell carcinoma]), lung cohort = 24 [69%; 63% adenocarcinoma]). Median age was 62 years; 60% were male and 89% had ECOG performance status 1. Twenty-nine patients were radiographically evaluable. Partial responses were observed in four patients (ORR 14%), and 13 patients (45%) experienced stable disease. Median duration of response was 11.1 months. Median progression-free survival (PFS) was 7.2 months and overall survival (OS) was 9.3 months. Treatment-related adverse events (TRAEs) of any grade occurred in 89% of patients; 47% experienced grade $\geq$3 TRAEs. No fatal TRAEs were reported. Plasma proteomic profiling identified on-treatment immune modulation relative to baseline, with increased T cell-associated cytokines/chemokines in patients with durable clinical benefit (PFS $>$ 6 months). Among three patients with paired pre- and on-treatment tumor scRNAseq, an increase in intratumoral T-cell abundance was observed in one patient with tumor shrinkage but not in two patients with progressive disease. On-treatment increases in T-cell radiomic score relative to baseline were significantly greater in responders vs. non-responders, and were associated with improved PFS and OS ($P<$ 0.05). **Conclusions:** In patients with PD1-refractory HN cancer and lung cancers, pexmetinib plus nivolumab demonstrated an acceptable safety profile and durable clinical benefit. Multimodal translational profiling revealed increased inflammatory cytokine signaling and radiomic and molecular features consistent with enhanced $CD8^+$ T-cell engagement in responders. These findings suggest that targeting tumor-intrinsic p38 MAPK may represent a mechanistically informed strategy to overcome immunotherapy resistance. Clinical trial information: NCT04074967. PRaG 5.0: Personalized thymosin alpha-1 and radioimmunotherapy for advanced refractory solid tumors—Data from an expanded cohort. First Author: Yuehong Kong, Center for Cancer Diagnosis and Treatment, The Second Affiliated Hospital of Soochow University, Suzhou, China

Background: Treatment-related lymphopenia and inadequate anti-tumor immune activation remains major barriers to improving outcomes of combination immunoradiotherapy, especially for advanced refractory solid tumors. PRaG 5.0 innovatively integrates personalized thymosin alpha-1 (Tα-1) into the PRaG regimen (PD-1 inhibitor + radiotherapy + GM-CSF) to preserve lymphocytes and enhance anti-tumor immunity. We report updated efficacy and safety data of PRaG 5.0 in advanced refractory solid tumors. **Methods:** This is a prospective, single-armed, phase II study enrolled 43 heavily pretreated patients. Eligible patients were stratified by baseline T-lymphocyte counts to receive personalized Tα-1 dosing: 7-day loading dose for low baseline T-lymphocyte counts, and maintenance Ta-1 (1.6 mg, thrice weekly) for those with normal counts. Tα-1 was combined with the PRaG regimen for at least 2 cycles. After PRaG cycles, patients continued PD-1 inhibitor plus Tα-1 until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included median progression-free survival (mPFS), disease control rate (DCR), safety, and immune cell dynamics (assessed by flow cytometry, single-cell sequencing, and TCR sequencing). **Results:** Among the 43 screened subjects, 39 received treatment, of whom 30 required loading dose thymosin α1 (Tα1) therapy, 36 were treated with PRaG regimen and 17 entered the maintenance phase with PD-1 inhibitor combined with Tα1. The objective response rate (ORR) of the 39 patients was 30.8% (95%CI 17.0%, 47.6%), including 4 cases of complete response (CR) and 8 cases of partial response (PR); the median progression-free survival (PFS) was 4.2 months (95%CI 2.3, 6.9). No Grade 3 or above TRAE was reported. Immune analysis revealed significant increases in CD8+ T cells, NK cells, and CD4+TEM cells post-Tα-1 loading, with a notable decrease in Tregs (p = 0.001). Single-cell sequencing demonstrated higher clonality in GZMK-CD8+T in responders, while TRDV2-CD8+T cells expanded in non-responders. **Conclusions:** Integrating of Tα-1 into the PRaG regimen is a promising therapeutic strategy, offering enhanced efficacy and a favorable safety profile. Detailed immune profiling identified distinct T-cell dynamics associated with treatment response, highlighting potential biomarkers for clinical application. Further validation in larger cohorts is warranted. Clinical trial information: NCT05790447. Research Sponsor: None.

2517 **Rapid Oral Abstract Session**

Evaluation of the combination of regorafenib + avelumab in patients with HPV-associated cancer: The phase II REGOMUNE study. First Author: Sophie Cousin, Early Phase Clinical Trials Unit and Thoracic Unit, Institut Bergonié, Bordeaux, France

Background: HPV-associated malignancies—including cervical, anal, head and neck, and penile cancers—form a biologically distinct group with limited responsiveness to immune checkpoint inhibitors (ICP) in monotherapy. Combining anti-angiogenic agents with immunotherapy may enhance efficacy by reshaping the tumor microenvironment. REGOMUNE explores this rationale by evaluating regorafenib plus avelumab association. **Methods:** REGOMUNE is a French multicenter, open-label, phase II trial assessing the combination of regorafenib (160 mg daily for 3 weeks of a 4-week cycle) and avelumab (10 mg/kg biweekly) in patients with advanced/metastatic HPV-driven solid tumors. The primary endpoint is the 6-month disease control rate (DCR) per RECIST 1.1 after central review. Secondary endpoints include overall response rate (ORR), progression-free survival (PFS), overall survival (OS), and safety. Correlative studies will analyze baseline tumor samples to identify biomarkers of response. An exact single stage design was used testing 10% vs 25% DCR (5% type 1 error rate and 80% power), requiring $\geq$ 8 patients with disease control at 6 months among 40 patients to demonstrate efficacy. **Results:** From March 2023 and to February 2024, 44 patients were enrolled across 6 centers. Median age was 62 (range :33-80). Median follow-up was 18.3 months (95% CI : 14.9-21.1). Median number of prior treatment lines was 2 (range :0-7). Anal (41%) and cervical (32%) cancers were the predominant primary sites, with squamous cell carcinoma representing 70.5% of cases. Among 33 evaluable patients for efficacy, the 6-month DCR was 45.5% (N = 15) [90% CI : 30.5-61.1], with 12 (36.4%) partial response, 11 (33.3%) stable disease, and 10 (30.3%) progressions. Median PFS was 5.3 months (95% CI: [3.0 – 7.3]). Median OS was 15.0 months (95% CI [7.2 – 21.6]). Treatment modifications due to adverse events occurred in 33/42 (78.6%) patients. Common grade 3/4 adverse events included palmar-plantar eryhtrodysesthesia syndrome (11.9%), diarrhea (9.5%) and fatigue (7.1%). One treatment-related death was reported. **Conclusions:** REGOMUNE is the first phase II trial to demonstrate a clinically meaningful efficacy signal surpassing historical CPI outcomes as monotherapy with an anti-angiogenic plus immune CPI combination in patients with HPV-positive tumors. Biomarker analyses are ongoing to identify predictive signatures associated with the durable responses observed in this cohort. Clinical trial information: NCT03475953. Research Sponsor: None.

2518 **Rapid Oral Abstract Session**

Phase 1 study of NTX1088, a first-in-class anti-PVR monoclonal antibody, as monotherapy and combined with pembrolizumab, in patients with advanced solid malignancies. First Author: Sarina A. Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Poliovirus Receptor (PVR; CD155), a transmembrane protein upregulated across multiple solid tumors and associated with poor clinical outcomes and resistance to immune checkpoint inhibitors (CPIs), plays a central role in tumor-mediated immune suppression. PVR suppresses anti-tumor immunity by interacting with the co-stimulatory receptor DNAM1 (CD226) on T and NK cells, leading to its internalization and degradation. PVR also engages the inhibitory immune receptors, TIGIT, CD96, and KIR2DL5A. NTX1088 is a first-in-class monoclonal antibody targeting PVR. **Methods:** NTX-1088-01 (NCT05378425) is a Phase 1a/1b, open-label, multicenter dose-escalation and expansion study evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics, recommended dose for expansion (RDE), and preliminary efficacy of NTX1088 alone and in combination with pembrolizumab in patients (pts) with advanced solid tumors known to express PVR (prescreening not required). NTX1088 was administered intravenously (IV) every 3 weeks (Q3W) in dose levels (DLs) from 12-1750 mg as monotherapy or from 160-1750 mg in combination with pembrolizumab 200 mg IV Q3W. Phase 1a employed a standard 3+3 dose-escalation design. Phase 1b comprises dose-expansion monotherapy and combination cohorts in gastric, bladder, lung, and other PVR-expressing solid tumors at the RDE. **Results:** As of January 2026, 81 pts were treated with NTX1088 (24 monotherapy; 57 combination). Median age was 61 years; median lines of prior therapy was 4 and prior CPI exposure was 70%. NTX1088 was well tolerated with no dose-limiting toxicity and 1750 mg was selected as the RDE in monotherapy and in combination with pembrolizumab, based on PK and target occupancy. Preliminary efficacy analysis was focused on active DLs of NTX1088 (1200 and 1750 mg) in combination with pembrolizumab. Forty-eight pts were treated at these DLs and 35 pts were evaluable for response. Of these 35 pts, median age was 57, median lines of prior therapy was 4 and 89% received prior CPI. Six (17%) pts achieved confirmed partial responses (PR) including gastric (2), bladder (1), non-small cell lung (1), squamous cell carcinoma of the head and neck (1), and melanoma (1). All PRs were seen in pts with prior CPI exposure. Sixteen (46%) pts achieved stable disease. At data cutoff, all but one PR pt remain on treatment, with a maximum treatment duration of 20 months. Exploratory analyses of tumor biopsies identified potential predictive biomarkers. **Conclusions:** NTX1088 demonstrated favorable tolerability and encouraging clinical activity in heavily pretreated pts who had progressed on prior PD-1/PD-L1 inhibitors. These findings support further evaluation of NTX1088 in Phase 2 studies, incorporating less heavily pre-treated pts and biomarker selection. Clinical trial information: NCT05378425. Research Sponsor: Nectin Therapeutics; Cancer Focus Fund; European Innovation Council.

KEYNOTE-B59: An open-label, multicenter, phase 1/2 study of efdelikofusp alfa (GI-101A; CD80-IgG4 Fc-IL2v2) in advanced solid tumors (part E & F of GII-101-P101). First Author: Jae Lyun Lee, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Efdelikofusp alfa is a novel immunocytokine consisting of CD80 fused to an engineered IL-2 variant (IL-2v2) optimized to reduce IL-2Rα affinity. It blocks CTLA-4–mediated immune suppression while preferentially activating and expanding immune effector cells over regulatory T cells. Here, we report results from the dose-escalation phases of Part E (monotherapy) and Part F (combination with pembrolizumab) of the ongoing KEYNOTE-B59 study. **Methods:** KEYNOTE-B59 is an open-label, phase 1/2 study evaluating efdelikofusp alfa alone or in combination with pembrolizumab in patients (pts) with advanced solid tumors. In Part E, escalating doses of efdelikofusp alfa (0.05–0.3 mg/kg) were administered intravenously every 3 weeks (Q3W). In Part F, pts received efdelikofusp alfa (0.05–0.3 mg/kg) plus pembrolizumab (200 mg) Q3W. Primary objectives were to assess safety, tolerability, and to determine maximum tolerated dose (MTD) and/or recommended phase 2 dose. **Results:** As of 29 December 2025, a total of 84 pts who had progressed on available therapies were enrolled, including 36 pts in Part E and 48 pts in Part F. In Part E, one dose-limiting toxicity (DLT) occurred at 0.1 mg/kg (grade 3 hypertension). However, MTD was not reached up to 0.3 mg/kg, and efdelikofusp alfa was generally well tolerated. At the biologically effective dose range (0.2–0.3 mg/kg), monotherapy demonstrated clinical activity in immunotherapy (IO)-experienced bladder cancer (confirmed CR; DoR 5.8 months; PFS 13.9 months) and mesothelioma (confirmed PR; DoR 5.6 months; PFS 6.7 months). In Part F, 48 pts were treated with efdelikofusp alfa in combination with pembrolizumab. Median age was 63 years and 45.8% of pts had received prior IO. The overall safety profile of the combination was comparable to monotherapy, with common treatment-related adverse events including pyrexia (89.6%), liver enzyme elevation (47.9%), chills (37.5%), and decreased platelet count (33.3%). Objective responses were observed across multiple tumor types, including ccRCC, urothelial cancer, squamous NSCLC, cutaneous squamous cell carcinoma, pancreatic adenocarcinoma, and cervical cancer, irrespective of prior IO exposure. In pts with ccRCC (n = 10), the most frequently enrolled indication (70.0% prior IO-treated), the objective response rate was 40.0% and the disease control rate was 70.0%, with durable responses observed from 5.5+ to 16.7+ months; median DoR was not reached. Efdelikofusp alfa induced robust peripheral lymphocyte expansion, mainly $CD8^+$ T and NK cells, which correlated with longer median PFS. **Conclusions:** Efdelikofusp alfa was well tolerated as a monotherapy and in combination with pembrolizumab. Antitumor activity was observed with a favorable benefit–risk profile, supporting continued development in selected tumors, including ccRCC. Clinical trial information: NCT04977453. Research Sponsor: GI Innovation, Inc.; Korea Drug Development Fund; HN22C0451.

2521 **Poster Session**

CS2009, a novel PD-1/VEGF/CTLA-4 trispecific antibody, in patients with advanced solid tumors: Updated results from an open-label, multicenter, phase 1 first-in-human study. First Author: Charlotte Rose Lemech, Medical Oncology, Scientia Clinical Research and Prince of Wales Clinical School, UNSW Sydney, Randwick, NSW, Australia

Background: CS2009 is a first-in-class trispecific antibody targeting PD-1, VEGF and CTLA-4. Initial data from this phase 1 study showed a favorable safety profile and encouraging antitumor activity. Here, we report updated safety and efficacy results in 98 patients. **Methods:** This ongoing, open-label, multicenter, phase 1 dose-escalation trial enrolled patients with advanced solid tumors who progressed on standard therapy or had no available standard therapy. CS2009 was administered intravenously every 3 weeks at 6 dose levels ranging from 1 to 45 mg/kg. Dose escalation followed an accelerated titration design at the first dose level and a 3+3 design thereafter. In parallel, additional patients were backfilled to selected dose levels deemed safe to further evaluate safety and efficacy. Primary objectives include safety, tolerability and determination of the maximum tolerated dose (MTD)/tentative recommended phase 2 dose (RP2D). Secondary and exploratory objectives include pharmacokinetic/pharmacodynamic profile and preliminary efficacy per RECIST v1.1, etc. **Results:** As of January 4, 2026, 98 patients (55.1% male; median age 61 [range 19-80] years; 54.1% Asian, 43.9% White) had received CS2009 across 6 dose levels, with half (49/98) remaining on study treatment. Tumor types included non-small cell lung cancer (NSCLC, n = 49), ovarian cancer (n = 12), soft tissue sarcoma (n = 9), renal cell carcinoma (RCC, n = 6), triple-negative breast cancer (TNBC, n = 6), colorectal cancer (n = 4), and others. Most (98.0%) patients received at least one prior line of systemic anti-cancer therapy. No dose-limiting toxicities (DLTs) occurred; MTD was not reached. The incidences of any-grade and grade ≥3 treatment-related adverse events (TRAEs) were 69.4% and 20.4%, respectively. The most common (≥10%) TRAEs were pruritus (n = 14, 14.3%), alanine aminotransferase increased (n = 11, 11.2%) and aspartate aminotransferase increased (n = 10, 10.2%). Five (5.1%) patients discontinued treatment due to TRAEs. There were no treatment-related deaths. Encouraging antitumor activity was observed across multiple tumor types that have received heavy prior treatment including PD-1/PD-L1 inhibitors or antiangiogenesis therapies where appropriate, including NSCLC without known actionable oncogenic alterations (n = 27), soft tissue sarcoma (n = 9), non-clear cell RCC (n = 5), and TNBC (n = 6) with ORR of 18.5%, 33.3%, 20.0%, 16.7%, respectively, and DCR of 74.1%, 66.7%, 100.0%, 50.0%, respectively (detailed and updated data to be presented at the conference). **Conclusions:** CS2009 demonstrated a manageable safety profile and promising antitumor activity in heavily pretreated patients with advanced solid tumors, which warrants further clinical development in an ongoing phase 2 study in nine tumor types. Clinical trial information: NCT06741644. Research Sponsor: CStone Pharmaceuticals.

2522 **Poster Session**

Pemivibart for prevention of COVID-19: Subset analysis of CANOPY participants with solid tumor or hematologic malignancies. First Author: Meredith Leston, Invivyd, Inc., New Haven, CT

Background: Due to the chronic immunosuppression associated with both their condition and treatments, patients with solid tumors or hematologic malignancies experience reduced vaccine protection and are at high risk of infections, including COVID-19. This post hoc analysis of the phase 3 CANOPY study assesses the safety and outcomes of pemivibart in the oncology subset from the open-label, single-arm, immunocompromised Cohort A. **Methods:** Cohort A dosing: 4500 mg of pemivibart (intravenous) on day 1; 2nd dose at month 3. Primary objectives: 1) Evaluation of pemivibart safety and tolerability via study drug-related treatment emergent adverse events (TEAEs), serious adverse events (SAEs), and treatment interruption/discontinuation, 2) Evaluation of protection against symptomatic COVID-19 based on sVNA titers against SARS-CoV-2 after receiving pemivibart. Exploratory endpoint: composite incidence of RT-PCR-confirmed symptomatic COVID-19, including COVID-19-related hospitalization and all-cause mortality. Data were analyzed through Month 6. **Results:** Enrollment began in Sep 2023. The oncology subset included 55 (18.0%) Cohort A participants; median age [range] 65 [35-83] years; 25 (45.5%) female. Eight participants (14.5%) were receiving immunosuppressants, including 6 (10.9%) receiving corticosteroids. Prior to enrollment, 89.1% received ≥1 COVID-19 vaccine; seropositivity: N antigens (43.6%), S antigens (98.2%). Month 6 TEAEs were reported in 32 (58.2%) participants; 5 (9.1%) were considered study drug-related with 1 (1.8%) requiring treatment interruption due to infusion site extravasation and tachycardia (Table). SAEs occurred in 5 (9.1%) participants; none were considered drug-related. Following pemivibart dosing, sVNA titers in the oncology subset were elevated to levels associated with protection against COVID-19 and comparable with Cohort A. No anaphylaxis was reported in the oncology subset; 4 cases among 306 participants in Cohort A. Through Month 6, there was no RT-PCR-confirmed symptomatic COVID-19 in the oncology subset; with 9/298 (3.0%) in Cohort A. **Conclusions:** Pemivibart was well tolerated in the CANOPY Cohort A oncology subset. These data showed limited events overall and no development of symptomatic COVID-19 in the oncology subset through Month 6. Clinical trial information: NCT06039449. Research Sponsor: Invivyd, Inc.

Select outcomes through month 6.

Parameter	Immunocompromised Cohort A	Cohort A Oncology Subset[a]

A phase 1 study of BGB-A3055 (anti-CCR8) with or without tislelizumab (anti−PD-1) in patients with solid tumors. First Author: Judith Raimbourg, Institut de Cancerologie de l'Ouest, Saint-Herblain, France

Background: BGB-A3055 is a humanized monoclonal antibody targeting C-C motif chemokine receptor 8 (CCR8), a receptor highly expressed on intratumoral regulatory T cells (Tregs). CCR8 overexpression correlates with poor prognosis in certain tumor types. Preclinical studies have shown potent antitumor activity of BGB-A3055. Here, we present results from a phase 1a dose-escalation trial of BGB-A3055 alone (Part A [A]) or combined with tislelizumab (TIS; Part B [B]) in patients (pts) with advanced or metastatic solid tumors (NCT05935098). **Methods:** Eligible pts had histologically confirmed advanced or metastatic solid tumors with high prevalence of CCR8 expression. In A, pts received BGB-A3055 (six dose levels) intravenously (IV) every 3 weeks (Q3W). In B, pts received BGB-A3055 (six dose levels) and TIS 200 mg IV Q3W. Primary endpoint was safety; secondary endpoints included preliminary antitumor activity (RECIST v1.1). **Results:** As of Nov 19, 2025, 98 pts were treated with BGB-A3055 ± TIS (A: n=42; B: n=56). Median (range) study follow-up was 3.94 (0.9-19.0) months in A and 4.67 (0.5-16.8) months in B. Treatment-emergent adverse events (TEAEs) are provided in the Table. The most common BGB-A3055-related TEAEs were neutrophil count decreased (23.8%) in A and pyrexia (23.2%) in B. The most common serious TEAE was immune-mediated enterocolitis (A: 4.8%; B: 7.1%). The most common immune-mediated adverse events (imAEs) were rash, rash maculo-papular, and hypothyroidism in A (7.1% each) and rash maculo-papular in B (17.9%). Dose-limiting toxicities occurred in 1 pt in A (immune-mediated hepatitis) and 3 pts in B (colitis, nephrotic syndrome, and rash maculo-papular in a single pt each). No treatment-related TEAEs leading to death were reported. Maximum tolerated dose was not reached. Unconfirmed objective response rate was 7.5% (95% confidence interval [CI]: 1.6-20.4; 3 partial responses [PRs]) in A and 18.2% (95% CI: 9.1-30.9; 1 complete response and 9 PRs) in B. Disease control rate was 35.0% (95% CI: 20.6-51.7) in A and 56.4% (95% CI: 42.3-69.7) in B. Among the 13 responders, 6 received prior immunotherapies. Robust Treg reduction was observed in peripheral blood and tumor tissue post-treatment, indicating potent on-target pharmacodynamic activity of BGB-A3055. **Conclusions:** BGB-A3055 ± TIS demonstrated a safety profile consistent with selective CCR8 on-target effects in pts with advanced solid tumors and had preliminary antitumor activity. Clinical trial information: NCT05935098. Research Sponsor: BeOne Medicines Ltd.

Phase 1b dose-expansion study of IMC-002, a anti-CD47 monoclonal antibody, in patients with advanced triple negative breast cancer (TNBC). First Author: Ji Hyung Hong, Center for Breast Cancer, National Cancer Center, Goyang, South Korea

Background: IMC-002 is a novel therapeutic agent with a distinct mechanism of action. In a phase 1a dose-escalation study, IMC-002 demonstrated favorable safety and tolerability, and clinical activity was observed in patients with hepatocellular carcinoma (HCC) in a subsequent phase 1b trial. Here, we present results from the phase 1b expansion cohort in patients with triple-negative breast cancer (TNBC), focusing on safety, efficacy, and analyses of soluble biomarkers. **Methods:** Eligible pts had advanced TNBC with progression after ≥1 prior systemic therapy and ECOG PS ≤1. IMC-002 (20 mg/kg Q3W) was administered in combination with gemcitabine plus carboplatin or paclitaxel and continued until disease progression. Tumor response was assessed every 6 weeks per RECIST 1.1 and iRECIST. Baseline ctDNA was analyzed using the AlphaLiquid 1000 platform (1,023 -gene panel). To exclude germline and clonal hematopoiesis of indeterminate potential (CHIP) variants, paired PBMC sequencing was performed. The assay detected single nucleotide variants (SNVs), small insertions and deletions (INDELs), fusions, copy number alterations (CNAs), microsatellite instability (MSI), and blood-based tumor mutational burden (bTMB). **Results:** A total of 12 pts with advanced TNBC received IMC-002 in combination with gemcitabine plus carboplatin (n=9) or paclitaxel (n=3). Most pts had received ≥2 prior systemic therapy (n=11), and ECOG PS 1 was observed in 10 pts. TRAEs reported in > 1 pt included grade 3 hematologic events, namely anemia (n=6) and hemolytic anemia (n=5). Non-hematologic TRAEs were limited to grade 1–2 and included skin rash (n=9), vitreous floaters (n=4), photopsia (n=3), and IRR (n=2). Among 12 efficacy-evaluable pts, the ORR was 25%, the DCR was 75%, and the CBR (disease control ≥ 6 months) was 42%. Exploratory ctDNA analyses identified no MSI-H tumors. One patient with a partial response was BRCA-positive. Patients achieving clinical benefit showed a higher median maximum somatic allele frequency (MSAF) than those without clinical benefit (32.65 vs 1.00; p=0.19). No clear association between bTMB and clinical activity was observed. **Conclusions:** IMC-002 in combination with gemcitabine plus carboplatin or paclitaxel demonstrated encouraging antitumor activity with a manageable safety profile in heavily pretreated patients with advanced TNBC. Exploratory baseline ctDNA analyses did not identify molecular features clearly associated with clinical benefit. Clinical trial information: NCT05276310. Research Sponsor: ImmuneOncia Therapeutics Inc.

2525 **Poster Session**

Phase I trial of the anti-CAPRIN1 antibody TRK-950 alone or with nivolumab in Japanese patients with advanced solid tumors. First Author: Takafumi Koyama, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan

Background: CAPRIN-1 is expressed on the tumor-cell membrane across many solid cancers but not on normal cells. TRK-950 is a first-in-class humanized IgG1 that mediates antibody-dependent cellular phagocytosis and cytotoxicity. A series of preclinical studies demonstrates its potency and safety. In the phase I study of TRK-950 monotherapy (NCT02990481) in US and France, it appears safe and well tolerated. No DLT was observed and MTD was not reached at doses of 3-30mg/kg IV weekly. Here, we evaluated safety/tolerability, pharmacokinetics (PK), and preliminary antitumor activity in Japanese patients with advanced solid tumors. **Methods:** Open-label, single-center, dose-escalation study in Japan (NCT05423262). Part 1 evaluated TRK-950 at 5 or 10 mg/kg IV weekly in patients with locally advanced or metastatic solid tumors. Part 2 evaluated TRK-950 at 10 mg/kg weekly or 20 mg/kg every 2 weeks in combination with nivolumab 240 mg every 2 weeks in patients with locally advanced or metastatic solid tumors who were eligible for standard nivolumab monotherapy. Primary endpoints were safety/tolerability (DLT; Treatment-related AEs per CTCAE v5.0). Secondary endpoints included PK, immunogenicity, and antitumor activity by RECIST v1.1. **Results:** Thirteen patients were treated (Part 1 n=7; Part 2 n=6). No DLTs occurred and the MTD was not reached; both monotherapy and combination regimens were well tolerated. TRK-950 PK was consistent with IgG1; exposures were comparable between 10 mg/kg weekly and 20 mg/kg every 2 weeks, with no meaningful PK interaction with nivolumab. In Part 1, a partial response was achieved in a patient with melanoma achieved a partial response, and the response was sustained for an extended period. In Part 2, no response were observed. **Conclusions:** TRK-950, as monotherapy and with nivolumab, was safe and tolerable in Japanese patients with advanced solid tumors. Durable antitumor activity with monotherapy supports continued development. Both the 10 mg/kg weekly and the more convenient 20 mg/kg biweekly dosing regimens of TRK-950 in combination with nivolumab were safely administered, supporting the potential for further development of this combination. Clinical trial information: NCT0542326. Research Sponsor: Toray Industries, Inc.

2526 **Poster Session**

Safety, pharmacokinetics, and immunogenicity of HLX6018, a monoclonal antibody targeting the GARP/TGF-β1 complex, in healthy subjects: A randomized, double-blind, placebo-controlled, phase I clinical study. First Author: Yanhua Ding, The First Hospital of Jilin University, Jilin, China

Background: HLX6018 is a novel anti-GARP/TGF-β1 monoclonal antibody that inhibits TGF-β1 release and suppresses the activation, proliferation, and extracellular matrix secretion of fibroblasts. Preclinical studies have shown its efficacy in improving pulmonary fibrosis with a manageable safety profile. A phase 1 first-in-human study was conducted to evaluate the safety and tolerability of single-dose HLX6018 in healthy Chinese subjects. **Methods:** In this dose escalation phase 1 study, healthy subjects of age 18 to 55 were randomized to receive intravenous, single dose of either HLX6018 or placebo at 0.25 mg/kg, 1.0 mg/kg, 4.0 mg/kg, 12 mg/kg, 25 mg/kg, 50 mg/kg, and 70 mg/kg. A sentinel dosing approach was adopted: each dose group initially enrolled 2 subjects, with 1 receiving HLX6018 and the other receiving placebo in a blinded manner. These 2 subjects then entered a safety observation period after the infusion before the enrolment of remaining subjects for that dose group. The primary endpoint was safety. Secondary endpoints included pharmacokinetics (PK) and immunogenicity. **Results:** A total of 180 subjects were screened and 66 were randomized. 52 subjects received HLX6018 (0.25 mg/kg, 6; 1.0 mg/kg, 6; 4.0 mg/kg, 8; 12 mg/kg, 8; 25 mg/kg, 8; 50 mg/kg, 8; 70 mg/kg, 8) while 14 received placebo (2 subjects in each dose group). The median age was 42.0; 93.9% of the subjects were of Han ethnicity, 50.0% were male. Overall, 46 subjects (69.7%) experienced treatment-emergent adverse events (TEAEs), with 1 subject (1.5%) receiving HLX6018 at 25 mg/kg reporting a serious TEAE of osteonecrosis that was unrelated to HLX6018. 39 subjects (59.1%) experienced treatment-related adverse events (TRAEs). Most common TRAEs (≥ 10% in any dose group) included neutrophil count decreased (HLX6018 vs placebo group: 11.5% vs. 21.4%), injection site pain (11.5% vs. 21.4%), blood corticotrophin decreased (9.6% vs. 14.3%), blood triglycerides increased (9.6% vs. 14.3%) and blood follicle stimulating hormone increased (5.8% vs. 14.3%). There were no TEAEs leading to death, TRAEs leading to drug discontinuation, TRAEs of grade 3 or more in severity, or serious TRAEs. The incidence of TEAEs and TRAEs across the HLX6018 dose groups showed no clear dose-related pattern and was comparable to the placebo group. HLX6018 exhibited approximately linear PK characteristics after single intravenous infusion with the dose range of 0.25–70 mg/kg. Anti-drug antibody was detected in 3 subjects (5.8%) who received HLX6018; no neutralizing antibody was detected. **Conclusions:** HLX6018 is safe and well tolerated across the investigated doses. Further clinical investigation of its efficacy is warranted. Clinical trial information: NCT06310746. Research Sponsor: Shanghai Henlius Biotech, Inc.

2527 **Poster Session**

Safety and efficacy of a novel PD-L1/4-1BB bispecific antibody QLF31907 in previously-treated patients with advanced melanoma: Results from a phase 2 study. First Author: Jun Guo, Department of Melanoma and Sarcoma, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China

Background: QLF31907, a bispecific antibody that simultaneously block PD-1/L1 immunosuppressive pathway on cancer cells and conditionally activate 4-1BB co-stimulatory pathway on tumor-specific T cells, was designed to restrict 4-1BB agonism to the tumor microenvironment, which might overcome resistance to PD-(L)1 inhibitor and reduce hepatoxicity as traditional 4-1BB monoclonal antibodies reported. Although immunotherapy (IO) has revolutionized the treatment of melanoma, a significant proportion of patients (pts), particularly those with mucosal and acral subtypes, either fail to respond initially or experience disease relapse after treatment. Here, we present results of QLF31907 in previously-treated pts with advanced melanoma, including IO-exposed. **Methods:** This phase 2 trial was comprised of safety observation stage and efficacy expansion stage. Pts with unresectable locally advanced or metastatic melanoma who failed, were intolerable to, or refused standard treatment were recruited and administered QLF31907 via intravenous infusion from 5 mg/kg to 20 mg/kg every 2 weeks (Q2W) or 3 weeks (Q3W). The primary endpoints were dose-limiting toxicity (DLT) and safety in safety observation stage, and was objective response rate (ORR) per RECIST v1.1 assessed by investigator in efficacy expansion stage. **Results:** As of Dec 31, 2025, 59 pts were enrolled (median age: 57.0 years; male: 47.5%; ECOG PS of 1: 42.4%; stage IV: 93.2%). The mucosal subtype accounted for the most (40.7%), followed by acral (33.9%), cutaneous (non-acral; 18.6%) and primary unknown (6.8%). Median prior lines of therapies were 2.0 (range, 1–5). Fifty-five (93.2%) pts received prior immunotherapy, including 50 (87.7%) pts received prior anti-PD-1/PD-L1 agents. No DLT occurred. Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 34 (57.6%) pts. The most common grade ≥3 TEAEs (≥10%) were liver injury (18.6%), neutrophil count decreased (15.3%), anemia (13.6%), white blood cell count decreased (11.9%). In 57 efficacy-evaluable pts, seven had partial response. The ORR and disease control rate (DCR) was 12.3% (95% confidence interval [CI], 5.1%-23.7%) and 56.1% (95% CI, 42.4%-69.3%), respectively. The median progression-free survival, duration of response, and overall survival was 2.6 months (95% CI, 1.6-3.7), 5.8 months (95% CI, 2.3-not evaluable [NE]), and 15.3 months (95% CI, 11.6-NE), respectively. **Conclusions:** QLF31907 showed potential anti-tumor activity and acceptable safety profile in heavily-treated pts with advanced melanoma, including IO-exposed pts. These results warrant validation in further clinical trials. Clinical trial information: NCT05823246. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Preliminary results of safety and antitumor activity from a first-in-human phase 1 study of AWT020, a bifunctional anti–PD-1/IL-2 fusion protein, in patients with advanced tumors. First Author: Jermaine Ian George Coward, ICON Cancer Care, South Brisbane, QLD, Australia

Background: Immune checkpoint inhibitors have transformed treatment landscape across multiple cancer types, however, resistance to anti-PD-(L)1 therapies remains a significant unmet medical need. AWT020 is a bifunctional fusion protein comprised of an anti-PD-1 antibody and a potency optimized IL-2. In preclinical studies, the mouse surrogate of AWT020 demonstrated superior antitumor activity compared to anti-mPD-1 alone or in combination with IL-2. These findings suggest that AWT020 monotherapy may benefit patients resistant to anti-PD-1 therapies. **Methods:** This first-in-human Phase 1 dose escalation study evaluates AWT020 monotherapy in adults with advanced or metastatic cancers who failed or were intolerant to standard therapies. The dose-escalation utilizes a Bayesian Optimal Interval design. Key endpoints include safety, maximum tolerated dose (MTD)/recommended phase 2 dose (RP2D), pharmacokinetics (PK), pharmacodynamics, immunogenicity, and antitumor responses. Initial dose escalation results are presented herein. Clinical trial information: NCT06092580. **Results:** As of January 14, 2026, 41 patients received AWT020 at doses of 0.3, 0.6, and 1 mg/kg, including single-step (0.1 or 0.3 mg/kg) and two-step (0.1→0.3 mg/kg) priming regimens. Preliminary PK analysis showed approximately dose-proportional exposure. The majority of treatment-related adverse events (TRAEs) were low grade. The most frequently reported TRAEs were arthralgia (59%), rash (34%), fatigue (32%), and nausea (32%). Grade ≥3 TRAEs occurring in more than one subject included arthralgia (n=4), colitis (n=2), and thrombocytopenia (n=2). No patient experienced vascular leak syndrome. Among the 27 RECIST-evaluable patients, the overall response rate was 30%, and the disease control rate was 67%. Of the eight responders, five partial responders (thymic carcinoma, thymoma, clear cell renal cell carcinoma, neuroendocrine non-small cell lung cancer, and cholangiocarcinoma) had developed secondary resistance to anti-PD-(L)1 therapies. The remaining three responders were anti-PD-(L)1-naïve, including a cervical cancer patient who experienced confirmed complete response, and two partial responders with proficient mismatch repair (pMMR) tumors (adrenocortical carcinoma and uterine sarcoma). Ten additional patients with diverse cancer types achieved stable diseases, with tumor shrinkage observed in half of the patients, further supporting preliminary antitumor activity across broad tumor types. **Conclusions:** AWT020 demonstrates a manageable safety profile and promising early antitumor activity, including in patients with acquired resistance to anti-PD-(L)1 therapies and in patients with pMMR tumors which typically are unresponsive to immune monotherapy. Dose escalation is ongoing to establish MTD/RP2D. Clinical trial information: NCT06092580. Research Sponsor: Anwita Biosciences Inc.

A phase II study of perioperative cadonilimab (AK104) in patients with recurrent resectable head and neck squamous cell carcinoma. First Author: Lei Liu, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Salvage surgery is standard of care for patients with recurrent, resectable head and neck squamous cell carcinoma (HNSCC); However, the efficacy of salvage surgery remains limited. Therefore, there is an urgent need to explore new therapeutic strategies to further improve the survival of this patient subset. Cadonilimab, a PD-1/CTLA-4 bispecific antibody, uses an IgG-ScFv structure with Fc domain point mutations, allowing for high retention in tumor tissue, and providing enhanced stability and improved safety. In this study, we aim to explore the efficacy and safety of neoadjuvant and adjuvant Cadonilimab combined with salvage surgery in patients with recurrent, resectable HNSCC. **Methods:** This was an open-label, single-institutional phase II clinical trial (ChiCTR2400079741). Patients aged 18-75 years, pathologically confirmed recurrent HNSCC (oral, laryngeal, hypopharyngeal, and oropharyngeal carcinoma), and with resectable diseases assessed by surgeons were included. Eligible patients received two cycles of Cadonilimab (6mg/kg, ivgtt, q2w) 2-4 weeks before surgery, then treated by salvage surgery, followed by 12 cycles of adjuvant Cadonilimab. Primary endpoint was 1-year disease free survival (DFS), and secondary endpoints were objective response rate (ORR), major pathological response (MPR), OS and safety. **Results:** From November 2023 to December 2024, a total of 32 patients were enrolled. One patient refused surgery, and 31 patients were included in the final analysis. According to radiological assessment, the ORR was 28.1% (9/32), with 2 cases of complete response (CR) and 7 cases of partial response (PR). Among the patients receiving surgical resection, the MPR rate was 32.3% (10/31), with 9.7% (3/31) of patients achieving pathological CR. With a median follow-up of 18.8 months (range, 13.0-25.7 months), the 1-year DFS rate was 77.4%, and the 1-year OS rate was 87.1%. Treatment-related adverse events (TRAEs) occurred in 74.2% (23/31) of patients. The majority of TRAEs were grade 1 or 2. Grade $\geq$3 TRAEs occurred in 6.5% (2/31) of patients, including one case of grade 3 neutropenia and one case of grade 4 immune-related hepatitis. The most common TRAEs were hypothyroidism (25.8%, n=8), anemia (25.8%, n=8), lymphocytopenia (19.4%, n=6), fatigue (16.1%, n=5), myocarditis (12.9%, n=4), constipation (12.9%, n=4), rash (12.9%, n=4), elevated ALT/AST levels (12.9%, n=4), and neutropenia (6.5%, n=2). **Conclusions:** Cadonilimab demonstrated encouraging anti-tumor activity and acceptable safety profile in patients with recurrent, resectable HNSCC. Cadonilimab may change the therapeutic approach for recurrent, resectable HNSCC. Clinical trial information: ChiCTR2400079741. Research Sponsor: None.

Anti-tumor activity of Man 9 x PS targeting immunotherapies in diffuse intrinsic pontine glioma (DIPG) and pancreatic cancers. First Author: Shabnam Samimi, Vitruviae, Nutley, NJ

Background: Aberrant cell-surface glycans and lipids are attractive immunotherapy targets due to their stable tumor expression. High-mannose glycan mannose-9 (Man9), and phosphatidylserine (PS) are co-expressed across multiple malignancies and contribute to immune suppression. We developed Man9×PS-targeting effector immunotherapy platforms for the treatment of solid tumors, with a focus on pancreatic cancer and diffuse intrinsic pontine glioma (DIPG). **Methods:** The Man9×PS×CD3 trispecific T cell engager (TCE), VTRU200, was expressed and purified from CHO cells. The Man9×PS CAR T cell, VCAR300, was generated from murine splenic T cells transduced with a Man9×PS CAR-encoding viral vector. In vitro tumor cytotoxicity of VTRU200 was assessed using human T cells co-cultured with cell lines (PANC-1, AsPC-1) or patient-derived primary cultures (DIPG-008, DIPG-011) and compared with bispecific Man9×CD3 or PS×CD3 controls. Tumor selectivity and potential off-target binding were evaluated by immunohistochemistry (IHC) on pancreatic and breast tumors with matched normal tissues, and by immunofluorescence (IF) across a panel of 33 normal human tissues. *In vivo* dose escalation of VCAR300 was evaluated by bioluminescence imaging in a Panc02 murine orthotopic pancreatic tumor model. Cancer stem cell binding was verified by co-staining with anti-CD133 antibody. Previously, VTRU200 was evaluated in syngeneic, xenograft, and patient-derived xenograft (PDX) acute myeloid leukemia (AML) models, and VCAR300 persistence was tested in a pilot orthotopic pancreatic cancer model. **Results:** VTRU200 demonstrated potent, target-dependent cytotoxicity with 0.1-5 nM EC50 values across multiple solid tumor cell lines in the presence of human T cells. Cytotoxicity required engagement of both Man9 and PS, with additive effects relative to bispecific controls. IHC demonstrated strong staining in pancreatic and breast tumors with absence of staining in corresponding paired normal tissues, while there was no detectable reactivity across normal human tissue panels by IF. Consistent with prior AML studies showing robust anti-leukemic activity, VCAR300 exhibited high anti-tumor activity in vitro with an effector:target ratio at 50% maximum killing (ET50) of less than 1, and in a murine orthotopic pancreatic cancer model (25-fold reduction in tumor size after 2 weeks of treatment with $2x10^6$ CAR T/mouse) with an excellent safety profile. Anti-tumor activity was associated with tumor stem cell targeting and release of inflammatory cytokines. **Conclusions:** Man9 x PS dual targeting is a promising strategy for treating solid tumors. VTRU200 and VCAR300 are potential therapeutic candidates with potent anti-tumor activity across multiple tumor types and impressive safety. Following a successful pre-IND interaction with the FDA, first-in-human studies are planned to initiate in 2027. Research Sponsor: None.

Multiomic machine learning integration of DNA and RNA features to predict immunotherapy benefit in MSS-CRC and other rare cancers. First Author: Michelle Ting-Lin, Tempus AI, Inc., Chicago, IL

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the oncology landscape, yet remain constrained by imprecise predictive biomarkers (i.e., PD-L1, TMB, MSI), which fail to capture the complexity of the tumor microenvironment. The Immune Profile Score (IPS), an AI/machine learning (ML) driven DNA-/RNA-based molecular signature addresses this gap in translational molecular biomarkers of ICI response. IPS integrates TMB, single-gene RNA features and RNA signatures, and was independently validated for prognostic utility in $>$ 1,500 advanced solid tumor patients (pts) treated with FDA-approved ICI. Here we evaluated the ability of IPS to accurately stratify ICI treatment outcomes in two independent cohorts representing traditionally ICI-resistant populations. **Methods:** From our multimodal real-world database, we used the ML-derived IPS algorithm to analyze two cohorts of high unmet need for which ICI is not approved: 1) microsatellite stable colorectal cancer (MSS CRC); and 2) rare solid cancer as defined by FDA ($<$ 200,000 cases/year) treated with off-label ICI. Pts were categorized as IPS-H and IPS-L using a previously independently validated and published threshold. Cox proportional hazards models were fit to demonstrate prognostic utility for real-world overall survival (rwOS). Association with time-to-next-treatment (TTNT) on prior chemotherapy (CT) was compared in the same pts to rwOS on subsequent ICI therapy to assess ICI-specific predictive value of IPS . **Results:** IPS-H consistently identified a subset of pts with improved clinical outcomes across both cohorts. In the MSS-CRC cohort (n = 46): IPS-H pts (6/46 = 13%) had longer rwOS than IPS-L pts (40/46 = 87%) (HR 0.22; 90% CI: 0.04-1.16). No difference was observed in TTNT between IPS-H and IPS-L for prior CT (HR 1.07; 90% CI: 0.60-1.91), while there was improvement in rwOS IPS-H vs IPS-L on subsequent ICI therapy (HR 0.21; 90% CI: 0.04-1.22). In the rare cancer cohort (n = 90): there were 26 solid tumor subtypes without an FDA-approved ICI label; carcinosarcoma (n = 19, 21%) and pancreatic ductal adenocarcinoma (n = 17, 19%) were the most commonly represented. IPS-H pts (16/90 = 18%) had longer rwOS than IPS-L pts (HR 0.26, 95% CI: 0.09-0.73). In this rare cancer cohort, IPS remained significant even when restricted to subtypes with representation from both IPS-H and IPS-L (HR = 0.18, 95% CI: 0.04-0.69). **Conclusions:** IPS is a novel multiomic genomic signature that identifies a subset of advanced MSS-CRC and rare solid cancer patients who may benefit from ICI therapy. By integrating multimodal genomic features, IPS emerged as a possible predictive biomarker in a population where ICI is not currently approved. IPS suggests a paradigm shift toward AI/ML-driven signatures to refine ICI candidate selection and personalize clinical decision-making in oncology. Research Sponsor: None.

AI-powered spatial tumor microenvironment analysis in metastatic microsatellite-stable colorectal cancer receiving immunotherapy. First Author: Sojin Kim, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Microsatellite-stable (MSS) colorectal cancer (CRC) is typically immune-cold, limiting the routine use of immune checkpoint inhibitors (ICIs). However, a subset of MSS CRC patients may still derive benefit from ICIs. Leveraging an AI-powered whole-slide image (WSI) analyzer applied to hematoxylin and eosin (H&E)–stained slides, we sought to identify subsets of MSS CRC more likely to benefit from ICIs. **Methods:** Between August 2016 and May 2024, pretreatment H&E–stained WSIs were collected from patients with metastatic MSS CRC treated at Asan Medical Center, Seoul, Korea. After quality control, 91 WSIs (93.8%) from 51 patients were included in the final analysis. Patients were treated with anti-PD-1/PD-L1 ICIs in clinical trials, with the majority treated in the third-line setting (n = 46, 90.2%). An AI-powered WSI analyzer (Lunit SCOPE IO, Lunit, Seoul, Korea) segmented cancer area (CA) and stromal area and identified tumor-infiltrating lymphocytes (TILs), tertiary lymphoid structures (TLS), fibroblasts, and endothelial cells within tumor tissue. We then evaluated the associations between CA-specific densities of TILs, macrophages, and endothelial cells, as well as the summed TLS area, and progression-free survival (PFS) and overall survival (OS). **Results:** Using maximally selected rank statistics based on PFS, patients were dichotomized into high and low groups according to the summed TLS area and the densities of TILs, macrophages, endothelial cells, and fibroblasts within the CA. Notably, patients with a high summed TLS area had significantly improved PFS and OS compared with those with a low TLS area (median PFS, 3.6 vs. 1.6 months; P=0.026; median OS, 11.6 vs. 6.6 months; P=0.024). High endothelial cell and fibroblast densities within the CA were not significantly associated with PFS (P=0.160, P=0.112, respectively), but were associated with worse OS, with a significant association for endothelial cells (median, 7.6 vs. 14.7 months; P=0.024) and a trend toward worse OS for fibroblasts (median, 8.9 vs. 12.2 months; P=0.056). Higher macrophage density within the CA showed a favorable trend toward improved PFS (median, 10.2 vs. 8.5 months, P=0.092), but was not associated with OS (P=0.399). In contrast, none of these biomarkers were associated with clinical outcomes in the first-line chemotherapy. **Conclusions:** Despite microsatellite-stable status, a higher summed TLS area was associated with improved progression-free and overall survival following immunotherapy, with endothelial cell and fibroblast densities providing additional prognostic information. AI-powered WSI analysis enabled effective stratification of these features. Research Sponsor: Lunit.

Multimodal immunoprofiling of peripheral blood using foundation models of the immune system for predicting immunotherapy response and toxicity in the RADIOHEAD pan-cancer cohort. First Author: Artemii Nikitin, BostonGene Corporation, Waltham, MA

Background: While immune checkpoint inhibition (ICI) is an emerging gold standard for cancer therapy, positive response is limited among treated patients and up to 70% experience toxicity. Early and accurate response prediction that accounts for immune-related adverse events (irAEs) is crucial for identifying patients who may benefit from ICI. We present AI-powered approaches for predicting ICI response by transcriptional and cellular profiling of blood immune cells from a pan-cancer cohort. **Methods:** Peripheral blood mononuclear cells (PBMC) were isolated at pre- (baseline) and early on-treatment for flow cytometry and RNA-seq profiling from the RADIOHEAD cohort *(Quandt et al. 2025)* receiving ICI (n=1,070). Patients were clustered based on variational autoencoder embeddings for real-world progression-free survival (rwPFS) and irAEs derived by a peripheral immune system encoder trained on the BostonGene patient database (n=45,000). The logrank test and Fisher's exact test were used to analyze survival and compare irAE frequencies between clusters, respectively. RNA-seq trajectory features were identified using hierarchical clustering, along with elastic net-regularized and simple multivariate Cox regression models for feature selection. **Results:** Pre-trained immunotype models (Dyikanov et al. 2024) applied to baseline PBMC revealed that G2-primed (memory CD4+ T cell-enriched) and G5-suppressive (monocyte enriched) immunotype scores stratified patients into responders (R) and non-responders (NR) ($p = 0.00001$). T cell receptor (TCR) dynamics revealed a significantly greater decrease in TCR diversity in NR during treatment ($p = 0.046$). We discovered a baseline gene set containing immune checkpoint and cancer antigen genes as well as a longitudinal trajectory set of monocyte and myeloid cell activation markers that both stratified patients by rwPFS (p=0.006; 0.03). Trained immune system embeddings identified a novel severe-risk patient group with both a high irAE incidence ($p = 0.025$) and short rwPFS. This group displayed both active inflammatory and tolerance pathways that stratified patients with irAEs by rwPFS ($p = 0.003$). **Conclusions:** Using pre-trained multimodal immune system projections, we 1) independently confirmed the association of peripheral immunotypes with ICI response; and 2) identified a novel severe-risk signature from patients with high irAE incidence (≥Grade 3) and short rwPFS. We also found that greater TCR diversity and T cell differentiation were associated with ICI response, while innate myeloid activation and trafficking correlated with non-response. Our unique AI-driven analytical framework underscores the potential of peripheral blood immunoprofiling for ICI treatment selection and patient stratification in prospective trials. External validation of a deep learning CT biomarker to predict first-line immune checkpoint inhibitor monotherapy-associated survival in PD-L1–high metastatic non–small cell lung cancer. First Author: Ravi Bharat Parikh, Emory University, Atlanta, GA

Background: Immune checkpoint inhibitor (ICI) monotherapy is a standard first-line treatment for patients with metastatic non–small cell lung cancer (mNSCLC) with high PD-L1 expression. However, 60% of patients treated with ICI monotherapy progress within 1 year of treatment. Imaging-based biomarkers from routine pretreatment computed tomography (CT) scans may provide a noninvasive approach to refine patient selection and guide treatment decisions. **Methods:** Enhanced CT Response Score (eCTRS v0.0.2; Sako et al, JCO CCI, 2024) is an imaging-based biomarker that stratifies patient survival among mNSCLC patients receiving ICI monotherapy. eCTRS is derived from pre-treatment CT scans, using deep-learning extracted imaging features, lesion features, and clinical variables of age and sex. eCTRS was previously trained on a diverse, real-world multi-institutional dataset of 1,058 mNSCLC patients. This retrospective study externally validated eCTRS using a deidentified, EHR-derived longitudinal database with imaging from Flatiron Health. Patients with PD-L1–high (PD-L1 tumor proportion score ≥ 50%) mNSCLC without actionable mutations who received first-line ICI monotherapy and had imaging from 12 weeks before to 2 weeks after treatment start were included. Patients were stratified into eCTRS High and eCTRS Low groups using a pre-determined threshold. Survival analyses were conducted by an external, independent group. Kaplan-Meier and Cox proportional hazards analyses evaluated progression-free survival (PFS) and overall survival (OS) stratification. PFS was derived from RECIST 1.1 assessments by a centralized multi-reader radiologist adjudication process, and OS was defined as time from treatment start to death by any cause. **Results:** 205 patients met all inclusion criteria (median age 72 years, 48% female, 20% non-White). Eighty (39%) patients were classified as eCTRS Low and 125 (61%) as eCTRS High. PFS was improved among eCTRS High patients (Hazard Ratio [HR], 0.71; 95% CI, 0.51–1.00; p=0.048), with median PFS of 231 (95% CI: 133, 350) days versus 88 (95% CI: 57, 179) days in eCTRS Low patients. eCTRS High patients demonstrated significantly improved OS (HR, 0.56; 95% CI, 0.39–0.80; p=0.001), with median OS of 484 (95% CI: 361, NA) days for eCTRS High, versus 155 (95% CI: 75, 295) days for eCTRS Low. **Conclusions:** A deep learning–based imaging biomarker derived from routinely acquired pretreatment CT imaging identified survival benefit in patients with PD-L1–high metastatic NSCLC treated with first-line ICI monotherapy. These findings suggest that imaging-based biomarkers may serve as complementary, noninvasive tools to identify patients most likely to derive benefit from ICI monotherapy and to support risk-adapted treatment strategies. Artificial intelligence (AI) foundation model as a predictor of efficacy of next-generation checkpoint inhibition with botensilimab (BOT) + balstilimab (BAL) in solid tumors using pretreatment H&E images. First Author: Ryan Dalton, Noetik, South San Francisco, CA

Background: Predicting immunotherapy response is challenging in treatment-refractory/resistant (R/R) tumors where heterogeneity limits conventional biomarker utility. BOT (Fc-enhanced anti–CTLA-4) augments T-cell priming, depletes Tregs, and activates antigen-presenting cells. BOT+BAL (anti–PD-1) has shown activity across "cold" and R/R tumors including PD-L1–low and tumor mutational burden–low disease; thus, non-conventional predictive biomarkers are needed. A self-supervised AI foundation model applied to routine pretreatment H&E images was used to infer spatial transcriptomics and identify features associated with therapeutic benefit from BOT+BAL in microsatellite-stable colorectal cancer (MSS CRC), sarcoma, and ovarian cancer. **Methods:** A self-supervised AI foundation model was trained to infer spatial transcriptome expression from H&E images using purpose-built multimodal training data from thousands of human tumors profiled with multimodal assays. Pretreatment H&E images (not used for training) from 121 BOT+BAL–treated patients (pts) with R/R MSS metastatic CRC (included 20 pts with liver metastases), sarcoma, and ovarian cancer from the phase 1b C-800-01 trial (NCT03860272) were analyzed. Pt-specific embeddings were used to fit cross-validated classifiers predicting BOT+BAL clinical benefit (defined as complete or partial response [CR/PR] or stable disease [SD]). **Results:** Fitted logistic regression classifiers separated responders and non-responders in all tumor types, as measured by area under the receiver operating characteristic curve (AUROC; ranges from 0.5 [chance] to 1.0 [perfect separation]). Cross-validated AUROC was 0.61 in MSS CRC, 0.67 in sarcoma, and 0.77 in ovarian cancer (table; shows all findings). The model-recommended population is predicted to have a higher rate of clinical benefit, as measured by cross-validated precision. Beyond this binary analysis, the concordance index (C-index; measures accuracy and ranges from 0.5 [chance] to 1.0 [perfect]) for predicting overall survival (OS; via Cox proportional hazards model) was >0.5 in all tumor types, and highest in ovarian cancer. **Conclusions:** A self-supervised AI foundation model applied to routine pretreatment H&E images predicted BOT+BAL responses in MSS CRC, sarcoma, and ovarian cancer. These findings support AI-derived, H&E–based biomarker strategies for BOT+BAL and warrant prospective validation. Research Sponsor: Agenus Inc.; Noetik Inc.

Clinical and translational results from the phase 1 portion of the phase 1/2 study to evaluate CHM-2101, an autologous cadherin 17 (CDH17) chimeric antigen receptor (CAR) T cell therapy for the treatment of relapsed or refractory gastrointestinal cancers. First Author: Jennifer Rachel Eads, University of Pennsylvania, Abramson Cancer Center, Philadelphia, PA

Background: CHM-2101 is a Cadherin 17 directed autologous CAR T-cell product being developed to address the continuing unmet medical need for effective therapy against relapsed or refractory gastrointestinal (GI) cancers. Solid tumors of the GI tract such as gastric cancer, colorectal cancer (CRC) and neuroendocrine tumors (NETs) are devastating diseases associated with poor outcomes and more than 1.3 million global deaths annually. Despite advances in surgical and medical treatment of these solid tumors, the prognosis for patients with relapsed or refractory disease remains poor. There remains a need for innovative and effective treatments for patients with advanced and treatment-recalcitrant GI malignancies. **Methods:** The ongoing clinical trial is a seamless Phase 1/2 study enrolling subjects with gastric cancer, CRC or NETs of the midgut or hindgut. Enrolled subjects undergo screening and apheresis to enable manufacturing of CHM-2101. After completing apheresis, bridging therapy is permitted to provide disease control. After confirming successful CHM-2101 manufacturing and washout of bridging therapy, study subjects receive 3 days of lymphodepleting chemotherapy (fludarabine 30mg/m2/day and cyclophosphamide 500mg/m2/day). After two days of rest, subjects receive a one-time IV infusion of CHM-2101. **Results:** As of October 24, 2025, 13 subjects have been enrolled with 2 screen failures. Eleven of eleven successful manufacturing runs enabled treatment of 9 subjects to date (4 subjects at Dose Level 1 and 5 subjects at Dose Level 2). Most AEs were Grade 1-2. Aside from lymphodepleting chemotherapy-related cytopenias, Grade 3 Treatment-Related Adverse Events (TRAEs) were Cytokine Release Syndrome (CRS) and Enterocolitis in 1 subject each. There have been no Grade 4 or 5 TRAEs or DLTs. After IV infusion, CHM-2101 was noted to expand and persist (by flow and ddPCR) in the peripheral blood of all treated subjects. **Conclusions:** CHM-2101 has demonstrated cellular expansion and persistence with clinical tolerability in study subjects with advanced GI cancers at two dose levels. Enrollment of patients at Dose Level 3 is ongoing at US Cancer Centers. Clinical trial information: NCT06055439. Research Sponsor: None.

Tumor infiltrating lymphocytes (LM103 infusion) in solid tumors: A phase I trial evaluating clinical and immunological anti-tumor activity. First Author: Fenge Li, The First Affiliated Hospital of Nankai University, Tianjin, China

Background: Tumor-infiltrating lymphocyte (TIL) therapy has shown clinical promise in melanoma, but its applicability across diverse solid tumors in Asian patients remains unclear, and exploring molecular targets to improve anti-tumor responses of TIL are needed. **Methods:** In the phase I investigator-initiated trial, we evaluated the safety, feasibility, and preliminary efficacy of autologous TIL therapy in twelve patients with advanced melanoma, cervical, lung, or head and neck cancers. Twelve patients who failed with standard treatments were successfully enrolled in the trail from August 2022 to December 2024. The patients received a lymphodepletion therapy which consisted of cyclophosphamide (30mg/kg) for 2 days, followed by fludarabine (25mg/m^2) for 5 days, approximately 24 hours before receiving the intravenous autologous TILs infusion, and then received high doses of IL-2 for 6-12 days with the purpose of maintaining T cell survival and proliferation. After a 28 days safety observation, tumor assessment according to RECIST 1.1 was conducted every 6 weeks until 6 months followed by every 12 weeks long-term follow-up. T cell receptor (TCR) sequencing was performed to explore TIL persistence in vivo after TIL infusion. Differential genes were identified via Bulk-RNA sequencing on TILs of responders and non-responders. Target gene knocking out of TIL using CRISPR/Cas9 technology was performed to enhance its anti-tumor function. **Results:** The most common adverse observed events were fever, anemia, nausea, hypertension, and hyponatremia. The objective response rate (ORR) was 33.3% (4/12), including one complete response (CR) and three partial responses (PR), and the disease control rate (DCR) reached 75% (9/12). Infused TILs persisted in peripheral blood and induced reversed peripheral CD4+T and CD8+T percentages. T cell receptor (TCR) sequencing revealed dynamic clonal remodeling in responders. Transcriptomic profiling of infused TILs identified ASS1 and CEP20 as genes negatively associated with therapeutic activity. CRISPR/Cas9-mediated knockout of these targets enhanced TIL memory phenotypes, cytokine production, and tumor cytotoxicity *in vitro* and *in vivo*. **Conclusions:** Autologous TIL monotherapy is feasible and safe. This study reveals effective TIL therapy in diverse solid tumors of Asian patients and potent anti-tumor activity of genetically enhanced ASS1 KO and CEP20 KO TILs, which offer mechanistic insights that may guide optimization of TIL therapy for broader clinical application. Trial registration number: NCT05366478. Clinical trial information: NCT05366478. Research Sponsor: None.

2538 **Poster Session**

Extended monitoring and biomarker analysis in metastatic melanoma patients treated with TIL therapy and conditioning-replacing igrelimogene litadenorepvec virotherapy: Pre-infusion immune cell and cytokine profiles associated with survival. First Author: Victor Cervera-Carrascon, TILT Biotherapeutics Ltd., Helsinki, Finland

Background: Adoptive transfer of tumor-infiltrating lymphocytes (TILs) can be effective in metastatic melanoma, but its routine use is limited by the need for lymphodepleting chemotherapy and systemic high-dose IL-2. To reduce toxicity while preserving anti-tumor activity, a strategy pairing TIL therapy with the oncolytic adenovirus igrelimogene litadenorepvec (TILT-123) was assessed. This virus selectively replicates in malignant tissue and drives local expression of TNF and IL-2 within tumors, functionally replacing the need for pre-infusion chemotherapy and post-infusion IL-2 administration. **Methods:** Seventeen patients with advanced melanoma resistant to immune checkpoint inhibitors were treated and sampled (NCT04217473). Treatment with igrelimogene litadenorepvec started upon tumor biopsy collection for TIL manufacturing took place and eventually followed by autologous TIL infusion around 36 days after. Hypotheses generated during data analysis were validated using additional patient datasets (NCT04695327, NCT05271318). **Results:** The regimen was well tolerated, with no dose-limiting toxicities. Objective response rate was 11.7%, with disease control in 35% by RECIST 1.1 and 47% by PET; metabolic responses were seen in 27%. Among those patients, higher baseline expression of epidermal and hepatocyte growth factors (EGF and HGF respectively) was associated with poorer prognosis. Higher than median HGF was negatively correlated with survival (p=0.032). Additionally, patients that achieved disease stabilization or better had a lower presence of circulating MDSCs (p=0.017). The link between growth hormones, MDSCs and disease progression was extrapolated to a larger dataset including other patients treated with igrelimogene litadenorepvec to find out the same trend for survival (HGF; p = 0.003, EGF; p = 0.029). In parallel, baseline circulating young memory T cells (CD27+CD28+CD8+) and an early expansion of NK cells (CD45+CD56+CD3-) correlated with a lower chance of progressing (T cells p=0.005, NK cells p=0.003). **Conclusions:** Combining TILT-123 with TIL therapy was safe and produced meaningful clinical activity in checkpoint inhibitor-refractory melanoma, especially in patients with lower HGF and EGF at baseline and a higher presence of young memory T cells and NK cells. In this clinical set-up, adapting the inclusion exclusion criteria to select patients with those defined immune system features, could help improve efficacy beyond. This approach may substantially broaden the feasibility and accessibility of TIL-based immunotherapy, especially due to the omission of the toxic conditioning regimens. Clinical trial information: NCT04217473. Research Sponsor: None.

Immunologic and clinical outcomes of perfluoroalkyl substances (PFAS) exposure in solid tumors treated with pembrolizumab. First Author: Charles Jeffrey Lay Tan, Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) are two major PFAS with persistent and widespread human exposure. Epidemiologic studies in non-cancer individuals suggest PFAS-associated immune dysregulation and anti-inflammatory effects. We assessed immunologic and clinical effects of PFAS on patients (pts) with advanced solid tumors treated with pembrolizumab. **Methods:** In the investigator-initiated INSPIRE study (NCT02644369) (n = 106) of advanced solid cancer pts treated with pembrolizumab (head and neck squamous cell cancer, triple-negative breast cancer, high-grade serous carcinoma, melanoma and other mixed solid tumors), we quantified baseline PFOS and PFOA via HPLC-tandem mass spectrometry. PFAS were evaluated as continuous variables and dichotomized at the median ($<$ median vs $>$ median; PFOS 3.6 ng/ml; PFOA 1.0 ng/ml). Associations with clinical and demographic factors were assessed using correlation/regression analyses. Association with toxicity and objective response (ORR) used Wilcoxon rank-sum tests; progression-free survival (PFS) and overall survival (OS) used Cox proportional hazards models. Immune correlates (immune infiltration measured by multiplex IHC, bulk-RNA sequencing of tumor tissue and plasma cytokine levels measured by Luminex multiplex cytokine assay) were evaluated using median-split Wilcoxon comparisons with Benjamini-Hochberg false discovery rate (FDR) control ($q < 0.2$). **Results:** Baseline PFOS and PFOA levels were moderately correlated (Pearson r = 0.49, $p < 0.001$). PFOS levels were significantly higher with increasing age (median age 59.4 years; range 21.1-81.8; p = 0.016). PFOA levels were significantly higher with increasing age (p = 0.001), in males (p = 0.042), and in the melanoma cohort (p = 0.015), and significantly lower in pts with prior systemic therapy (p = 0.001). For immune parameters, higher PFOA exposure was associated with reduced CD4 T-cell infiltration in tumor and stromal areas (q = 0.07). RNA sequencing of genes and immune signatures showed no associations reaching FDR significance. 10 cytokines were significantly lower in pts with high PFOA levels: IL-16, IL-2R, IL-3, HGF, IFN-γ, MCP-2/CCL8, MDC/CCL22, TNF-RII, TSLP, and BLC/CXCL13 (all q = 0.15) in ovarian cancer and melanoma pts. Neither PFOS nor PFOA levels showed significant associations with ORR, toxicity, PFS or OS. **Conclusions:** PFOS and PFOA levels vary by demographic and clinical factors but show no direct association with toxicity and treatment outcomes in pts treated with pembrolizumab. Elevated PFOA exposure correlates with reduced T-cell infiltration and cytokine suppression, potentially inducing systemic and local immune dysregulation. These findings highlight immunologic effects of PFAS and warrant mechanistic and longitudinal studies. Research Sponsor: None.

GK01 stemness-enriched tumor-reactive T-cell therapy plus IL-2 in advanced solid tumors: ORR and clonal persistence results in a first-in-human phase I study (GUARDIAN-01). First Author: Jun Yu, Tianjin Medical University Cancer Institute & Hospital, Tianjin, Tianjin, China

Background: T-cell exhaustion and poor persistence limit tumor infiltrated lymphocytes (TILs) efficacy in solid tumors. GK01 is an autologous tumor-reactive T-cell product enriched for stem cell memory T cells (TSCM: CD45RA$^+$CD62L$^+$) and diverse T-cell receptor (TCR) clonotypes to promote durable engraftment. We conducted GUARDIAN-01 (NCT06954558), a phase I study of GK01 plus IL-2 in advanced solid tumors. **Methods:** This single-arm, open-label study enrolled patients with advanced solid tumors (ECOG PS 0-1; measurable disease per RECIST v1.1). Patients received standard lymphodepletion, GK01 (5×10^9-1×10^{11} cells per manufacturing yield), and IL-2 (300,000 IU/kg IV q12h, up to 5 days). Repeat infusion was permitted at investigator discretion based on clinical benefit. Primary endpoint was safety; secondary endpoints included objective response rate (ORR), disease control rate (DCR), and cellular kinetics via absolute lymphocyte count (ALC) and TCR sequencing. **Results:** From March 2025 to January 2026, 6 patients were enrolled (median age 53.5 years; median 2 prior lines; tumor types included gastric n = 3, pancreatic n = 1, penile SCC n = 1, and melanoma n = 1). Manufacturing succeeded in all patients; median time from tissue procurement to infusion was 28 days (range 25-39). Infused GK01 exhibited median TSCM frequency of 71% (range 42-92%) and demonstrated robust expansion and stemness properties. Upon tumor challenge, these T cells secreted IFN-γ at a median of 1,632 pg/mL (range, 35 - 4,886). Median dose was 2.8×10^{10} cells (range 1.4×10^{10}-8.8×10^{10}); 2 patients received repeat infusion. The median total IL-2 dose administered was 4 (range 1-5), with the first dose administered approximately 6 hours after GK01 infusion. No dose-limiting toxicities (DLTs) occurred. G3/4 adverse events were exclusively hematologic (neutropenia, thrombocytopenia, leukopenia, lymphopenia in all patients), attributable to lymphodepletion. Chills, fever, and erythroderma occurred in all patients but G1-2, resolving within 2 weeks. At median follow-up of 169 days (range 80-297), ORR was 66.7% (4/6 PR; 2/6 SD), and DCR was 100%. The median peak ALC reached at 11.3×10^9/L (range 4.9-22.7) at days 7-9 post-infusion, remained elevated at 3.1×10^9/L (range 2.0-6.4) at 1 month. Among patients with available peripheral-blood samples (n = 4), product-derived TCR clonotypes comprised 94% of the circulating repertoire at day 7 and 92% at 2 months. **Conclusions:** In this first-in-human study, GK01 plus IL-2 demonstrated a favorable safety profile with no DLTs and manageable toxicity. The TSCM-enriched product achieved a 67% ORR and 100% DCR, with product-derived clonotypes persisting at $>$ 90% of the T-cell repertoire at 2 months. These findings validate the stemness-enriched T-cell platform and support expansion cohorts in selected solid tumor indications. Clinical trial information: NCT06954558. Research Sponsor: Geekgene.

Longitudinal immune programs and association with toxicity burden and antitumor response during immunotherapy. First Author: Mireille Diane Langouo Fontsa, Molecular Immunology Laboratory, Institute Jules Bordet, Universisté Libre de Bruxelles, HUB, Brussels, Belgium

Background: Immune-related adverse events (irAEs) and tumor responses often co-occur during immune checkpoint inhibitor (ICI) therapy. We investigated whether blood immune programs associated with toxicity can be temporally and biologically dissociated from response programs. **Methods:** ICI-naïve patients with advanced solid tumors (n=37; enriched for melanoma and NSCLC) were profiled at baseline (T0), early on-treatment (T1; week 4), and later timepoints (T2–T3); patients with irAEs had an additional sample at onset (Ttox) before immunosuppression. PBMCs were analyzed by multiparameter flow cytometry and plasma cytokines by 48-plex multiplex assay (log2). We compared timepoints and delta windows (ΔT1−ΔT3), controlled multiple testing with Benjamini–Hochberg ($q<0.1$), and evaluated baseline predictors from T0 alongside landmark Cox models from T1 for ΔT1 predictors to avoid immortal-time bias; baseline multiple-irAE signatures were tested in penalized multivariable models with clinical covariates. **Results:** irAEs occurred in 20/37 (54%) patients (grade ≥3: 8/37, 22%); multiple irAEs occurred in 14/37 (38%). Objective response occurred in 15/37 (41%), and 10/15 (67%) responders developed irAEs; median time to first irAE was 86 days (IQR 63–108). Baseline multiple-irAE susceptibility centered on Tfh states (higher Tfh1/Tfh17 PD1+ICOS− and lower Tfh1 PD1−ICOS+), and a MultiTox signature predicted multiple irAEs (OR 5.46; p=0.033). Early dynamics strengthened toxicity prediction: ΔT1 Tfh2 PD1+ICOS− decreased in AnyTox/MultipleTox and predicted subsequent irAEs (HR 0.41; p=0.0019), whereas ΔT1 PDGF-BB (log2) increased risk (HR 2.25; p=0.006). Approaching onset, activated regulatory compartments (activated Treg and Tfr) contracted, followed at Ttox by a surge in IFN-inducible CXCR3 chemokines (CXCL9/MIG $p=3.1\times10^{-5}$; CXCL10/IP-10 p=0.0021), consistent with a Th1/IFN axis. In contrast, response-associated programs emerged later and reflected a Tfh/B cell–activated CD8 axis (memory B at T1 p=0.036; ΔT2 Tfh2 PD1−ICOS− $q<0.1$, p=0.0010; ΔT2 eosinophils $q<0.1$, p=0.0071) and remained independently associated with response (p≈0.02–0.03). **Conclusions:** Toxicity—particularly high-burden toxicity—appears to reflect a baseline susceptibility that is amplified by early on-treatment immune trajectories and culminates in a chemokine-rich onset state. In contrast, response-associated programs emerge later and are at least partly dissociable from high-burden toxicity. Distinct Tfh states—especially early Tfh2 dynamics—may support timing-informed monitoring and improved benefit–risk stratification during ICI therapy. Research Sponsor: None.

Phase 1 trial of a KRAS G12V/HLA-A*11:01–restricted TCR-engineered T-cell therapy in advanced solid tumors. First Author: Ding Xiaoyan, Medical Oncology Department, Beijing Ditan Hospital, Capital Medical University, Beijing, Beijing, China

Background: KRAS G12V is a prevalent oncogenic driver in solid tumors, particularly pancreatic cancer (PC), occurring in approximately 20-30% of patients (pts). Advanced solid tumors harboring this mutation carry a poor prognosis and limited treatment options following standard chemotherapy. This phase 1 study evaluates a novel TCR-engineered T cell (TCR-T) therapy derived from a naturally occurring, KRAS G12V/HLA-A*11:01–restricted T cell receptor (TCR) isolated from patient tumor-infiltrating lymphocytes. **Methods:** This open-label, single-arm, dose-escalation phase 1 trial assessed the safety, tolerability, and preliminary efficacy of autologous TCR-T cells in pts with advanced solid tumors. Eligible pts had confirmed KRAS G12V mutation and HLA-A*11:01 positivity. Using a standard 3+3 design, autologous T cells were transduced with a lentiviral vector encoding the TCR and a CD8 co-receptor. Pts received lymphodepletion with cyclophosphamide and fludarabine, followed by a single infusion of TCR-T cells at either 5×10^9 (DL1) or 1×10^{10} (DL2) cells, with adjunctive interleukin-2. **Results:** As of January 2026, 8 pts were enrolled; of whom 6 (median age 69.5 years, ECOG PS 1) received the planned infusion, including pts with colorectal cancer (n = 2), pancreatic cancer (n = 3), and endometrial cancer (n = 1). All pts had liver or lung metastases and > 2 metastatic sites. No dose-limiting toxicities (DLTs) or grade ≥3 treatment-related adverse events (TRAEs) were observed. The treatment was generally well-tolerated; the most common (≥50%) treatment-emergent adverse events (TEAEs) were pyrexia, cytokine release syndrome (CRS), neutropenia, anemia, and thrombocytopenia. Grade 1-2 CRS occurred in 4/6 pts and resolved without sequelae. No immune effector cell–associated neurotoxicity syndrome (ICANS) was observed. TCR-T cells peaked in peripheral blood at a median of day 4 (range, 1–10), with a median peak expansion of 61,863 copies/μg DNA (range, 40,394–80,824). The objective response rate (ORR) was 50.0% (3/6), with a disease control rate (DCR) of 83.3% (5/6). In the pancreatic cancer subset, the ORR was 66.7% (2/3) and the DCR was 100%. **Conclusions:** This KRAS G12V/HLA-A*11:01–restricted TCR-T therapy demonstrated a favorable safety profile and encouraging preliminary antitumor activity in advanced solid tumors. Notably, a high response rate was observed in heavily pretreated pancreatic cancer patients, supporting further clinical development of this novel cellular therapy. Clinical trial information: NCT06767046. Research Sponsor: Beijing CorreGene Biotechnology Co., Ltd; 2023YFC3403800, 2024ZD0520500, Z221100007922022.

Safety and preliminary efficacy of a novel armored mesothelin-targeted CAR-T therapy in advanced solid tumors. First Author: Changsong Qi, State Key Laboratory of Holistic Integrative Management of Gastrointestinal Cancers, Beijing Key Laboratory of Carcinogenesis and Translational Research, Department of Early Drug Development Centre, Peking University Cancer Hospital & Institute, Beijing, Beijing, China

Background: UCMYM802 is an autologous mRNA-electroporated CAR-T cell therapy targeting mesothelin (MSLN), incorporating a lymphocyte-antigen-presenting cell costimulatory (LACO-Stim) molecule. This first-in-human study aimed to assess its safety, tolerability, preliminary efficacy, and pharmacokinetic/pharmacodynamic (PK/PD) profiles. **Methods:** This phase I study enrolled patients with metastatic or recurrent MSLN-positive solid tumors who failed standard therapies. Three dose levels were evaluated: 1×10^8 (n = 1), 5×10^8 (n = 1), and 1×10^9 CAR-T cells (n = 7). No lymphodepletion was required prior to infusion. Patients received up to 4 weekly infusions. Primary endpoints were safety and determination of the maximum tolerated dose (MTD). Secondary endpoints included objective response rate (ORR) by RECIST v1.1, disease control rate (DCR), and PK/PD parameters. **Results:** As of Nov. 2025, 9 patients were enrolled and treated (median age 67, range 52-67). Tumor types included pancreatic cancer (n = 3), peritoneal malignant mesothelioma (n = 1), adenocarcinoma of unknown primary, consistent with a gynecologic or peritoneal origin (n = 1), extrahepatic cholangiocarcinoma (n = 1), cholangiocarcinoma (n = 1), ovarian cancer (n = 1), and lung cancer (n = 1). All patients received at least one infusion. The 1×10^9 dose level was defined as the MTD, with one dose-limiting toxicity (DLT) observed (grade 4 cytokine release syndrome [CRS] with hypotension). Treatment-related adverse events (TRAEs) occurred in all patients, most commonly CRS (88.9%), fever (88.9%), decreased lymphocyte count (77.8%), anemia (77.8%), prolonged prothrombin time (66.7%), and hypoxia (55.6%). Grade ≥3 CRS occurred in 25% of patients. Among seven efficacy-evaluable patients, two patients achieved partial response (PR; one each in 5×10^8 and 1×10^9 cohorts), and two had stable disease (SD; one each in 1×10^8 and 1×10^9 cohorts). The ORR was 28.6% (2/7) and DCR was 57.1% (4/7). Notable responses included a PR in gynecologic or peritoneal origin adenocarcinoma and a PR at 6 months (converted to SD at 7.5 months) in extrahepatic cholangiocarcinoma. PK analysis showed peak CAR-T expansion (by copy number) at 1-hour post-infusion, with the highest and most sustained exposure after the first infusion. PD analysis indicated IFN-γ elevation correlating with CAR-T peak expansion. CAR-T exposure and activation marker expression showed a dose-dependent trend. **Conclusions:** UCMYM802 demonstrated a manageable safety profile consistent with expected CAR-T-related toxicities, primarily CRS. Preliminary anti-tumor activity was observed in heavily pretreated patients with MSLN-positive advanced solid tumors, with encouraging signals in gynecologic or peritoneal origin adenocarcinoma and biliary tract cancers. The recommended dose for expansion is 1×10^9 CAR-T cells. These results support continued investigation of UCMYM802. Clinical trial information: NCT06256055. Research Sponsor: None.

Phase 1 dose escalation study of CD34 selected CD19 directed CAR T with metabolic programming in relapsed/refractory B-cell lymphoma. First Author: Brian Hess, Medical University of South Carolina, Hollings Cancer Center, Charleston, SC

Background: CD19 CAR T cell therapy (CAR-19) has been a breakthrough for relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (B-cell NHL). However, both relapse and toxicity remain major challenges. We utilized novel programming conditions aimed at enhancing the function and persistence of our CAR T products by improving metabolic fitness, via promotion of a hybrid Th1/Th17 phenotype. Additionally, CD34 selection was employed, via CD34 tag, to yield a more purified product and reduce potential toxicity. **Methods:** This single institution IRB approved phase 1B trial (NCT 05702853) evaluated a novel CD28 co-stimulated CAR-19 product, with metabolic programming and CD34 selection (CD19-CAR-CD34t hybrid T cells). Eligible patients had R/R B-cell NHL and were enrolled at dose level (DL) 1, 2, or 3 ($1x10^6$, $1.5x10^6$, $2x10^6$ CAR T cells/kg with max dose of $2.0x10^8$). Dose escalation (Desc) used a model-assisted keyboard design. Dose-limiting toxicity (DLT) evaluation occurred in the first 28 days following infusion per CTCAE v5.0, with CRS and ICANS assessed per ASTCT criteria. The primary objectives were to evaluate safety and determine recommended dose for expansion. **Results:** Desc completed enrollment with 15 patients across dose levels DL1-3, DL2-3, DL3-9. NHL subtypes included DLBCL (8), mantle cell (4), follicular (2), and marginal zone lymphoma (1). Patients received a median of two prior systemic therapies (range 1-5), and 11 (73%) received bridging therapy. All patients underwent successful leukapheresis, manufacturing, CAR T infusion, and completion of the 28-day DLT evaluation. Common AEs included neutropenia (100%), fatigue (53%), and nausea (47%). One DL3 patient experienced a DLT (grade 4 lung infection). CRS was noted in 9 patients (60%; (grade 1: 7 pts; grade 2: 2 pts), with no grade 3+ events. No ICANS was observed. Six patients (40%) received tocilizumab (toci) and two (13%) received corticosteroids for CRS management with cumulative administration of 8 doses of toci (mean 0.5 doses/patient) and 20 mg of dexamethasone (mean 1.3 mg/patient) for entire cohort. With 11.1-month median follow-up, ORR/CR rates were 73%/67% (1-year PFS 0.67; 95% CI 0.47-0.95). All 10 patients with CR remained relapse-free as of 1/1/26; 2 deaths occurred due to lymphoma progression. The median percentage of CD34 CAR T cells at infusion was 67%. Median total T-cell doses were 165.1 (DL1), 262.8 (DL2), and 236.2 (DL3) x 10^6. Data on persistence/expansion of Desc cohort are forthcoming. **Conclusions:** CD19-CAR-CD34t hybrid T cells showed promising efficacy and durability, with no relapses among patients with CR. There were no occurrences of either ICANS or grade 3+ CRS and limited CRS intervention needed. This is a promising toxicity profile for a CD28 co-stimulated CAR-19, likely owing to a more purified product via CD34 selection. DL3 was chosen for dose expansion and currently ongoing. Clinical trial information: NCT05702853. Research Sponsor: None.

Effects of resorcinol isoprenyl benzene derivative IPI201 on natural killer cell cytotoxicity and tumor cell viability in human colorectal adenocarcinoma cells. First Author: Brett Lanier, Isosceles Pharmaceuticals, Wilmington, NC

Background: Natural killer (NK) cells play a critical role in anti-tumor immunity, yet their cytotoxic efficacy can be limited by tumor resistance. Resorcinyl isoprenyl benzene derivatives have previously shown anti-tumor activity, but effects on NK cell-mediated cytotoxicity remain unclear. IPI201 is a synthetic resorcinyl isoprenyl benzene derivative. We evaluated whether IP201 augments NK cell cytotoxicity and explored potential mechanisms. **Methods:** Cytotoxicity assays were performed using HT-29 colorectal carcinoma cells co-cultured with either standard NK cells or activated NK cells genetically modified to produce soluble IL-15 (sIL15 NK) under conditions of IPI201 pre-treatment or co-treatment. Cancer cell lysis was quantified over time to assess total cytolysis (AUC), maximum rate of killing (V_{max}), and time to 50% maximal cytolysis (T_{50}). NK activation markers were assessed by flow cytometry. NK cell survival following IPI201 exposure was assessed over 7 days using cell density quantification. **Results:** IPI201 enhanced NK cell-mediated cytotoxicity against colorectal cancer cells. Pre-treatment increased overall cytolysis and killing rates by 625% in standard NK cells and 50% in sIL15 NK cells ($P<0.05$). Co-treatment similarly increased tumor cell lysis ($P<0.05$). IPI201 alone induced rapid tumor cell death, outperforming standard NK cells alone in overall cytolysis, killing rate, and time to peak effect ($P<0.05$). Enhanced cytotoxicity was not associated with changes in NK activation markers. Instead, IPI201 increased NK cell survival across doses, with the highest dose increasing Day 7 density by 117% in standard NK cells and 214% in sIL15 NK cells ($P<0.05$). Further, IPI201 sensitized tumor cells to NK-mediated killing following tumor cell pre-treatment (+130% in both NK cell types; $P<0.05$). **Conclusions:** IPI201 induces tumor cell death independent of NK cells and enhances NK cell-associated cytotoxicity during pre- or -co-treatment. These effects may arise from increased NK cell survival and/or heightened tumor cell susceptibility to immune-mediated killing. To our knowledge, IPI201 is now the third known molecule alongside IL-2 and IL-15, that is independently sufficient to support NK cell survival. These findings support further investigation of IPI201 as a multifunctional immunomodulatory and cytotoxic agent in combination cell-based cancer therapies. Research Sponsor: None.

Epigenetic reprogramming of allogeneic NK cells via antigen-specific "training" to generate target-specific memory-like NK cells for B-cell lymphoma without genetic engineering. First Author: Jialu Kang, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Clinical application of CAR-NK cells is restricted by manufacturing complexity, cost, and potential genotoxicity. Furthermore, synthetic CAR expression may disrupt native NK biology and impose steric hindrance. We hypothesized that NK cells can be epigenetically reprogrammed ex vivo to acquire antigen-specific, memory-like cytotoxicity via a novel, non-genetic "Targeted Priming Platform" (TPP), bypassing the fundamental constraints of CAR engineering. **Methods:** Healthy donor NK cells were co-cultured with CD19+ Raji cells in the presence of a CD16xCD19 bispecific engager (BiKE) and IL-12/15/18 cytokines. After a 7-day priming phase and subsequent rest, cells were re-challenged to assess recall responses. Deep profiling was performed using mass cytometry, ATAC-seq, and ChIP-seq. In vivo efficacy was evaluated in NSG mice engrafted with CD19+ Raji lymphoma. Comparisons were made against cytokine-only primed (Cyt-NK) and naïve NK cells. **Results:** TPP-NK cells demonstrated a stable, antigen-specific recall response. Upon secondary challenge with CD19+ targets, TPP-NKs exhibited superior expansion, degranulation (CD107a), and IFN-γ production compared with Cyt-NK or naïve controls. This specificity was absent in mismatched target settings. Epigenetic analysis revealed that TPP induced durable chromatin remodeling, characterized by stable hypomethylation and open chromatin at critical cytotoxicity loci (e.g., IFNG, PRF1, GZMB), distinct from the transient changes observed in Cyt-NKs. In vivo, a single infusion of TPP-NKs combined with low-dose BiKE induced sustained remission and significantly prolonged survival compared with controls ($P < 0.001$). **Conclusions:** We demonstrate a paradigm-shifting strategy to generate "target-trained" memory NK cells without genetic engineering. TPP epigenetically imprints antigen specificity, combining the precision of antibody therapy with the persistence of cellular therapy. This scalable, "off-the-shelf" platform offers a safer, cost-effective alternative to CAR-based modalities for B-cell malignancies. Research Sponsor: None.

An LNP-mRNA–based in vivo cell engager as a producer of T macrophage tumor triads in situ for targeted anti-solid tumor therapies. First Author: Xudong Wang, Liangzhu Laboratory, Hanghzou, Zhejiang, China

Background: The solid tumor microenvironment promotes infiltration of myeloid cells, with tumor-associated macrophages as the most abundant innate immune population. A recent study showed tumor-reactive T cells enriched in functional clusters with tumor or antigen-presenting cells, and T cells expanded from these clusters ex vivo exhibit enhanced tumor-killing activity. Bispecific and trispecific antibodies have emerged to link T cells with tumor and myeloid cells, improving antitumor immunity. However, their clinical use is limited by structural complexity, manufacturing challenges, and immunogenicity risks. Here, we developed a "live-cell engager" by harnessing and engineering macrophages in vivo to form T-macrophage-tumor triads, activating both T cells and macrophages near tumor cells to boost antitumor responses. **Methods:** We engineered macrophages to express a single-chain variable fragment (scFv) targeting CD3 (αCD3), a tumor-specific chimeric antigen receptor (CAR) and CD80 on their surface. Each was encoded by separate mRNAs encapsulated within one lipid nanoparticle formulation (LNP-C-3-80). Mouse bone marrow-derived macrophages (BMDMs) were used ex vivo to evaluate T cell activation and antitumor function. The efficacy of LNP-C-3-80 was further tested in immunocompetent syngeneic models including ID8 ovarian cancer and Hepa1-6 hepatocellular carcinoma. **Results:** In vitro, BMDMs engineered with LNP-3-80 effectively engaged T cells with macrophages, significantly boosting T cell activation compared to LNP-3 alone, as shown by increased CD69 expression and elevated secretion of IFN-γ, IL-2, and Granzyme B. Furthermore, BMDMs engineered with LNP-C-3-80 were able to engage both T cells and tumor cells, and when co-cultured with T cells, showed tsuperior antitumor activity over control groups (LNP-3-80, LNP-3, LNP-GFP). The LNP-delivered αCD3 and CD80 mRNAs were mainly expressed on macrophages but not on T cells, facilitating macrophage-T cell-tumor cell cluster formation. This proximity enabled mutual activation and synergistic tumor cell killing. In vivo, LNP-C-3-80 achieved nearly complete tumor regression and strong prevention of recurrence in ovarian and liver cancer models after intraperitoneal or intravenous administration. Toxicity studies in healthy C57BL/6J mice showed no organ damage or adverse serum biochemical changes, indicating a favorable safety profile. **Conclusions:** In summary, in vivo macrophage engineering promotes the formation of T cell–macrophage–tumor cell clusters, reducing immune cell–cancer cell distance and concurrently activating T cells. LNP-C-3-80 shows significantly enhanced antitumor efficacy in syngeneic solid tumor models with minimal toxicity. These results highlight LNP-C-3-80's strong potential as a promising therapeutic strategy against diverse solid tumors. Research Sponsor: None.

Combining immune checkpoint inhibition and dendritic cell vaccination in advanced pleural and peritoneal mesothelioma: The phase 1b MESOVAX trial. First Author: Laura Ridolfi, IRCCS Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST, Meldola, Italy

Background: Mesothelioma (M) remains a rare malignancy with limited therapeutic options. While immunotherapy combinations have recently become the standard of care for non-epithelioid subtypes, further strategies are required to enhance clinical outcomes. Dendritic cell vaccines (DCvax) have demonstrated preliminary activity and a favorable safety profile in M. Preclinical data suggest that DCvax induces PD-L1 expression on tumor cells; therefore, combining DCvax with Pembrolizumab (P) may sensitize patients (pts) to PD-1 blockade. **Methods:** MESOVAX is a proof-of-concept, Phase Ib, study evaluating the safety of P 200 mg combined with an autologous anti-tumor DCvax administered every 3 weeks (Q3W) for 6 cycles, followed by P monotherapy until disease progression or up to 2 years. Subcutaneous IL-2 (3 MU) was administered for 5 days following each vaccination. The primary endpoint was safety. Secondary endpoints included: changes in PD-L1 expression evaluated in pre- and post-therapy tumor samples by immunohistochemistry (IHC); immunological efficacy evaluated *in vivo* by DTH test and *ex vivo* measuring the immune response against selected tumor antigens (i.e MESOTHELIN, WT1, 5T4, TWIST-1, KRT-18, THBS2) by Interferon gamma (IFNγ) Enzyme-Linked Immunosorbent Spot (ELISpot) Assay; and treatment activity (objective response rate [ORR], duration of response [DOR], progression-free survival [PFS], and overall survival [OS]). **Results:** As of 28/11/2025, 9 pts (median follow-up: 32.5 months (mths)) were evaluable for safety and efficacy. Median age was 62 years; 89% (n = 8) were male, and all had epithelioid histology. Treatment-related adverse events (TRAEs) of any grade occurred in all 9 pts, with the most frequent being injection site reactions, asthenia, and fever. No grade 3–4 TRAEs were reported. Regarding treatment exposure, 4 pts received 6 cycles of P+DC, 6 pts received maintenance P, and one pt completed the maintenance phase. Best overall responses included 1 partial response (PR), 4 stable diseases (SD), and 4 progressive diseases (PD), with a median PFS of 5.3 mths (95% CI 1.8–17.3). Notably, one pt with prolonged SD (duration 9 mths) exhibited a PD-L1 conversion in the tumor tissue (from negative to positive) following treatment. Regarding the immunological activity, 4 pts experienced a positive DTH test during treatment, and interestingly for 3 of them we were able to measure a concomitant increase of the *ex vivo* antitumoral immune response against the tested antigens. **Conclusions:** The combination of DCvax and P is safe and demonstrates encouraging clinical activity in pretreated epithelioid M. The observed PD-L1 induction at the tumor site supports the synergistic potential of this combinatorial immunotherapeutic strategy. This trial is supported in part by a research grant from Investigator-Initiated Studies Program of MSD Italia S.r.l. Clinical trial information: NCT03546426. Research Sponsor: MSD Italia S.r.l.

B cell responses in recurrent respiratory papillomatosis patients treated with DNA immunotherapy INO-3107. First Author: Nabil F. Saba, Emory University Winship Cancer Institute, Atlanta, GA

Background: Recurrent respiratory papillomatosis (RRP) is a chronic, debilitating disease of the airway primarily caused by infection with human papillomavirus (HPV) types 6 and/or 11 and characterized by recurrent, benign tumor growth with potential for malignant transformation. Current standard of care consists of repeated surgical removal of papillomas, which can lead to lasting airway damage and impaired vocal function. Thus, a non-surgical approach to treat RRP is paramount. Previously, we described T cell responses associated with an overall clinical response rate of 81% (26/32) to INO-3107, a DNA immunotherapy designed to generate T cells capable of targeting HPV-infected cells, in adult RRP patients during a Phase 1/2 trial (NCT04398433). Here, we describe B cell responses in these patients. **Methods:** INO-3107 was administered during study weeks 0, 3, 6 and 9. Peripheral blood mononuclear cells (PBMCs) were obtained at screening/day 0, weeks 6, 9, 11, 26 and 52. Formalin-fixed, paraffin-embedded papilloma tissue was obtained prior to INO-3107 treatment (Scr) and at the end of the 52-week study (EOS). Both PBMCs and tissue were subjected to RNA and BCR sequencing, which additionally underwent single sample gene set enrichment analysis and CloneTrack analysis, respectively. Clinical response was defined as any reduction in frequency of RRP surgical interventions in the 52 weeks following dose 1 of INO-3107 (Y1) compared to the 52 weeks prior. **Results:** Following INO-3107 treatment, 85% (23/27) of patients exhibited B cell expansion in PBMCs that was sustained through Y1 for responders, which in contrast began to contract at week 26 for non-responders. Enrichment of B cell signatures, inclusive of total, naïve, memory, and plasma B cells, in papilloma tissue increased significantly by EOS in responders compared to non-responders. Increases in tissue BCR clone counts from Scr to EOS correlated significantly with clinical response during Y1. BCR sequences detected in tissue taken at EOS displayed a low degree of overlap with those detected at Scr. Newly detected BCR sequences in EOS tissue were present in PBMCs prior to EOS. Some of these B cell clones were detectable in PBMCs and papilloma tissue only after INO-3107 treatment. **Conclusions:** B cell immunogenicity may play a role in mediating clinical responses to DNA immunotherapy INO-3107 for the treatment of RRP. INO-3107 treatment induced expansion and emergence of B cells in the blood of RRP patients, which trafficked to and infiltrated papilloma tissue by EOS as evidenced by increased B cell enrichment and clone counts. These immune responses were associated with improved clinical outcomes. These results suggest that INO-3107 engages B cells equipped with the potential to promote activation of T cell responses described previously (doi: 10.1038/s41467-025-56729-6) and that they may play a role in long-term immunity against RRP. Clinical trial information: NCT04398433. Research Sponsor: Inovio Pharmaceuticals, Inc.

Anitocabtagene autoleucel (anito-cel) clinical trial manufacturing experience in patients with relapsed/refractory (RR) or newly diagnosed (ND) multiple myeloma (MM). First Author: Krina K. Patel, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Anito-cel is an autologous D-Domain–based anti-BCMA chimeric antigen receptor (CAR) T-cell therapy that demonstrated deep and durable efficacy and manageable safety in a Phase 1 study and a Phase 2 registrational study (iMMagine-1) in 4L+ RRMM (Bishop et al. ASH 2024; Patel et al. ASH 2025). The D-Domain has a fast off-rate and facilitates high transduction efficiency, high CAR expression, decreased risk of tonic signaling, and potential for enhanced manufacturing efficiency and optimal tumor cytotoxicity. Anito-cel is also being investigated in patients with RRMM with 1-3 prior therapies and in patients with NDMM. The anito-cel CAR T-cell therapy manufacturing process has been optimized by leveraging the learnings from the robust development process of another CAR T-cell therapy, axicabtagene ciloleucel (axi-cel). Axi-cel is an autologous anti-CD19 CAR T-cell therapy approved in 2L large B-cell lymphoma based on the ZUMA-7 trial, with a demonstrated high manufacturing success rate (MSR) in both clinical trial and commercial real-world settings (100% and 99%, respectively; Alquist et al. TCT 2024). Here we report initial anito-cel manufacturing experience from 2 MM clinical trials. **Methods:** Pooled manufacturing outcomes from adults with MM enrolled and leukapheresed in iMMagine-3 or GEM-AnitoFIRST from 09/2024 to 10/2025 were included. First pass (FP)-MSR was defined as anito-cel lots manufactured on first attempt and within specification per total first attempt lots dispositioned plus lots not dispositioned due to termination in the period (excluding those terminated for patient withdrawal). The median turnaround time (mTAT) was defined as the time from leukapheresis to the quality release of final anito-cel product. **Results:** There was a total of 104 patients who were leukapheresed and whose lots were dispositioned as of October 31, 2025; anito-cel was successfully manufactured for 100% of these patients. The FP-MSR was 99.0% with 1/102 lots rejected on disposition (Table). The global mTAT was 18 days (interquartile range [IQR], 17-20 days) for the 101 lots released. Updated data to be presented. **Conclusions:** Our results demonstrate rapid and reliable anito-cel manufacturing for MM clinical trials globally, with high manufacturing success rates and consistent turnaround times. These results were consistent with axi-cel manufacturing outcomes and highlight the importance of leveraging axi-cel manufacturing experience in the development of anito-cel. Clinical trial information: NCT06413498 and NCT07045909. Research Sponsor: Arcellx Inc. and Kite, a Gilead Company.

FP-MSR, n/N (%)	101/102 (99.0)
Global mTAT, days (IQR)	18 (17-20)

A phase 3 trial of adagloxad simolenin/OBI-821 in patients with high-risk early-stage triple-negative breast cancer. First Author: Hope S. Rugo, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Adagloxad simolenin (AS) is a therapeutic cancer vaccine composed of Globo H linked to the carrier protein keyhole limpet hemocyanin. OBI-821 is an adjuvant administered with AS to strengthen immune response. This phase 3 trial assessed safety/efficacy of AS/OBI-821 in patients with triple negative breast cancer (TNBC; NCT03562637). **Methods:** Eligible patients for this randomized, open-label trial were adults with high-risk ($\geq$1cm residual primary, $\geq$1 residual axillary node after neoadjuvant chemotherapy, or stage IIB or III cancer treated with adjuvant chemotherapy alone), primary localized early-stage, Globo H-positive (H-score $\geq$15) TNBC. Patients were required to have received $\geq$4 cycles of standard taxane- and anthracycline-based chemotherapy. Patients were randomized 1:1 to receive standard of care (SOC; observation alone [29%], capecitabine [69%], or a checkpoint inhibitor $\pm$ capecitabine [2%]) or AS/OBI-821 and SOC (observation alone [26.6%], capecitabine [69.6%], or a checkpoint inhibitor $\pm$ capecitabine [3.8%]). Patients in the AS/OBI-821 arm received 4 weekly doses of study drug administered via subcutaneous injection, followed by 4 biweekly doses, 4 doses every 4 weeks, then doses every 8 weeks up to 100 weeks. The primary endpoint was invasive disease-free survival (IDFS); secondary endpoints included safety assessed via treatment-emergent adverse events (TEAEs) and overall survival (OS). Patients were followed for up to 5 years after randomization for OS. **Results:** The intent-to-treat (ITT) population was comprised of 575 patients, with 286 in the AS/OBI-821 arm, and 289 in the SOC arm. Patients were a median age of 51 years (range 24-85), all were female, and most were white (52.7%). A total of 5.2% of patients had stage I cancer, 50.3% had stage II, and 37.1% had stage III. IDFS in the AS/OBI-821 arm was not statistically different than in the SOC arm (IDFS hazard ratio [HR], 1.23 [95% CI: 0.88, 1.73]; P= 0.23). Three-year IDFS rate was 54.5% for AS/OBI-821 arm and 56.4% for the SOC arm. Similar pattern was observed for OS with HR = 1.36 [95% CI: 0.77, 2.38). TEAEs occurred in 79.6% of patients in the AS/OBI-821 arm and 66.7% in the SOC arm. The most common TEAEs in the AS/OBI-821arm were palmar-plantar erythrodysaesthesia syndrome (18.7%), fatigue (11.6%), and headache (11.3%). Serious TEAEs occurred in 5.3% of patients in the AS/OBI-821 arm vs 6.2% in the SOC arm. One patient (0.4%) in the AS/OBI-821 arm had a TEAE of interstitial lung disease, assessed as unlikely related to treatment and one patient (0.3%) in the SOC arm had acute coronary syndrome that led to death. **Conclusions:** In this phase 3, randomized, open-label trial, AS/OBI-821 was well-tolerated, with a safety profile similar to SOC. IDFS and OS were similar between the AS/OBI-821 and SOC arms. The trial was terminated per recommendation by the Data and Safety Monitoring Board as it met prespecified futility criteria. Clinical trial information: NCT03562637. Research Sponsor: None.
