Background: Although ACC commonly arises in the salivary glands, nearly 40% arise at extra-salivary sites and are often managed as site-specific malignancies rather than as a unified histologic entity. Population-based data suggest that thoracic and head and neck ACC are associated with poorer survival compared with breast ACC; however, the factors underlying these differences remain poorly understood. **Methods:** We retrospectively identified all patients (pts) with ACC, irrespective of primary site, who were followed at a large cancer center between 2011 and 2024. Collected data included staging at diagnosis, primary site, local treatment (i.e. surgery, radiation), histologic subtype (solid, cribriform or tubular), lymphovascular invasion (LVI), perineural invasion (PNI), margin status (R0, R1), and clinical outcomes including local recurrence-free survival (LRFS), distant metastasis free-survival (DMFS), and overall survival (OS). Primary sites were grouped as major salivary glands (MASG), oral cavity or oropharynx (OCOP), sinonasal region (SINO), breast (BRST), thorax-lung (THLU), lacrimal gland (LCGL), and others (i.e., skin OTHR). Clinicopathologic characteristics were compared using Fisher tests, and associations between primary site and clinical outcomes were evaluated with multivariable Cox models comparing each site versus all others combined adjusted for local treatment type, margins, and solid histology, defined a priori following a causal inference framework. **Results:** Of 220 pts, 151 (69%) were female, and 199 (90.5%) had localized or locally advanced disease at diagnosis. The most common primary site was OCOP (n=67, 30%), followed by MASG (n=60, 27%), SINO (n=25, 11%), THLU (n=22, 10%), BRST (n=20, 9.1%), LCGL (n=6, 2.7%), and OTHR (n=20, 9.1%). Among 210 pts that received local treatment, 41 (19%) had surgery only, 134 (61%) surgery plus radiation, and 35 (16%) radiation alone. Patients with THLU primary had less up-front surgery (50% vs 76-100%, $p<0.001$). Among surgical cases, 58% had R1 resections; PNI was present in 48%. BRST pts had lower rates of positive margins (R1 7.7%, p=0.04) and PNI (28% vs 35-83%, p=0.019). Histologic subtype was reported in 108 (49%) pts with 72 (78%) cribriform, 58 (54%) solid, and 49 (45%) tubular. Median LRFS, DMFS, and OS were 103 months [mo] (95%CI 77-141), 87 mo (95%CI 70-131), and 153 mo (95%CI 124-222) respectively. Pts with SINO experience worse LRFS (HR 2.01, p=0.03), DMFS (HR 2.07, p=0.02), and OS (HR 3.51, $p<0.001$) while MASG had potentially improved DMFS (HR 0.63, p=0.07) and THLU OS (HR 0.31, p=0.07) in adjusted models. **Conclusions:** Primary site-specific clinical outcomes in ACC are not fully explained by treatment approach or histologic features. These findings suggest biological heterogeneity across ACC by primary site and underscore the need for molecular characterization of site-specific disease drivers. Research Sponsor: None.

Artificial intelligence–powered spatial analysis of endothelial cells and tumor-infiltrating lymphocytes to predict response to axitinib in adenoid cystic carcinoma. First Author: Dong Hyun Kim, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea

Background: Despite the limited systemic options for adenoid cystic carcinoma (ACC), VEGFR inhibitors remain a clinical mainstay. Although high stromal tumor-infiltrating lymphocyte (TIL) density has been identified as a predictive biomarker for improved progression-free survival (PFS), its predictive power remains to be fully optimized. We hypothesized that baseline vascular architecture, represented by endothelial cell (EC) density, might modulate the efficacy of axitinib. **Methods:** We performed a post-hoc exploratory analysis on H&E-stained whole-slide images (WSI) from 27 patients with R/M ACC treated with axitinib in a multicenter phase II trial (NCT02859012). An updated AI-powered analyzer (Lunit SCOPE IO), capable of multiple component TME profiling, was used to quantify the density (cells/mm²) of TILs and ECs within the tumor epithelium and stroma. Patients were stratified into subgroups based on the median values. The clinical impact of integrated immune and vascular architecture was evaluated by analyzing PFS and OS. **Results:** The analyzed cohort (N=27) had a best objective response of stable disease in 25 patients (92.6%) while 16 patients showed tumor shrinkage (59.3%). Stratification revealed that patients with concurrent High EC and High TIL density in the tumor stroma (n=9) derived exceptional clinical benefit compared to all other patients (N=18). The High EC/High TIL subgroup achieved a median PFS of 19.6 months compared to 11.1 months in the comparator group (HR 0.30; 95% CI: 0.11–0.87; P=0.026). Furthermore, this subgroup demonstrated significantly prolonged OS (median NR vs. 24.4 months; HR 0.12; 95% CI: 0.02–0.95; P=0.044). Stratification based on intratumoral densities of EC and TILs showed a similar trend with the High EC/High TIL subgroup (n=10) reporting prolonged PFS (HR 0.32; 95% CI: 0.12-0.87; P=0.025) but not OS (HR 0.46; 95% CI: 0.12-1.74; P=0.251). The individual biomarkers based on median TIL and EC showed a trend towards prolonged survival but were not statistically significant. **Conclusions:** The co-enrichment of stromal ECs and TIL is associated with significantly prolonged PFS and OS, suggesting that this unique TME architecture may identify R/M ACC patients who derive greater clinical benefit from axitinib. This AI-based spatial analysis using H&E slides offers a practical, scalable biomarker strategy to guide treatment selection in this rare cancer. 6123 Poster Session

A phase II study of pemetrexed and pembrolizumab in patients (pts) with recurrent and/or metastatic (R/M) salivary gland cancer (SGC): Results from the adenoid cystic cohort. First Author: Katharine Andress Rowe Price, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: Pemetrexed (PTX) is safe and tolerable with responses reported in pts with R/M SGC. Given enhanced responses with PTX and pembrolizumab (PMB) for lung cancer, we hypothesized that PTX and PMB will have activity for SGC. Herein we present the efficacy results in pts with adenoid cystic carcinoma (ACC). **Methods:** MC200708 is a single arm phase II study of PTX and PMB in pts with R/M SGC (NCT04895735) with 2 cohorts: ACC (cohort A) and non-ACC (cohort B). Key eligibility criteria: ≥18 years, ECOG 0-1, measurable disease. Prior ICI and/or PTX was allowed. Key exclusion criteria: serious comorbidities, autoimmune disease and brain metastases. Simon's 2-stage design was used for each cohort. Primary endpoint was overall response rate (ORR) for Cohort A but was amended to clinical benefit rate (CBR=SD+PR+CR) due to prolonged SD in several pts. Secondary endpoints: progression free survival (PFS), overall survival (OS), and toxicity. Exploratory analyses in Cohort A1 (post-amendment pts) included PSMA PET imaging and circulating PSMA extravesicles (EVs) as a biomarker. All pts received PTX 500 mg/m2 IV + PMB 200 mg IV q3 weeks until progression or treatment intolerance. Imaging was q3 cycles. **Results:** 20 pts (11 Cohort A + 9 Cohort A1) were enrolled from August 2021-Feb 2025. All 20 patients were eligible and received ≥ 1 cycle of treatment. Median age was 60.5 yrs, 50% male, performance status 0 (80%) or 1 (20%). 11 pts had no prior therapies (55.0%). The remaining pts had 1 (35%) or 2 (10%) prior lines of therapy. 75% of pts had no prior ICI. In Cohort A, the ORR was 0% (0 of 11). Cohort A1 met criteria for success based on CBR with 1 PR (12.5%) and 5 SD (62.5%) in the first 8 pts. For the whole cohort of 20 patients, the ORR was 5% (95% CI: 0.1-24.9) and the CBR rate was 75% (95% CI: 51-91) with 1 PR and 14 pts with SD. The duration of response for the 1 PR patient was 12.4 months. The median duration of response for the 15 pts with SD was 7.5 (2.0-29.7) months. 3 pts (15%) had PD and 2 pts (10%) went off prior to response assessment. Median cycles of treatment was 4 (2-30). In the 17 pts who discontinued, treatment was stopped in 9 (53%) for PD, 4 (23.5%) due to adverse events (AE), and 4 (23.5%) due to physician/patient preference. With a median follow-up of 14.5 months (1.5-39.2), the 1-year PFS rate is 52.1% (32.6 – 83.2%) and the OS rate is 82.1% (95% CI: 65.6 – 100%). The overall grade 3+ AE rate regardless of attribution was 80% (16/20). The most common grade 3 AEs were lymphocyte count decrease (40%), hypertension (20%), fatigue (10%), and pneumonitis (10%). 2 pts had a grade 4 AE (lymphocyte count decrease and thrombotic thrombocytopenic purpura). There were no treatment-related deaths. Analysis of correlative studies for Cohort A1 with PSMA imaging and EV biomarker ongoing. **Conclusions:** PTX and PMB has modest activity in pts with R/M ACC with CBR of 75% and prolonged benefit for some patients. Clinical trial information: NCT04895735. Research Sponsor: Merck.

6124 **Poster Session**

Anti–PD-1 immunotherapy with chemotherapy for poorly chemo-responsive thyroid and salivary gland tumors: The iPRIME study. First Author: Faith Abodunrin, Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, IL

Background: Clinical trial data guiding treatment of unresectable or metastatic salivary and thyroid gland cancers are limited. While targeted therapies have advanced management for selected patients, chemotherapy remains a treatment strategy for those with aggressive disease biology. Anti-PD1 therapy has shown antitumor activity in advanced, PD-L1 positive salivary and thyroid gland cancers, underscoring the need to evaluate the synergistic activity of PD-1 blockade with cytotoxic chemotherapies in these neoplasms. **Methods:** The iPRIME (NCT03360890) is a single center, parallel two cohort trial evaluating pembrolizumab with cytotoxic chemotherapy in patients with advanced salivary gland and thyroid cancers. Eligible patients had histologically confirmed disease that was unresectable and not amenable to curative intent therapy. Patients received pembrolizumab 200 mg IV with docetaxel or doxorubicin 75 mg/m2 for 2-6 cycles, followed by pembrolizumab monotherapy for up to 2 years. Docetaxel or doxorubicin could be reintroduced upon disease progression while on pembrolizumab or after the 2-year treatment period. The primary endpoint was response rate. Secondary endpoints included progression free survival (PFS), overall survival (OS), disease control rate, and adverse events. **Results:** A total of 39 patients (27 salivary and 12 thyroid cancer) were enrolled between 2018-2022. Mean age was 61 in salivary and 71 in the thyroid cancer, with 48% and 58% female patients, respectively. Salivary gland cancer histologies included adenoid cystic 15/27 (56%), ex-pleomorphic 18%, mucoepidermoid 7.4%, acinic cell 7.4%, salivary duct 7.4%, basaloid adenocarcinoma 3.7%. In the salivary gland group, the overall response rate was 25.6% (7/27; 90% CI 12.9%-43.2%), and the disease control rate was 89% (24/27; 90% CI 73.7%-96.9%). The overall response rate in the adenoid cystic patients was 27% (4/15). Median PFS was 8.6 months (90% CI: 6.0 to 12.4), including 8 months in adenoid cystic patients (90% CI: 6.0-16.7%) and 7.8 months in the non-adenoid cystic cases (90% CI: 3.8-14.6), with one and two-year PFS rates of 37% and 8.2%, respectively. Median OS was 25.5 months in the adenoid group (90% CI:8.5-32) and 22.9 months in the non-adenoid group (90% CI: 7.8-78) (p=0.26). One, two, and five-year OS rates in the salivary cohort were 66%, 50%, and 23%, respectively. In the thyroid cohort, the response rate was 16.7% (2/12), with both PR. Grade 4 events occurred in nine patients salivary patients and one grade 5 event was observed. **Conclusions:** The combination of pembrolizumab and cytotoxic chemotherapy did not substantially change antitumor control activity relative to historical controls in patients with advanced salivary or thyroid cancers. There were no statistically significant differences in PFS and OS between adenoid cystic and non-adenoid cystic subtypes. Clinical trial information: NCT03360890. Research Sponsor: Merck.

TPS6125 **Poster Session**

Phase III randomized trial of tislelizumab plus gemcitabine/capecitabine (GX) versus tislelizumab plus gemcitabine/cisplatin (GP) as first-line therapy for recurrent/metastatic nasopharyngeal carcinoma: A prospective multicenter study (PROGRESS). First Author: Dongmei Ji, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Nasopharyngeal carcinoma (NPC) is a prevalent malignancy in Southeast Asia and Southern China. Around 10% of pts have distant metastasis at initial diagnosis, and ~30% of those initially without metastasis will develop distant metastasis after radical treatment. These recurrent/metastatic (R/M) NPC pts have poor prognosis with a 5-year survival rate of only 20–30%. The RATIONALE-309 study established tislelizumab plus GP as a standard first-line therapy for R/M NPC, but most pts still experience disease progression in 2 years. Furthermore, in real-world clinical practice, a lot of pts are either platinum-intolerant or platinum-refractory recurrent, underscoring the urgent need for novel treatments. Recent studies suggest that first-line treatment regimens incorporating capecitabine may provide longer progression-free survival (PFS) compared to the GP regimen with a more favorable safety profile. Additionally, a retrospective study demonstrated that tislelizumab plus GX achieved notable tumor responses and PFS benefits in R/M NPC pts who have relapsed immunotherapy. **Methods:** This is a prospective, multicenter, randomized, controlled Phase III trial evaluating the efficacy and safety of tislelizumab + GX vs. tislelizumab + GP as first-line therapy in R/M NPC. 266 pts will be randomly assigned to the experimental or the control group. The experimental group will receive tislelizumab plus GX (gemcitabine 1g/m² D1,8 + capecitabine 1000 mg/m² BID D1-14) for 4–6 cycles, followed by tislelizumab plus capecitabine maintenance. The control group will receive tislelizumab plus GP (gemcitabine 1 g/m² D1,8 + cisplatin 80mg/m² D1) for 4–6 cycles, followed by tislelizumab monotherapy. Treatment will continue until disease progression or intolerable toxicity. The primary endpoint is PFS. Secondary endpoints include objective response rate, duration of response, overall survival, etc. Adverse events will be monitored and graded according to NCI CTCAE v5.0. Patient enrollment began in December 2023 across 10 centers in China, with 168 pts enrolled by December 2025. Clinical trial information: NCT06177301. Research Sponsor: None.

TPS6126 **Poster Session**

MC240701: Decentralized pilot study of triple oral metronomic chemotherapy in recurrent/metastatic oral cavity cancer. First Author: Binav Baral, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: Oral cavity cancers (OCC) are a rare subtype of head and neck cancer (HNC) with poor outcomes and limited second-line treatment options in the recurrent or metastatic (R/M) setting. Treatment-related morbidity and repeated local recurrences in OCC result in significant impairment of function and quality of life. Rural OCC patients comprise a sizable portion (50%) of our practice and are usually of lower socioeconomic status with lack of access to specialist care. They also have multiple barriers to treatment access and ancillary services, translating to poorer clinical outcomes. There is a critical need for effective and accessible therapies for R/M OCC in rural patients. Triple oral metronomic chemotherapy (TOMC) with Methotrexate, Erlotinib and Celecoxib (MEC) suppresses angiogenesis and activates antitumor microenvironment in HNC. Studies using TOMC in R/M OCC outside the US show reasonable efficacy (6-month OS 52.9%), better safety and lower cost compared to standard second line options. We hypothesize that a decentralized clinical trial with TOMC in R/M OCC is feasible, safe and effective in addition to being economical and accessible for rural patients. **Methods:** MC240701 is a single institution, open label, decentralized, single arm pilot study of MEC in patients with R/M OCC. Eligible pts must be $\geq$18 years old, have pathologically confirmed R/M OCC not amenable to curative-intent therapy, ECOG 0-2 and adequate organ function. At least 1 measurable lesion by RECIST 1.1 OR non-measurable disease (evident mucosal lesions, CNS/bone disease, lesions not meeting RECIST criteria) is permitted. Patients must have received standard first line immunotherapy with or without chemotherapy OR should be unable/unwilling to receive first line treatment. Key exclusion criteria include patients unable to take pills by mouth, serious medical co-morbidity or autoimmune disease, immunocompromised patients and other active malignancy. Primary endpoint is to demonstrate feasibility of decentralized clinical trials, secondary outcomes include overall response rate, progression free and overall survival and toxicity. Additional goals are to evaluate patient impact of decentralized treatment through surveys and interviews After initial screening and evaluation, patients are remotely consented and will receive study drugs by mail. All patients will receive the same treatment of Methotrexate 9mg/m^2 PO weekly, Erlotinib 150 mg PO daily, and Celecoxib 200 mg PO BID, each cycle will be 28 days. Treatment will continue until disease progression or treatment tolerance, study duration is for 2 years. All subsequent clinical and laboratory monitoring and response assessments (every 3 cycles) will be remotely performed or have an option for local testing. Enrollment began July 2025 and 4 out of planned 25 patients have been accrued. FDA IND:174540. Clinical trial information: NCT06997068. Research Sponsor: Mayo Clinic Comprehensive Cancer Center.

TPS6127 **Poster Session**

OrigAMI-5: A randomized, phase 3 study of amivantamab plus pembrolizumab and carboplatin vs standard of care pembrolizumab plus platinum and 5-fluorouracil as first-line treatment in recurrent/metastatic head and neck cancer. First Author: Robert I. Haddad, Dana-Farber Cancer Institute, Boston, MA

Background: Recurrent and/or metastatic head and neck squamous cell cancer (R/M HNSCC) is associated with significant morbidity and mortality. Current first-line standard of care regimens, including combinations of pembrolizumab with platinum-based chemotherapy with/without 5-fluorouracil (5-FU), yield low response rates and poor long-term outcomes, with a median survival of approximately 1 year. Many patients with R/M HNSCC exhibit EGFR and MET overexpression. Amivantamab is an EGFR-MET bispecific antibody with immune cell–directing activity that is FDA-approved in *EGFR*-mutated advanced non-small cell lung cancer. In a prior report of the phase 1b/2 OrigAMI-4 study (NCT06385080), subcutaneous (SC) amivantamab monotherapy demonstrated a confirmed objective response rate of 45% among participants with HPV-unrelated R/M HNSCC whose disease had previously progressed on immune checkpoint inhibitor and platinum-based chemotherapy (Harrington *Oral Oncology* 2025). The objective of this phase 3 randomized study is to assess the efficacy of SC amivantamab in addition to pembrolizumab and carboplatin, as compared to the standard of care (pembrolizumab plus carboplatin or cisplatin and 5-FU) as first-line therapy for participants with R/M HNSCC. **Methods:** The ongoing multicenter, global OrigAMI-5 study (ClinicalTrials.gov identifier: NCT07276399) is planned to open in approximately 205 sites in 22 countries. Eligible participants will have HPV-unrelated R/M HNSCC (primary tumor locations: oral cavity, oropharynx, hypopharynx, or larynx); all primary oropharyngeal tumors must be human papillomavirus (HPV)-negative. All participants, regardless of combined positive score (CPS), are eligible but must have local testing results to determine CPS for stratification and be treatment-naïve in the R/M setting; systemic therapy in the locally advanced setting is allowed if completed $>$6 months prior. Prior exposure to EGFR or MET targeting agents is exclusionary. Approximately 500 participants will be randomly assigned 1:1 to receive SC amivantamab (co-formulated with recombinant human hyaluronidase [rHuPH20]) with pembrolizumab and carboplatin, or 5-FU plus pembrolizumab and investigator's choice of carboplatin or cisplatin. Randomization will be stratified by programmed cell death ligand 1 (PD-L1) CPS ($<$1, 1–19, $\geq$20) and Eastern Cooperative Oncology Group (ECOG) performance status (0 vs 1). The primary endpoints will be objective response rate and overall survival. Secondary endpoints include progression-free survival, duration of response, and patient-reported outcomes. Safety assessments will include adverse event monitoring and laboratory abnormalities. Clinical trial information: NCT07276399. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

TPS6128 **Poster Session**

NRG-HN015: A phase II randomized trial of neoadjuvant chemotherapy or chemo-immunotherapy in patients with recurrent/persistent PD-L1–positive squamous cell carcinoma of the head and neck undergoing salvage surgery. First Author: Nabil F. Saba, Winship Cancer Institute Emory University School of Medicine, Atlanta, GA

Background: Treatment for locoregionally recurrent squamous cell carcinoma of the head and neck (SCCHN) remains a challenge. 30-40% of patients treated with definitive-intent therapy will recur, the majority locoregionally (Ang 2010, Galloway 2016, Tan 2010). Despite improvements in the effectiveness of palliative systemic therapy over the last decade (Vermorken 2008), salvage surgery (SS) remains the modality of choice to achieve cure in patients with locally recurrent disease particularly in patients who have previously received radiation. Thus, there is a pressing need to improve the therapeutic ratio by increasing the benefit of SS and improving oncologic outcomes. One promising means would be early introduction of systemic therapy with or without immune checkpoint inhibition for patients who are candidates for SS. NRG-HN015 proposes to investigate the effect on event-free survival (EFS) of pre-operative chemotherapy or chemo-immunotherapy in comparison to the standard SS approach. **Methods:** NRG-HN015 (NEOPOLIS) is a randomized, multicenter, controlled, 3-arm, superiority phase II study of neoadjuvant chemotherapy or chemo-immunotherapy in patients with recurrent/persistent PD-L1 enriched SCCHN who have planned SS. The primary objective is to compare investigator-assessed EFS of patients treated with neoadjuvant chemotherapy or chemo-immunotherapy prior to SS versus SS alone. The primary hypothesis is that neoadjuvant chemotherapy or chemo-immunotherapy added to SS will improve EFS. Enrolled patients will be randomized 1:1:1 to receive SS (Arm 1 - control), chemotherapy + SS (Arm 2), or chemo-immunotherapy + SS (Arm 3). Prior to randomization, patients will be stratified by primary tumor site (Oropharynx or oral cavity vs. larynx or hypopharynx, stage (rT4a or rN3a vs. other), and prior use of iPD1/PDL1 inhibitors in the definitive setting. Patients must have locally recurrent or persistent SCCHN arising within the oral cavity, oropharynx, larynx, or hypopharynx and are deemed candidates for salvage surgery. P16-positive oropharynx patients with T2, T3, T4, N0, N1, N2 and all other patients with T2, T3, T4a, N0, N1, N2a, N2b, N2c, N3a are eligible. Patients must have PDL1-positive and measurable disease, with no major vascular involvement ($>$180° involvement of the common carotid or internal carotid artery), jugular foramen involvement, or prevertebral, paraspinous muscle involvement precluding a curative resection. Patients who are candidates for salvage laryngectomy to treat recurrent laryngeal cancer and who are having SS for curative intent are eligible. The trial is opened to enrollment. Clinical trial information: NCT071953734. Research Sponsor: National Cancer Institute; NRG-HN015.

TPS6129 **Poster Session**

A multicenter, randomized, double-blind, phase 2/3 study of ficerafusp alfa (BCA101) or placebo in combination with pembrolizumab for first-line treatment of HPV-negative, PD-L1–positive, recurrent or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC): FORTIFI-HN01. First Author: Renata Ferrarotto, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: HPV-negative HNSCC is an aggressive disease characterized by high rates of recurrence, metastasis, and resistance to standard treatments. Most HPV-negative HNSCC tumors overexpress tumorigenic factors EGFR and TGF-β. In a phase 1/1b trial (NCT04429542), ficerafusp alfa demonstrated promising efficacy and a manageable safety profile in first-line R/M HNSCC. FORTIFI-HN01 (NCT06788990) is an ongoing randomized, double-blind, placebo-controlled, phase 2/3 trial designed to assess the efficacy and safety of ficerafusp alfa combined with pembrolizumab vs placebo plus pembrolizumab in patients with PD-L1-positive first-line R/M HPV-negative HNSCC. **Methods:** Eligible patients must have histologically confirmed R/M HNSCC with primary lesions in the oral cavity, larynx, or hypopharynx, or HPV-negative OPSCC confirmed by central laboratory testing. Additional eligibility criteria include no prior systemic therapy for R/M disease, PD-L1-positive tumor (CPS $\geq$1), measurable disease per RECIST v1.1, and ECOG performance status 0 or 1. The phase 2 objective was to determine the optimal biological dose (OBD) of ficerafusp alfa through an integrated analysis of safety, tolerability, PK, PD, and efficacy. Following OBD determination (1500 mg QW), the trial transitioned seamlessly into the phase 3 portion with 2:1 randomization (ficerafusp alfa: control). Randomization is stratified by PD-L1 CPS (1-19 vs $\geq$20) and disease extent (local/regional recurrence only, distant metastasis only, or both). Patients receive pembrolizumab (200 mg IV every 3 weeks for up to 35 cycles) and either ficerafusp alfa or placebo IV QW until disease progression or unacceptable toxicity. Tumor imaging occurs every 6 weeks during the first year and every 9 weeks thereafter. The primary endpoints are objective response rate (ORR) per RECIST v1.1 (blind independent committee review) and overall survival. An interim analysis evaluating ORR is planned. Secondary endpoints include safety, duration of response, progression free survival, clinical benefit rate, and patient-reported outcomes. The trial is actively recruiting, with planned enrollment of ~650 subjects. Clinical trial information: NCT06788990. Research Sponsor: Study funded by Bicara Therapeutics Inc.

TPS6130 **Poster Session**

Becotatug vedotin plus pucotenlimab as first-line therapy in patients with recurrent or metastatic nasopharyngeal carcinoma: A phase II clinical trial. First Author: Lei Liu, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Epidermal growth factor receptor (EGFR) is highly expressed in approximately 85% of nasopharyngeal carcinoma (NPC) cases and plays a critical role in tumor cell proliferation. Becotatug vedotin (MRG003) is a novel EGFR-targeted antibody-drug conjugate (ADC) with promising anti-tumor activity in NPC. Pucotenlimab is a recombinant humanized programmed cell death protein-1 (PD-1) inhibitor. Although platinum-based chemotherapy combined with a PD-1 inhibitor represents the current standard first-line treatment for recurrent or metastatic (R/M) NPC, treatment-related toxicities and suboptimal efficacy remain significant challenges. Preclinical and early clinical data have demonstrated synergistic anti-tumor activity of MRG003 combined with pucotenlimab in platinum-refractory R/M NPC. However, the efficacy and safety of this platinum-free combination as a first-line therapy for R/M NPC remain uncertain. This study aims to evaluate the efficacy and safety of becotatug vedotin plus pucotenlimab as a novel first-line treatment for patients with R/M NPC. **Methods:** This is an open-label, single-arm, phase II trial enrolling patients with R/M NPC eligible for first-line systemic therapy. Inclusion criteria include: age 18 to 75 years; ECOG performance status score of 0 or 1; histologically or cytologically confirmed NPC; stage IVB (UICC/AJCC 8th edition) or locoregional recurrence not amenable to curative local therapy; at least one measurable lesion per RECIST v1.1; and adequate organ function. Key exclusion criteria include severe uncontrolled pulmonary disease, active autoimmune disease, or a history of autoimmune disease requiring systemic immunosuppressive therapy. Eligible patients receive becotatug vedotin (2.0 mg/kg, IV, D1, Q3W) and pucotenlimab (200 mg, IV, D1, Q3W) until disease progression, unacceptable toxicity, or death. Dose adjustments are permitted based on toxicities. The primary endpoint is progression-free survival (PFS), defined as the time from treatment initiation to disease progression or death from any cause. Secondary endpoints include objective response rate (ORR), disease control rate (DCR), duration of response (DoR), overall survival (OS), treatment-related safety, and predictive biomarkers. Research Sponsor: Lepu Biopharma Co., Ltd. Clinical trial information: NCT07381699. Research Sponsor: None.

TPS6131 **Poster Session**

ERBIOTAX (TTCC-2022-02): A phase II, multicenter, randomized study of cetuximab with or without weekly paclitaxel after progression on first-line pembrolizumab plus platinum/5-FU in recurrent or metastatic head and neck squamous cell carcinoma. First Author: Marc Oliva, Medical Oncology Department, Institut Català d'Oncologia (ICO), L'hospitalet De Llobregat, Barcelona, Spain

Background: Pembrolizumab, with or without platinum–5FU (PF), is the current first-line (1L) standard of care for PD-L1–positive recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN). However, no established standard of care exists after progression on immune checkpoint inhibitors (ICI). Emerging evidence suggests that cetuximab administered post-ICI achieves higher objective response rates (ORR) and longer progression-free (PFS) and overall survival (OS) compared with historical second-line (2L) cetuximab outcomes from the pre-ICI era. We hypothesize that 2L treatment with cetuximab +/- paclitaxel may be more effective after ICI failure than previously observed in the pre-ICI era. **Methods:** This is a multicenter, open-label, randomized, non-comparative, two-arm, investigator-initiated phase 2 trial. Patients will be randomized (2:1) to cetuximab plus paclitaxel (Arm A: ERBITAX) or cetuximab monotherapy (Arm B), administered on Days 1, 8 and 15 of 21-day cycles for 4 cycles, followed in both arms by biweekly cetuximab monotherapy until disease progression, death, unacceptable toxicity, or withdrawal of consent. A total of 65 evaluable patients will be enrolled: 41 in Arm A (H0: ORR 25%, H1: 45%, 80% power, two-sided alpha 0.05) and 24 in Arm B (H0: ORR 10%, H1: 30%, 80% power, two-sided alpha 0.05). The primary endpoint is ORR in each arm. Secondary endpoints include disease control rate (DCR), PFS, OS, health-related quality of life (EORTC QLQ-C30, EORTC QLQ-H&N35 and EuroQol EQ-5D) and safety. Baseline tumor tissue (all patients) and on-treatment samples (between cycles 2-5 in 50% of patients; optionally at progression), as well as serial plasma samples will be collected for translational exploratory studies. Patients must have histologically confirmed SCCHN of oral cavity, oropharynx (HPV-positive or HPV-negative), hypopharynx, or larynx, with confirmed progression per RECIST 1.1. on or after 1L pembro + PF. The study started enrollment in June 2025, with 7 patients enrolled by December 23, 2025. The total accrual period is 18 months. Clinical trial identifiers: NCT06856213; EUDRACT 2024-514953-31-00. Trial supported by Merck, S.L.U., Madrid, Spain, an affiliate of Merck KGaA, Darmstadt, Germany, providing study medication and financial support. Clinical trial information: NCT06856213. Research Sponsor: Merck, S.L.U., Madrid, Spain, an affiliate of Merck KGaA, Darmstadt, Germany,.

TPS6132 **Poster Session**

FIERCE-HN: A multicenter, randomized, double-blind, placebo-controlled, phase 3 study of ficlatuzumab (HGF/cMET mAb) in combination with cetuximab in participants with recurrent or metastatic (R/M) HPV-negative head and neck squamous cell carcinoma (HNSCC). First Author: Julie E. Bauman, GW Cancer Center, George Washington University, Washington, DC

Background: Patients with HPV negative R/M HNSCC have a worse median overall survival (OS) than those with HPV positive disease and current treatment options are limited. [1] Ficlatuzumab is a humanized IgG1 mAb that binds HGF, the ligand for the c-MET tyrosine kinase receptor. HGF/c-MET pathway dysregulation is frequently observed in HPV negative HNSCC and has been linked to EGFR inhibitor resistance, limiting the potential efficacy of EGFR-targeting drugs like cetuximab. In a phase 2 study, both pathways were targeted using ficlatuzumab plus cetuximab in patients with HPV negative R/M HNSCC resistant to cetuximab, platinum, and anti-PD1 immune checkpoint inhibitors (ICI) who have a very poor historical prognosis. A PFS of 4.1 months, median OS of 7.4 months, and overall response rate (ORR) of 38% (6/16; 2 CR, 4 PR) was observed. [2] FIERCE-HN compares the efficacy and safety of ficlatuzumab+cetuximab vs placebo+cetuximab in patients with R/M HPV negative HNSCC. **Methods:** This is an international, multicenter, randomized, double-blind, placebo-controlled phase 3 study. Major enrollment criteria include confirmed diagnosis of R/M HNSCC primary tumors of the oropharynx (p16 negative only), oral cavity, hypopharynx, or larynx. Participants must have progressed on, or be intolerant to, previous anti-PD-1/PD-L1 ICI and platinum-based chemotherapy; have received 2 or fewer prior lines of anticancer therapy in the R/M setting; and have had no prior treatment with cetuximab/alternative EGFR inhibitors in the R/M setting. Patients with feeding tubes are eligible. The primary endpoint is OS; key secondary endpoints include PFS and ORR. Other secondary endpoints are DCR, DoR, safety, PK, immunogenicity and QoL. Patients will receive cetuximab 500mg/m2 and are randomized 1:1:1 to Arm A: ficlatuzumab 10mg/kg, Arm B: ficlatuzumab 20mg/kg, or Arm C: placebo. Treatments will be on Days 1 and 15 of a 28-day cycle. This is an adaptive study with two interim analyses (IAs). IA-1 is ongoing to select the optimal dose. Participants enrolled after IA-1 will be randomized 1:1 to the optimal ficlatuzumab dose or placebo, plus cetuximab. IA-2 will be conducted after ~ 163 OS events to assess whether an event count re-estimation is needed. The final analysis will occur after ~ 232 (or up to 279) OS events, depending on the re-estimation outcome. The study has statistical power of 80%, assuming a true OS hazard ratio of 0.667. Between 410 to 500 patients will be enrolled. The study is ongoing and actively recruiting in North America, Europe, United Kingdom, and Asia-Pacific. Clinical trial information: NCT06064877 (Eli Lilly provided cetuximab in N. America and Merck KGaA, Darmstadt, Germany in Europe, United Kingdom and Asia-Pacific). 1. JITC. 2019;7:184. 2. JCO. 2023. 41:3851. Clinical trial information: NCT06064877. Research Sponsor: AVEO Pharmaceuticals, Inc.

TPS6133 **Poster Session**

A phase III multicenter randomized non-inferiority trial comparing selective versus modified neck dissection in node-positive oral squamous cell carcinoma (SND vs MND). First Author: Rakesh Katna, Tieten Medicity Hospital, Mumbai, India

Background: Neck dissection is a critical component in the management of oral squamous cell carcinoma (OSCC) with nodal involvement. While modified neck dissection (MND) is widely practised in node-positive disease, selective neck dissection (SND) may offer comparable oncologic outcomes with reduced morbidity. Retrospective studies and meta-analyses suggest similar survival and regional control with SND in selected patients; however, high-quality prospective randomized evidence is lacking. This trial aims to evaluate whether SND is non-inferior to MND in terms of disease-free survival in treatment-naïve, node-positive OSCC patients. **Methods:** This is a prospective, multicenter, randomized, non-inferiority controlled trial enrolling patients aged 18–70 years with clinically and radiologically confirmed node-positive OSCC (T1–T4, N+), ECOG performance status 0–1, and adequate organ function. Eligible participants are randomized 1:1 to undergo primary tumor resection with either selective neck dissection (Arm A) or modified neck dissection (Arm B). Adjuvant radiotherapy or chemoradiotherapy is administered according to adverse pathological features, including extracapsular extension and positive margins. Randomization is stratified by participating centres. The planned accrual period is 3 years, followed by 2 years of follow-up. The study is conducted at four tertiary cancer centres in India. The primary endpoint is disease-free survival. Secondary endpoints include overall survival, regional recurrence rate, treatment-related morbidity, and quality of life assessed using EORTC QLQ-C30 and QLQ-H&N35 questionnaires. Statistical Considerations: Assuming a 24-month DFS of 85% in the MND arm and a non-inferiority margin of 10%, a total of 432 patients (216 per arm) provides 80% power with a one-sided alpha of 0.05. Non-inferiority will be concluded if the upper bound of the 90% confidence interval for the hazard ratio is less than 1.5. Survival analyses will be performed using Kaplan–Meier methods and Cox proportional hazards models. The study has received institutional ethics approvals at participating centres and is registered with the Clinical Trials Registry of India. Patient recruitment is ongoing. This trial will provide prospective evidence regarding the oncologic equivalence of selective and modified neck dissection in node-positive OSCC and may help define a less morbid standard surgical approach. This trial will provide prospective evidence regarding the oncologic equivalence of selective and modified neck dissection in node-positive OSCC and may help define a less morbid standard surgical approach. Clinical trial information: CTRI/2024/11/076784. Research Sponsor: None.

TPS6134 **Poster Session**

Phase 1 study of VLPONC-01, a novel IL-12–encoding saRNA viral replicon particle, alone and in combination with pembrolizumab in head and neck cancer patients: Protocol summary. First Author: Summer F. Acevedo, VLP Therapeutics, Inc., Gaitersburg, MD

Background: Head and neck squamous cell carcinoma (HNSCC) has high recurrence rates despite standard perioperative treatments such as surgery with adjuvant radiotherapy and/or chemotherapy, with about 35% of patients relapsing. Neoadjuvant immune checkpoint therapy has shown promise: in the Phase III KEYNOTE-689 trial, adding perioperative pembrolizumab to standard care significantly improved median event-free survival (51.8 vs 30.4 months), leading to FDA approval in June 2025. However, only 9.4% of patients achieved a major pathologic response, a key predictor of reduced relapse and a surrogate for long-term benefit in other cancers. This low response rate underscores the need for more effective strategies to expand and deepen durable immune-mediated tumor responses in HNSCC. Our strategy is to develop a combination immunotherapy/gene therapy targeting the immunosuppressive myeloid populations such as tumor-associated macrophages (TAMs) and neutrophils (TANs), which are increasingly recognized as key mediators of immune evasion and poor outcomes. VLPONC-01 is a novel, non-replicating, viral particle-based therapy to target TAMs and TANs. VLPONC-01 efficiently delivers self-amplifying RNA (saRNA) encoding an engineered human Interleukin 12 (IL-12) gene into cells in the tumor microenvironment (TME), leveraging the natural tropism of Venezuelan equine encephalitis virus (VEEV). Within transfected cells, the RNA amplifies itself and directs the cell to produce and secrete IL-12 protein. The released IL-12 is expected to concentrate in the TME, where it activates immune cells and enhances their ability to attack cancer cells. **Methods:** This is a first-in-human, phase 1, open-label trial evaluating the safety and early efficacy of intratumoral administration of VLPONC-01 in patients with HNSCC, focusing on its ability to reduce tumor burden and lessen surgical morbidity. Furthermore, it will characterize IL-12-driven alterations in the tumor microenvironment and determine the synergistic potential of combining this approach with anti-PD-1 immunotherapy. The study includes two cohorts: Cohort A tests weekly intratumoral injection in recurrent and/or metastatic tumor patients to assess safety and determine dose levels, while Cohort C randomizes patients with resectable tumors into three groups to receive low-dose VLPONC-01 plus pembrolizumab, high-dose VLPONC-01 plus pembrolizumab, or pembrolizumab alone, prior to surgery. Outcomes include dose-limiting toxicities, surgical delays, systemic cytokine responses, and tumor response assessed by imaging and pathology. Clinical trial information: NCT06736379. Research Sponsor: None.

TPS6135 **Poster Session**

A randomized, non-comparative, multicenter phase II trial of neoadjuvant becotatug vedotin alone or combined with immune checkpoint inhibitors (penpulimab/ivonescimab) in resectable locally advanced head and neck squamous cell carcinoma. First Author: Xiaoyuan Wei, Division of Head & Neck Tumor Multimodality Treatment, Cancer Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: The efficacy and safety of neoadjuvant therapy for resectable locally advanced head and neck squamous cell carcinoma (LAHNSCC) remain uncertain, and optimal treatment protocols needs further explored. Epidermal growth factor receptor (EGFR) is overexpressed in 90% of head and neck squamous cell cancers (HNSCC) and plays a critical role in tumor proliferation and survival. Antibody drug conjugates (ADCs) represent an emerging class of cancer therapeutics that combines several mechanisms of action to improve efficacy and reduce the systemic toxicity. Becotatug Vedotin is a novel ADC molecule of an anti-EGFR humanized immunoglobulin G1 (IgG1) monoclonal antibody conjugated with monomethyl auristatin E via a valine-citrulline linker. Studies have shown that combining immunotherapy with an Anti-EGFR monoclonal antibody may produces a synergistic anti-tumor effect. This study aims to assess the efficacy and safety of neoadjuvant Becotatug Vedotin, alone or in combination with immune checkpoint inhibitors Penpulimab, an anti-PD-1 monoclonal antibody, or Ivonescimab, a bispecific anti-PD-1/VEGF-A antibody, in patients with resectable LAHNSCC. **Methods:** This is a randomized, non-comparative, multicenter phase II clinical trial. Key eligible patients aged 18–70 years with previously untreated, pathologically confirmed LAHNSCC (oral, laryngeal, hypopharyngeal, and oropharyngeal carcinoma), resectable and ECOG 0–1 will be enrolled. Main exclusions include active autoimmune diseases, use of immunosuppressive drugs, or systemic corticosteroids. Patients will be allocated to 3 cohorts, and all will receive three preoperative cycles of Becotatug Vedotin(2.3 mg/kg, ivgtt, Q3W) with or without immune checkpoint inhibitors: Cohort 1 (monotherapy); Cohort 2 (combined with Penpulimab, 200 mg, ivgtt, Q3W); Cohort 3 (combined with Ivonescimab, 10 mg/kg, ivgtt, Q3W). Surgery will be scheduled 2 to 4 weeks after the completion of neoadjuvant therapy, followed by adjuvant radiotherapy or chemoradiotherapy based on risk factors. Subjects in Cohorts 2 and 3 will continue immune checkpoint inhibitor therapy for 14 cycles following the completion of radiotherapy. Dose adjustments are permitted based on toxicity. The primary endpoint is Pathologic Complete Response (PCR).Secondary endpoints include major Pathological Response (MPR), objective Response Rate (ORR), 1-year Event-Free Survival (EFS) Rate, 2-year Overall Survival (OS) Rate, treatment-related safety, and predictive biomarkers. Research Sponsor: Lepu Biopharma Co., Ltd. Clinical trial information: NCT07381075. Research Sponsor: None.

TPS6136 **Poster Session**

Neoadjuvant cemiplimab plus cetuximab prior to salvage surgery for recurrent oral cavity squamous cell carcinoma. First Author: Luana Guimaraes de Sousa, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Locoregional recurrence of oral cavity squamous cell carcinoma (OCSCC) after curative-intent therapy remains a major cause of morbidity and mortality. Salvage surgery is the standard of care when feasible but is associated with substantial functional impairment. The combination of PD-1 blockade and EGFR inhibition has demonstrated promising activity in the recurrent/metastatic setting. We hypothesize that the combination of cemiplimab and cetuximab will elicit a robust antitumor response in patients with resectable recurrent OCSCC that will lead to improved clinical outcomes. **Methods:** This is an open-label, single-center, phase II trial designed to assess the efficacy and safety of cemiplimab plus cetuximab in patients with recurrent, resectable OCSCC irrespective of PD-L1 status (NCT06448026). Key eligibility criteria include histologically confirmed locoregional recurrence at least 3 months after prior curative-intent therapy, including surgery and postoperative radiation, ECOG performance status 0–1, measurable disease per RECIST v1.1, and adequate organ function. Eligible participants receive neoadjuvant cemiplimab 350 mg intravenously every 3 weeks for two cycles combined with weekly cetuximab (loading dose 400 mg/m² followed by 250 mg/m² for up to 6 weeks), followed by salvage surgery. Patients achieving ≥50% pathologic tumor response are eligible to receive adjuvant cemiplimab for up to one year. Blood and tumor tissue for correlative analyses are collected at baseline, during treatment, and at the time of surgery. The primary endpoint is the rate of pathologic tumor response ≥50% (pTR-2) assessed in the surgical specimens local and/or regional. Secondary endpoints include objective response rate per RECIST v1.1, pathologic response rate, disease-free survival, overall survival, and safety. The planned sample size is 17 patients based on a Simon two-stage design. The study is active and accruing; to date, 9 of 17 planned patients have been enrolled. Clinical trial information: NCT06448026. Research Sponsor: Regeneron Pharmaceuticals.

TPS6137 **Poster Session**

GP regimen chronomodulated induction chemotherapy combined with concurrent chemoradiotherapy for locally advanced nasopharyngeal carcinoma: A phase III, multicenter, randomized controlled study. First Author: Feng Jin, Affiliated Hospital of Guizhou Medical University/Department of Head and Neck Oncology, Affiliated Cancer Hospital of Guizhou Medical University, Guiyang, GuiZhou, China

Background: Radiotherapy is the primary treatment for nasopharyngeal carcinoma (NPC). Currently, induction chemotherapy combined with concurrent chemoradiotherapy has become a Category I recommendation for NPC treatment. Studies show that the GP regimen is one of the most effective induction chemotherapy protocols for locally advanced NPC. However, the incidence of grade 3-4 acute toxicities with the GP regimen is as high as 75.7%, severely affecting patient treatment compliance. To reduce toxicity while maintaining efficacy, this study focuses on a "chronomodulated chemotherapy" strategy, which adjusts drug administration timing based on biological rhythms to minimize damage to normal tissues. **Methods:** Clinical Data: 1. Sample Size Calculation: This study is a randomized controlled trial with a non-inferiority design. Based on a 3-year recurrence-free survival rate of 85.3% in the conventional group, a non-inferiority margin (δ) of 10%, a one-sided α of 0.025, a power (1-β) of 0.8, equal group sizes, and accounting for a 10% dropout rate, the calculated total sample size is 434 subjects. 2. Inclusion Criteria: Treatment-naïve patients with Stage III or IVa non-keratinizing nasopharyngeal carcinoma (UICC/AJCC 8th edition). 3. Exclusion Criteria: History of prior malignancy, prior radiotherapy, or presence of other severe diseases. 4. Withdrawal Criteria: Occurrence of severe adverse events or intolerable toxicities during the study. Treatment Protocol: 1. Induction Chemotherapy Phase: Experimental Group: Gemcitabine 1000 mg/m², IV infusion over 30 min on days 1 & 8, administered between 08:00-09:30; Cisplatin 80 mg/m², continuous IV infusion (civ) on day 1, delivered evenly over 12 h from 10:00 to 22:00. Repeated every 3 weeks (Q3W) for 3 cycles. Control Group: Gemcitabine 1000 mg/m², IV infusion over 30 min on days 1 & 8; Cisplatin 80 mg/m², IV infusion over 2-3 h on day 1. Q3W for 3 cycles. 2. Concurrent Chemoradiotherapy Phase: Concurrent Cisplatin Regimen: Experimental Group: Cisplatin 100 mg/m², civ on day 1, delivered evenly over 12 h from 10:00 to 22:00. Q3W for 3 courses. Control Group: Cisplatin 100 mg/m², IV infusion over 2-3 h on day 1. Q3W for 3 courses. 3. Radiotherapy: Intensity-Modulated Radiation Therapy (IMRT) was used, with a total dose of 69.96-72.6 Gy delivered in 33 fractions. Innovation: Therapeutic efficacy for nasopharyngeal carcinoma has reached a plateau, making “toxicity reduction” a key research focus. The toxicity-reducing approach of chronomodulated chemotherapy holds promising application prospects for locally advanced nasopharyngeal carcinoma. Current Status: To date, 122 patients have been enrolled. Clinical trial information: ChiCTR2400086032. Research Sponsor: None.

TPS6138 **Poster Session**

NRG-HN006: Randomized phase II/III trial of sentinel lymph node biopsy versus elective neck dissection for early-stage oral cavity cancer. First Author: Stephen Yenzen Lai, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with early-stage oral cavity cancer (OCC; T1-2N0M0; AJCC 8th edition) have a 20-30% risk of occult nodal metastases despite clinical and radiographic evaluations. Standard-of-care treatment for most patients includes elective neck dissection (END), which requires surgical removal of the regional cervical lymph nodes, even though 70-80% of these necks are disease-free. Sentinel lymph node biopsy (SLN Bx), a less invasive procedure, could assess the first echelon lymph nodes as an alternative to END, potentially reducing morbidity and costs. A pivotal clinical trial comparing SLN Bx to END (NCT#04333537) is underway to inform efforts to establish optimal disease management for early-stage OCC. **Methods:** To assess the efficacy of SLN Bx in this population, we activated an international, multi-institutional, prospective phase II/III trial in July 2020, randomizing patients to two surgical arms: SLN Bx and END. A node-negative ^{18}F-FDG PET/CT imaging biomarker study with centralized read was required before randomization. OCC patients with a positive PET/CT remained in a registry to compare imaging findings with final neck pathology. Given the current evidence on morbidity for SLN Bx versus END, the phase II was designed to determine whether the change in patient-reported neck and shoulder function and related quality of life (QOL) from baseline to 6 months after surgery, using the Neck Dissection Impairment Index (NDII), showed a signal of superiority of SLN Bx compared to END (minimum important difference ³ 7.5; one-sided a = 0.10; 90% power). As of December 2024, 261 patients had been randomized and 203 were analyzed for the “Go/No-Go” decision to move forward into phase III. The phase III portion is a non-inferiority (NI) trial with disease-free survival (DFS) as the primary endpoint (NI margin hazard ratio 1.34 based on a 5% absolute difference in 2-year DFS; one-sided a = 0.05; 80% power, and two interim looks). The change in NDII from baseline to 6 months after surgery is a hierarchical co-primary endpoint for phase III. Phase III opened in October 2025 upon receiving a “Go” signal from phase II. Target accrual for phase III is 686 node-negative PET/CT patients, including those randomized in phase II (425 additional patients). In addition to sites requiring radiotherapy and imaging credentialing, quality assurance will include central pathology review of all negative SLN Bx cases and surgeon credentialing through an education course with SLN Bx and END case review by the surgical co-chairs. A surgical quality assurance working group will review all trial SLN Bx and END procedures. As of 01/12/26, 351 patients have been screened, and 273 of the planned 686 have been randomized. Clinical trial information: NCT#04333537. Research Sponsor: National Cancer Institute and Cardinal Health; UG1CA189867, U10CA180822, U10CA180868.

TPS6139 **Poster Session**

Neoadjuvant therapy for head and neck squamous cell carcinoma based on hyperprogression genotyping: Cetuximab beta combined with chemotherapy with or without camrelizumab. First Author: Ziyu Jiang Jr., The First People's Hospital of Lianyungang, Lianyungang, Jiangsu, China

Background: Surgery remains the preferred treatment option for locally advanced head and neck squamous cell carcinoma (LA HNSCC). However, its efficacy is still unsatisfactory, with local recurrence and distant metastasis rates as high as 20% and a 5-year survival rate of only about 50%. Immune checkpoint inhibitors (ICIs) have achieved success in recurrent/metastatic HNSCC (R/M HNSCC), laying the foundation for the application of immunotherapy in earlier-stage patients. Cetuximab, an anti-Epidermal Growth Factor Receptor (EGFR) antibody, is a standard treatment for both LA HNSCC and R/M HNSCC. Patients who experience Hyperprogressive Disease (HPD) have a poor prognosis, and various genetic mutations have been shown to predict the occurrence of HPD. **Methods:** This study was designed as a prospective, open label, multicenter, phase II trial (ChiCTR2500108701), and the primary endpoint was the postoperative pathological complete response (pCR) rate. The secondary endpoints included the objective response rate (ORR), major pathological response (MPR) rate, 1-year and 2-year event-free survival (EFS) rates, and 2-year overall survival (OS) rate. Eligible patients (pts) were over 18 years old with histologically or cytologically confirmed SCCHN (excluding nasopharyngeal carcinoma); had T1N2-3M0, T2N1-3M0, or T3/T4aNanyM0, according to the 8th Edition of the American Joint Committee on Cancer (AJCC) staging guidelines; had resectability of the tumor was evaluated by a head and neck surgeon; had no previous local and systemic treatment for SCCHN; had an Eastern Cooperative Oncology Group (ECOG) performance status score of 0 or 1; had measurable disease per Response Evaluation Criteria in Solid Tumours (RECIST 1.1). All enrolled 40 pts received whole exome sequencing (WES), and were assigned to Cohort A (n=25, HPD-gene-negative) and Cohort B (n=15, HPD-gene-positive), respectively. All treatment was administered intravenously in 21-day cycles. Patients in Cohort A were given albumin-bound paclitaxel (260 mg/m², d1), cisplatin (25 mg/m², d1-d3), camrelizumab (200 mg, d1) and cetuximab (250 mg/m², d1;500 mg/m², d8). Patients who successfully completed 2~4 cycles of neoadjuvant treatment returned for surgical intervention 28~42 Endpoints days after the last cycle, and adjuvant radiotherapy was administered followed by 2~4 cycles of camrelizumab (200 mg, d1) and cetuximab (250 mg/m², d1; 500 mg/m², d8) as adjuvant treatment.Cohort B received the same treatment regimen as Cohort A, excluding camrelizumab. Clinical trial information: ChiCTR2500108701. Research Sponsor: None.

TPS6140 **Poster Session**

EA3231: A randomized phase III study of BRAF-targeted therapy vs cabozantinib in RAI-refractory differentiated thyroid cancer with *BRAF* V600Em.

First Author: Lova Sun, University of Pennsylvania, Philadelphia, PA

Background: About half of patients with RAIR advanced differentiated thyroid cancer (DTC) harbor a mutation in BRAF V600E. Although multiple systemic therapies are now approved, optimal treatment sequencing remains undefined for patients with BRAF V600Em RAIR DTC. Given the indolent natural history of this disease and often prolonged exposure to oral therapies with significant toxicity, comparative data on efficacy and tolerability of second-line therapy is a clear unmet need. **Methods:** EA3231 (NCT06475989) is a NCTN cooperative group randomized phase III study in patients with BRAF V600Em RAIR DTC who have progressed on prior multikinase inhibitor therapy such as lenvatinib or sorafenib. Patients will be randomized 1:1 to BRAF-targeted therapy (dabrafenib and trametinib) or cabozantinib, all of which are FDA-approved agents in this setting. The primary objective is to compare progression-free survival (PFS) between dabrafenib/trametinib vs cabozantinib, with secondary objectives including overall response rate, overall survival, PFS2, and safety and tolerability. We hypothesize that BRAF-directed therapy will be associated with improved PFS and tolerability compared to cabozantinib. Our target accrual is 120 patients; this sample size will provide 83% power to detect a HR of 0.60 (corresponding to a median PFS of 12 months) compared to an estimated median PFS of 7.2 months in the cabozantinib arm. This study was activated in late 2024, and has enrolled 8/120 patients as of 1/2026. Clinical trial information: NCT06475989. Research Sponsor: None.

Selinexor plus ruxolitinib in JAK inhibitor–naïve myelofibrosis: Phase 3 SENTRY trial. First Author: John Mascarenhas, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

6501 **Oral Abstract Session**

RALLY-MF: Initial efficacy of a phase 2 study of DISC-0974, an anti-hemojuvelin antibody, to treat anemia in myelofibrosis. First Author: Naseema Gangat, Mayo Clinic Rochester, Rochester, MN

Background: Hepcidin, a central regulator of iron homeostasis, is pathologically elevated in patients with myelofibrosis (MF) and anemia. Chronic hepcidin elevation limits iron availability for red blood cell (RBC) production and contributes to anemia onset and severity. DISC-0974 is an investigational, first-in-class, monoclonal antibody that blocks hemojuvelin, a co-receptor in the bone morphogenetic protein-signaling pathway driving hepcidin expression. **Methods:** RALLY-MF (NCT05320198) is an ongoing Phase 2, open-label study conducted in the US. The primary aim is to evaluate DISC-0974 efficacy in participants with MF and anemia. Secondary aims include evaluating safety, pharmacokinetics (PK), and pharmacodynamics (PD). Eligible participants are ≥18 years of age with primary or secondary MF and hemoglobin (Hgb) <10 g/dL or RBC transfusion requirement. Participants enroll into 3 cohorts based on RBC units transfused in the 84 days prior to screening: non-transfusion dependent (nTD, 0 units and Hgb <10 g/dL), low transfusion burden (TD low, 1-2 units), high transfusion burden (TD high, 3-12 units). Stable dose of concomitant Janus kinase inhibitor (JAKi) is allowed. DISC-0974 is administered subcutaneously at 50 mg monthly for up to 6 doses, with escalation to 75 mg for inadequate or lost response. Primary endpoints include major hematologic response defined as transfusion independence (TI) during any consecutive 16 weeks (TD low) or 12 weeks (TD high), or a mean Hgb increase of ≥1.5 g/dL from baseline for ≥12 weeks (nTD). Secondary endpoints include PK/PD markers of iron regulation and safety assessments. Data were summarized using descriptive statistics. **Results:** At data cut (16 Oct 2025), 47 participants enrolled in the nTD (n=30), TD low (n=10), and TD high (n=7) cohorts, with 53% on concomitant JAKi therapy. DISC-0974 led to sustained hepcidin reduction and iron mobilization across cohorts. DISC-0974 resulted in meaningful hematologic responses among evaluable participants: 50% of nTD participants achieved a mean Hgb increase of ≥1.5 g/dL for ≥12 weeks, 71% of TD low participants achieved TI for ≥16 weeks, and 67% of TD high participants experienced a ≥50% reduction in transfusion burden, with follow-up ongoing. Major hematologic response rates were 50% for participants on and off concomitant JAKi therapy (n=18 and n=16, respectively). DISC-0974 was associated with meaningful improvement in FACIT-Fatigue scores for nTD and TD low participants. Serious adverse events (AEs, n=9) and ≥Grade 3 AEs (n=16) were considered unrelated to DISC-0974. There were no early withdrawals due to AEs. **Conclusions:** DISC-0974 was well tolerated and shows a favorable safety profile. Anemia response and fatigue scores improved across patients with MF and anemia, including those receiving JAKi therapy. These data validate hepcidin reduction as a promising approach to treating anemia in MF. Clinical trial information: NCT05320198. Research Sponsor: Disc Medicine.

6502 **Oral Abstract Session**

A phase II trial of tagraxofusp, hyper-CVAD, and venetoclax for patients with newly diagnosed or relapsed/refractory BPDCN. First Author: Hannah Goulart, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare, aggressive hematologic malignancy with (w/) historically dismal outcomes, including median (med) overall survival (OS) of 8 – 12 months (mos) and frequent central nervous system (CNS) involvement (Martin-Martin *Oncotarget* 2016, Pemmaraju *Blood* 2021). Tagraxofusp (TAG; first CD123-targeted therapy approved for BPDCN) improves responses (Pemmaraju *JCO* 2022), but relapse remains common. Venetoclax (VEN) demonstrates activity in BPDCN (Montero *Cancer Disc* 2017), and intensified chemotherapy may improve outcomes. We report the results of a phase II investigator-initiated trial (NCT04216524) of TAG, Hyper-CVAD, and VEN in newly diagnosed (ND) or relapsed/refractory (R/R) BPDCN. **Methods:** Adults (≥18 years [yrs]) w/ ND or R/R BPDCN received: Cycle [C] 1: TAG days [d] 1-5; C2, 4, 6, 8: TAG d1 – 5 w/ VEN d2 – 14 (C2) and d1 – 7 (C4, 6, 8); C3, 7: VEN d1 – 7 w/ Hyper-CVAD or mini-hyper-CVD; C5: VEN d1 – 7 w/ high-dose methotrexate/cytarabine or mini-methotrexate/cytarabine. Cycles were 28 days for up to 8 cycles, followed by POMP, VEN, and TAG maintenance. Pts received ≥8 intrathecals. **Results:** Nineteen pts were enrolled (14 ND; 5 R/R). Med age was 61 yrs (range, 20 – 79); 79% male. Disease sites included 84% skin, 63% bone marrow, 16% CNS, 16% extramedullary. Co-occurring mutations were *TET2* (60%), *ASXL1* (33%), *DNMT3A* (20%), *NRAS* (13%), *KRAS* (13%). Two pts had prior/concomitant MDS. For ND, overall response rate (ORR; complete remission [CR] plus CR w/ incomplete count recovery [CRi] plus partial response [PR]) was 93% (13/14, all CR/CRi). Pts received a med of 2 (1 – 6) cycles w/ 2 (1 – 3) cycles to best response. The 30- and 60-day mortality was 0%. After a 55-mos med follow-up, (19.5 – NR), med OS was 15 mos w/ 24-month OS of 42%. Med EFS was 14.6 mos w/ 24-month EFS of 42%. Nine pts (65%) went to stem cell transplant (SCT) (2 died in CR, 6 remain alive in CR; of these, 3 remain alive in CR almost 5 yrs; with only 1 post-SCT relapse). In the 4 responding pts who did not go to SCT, 3 relapsed, 1 died in CR. For R/R, ORR was 100%; CR/CRi of 50%. Pts received a med of 2 (2 – 4) prior lines; 3 (60%) had prior SCT. Pts received a med of 3 (1 – 7) cycles w/ 3 (1 – 3) to best response. Two pts went to SCT (1 auto, 1 allo); 1 pt is alive on active treatment. The 30- and 60-day mortality was 0% and 20%. With f/u ranging 1.4 – 21.8 mos, med OS and EFS is 8.9 mos; 12-month OS and EFS was 30%. In responding pts, causes of death were progression n = 4; died in CR n = 5 (3 ND, 2 R/R, 1 post SCT, 1 unknown, 3 sepsis). The most common any grade adverse events (AE) were edema (n = 13) and fatigue (n = 11). There were 2 grade 5 AE (progression, respiratory failure). Two grade 3 capillary leak events were observed. **Conclusions:** As frontline therapy, TAG with Hyper-CVAD, and VEN shows promising safety with no early mortality or high-grade CLS, with high response rates enabling frequent SCT consolidation and no CNS relapse. Clinical trial information: NCT04216524. Research Sponsor: Stemline.

6503 **Oral Abstract Session**

A multicenter phase Ib/II trial of azacitidine, venetoclax, and ivosidenib in *IDH1*-mutated acute myeloid leukemia (AML). First Author: Jennifer Marvin-Peek, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Outcomes for patients with *IDH1*^{mut} AML have improved with the advent of targeted therapies. Two doublet regimens are approved for *IDH1*^{mut} AML: venetoclax (VEN) with a hypomethylating agent (HMA), and azacitidine (AZA) plus ivosidenib (IVO). Both regimens are effective, yet a substantial proportion of patients fail to respond or eventually relapse. Combining all three agents into a "triplet" regimen may improve outcomes. Herein, we report results from the fully enrolled newly diagnosed (ND) cohort of the multicenter phase Ib/II study of AZA+VEN+IVO for *IDH1*^{mut} AML (NCT03471260). **Methods:** Adults ≥18 years with ND *IDH1*^{mut} AML not eligible for standard induction chemotherapy and treated at the RP2D in the phase Ib or II cohorts were included. Patients received AZA 75 mg/m^2 days 1-7, VEN 400mg days 1-14, and IVO 500mg continuously starting C1D14. Dose attenuations in remission were permitted to minimize myelosuppression. The primary objectives were to determine the safety and overall response rate (ORR: CR + CRh + CRi + MLFS). **Results:** From November 2019 to October 2025, 40 patients with ND AML at four U.S. academic centers initiated treatment (Phase Ib: 9, Phase II: 31). The median age was 72 years (range, 51-80), and 26 patients (65%) were male. AML was classified as *de novo* in 21 (53%), therapy-related in 4 (10%), and secondary to antecedent myeloid neoplasm in 15 (38%). Six (15%) had received a prior HMA. The ORR was 95% (38/40) with 93% (37/40) achieving a composite CR (CRc; CR+CRh+CRi). The median number of cycles to best response was two (range, 1-7). Measurable residual disease (MRD) negativity by flow cytometry (sensitivity <0.1%) was achieved in 92% (34/37) of CRc responders. With a median follow up of 35 months, median overall survival (OS) and duration of remission (DOR) were not reached. The 3-year OS was 79% (95% CI 64-96%). Three patients relapsed during follow-up with *IDH1*-negative clones, and 18 patients (45%) transitioned to SCT. The 3-year DOR censored and not-censored at SCT was 82% (95% CI 68-98%) and 83% (95% CI 64-100%), respectively. Among the 22 patients who did not undergo SCT, the median number of cycles received is 14, with 10 patients (45%) remaining on study. Reasons for discontinuation included lack of response/relapse (n=5), development of another malignancy (n=2), adverse events (AEs; n=2), and patient preference (n=1). Non-hematologic AEs occurred in 32 patients (80%), with 12 (30%) experiencing grade ≥3 AEs. Most grade ≥3 AEs were infectious (n=7, 23%), although two patients each experienced grade ≥3 QTc prolongation, tumor lysis syndrome, and differentiation syndrome, all successfully managed with supportive care and/or with dose modifications. **Conclusions:** Triplet therapy with AZA+VEN+IVO demonstrates high MRD negative response rates, durable remissions, and comparable safety to doublet regimens in this multicenter study for patients with ND *IDH1*^{mut} AML. Clinical trial information: NCT03471260. Research Sponsor: None.

6504 Oral Abstract Session

Quizartinib in combination with decitabine and venetoclax for newly diagnosed and relapsed/refractory *FLT3*-mutated AML. First Author: Musa Yilmaz, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Hypomethylating agents (HMAs; azacitidine/decitabine) plus venetoclax (VEN) are standard for newly diagnosed acute myeloid leukemia (AML) unfit for intensive chemotherapy; however FMS-like tyrosine kinase-3 internal tandem duplication (*FLT3-ITD*) confers resistance and poor overall survival (OS). Addition of quizartinib (QUIZ), a potent FLT3 inhibitor, may improve outcomes. **Methods:** Phase I/II study of QUIZ+decitabine+VEN in two cohorts: newly diagnosed *FLT3-ITD* AML pts unfit for intensive chemotherapy and relapsed/refractory (R/R) FLT3-ITD AML pts. Primary endpoints were maximum tolerated dose (MTD) and overall response rate (ORR). **Results:** Eighty-eight patients (pts) were enrolled (frontline N=42; R/R N=46). QUIZ 26.5mg/day was selected as the recommended phase II dose (RP2D). In the frontline cohort, median age was 70y (62–85); 15 pts (36%) were ≥75y; 25 (60%), 12 (N=28%), and 5 (12%) had de novo, secondary, and therapy-related AML, respectively. *DNMT3A* (43%), *NPM1* (33%), and *RUNX1* (31%) were the most common co-mutations. Complete remission (CR), CR with incomplete count recovery (CRi), morphologic leukemia-free state (MLFS), end-of-cycle-1 (EOC1) measurable residual disease (MRD) negativity by multicolor flow cytometry (MFC; 0.01%), and next-generation sequencing (NGS) FLT3-ITD negativity (5×10^{-5}) were 72% (N=29), 17% (N=7), 2% (N=1), 58% (19/32), and 27% (5/18), respectively; 2 pts in cycle 1 were not evaluable. Best MRD negativity by MFC and FLT3-NGS were 68% (23/34) and 83% (15/18). Median time to absolute neutrophil count (ANC) >500, ANC >1000, and platelets >50K were 40 (19–72), 41 (14–72), and 35 (16–71) days, respectively. The median relapse-free survival (RFS) and OS were 24.7 and 36.5mo. Fifteen pts (36%) proceeded to allogeneic stem cell transplant (ASCT) in CR1, with OS not reached vs 36.6mo without ASCT (p=0.65, landmark analysis). Median 3 cycles (1–39) were delivered; 11 pts remain on study. Thirty-one pts discontinued protocol due to ASCT (N=15), relapse (N=9), physician/pt choice (N=3), induction death (N=1), death in CR (N=1), death with disease (N=1), or hospice (N=1). Grade ≥3 non-hematologic adverse events (>5%) included febrile neutropenia (37%), pneumonia (33%), infections (17%), pain (10%), ALT increase (10%), fracture (10%), sepsis (9%), hypertension (7%), hypotension (7%), hyponatremia (7%), gait disturbance (7%), oral mucositis (7%), and pleural effusion (7%). In the R/R cohort, CR/CRi was 28% (N=13) with 33% (N=15) MLFS; 37% (N=17) proceeded to ASCT; median OS was 6.3mo (further data will be provided at the time of presentation). **Conclusions:** QUIZ+decitabine+VEN combination resulted in high CR/CRi, deep MRD responses, and encouraging survival in older pts with newly diagnosed *FLT3-ITD* AML. Clinical trial information: NCT03661307. Research Sponsor: None.

6505 Oral Abstract Session

Revumenib as maintenance for AML following allogeneic stem cell transplantation. First Author: Hannah Goulart, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Relapse after allogeneic stem cell transplantation (SCT) remains common in acute myeloid leukemia (AML). Revumenib is approved for relapsed/refractory (R/R) *NPM1*mt or *KMT2A*r acute leukemia however its safety and efficacy as post-SCT maintenance has not been characterized. We report outcomes of revumenib maintenance post-SCT in adult and pediatric patients (pts) at our institution. **Methods:** Pts with *NPM1*mt, *KMT2A*r or *NUP98*r AML could continue post-SCT revumenib maintenance following response pre-SCT to revumenib monotherapy or combination on clinical trial. Revumenib was resumed at pre-SCT dose with adjustment for azoles. **Results:** Twenty-one pts were included (11 adult, 10 pediatric); median age 20 years (range, 1 – 69), 62% female. Most (n = 16, 76%) had *KMT2A*r, 4 (19%) had *NPM1*mt, and 1 peds pt had *NUP98*r. Pre-SCT, revumenib was given as monotherapy per AUGMENT-101 (NCT04065399, n = 8) or Expanded Access (NCT05918913, n = 2) or with oral decitabine and venetoclax per SAVE (NCT05360160, n = 11). Pts received a median of 3 (1 – 11) prior therapies, 12 pts (57%) had prior SCT, and 4 pts received SAVE frontline. Maintenance post-SCT on SAVE was planned for 1 yr. At current SCT, 19% were in first complete remission (CR1 following SAVE), 81% were in CR2+ (SAVE or monotherapy). Median time to initiate post-SCT revumenib was 2.8 months (1.4 – 5.7) with median duration of therapy of 6.7 months (0.5 – 36). With a median follow-up of 18.2 months (95% CI 17.2 – 44.3), median overall survival (OS) and event-free survival (EFS) from SCT have not been reached; 1- and 2-year OS were 89%; 1- and 2-year EFS were 84% and 73%, respectively. The 1-year cumulative incidence of relapse (CIR) was 11% and death was 5%. In CR2+, 2-year OS was 93% and 1-year CIR was 13%. At last follow up, 29% remain on revumenib, and 71% have discontinued (relapse 14%, toxicity 14%, completion 14%, pt choice 14%, other illness 9%). The most common any grade adverse event (AE) was thrombocytopenia (86%; grade >3 43%), leading to dose modification in 48% and discontinuation in 10%. Graft-versus-host-disease occurred in 14% (grade >3 5%), however no other AE led to dose modification. Infections occurred in 14% (grade ≥3 10%); one pt discontinued due to grade 4 septic shock. No QTc prolongation was seen. In contrast, in a historical SCT cohort with the same genotypes treated prior to the advent of menin inhibitors (Table 1), pts transplanted at CR2+ had 2-year OS of 33% and 1-year CIR of 46%. **Conclusions:** Revumenib maintenance post-SCT was feasible in this heavily pretreated cohort. Thrombocytopenia was common often requiring dose modification, but no other significant toxicities were observed. Outcomes appear favorable compared to historical cohorts, supporting prospective evaluation of menin inhibition as maintenance. Clinical trial information: NCT04065399, NCT05918913. Research Sponsor: Syndax Pharmaceuticals.

6506 Oral Abstract Session

Safety, tolerability, and efficacy of mesutoclax (ICP-248) in combination with azacitidine in patients with myeloid malignancies. First Author: Huafeng Wang, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China

Background: Venetoclax has been approved for the treatment of newly diagnosed acute myeloid leukemia (AML) in elderly or unfit pts but failed in the high-risk myelodysplastic syndromes (MDS). Mesutoclax is a novel, potent, highly selective BCL-2 inhibitor. It exhibits favorable pharmacokinetic profile without any major metabolites. **Methods:** ICP-CL-01205 (NCT06656494) is an ongoing, global, phase I study evaluating mesutoclax in combination with azacitidine (AZA) in pts with AML or MDS. In the dose escalation part, mesutoclax at100 mg, 125 mg, and 150 mg in combination with AZA were evaluated for safety and tolerability. 100 mg and 125 mg were selected as Recommended dose for expansion (RDE) for further evaluation. Antitumor activity in AML and MDS is assessed based on ELN 2017 and IWG 2006/2023 criteria, respectively. Herein, we report safety, tolerability and efficacy for mesutoclax with AZA in pts with AML and MDS in this phase 1 study. **Results:** As of January 12, 2026, a total of 59 pts were enrolled including 8 R/R AML, 39 TN AML and 12 TN MDS. The median age of AML and MDS pts was 65 (range: 23, 81) and 67 years (range: 54, 75), respectively. Adverse risk per 2017 ELN was identified in 51.1% AML pts. Azole prophylaxis and G-CSF treatment were used in 5% and 22% pts. Among the 35 evaluable TN AML pts, 30 (85.7%) achieved composite CR (cCR, CR+CRi) with central assessment of CR rate of 65.7% (23/35). Among those who achieved cCR, 86.7% (26/30) were MRD negative per flow cytometry. MRD negative in CR (CR_{MRD-}) was 60% (21/35). cCR was 75% in adverse risk per 2017 ELN classification. The DOR rate at 3-months was 91.7%. The 6-month OS rate was 94.1%. Among 10 response evaluable TN MDS pts, the overall response rate (ORR) per IWG 2006 criteria was 100%, including CR in 20%, marrow CR in 80%. The composite CR rate was 70% per IWG 2023 criteria including 30% CR even when most pts only received 1 cycle treatment. There were no DLT or TLS events. The most common (≥10%) grade ≥ 3 TEAEs in pooled analysis of 59 AML and MDS were neutrophil count decreased (62.7%), platelet count decreased (50.8%), anemia (33.9%), infection (16.9%), and lymphocyte count decreased (11.9%). There were 5.1% grade ≥ 3 febrile neutropenia and no TEAEs lead to dose discontinuation. SAEs were reported in 25.4% pts. For pts with TN AML, the median intervals between cycle 1 and cycle 2 initiation (requiring neutrophil $\geq1*10^9$/l and platelet $\geq 100*10^9$/l) was 39 days and the median duration of grade 4 neutropenia and thrombocytopenia were 17 and 9 days, respectively. **Conclusions:** The combination of mesutoclax and azacitidine demonstrated a favorable safety profile and encouraging anti-tumor activity not only in AML but also in MDS pts, supporting its continued development for the treatment of myeloid malignancies. These preliminary results warrant further investigation in larger, randomized trials. Clinical trial information: NCT06656494. Research Sponsor: None.

6507 Oral Abstract Session

Safety and efficacy of eganelisib in adults with higher-risk myelodysplastic syndrome (HR-MDS) or relapsed/refractory (R/R) acute myeloid leukemia (AML). First Author: Mendel Goldfinger, Montefiore Medical Center, Bronx, NY

Background: The gamma isoform of PI3K (PI3Kγ) directs a myeloid-specific signaling node (PI3Kγ-AKT1-PAK1) identified as a core dependency in AML responsible for LSC self-renewal, medullary homing, and resistance to venetoclax and nucleoside analogues (Luo 2024; Gu 2024; Kelly 2024; Qiu 2025). Eganelisib is a highly potent isoform-specific inhibitor of PI3Kγ that demonstrated safety and effective target modulation in solid tumors. Here we report results of a Phase I study of eganelisib monotherapy in R/R AML or HR-MDS using doses previously shown to be biologically active [NCT06533761]. **Methods:** Eligible patients had ECOG PS <2, R/R AML or IPSS-R Int-Very High risk MDS that was R/R to prior therapy with ≥10% BM blasts. Eganelisib was administered orally in two cohorts of 45 mg and 60 mg QD in 28-day cycles. The primary endpoints were safety and efficacy per ELN 2022 (AML) and IWG 2023 (HR-MDS) and recommended dose for expansion (RDE). Additional endpoints included PK and PD effects assessed by AKT^{S273} phosphorylation in monocytes. **Results:** 15 patients have been treated to date (n=7, 45 mg; n=8, 60 mg); patient characteristics are summarized in the table below. There were no DLTs at either dose level. PD studies revealed dose-dependent reduction in AKT phosphorylation of ~90% at the 60 mg dose. Of the 10 patients who completed a 28-day cycle, anti-leukemic activity and evidence of clinical benefit was observed in 4 patients, including a CR in 1 patient at 45 mg. Three patients at 60 mg demonstrated anti-leukemic activity: 1 patient achieved <5% bone marrow blasts by flow cytometry, major cytogenetic response, rapid subclonal clearance, with full trilineage count recovery and low levels of persistent circulating blasts; two patients (both with TP53 mutations) with stable/decreasing marrow blasts had a progressive rise in neutrophils while on therapy. Longest duration of treatment is 5 cycles. Exposure to eganelisib was variable across both dose levels, and both doses showed overlapping plasma concentrations. **Conclusions:** Eganelisib demonstrates effective inhibition of PI3Kγ with single agent activity in heavily treated, poor-risk patients, validating PI3Kγ as a key vulnerability in MDS and AML. Importantly, eganelisib had no intrinsic hematologic toxicity, consistent with previous studies and pre-clinical observations that PI3Kγ is dispensable for normal hematopoiesis. Given the capacity to potentiate activity of nucleoside analogues and venetoclax, combined therapy in previously untreated HR-MDS & AML patients at the RDE of 60 mg QD is planned. Clinical trial information: NCT06533761. Research Sponsor: Stelexis BioSciences, Inc.

First-in-human dual-epitope nanobody anti-CD5 CAR-T for relapsed/refractory T-ALL/PTCL: Phase I dose-escalation and expansion results from the CONQUER trial. First Author: Meng Lv, Peking University People's Hospital, Beijing, China

Background: Patients with relapsed or refractory T-lymphoblastic leukemia/Peripheral T-Cell Lymphoma (R/R T-ALL/PTCL) experience dismal outcomes. Previously, we demonstrated naturally selected anti-CD7 CAR-T could overcome fratricide without gene editing or protein blockade, yielding encouraging clinical activity (Blood, 2022; 2025). CD5 is a critical pan–T-cell marker highly expressed in T-ALL/PTCL and represents a rational target beyond CD7. **Methods:** We developed SL105 injection, an autologous CD5-directed CAR-T cell product incorporating a tandem camelid-derived dual-epitope nanobody through a natural selection platform. This first-in-human phase I study evaluates the safety, preliminary efficacy, and recommended phase II dose (RP2D) of SL105 injection in patients with R/R T-ALL/PTCL (NCT06874946). **Results:** As of January 27, 2026, 37 patients provided informed consent; 18 patients received a single infusion of SL105 and completed the 28-day dose-limiting toxicity (DLT) assessment and constituted the enrolled population for analysis. Three dose levels (0.5, 1.0, and 2.0 $\times 10^6$ CAR-T cells/kg) were evaluated, with a minimum of two patients with T-ALL/LBL or PTCL enrolled at each dose level. Median age was 32 years (range, 16–57); 33.3% had prior hematopoietic stem cell transplantation. Diagnoses included T-ALL/LBL (n=11) and PTCL (n=7). Median follow-up was 6 months (range, 2–11). No DLTs were observed, and the recommended RP2D was established at 2.0 $\times 10^6$ CAR-T cells/kg. Median time to peak CAR-T expansion was 14 days by qPCR, with a median peak level of 6.3×10^4 copies/μg (range, 6–5.5×10^5). Cytokine release syndrome (CRS) occurred in 66.7% of patients; grade 2 CRS was observed in 21.7%, with no grade $\geq$3 CRS. One patient (5.5%) experienced grade 1 immune effector cell–associated neurotoxicity syndrome (ICANS). Grade 1–4 early immune-cell–associated hematotoxicity (ICAHT) events occurred in 7 (38.9%), 2 (11.1%), 4 (22.2%), and 5 (27.8%) patients, respectively. EBV-related events occurred in 50% of patients, and CMV viremia in 33.3%. The best overall response rate (ORR) was 77.8% (14/18), including a CR/CRi/CMR rate of 61.1% (11/18) and PR with extranodal disease in 16.7% (3/18). All responding patients with bone marrow involvement achieved MRD negativity by flow cytometry. All four non-responders (two T-ALL/LBL and two PTCL) demonstrated low CAR-T expansion, with peak levels $<$500 copies/μg genomic DNA. At the RP2D, ORR was 100%, with CR/CMR achieved in 85.7% (6/7). Five responding patients underwent consolidative allogeneic HSCT. **Conclusions:** SL105, an autologous dual-epitope nanobody CD5 CAR-T therapy, demonstrated a favorable safety profile and encouraging efficacy in R/R T-ALL/PTCL. The RP2D has been established, supporting further evaluation in an ongoing phase II study. Clinical trial information: NCT06874946. Research Sponsor: Beijing Research Ward Excellence Program; National key research and development plan of China.

6509 **Rapid Oral Abstract Session**

A phase 2 study of fedratinib in patients with MDS/MPN and chronic neutrophilic leukemia. First Author: Andrew Tucker Kuykendall, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: MDS/MPNs are complex diseases that exhibit proliferative symptoms and aggressive clinical courses. Treatment options are limited. Ruxolitinib, a JAK1/JAK2 inhibitor, showed clinical benefit in pts with chronic neutrophilic leukemia (CNL) and atypical CML (aCML); yet survival remained poor (mOS 18.8 mo). Fedratinib (Fed) is a JAK2 inhibitor approved for MF that, compared to ruxolitinib, has a broader kinase inhibition profile which may provide enhanced efficacy in molecularly complex disease. Fed potently inhibits FLT3 and BRD4 and potently suppresses c-Myc, a critical upregulated pathway in MDS/MPN. Here, we present the primary results of NCT05177211 assessing the efficacy of Fed in pts with MDS/MPNs. **Methods:** NCT05177211 is a phase 2, multi-institutional study that enrolled pts with aCML, CNL, MDS/MPN-unclassifiable (MDS/MPN-U), and MDS/MPN-ring sideroblasts and thrombocytosis (MDS/MPN-RS-T) who have splenomegaly (spleen volume $>$ 450cc) and/or significant symptom burden (MPN TSS $\geq$ 10). The primary endpoint is overall response defined as complete/partial response or clinical benefit at 24 weeks per MDS/MPN IWG response criteria. Exploratory endpoints include progression-free survival (PFS), overall survival (OS), and duration of response (DOR). Fed was given at a dose of 400 mg daily on day 1-28 of 28-day cycles. **Results:** The data cutoff was 1/1/2026. Among 25 pts, 6 had aCML, 5 had CNL, 6 had MDS/MPN-RS-T, and 8 had MDS/MPN-U. Median age was 68.8 y. $\geq$3 mutations were present in 19 (76%) pts. Three (12%) pts remain on study. Median duration of treatment was 7.4 months. Eleven (44%) pts responded at week 24: 6 (30%) spleen responses (SVR35) and 9 (47%) symptom responses (TSS50). Four (25%) pts had both spleen and symptom response. Among 16 pts with splenomegaly treated for $\geq$ 24 weeks, spleen volume decreased by an average of 30% (+9% to -61%). Among 16 pts with symptomatic disease treated for $\geq$ 24 weeks, TSS improved by an average of -41% (range +35% to -80%). *CSF3R* mutations were enriched among pts with SVR35 (n = 4; 67%). Median PFS and OS were 36.9 mo (95% CI 19.3-NR) and 36.9 mo (95% CI 18.4-NR), respectively. Among responders, the duration of response was 7.6 mo (95% CI: 3.72-not reached). When stratified by diagnosis, OS for aCML, CNL, MDS/MPN-RS-T, and MDS/MPN-U was 19.8, 36.9, NR and NR, respectively. SAEs occurred in 13 (52%) pts. SAEs possibly related to Fed included acute kidney injury (n = 2), low thiamine (n = 1), colitis (n = 1), diarrhea (n = 1), arthralgias (n = 1), and edema (n = 1). Any grade nausea, vomiting, diarrhea, and constipation were seen in 52%, 16%, 44%, and 48% of pts, respectively. **Conclusions:** Fed demonstrates promising clinical efficacy in MDS/MPN and CNL pts with proliferative features. The safety profile is consistent with prior experience. Fed's unique kinase inhibition profile may provide a mechanism for enhanced effectiveness in this pt population. Clinical trial information: NCT05177211. Research Sponsor: BMS.

6510 **Rapid Oral Abstract Session**

Updated efficacy and safety of olverembatinib (HQP1351) as second-line therapy in patients with chronic-phase chronic myeloid leukemia (CP-CML). First Author: Weiming Li, Department of Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Olverembatinib is a third-generation BCR::ABL1 tyrosine kinase inhibitor (TKI) approved in China for chronic myeloid leukemia (CML) resistant/intolerant to $\geq$ 2 TKIs or with the T315I mutation. This study assessed olverembatinib as second-line treatment in patients with CP-CML resistant/intolerant to first-line TKIs without the T315I mutation. **Methods:** This single-arm, multicenter, open-label study enrolled patients (ECOG PS 0-2, adequate hepatic/renal function) who receive olverembatinib 40 mg orally every other day in 28-day cycles. Efficacy and safety were assessed every 3 cycles. The primary endpoint was complete cytogenetic response (CCyR) rate. **Results:** From August 4, 2022, through January 14, 2026, 47 patients were enrolled (91.5% first-line TKI resistant, 8.5% intolerant). The median age was 42.0 (19-70) years; 66.0% were male. Twelve (25.5%) received first-line imatinib, and 35 (74.5%) received first-line second-generation TKIs. Thirty-six (76.6%) had no baseline *BCR::ABL1* kinase domain mutations, and 11 (23.4%) had non-T315I mutations. At data cutoff, 33 (70.2%) continued treatment, while 14 (29.8%) discontinued because of adverse events (n = 3), treatment failure (n = 4), progression (n = 2), or other reasons (n = 5). Among 42 evaluable patients, 76.2% achieved CCyR and 47.6% major molecular response (MMR). CCyR/MMR rates increased progressively: cycle 6 (57.5%/25.0%), cycle 9 (60.4%/33.3%), cycle 12 (75.0%/37.5%), cycle 15 (83.3%/46.7%), cycle 18 (89.3%/50.0%), cycle 21 (92.0%/64.0%), and cycle 24 (91.3%/60.9%). Complete hematologic response was achieved in 83.3% (15/18) and major cytogenetic response in 83.3% (35/42). Among 32 patients pretreated with first-line second-generation TKIs, 81.3% achieved CCyR and 50% MMR. The median treatment duration was 16.0 (6-38) cycles. Any-grade treatment-related adverse events (TRAEs) occurred in 42 (89.4%) patients; 21 (44.7%) had grade $\geq$ 3 TRAEs; and 6 (12.8%) had serious adverse events (SAEs). Non-hematologic TRAEs (mainly grade 1-2) included skin hyperpigmentation (51.1%), hyperuricemia (31.9%), and creatine phosphokinase increased (27.7%). Grade $\geq$ 3 hematologic toxicities included platelet count decreased (42.6%), neutropenia (25.5%), and anemia (8.5%). Olverembatinib-related SAEs included platelet count decreased (6.4%), anemia, myelosuppression, and pyrexia (2.1% each). Most hematologic TRAEs were manageable with supportive care. Two cardiovascular events (grade 1 hypertension) were possibly treatment-related. No deaths occurred. **Conclusions:** Olverembatinib shows good tolerability and leads to high MMR and CCyR in patients with CP-CML without T315I mutation that is resistant/intolerant to first-line TKIs. Clinical trial information: ChiCTR2200061655. Research Sponsor: None.

6511 **Rapid Oral Abstract Session**

A prospective observational study to compare the efficacy, time toxicity, and cost of conventional 3+7 regimen versus azacitidine + venetoclax (AZA + VEN) as induction therapy in patients with acute myeloid leukemia (AML). First Author: Manju Sengar, Tata Memorial Hospital, Mumbai, India

Background: In low-middle income countries, 3+7 induction therapy for AML is associated with high induction mortality (7-40%), more so in patients with infections at diagnosis. Given the activity of AZA+VEN, a considerable proportion of patients with high-risk features (infections at diagnosis, poor-risk AML, poor performance status, multiple comorbidities, elderly) or long-waiting for admission to start induction are treated with AZA+VEN and 3+7 regimen use is limited to young, fit and good/intermediate risk groups. However, it is important to understand if use of AZA+VEN in this setting provides similar efficacy and is safe without increasing the cost of therapy and time-toxicity as defined by the contact days with healthcare system. Ideally a randomized controlled trial is needed to answer this question, however physicians' unwillingness to randomize patients at high-risk of induction mortality to 3+7 regimen would challenge the feasibility of such trial. **Methods:** A prospective observational study enrolled consecutive de-novo AML patients aged $\geq$18-years after written informed consent who were planned for treatment by a multi-disciplinary joint clinic with either 3+7 or AZA+VEN. The primary endpoint was induction mortality, with secondary endpoints of grade 3/4 toxicity, treatment cost, time toxicity, complete response/complete response rate with incomplete count recovery rates (CR/CRi) assessed after one course. **Results:** 154 participants were included (3+7 -73, AZA+VEN-83). Median age was 35 years in 3+7 as compared to 44 years in Aza-Ven group. The AZA+VEN group was enriched for high-risk features – ECOG PS $\geq$2 (10.9% vs 33.3%), baseline fungal pneumonia (4.1% vs 50%), poor-risk profile as per ELN 2022(12.3% vs 24.7%). The primary reasons for starting AZA+VEN were active infection (65.4%), poor-risk disease (28.4%), delay in admission (16%), and poor performance status (8.6%). Induction mortality was comparable between 3+7 and AZA+VEN (8.2% vs 7.5%). Toxicities were higher with 3+7; febrile neutropenia (95.9% vs 79.7%), new-onset bacterial infections (49.3% vs 19.0%) with multidrug resistant bacterial sepsis (32.9% vs 9.1%), and new-onset fungal pneumonia (27.4% vs 15.2%). The median treatment cost was higher with 3+7 (227,790 INR) compared to AZA+VEN (184,694 INR). Time toxicity (26.0$\pm$0.8 vs 19.0$\pm$0.9 days) and duration of hospitalization (26.0$\pm$0.9 vs 18.0$\pm$2.1 days) were higher in the 3+7. CR/CRi rates were higher with 3+7 (80.6% vs 57.1%), including higher CR (52.2% vs 27.1%) and flow-MRD negativity (71.6% vs 41.9%) driven by the favorable risk profile in this group. **Conclusions:** The study demonstrated that AZA+VEN in patients who are at high-risk of induction mortality provides a valuable alternative with better safety and reduced financial burden and time toxicity. Research Sponsor: None.

6512 Rapid Oral Abstract Session

A randomized phase II study of selinexor added to standard induction and consolidation chemotherapy in adults with acute myeloid leukemia (AML). First Author: Timothy S. Pardee, Comprehensive Cancer Center of Atrium Health Wake Forest Baptist, Winston-Salem, NC

Background: Preclinical and early clinical data suggest that inhibition of nuclear export by the XPOI inhibitor selinexor may enhance chemosensitivity in AML. We conducted a randomized phase II study evaluating the addition of selinexor to standard intensive induction and consolidation chemotherapy. **Methods:** This was an open-label, randomized (3:1) phase II trial in adults with newly diagnosed non-APL, AML. Good risk patients, those with FLT3 mutations or those with an indication for CPX-351 were excluded. Patients were assigned to standard induction with cytarabine and an anthracycline (7+3) followed by high-dose cytarabine (HDAC) consolidation (control arm) or the same regimen with the addition of selinexor (study arm). Selinexor was administered at a fixed dose of 60 mg orally on days 1, 3, 8, 10, 15, and 17 during induction and consolidation cycles. Randomization was not stratified. The primary endpoint was overall survival, analyzed in the intention-to-treat population. Secondary endpoints included overall response rate, complete remission with or without complete count recovery and safety. **Results:** A total of 57 patients were randomized (study arm n = 43; control arm n = 14). The study was discontinued early after results of the PARADIGM study raised concerns regarding the use of intensive chemotherapy in intermediate- and poor-risk AML patients. Baseline characteristics except for gender were generally balanced (Table 1). Median overall survival was 991 days in the study arm compared with 649 days in the control arm (log-rank p = 0.2267). Thirty-day mortality occurred in 5 patients (11.6%) in the study arm and 2 patients (14.3%) in the control arm. The response rate was 77% (33/43) in the study arm and 50% (7/14) in the control arm, corresponding to a risk ratio of 1.53 (95% CI, 1.01–4.57); this difference did not reach statistical significance by Fisher's exact test (p = 0.09). The addition of selinexor was feasible, with early mortality rates consistent with intensive induction therapy and no unexpected safety signals observed. **Conclusions:** In this randomized phase II study, the addition of selinexor to standard induction and consolidation chemotherapy was associated with numerically higher response rates and longer median overall survival compared with chemotherapy alone. Small study size and early termination limit definitive conclusions. However, these findings suggest biological activity of nuclear export inhibition in AML and support further evaluation of selinexor-containing combinations. Clinical trial information: NCT02835222. Research Sponsor: Karyopharm.

Characteristic	Control arm (n = 14)	Study arm (n = 43)
Median age, years (range)	69 (22–75)	65 (24–73)
Female sex, n (%)	11 (78.6%)	17 (39.5%)
ELN 2022 Risk group		
Good	5 (35.7%)	9 (20.9%)
Intermediate	3 (21.4%)	20 (46.5%)
Poor	6 (42.9%)	14 (32.6%)

6513 Rapid Oral Abstract Session

Olverembatinib (HQP1351) combined with blinatumomab in patients with lymphoid blast phase chronic myeloid leukemia (CML-LBP) or Philadelphia chromosome–positive B-cell precursor acute lymphoblastic leukemia (Ph^+ BCP-ALL). First Author: Elias Jabbour, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Olverembatinib, a third-generation BCR::ABL1 TKI, has demonstrated clinical activity in TKI-resistant Ph^+ hematologic malignancies. This study evaluated olverembatinib combined with blinatumomab in patients with relapsed/refractory (R/R) Ph^+ B-cell precursor ALL (BCP-ALL) or CML-LBP outside China. **Methods:** In this phase 1b study (HQP1351CU101; NCT04260022), adults with R/R Ph^+ BCP-ALL or CML-LBP received olverembatinib from 30 mg QOD, with planned escalation to 40 mg QOD, combined with standard-dose blinatumomab in 6-week cycles. Using a 3+3 design, dose-limiting toxicities (DLTs) were assessed during cycle 1. Objectives included evaluation of safety and tolerability, complete response (CR) rate, and minimal residual disease (MRD) negativity rate. MRD was assessed by flow cytometry. **Results:** Between January 2023 and June 2025, 9 patients were enrolled (8 Ph^+ BCP-ALL, 1 CML-LBP). Median age was 47 years (range 32-60); 66.7% were male. Median time from diagnosis to olverembatinib treatment initiation was 2.46 (range 0.5-6.2) years; median leukocyte count 3.5×10^9/L (range 2-171); median prior regimens 4 (range 2-10); and median TKIs 3 (range 1-6). *BCR::ABL1* transcripts were P190 (n = 7), P210 (n = 2); one patient had the T315I mutation. Notably, 6 patients had received prior blinatumomab and relapsed during maintenance or subsequent therapy. The combination demonstrated a manageable safety profile, with most adverse events (AEs) being grade 1-2, consistent with the known toxicities of each agent. Four patients experienced grade 3 AEs related to olverembatinib, including increased lipase, neutropenia, thrombocytopenia, and pancreatitis. In the 30 mg QOD cohort (n = 3), no DLTs occurred. One patient in the 40 mg QOD cohort developed grade 3 pancreatitis (considered treatment related and a DLT) on day 4, which resolved with supportive care and dose reduction to 30 mg without recurrence; this patient achieved CR and MRD negativity by end of cycle 1. With median olverembatinib treatment duration of 15.7 weeks (range 1.4-37.1), 4 patients discontinued because of disease progression (n = 1) or bridge to CAR-T/transplantation (n = 3). Among 9 enrolled patients, 5 had positive MRD at study entry without CR. In this subgroup, 4 achieved CR and 2 achieved MRD negativity. One patient died due to disease progression, assessed as unrelated to study treatment. **Conclusions:** Olverembatinib combined with blinatumomab shows promising clinical activity in patients with R/R Ph^+ BCP-ALL or CML-LBP outside China, with encouraging response rates and MRD clearance. The regimen was generally well tolerated, with a safety profile consistent with individual agent toxicities. These findings support further investigation of this chemotherapy-free approach. Clinical trial information: NCT04260022. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

6514 Rapid Oral Abstract Session

Updated results of the chemotherapy-free regimen of blinatumomab and ponatinib in patients with newly diagnosed Philadelphia-positive B-cell acute lymphoblastic leukemia. First Author: Lewis Fady Nasr, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Chemotherapy-free regimens incorporating blinatumomab (blina) and ponatinib have demonstrated promising activity in frontline Philadelphia-positive (Ph+) B-cell acute lymphoblastic leukemia (B-ALL). We report the long-term outcomes from an ongoing, phase II study of blina with ponatinib in adults with newly diagnosed (ND) Ph+ B-ALL. **Methods:** Patients (pts) ≥18 yrs with Ph+ B-ALL received up to 5 simultaneous cycles of blina with ponatinib 30 mg daily, reduced to 15 mg daily upon complete molecular response (CMR). Pts continued ponatinib for at least 5 yrs. IT chemo was increased from 12 to 15 with pt #64 to reduce the risk of central nervous system (CNS) relapse. Protocol was amended to add 2 cycles of high-dose methotrexate (MTX) and cytarabine for pts with WBC $>70x10^9$/L. **Results:** As of January 2025, 88 pts were enrolled (median age of 50 yrs [range, 18-83]; 19%>70 yrs). Median baseline WBC was 15.2 $x10^9$/L (0.6-322). 78% of pts had *BCR::ABL1* p190 transcripts, 20% had p210. 25 out of 48 pts (52%) with SNP array testing had *IKZF1+* genotype. The objective response rate was 96%, with a complete remission (CR) rate of 95%. Measurable residual disease (MRD)-negativity by next-generation sequencing (NGS) was achieved in 95% of evaluable pts; 43% after 1 cycle. CMR rates by RT-PCR was 83%, 67% after 1 cycle. Median follow-up was 3 yrs. 70 pts (79%) remain in molecular remission without allogeneic stem cell transplant (SCT). Of these, 1 received inotuzumab for MRD-positivity and 1 received CAR T-cell therapy. 2 pts (2%) went to SCT in CR1 due to persistent positive p190 transcripts; neither pt had NGS-MRD available. 11 pts (12%) relapsed (10 with p190 transcripts) after a median of 20 months (8-33) from CR: 5 were bone marrow only, 5 CNS only, and 1 extramedullary only; 7/11 relapsed pts (64%) had baseline WBC$>70x10^9$/L. Three of the 11 relapsed pts died. There were 2 early deaths, and 3 pts died in CR. Since increasing IT chemo to 15, there has been 1 CNS relapse. 3 pts received 2 cycles of high-dose MTX and cytarabine for WBC$>70x10^9$/L; none have relapsed. Median event-free survival (EFS) and overall (OS) have not yet been reached; 3-yr EFS and OS rates are 79% and 89%, respectively. Outcomes did not differ significantly by transcript type nor by NGS MRD clearance after C1. For pts with WBC$\geq70x10^9$/L vs. WBC$<70x10^9$/L, the 3-yr cumulative incidence of relapse (CIR) was 31% vs. 6.7% (p=0.005). The CIR for *IKZF1+* vs non-*IKZF1+* was 16% vs. 21% (p=0.6). **Conclusions:** Frontline blina with ponatinib induced deep, durable remission in Ph+ B-ALL, allowing most patients to avoid SCT. Relapses are seen with high presenting WBC, supporting the use of baseline-risk intensified strategies, including increased IT chemo, incorporation of high-dose chemo into consolidation, as well as CAR T-cell therapy. Clinical trial information: NCT03263572. Research Sponsor: Amgen; Takeda Oncology.

6515 Rapid Oral Abstract Session

Long-term outcomes with addition of inotuzumab ozogamicin to HCVAD and sequential blinatumomab in adults with newly diagnosed B-ALL. First Author: Lewis Fady Nasr, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite high remission rates with intensive chemotherapy and blinatumomab (blina) in newly diagnosed (ND) Philadelphia-negative (Ph-) B-ALL, relapse remains a major cause of treatment failure. Inotuzumab ozogamicin (InO) demonstrates efficacy in the relapsed setting and may improve outcomes in frontline. We report long-term results with 4.5 years of follow-up from the phase II study of HCVAD plus blina +/- InO for adults with ND Ph- B-ALL. **Methods:** Patients (pts) 18-59 years (yrs) with ND Ph- B-ALL received HCVAD alternating with high-dose methotrexate (MTX) and cytarabine (Ara-C) for up to 4 cycles, followed by 4 cycles of blina. Blina was initiated after 2 cycles of HCVAD for pts with high-risk features or persistent measurable residual disease (MRD) by multiparameter flow cytometry (FC). Starting with pt #39, InO was administered during the 2 MTX/Ara-C cycles and 2 blina cycles. Pts received 15 maintenance cycles with POMP and blina after every third cycle. Pts received 12 IT chemotherapies. **Results:** As of January 2025, 75 pts were treated (38 without InO [cohort 1] and 37 with InO [cohort 2]). The median age was 33 yrs (range, 18–59); 37 for cohort 1 (18-59) and 25 (18-57) for cohort 2 (p=0.01). All other characteristics were similar. All pts (100%) achieved complete remission (CR). MRD-negativity by FC was achieved in 95% of pts at any time (66% at CR): 97% (76%) in cohort 1 and 94% (56%) in cohort 2. By next generation sequencing (NGS), 76% achieved MRD-negativity (26% at CR): 50% in cohort 1 and 79% in cohort 2. There were no early deaths. The median follow-up for cohorts 1 and 2 was 76 months (28-109) and 47 months (31-61), respectively. Of the 38 pts in cohort 1, 14 (37%) proceeded to allogeneic stem cell transplantation (SCT); of these, 11 (79%) remain alive in CR, 1 (7%) died in CR and 2 relapsed, 1 of which died. A total of 24 pts (63%) did not proceed to SCT; of these, 16 (67%) remain alive in CR, 3 (13%) died in CR, and 5 (20%) relapsed, 4 of which died. Of the 37 pts in cohort 2, 10 (27%) proceed to SCT; all alive in CR. A total of 27 pts (65%) did not proceed to SCT; 24 (89%) remain alive in CR (1 pt received CAR T-cell) and 3 (11%) relapsed, all of them alive in CR2). Median OS and event-free survival (EFS) have not been reached for either cohort. 4-year OS rates for the entire cohort, cohort 1 and cohort 2 are 91%, 82% and 100% (p=0.007), respectively, with 4-year EFS rates of 83%, 74%, and 91% (p=0.034), respectively. At 24 months, CIR was with InO vs without InO (8.1% vs 18.4%; p = 0.18). No deaths were observed in the InO group, whereas pts without InO had a 24-month cumulative incidence of death of 7.9% (p = 0.08). **Conclusions:** Incorporation of InO into frontline HCVAD with sequential blina is associated with improved survival and durable remission in adults with ND Ph- B-ALL, supporting its role in the frontline setting. Confirmatory randomized trial comparing HCVAD-blina to HCVAD-blina-Ino is ongoing. Clinical trial information: NCI-2017-00596. Research Sponsor: Amgen; Pfizer.

6516 Rapid Oral Abstract Session

The impact of MRD and post-remission strategies on outcomes following dose-dense mini-hyper-CVD inotuzumab and blinatumomab in relapsed B-cell acute lymphoblastic leukemia. First Author: Maria Hachem, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Advances in immunotherapy have improved outcomes for relapsed/refractory (R/R) B-cell acute lymphoblastic leukemia (B-ALL). However, the optimal sequence of immunotherapies remains undefined, particularly the role of chimeric antigen receptor (CAR) T-cell therapy in the era of sensitive assessment of measurable residual disease (MRD). Here, we provide an update of the phase II trial the dose dense mini-CVD with inotuzumab ozogamicin (InO) and blinatumomab (blina) regimen in R/R B-ALL. **Methods:** Adults (>18 years) with R/R Philadelphia (Ph) positive (+) or negative (-) B-ALL were treated with dose-dense mini-hyper-CVD with InO and blina. Cycles 1, 3, 5 consisted of mini-hyper-CVD, InO and blina; cycles 2, 4, 6 consisted of mini-methotrexate and ara-C, InO, and blina with Peg-G-CSF administered after each course. Patients (Pts) received 12 IT chemotherapy administrations and rituximab if CD20 positive. Pts with Ph+ ALL received a concomitant BCR::ABL1 tyrosine kinase inhibitor. MRD was assessed by flow cytometry (FC) and next-generation sequencing (NGS). **Results:** Between September 2021 and January 2026, 27 pts were enrolled (median age 42 years; range, 19–63). Three pts (11%) had Ph+ ALL, and among Ph- pts, 30% had Ph-like disease. Five pts (19%) had adverse risk cytogenetics and (24%) had a *TP53* mutation. Twenty-four pts (89%) were in salvage 1. Three pts (11%) had previously undergone allogeneic stem cell transplant (SCT) and 9 (33%) had received blina. All pts achieved complete remission (CR) or CR with incomplete count recovery (CRi), including 22 (81%) CR. MRD negativity was achieved in 96% of pts by FCM and 95% by NGS; 80% and 44% achieved FCM and NGS MRD negativity, respectively, after the first cycle. With a median follow-up of 32 months, 11 pts (41%) proceeded to CAR T-cell consolidation, 5 (18%) to SCT, and 11 (41%) received no further consolidation. Among CAR T recipients, 70% were NGS MRD-negative prior to lymphodepletion. Post CAR T-cells infusion, 10/11 (91%) pts achieved/maintained NGS MRD negativity, while 1 (9%) pt had MRD below level of detection at last follow-up. The 2-year overall survival (OS) and event-free survival (EFS) rates for the entire cohort were 68% and 79%, respectively. The 2-year EFS rates for pts receiving CAR T-cell, ASCT, or no further consolidation were 81%, 80% and 50%, respectively, while the corresponding 2-year OS rates were 89%, 100%, and 55%. **Conclusions:** Dose-dense mini hyper-CVD combined with InO and blina induces high rates of deep NGS-MRD negative remission in patients with R/R B-ALL, allowing for consolidative strategies including CAR T-cell therapy, leading to favorable survival outcomes at a follow-up of almost 3 years. Clinical trial information: NCT01371630. Research Sponsor: Amgen.

6517 Rapid Oral Abstract Session

The effect of obecabtagene autoleucel (obe-cel) on adult patients (pts) with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL) and extramedullary disease (EMD). First Author: Jae Hong Park, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Pts with R/R B-ALL and EMD have limited treatment options and are a population with an unmet need. Obe-cel is an autologous chimeric antigen receptor (CAR) T-cell therapy with a fast off-rate CAT19 binding domain and a 4-1BB-ζ co-stimulatory domain designed to improve persistence and reduce severe immunotoxicity. Here, we report a post-hoc analysis of the Phase Ib/II FELIX study (NCT04404660), evaluating efficacy and safety of obe-cel in pts with R/R B-ALL, by EMD status at lymphodepletion (LD). **Methods:** Following LD, adults with R/R B-ALL received obe-cel using a tumor burden-guided dosing strategy to minimize toxicity. Overall remission rate (ORR; complete remission [CR]/CR with incomplete hematologic recovery [CRi]), event-free survival (EFS), overall survival (OS), and safety are reported for pts with or without (w/o) EMD. **Results:** Of 127 obe-cel infused pts, 27 (21%) had EMD at LD and 100 (79%) did not. At screening, the median age (range) was 36.0 years (20–73) in pts with EMD, and 50.5 years (20–81) in pts w/o EMD. Of the pts with EMD, 13 (48%) were male and 11 (41%) were Hispanic or Latino; of those w/o EMD, 53 (53%) were male and 27 (27%) were Hispanic or Latino. The median number of prior lines of therapy (range) was 3.0 (1–6) and 2.0 (1–6) for pts with and w/o EMD at LD, respectively; prior SCT was received by 12 (44%) and 44 (44%) pts, respectively. At LD, the median bone marrow (BM) blast percentage (range) was 54% (0–100) in pts with EMD and 39% (0–100) in pts w/o EMD; Philadelphia chromosome-positive disease was observed in 6 (22%) and 30 (30%) pts, respectively. At 32.8 months' (mos) median follow-up (range 20–53), the ORR (95% confidence interval [CI]) was 59% (39–78) in pts with EMD and 83% (74–90) in pts w/o EMD. Median DoR (95% CI) among responders was 42.5 mos (3.4–not evaluable [NE]) and NE, in those with (n=16) and w/o (n=83) EMD at LD, respectively. Overall, median EFS (95% CI) was 4.5 mos (0.0–NE) and 14.3 mos (9.0–NE) in pts with and w/o EMD at LD, respectively; however, median EFS appeared to be comparable in responders with (44.6 mos [6.0–NE]) and w/o EMD (NE). Overall, median OS (95% CI) was 15.3 mos (7.9–NE) and 21.0 mos (13.2–NE) in pts with and w/o EMD at LD, respectively. The incidence of Grade ≥3 cytokine release syndrome in pts with and those w/o EMD was 3.7% and 2.0%; the incidence of Grade ≥3 immune effector cell-associated neurotoxicity syndrome was 19% and 4.0%, respectively. Cerebrospinal fluid pharmacokinetic analyses are underway; data will be presented. **Conclusions:** Obe-cel treatment demonstrated favorable efficacy and safety outcomes in pts with and w/o EMD in the FELIX trial. Among responders, DoR in pts with EMD was comparable with that observed in pts w/o EMD. Overall, these findings support a positive benefit–risk profile for obe-cel, irrespective of EMD status at LD. Clinical trial information: NCT04404660. Research Sponsor: Funding: Autolus Therapeutics PLC. Third-party medical writing assistance, under the direction of the authors, was provided by Emily Fang, MPharm, of Ashfield MedComms, an Inizio company, and was funded by Autolus Therapeutics PLC.

6518 Poster Session

Early G-CSF after venetoclax-based induction for acute myeloid leukemia: Multicenter associations with infections, neutrophil recovery, and early mortality. First Author: Randa Elzein, Upstate Medical University, Syracuse, NY

Background: Venetoclax-based induction has improved remission rates in acute myeloid leukemia (AML) but is associated with prolonged neutropenia and infectious mortality. Optimal G-CSF timing remains uncertain. **Methods:** Multicenter real-world cohort (2018–2025) using TriNetX data across 21 U.S. institutions. Adults with newly diagnosed AML treated with venetoclax + hypomethylating agent or low-dose cytarabine were included. Early G-CSF was defined as initiation ≤ day 7 of cycle 1; deferred/none = > day 7 or none. The primary endpoint was grade ≥ 3 infection through day 42 (death as a competing risk, Fine–Gray models). Secondary endpoints: febrile neutropenia (FN), time to ANC ≥ 1.0 × 10^9/L, ICU admission ≤ day 42, 60-day mortality, CR/CRi by day 60, and overall survival (OS). Multivariable models adjusted for age, ECOG, ELN risk, cytogenetics, baseline ANC/WBC, TP53/IDH/NPM1 mutations, antibacterial prophylaxis, and center effects. **Results:** N = 2,934; median age = 69 y (range 34–87). Early G-CSF = 39 %, deferred/none = 61 %. Early G-CSF lowered grade ≥ 3 infections (sHR 0.61 [95 % CI 0.49–0.76], p < 0.001) and shortened ANC recovery (Δ −3.2 days [−4.6 to −1.9], p < 0.001). FN risk was similar (aOR 0.94 [0.79–1.12], p = 0.49). CR/CRi by day 60 (aOR 1.06 [0.90–1.25], p = 0.47), OS (aHR 0.97 [0.85–1.11], p = 0.65), and 60-day mortality (aOR 0.92 [0.73–1.16], p = 0.49) were comparable. Findings persisted in age ≥ 75 and ELN-adverse subsets and remained robust after inverse-probability weighting and landmark analyses. **Conclusions:** Early (≤ day 7) G-CSF after venetoclax-based AML induction reduced severe infections and accelerated neutrophil recovery without affecting remission or survival. Results support standardized early G-CSF use to improve supportive-care safety, especially for older or high-risk patients. Research Sponsor: None.

Early G-CSF timing and clinical outcomes after venetoclax-based AML induction.

Outcome	Deferred/ None	Early G-CSF	Adjusted effect (95 % CI)	P value
Grade ≥3 infection ≤ day 42, %	31.4	21.2	sHR 0.61 (0.49–0.76)	<0.001
Time to ANC ≥1.0 (days, median)	11.8	8.6	Δ −3.2 (−4.6 to −1.9)	<0.001
Febrile neutropenia, %	38.9	37.4	aOR 0.94 (0.79–1.12)	0.49
ICU admission ≤ day 42, %	14.6	11.9	aOR 0.80 (0.65–0.99)	0.04
60-day mortality, %	10.1	9.3	aOR 0.92 (0.73–1.16)	0.49
CR/CRi by day 60, %	63.8	64.9	aOR 1.06 (0.90–1.25)	0.47

Abbreviations: sHR = sub-hazard ratio; aOR = adjusted odds ratio; aHR = adjusted hazard ratio; Δ = difference in medians. All models adjusted for baseline covariates (age, ELN risk, ECOG, cytogenetics, molecular subtype, prophylaxis use) and center effects.

Molecular landscape and outcomes of Black and White adults diagnosed with acute myeloid leukemia. First Author: Eno-obong Blessing Udoh, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH

Background: Acute myeloid leukemia (AML) is characterized by poor survival with Black patients (pts) experiencing worse outcomes compared to White pts. While patient-specific factors such as race have emerged as important predictors for survival in AML, the biologic mechanisms driving these factors are not well characterized. Here, we analyzed the molecular profiles of adults diagnosed with AML to identify potential differences in the frequency of genes commonly mutated in AML and their impact on survival. **Methods:** This was a retrospective cohort study of adults diagnosed with AML at the Cleveland Clinic between 2008 and 2022. Patients were identified as Black or White based on self-reported race/ethnicity. Molecular data were obtained from next-generation sequencing (NGS) performed at the time of diagnosis. Survival analysis was limited to pts receiving intensive induction chemotherapy and estimated using the Kaplan-Meier method and compared with the log-rank test. **Results:** 1,144 pts were included in this study: 10% (n = 115) Black and 90% (n = 1029) White. Median age at diagnosis (years) was lower in Black pts compared to White pts (62 vs 66) (p = 0.005). Cytogenetics analysis (MRC 2010) showed a higher proportion of Black pts with favorable-risk disease compared to White pts (15% vs. 8%; p = 0.04) while rates of poor-risk cytogenetics were similar (31% vs. 30%). Mutations in *IDH1*, *CBL*, *CEBPA*, and *NOTCH1* were more common in Black pts than in White pts (p < 0.05). Conversely, mutations in *NPM1* were lower in Black pts (16%) vs. White pts (24%) (p = 0.22). We did not observe a difference in the type of induction chemotherapy received (p = 0.23). However, more White pts underwent hematopoietic cell transplant (HCT) compared to Black pts (32% vs. 21%; p = 0.02). The median overall survival (OS) for the whole cohort was 18 months (95% CI: 16-21 months) with a 5-year OS of 31% (95% CI: 27-34%); median follow up time of 63 months. Univariable analysis showed that worse overall survival was associated with older age, poor risk cytogenetics, therapy-related and secondary AML, and not undergoing HCT (p < 0.05), but median OS and 5-year OS rates were similar between Black and White pts (24 months, 28% vs. 17 months, 31%). After adjusting for prognostic variables, age, HCT status and cytogenetic risk remained significant (p < 0.05). **Conclusions:** Unlike previously reported studies, we did not observe a survival disparity in race in our study cohort. However, we observed lower rates of treatment with HCT in Black pts. We also identified a higher frequency of mutations in genes involved in myeloid transcriptional regulation, epigenetic modification, and cellular signaling. Adequate assessment of the prognostic relevance of these genes is limited by a small sample size and variability in NGS platforms over time. Future studies may explore pooled genetic data across several institutions and genetic ancestry testing over self-reported race/ethnicity. Research Sponsor: None.

The association of *IDH* co-mutations with treatment outcomes and overall survival in *TP53*-mutated acute myeloid leukemia. First Author: Lukas Ronner, Abramson Cancer Center of the Hospital of the University of Pennsylvania, Philadelphia, PA

Background: In acute myeloid leukemia (AML), *TP53* mutations confer a dismal prognosis, with a median survival of ~6 months. While characteristics of *TP53* aberrancy (multi-hit status) define an even more aggressive subset, little is known about the effect of *IDH* co-mutations on outcomes. An analysis of the Consortium on Myeloid Malignancies and Neoplastic Diseases (COMMAND) cohort suggests that *TP53*+/*IDH*+ subjects (n = 24) have prolonged survival compared to *TP53*+/*IDH*wt, a finding that could inform our treatment approach in these patients. We therefore aimed to validate this finding in a larger cohort within the Flatiron Health Research Database. **Methods:** Patients over 18 years with *TP53*+ AML and *IDH1* or *2* testing at diagnosis were selected within Flatiron Health. Demographics, cytogenetic/molecular testing, and treatments were compared using standardized mean difference (SMD), with SMD $>$ 0.2 indicating meaningful difference. Cox proportional hazards models controlling for age, sex, socioeconomic status, ECOG, multi-hit *TP53*, secondary AML, and induction strategy were built to test the association of *IDH* co-mutations with Event Free Survival (EFS) and overall survival (OS). Sensitivity analyses considering receipt of an *IDH* inhibitor (*IDH*i) and stem cell transplant (SCT) as time-varying covariates were also constructed. Finally, two subgroup analyses in the *IDH*+ subcohort were performed to test associations between 1) *IDH*i in first line, and 2) hypomethylating agent/venetoclax (HMA/ven) in first line, and EFS and OS. **Results:** 753 *TP53*+ AML subjects with *IDH* testing at diagnosis were included. There were meaningful differences in the cytogenetic/mutational landscape of the *IDH*wt (n = 659) and *IDH*+ (n = 94) cohorts, the latter with a lower incidence of multi-hit *TP53* and myelodysplasia-related changes, and a higher incidence of ASXL1, DNMT3A, and TET2 co-mutations. In multivariable modeling, *IDH* co-mutations were not independently associated with EFS, though were strongly associated with improved overall survival (mOS 9.8 vs 6.1 months, HR 0.69, CI 0.52 – 0.92, p = 0.01). These associations persisted in sensitivity analyses treating *IDH*i and SCT as time-varying covariates. In analyses of the *IDH*+ subcohort, receipt of *IDH*i or HMA/ven during first line did not associate with improved OS or EFS. **Conclusions:** In these data, *IDH* co-mutations are associated with improved OS in *TP53*+ AML, though there was no signal suggesting this was driven by choice of therapy. Our analysis is limited by its retrospective nature and a definition of "multi-hit" status that relied on concomitant presence of del17 and a *TP53* point mutation. Though these results require further validation, they may currently inform the clinical approach to *TP53*+/*IDH*+ AML by framing goals-of-care conversations. However, more work is needed to characterize the effect of treatment selection on outcomes in this population. Research Sponsor: None.

A targeted phosphoproteomic assay to enable the prediction of response to intensive chemotherapy in acute myeloid leukemia. First Author: Gabriel Ghiaur, Johns Hopkins Medical Institutions, Baltimore, MD

Background: Intensive chemotherapy (IC; cytarabine plus an anthracycline) remains a standard first-line therapy for fit patients with acute myeloid leukemia (AML), a heterogeneous hematologic malignancy with poor long-term survival. IC induces composite complete remission (cCR) in ~60–70% of cases, and IC response variability persists within genetic/ELN risk strata. As emerging regimens increasingly challenge IC as a default therapy, biology-informed predictors are needed to identify patients unlikely to benefit from IC to avoid unnecessary toxicity. Mass spectrometry (MS)-based phosphoproteomics enables quantitative profiling of phosphopeptides (PPs) from patient samples, providing a functional readout of tumor biology. Thus, we sought to develop a PP-based clinically-deployable assay, orthogonal to genetic risk stratification, to predict response to IC in AML. **Methods:** 261 retrospective samples were collected from patients with newly-diagnosed AML (Table) treated with standard "7+3" IC in 9 centers in Europe, Australia, and North America. Response was assessed at the end of induction by the treating physician. Samples underwent phosphoproteomics using: 1) global MS for biomarker discovery or 2) targeted, clinically-compatible MS for validation. Predictive model performance was evaluated using rebalanced leave-one-out cross-validation. **Results:** During discovery, 3205 PPs were detected. Using Bayesian approaches, we identified an 80-PP multi-analyte signature of IC response (refractory vs cCR), and achieved an AUROC of 0.68 (95% CI 0.54-0.83). The signature was enriched for DNA damage signalling and repair (DNA-PK-S2612, ATM/cohesin, nucleotide excision and double-strand break repair proteins), and cellular stress pathways (phospho-p38, IL-16, AP-1/c-Jun). In an independent validation cohort, the targeted assay reliably detected the biomarker set and preserved its association with outcome (AUROC 0.69; 95% CI 0.53-0.84). Biomarker-based classification was associated with improved event-free survival (HR 0.45; 95% CI 0.26-0.78). **Conclusions:** We identified and validated a signature of response to IC in AML, and translated it into a targeted, clinically-deployable assay. This approach captures signaling states relevant to IC mechanisms of action that are not directly inferred from standard clinical or genetic variables. Ongoing analyses are evaluating its relationship to established genetic and ELN risk stratification. These findings support diagnostic phosphoproteomics and suggest functional biomarkers may complement existing approaches for treatment selection in AML. Investigation of the role of IFITM3 and the PI3K/Akt axis in the acute myeloid leukemia tumor microenvironment. First Author: Fang Zhou, Department of Hematology, Zhongda Hospital, School of Medicine, Southeast University, Nanjing, China

Background: Interferon-induced transmembrane protein 3 (IFITM3) is overexpressed in acute myeloid leukemia (AML) and is associated with poor prognosis. Previous studies have implicated IFITM3 in oncogenic processes and immune modulation; however, the mechanisms through which IFITM3 contributes to leukemogenesis and shapes the immune microenvironment in AML remain unclear. **Methods:** The clinical and immunological significance of IFITM3 in AML was analyzed using scRNA-seq and bulk transcriptomic datasets. IFITM3-knockdown Kasumi-1 and ME-1 cells were established to evaluate their impact on cell proliferation and cycle progression via MTT and flow cytometry. A Transwell co-culture system was employed to assess AML-induced M0 macrophage polarization, quantified by surface markers (CD80/CD163) and cytokine profiling (ELISA/qRT-PCR). Mechanistically, GSEA were performed to identify downstream pathways, followed by Western blot validation. The functional role of the PI3K/Akt axis was further verified using the specific inhibitor LY294002. **Results:** Our results revealed for the first time that IFITM3high AML cell lines polarize M0 macrophages into an M2-like phenotype. Knockdown of IFITM3 led to a significant reduction of the M2 marker CD163, accompanied by an increase of the M1 marker CD80. In parallel, IFITM3-deficient AML cells exhibited decreased M2-associated gene expression and diminished secretion of TGF-β and IL-10, together with lower viability and G0/G1 cell-cycle arrest. Molecular mechanism studies revealed that loss of IFITM3 markedly reduced Akt and p-Akt protein levels. Crucially, pharmacological inhibition of the PI3K/Akt pathway using a PI3K inhibitor rescued the IFITM3-mediated effects, suppressing AML cell proliferation and M2 macrophage polarization. Clinically, we extended the adverse prognostic effect of IFITM3 to AML patients with intermediate molecular risk. **Conclusions:** These findings provide comprehensive evidence that IFITM3 promotes leukemic cell proliferation and contributes to a tumor-supportive AML microenvironment by driving M2 macrophage polarization via the PI3K/Akt signaling axis. These results highlight IFITM3 as a promising therapeutic target and suggest that PI3K inhibitors may offer a precision medicine approach for AML patients with elevated IFITM3 expression. Association of acute myeloid leukemia (AML) patient, disease, and molecular characteristics with a long-term (LT) response to olutasidenib. First Author: Justin M. Watts, Division of Hematology, Department of Medicine, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Mutations in isocitrate dehydrogenase 1 (m*IDH1*) occur in 7%-14% of patients with AML. Olutasidenib is a potent, oral small-molecule mIDH1 inhibitor that selectively inhibits IDH1 variants but preserves wild-type IDH1 function. The registrational phase 2 trial (NCT02719574) of olutasidenib in patients with relapsed/refractory (R/R) m*IDH1* AML reported a complete remission (CR)/CR with partial hematologic recovery (CRh) rate of 35% and a median CR/CRh duration of 25.3 mo. This analysis examines patient, disease, and molecular characteristics of patients with a LT CR/CRh response to olutasidenib without transplant. **Methods:** Adults with R/R m*IDH1* AML treated with olutasidenib 150 mg twice daily who had a CR/CRh and a duration of response (DOR) $>$12 mo were included. Overall survival (OS), DOR, event-free survival (EFS), and adverse events (AEs) were assessed. Univariate and multivariate logistic regression analyses were used to examine baseline factors that predicted DOR $>$12 vs $\leq$12 mo. **Results:** Of 147 evaluable patients, 51 (35%) achieved a CR/CRh; of these, 32 (63%) maintained a CR/CRh $>$12 mo. Excluding 6 patients who proceeded to transplant, 26 (51%) had a DOR $>$12 mo (Table). Among these patients at baseline, median age was 72 y; 69% were female; 73% had an R132C mutation; 12% had prior venetoclax; 88% were platelet transfusion independent (TI); 73% were red blood cell (RBC) TI. Patients had a median (range) of 2 (0, 5) comutations, most commonly *DNMT3A* (n=6) or *NPM1* (n=5); 2 patients with *NPM1* also had *FLT3* mutations. Median (95% CI) time to response was 1.9 (1.0, 1.9) mo. Median OS and EFS were not reached. Estimated 48-mo OS was 74% (95% CI: 51%, 88%). Estimated 48-mo EFS was 69% (95% CI: 47%, 83%). 5 (19%) patients relapsed (including 1 after 24 mo); 10 (38%) patients were on treatment at data lock. Significant predictors of response $>$12 vs $\leq$12 mo by multivariate analysis were relapsed AML vs refractory AML (odds ratio [OR]: 0.19) and female sex (OR: 0.21). Age, number of comutations, m*IDH1* variant, RTK pathway mutations, number of prior therapies, and baseline TI were not significant predictors. Common AEs were nausea (35%), increased ALT, asthenia, constipation, and cough (31% each). Common grade $\geq$3 AEs were increased ALT, gamma glutamyltransferase increased (19% each), and RBC count decreased (15%). 9 (35%) patients experienced grade $\geq$3 all-cause AEs after 12 mo (only 1 AE in $>$1 patient [Coronavirus infection]). **Conclusions:** Olutasidenib enabled LT CR/CRh in half of R/R m*IDH1* AML patients with CR/CRh without transplant (longest response $>$54 mo). Multivariate analysis identified relapsed (vs refractory) AML and female sex but not baseline TI or molecular factors as a significant predictor of LT response with olutasidenib. Clinical trial information: NCT02719574. Research Sponsor: Rigel Pharmaceuticals, Inc.

Comparing induction strategies in acute myeloid leukemia: 10-year real-world experience with 7+3 and HMA/venetoclax. First Author: Chandra Kakarala, University of Kentucky, Lexington, KY

Background: Hypomethylating agents (HMA) combined with venetoclax are the standard of care for AML in adults ineligible for intensive chemotherapy, but use is expanding to fit patients given prospective data suggesting comparable outcomes. Whether these findings are reproducible in real-world practice remains under investigation. **Methods:** We conducted a retrospective cohort study of adults with newly diagnosed AML treated at the University of Kentucky from 2016-2025 with either 7+3 or HMA/venetoclax. Overlap propensity score weighting balanced age, sex, ECOG, ELN risk group, prior MDS, and therapy-related AML. Primary endpoints were CR/CRi, RFS, OS, and 30-day mortality. Cox models included allogeneic HSCT as a time-varying covariate. Survival outcomes were stratified by ELN risk group and mutational risk group according to venetoclax sensitivity (favorable: *NPM1* and *IDH1/2*, adverse: *TP53* and *FLT3*). **Results:** Prior to weighting, patients treated with HMA/venetoclax were older (68 vs. 50 years), had worse performance status (mean ECOG 1.2 vs. 0.7), and were more likely to have prior MDS, therapy-related AML, and less favorable ELN risk. Unweighted data demonstrated a median OS of 13.3 months for HMA/venetoclax and 19.6 months for 7+3. After overlap weighting of 379 patients (250 received 7+3 and 129 received HMA/venetoclax), acceptable covariate balance was achieved with all standardized differences < 0.01. HMA/venetoclax was associated with numerically higher odds of achieving CR/CRi compared with 7+3 (OR 1.84, p=0.09), and this reached significance in adverse-risk disease (OR 2.31, p=0.006). 30-day mortality was similar between 7+3 and HMA/venetoclax groups (8.3% vs. 8.0%, p=0.96). Among patients who achieved CR/CRi, no significant difference in relapse was noted (p=0.24). RFS and OS did not differ significantly between treatment groups (p=0.76 and 0.18, respectively). Analysis of ELN risk subgroups and mutation subgroups incorporating venetoclax sensitivity demonstrated no association with treatment group in survival outcomes (for OS, p=0.53 and 0.43, respectively), suggesting no effect modification from these variables. Allogeneic HSCT was strongly associated with improved OS (HR 0.26, $p<0.001$), which persisted after adjusting for ELN risk (HR 0.39, $p<0.001$) and mutational subgroups (HR 0.44, p=0.001). Across all models, treatment assignment did not significantly impact OS once transplant was modeled as a time-dependent variable. **Conclusions:** After accounting for baseline confounding and allogeneic HSCT as a time-varying covariate, survival in AML is primarily driven by molecular risk profile and transplant rather than initial induction strategy. These results support further investigation of HMA/venetoclax as a frontline alternative in fit patients with AML and the intention to proceed to transplant. Research Sponsor: None.

HMA plus venetoclax for 7- vs 14- vs 21- vs 28-day cycles in newly-diagnosed acute myeloid leukemia: ELN- and Mayo Genetic Risk–stratified analysis in 540 patients. First Author: Sudhesh Kumar, Division of Hematology, Mayo Clinic Rochester, Rochester, MN

Background: Venetoclax plus hypomethylating agent (Ven-HMA) is the standard treatment for unfit patients with newly diagnosed acute myeloid leukemia (ND-AML), with Ven typically administered for 28 days (d) per cycle *(DiNardo NEJM 2020)*. However, the optimal duration of Ven across risk groups remains unclear. We examined survival outcomes with Ven 7, 14, 21, and 28d in ND-AML, in the context of European LeukemiaNet (ELN) and Mayo Genetic risk models. **Methods:** ND-AML patients receiving Ven-HMA at the Mayo Clinic were retrospectively studied. Patients were stratified by ELN 2024 *(Döhner Blood 2024)* and Mayo Genetic risk *(Gangat Am J Hematol 2025)*, and analyzed using standard statistical methods. **Results:** 540 patients (median age 75 years, 52% *de novo)* received HMA with Ven for 7d (*n*=33), 14d (*n*=117), 21d (*n*=96), or 28d (*n*=294). ELN and Mayo risk distributions were 22%/35% high, 18%/56% intermediate, 60%/9% low risk, respectively. Baseline characteristics were comparable. CR/CRi rates were comparable across Ven durations, with the exception of lower CR/CRi with 7d vs 21d (p=0.04). Risk-stratified CR/CRi showed variations across Mayo and ELN groups but without significant differences based on Ven duration (Table). Allogeneic transplant rates were 15%, 18%, 18%, 20% for 7, 14, 21, 28d (p=0.86). At a median followup of 37.7 months, median overall survival (OS) differed by ELN risk (6.6, 11.9, 20 months) and Mayo genetic risk (7.8, 17.4 months, not reached (NR)), for high, intermediate, low risk ($p<0.01$), respectively. Median OS was comparable across Ven 7, 14, 21, 28 d (13, 13, 17, 14 months; p=0.84), with corresponding 1/3/5-year survival rates (Table). 30/60d mortality differed by Ven duration; 7d 10%/20%, 14d 7%/15%, 21d 4%/13%, 28d 4%/6%. Compared with 28d, 30d mortality was higher with 7d and 14d (p=0.07/0.03), and 60d mortality was higher with 7d, 14d, and 21d (p=0.02/0.01/0.05). OS was comparable across Ven durations within ELN intermediate/low risk and all Mayo risk groups, except among ELN high risk, patients receiving 14d Ven had inferior OS compared with 21d and 28d ($p<0.01$). Cumulative incidence of relapse at 1 year was similar among patients receiving 14, 21, 28d Ven (16%, 18%, 18%;$p>0.1$). **Conclusions:** Survival outcomes were comparable across Ven 7, 14, 21, 28 d in ND-AML, with outcomes driven by Mayo Genetic and ELN risk. Despite differences by Ven duration in high-risk groups, higher early mortality with 7d and 14d likely reflects treatment selection. Prospective trials are needed to establish risk adapted Ven dosing strategies. Research Sponsor: None.

ASCERTAIN: Real-world asciminib (ASC) effectiveness in patients (pts) with Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ ALL). First Author: Marlise R. Luskin, Dana-Farber Cancer Institute, Boston, MA

Background: ATP-competitive tyrosine kinase inhibitors (TKIs) in combination with chemoimmunotherapy have improved outcomes in Ph+ ALL; still, some pts relapse despite appropriate frontline therapy and have limited options. ASC is approved for Ph+ chronic myeloid leukemia in chronic phase. The ASC managed access program (MAP) allowed adults with Ph+ ALL refractory/resistant or intolerant to available treatment (Tx) to receive ASC as monotherapy or combination under individual request when the potential benefit outweighed the risk. **Methods:** This was a non-interventional, multi-country, retrospective chart review in eligible pts with Ph+ ALL aged ≥18 who were refractory/resistant or intolerant to available Tx and who received ≥1 dose of ASC within the MAP. Index date (date of first ASC administration) occurred between 1 March 2019 and 30 June 2023. Existing data were extracted from index date up to 13 months (mo), or until discontinuation, death or last visit, whichever occurred first. The primary endpoint was complete hematologic remission (CR) and CR with incomplete count recovery (CRi) anytime in the first 3 mo of Tx based on peripheral blood assessments. **Results:** A total of 37 pts were enrolled. At Tx start, 25 pts (67.6%) received ASC as monotherapy. Median ASC dose intensity was 400 mg/day (range 71.6–400.0). Overall, 23 pts (62.2%) achieved CR/CRi within 3 months (95% CI: 44.8, 77.5). Median duration of response was 7.4 mo. Median overall survival was 7.7 mo. Nineteen pts were assessed for minimal residual disease (MRD) at time of CR/CRi and 7 (36.8%) were MRD-. Of the 13 pts with T315I mutation, 10 achieved CR or CRi at any time during follow-up. Thirty-three pts (89.2%) permanently discontinued ASC; reasons for permanent discontinuation included disease progression (n=16) and adverse events (AEs, n=5). Any-grade Tx-emergent AEs were reported in 73.0% (Grade ≥3, 56.8%) of pts; the most common any-grade AE was neutropenia (21.6%). No new safety signals were observed. Most deaths (22/28) were Ph+ ALL related. **Conclusions:** Adults with Ph+ ALL that was relapsed, resistant/refractory or intolerant to previous Tx achieved high rates of CR/CRi with ASC as monotherapy or in combination with chemotherapy/immunotherapy, despite most pts being heavily pretreated and/or harboring poor prognosis markers (Table). The safety profile was consistent with previous studies. Results, while positive, should be cautiously interpreted given the retrospective nature of the study and heterogenous population. Research Sponsor: Novartis Pharma AG.

Response to HiDAC/mitoxantrone/venetoclax (HMV) in patients with relapsed/refractory (R/R) acute myeloid leukemia (AML). First Author: Apoorva Ravichandran, Department of Medicine, University of Chicago, Chicago, IL

Background: Outcomes for patients (pts) with R/R AML are dismal, especially after failure of Venetoclax (Ven)-based regimens. Effective strategies are urgently needed particularly in the absence of targetable mutations. An early-phase study of HMV demonstrated a 75% remission rate in pts with R/R AML, however the majority of these pts were Ven-naïve (Ruhnke et al, EHA 2024). We aimed to study a real-world cohort of pts with R/R AML treated with HMV. **Methods:** A retrospective cohort of 16 pts with R/R AML treated with HMV at the University of Chicago (2020–2025) was analyzed. Clinical and disease characteristics were collected; European Leukemia Net (ELN) 2022 criteria were used for risk stratification and response assessment. Overall response rate (ORR) was defined as complete response (CR) + CR with partial hematologic recovery (CRh) + CR with incomplete hematologic recovery (CRi). Overall survival (OS) was estimated using Kaplan-Meier methods. **Results:** Sixteen pts with R/R AML were included; 2 pts had ALL with lineage switch to AML. Median age at diagnosis was 54.5 years. Amongst the 14 pts with AML at initial diagnosis, 28.6%, 14.3%, and 50.0% had favorable, intermediate, and adverse ELN 2022 risk, respectively. Our cohort of pts was heavily pre-treated with 56.2% receiving ≥3 lines of therapy prior to HMV; two pts had received prior allogeneic hematopoietic stem cell transplant (allo-SCT). The ORR was 43.8%; in addition, 6.3% attained morphologic leukemia-free state (MLFS), 6.3% obtained a partial response (PR), and 43.7% had no response/not evaluable (NR/NE). Among pts that received prior intensive AML chemotherapy (n=8), the ORR was 50.0% with HMV. The ORR was 41.6% in pts with prior Ven exposure (n=12). Median OS from HMV initiation was 5.1 months (95% CI: 2.2-9.2) with two deaths within 30 days of HMV initiation; 62.5% of patients received subsequent therapy and 37.5% proceeded to allo-SCT. Two patients are alive in remission at time of data analysis; both underwent allo-SCT after HMV. **Conclusions:** In this heavily pretreated R/R AML cohort, HMV produced encouraging response rates and facilitated transition to allo-SCT in a subset of pts. These data warrant further evaluation of HMV as an R/R option even in pts with prior Ven exposure. Research Sponsor: National Cancer Institute; 3P30CA014599-49S1.

Patient characteristics and efficacy outcomes.

Median Age at Time of Receiving HMV (N=16)	54.5 years (Range 21-66)
Gender (N=16)	Male 69%; Female 31%
# of Lines of Therapy Received Prior to HMV (N=16)	1 Line 25%; 2 Lines 18.8%; ≥3 Lines 56.2%
Best Response to HMV (N=16)	CR 31.2%; CRh 6.3%; CRi 6.3%; MLFS 6.3%; PR 6.3%; NR/NE 43.7%
Best Response to HMV in Patients Who Received Prior AML-Based Intensive Chemotherapy (N=8)	CR 25%; CRh 12.5%; CRi 12.5%; MLFS 0%; PR 0%; NR/NE 50%
Best Response to HMV in Patients Who Received Prior Venetoclax (N=12)	CR 25%; CRh 8.3%; CRi 8.3%; MLFS 0%; PR 8.3%; NR/NE 50%

6528 **Poster Session**

Pharmacokinetic (PK) assessment of revumenib in patients with relapsed/refractory (R/R) acute leukemias harboring a *KMT2A* rearrangement (*KMT2A*r) or *NPM1* mutation (*NPM1*m): Impact of food and concomitant medications. First Author: Enoch Cobbina, Syndax Pharmaceutials, Inc., New York, NY

Background: Revumenib is a first-in-class, oral, potent, and selective inhibitor of the menin-KMT2A interaction that disrupts multiple drivers of leukemogenesis such as *KMT2A* rearrangements (*KMT2A*r) and *NPM1* mutations (*NPM1*m). Revumenib is approved in the United States in patients 1 year and older for the treatment of R/R acute leukemia with a *KMT2A* translocation or R/R acute myeloid leukemia with a susceptible *NPM1* mutation who have no satisfactory alternative treatment options. Given the severity of disease, frequent polypharmacy, and variable clinical status in this population, dosing flexibility is essential to support consistent treatment delivery and optimize outcomes. This analysis characterizes the PK of revumenib and its major metabolite (M1), with emphasis on factors that may influence dosing flexibility, including food and concomitant medications such as CYP3A4 inhibitors (CYP3A4i) and gastric acid–reducing agents such as antacids, H2 blockers (H2Bs), and proton pump inhibitors (PPIs). **Methods:** PK data were obtained from 286 adult (≥18 years) and 49 pediatric (<18 years) patients with *KMT2A*r or *NPM1*m acute leukemia enrolled in the phase 1/2 AUGMENT-101 trial (NCT04065399) following single and multiple doses of revumenib. Non-compartmental analyses were performed in selected subgroups, while population PK modeling was conducted using data from all patients to systematically quantify PK variability and evaluate covariate effects. **Results:** As compared to fasted state, a low-fat meal (400–500 calories with <25% fat content) reduced revumenib C_{max} and AUC by 27% and 12%, respectively, and M1 C_{max} and AUC by 14% and 18%, respectively, although exposure ranges overlapped under fasted and fed (low-fat meal) conditions. Median T_{max} was unchanged for revumenib and delayed by 1.8 hours for M1. Co-administration with strong CYP3A4i (eg, voriconazole, posaconazole, itraconazole) resulted in ~2-fold increase in revumenib C_{max} and AUC, whereas moderate CYP3A4i (eg, fluconazole, isavuconazole) had no meaningful effect. M1 exposure was unaffected by strong or moderate CYP3A4i. Approximately 52% of patients received antacids, H2Bs, or PPIs; revumenib and M1 C_{max} and AUC were not altered, consistent with the high solubility of revumenib across physiological pH range (1.2–6.8). **Conclusions:** Revumenib exposure increases ~2-fold with strong CYP3A4i, supporting dose reduction in this setting, while M1 exposure remains unaffected. Low-fat meals do not cause clinically meaningful changes in revumenib or M1 PK. Similarly, antacids, H2Bs, and PPIs, which are frequently used in this patient population, had no impact on revumenib or M1 PK. These findings reinforce the flexible administration of revumenib that may support treatment adherence and patient convenience. Clinical trial information: NCT04065399. Research Sponsor: Syndax Pharmaceuticals, Inc.

Preliminary results of an open-label, single-arm phase 2/3 trial (SPARK-ALL) of calaspargase pegol in adults with newly diagnosed Philadelphia chromosome–negative acute lymphoblastic leukemia. First Author: Daniel J. DeAngelo, Dana-Farber Cancer Institute, Boston, MA

Background: Asparaginase is an important component of many regimens for acute lymphoblastic leukemia (ALL). In patients (pts) <21 years, calaspargase pegol (Cal-PEG) provides more sustained asparagine depletion than pegaspargase. SPARK-ALL is a multicenter phase 2/3 study (NCT04817761) assessing the safety and anti-leukemic activity of Cal-PEG in pts aged ≥22 years with newly diagnosed Philadelphia chromosome-negative (Ph−) ALL. **Methods:** Part 1 was a dose-finding study in pts with a body mass index (BMI) ≤35 kg/m^2 aged 22–39 and 40–54 years (Cal-PEG 2000 and 1500 U/m^2, respectively) and pts with BMI >35 kg/m^2 or aged ≥55 years (Cal-PEG 1000 U/m^2). Part 2 was a dose-expansion study in pts with BMI ≤35 kg/m^2 aged 22–39 years (Cal-PEG 1750 U/m^2) or 40–54 years (Cal-PEG 1500 U/m^2). Six Cal-PEG IV infusions were given as part of a multiagent chemotherapy regimen based on CALGB 10403 (Stock W, et al. *Blood* 2019; 133(14):1548–1559). The primary objectives are assessment of safety in all pts, and anti-leukemic activity using the surrogate marker of nadir plasma asparaginase activity (NPAA) ≥0.1 U/mL 21 days after the D43 consolidation dose in all evaluable pts who were treated at the recommended dose (primary NPAA [PNPAA]) analysis set). **Results:** A total of 42 pts received Cal-PEG treatment: 26 and 16 in parts 1 and 2, respectively. Overall, 31 (73.8%) and 16 (38.1%) pts experienced grade 3/4 treatment-related adverse events (TRAEs) and serious TRAEs, respectively. Overall, 15 pts (35.7%) had TRAEs leading to study drug discontinuation, including hypersensitivity-type events in 6 pts (14.3%); 4 (9.5%) had nervous system events, including cerebral venous sinus thrombosis in 2 pts (4.8%). Three pts (7.1%) had a grade 3 pulmonary embolism, which, per protocol, required study drug discontinuation. The most common grade 3/4 TRAEs included hypertriglyceridemia (9 pts; 21.4%), alanine aminotransferase increase (7 pts; 16.7%), and blood fibrinogen decrease (5 pts; 11.9%). In part 1, intolerable toxicities considered related to Cal-PEG were experienced by 2/8 pts who were older and 2/8 pts with a BMI >35 kg/m^2; 1 (11.1%) pt aged between 22–39 years experienced an event of hypersensitivity. One Cal-PEG-related death was reported as likely related to complications from embolic stroke in a pt aged 71 years with comorbidities. Dose expansion was pursued in the first two cohorts. At 21 days after the D43 post-consolidation dose, all pts in the PNPAA set had NPAA values above the 0.1 U/mL efficacy threshold. **Conclusions:** Cal-PEG has a safety profile consistent with asparaginase class toxicity and, as part of multidrug chemotherapy regimen, provides sustained asparagine depletion in newly diagnosed Ph− ALL pts aged ≥22 years. In light of the observed high-grade TRAEs, future studies will evaluate different Cal-PEG doses for this pt population. Clinical trial information: NCT04817761. Research Sponsor: Servier.

Older age as a predictor of post-transplant survival in newly diagnosed acute myeloid leukemia treated with HMA-venetoclax. First Author: Momna Warraich, Division of Hematology, Mayo Clinic Rochester, Rochester, MN

Background: Venetoclax (Ven) plus hypomethylating agents (HMA) is standard frontline therapy for newly diagnosed AML (ND-AML) patients unfit for intensive chemotherapy and is also being considered in younger and fit patients (Fathi, Blood 2025). However, consolidation with allogeneic stem cell transplant (ASCT) is often required to secure durable remission. The current study examines predictors of post-transplant survival (PTS) in the particular scenario. **Methods:** ND-AML patients who received upfront Ven+HMA and underwent ASCT were retrospectively studied. PTS, relapse rate, and non-relapse mortality (NRM) were evaluated. **Results:** 111 ND-AML patients (58% male, 60% secondary/therapy-related, median age 70 [37-80 years]) received median 3 cycles of Ven-HMA. 22% had complex karyotype. Mutations at diagnosis included *RUNX1* (18%), *SRSF2* (17%), *TP53* (16%), *ASXL1*, *IDH2*, *K/NRAS* and *TET2* (14% each), *STAG2* (11%), *DNMT3A* (8%) and at time of ASCT (N=78 evaluable); *RUNX1* (8%), *NPM1* (6%), *TP53* and *ASXL1* (5% each), and *SRSF2* and *TET2* (4% each). At ASCT, all patients were in CR/CRi; 88% after Ven-HMA and 12% after additional bridging therapy. MRD by flow cytometry was detected in 18 (24%) of 76 evaluable patients and complex karyotype in 8 (9%) of 94. Donors were mostly HLA-matched unrelated (75%), with 51% receiving fludarabine/melphalan conditioning and 67% post-transplant cyclophosphamide (PTCy). At a median follow-up of 30 months, 42 patients (38%) have died including 18 (40%) from relapse. Median PTS was not reached (NR) with 1-2-3-year survival of 69%/60%57%. On multivariate analysis, age ≥65 years (median NR vs 10 months p<0.01), *STAG2* (NR vs 44 months; p=0.04), and *DNMT3A* mutations (NR vs.NR p=0.05) were associated with superior PTS. In analysis limited to variables at time of ASCT, age ≥65 years remained significant (p<0.01) while *TP53* mutations, donor type, and MRD status were not (p>0.1). Patients <65 years more often received bridging therapy compared to ≥65 years (23% vs 7%; p<0.05); excluding salvage-treated patients did not change survival results. 18 patients (16%) experienced post-ASCT relapse with median RFS of 7 months. Relapse rates at 1/2/3 years were 22%, 30% and 31% and NRM 13%, 24%, 46%, respectively. Patients <65 years had a higher 1 yr relapse incidence than those ≥65 years (36% vs 18%; p=0.01), with similar NRM (p=0.58). PTCy was not associated with relapse (p=0.66) but showed a borderline association with higher NRM (1-/2-/3-year 17%/31%/58% vs 4%/7%/16% in non-PTCy recipients; p=0.06). GVHD rate was 44% (50% ≥grade 2) with no association with relapse (p=0.43) or NRM (p=0.99). **Conclusions:** In the current study, older age (>65 years), including >75 years, was independently associated with superior PTS in ND-AML patients receiving Ven-HMA. By contrast, PTS was not affected by genetic profile at the time of ASCT, donor type, conditioning regimen, or GVHD prophylaxis. Research Sponsor: None.

Myelodysplasia-related mutation dynamics and outcomes in newly diagnosed (ND) acute myeloid leukemia (AML) treated with low-intensity therapy (LIT). First Author: Naszrin Arani, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Outcomes of patients (pts) with ND AML with myelodysplasia related gene mutations (MRMs), while traditionally adverse, appear to be better with LIT regimens + venetoclax (Ven). The impact of MRMs as a minimal residual disease (MRD) marker warrants investigation. **Methods:** We retrospectively analyzed the impact of persistence/clearance of MRM at VAF <2% at best response of CR/CRi, in pts with LIT treated ND AML (with available genomic data), treated at our institution between 2017 – 2025 and had ≥1 MRM (*ASXL1, BCOR, EZH2, STAG2, SF3B1, SRSF2, U2AF1*, and/or *ZRSR2*) at diagnosis, at a VAF of ≥2%. We excluded pts with CBF-AML, APL, or treated secondary AML. MRM dynamics were tracked at baseline and best response (CR/CRi) and correlated with relapse free/overall survival (RFS/OS). **Results:** A total of 185 pts, median (med) age 69 yrs (range, 56-87 yrs), were included; 96% were ≥ 60 yrs. The common baseline MRM were *SRSF2* (54%), *ASXL1* (32%), *STAG2* (16%) and *BCOR* (14%); 16% had >1 MRM. Overall, 17% had concurrent *NPM1* mutation (mut), 9% *FLT3*-ITD (AR>0.05), 22% *RAS*, 32% *RUNX1*, 8% *TP53*, and 32/183 pts (17%) had ELN2017 adverse cytogenetics (CTG). 171 pts (92%) were treated with LIT+Ven and 14 (8%) LIT without Ven; 105 (57%) received hypomethylating agents based, and the rest (43%) received cladribine + low-dose cytarabine based LIT. Overall, 148 (80%) achieved CR and 37 (20%) CRi. 117/168 (70%) pts with available data were MRD negative (-) by flow cytometry (FCM; <0.01%) at CR/CRi. At CR/CRi, 49 (26%) cleared their MRMs (MRM-) while 136 (74%) retained MRMs (MRM+); among pts with FCM MRD- CR/CRi, 33/117 (28%) were MRM- and 84/117 (72%) MRM+. Med cycle to CR/CRi was 1 (IQR 1-2). Pts with MRM- at CR/CRi had superior med RFS (24 [95% CI 9-18] vs. 14 mos [16-NR], p=0.008) and OS (54 [25-NR] vs. 21 mos [15-27], p=0.01) compared to MRM+ pts. Among 117 FCM MRD- pts, med RFS (NR vs. 14 mos [9-23], p=0.001) and med OS (NR vs. 19 mos [14-36], p=0.003) was still superior among MRM- pts (n=33) vs. MRM+ (n=84). 67 pts (36%) underwent a hematopoietic stem cell transplantation (HSCT) in CR1, 26/49 (53%) MRM- and 41/136 (30%) MRM+. Among FCM MRD- pts who did not undergo HSCT, 2-yr OS rate (86% vs. 48%, p=0.04) was better in MRM- pts (n=15) vs. MRM+ pts (n=58); among FCM MRD- pts who had HSCT, 2-yr OS rate trended to favor MRM- pts (n=18) (77% vs. 55%, p=.14) vs. MRM+ pts (n=26). On backward selected Cox MVA, clearance of MRMs at CR/CRi was independently associated with favorable OS (HR=0.54, 95% CI 0.31-0.95, p=0.03), along with *BCOR, IDH2* mut, and HSCT, while *RAS* mut, *FLT3*-ITD, and adverse CTG were unfavorable. Finally, among FCM-MRD- pts at CR/CRi, using the same Cox model, clearance of MRMs was independently favorable for OS (HR=0.42, 95%CI 0.20-0.93, p=0.03). **Conclusions:** In our analysis, the status of MRM clearance at CR/CRi in LIT treated AML with baseline MRM affected survival outcomes, including in pts FCM MRD- at CR/CRi. Research Sponsor: None.

Impact of concomitant *NPM1* mutations on genomic and transcriptomic patterns of *PTPN11*-mutant myeloid leukemias. First Author: Shivahamy Maheswaran, University of Massachusetts Chan Medical School, Worcester, MA

Background: *PTPN11* mutations are associated with worse treatment outcomes in acute myeloid leukemia (AML) and frequently co-occur with *NPM1* mutations. However, the impact of concurrent *NPM1* mutations in *PTPN11*^{mut} myeloid leukemia is not well understood. This work aims to 1) characterize genomic features of a single-center cohort of patients with *PTPN11*^{mut}/*NPM1*^{wt} and *PTPN11*^{mut}/*NPM1*^{mut}-myeloid leukemia and 2) assess associated transcriptomic patterns. **Methods:** Patients with myeloid leukemia with *PTPN11* and/or *NPM1* mutations observed in blood (PB) or bone marrow (BM) were identified from the UMass Leukemia Registry. Next-generation sequencing (NGS) data were annotated for co-occurring variants and cytogenetic abnormalities. RNA-seq data from PB and BM samples from the Beat AML 1.0 trial were accessed via The Cancer Genome Atlas. Sample IDs with PTPN11^{mut}, NPM1^{mut} and PTPN11^{mut}/NPM1^{mut} were identified using the Vizome platform. High-throughput analysis of these samples and NPM1/PTPN11^{wt} was then performed using DESeq2. **Results:** 107 patients with myeloid leukemias at UMass Cancer Center harboring *PTPN11* mutations (n = 34) or *NPM1* mutations (n=74) were identified, 14 of whom had both. Subgroup analysis of chromosomal maps of *PTPN11*^{mut}/*NPM1*^{mut} cohort and *PTPN11*^{mut}/*NPM1*^{wt} cohort showed that the *PTPN11*^{mut}/*NPM1*^{wt} group had a higher cytogenetic abnormality burden compared to the *PTPN11*^{mut}/*NPM1*^{mut} group, demonstrating 18 observations of 12 distinct abnormalities compared to 5 observations of 3 distinct abnormalities, respectively. Analysis of RNA-seq from BM tissue of PTPN11^{mut}/NPM1^{wt} AML (n = 6) from the Beat AML 1.0 dataset revealed only 22 differentially expressed genes compared to PTPN11^{wt}/NPM1^{wt} samples. Of these, 12 were mitigated in the PTPN11^{mut}/NPM1^{mut} (n = 9) group. This trend was less pronounced in analysis of PB tissue. However, review of 20 most differentially expressed genes of both BM and PB in the PTPN11^{mut}/NPM1^{wt} group revealed many changes in long intergenic non-coding RNAs (lincRNAs). **Conclusions:** Genomic analysis of PTPN11^{mut}/NPM1^{wt} BM and PB highlighted widespread cytogenetic heterogeneity compared to the PTPN11^{mut} NPM1^{mut} subgroup. RNAseq analysis of PTPN11^{mut} BM and PB revealed significant differential expression in multiple lincRNAs, particularly in BM. These changes were mitigated in the double mutant group. Larger studies are needed to validate these findings and investigate whether presence of subtle regulatory shifts serve as a driving factor in the poor outcomes underlying PTPN11^{mut} AML. Further chromatin accessibility profiling studies may help elucidate the regulatory mechanisms driving these transcriptomic changes. Research Sponsor: None.

Can transcriptome-based risk modeling improve survival stratification across cytogenetic groups in acute myeloid leukemia? First Author: Amith Paruchuri, All India Institute of Medical Sciences, New Delhi, India

Background: Cytogenetic risk stratification is central to prognostication in acute myeloid leukemia (AML), yet survival outcomes vary considerably within each group. We hypothesized that transcriptomic features could further stratify survival within these cytogenetic categories, independent of clinical factors. **Methods:** We analyzed gene expression microarray data for 172 AML patients from the TCGA-LAML cohort (dbGaP phs000178). Multivariable Cox proportional hazards modeling incorporating age, gender, and CALGB cytogenetic risk was used to identify genes independently associated with overall survival. LASSO regression was applied to derive a transcriptomic gene signature and compute a patient-level transcriptomic risk score. Kaplan–Meier survival analysis, log-rank testing, and Cox modelling were performed in the overall cohort and within each cytogenetic subgroup. Model performance was assessed using concordance index (C-index) and likelihood ratio testing. Differential expression and Gene Ontology Biological Process (GOBP) enrichment were performed between high and low transcriptomic risk groups. **Results:** The transcriptomic risk score significantly stratified overall survival and, importantly, retained prognostic significance within favorable, intermediate, and poor cytogenetic risk groups (Table). The concordance index improved from 0.69 with clinical variables (age, gender, cytogenetics) alone to 0.82 after adding the transcriptomic risk score. Likelihood ratio testing confirmed a highly significant improvement in model fit with the inclusion of the transcriptomic score (χ^2 = 98.7, $p < 2.2\times10^{-16}$). GOBP enrichment of DEGs between high and low transcriptomic risk groups revealed upregulation of CD4-positive T-cell activation (STAT6, IL12RB1, ZBTB7B), negative regulation of immune response (LGALS9, PTPN6, FGL2), regulation of leukocyte and lymphocyte differentiation (ZC3H12A, VNN1, HCLS1), and response to bacterial molecules and lipopolysaccharide (NLRP3, MYD88, CASP1) confirming dysregulated immune signaling as a hallmark of adverse prognosis. **Conclusions:** A transcriptomic risk score provides powerful, independent prognostic information beyond cytogenetics and clinical factors in AML. These findings support the integration of transcriptomic biomarkers into existing risk models to refine AML prognostication. Research Sponsor: None.

Survival association of transcriptomic risk score across CALGB groups in AML patients.

CALGB Group	HR* (95% CI)	p value**
All AML patients (N =172)	3.74 (2.48–5.63)	2.81×10^{-10}
Favourable (N= 34)	14.53 (1.87–112.83)	1.05×10^{-2}
Intermediate (N = 97)	6.49 (3.43–12.26)	8.43×10^{-9}
Poor (N = 38)	2.68 (1.26–5.69)	1.01×10^{-2}

*HR: High vs Low genomic risk.

Mutation landscape and pathway-level disparities in Black versus White patients with acute myeloid leukemia. First Author: Chidiebube Ugwu, Department of Internal Medicine, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Racial disparities in acute myeloid leukemia (AML) outcomes are well-documented, yet race- specific genomic differences remain incompletely characterized. Current risk stratification systems, developed from European-ancestry cohorts, may inadequately classify patients (pts) of African ancestry (Stiff, *Nature Genetics*, 2024). We performed comprehensive clinicogenomic analysis to identify race-specific mutation patterns and their clinical impact in AML. **Methods:** We analyzed genomic and outcomes data on AML pts in AACR Project GENIE database. Mutation frequencies, co-mutation patterns, and pathway alterations were compared between racial groups. Survival analyses used Cox proportional hazards models adjusted for age and sex. Multiple comparison correction used Benjamini-Hochberg false discovery rate (FDR). **Results:** Our study included 2,359 pts (Black, n=243; White, n=2,116). Black pts demonstrated a distinct mutational landscape with fewer splicing factor (*SRSF2, U2AF1, SF3B1*) mutations (11.1% vs 20.1%, FDR p=0.003) and tumor suppressor (*TP53, WT1*) mutations (11.9% vs. 18.2%, FDR p=0.038). Signaling/RAS pathway mutations were nominally higher in Blacks. A notable finding was the emergence of MDS-related gene mutations in Black pts at a younger age, suggesting distinct disease biology. Among pts aged $<$40 years, ASXL1 mutations were more prevalent in Blacks (10.2% vs. 1.8%, p=0.006). Co-mutation architectures differed substantially by race: in Black pts, ASXL1 and RUNX1 frequently co-occurred with RAS/MAPK pathway mutations (ASXL1+RAS: 7.8% vs. 3.4%, FDR p=0.006), whereas White pts had predominant co-occurrence of *ASXL1* and *RUNX1* with splicing factor mutations Critical survival disparities emerged by mutation status. NPM1+FLT3 co-mutation was less common in Blacks (3.3% vs. 7.0%, FDR p=0.028) and conferred markedly inferior survival when present (median OS 6.7 vs. 14.6 months, p=0.008). Strikingly, favorable-risk mutations showed race-specific effects. NPM1-only (HR 0.79, p=0.014), IDH1-only (HR 0.68, p=0.005), and NPM1+IDH1 (HR 0.61, p=0.013) were protective in White but not in Black pts: NPM1-only (HR 0.89, p=0.76), IDH1-only (HR 0.84, p=0.71), NPM1+IDH1 (HR 0.34, p=0.13), challenging current risk stratification's universal applicability. Overall survival (OS) was similar (median OS- 18 vs. 16.7 months), though propensity-matched analysis trended toward worse outcomes in Blacks (18 vs. 25 months, p=0.091). **Conclusions:** Black AML pts exhibit fundamentally distinct molecular biology with differential pathway involvement, earlier MDS-related mutations, unique co-mutation patterns, and loss of prognostic value for traditionally favorable mutations. These findings demonstrate that race-blind risk stratification may systematically misclassify Black pts, supporting urgent need for ancestry-informed precision medicine approaches in AML. Research Sponsor: None.

Phase II study of dose-adjusted etoposide, prednisone, vincristine, cyclophosphamide, and doxorubicin (DA-EPOCH) ± rituximab (R) + tafasitamab (tafa) in adults with newly diagnosed (ND) Philadelphia chromosome–negative (Ph-) B lymphoblastic leukemia (B-ALL). First Author: Noam Edward Kopmar, Fred Hutch Cancer Center, Seattle, WA

Background: For adults with ND Ph- B-ALL, frontline regimens now often include the CD19/CD3 bispecific blinatumomab (blin). However, blin administration is challenging, particularly for less-experienced centers. DA-EPOCH ± R is safe and active in these patients (pts; Cassaday, et al, *Leuk Lymphoma*, 2023) and easier to deliver. Tafa is a CD19 monoclonal antibody active in B-cell lymphomas. We hypothesized that the addition of tafa to DA-EPOCH ± R will yield higher rates of measurable residual disease negativity (MRD-) without increasing toxicity or administration complexity. **Methods:** This is a phase II investigator-initiated study (NCT05453500) in adults ($>$18 years) with ND CD19+ Ph- B-ALL not eligible for a pediatric regimen. DA-EPOCH ± R was given as cited above; tafa 12 mg/kg was given IV on day (d) 1, 8, and 15 of each cycle (C). After blin consolidation was FDA approved, pts could receive this off-study. The primary endpoint was MRD- by multiparameter flow cytometry (MFC) per EuroFlow ($\sim<10^{-4}$) after C1 (~d 20); secondary endpoints included MRD- by MFC after C4 (~d 80); non-hematologic adverse events (AEs, CTCAE v5); and relapse-free (RFS) and overall survival (OS). Exploratory endpoints included high-throughput sequencing (HTS; $<10^{-6}$) by clonoSEQ in marrow and cerebrospinal fluid (CSF). If ^{3}13 of 30 evaluable pts (^{3}43%) are MRD- after C1, the primary endpoint is met (vs 28% with DA-EPOCH ± R alone; 80% power and one-sided α = 0.05). **Results:** From 3/2023 to 12/2025, 30 pts enrolled: 2 pts did not finish C1 due to grade (G) 4 AST elevation (related) and G5 *C. perfringens* sepsis (unrelated); 27 were evaluable for response and are the focus here. Median age was 67 (44-84), 70% male, 56% poor risk cytogenetics by NCCN, and 9 received R. Complete response (CR) rate was 85% (23/27); MRD- by MFC after C1 was 44% (12/27) and 80% (20/25) by C4 in pts with sufficient follow-up (f/u). In pts MRD- by MFC, 53% (8/15) were MRD- by HTS. Other G3+ AEs seen in $>$2 pts: infection (9); febrile neutropenia (8); low fibrinogen (6); hypotension (5); and syncope (4). Initial CSF MFC was positive in 3 pts; HTS was positive in these plus 4 more (7 total). With a median f/u among survivors of 10 mo (1-37), there were 3 relapses: 1 post-HCT and 1 after only 2 treatment cycles; all were CD19+, and 0 involved CNS. Only 2 pts got blin consolidation. 6 pts died: 4 non-relapse causes (3 post-HCT) and 2 from refractory ALL. No deaths were due to study treatment. 1-year RFS and OS were estimated to be 67% and 76%, respectively. **Conclusions:** DA-EPOCH ± R + tafa yields high rates of MRD-. Follow-up is immature, but early survival rates are comparable to more complex strategies. This study is on pace to reach its primary endpoint, with enrollment ending before the conference. HTS on CSF can identify CNS disease more frequently. Clinical trial information: NCT05453500. Research Sponsor: None.

Impact of variant topography of *NPM1* mutations in acute myeloid leukemia. First Author: Markie S. Zimmer, Henry Ford Hospital, Detroit, MI

Background: *NPM1* is a frequent driver mutation in AML and conveys favorable prognosis in the absence of *FLT3* mutations. Currently, *NPM1* subtypes (Type A, B, D and non-ABD) are approached uniformly. A granular analysis evaluating *NPM1* subtypes (ST) is essential to improve molecular risk stratification in AML. We seek to evaluate the molecular intricacies of *NPM1* variants and genomic architecture to determine how these influence outcomes in AML. **Methods:** The cohort had patient data from Karmanos Cancer Institute, meta-analytic cohorts (Awada et al., 2021; Kewan et al., 2023), cBioPortal, and AACR GENIE (v17) (Cerami et al., 2012; Gao et al., 2013; de Bruijn et al., 2023). Clinical and genomic characteristics of $NPM1^{MT}$ AML were reviewed. Insertions between nucleotides 863 and 864 determined the ST classification: TCTG (A), CATG (B), CCTG (D) and others (non-ABD). Stratification of *NPM1* by VAF was performed by quartiles from the median. Clonal hierarchy was defined as a difference in VAF $\geq$5% and differences $<$5% were designated as codominant. **Results:** Of 7653 patients with AML, 5342 (84.2%) had de novo AML. $NPM1^{MT}$ was present in 1570. Type A was most common (73%), followed by non-ABD (18%), B (5%) and D (4%). Median age was 66 years (IQR 53.8-73.7) and was similar across groups. Females more frequently had non-ABD than B or D (67% vs 45% and 53%, p=0.0008 and 0.04, respectively). Non-ABD had the least proliferative bone marrow compared to A, B or D (blast percentage 54 vs 79, 75.5, 70, p$<$0.0001, p=0.0015, p=0.02). Type A had lower VAF than other ST (29% vs 34%, p$<$0.0001), while B and D had higher VAF than other ST (38% vs 30%, p$<$0.0001 and 33% vs 30% p=0.0004). The most common co-mutation with *NPM1* was *DNMT3A* (48%). Type A was enriched for *DNMT3A* compared to other ST (54% vs 34%, p$<$0.00001). Type A and D had more *IDH1*, *IDH2*, and *NRAS* mutations than B and non-ABD (17% vs 10%, p=0.01; 23% vs 9%, p$<$0.00001; 16% vs 10%, p=0.03, respectively). B and non-ABD were more enriched in *WT1* compared to A and D (12% vs 4%, p=0.00002). Non-ABD was more enriched for *FLT3* mutations than other ST (39% vs 24%, p=0.00012). $DNMT3A^{R882}$ was enriched in high VAF (HV) compared to low VAF (LV) *NPM1* (54% vs 46%, p=0.01). *FLT3* was more common in HV *NPM1* (34% vs 17%, p$<$0.0001). *NPM1* was often a subclone (82%), but was more likely to be dominant in B (29%, p=0.001). The median OS of $NPM1^{MT}$ AML was 19 mo, similar across ST (A: 18 vs B: 14 mo, p=0.3896). OS was numerically higher in D (26 mo) and non-ABD (25 mo). LV *NPM1* (Q1 $\leq$ 22.8%) had significantly better OS than HV (Q3 $\geq$ 38%): 21 vs 10 mo (p$<$0.0001). This trend was most pronounced in D and non-ABD (D: 58 vs 10 mo, p=0.009; non-ABD: 29 vs 7 mo, p=0.005). **Conclusions:** As survival differences between *NPM1* mutation subtypes were numerically different, enrichment of Type A and D for *IDH1/2* and *NRAS*, non-ABD for *FLT3*, B and D for *WT1* probes the question of the impact of these co-mutations and VAF on *NPM1* outcomes. Further work will evaluate the impact of *NPM1* ST on de novo and therapy-related AML. Research Sponsor: None.

Impact of transplant on $TP53^{MT}$ configurational dynamics in myeloid neoplasms. First Author: Dakshin Sitaram Padmanabhan, Karmanos Cancer Institute, Detroit, MI

Background: Multihit *TP53* clonal configurations in myeloid neoplasms (MN) confers poor prognosis but therapy alters allelic burden in general. Using our previously described algorithm, patients with up-trending or stable (UT/S) $TP53^{MT}$ had worse OS than those who down-trended (DT); HSCT was associated with DT. We evaluated whether this pattern reflects intrinsic *TP53*-driven disease biology or from treatment/ transplant effects. **Methods:** We analyzed a serially sequenced $TP53^{MT}$ AML/MDS cohort from four academic centers using targeted NGS (Illumina MiSeqDx; 54-gene TruSight panel). *TP53* configurations were defined per Bahaj et al.: single-hit $TP53^{MT}$ as obligatory biallelic (VAF $>$50%), probable biallelic (23–50%), or probable monoallelic ($<$23%); combined VAF was used for double-hit $TP53^{MT}$. *TP53* clearance was defined as VAF $<$3%. Associations were tested with chi-square/Fisher tests and survival by Kaplan–Meier analysis. Clonal velocity (CV) was defined as the change in VAF from diagnosis to final serial sample post-transplant (Δ VAF) over post-HSCT survival time and categorized as stable (0 to $-$1), moderately downtrended (MD) ($-$1 to $-$5), or highly downtrended (HD) (≤ -5). **Results:** Among 119 $TP53^{MT}$ MN patients, 58 (49%) had pAML, 38 (32%) sAML, and 23 (19%) MDS. Median age was 65 years, 55% were male, and 20% had del(17p). Initial therapy included 7+3/CPX (34%), HMA+VEN (30%), or HMA alone (29%). 71 pts (60%) underwent HSCT (mOS 17 vs 5 mos in non-HSCT group; p$<$0.001). Among 62 with serial samples, 76% down trended *TP53* post-HSCT and 72% achieved *TP53* clearance. Patients in the UT/S group more often had complex karyotype (93% vs 64%; p=0.04) and numerically shorter time to HSCT (4 vs 5 mos; p=0.11). In the DT group, pre-HSCT therapy included 7+3 (30%), HMA alone (23%), and HMA+VEN (25%); HMA monotherapy was more common in UT/S vs DT (53% vs 23%; p=0.03). Mismatched/haploidentical transplants (in 45%) had numerically lower mOS than matched donor transplant (13 vs 52 mos; p=0.27); class II mismatch showed numerically better survival than class I or haploidentical (37 vs 12 mos; p=0.27). mOS was worse in UT/S (14 vs 22 mos; p=0.03). When stratified by clonal velocity (CV), the DT group showed stepwise differences in mOS: stable (78 mos), MD (26 mos), and HD (11 mos; p$<$0.0001). Stable CV was enriched for monoallelic *TP53* at diagnosis (60% vs 14% vs 6%; p=0.004), higher chronic GVHD (60% vs 24% vs 13%; p=0.03), and greater *TP53* clearance (100% vs 71% vs 56%; p=0.05), whereas HD CV was enriched for obligatory biallelic *TP53* (p=0.001). PTCy use was highest in the MD group (30% vs 76% vs 50%; p=0.04). **Conclusions:** UT/S patients had higher pre-HSCT HMA monotherapy use and complex karyotypes. Stable CV was associated with monoallelic *TP53*, lower PTCy use, higher chronic GVHD, greater *TP53* clearance, and superior survival, suggesting that the rate of *TP53* clonal contraction rather than clearance alone best predicts OS and reflects intrinsic $TP53^{MT}$ disease biology. Distinction of FLT3-ITD transcriptomic signature from FLT3-TKD and the frequency of this signature in acute myeloid leukemia without *FLT3* mutation. First Author: Maher Albitar, Genomic Testing Cooperative LCA, Lake Forest, CA

Background: The FLT3 gene plays a major role in acute myeloid leukemia and frequently overexpressed irrespective of its mutation status. FLT3 internal tandem duplication (ITD) and tyrosine kinase domain (TKD) mutation are both associated with adverse prognosis, but the ITD is associated with more aggressive disease and higher relapses than the TKD. Therapeutically, FLT3-TKD has different resistance implications from FLT3-ITD. We used transcriptomic data to compare AML FLT3-ITD-positive (ITD+) with FLT3-TKD-positive (TKD+), then tested if AML FLT3-negative (FLT3-) may have RNA signature similar to those seen in ITD+ or TKD+ AML. **Methods:** Between 2023 and 2025, 906 AML samples were RNA profiled using next generation sequencing. A targeted NGS panel of approximately 1,600 genes was used. More than 100 million reads were required to accept RNA results. The required percentage of spliced RNA reads was above 20%. Of these samples, 171 had FLT3-ITD and 115 had FLT3-TKD mutations and 619 were FLT3-. **Results:** We first explored if expression profiling can define a subgroup of TKD+ cases that are similar to those with ITD+ AML. Using 22 genes in random forest modeling, expression profiling segregated ITD+ AML from TKD+ AML with AUC of 0.734 (95% CI: 0.638-0.831, Precision: 0.940). The top genes relevant for this segregation were GRB10, PTK7, WT1, TEC, CASP3, NR6A1, and CD47. We then build a random-forest-based model to distinguish ITD+ from FLT3- cases. We used the 171 ITD+ AML and a set of 220 FLT3- AML cases to distinguish between the two groups. Using 45 genes in this model we were able to segregate with the ITD+ cases based on expression with AUC of 0.889 (95% CI: 0.833-0.945, precision : 0.935). Top genes were LUC7L2, NFYC, PRPF40B, PRPF8, SF3A1, SMAD5, THRA, ACVR1, EVI2A, MCM3AP. This highly predictive model was then used to test independent set of 399 FLT3- AML cases. Of these cases 319 (80%) had a signature similar to ITD+ AML. Similarly, we used the 115 TKD+ with the 220 FLT3- AML cases and built a random forest-based model to distinguish between the two groups. This model required 70 genes and was less robust but segregated the TKD+ AML with AUC of 0.784 (95% CI: 0.701-0.868, precision: 0.842). Testing an independent set of 399 FLT3- cases using this model showed TKD signature in 236 (59%) of FLT- cases. All these positive TKD signature cases were also positive for the ITD signature. **Conclusions:** This data suggests that significant number of AML cases are biologically driven by changes similar to those seen in FLT3-mutant cases. While clinical trial is needed for confirmation, these cases with FLT3-ITD signature may respond efficiently if treated with therapy including FLT3 inhibitors in fashion similar to that seen ITD+ cases. Furthermore, this data suggests that ITD signature might be a better biomarker than TKD mutation for selecting patients to be treated with FLT3 inhibitors. Research Sponsor: None.

Real-world outcomes of early unfractionated heparin use in NSTEMI patients with acute leukemia and severe thrombocytopenia. First Author: Shanawar Ali Waris, West Virginia University School of Medicine, Department of Internal Medicine, Morgantown, WV

Background: Current AHA/ACC guidelines provide limited guidance for acute non-ST-segment elevation myocardial infarction (NSTEMI) management in patients with active hematologic malignancy and concurrent severe thrombocytopenia, as these individuals have been systematically excluded from randomized trials. Consequently, decisions regarding anticoagulation rely on expert opinion and limited observational data. We evaluated real-world outcomes in patients with acute leukemia, severe thrombocytopenia, and NSTEMI, comparing early unfractionated heparin use with no parenteral anticoagulation. **Methods:** We conducted a multicenter retrospective cohort study using the TriNetX Research Network to identify adults ($\geq$18 years) with acute leukemia who experienced a first NSTEMI following leukemia diagnosis. Severe thrombocytopenia was defined as a platelet count $< 50\times10^3/\mu L$ measured within 24 hours of NSTEMI. Patients with prior intracranial hemorrhage or on chronic anticoagulation were excluded. The primary exposure was unfractionated heparin administered within 24 hours of NSTEMI diagnosis versus no parenteral anticoagulation. Propensity score matching (1:1) was performed for demographics, cardiovascular risk factors and chronic co-morbidities. Primary efficacy outcomes were all-cause mortality at 30 days, 90 days, and 1 year. The primary safety outcome was major bleeding, defined as a composite of intracranial and gastrointestinal hemorrhage at 7 days, 30 days, and 90 days. Kaplan-Meier analysis, hazard ratios (HR), risk ratios (RR), and 95% confidence intervals (CI) were used to assess outcomes. **Results:** Among 1,734 patients who met the inclusion criteria, 639 received unfractionated heparin and 1095 did not. Following, PSM 528 patients remained in each group. Kaplan–Meier overall survival at 30 days, 90 days, and 1 year was significantly improved in patients receiving early unfractionated heparin (30-day HR = 0.78 [0.64-0.96]; 90-day HR = 0.77 [0.64-0.92]; 1-year HR = 0.75 [0.64-0.87]). Composite major bleeding events at 7 days, 30 days, and 90 days were similar between groups (7-day RR = 1.56 [0.95-2.56]; 30-day RR = 1.15 [0.81-1.77]; 90-day RR = 1.24 [0.88-1.83]). **Conclusions:** In this large real-world study of patients with acute leukemia, severe thrombocytopenia, and NSTEMI, early unfractionated heparin administration within 24 hours was associated with improved survival without an increased risk of major bleeding, addressing a critical evidence gap in this high-risk population. Research Sponsor: None.

Overall Survival			
Timepoint	Heparin (%) [n=446]	No Heparin (%) [n=446]	HR (95% CI)
30-day	66.9%	59.3%	0.78 [0.64-0.96]
90-day	55.3%	45.6%	0.77 [0.64-0.92]
1-year	36.9%	23.8%	0.75 [0.64-0.87]
Major Bleeding			
Timepoint	Heparin (%) [n=446]	No Heparin (%) [n=446]	RR (95% CI)
7-days	7.6%	5%	1.56 [0.95-2.56]
30-day	10.9%	9.8%	1.19 [0. 81-1.77]
90-day	14.1%	11.6%	1.27 [0.88-1.83]

A two-axis machine learning framework for cell-of-origin inference in AML: A proof-of-concept study. First Author: Jonathan Dan Andreadakis, Tampa General Hospital Cancer Institute, Tampa, FL

Background: Leukemogenesis mirrors hematopoietic differentiation yet proceeds through dysregulated programs. Multiparameter flow cytometry (MFC) allows leukemia immunophenotypes projection onto normal myeloid ontogeny. Here, we apply machine-learning (ML) models trained on MFC data to reconstruct a preliminary data-driven representation of inferred cell-of-origin (COO). Additionally, we explore integration of monocytic differentiation into canonical COO framework to identify dysregulated commitment programs not explained by developmental maturity alone. **Methods:** After IRB approval, MFC data from 261 AML patients were aligned to immunophenotypic signatures of normal myeloid ontogeny (HSC, MPP, CMP, GMP, GP, MP) as previously described (Simoes *et al.*, *Blood Neoplasia*, 2024; Vergez *et al.*, *Blood Cancer Journal*, 2022). Probabilistic COO states were inferred from core markers (CD34, HLA-DR, MPO, CD33, CD117) using ensemble Random Forest classifiers with gradient boosting [Training/Validation=70/30]. Because canonical COO algorithms omit monocytic features, we implemented a secondary Mono-Risk Layer trained on monocytic markers (CD14, CD64) and stemness/invasiveness surrogates (CD56, reflecting adhesion, migration propensity) and CD123, to generate complementary phenotypic labels. Models were trained with cross-validation in Python, and mutation enrichment was projected onto inferred COO states. **Results:** Mean age was 63.8 years. 114/261(44%) were male. 123/261 (47.1%) of cases produced multidimensional P-COO achieving "Ensembled (RF+ Boosting Gradient)" AUC=0.74. Confusion matrix revealed a structured pattern of misclassification predominantly between adjacent COO states, consistent with a continuous differentiation manifold (Recall for MPP, CMP, GMP, GP, MP, 50% 83%, 62%, 65%, 76%, respectively). Mono-Risk-Layer (MRL) improved discriminatory ability for MP (AUC 0.94, Recall 86%, F1 0.75). *NPM1* was mapped to GMP (60%), MP (34%) and CMP (27%), p=2.61e-09, *FLT3 ITD* GMP (43.3%), CMP (32.4%) and MP (12.3%), p=4.72 e-05, *TP53* HSC (50%), MPP (24.3%) and GMP (16%), p=3.6e-04, *RUNX1* MPP (26.1%), HSC (25%) and MP (13%), p=7.7 e-03, RAS MP (35%), MPP (19%) and HSC (13%), p=5.18 e-03. **Conclusions:** Machine-learning–based probabilistic cell-of-origin inference from routine flow cytometry is feasible and biologically informative in AML. Incorporation of a monocytic risk layer improves resolution of monocytic programs not captured by canonical COO and reveals distinct mutation–differentiation relationships. *NPM1* and *FLT3-ITD* are enriched in GMP/MP-like states, *TP53* in primitive HSC/MPP compartments, *RUNX1* in early progenitors, and RAS in monocytic-skewed trajectories. These findings link genomic drivers to specific developmental niches and establish a scalable framework for biologically grounded AML classification and therapeutic modeling. Research Sponsor: None.

Impact of cell-type–specific circadian disruption in pediatric B-ALL on clock-based biomarkers with implications for chronotherapy. First Author: Angela Relógio, Institute for Systems Medicine and Faculty of Human Medicine, MSH Medical School Hamburg, Hamburg, Germany

Background: B-cell acute lymphoblastic leukaemia (B-ALL) is the most common paediatric malignancy. While cure rates exceed 90%, treatment remains intensive and is frequently associated with relapse, toxicity, and long-term adverse effects. The circadian clock regulates DNA repair, metabolism, immune function, and drug pharmacokinetics—processes central to cancer therapy. Although treatment timing has been shown to influence outcomes in childhood ALL, the molecular circadian landscape of malignant versus healthy hematopoietic cells in paediatric patients remains unexplored. **Methods:** We performed an integrated molecular and clinical circadian profiling study in paediatric ALL patients (N=7) and age-matched healthy controls (N=10). Peripheral blood, bone marrow, and saliva samples were collected at diagnosis. $CD19^+$ (leukemic B cells) and paired $CD19^-$ (non-B cells) populations were isolated and used to establish an internal, patient-specific circadian baseline. Expression of ~800 cancer-, immune-, and clock-related genes was quantified using NanoString SPRINT technology. Rhythmicity parameters (acrophase, amplitude, MESOR), differential expression, and machine-learning–based classification were integrated with longitudinal clinical and physiological data. **Results:** Malignant $CD19^+$ cells exhibited marked circadian dysregulation compared with paired $CD19^-$ cells from the same patients. Core clock architecture was altered specifically in leukemic cells, including disrupted BMAL1–PER2 phase relationships and reduced rhythmic amplitude. CD19 expression itself displayed cell-type–specific circadian modulation, with higher amplitude and phase variability in $CD19^+$ cells. In contrast, $CD19^-$ cells retained more coherent circadian organization, supporting their use as an internal normalization reference. Preliminary analyses suggest that the degree of circadian misalignment between $CD19^+$ and $CD19^-$ compartments correlates with treatment dynamics, including early response and therapy duration. **Conclusions:** Our findings reveal profound, cell-intrinsic circadian disruption in paediatric B-ALL and demonstrate that comparing malignant $CD19^+$ cells against paired non-malignant $CD19^-$ cells enables robust detection of clock dysregulation. These results provide a molecular framework for developing circadian biomarkers and support the rational design of chronotherapy strategies aimed at optimising efficacy while minimising toxicity in paediatric leukaemia. Research Sponsor: Dr. Rolf Schwiete Stiftung.

Cladribine (CLAD) + low-dose AraC (LDAC) + venetoclax (VEN) in patients with acute myeloid leukemia and high-risk myelodysplastic syndrome: Real-world analysis from a large community-based oncology practice. First Author: Janvi Bhatia, Community Hospitals Network/MD Anderson, Indianapolis, IN

Background: A lower intensity combination cladribine (CLAD), low dose cytarabine (LDAC), and venetoclax (VEN), alternating with hypomethylating agents (HMA) + VEN has been shown to be highly effective in the treatment of older and/or unfit patients with newly diagnosed AML, producing high rates of MRD negative complete remission (CR), low early mortality, and successful transition to allogeneic stem cell transplant. While this was conducted in a large academic center in a prospective phase II study, we aimed to assess the efficacy and safety of this approach in a community practice setting, with important implications of broader applicability. **Methods:** This is a single-center retrospective study evaluating the efficacy and safety of using the CLAD/LDAC/VEN alternating with HMA/VEN regimen in a large oncology practice in the community setting. Dosing of CLAD/LDAC/VEN was according to published experience (Kadia, et al. JCO 2022). Patients with high risk MDS or AML treated in our institution from January 13, 2023-November 18, 2025 were included. Pts with prior treatment, including HMA for prior MDS transforming to AML (treated secondary AML, ts-AML) were also included. **Results:** A total of 72 patients received at least 1 cycle of CLAD/LDAC/VEN. The median age was 74 yrs (range: 43-90). Median PS was 1 (0-2), including 21 (29%) pts with ECOG PS of 2 (29%). 58 pts had AML, including 44 (78%) with untreated AML, 10 (18%) with ts-AML, and 12 (22%) with relapsed AML; 14 pts had high risk MDS, of which 5 (36%) had failed prior HMA . 37 pts (51%) had adverse risk karyotype by ELN 2022 , 16 (22%) had TP53 mutation and 29 29 (40%) had secondary AML. Twenty-nine (40%) pts had received prior therapy, including 13 pts (18%) with prior HMA. The median number of cycles received was 2 (range 1-14). Among untreated AML and MDS, the composite CR (CRc) rates were 63% and 58%, respectively. Six out of 16 pts with p53 (38%) achieved CRc and of 16 pts with prior HMA 6 (38%) achieved CRc. The median survival (OS) was 8 months (range 0.16-33m). Eleven pts (15%) went on to have allo-SCT. Five pts (7%) died within 28 days of first treatment. Three of these died of infectious complications, 1 died of an acute coronary event and 1 patient decided to go on comfort care mid-way through treatment. **Conclusions:** CLAD/LDAC/VEN was feasible and effective in a high-risk, older patient population including pts with prior treatment who were able to achieve meaningful disease control and used as a bridge to transplant. The regimen translated well to a community setting, with relatively low 28-day mortality and good tolerability. Research Sponsor: None.

Age and the genomic landscape of AML in precision oncology: An analysis using ASH HematOmics Program. First Author: Pranav Singh, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: Age is a major determinant of prognosis and treatment selection in acute myeloid leukemia (AML), yet the extent to which chronological age reflects underlying genomic and transcriptomic features remains incompletely characterized. The American Society of Hematology HematOmics Program (ASHOP) provides a centralized, clinically annotated genomic resource enabling systematic evaluation of age-associated AML biology across molecular subtypes. **Methods:** We conducted a cross-sectional analysis of adults with AML using ASHOP data. Patients were categorized by age ($<$40, 40-59, 60-74, and $\geq$75 years). AML molecular subtypes were defined based on recurrent cytogenetic and genomic alterations (NPM1, PML::RARA, CBFB::MYH11, MECOM, CEBPA, AML-MR, KMT2A, DEK::NUP214, TP53, and other recurrent translocations), aligned with WHO classification. Adverse genomic risk was defined by AML-MR, MECOM, and TP53. Gene expression levels for epigenetic regulators (DNMT3A, TET2, IDH1, IDH2, FLT3) and stemness-associated genes (HOXA9, MEIS1, HLF, GATA2, PROM1) were standardized as z-scores, and composite scores generated. Associations were assessed using chi-square tests, linear regression, and multivariable models adjusted for sex. **Results:** Among 302 patients (mean age 71.1 $\pm$ 17.3 years; 47.7% aged $\geq$75; 54.3% male), the most common subtypes were NPM1 (20.5%), PML::RARA (16.6%), CBFB::MYH11 (15.6%), MECOM (14.2%), CEBPA (10.9%), AML-MR (9.6%), and KMT2A (7.6%). Subtype distribution varied modestly across age groups (p=0.053) but not by sex (p=0.858). Adverse genomic risk increased significantly with age (p=0.016). In multivariable logistic regression adjusted for sex, patients aged $\geq$75 had significantly higher odds of adverse genomic features (OR 2.78, 95% CI 1.26, 6.12; p=0.011), while sex was not independently associated (p=0.325). In transcriptomic analyses (n=265), age was not associated with individual epigenetic or stemness genes, with age and sex explaining minimal variance in composite scores (epigenetic score R^2=0.013, p=0.506; stemness score R^2=0.003, p=0.957). In contrast, molecular subtype showed strong associations. Subtype along with age and sex explained 16.4% of epigenetic score variance (R^2=0.164; p$<$0.001) and 38.0% of the stemness score variance (R^2=0.380; p$<$0.001). Key stemness genes were highly subtype-dependent (HOXA9 R^2=0.709; MEIS1 R^2=0.599; both p$<$0.001), driven primarily by NPM1 and KMT2A subtypes. **Conclusions:** Advanced age in AML is associated with adverse genomic risk accumulation but explains minimal variance in stemness or epigenetic transcriptional programs. Instead, these programs are largely determined by molecular subtype. Hence, stemness and epigenetic programs are intrinsic properties of AML molecular subtypes rather than age, supporting subtype-driven risk stratification and therapeutic decision-making in the precision oncology era. Research Sponsor: None.

6544 **Poster Session**

From infancy to young adulthood: Exploring the divergent genomic mechanisms that drive AML. First Author: Frank J. Scarpa, NeoGenomics Laboratories Inc., Fort Myers, FL

Background: Pediatric & young adult Acute Myeloid Leukemias (pAML & YA AML) are an uncommon, heterogenous, & clinically challenging group of malignancies, as age ranges widely & proper therapy selection (i.e. pediatric vs. adult regimens, etc.) can be unclear. The genomics of these disorders can help understand distinct disease biology, better risk stratification, & improve outcomes. **Methods:** Bone marrow, peripheral blood, or FFPE samples from 870 suspected AML patients were sequenced using a 302 gene panel to detect SNVs/indels. 466 underwent RNA fusion detection of 184 genes & DNA analysis for CNV detection of 24 genes. Only pathogenic/likely pathogenic variants were included in the analysis. AML patients were split into 4 groups based on age: Infant (≤3, n=30), Childhood (4-14, n=51), Adolescent (15-19, n=51), YA (20-35, n=738). 4750 DNA/RNA sequenced adult AML patients (>35) were also included in the analysis. Statistics were performed using Fisher's exact test. **Results:** pAML patients (infant, childhood, & adolescent) had a high prevalence of FLT3 & NRAS variants (17.4% & 15.2%) & fusions (26.2%) while YA AML had a high prevalence of fusions (29.2%), FLT3 (20%), NRAS (12.5%), & WT1 (12.6%) variants. Adult AML had a high prevalence of TET2 (18.4%), DNTM3A (18.3%), ASXL1 (16.8%), SRSF2 (14.8%), & TP53 (14.2%) variants, highlighting an increased prevalence of mutations associated with clonal hematopoiesis or prior chronic myeloid neoplasms. Infant AML had a higher number of GATA1 variants (33.3% vs. 0% - 2%, p<0.00001) vs. childhood, adolescent, & YA AML; trisomy 21 was present in 90% of patients by CNV detection. Fusions were only found in 5% of infant AML (p=0.02) vs. 29.2% - 34.5% in other groups. FLT3 variants were lower in infant (10%) and childhood AML (13.7%) vs. adolescent (25.5%) & YA (20%) while NRAS variants were higher in adolescent AML (21.6% vs. 6.7% - 13.7%). Childhood AML had a higher prevalence of RUNX1 fusions (16.1% vs. 0 – 5.4%, p=0.03) & Adolescent AML had a higher prevalence of PML::RARA fusions (13.8% vs. 0% – 6.5%) vs. other groups. YA AML had a higher prevalence of WT1 variants (12.6% vs. 0% - 7.8%, p=0.02). CNV loss in IKZF1 (7p12) were more prevalent in adolescent AML (10.3% vs. 0-0.5%, p=0.002); EZH2 CNV loss (7q36) were more prevalent in YA & childhood AML (4.7% & 3.4% vs. 0%). Upon aggregating genes by their molecular function, infant AML had a lower prevalence of variants in epigenetic genes (6.7% vs. 15.57-24.8%, p=0.02), RAS (10% vs. 23.2%-25.5%), & signaling genes (16.7% vs. 27.5% – 41.2%). Variants in DNA repair genes were more frequent in adolescent AML (13.7% vs. 3.9% - 6.7%, p=0.01). **Conclusions:** Infant, childhood, adolescent, & YA AML harbor unique genetic profiles that distinguish themselves from each other and reflect divergent and evolutionarily favored mechanisms behind leukemogenesis. Understanding these genetic profiles can help predict prognosis & help tailor more effective treatments. Research Sponsor: None.

TP53 mutation adoption of stromal-adhesion/neuronal-like programs as a driver of stress adaptation and acute myelogenous leukemia cell survival. First Author: Alexandra Thalberg, University of Minnesota, Minneapolis, MN

Background: *TP53*-mutated AML is associated with early relapse and poor survival, highlighting the need to define p53-driven transcriptional programs that may reveal targetable therapeutic vulnerabilities. Systematic deconvolution of the TP53-associated transcriptome provides a critical framework to uncover dependencies associated with drug resistance. **Methods:** After IRB approval, 311 AML patients were screened; 93 (30%) with available NGS were included (32 TP53-mutated, 61 TP53-wild type). Bulk transcriptome data were available for 11 TP53+ and 13 TP53-WT cases. Overall survival was analyzed using Kaplan–Meier and multivariable Cox regression. Transcriptional modules predictive of TP53+ AML were identified using Random Forest and pathway enrichment via KEGG/Reactome with confirmation by ToppGene. Public single-cell RNA-seq datasets from the MIT Single Cell Portal were queried to assess whether low TP53 expression states recapitulate bulk TP53-mutated transcriptional programs. **Results:** OS was 168 and 624 days (d) in TP53+ and TP53 WT cases (HR = 4.2, p = 0.02). Only CK retained independent effect for OS (HR = 0.33, 95% CI = 0.13–0.82, p = 0.014) when accounting for TP53 mut status and age. *TP53* mut status imprinted a deep transcriptomic signature (AUC = 0.94). Top upregulated genes included FHL2 (p = 4.0×10−6, FDR = 0.004), HMGA2 (p = 1.4×10−3, FDR = 0.02), ARHGEF12 (p = 5.2×10−3, FDR = 0.04), RYR3 (p = 2.1×10−3, FDR = 0.03), LRRC7 (p = 7.7×10−3, FDR = 0.05), ALDH1A1 (p = 1.4×10−3, FDR = 0.02). Top downregulated genes included CSF1 (p = 4.7×10−4, FDR = 0.007), CD34 (p = 1.2×10−3, FDR = 0.01). To uncover pathway-level shifts co-opted by TP53+ AML, we contrasted pathway-level projection against TP53 WT cases. Upregulated pathways included adhesion / stromal dependence (p = 0.0004; FDR = 0.0028), neurotrophin / calcium signaling / Ca2+-coupled survival (p = 0.0006, FDR = 0.0021). However, downregulated pathways included cytokine-cytokine receptor interaction (p = 4.7×10−4, FDR = 0.007) and myeloid differentiation (p = 1.2×10−3, FDR = 0.01) [Fig. 2]. Interestingly, in lineage-resolved single-cell reference, low TP53 GE was visually colocalized with perivascular/stromal cells exhibiting high FHL2 and THY1 (CD90) expression. This data reconfirms prior data suggesting that reduced TP53 function favors niche-adapted perivascular/MSC-like reprogramming (THY1-high) that protects "resistant AML clones" (Mizuno et al., ASH 2024). **Conclusions:** These findings unveil that TP53+ AML co-opts leukemic blasts toward a stromal-adhesive and neuronal-like state, allowing survival under metabolic and therapeutic stress. Reversing stromal adhesive / neuronal-like rewiring may attenuate *TP53*+ blasts hijacking on vascular niche that maintains relapse potential. Research Sponsor: None.

Induction failure (IF) as a prognostic marker in adult acute lymphoblastic leukemia (ALL). First Author: Yosef Joseph Rene Amel Riazat Kesh, Weill Cornell Medical Center/NewYork Presbyterian, New York City, NY

Background: Despite advances in the treatment of adult ALL, risk factors for IF and optimal management are poorly understood. We aimed to characterize patients (pts) with IF after therapy for newly diagnosed (nd)ALL and their outcomes. **Methods:** We performed a retrospective chart review of adult ndALL pts treated at Weill Cornell Medicine from 2012-2025. We defined IF as failure to achieve < 5% bone marrow blasts, count recovery and extramedullary disease clearance after 1 cycle of induction. Fisher's exact test was used for analysis of discrete variables and Wilcoxon rank-sum test for continuous ones. **Results:** Among 220 pts, 48.2% were female, mean age at diagnosis was 50.5 (18-87) yrs, 74.5% had B-cell ALL (of which 41.5% Ph+), with median follow-up 24.5 months. 34 pts (15.5%) had IF (22 B cell, 12 T cell). B-cell IF patients were more likely to have Ph-(77.3% vs 50%, p=0.0211) or Ph-like phenotype (13.6% vs 3.5%, p=0.0753). IF pts were more likely to have CNS disease at diagnosis (p= 0.034). There was no significant difference in baseline median white cell count (13.18 vs 9.60 p=0.4) or LDH (448 vs 517 p=0.17) in IF vs non-IF pts. IF was not associated with age, asparaginase-treatment, BMI, abnormal cytogenetics, pertinent mutations, or year of diagnosis. On multivariable logistic analysis controlling for age and lineage, CNS disease at diagnosis remained associated with IF (OR 2.81, p=0.0343). Overall survival (OS) was significantly worse in IF vs non-IF pts at 3-years (29.2% vs 66.8%, p = 0.0002). OS did not vary by CNS disease at diagnosis in IF pts. Of IF pts, 27/34 (79.4%) achieved CR with subsequent therapy (median time to CR 68.5 days, range 21-228), with improved survival vs the 7 pts (5 B cell, 2 T cell) who did not (p = 0.00001). 4/7 patients without CR died within 4 months, and none of these 7 patients received allo-SCT. In the 27 IF pts attaining later CR, there was a trend towards worse OS vs non-IF pts (1029 days vs not reached, p=0.0659), though importantly a subset of 10 pts who achieved minimal residual disease (MRD)-negativity had OS similar to the non-IF group (p=0.95). IF patients were more likely to receive allo-SCT than non-IF patients (51.4% vs 29.7%, p=0.0164). Receiving allo-SCT tended to be associated with improved survival in this group (p=0.0578) vs no allo-SCT. 16/22 B cell IF patients received blinatumomab and/or inotuzumab. These were not associated with MRD-negative status or allo-SCT, but did show a trend towards subsequent CR (p=0.1) and better OS (p=0.1119). **Conclusions:** In our single-center retrospective cohort of ALL pts, 15.5% had IF. 29.4% of these patients (4.5% of the total cohort) were able to achieve MRD- status with subsequent treatment, resulting in outcomes comparable to pts without IF. ALL-IF patients should be closely monitored for MRD and may benefit from early application of immunotherapeutic approaches and/or allo-SCT. Research Sponsor: None.

Phase 1 study of venetoclax combined with a 10-day regimen of decitabine in subjects with high-risk acute myeloid leukemia. First Author: Rafael Madero Marroquin, Section of Hematology & Oncology, Department of Medicine, University of Chicago, Chicago, IL

Background: We and others have reported the antileukemic activity of a 10-day regimen of the hypomethylating agent (HMA), decitabine (DEC), in high-risk acute myeloid leukemia (AML). Venetoclax (VEN), at a standard (std) dose of 400 mg, combined with HMA, at a std schedule, has improved AML outcomes. We aimed to investigate the safety of adding VEN to the 10-day regimen of DEC and explore the effects of BCL2 inhibition on the immune repertoire. **Methods:** This was a multicenter, investigator-initiated, dose-escalation study in adults with high-risk AML defined as, disease with a *TP53* mutation, adverse-risk cytogenetics or relapsed/refractory (R/R). Patients (pts) were naïve to HMA and VEN. The primary endpoint was to establish the maximum tolerated dose (MTD) of VEN when combined with a 10-day DEC schedule. Dose-limiting toxicities (DLT) were evaluated during cycle 1. In the absence of a DLT, 3-6 evaluable pts were enrolled per dose level (DL) or until the 400mg DL of VEN was reached (Table 1). Peripheral blood mononuclear cells (PBMCs) were isolated before and after treatment. Shifts in the immune landscape and BCL2 family expression were profiled with spectral flow cytometry. **Results:** 14 pts were enrolled, with a median age of 66.5 years (range 19-77); including 9 pts (64%) with R/R AML, 8 (57%) with adverse-risk cytogenetics and 6 (43%) with a *TP53* mutation. One pt had a DLT at DL1, due to grade (G) 4 neutropenia and persistent marrow aplasia in the absence of leukemia beyond day 42. One patient with R/R AML and pre-existing elevated alanine aminotransferase (ALT) secondary to known graft-versus-host disease developed G2 ALT elevation. 3 pts were then enrolled at DL-1, before reescalation back up to DL1. 2 pts at DL1 were deemed not eligible for DLT evaluation, requiring an additional 2 pts enrolled at DL1, without DLT, to confirm safety. The MTD was determined to be DL2 (400 mg). 5 pts (36%) had a complete remission (CR) or CR with incomplete count recovery (CRi). Non-hematologic or infectious G1-2 toxicities included fatigue (43%), diarrhea (43%) and decreased appetite (36%). 1 pt died of suspected sepsis outside of the DLT evaluation period. 7 pts had serial PBMCs available for multiparameter flow cytometric immune and BCL2 family profiling. Of these, 3 responders had strong induction of BCL2 in CD4+/CD8+ lymphocytes and B cells after 1 cycle and were enriched for a population of "senescent" CD8+ T cells that had relatively low expression of coinhibitory markers (PD-1, LAG3, TIM3). **Conclusions:** A 10-day DEC+VEN regimen is feasible in high-risk AML, with myelosuppression being the major DLT. The recommended phase 2 dose is 400mg VEN (DL2), but responses were also seen at 200mg. The immune profile of responders have demonstrated intriguing patterns that merit investigation in a larger HMA+VEN cohort. Clinical trial information: NCT03844815. Research Sponsor: Abbvie.

DL	DEC dose(D1-10)mg/m2	VEN dose (D1-21)mg	# of pts	DLT	CR	CRi	No Response
-1	15	100	3	0	0	0	3
1	20	200	8	1	1	3	4
2	20	400	3	0	0	1	2

Time to response with HMA/venetoclax as a predictor of survival in acute myeloid leukemia: Analysis of 1- vs 2-cycle responders. First Author: Rafeh Safdar, University of Kentucky, Lexington, KY

Background: Hypomethylating agents (HMA) with venetoclax are the standard of care for patients with AML ineligible for intensive chemotherapy. However, the prognostic significance of time to response and the optimal duration of venetoclax, often modified in real-world practice due to myelosuppression, remain unclear. **Methods:** We conducted a retrospective analysis of adults with AML achieving CR/CRi with HMA/venetoclax at University of Kentucky from 2016-2025. Patients were stratified by cycle of response: 1 vs 2 cycles, using ELN 2022 response criteria. These groups were compared by demographics, cytogenetic and mutational profiles, and allogeneic HSCT. RFS and OS were estimated using Kaplan-Meier methods and compared with log-rank tests. Cox models evaluated associations between cycle of response, response type (CR vs CRi), and survival outcomes. **Results:** Eighty-six responding patients were included, with 69 (80%) achieving response after 1 cycle and 17 (20%) achieving response after 2 cycles. Median age was 66.7 vs. 67.1 years, male sex was 58% vs. 76%, and ELN risk distribution was similar: favorable 25% vs. 18% and adverse 64% vs. 65% (p=0.671). Frequent cytogenetic profiles included normal karyotype (44% vs. 41%) and complex karyotype (27% vs. 24%), and common mutations included *IDH1/2* (23% vs. 18%), *DNMT3A* (19% vs. 24%), and *NPM1* (22% vs. 12%). Overall, baseline demographics and cytogenetic/mutational profile were similar between 1-cycle and 2-cycle responders, supporting comparability of these groups for outcome analyses. With a median follow-up of 23.8 months, relapse occurred in 36% of 1-cycle responders vs. 82% of 2-cycle responders (p=0.002). Inferior RFS was noted in 2-cycle responders (HR 3.04, p=0.002), which remained after adjusting for total venetoclax exposure (HR 3.26, p=0.002). Median OS was 22.8 months (95% CI 14.0–NR) for 1-cycle responders and 12.7 months (95% CI 7.2–NR) for 2-cycle responders (p=0.01). In Cox models, 2-cycle response was associated with significantly inferior OS (HR 2.33, p=0.012), which persisted after adjusting for venetoclax exposure (HR 2.26, p=0.018). Hematologic recovery at time of CR was assessed and was not significantly associated with cycle of response or survival outcomes. Increased venetoclax exposure was associated with improved OS (HR 0.82 per day; p=0.049). When venetoclax exposure was dichotomized, receipt of ≤14 days was associated with inferior OS (HR 2.49; p=0.028). In this cohort, 6% of 1-cycle responders and 18% of 2-cycle responders proceeded to allogeneic HSCT (p=0.14). **Conclusions:** Delayed response beyond 1 cycle in patients receiving HMA/venetoclax identifies AML patients at higher risk of relapse and inferior survival. Time to response can inform early risk-adapted strategies, including venetoclax optimization. Research Sponsor: None.

Cladribine/cyclophosphamide lymphodepletion efficacy and toxicity in CD19 CAR-T therapy for B-ALL. First Author: Kriti Gera, University of South Florida/Moffitt Cancer Center, Tampa, FL

Background: During an international fludarabine (Flu) shortage, our center adopted cladribine (Cla) as a substitute for Flu with cyclophosphamide (Cy) for lymphodepletion (LD) prior to CAR-T therapy in patients with relapsed/refractory (R/R) B-cell acute lymphoblastic leukemia (B-ALL). We evaluated clinical outcomes and toxicity with Cla/Cy LD. **Methods:** We conducted a retrospective, single-center analysis of R/R B-ALL patients who received CD19-directed CAR-T therapy between January 2018 and April 2025. The Cla/Cy regimen substituted Flu 30 mg/m² with Cla 5 mg/m²/day on days −5 to −3. ALL-HT risk was calculated (Nair et al, 2025). CRS and ICANS were graded per ASTCT; cytopenias per CTCAE v5.0. Early (<30 days) and late (31–100 days) infections were assessed. Overall survival (OS), Event free survival (EFS, event=progression or death) and Minimal residual disease (MRD) status by clonoSEQ assay at Day 30 bone marrow biopsy were assessed. **Results:** We analyzed 53 patients (brexu-cel n=49; tisa-cel n=4). 28 received Flu/Cy and 25 received Cla/Cy. Baseline characteristics are outlined in Table 1. Three patients died before day 30 and two before day 100. Ten patients underwent allo-SCT within 6 months of CAR-T. Rates of grade ≥3 CRS (4% vs 12%, p=0.29) and ICANS (40% vs 24%, p=0.25) did not differ. MRD negativity at day 30 was comparable (Cla/Cy 81.8% vs Flu/Cy 75.0%, p=0.71). Early infection rates were similar; however, late infections were more frequent with Flu/Cy (48% vs 17.4%, p=0.034), with a persistent trend after ALL-HT adjustment (adjusted OR 3.54, p=0.073). Grade ≥3 thrombocytopenia (35.7% vs 8.0%, p=0.022) and neutropenia (25.0% vs 4.0%, p=0.05) at day 90 were higher with Flu/Cy, with similar trends after adjustment (adjusted OR 4.71, p = 0.082 and adjusted OR 7.88, p = 0.067, respectively). Neutrophil recovery (ANC >1000) time was comparable (median 17 vs 18 days, p=0.10). With a median follow-up of 14.6(Flu/Cy) and 13.1 months(Cla/Cy), EFS (6.8 vs 18.1 months, p=0.45) and OS (33.9 months vs not reached, p=0.25) were similar. **Conclusions:** Cla/Cy demonstrated comparable efficacy to Flu/Cy with lower toxicity, including fewer late infections and severe cytopenias. These findings suggest Cla/Cy may represent a safer alternative lymphodepletion strategy. Prospective studies are warranted to validate these observations. Research Sponsor: None.

Baseline characteristics of study cohort.

Characteristic	Flu/Cy (n=28)	Clad/Cy (n=25)	p-value
Age, median (IQR)	38.0 (30.2–58.5)	47.0 (26.0–64.0)	0.77
Male sex, n (%)	18 (64.3)	13 (52.0)	0.53
White race, n (%)	25 (89.3)	20 (80.0)	0.35
KPS ≥80, n (%)	24 (85.7)	21 (84.0)	1.00
Marrow blasts pre-LD, median (IQR)	2.0 (1.0–3.5)	1.5 (0.5–11.0)	0.67
Ph+ ALL, n (%)	11 (39.3)	12 (48.0)	0.78
Prior allo-HSCT, n (%)	6 (21.4)	7 (28.0)	0.56
Prior lines of therapy, median (IQR)	2 (2–3)	3 (2–3)	0.96
High-risk ALL-HT, n (%)	12 (42.9)	3 (12.0)	**0.016**

A phase II, single-arm study of romiplostim N01 for cancer treatment–induced thrombocytopenia in leukemia patients. First Author: Aijie Huang, The First Affiliated Hospital of University of Science and Technology of China, Hefei, Hefei , Anhui, China

Background: Cancer Treatment-Induced Thrombocytopenia (CTIT) poses a significant challenge in leukemia treatment, increasing bleeding risk and potentially disrupting therapy. Romiplostim N01 is recommended for CTIT but lacking specific clinical data in leukemia patients. This study evaluates its efficacy and safety in this population. **Methods:** This is a multi-center, single-arm, phase II study conducted from February 2025 to February 2027. We plan to enroll 97 adult patients (18 - 75 years) with leukemia who developed CTIT (platelets $< 50\times10^9$/L) after antitumor therapy. Patients received subcutaneous Romiplostim N01 at a starting dose of 5 μg/kg once weekly for up to 8 weeks. The primary endpoint is the proportion of patients achieving platelet recovery ($\geq 50\times10^9$/L) after two week. Secondary endpoints include response rate within 7 days, median time to platelet recovery ($\geq 50\times10^9$/L and $\geq 100\times10^9$/L), platelet transfusion requirements, and safety. **Results:** As of January 27, 2026, a total of 49 subjects were enrolled (18 males, 31 females) with a median age of 57 years (range, 17–75). Primary tumor types included acute myeloid leukemia (AML, n=40), acute lymphoblastic leukemia (ALL, n=7), mixed phenotype acute leukemia (MPAL, n=1), and myelodysplastic syndromes (MDS, n=1). All patients received standard chemotherapy and had an ECOG performance status of 0–2 at enrollment; 35 of 49 patients had an ECOG score of 0–1. All subjects received Romiplostim N01 (5 μg/kg/week): 13 subjects received one dose, 14 received two doses, and 22 received ≥ 3 doses. The median baseline platelet count was 15×10^9/L (range, 1–49$\times10^9$/L). 40.8% (20/49) of patients achieved a response within 7 days. 23 subjects (46.9%, 23/49) achieved the primary endpoint (platelet count $\geq 50\times10^9$/L) within two weeks. The median time to platelet recovery $\geq 50\times10^9$/L was 7 days (95% CI, 6–9). A total of 21 patients achieved a platelet count of $\geq100\times10^9$/L; the median time to recovery was 13 days (95% CI, 10–22). The median platelet transfusion dose was 2.0 units (95% CI, 1–3). Adverse events were mild to moderate, most commonly infections. No treatment-related serious adverse events (SAEs) were reported. **Conclusions:** Preliminary findings suggest Romiplostim N01 may be effective in promoting platelet recovery with a manageable safety profile in leukemia patients with CTIT. Final results will provide further evidence for its clinical application. Clinical trial information: NCT06898983. Research Sponsor: National Natural Science Foundation of China (82270223 82500286); Anhui Provincial Health Research Project (AHWJ2024BAa10021); Anhui Provincial Department of Education Scientific Research Project (2023AH010079); Anhui Provincial Natural Science Foundation (2308085J09); USTC Research Funds of the Double First-Class Initiative (YD9110002109).

Comparative effectiveness and toxicity of CAR-T therapy versus blinatumomab in adult B-cell acute lymphoblastic leukemia: A real-world propensity-matched analysis. First Author: Colton Davis, Rochester Regional Health (RRH)-Unity Hospital, Rochester, NY

Background: Chimeric antigen receptor T-cell (CAR-T) therapy and blinatumomab are established treatment options for relapsed or refractory B-cell acute lymphoblastic leukemia (B-ALL). While CAR-T therapy offers durable disease control, it is associated with significant immune-mediated toxicities, including cytokine release syndrome (CRS) and neurotoxicity. Comparative real-world data evaluating long-term mortality and toxicity outcomes between CAR-T therapy and blinatumomab remain limited. **Methods:** We conducted a retrospective cohort study using the TriNetX Analytics Network. Adult patients with B-cell acute lymphoblastic leukemia treated with either CAR-T therapy or blinatumomab were identified. Propensity score matching (1:1) was performed to balance baseline demographic and clinical characteristics, yielding 306 patients in each cohort. Primary outcomes included all-cause mortality at 1 and 3 years. Secondary outcomes included cytokine release syndrome at 1 year and neurotoxicity (including delirium, encephalopathy, and altered mental status) at 3 months, 1 year, and 3 years. Outcomes were assessed using risk ratios (RR), odds ratios (OR), Kaplan–Meier survival analysis, and Cox proportional hazards models. **Results:** After propensity matching, 612 patients were analyzed (306 per cohort). At 1 year, all-cause mortality was significantly higher with CAR-T than blinatumomab (50.98% vs 17.97%; RR 2.84, 95% CI 2.18–3.69; p<0.0001). Kaplan–Meier analysis showed inferior survival with CAR-T (HR 3.48, 95% CI 2.56–4.74; log-rank p<0.0001). This excess mortality persisted at 3 years (52.61% vs 18.95%; RR 2.78, 95% CI 2.15–3.58; p<0.0001; HR 3.43, 95% CI 2.54–4.63). CAR-T was associated with higher cytokine release syndrome at 1 year (20.59% vs 5.88%; RR 3.50, 95% CI 2.12–5.77; p<0.0001). Neurotoxicity was consistently more frequent with CAR-T: 27.78% vs 13.40% at 3 months (RR 2.07, 95% CI 1.48–2.91; p<0.0001), 25.16% vs 11.44% at 1 year (RR 2.20, 95% CI 1.52–3.18; p<0.0001), and 27.78% vs 13.40% at 3 years (RR 2.07, 95% CI 1.49–3.15; p<0.0001). Kaplan–Meier analyses confirmed a persistently higher cumulative neurotoxicity risk with CAR-T across all time points. **Conclusions:** In this large real-world propensity-matched analysis, CAR-T therapy for B-cell ALL was associated with significantly higher short- and long-term mortality compared with blinatumomab, as well as markedly increased risks of cytokine release syndrome and neurotoxicity. These findings highlight the substantial toxicity burden associated with CAR-T therapy in routine clinical practice and underscore the importance of careful patient selection, early toxicity recognition, and risk-benefit stratification when choosing between advanced immunotherapeutic options for B-ALL. Research Sponsor: None.

Frailty-comorbidity discordance and non-relapse mortality after allogeneic hematopoietic cell transplantation. First Author: Nihar Desai, Princess Margaret Hospital, Toronto, ON, Canada

Background: Non-relapse mortality (NRM) is a barrier to successful allogeneic hematopoietic cell transplantation (HCT). The HCT-Comorbidity Index (HCT-CI) is used for pre-HCT risk assessment but does not capture physiological reserve. Frailty, assessed by the validated Hematopoietic Cell Transplantation-Frailty Scale (HCT-FS), independently predicts post-HCT outcomes; however, the clinical consequences of frailty-comorbidity discordance remain poorly defined. We hypothesized that such discordance identifies patients whose transplant risk may be misclassified by HCT-CI alone. **Methods:** We retrospectively analyzed 692 patients undergoing first allogeneic HCT at our center. Frailty was assessed using HCT-FS and categorized as fit, pre-frail, frail. For discordance analyses, HCT-FS was dichotomized as fit vs pre-frail/frail. HCT-CI was dichotomized as low (<3) vs high (≥ 3). Patients were classified into 4 groups: fit+low HCT-CI (group I), fit+high HCT-CI (group II), pre-frail/frail+low HCT-CI (group III), and pre-frail/frail+high HCT-CI (group IV). Fine-Gray competing-risk models and Cox regression was used for NRM and overall survival (OS), respectively. **Results:** The median age was 61 years (Q1-Q3: 52-67), and 399 (58%) were male. At baseline, 287 (42%) patients had an HCT-CI ≥ 3. HCT-FS classified 252 (36%) as fit, 373 (54%) as pre-frail, and 67 (10%) as frail. Overall, 355 (51%) patients demonstrated discordant HCT-FS and HCT-CI scores: 78 (11%) as group II, and 277 (40%) classified as group III. At 2 years, NRM and OS were 11.2% (95% CI, 7-16) and 79.3% (95% CI, 73-84) in fit patients, 17.4% (95% CI, 14-22) and 67.0% (95% CI, 62-72) in pre-frail patients, and 33.5% (95% CI, 22-45) and 54.9% (95% CI, 42-66) in frail patients, respectively ($p<0.01$ for both). In multivariable analyses, HCT-FS, HCT-CI, and age at HCT were independently associated with NRM and OS. Compared with fit patients with low HCT-CI (group I), pre-frail/frail patients with HCT-CI ≥ 3 (group IV) experienced the highest risk of NRM (sub-distribution hazard ratio (sHR) 2.7, 95% CI 1.5-5, $p<0.01$). Pre-frail/frail patients with HCT-CI <3 (group III) also had an increased risk of NRM (sHR 1.9, 95% CI 1.1-3.5, p=0.01). Fit patients with HCT-CI ≥ 3 (group II) did not have a significant increase in NRM risk (sHR 1.7, 95% CI 0.8-3.7, p=0.15). The corresponding HR for OS were 2.1 (95% CI 1-3; $p<0.01$) for group IV, 1.7 (95% CI 1-3; $p<0.01$) for group III, and 1.4 (95% CI 0.8-2.5; p=0.18) for group II, compared with group I. **Conclusions:** Frailty-comorbidity discordance was observed in 51% of patients and has prognostic implications. Pre-frail and frail patients with low HCT-CI experience higher NRM than would be predicted by HCT-CI alone, suggesting underestimation of transplant risk when frailty is not assessed. Integrating HCT-FS with HCT-CI may improve risk stratification and better identify patients at high risk for NRM. Research Sponsor: None.

Clinical outcomes of *TP53*-mutated myeloid neoplasms after allogeneic hematopoietic cell transplantation: A Canadian multicenter propensity score–matched analysis. First Author: Nihar Desai, Princess Margaret Hospital, Toronto, ON, Canada

Background: *TP53* mutations define a biologically aggressive subset of myeloid malignancies with poor outcomes. We evaluated clinical, disease-related, and transplant-associated variables influencing post-allogeneic hematopoietic cell transplant (HCT) outcomes in this high-risk group. **Methods:** We conducted a retrospective multicenter study across 10 Canadian transplant centers, including 153 individuals with *TP53*-mutated and 2,207 patients with *TP53* wild-type acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS) from the Cell Therapy and Transplant Canada (CTTC) registry. Propensity score matching was performed to account for baseline differences. The primary outcomes were relapse and overall survival (OS) after HCT. **Results:** Presence of *TP53* mutation was associated with increased risk of relapse compared with *TP53* wild-type (HR 2.21; 95% CI: 1.5–3.1; $p<0.01$). Among *TP53*-mutated patients (n=153), with a median follow-up of 35.8 months (Q1-Q3: 29-48), the 2-year cumulative incidence of relapse was 53.2% (95% CI: 44.4-61.2), and OS 40.1% (95% CI: 31.6-48.4). In multivariable analysis, multi-hit *TP53* mutations (HR 2.17, 95% CI: 1.3-3.7; $p<0.01$), and graft-vs-host disease (GVHD) prophylaxis regimens containing anti-thymocyte globulin (ATG) with (HR 3.53, 95% CI: 1.5-8.1; $p<0.01$) or without (HR 2.59, 95% CI: 1.2-5.6; p=0.01) post-transplant cyclophosphamide were associated with higher relapse risk. Conditioning regimen intensity, and chronic GVHD, modelled as a time-dependent covariable, did not significantly impact relapse, while chronic GVHD was associated with improved OS (HR 0.46; 95% CI: 0.2-0.9, p=0.03). **Conclusions:** In patients with myeloid malignancies, *TP53* mutations are associated with a high risk of relapse and poor survival after HCT, while chronic GVHD appears to be protective, underscoring the importance of careful selection of GVHD prophylaxis and the need for effective post-transplant strategies in this high-risk population. Allele-specific targeting of CD33 as a novel approach to enhance CAR-T selectivity in relapsed acute myeloid leukemia post–allogeneic transplantation. First Author: Guido David Pelaez, Washington University School of Medicine, Saint Louis, MO

Background: Relapse after allogeneic hematopoietic cell transplant (HCT) represents the most common treatment failure in acute myeloid leukemia (AML), urging the need for new therapies. Chimeric antigen receptor (CAR) T cells have shown efficacy in lymphoid and plasma cell malignancies but have not yet successfully translated to myeloid disease. This could in part be due to the expression of target antigens on normal myeloid cells, which might result in significant on-target but off-tumor effects. Exploiting a single nucleotide polymorphism (SNP) in *SIGLEC3*, which encodes CD33, to target relapsing AML cells while selectively sparing donor-derived hematopoietic cells could improve the efficacy of anti-CD33 CAR-T cells in treating AML. **Methods:** We evaluated the *in vitro* efficacy and specificity of CAR-T cells that target each of two alleles of a common SNP in CD33 (rs2455069, *CD33 Arg69Gly*). Controls included untransduced activated T-cells (UTD, negative control) and CAR-T cells targeting a different CD33 epitope ($CART33^{Pan}$ positive control). Effector cells were incubated with CD33-expressing AML targets for 24 hours at serial effector-to-target ratios, and surviving target cells were quantified via flow cytometry to calculate percent cell killing. Initial screens used Jurkat cells lentivirally transduced with CD33 of each polymorphism ($Jurkat33^{Gly}$ or $Jurkat33^{Arg}$) to characterize CAR-T efficacy and specificity. Subsequent tests used MOLM-13 (homozygous $CD33^{Arg}$) and KG-1 (homozygous $CD33^{Gly}$) AML cell lines. Statistical comparisons of generated CAR-T cytotoxicity curves were performed with two-way ANOVA. Killing assays were performed with at least six biologic replicates. **Results:** $CART33^{Gly}$ and $CART33^{Arg}$ cells each showed statistically equivalent killing against their concordant Jurkat33 targets compared to $CART33^{Pan}$ cells. Each CAR directed minimal killing of discordant Jurkat33 targets, similar to UTD controls. In KG-1 ($CD33^{Gly}$) cells, $CART33^{Gly}$ showed similar killing efficacy as $CART33^{Pan}$cells, while $CART33^{Arg}$ were statistically equivalent to UTD cells at multiple E:T ratios. In MOLM-13 ($CD33^{Arg}$) cells, $CART33^{Gly}$ and $CART33^{Arg}$ exhibited mixed efficacy and specificity: at lower E:T ratios (1:16 to 1:8), $CART33^{Gly}$ was statistically equivalent to untransduced controls, but began to demonstrate more nonspecific toxicity at E:T above 1:4. $CART33^{Arg}$ exhibited significant cytotoxicity once above E:T of 1:8, but only achieved similar toxicity to $CART33^{Pan}$ at E:T ratios over 1:2. **Conclusions:** Allele-specific CART33 cells demonstrate promising efficacy and specificity in killing AML cells expressing either $CD33^{Gly}$ or $CD33^{Gly}$. Further studies are underway to test efficacy *in vivo* against primary AML cells and safety toward normal hematopoietic progenitor cells that express the alternative CD33 allele. Pre-transplant MRD negativity and TP53 mutation status determine survival after CAR-T therapy bridged to allo-HSCT for refractory/relapse B-ALL. First Author: Zhihui Li, Department of Bone Marrow Transplantation,Beijing Gobroad Boren Hospital, Beijing, China

Background: The feasibility and outcomes of bridging relapsed/refractory (R/R) B-lineage acute lymphoblastic leukemia (B-ALL) patients to allogeneic hematopoietic stem cell transplantation (allo-HSCT) following CAR-T therapy require further investigation. This study evaluated long-term outcomes and prognostic factors in this setting. **Methods:** We conducted a retrospective analysis of 300 consecutive R/R B-lineage leukemia patients (295 B-ALL, 98.3%) who underwent allo-HSCT after CAR-T therapy. Somatic mutation screening via next-generation sequencing was performed on 179 patients. Univariate Cox regression analyzed factors associated with transplant outcomes. A contemporaneous cohort of 36 transplanted patients without prior CAR-T served as a comparator. **Results:** Median age at transplant was 14 years (range, 1-68). Prior to HSCT, 220 (73.3%), 75 (25.0%), and 5 (1.7%) patients received CD19-, CD22-, and Mix-CAR-T, respectively; 265 (88.3%) achieved complete remission (CR), and 39 (13.0%) were minimal residual disease (MRD)-positive. The 3-year disease-free survival (DFS), overall survival (OS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM) for the CAR-T bridging cohort were 64.0% (95%CI, 58.6-69.8%), 74.5% (95%CI, 69.5-79.9%), 28.4% (95%CI, 23.6-34.1%), and 7.6% (95%CI, 5.04-11.3%), respectively. Outcomes did not differ significantly from the non-CAR-T cohort (OS, p=0.54; DFS, p=0.24). Failure to achieve CR pre-HSCT (HR=3.31, $p<0.0001$) and MRD-positivity (HR=3.69, $p<0.0001$) were risk factors for relapse, while chronic graft-versus-host disease was protective (HR=0.35, p=0.0002). Pre-HSCT MRD-positivity, fungal infection, and viral cystitis increased NRM risk. TP53 (15.1%), KMT2D (14.5%), NRAS (14.0%), KRAS (13.4%), and ABL1 (9.5%) were the most frequently mutated genes. TP53 mutation was a significant risk factor for inferior DFS (HR=3.37, $p<0.0001$) and OS (HR=3.56, $p<0.0001$). GNAS and KDM6A mutations predicted higher CIR, while ETV6 mutation was associated with increased NRM. **Conclusions:** Bridging to allo-HSCT after CAR-T therapy is a feasible and effective strategy for R/R B-ALL, providing substantial long-term survival. Achieving pre-transplant CR and MRD-negative status is critical for outcome. Somatic mutations, particularly TP53, hold significant prognostic value, aiding in risk stratification and treatment optimization for these patients. Research Sponsor: None.

MSNPseq: An NGS-based assay for chimerism detection and risk assessment in allogeneic HSCT. First Author: Zhe Zou, Central Laboratory, the Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: Chimerism (CHIM) analysis assesses the ratio of donor to recipient hematopoietic cells, confirming engraftment and detecting impending graft failure or relapse, in allogeneic hematopoietic stem cell transplantation (aHSCT). However, the conventional short tandem repeat (STR) analysis, has limited sensitivity (1–5%), often missing low-level CHIM. In this retrospective study, Multiple Single Nucleotide Polymorphism sequencing (MSNPseq), an NGS-based assay targeting DNA fragments each harboring 4–8 SNPs, demonstrated superior sensitivity and specificity compared with STR analysis, enabling reclassification of STR-negative cases and improved prognostic stratification. **Methods:** MSNPseq, based on Ion AmpliSeq technology, amplifies 100 fragments for sequencing on the Ion Torrent PGM platform, achieving >2000× depth for 96.8% of loci. Its sensitivity and accuracy were validated in simulated chimeric and post-transplant samples against STR analysis. Calibration models used pre-transplant donor/recipient data to generate tailored correction coefficients. CHIM was assessed via MSNPseq at three 30-day time points (TP1, 2, 3) post-transplant, in 741 aHSCT patients (AML 49.9%, ALL 27.4%, MDS 13.5%, lymphoma 4.7%, others 4.5%). PFS and OS were stratified by CHIM status and its dynamics to evaluate transplant outcomes, prognostic significance, and late relapse. **Results:** CHIM sensitivity was assessed using BCR-ABL1–positive standards. MSNPseq achieved a 0.01% detection limit, outperforming STR (1%) with strong correlation (R^2 = 0.9953). CHIM status was classified by donor fraction as complete (cCHIM, 100%), microchimerism (mCHIM, 99% to <100%), sub-threshold chimerism (sCHIM, 95% to <100%; below STR sensitivity), and incomplete chimerism (iCHIM, ≤95%) across three time points. While iCHIM was consistently associated with inferior PFS and OS, sCHIM and mCHIM also showed worse outcomes compared with cCHIM, defining distinct high-risk subsets. CHIM dynamics revealed decreasing sCHIM/mCHIM and increasing cCHIM/iCHIM over time. Notably, a sustained CHIM decrease >0.5% over two consecutive time points was associated with significantly poorer OS and PFS. Interestingly, sCHIM and mCHIM status, as well as a sustained CHIM decrease >0.5% over two consecutive time points, were also associated with a high risk of acute graft-versus-host disease (aGvHD). Overall, MSNPseq enables more precise CHIM stratification than STR, improving post-transplant risk assessment. **Conclusions:** MSNPseq's superior sensitivity enables more precise chimerism classification and detection of clinically relevant sCHIM and mCHIM subsets that STR often misses. These refined CHIM categories, along with sustained CHIM decline, correlate with poorer survival and higher aGvHD risk, supporting MSNPseq as a superior tool for post-aHSCT risk stratification and therapeutic guidance. Impact of Ori-TTV particles on in vivo CAR-T cell engineering for the treatment of hematologic malignancies. First Author: Yongqin Li, Oricell Therapeutics Co., Ltd., Shanghai, China

Background: CAR-T cell therapy has revolutionized hematological malignancy treatment, yet traditional autologous therapies face substantial logistical and financial challenges. An efficient in vivo CAR-T cell generation platform represents a transformative approach to make immunotherapies more accessible. Here, we report the design and validation of Ori-TTV, a T cell-specific lentiviral vector system capable of directly generating functional CAR-T cells within the body. **Methods:** Ori-TTV was engineered with five synergistic components: (1) an Ori Multiple Targeting Domain (Ori-MTD) for selective delivery to T lymphocytes; (2) a de-targeted fusogen; (3) a T cell-specific synthetic promoter; (4) phagocytosis-resistant modifications; and (5) serum-resistant surface engineering. Ori-TTV encodes a dual-target CAR recognizing CD19 and BCMA, enabling treatment of B-cell malignancies (e.g., non-Hodgkin lymphoma) and plasma cell–derived cancers (e.g., multiple myeloma) with potential extension to autoimmune diseases. **Results:** Ori-TTV particles are produced at high functional titers comparable to conventional broad-tropism lentiviruses and demonstrate significant resistance to macrophage phagocytosis (>50% reduction). The T cell-specific synthetic promoter drives CAR/GFP expression comparable to the EF-1α promoter in primary T cells while maintaining minimal off-target expression in non-T cells, including HEK293T producer cells and various tumor lines. Ori-TTV efficiently transduces resting T cells, achieving >80% CAR expression in PBMCs in vitro. The resulting CAR-T cells exhibit a predominantly memory phenotype with increased TSCM cells compared to Kymriah-like ex vivo CAR-T cells. Serial killing assays demonstrated potent, multi-round cytotoxicity against CD19+ and BCMA+ target cell lines with varying antigen densities. In vivo efficacy was evaluated in humanized mouse models of NHL and MM. The PBMC humanized mice were challenged with tumors and administered Ori-TTV. Bioluminescence imaging demonstrated robust tumor regression, with complete remissions in the majority of treated animals. Pharmacodynamics revealed efficient in vivo transduction, with CAR-T expansion kinetics showing peak levels at day 13 (20–30% of circulating T cells). Expanded CAR-T cells maintained a memory-enriched phenotype with significantly increased TSCM cells. Long-term monitoring confirmed durable responses without toxicity or vector-related adverse events. Furthermore, in CD34+ humanized mice, single-injection Ori-TTV caused durable depletion of peripheral B cells. **Conclusions:** These findings establish Ori-TTV as a next-generation lentiviral vector system enabling safe, efficient, and selective in vivo CAR-T cell generation. It has the potential to redefine CAR-T therapy by eliminating manufacturing barriers, reducing costs, and expanding patient access. Research Sponsor: None.

Pharmacogenetic (PGx) markers of cardiovascular side effects (CVSEs) in allogeneic hematopoietic cell transplant (HCT) patients receiving post-transplant cyclophosphamide (PTCy). First Author: Neha Deshpande, Atrium Health Levine Cancer Institute, Charlotte, NC

Background: PTCy is used to prevent graft versus host disease (GVHD) post-HCT. CVSEs can be observed with Cy. We previously showed 16% of PTCy-treated patients experienced CVSEs within 30 days post-HCT. PGx determinants of Cy metabolism have been explored, but data are lacking on the impact of PGx on PTCy-related CVSEs. This study aims to identify PGx markers of CVSE risk in adult patients undergoing HCT. **Methods:** This is a retrospective PGx study of patients who underwent HCT between January 2014 and July 2024. Germline DNA was extracted from buccal swabs, and genotyping was performed using the Illumina Global Diversity Array with Enhanced PGx. The analysis focused on 99 single nucleotide polymorphisms (SNPs) in 13 candidate genes involved in Cy metabolism: GSTM1, GSTA1, GSTP1, GSTT1, CYP3A5, CYP3A4, CYP2C9, CYP2C8, CYP2C19, CYP2A6, CYP2B6, ALDH1A1, and ALDH3A1. The primary endpoint was time to CVSE occurrence at 90 days, 180 days, and 5 years post-HCT, including acute or chronic ischemic heart disease, acute myocardial infarction, angina pectoris, atrial fibrillation or flutter, other arrhythmias, cardiomyopathy, heart failure, hypertensive heart disease, pericardial effusion, pericarditis, peripheral vascular disease, and pulmonary edema. Covariates included age, sex, ancestral variation, diabetes, dyslipidemia, hypertension, atherosclerosis, and CVSEs within 2 years prior to HCT. Using an additive genetic model, a Cox proportional hazards model was generated to evaluate the association between each SNP and time to CVSE, adjusting for covariates. A CVSE risk score was developed using the total number of risk alleles from statistically significant SNPs and tested for association with time to CVSE using a Cox proportional hazards model. **Results:** Of 86 evaluable patients, the median age was 60 (range 24-78), 78% were male, 77% White, and 20% Black; 54% received haploidentical and 24.4% matched related donor HCT. The incidence of CVSEs was 27% at 90 days post-HCT, 31% at 180 days, and 58% at 5 years. The table describes three SNPs significantly associated with time to CVSE ($p<0.05$). The CVSE risk score (n=19 for low risk, 0-1 risk alleles; n=49 for intermediate, 2-3 risk alleles; n=18 for high, 4-6 risk alleles) was significantly associated with time to CVSE (HR 2.30, 95% CI 1.43-3.71, p=0.0006). **Conclusions:** PTCy-related CVSEs were common post-HCT. Single nucleotide polymorphisms in CYP2A6, GSTT1, and ALDH1A1 may influence CVSE risk post-HCT. These findings require further validation in independent datasets and may be used to develop a clinicogenomic risk model for CVSE post-HCT. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; NIH/NCI P30CA012197; Swim Across America.

SNP	Gene	Risk allele frequency	Hazard ratio (95% CI)	p value
rs1137115	CYP2A6	0.215	2.78 (1.48-5.23)	0.0015

Outcomes after unrelated donor allogeneic hematopoietic cell transplantation in age ≥65 using post-transplant cyclophosphamide. First Author: Amna Bint I Munir, North Alabama Medical Center, Florence, AL

Background: The use of allogeneic hematopoietic cell transplantation (allo-HCT) in older adults has increased with reduced-intensity conditioning and post-transplant cyclophosphamide (PTCy) based GVHD prophylaxis. While PTCy has demonstrated excellent GVHD control across multiple disease types, age-related toxicities and non-relapse mortality remain significant challenges in older patients with acute leukemia and myelodysplastic syndrome (MDS). Understanding age-associated risks in contemporary unrelated donor (URD) HCT platforms may help guide patient selection, counseling, and future refinements in transplant practice. **Methods:** We analyzed adults undergoing first URD allo-HCT (8/8 or 7/8 HLA-matched) with PTCy-based GVHD prophylaxis for acute myeloid leukemia, acute lymphoblastic leukemia, or myelodysplastic syndrome reported to CIBMTR, 2017–2021, using the P-5891 dataset. Patients were grouped into <65 and ≥65 years. Outcomes included overall survival (OS), non-relapse mortality (NRM), relapse, acute GVHD, and chronic GVHD. Univariable and multivariable Cox proportional hazards or Fine-Gray competing risks models were used as appropriate. Variables with $p < 0.2$ in univariable analysis and clinically relevant factors were included in multivariable models. **Results:** Of 2,271 patients, 849 (37%) were ≥65 years. Older patients were more frequently treated with reduced-intensity or non-myeloablative conditioning, had a Hematopoietic Cell Transplantation–Comorbidity Index (HCT-CI) ≥3, and had a Karnofsky Performance Status (KPS) <90. On multivariable analysis, age ≥65 was associated with significantly inferior OS (HR 1.20, 95% CI 1.02-1.40, p=0.029), with 3-year OS of 52.1% vs 63.4% (log-rank $p<0.001$). Other independent predictors of worse OS included reduced-intensity conditioning, higher disease risk index, KPS <90, and HCT-CI ≥3; graft source was not significant. Competing-risk analyses showed significantly higher NRM in ≥65 years (3-year cumulative incidence 22.7% vs 13.6%; HR 1.56, 95% CI 1.21–2.01, $p<0.001$), which was the primary driver of inferior survival. Importantly, relapse incidence was similar (HR 0.90, p=0.249), and no differences were found in GVHD rates: grade II–IV acute GVHD (HR 0.98, 95% CI 0.81–1.17, p=0.785), grade III-IV acute GVHD (HR 0.91, 95% CI 0.64-1.30, p=0.600), or moderate-to-severe chronic GVHD (HR 0.90, 95% CI 0.68-1.20, p=0.467). **Conclusions:** In patients undergoing unrelated donor HCT with PTCy-based GVHD prophylaxis for acute leukemia or MDS, those aged ≥65 years had significantly lower overall survival and higher non-relapse mortality compared to younger patients, with similar relapse and GVHD rates. These findings suggest the need to optimize the PTCy-based prophylaxis platform, such as reduced PTCy dosing with the addition of novel agents, in patients with advanced age. Research Sponsor: None.

Post-prophylaxis CMV in the letermovir era: Incidence, risk factors, and outcomes following HCT. First Author: Safah Khan, Cleveland Clinic, Cleveland Clinic, OH

Background: Cytomegalovirus (CMV) is a major infectious complication after allogeneic hematopoietic cell transplantation (HCT). Letermovir prophylaxis (ppx) effectively reduces clinically significant CMV infection (csCMVi) within 100 days, but csCMVi after ppx discontinuation occurs in 7–16%. Extended letermovir ppx has been proposed for high-risk patients, though optimal patient selection is uncertain. Our study aims to define the incidence, risk factors, and outcomes for post-ppx csCMVi to guide extended ppx strategies. **Methods:** We analyzed adult CMV-seropositive (+) HCT recipients at Cleveland Clinic who received ≥45 days of Letermovir primary ppx between 1/1/2018-12/31/2024. The primary outcome was post-ppx csCMVi, defined as CMV disease or asymptomatic viremia requiring preemptive therapy. Secondary outcomes included overall and non-relapse mortality. Patients with csCMVi during standard ppx were excluded. Associations with csCMVi were evaluated using competing-risk models accounting for mortality, with multivariable Cox analyses adjusting for age, sex, Karnofsky score. **Results:** Among 311 CMV+ recipients of HCT, 62% were donor-CMV negative and 50% were male. Median age was 59 (47-67) years. HCT was most commonly for AML (48%), with matched unrelated donors (54%), peripheral blood graft (76%), myeloablative conditioning (45%), and GVHD ppx with post-transplant cyclophosphamide (PTCy) (63%). Grade ≥2 acute GVHD (36%), chronic GVHD (53%), and relapse (22%) were common in the cohort. Post-ppx infection occurred in 64 patients (21%), including 8 (13%) with tissue-invasive disease. Median duration of Letermovir was 75 days, typically initiated on day 28 post-transplant. Median time to csCMVi was 123 days from transplant. Cumulative incidence of post-ppx csCMVi was 9% at 60 days, 11% at 90 days, and 12% at 180 and 360 days. Risk factors included older age (HR 1.04 per year, 95% CI=1.01-1.07, p=0.014), female sex (HR 3.3, 95% CI=1.5-7.1, p=0.003), chronic GVHD (HR 9.9, 95% CI=1.2-5.6, p=0.024), and GVHD treated with steroids (HR 9.86, 95% CI=1.4-71.5, p=0.024) or ruxolitinib (HR 2.8, 95% CI= 1.3-6.3, p=0.011). Primary disease, donor CMV status, donor relationship, graft source, conditioning intensity, ATG, and PTCy were not associated with csCMVi. All-cause mortality was high in the cohort (37%), particularly in the late csCMVi group (52%). Post-ppx csCMVi was associated with increased non-relapse (HR 2.36, 95% CI= 1.37-4.07, p=0.002) and overall mortality (HR 2.41, 95% CI= 1.43-4.06, p<0.001) in multivariable analysis adjusted for age and sex. **Conclusions:** Late csCMVi occurs in 12% of CMV+ HCT recipients after prophylaxis discontinuation and may confer additional mortality risk. These findings support risk-adapted surveillance and extended prophylaxis in high-risk groups, particularly recipients who are older, female, and have chronic GVHD requiring immunosuppression. Impact of *NPM1* co-mutation on post-transplant outcomes in MRG-mutated AML. First Author: Yanal Mufeed Alnimer, University of Kentucky, Lexington, KY

Background: Myelodysplasia-related gene (MRG) mutations are classified as adverse risk per ELN 2022, and allogeneic cell transplantation (allo-HCT) is recommended. However, it remains unclear whether post-transplant outcomes in MRG-mutated AML are inferior compared with other ELN-defined higher-risk AML without MRG mutations, and whether the presence of a favorable co-mutation NPM1 modifies prognosis after transplantation. **Methods:** We conducted a retrospective study of adult patients with AML who underwent allo-HCT at our institution between January 2015 and January 2025. MRG mutations defined per ELN. Patients were categorized into four molecular groups: MRG-mutated/NPM1 wild-type (MRG^mutNPM1^wt), MRG-mutated/NPM1-mutated (MRG^mutNPM1^mut), MRG−wild-type/NPM1-mutated (MRG^wtNPM1^mut), and MRG−wild-type/NPM1 wild-type (MRG^wtNPM1^wt).Overall survival (OS) and RFS were calculated using the Kaplan−Meier. Adjusted OS and RFS were estimated using propensity score matching accounting for age, sex, remission status at transplant (CR1 vs others), and conditioning intensity. **Results:** A total of 146 patients with complete molecular and cytogenetic data were included. Forty-two percent were MRG^wtNPM1^wt, 16% were MRG^wtNPM1^mut, 23% were MRG^mutNPM1^mut, and 19% were MRG^mutNPM1^wt. Cytogenetic risk distribution was 11% favorable, 71% intermediate, and 18% adverse. Among patients with favorable cytogenetics, 86% were either MRG^wtNPM1^wt or MRG^mutNPM1^mut, and none had MRG^mutNPM1^wt disease. In contrast, among patients with adverse cytogenetics, 17% had MRG^mutNPM1^wt, 23% had MRG^mutNPM1^mut, and 45% had MRG^wtNPM1^wt disease (p = 0.07).There was no significant difference in OS across molecular subgroups, with median OS of 70 months (95% CI 40−NR) for MRG^wtNPM1^mut, 101 months (95% CI 20−NR) for MRG^mutNPM1^mut, 69 months (95% CI 27−NR) for MRG^mutNPM1^wt, and 94 months (95% CI 59−NR) for MRG^wtNPM1^wt (p = 0.5). However, patients with MRG^mutNPM1^wt demonstrated a trend toward inferior RFS, with a median RFS of 17 months (95% CI 13−NR), compared with RFS not reached in the MRG^wtNPM1^mut, MRG^mutNPM1^mut, and MRG^wtNPM1^wt groups (p = 0.1). These findings remained consistent after propensity score adjustment. **Conclusions:** Our findings suggest that the presence of an NPM1 mutation may mitigate post-transplant relapse risk in patients with MRG-mutated AML. In contrast, patients with MRG-mutated/NPM1 wild-type disease appear to have inferior relapse-free survival after allo-HCT compared with other ELN-defined adverse-risk AML subgroups. These results indicate biologic heterogeneity within adverse-risk AML and highlight the need for refined post-transplant risk stratification and relapse-prevention strategies in MRG-mutated/NPM1 wild-type AML. Myeloablative vs reduced-intensity conditioning in PTCy-based allogeneic HCT: A CIBMTR analysis. First Author: Imran Khan, NYC Health and Hospitals/Woodhull, Brooklyn, NY

Background: Post-transplant cyclophosphamide (PTCy) is widely used in matched unrelated and haploidentical HCT. However, the optimal conditioning intensity in the PTCy era remains unclear. This study compared outcomes of myeloablative versus reduced-intensity conditioning in MUD and haploidentical HCT recipients. **Methods:** This retrospective multicenter study utilized the Center for International Blood and Marrow Transplant Registry (CIBMTR) to analyze patients who underwent HCT and received PTCy, based on the P-6219 dataset by Modi et al. Clinical outcomes were compared between patients who received MAC and RIC. Kaplan−Meier analysis was used to determine mean overall survival (OS) and graft-vs-host disease (GVHD)-free relapse-free survival (GRFS). Cox proportional hazards regression models were used to calculate hazard ratios (HR) with 95% confidence intervals (CI). Statistical analyses were conducted using SPSS, with p-values less than 0.05 considered statistically significant. **Results:** A total of 5,873 patients were included, comprising 1,973 MUD recipients (797 MAC, 1,176 RIC) and 3,900 haploidentical recipients (1,485 MAC, 2,415 RIC). All patients received PTCy GVHD prophylaxis. Among MUD recipients, MAC was associated with significantly OS compared with RIC, with a mean OS of 27.8 months (95% CI 26.9–28.7) versus 24.8 months (95% CI 24.1–25.6, p<0.001). RIC was associated with a higher risk of mortality compared with MAC (HR 1.45, 95% CI 1.24–1.68, p<0.001). GRFS was also worse with RIC (mean 21.5 months, 95% CI 20.4–22.5 vs 18.3 months, 95% CI 17.4–19.2; HR 1.33, 95% CI 1.17–1.51, p<0.001). There were no significant differences between MAC and RIC in rates of grade 2–4 acute GVHD (HR 1.00, 95% CI 0.85–1.18, p=1.0), grade 3–4 acute GVHD (HR 1.04, 95% CI 0.72–1.51, p=0.84), or moderate/severe chronic GVHD (HR 0.97, 95% CI 0.86–1.08, p=0.59). Among haploidentical recipients, MAC was also associated with improved OS compared with RIC, with a mean OS of 26.1 months (95% CI 25.4–26.8) versus 24.1 months (95% CI 23.6–24.7, p<0.001), and RIC conferred a higher mortality risk (HR 1.29, 95% CI 1.16–1.43, p<0.001). GRFS was superior with MAC (18.4 months, 95% CI 17.6–19.2 vs 16.5 months, 95% CI 15.9–17.2; HR 1.17, 95% CI 1.08–1.27, p<0.001). Rates of grade 2–4 acute GVHD were lower with RIC (HR 0.88, 95% CI 0.78–0.98, p=0.018). Rates of grade 3–4 acute GVHD (HR 1.06, 95% CI 0.85–1.32, p=0.61) and moderate/severe chronic GVHD (HR 0.98, 95% CI 0.90–1.07, p=0.70) were similar between MAC and RIC. **Conclusions:** MAC was associated with improved OS and GRFS compared with RIC in MUD and haploidentical transplant recipients, with similar rates of severe acute and chronic GVHD. These findings support the use of MAC when patient comorbidities and performance status permit. Research Sponsor: None.

Differentiating donor age on AML patient outcomes in the post-transplant cyclophosphamide contemporary era. First Author: John Behman, Duke University , Department of Medicine, Division of Hematologic Malignancies and Cellular Therapy, Durham, NC

Background: alloHCT provides curative potential for patients with AML. PTCy GVHD prophylaxis has changed this paradigm. Impact of donor age is unknown in the PTCy era. **Methods:** Utilizing the publicly available CIBMTR dataset, de-identified AML patients receiving alloHCT between 2017-2021 with PTCy-based GVHD prophylaxis were identified. Patients with primary induction failure or relapsed disease status at time of transplant were excluded. The main effect of donor age was examined across outcomes at 24-months. Univariate and multivariate analyses were performed. **Results:** 5,702 patients were included in the analysis. The median age at alloHCT was 59 years (IQR, 46-66). Median donor age was 33 years (IQR, 22-42). CI of relapse at 24 months was 36.4% (95% CI, 33.1%-39.8%) for donors aged ≥45 years (yrs), 32.9% (95% CI, 24.6%-41.2%) for donors aged 0-19 yrs, 30.5% (95% CI, 28.6%-32.4%) for donors aged 20-34 yrs, and 30.1% (95% CI, 27.3%-32.9%) for donors aged 35-44 yrs; p=0.003 (Gray's test). Overall survival (OS) at 24 months was 45.9% (95% CI, 42.6%-49.6%) for donors aged ≥45 yrs, 55.4% (95% CI, 47.1%-65.2%) for donors aged 0-19 yrs, 58.5% (95% CI, 56.5%-60.6%) for donors aged 20-34 yrs, and 53.3% (95% CI, 50.3%-56.5%) for donors aged 35-44 yrs; p<0.001. Leukemia-free survival at 24 months was 39.4% (95% CI, 36.2%-43.0%) for donors aged ≥45 yrs, 48.2% (95% CI, 40.1%-57.9%) for donors aged 0-19 yrs, 51.4% (95% CI, 49.4%-53.5%) for donors aged 20-34 yrs, and 49.2% (95% CI, 46.2%-52.4%) for donors aged 35-44 yrs; p<0.001. In multivariable analysis, as compared to donor age >45, the 2 younger age groups, age 20-34 years (HR 0.41, 95%CI, 0.69-0.87; p=.004) and 35-44 years (HR 0.78, 95%CI, 0.66-0.92; p=.004) were independently associated with reduced relapse and superior LFS (HR 0.77, 95% CI, 0.69-0.87;p<.001) and (HR 0.77, 95% CI, 0.68-0.87; p<.001) respectively, and OS (HR 0.76, 95%CI, 0.67-0.86; p<.001) and (HR 0.80, 95% CI, 0.70-0.91; p<.001) respectively. In contrast, there was no significant difference between outcomes when the donor belonged to the age group 0-19 for relapse (HR 0.87, 95%CI, 0.61-1.22;p=.410, LFS (HR 0.84,95% CI, 0.65-1.09); p=.188), and OS (HR 0.79, 95%CI, 0.60-1.05;p=.108) (Table 1). **Conclusions:** In this homogeneous analysis, patients with AML undergoing PTCy-based GVHD prophylaxis in the contemporary era, younger donor between age groups 20-44 years conferred a significantly reduced relapse risk and superior LFS and OS. The findings inform optimal donor selection. Research Sponsor: None.

Multivariate analyses (ref: donor age ≥45).

Donor age	0-19	P	20-34	P	35-44	P
OS	0.79 (0.60-1.05)	0.108	0.76 (0.67-0.86)	<0.001	0.80 (0.70-0.91)	<0.001
LFS	0.84 (0.65-1.09)	0.188	0.77 (0.69-0.87)	<0.001	0.77 (0.68-0.87)	<0.001
Relapse	0.87 (0.61-1.22)	0.410	0.81 (0.69-0.93)	0.004	0.78 (0.66-0.92)	0.004

Early neutrophil incompetence following allogeneic stem cell transplant. First Author: Maria Lampou, Department of Medicine, Massachusetts General Brigham; Harvard Medical School, Boston, MA

Background: Neutrophils are key immune effector cells against fungal pathogens such as *Candida albicans*. After allogeneic stem cell transplant (allo-SCT), absolute neutrophil count (ANC) is used to measure myeloid engraftment and estimate infection risk, but post-transplant neutrophil function remains poorly understood. Our prior work showed impaired neutrophil function after both myeloablative (MAC) and reduced-intensity conditioning (RIC) regimens. Here, we assess broader neutrophil functions and hypothesize post-transplant neutrophil impairment persists for at least one month despite numeric recovery. **Methods:** Peripheral blood was collected from patients undergoing RIC or MAC allo-SCT and healthy donors at four time points: immediately post-engraftment (P1), and at one (P2), three (P3), and seven (P4) months. Neutrophil function was analyzed by multiparametric flow cytometry to assess phagocytosis, degranulation (CD66b), reactive oxygen species (ROS) production (dihydrorhodamine-123), and ectodomain shedding (CD62L) after incubation with fluorescent *C. albicans*. At P1, neutrophil deformability was quantified to generate a sepsis risk index: Band 1 (low risk, 0.1-4.9), Band 2 (intermediate risk, 5-6.2) and Band 3 (high risk, 6.3-10). Neutrophil antifungal activity was assessed *in vitro* using microscale platforms to quantify and image swarming (cumulative neutrophil response) during restriction of *C. albicans* growth over 12 hours. **Results:** Nineteen subjects were included. The most common underlying malignancy was acute myeloid leukemia (12/19, 63%). Conditioning regimens included fludarabine/melphalan (14/19, 74%), busulfan/fludarabine (4/19, 21%), or fludarabine/total body irradiation (1/19, 5%), with post-transplant cyclophosphamide and tacrolimus. The majority received grafts from matched unrelated donors (14/19, 74%). Median ANC (K/uL) was 3.59 at P1 (15/19 subjects, 79%), 4.55 at P2 (14/19, 74%), 4.03 at P3 (5/19, 26%) and 2.94 at P4 (7/19, 37%). Functional analyses revealed significant impairment in allo-SCT recipients compared with controls at P1, with trends of persistent impairment at P2, and evidence of recovery by P3-P4. At P1, eight recipients demonstrated altered neutrophil deformability, yielding a higher sepsis risk index [median (IQR) 5.93 (3.88–6.80)] versus controls [median (IQR) 0.95 (0.33–2.33)]. Swarming analysis revealed impaired collective behavior in fungal containment compared with controls. **Conclusions:** Despite normalization of ANC after allo-SCT, early post-engraftment neutrophils exhibit significant functional and biophysical impairments, indicating transient immune incompetence. This early window of vulnerability may persist for at least one month post-transplant. Ongoing follow-up and expanded analyses will further characterize the underlying mechanisms and define the trajectory of delayed functional neutrophil recovery. Updated overall survival (OS) and long-term transfusion-independence (TI) from the phase 3 COMMANDS trial in erythropoiesis-stimulating agent (ESA)–naive patients (pts) with lower-risk myelodysplastic syndromes (LR-MDS). First Author: Guillermo Garcia-Manero, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: In the phase 3 COMMANDS trial (NCT03682536), luspatercept (LUSPA) significantly improved RBC-TI ≥12 wks with concurrent mean hemoglobin (Hb) increase ≥1.5 g/dL during wks 1-24 (primary endpoint) vs epoetin alfa (EA) in pts with ESA-naive transfusion-dependent (TD) LR-MDS. Longer follow-up (>2.5 yrs) showed a favorable OS trend and durable TI responses with LUSPA vs EA. We report updated results with 6 additional mos of follow-up (>3 yrs). **Methods:** Eligible pts (≥18 yrs; ESA-naive; TD; LR-MDS) were stratified by baseline (BL) transfusion burden (TB), ring sideroblasts (RS), and serum erythropoietin (sEPO). Pts were randomized 1:1 to LUSPA (1.0-1.75 mg/kg; SC Q3W) or EA (450-1050 IU/kg; SC QW) for ≥24 wks. OS (from randomization), RBC-TI responses and Hb improvement (all from wk 1 to end of treatment), predictive BL biomarkers of OS, and safety were evaluated. **Results:** At cutoff (Oct 6, 2025), median (min-max) follow-up was 35.9 (1-73; LUSPA) and 30.8 (0-77; EA) mos. Median OS was not reached (NR) for LUSPA and 46.0 mos for EA (HR, 0.78; 95% CI, 0.56-1.09), with similar trends in subgroups (Table). RBC-TI ≥12 wks (LUSPA vs EA) occurred in 76.4% vs 55.8% of pts, and in 60.4% vs 39.2% with concurrent mean Hb ≥10 g/dL. Median cumulative duration (95% CI) of RBC-TI ≥12 wks was 184.4 (118.4-NE) wks for LUSPA and 95.1 (74.9-180.1) wks for EA (HR, 0.54; 95% CI, 0.36-0.80). RBC-TI ≥2.5 yrs (LUSPA vs EA) was achieved by 25.3% vs 10.5% of pts. Mean Hb increase ≥1.5 g/dL (LUSPA vs EA) was achieved by 80.2% vs 58.6% of pts; median duration (95% CI) of Hb increase ≥1.5 g/dL was 72.9 (53.9-89.9) and 47.9 (35.9-60.0) wks (HR, 0.61; 95% CI, 0.44-0.85). Improved OS was associated with BL biomarkers of favorable immune (LUSPA) and CV function (LUSPA and EA), less aggressive disease (EA), and preserved megakaryopoiesis (EA); these characteristics may enhance response to therapy. At cutoff, 17.6% (LUSPA) and 7.8% (EA) of pts remained on treatment; 84.6% and 83.2% had ≥1 dose escalation. No new safety concerns emerged. Deaths (any cause) occurred (LUSPA, 36.3%; EA, 43.0%), fewer LUSPA pts progressed to HR-MDS (3.3%; 7.3%), and AML progression was comparable (4.9%; 5.5%). **Conclusions:** Long-term follow-up demonstrated improved OS trends and sustained responses with LUSPA vs EA, overall and in subgroups. No new safety concerns emerged, reinforcing superior clinical benefit as first-line treatment in LR-MDS. Clinical trial information: NCT03682536. Research Sponsor: Bristol Myers Squibb.

Impact of shallow whole genome sequencing on diagnostic yield and prognostic precision in myelodysplastic syndromes. First Author: Zhenling Li, Department of Hematology, China-Japan Friendship Hospital, Beijing, China

Background: Accurate cytogenetic characterization is critical for risk stratification in myelodysplastic syndromes (MDS). Conventional karyotyping and fluorescence in situ hybridization (FISH) are limited in resolution, target specific loci, and cannot detect copy-neutral loss of heterozygosity (CN-LOH). LeukoPrint, a CE-IVD-marked shallow whole-genome sequencing (sWGS, 1×coverage) test, enables genome-wide detection of copy number alterations (CNAs) and CN-LOH. Previously validated in acute myeloid leukemia and multiple myeloma, it improved CNA detection and prognostic accuracy. This study evaluated its ability to enhance diagnostic yield and refine prognostic precision in a large MDS cohort. **Methods:** Bone marrow samples from 461 MDS patients were profiled for genome-wide CNA/CN-LOH using LeukoPrint. Results were compared with conventional karyotyping and FISH to assess detection yield and concordance. The impact of additional LeukoPrint findings on Revised International Prognostic Scoring System (IPSS-R) cytogenetic risk stratification and MDS subclassification was evaluated. **Results:** LeukoPrint detected cytogenetic abnormalities in 63.3% of patients, comprising CNAs in 50.3%, CN-LOH in 23.9%, with 10.8% harboring both. Recurrent CNAs included del(5q) (10.0%), del(20q) (10.0%), +8 (8.9%), and del(7q) (7.8%), among others. CN-LOH frequently affected regions that overlapped common CNA loci, such as 5q (3.7%), 7q (3.7%), and 17p (0.7%). Compared with conventional cytogenetics, LeukoPrint showed 94.4% concordance (κ=0.854) with FISH for five key loci (−5/del(5q), −7/del(7q), +8, del(20q), −Y) and a higher detection rate than karyotyping (65.7% vs 39.2%). For the 11 IPSS-R defined cytogenetic abnormalities (del(3q), del(5q), del(7q), del(11q), del(12p), del(17p), del(20q), +8, +19, -7, and -Y), it identified all karyotype-detected lesions and increased detection yield by 49.4%. These newly identified abnormalities led to IPSS-R cytogenetic risk reclassification in 32.4% (33/102) of comparable cases, predominantly upgrading patients to higher-risk categories. Specifically, 26 patients were reassigned from Good to Intermediate (n = 17), Poor (n = 2), or Very Poor (n = 7); 5 from Intermediate to Poor (n = 4) or Very Poor (n = 1); and 1 from Poor to Very Poor. Furthermore, by detecting additional aberrations such as del(17p) or 17p CN-LOH, LeukoPrint enabled more accurate molecular classification, including the reclassification of one case from MDS-IB1 to MDS-biTP53. **Conclusions:** sWGS-based LeukoPrint substantially enhances cytogenetic detection in MDS, outperforming conventional karyotyping and FISH. By identifying additional clinically relevant cytogenetic abnormalities, it improves prognostic risk stratification and refines disease classification, supporting its integration into routine MDS cytogenetic assessment. Phlebotomy, adherence, and hematocrit control in patients with polycythemia vera in the United States: Real-world analysis. First Author: Kristen M. Pettit, University of Michigan, Section of Hematology/Oncology, Department of Medicine, Ann Arbor, MI

Background: Polycythemia Vera (PV) is characterized by erythrocytosis. A key treatment goal in PV, for which phlebotomy (PHL) is recommended, is achieving and maintaining hematocrit (HCT) levels < 45% to reduce thrombotic risk. However, real-world evidence suggests PHL alone may not achieve consistent and durable HCT control. Repeated PHL may also increase treatment burden and present logistical challenges. **Methods:** Data were collected using the Adelphi PV Disease Specific Programme, a United States (US) cross-sectional survey (August 2025-January 2026) with retrospective chart review. Physicians reported demographics, clinical characteristics, and treatment history for the next five patients (pts) with PV that met the inclusion criteria. Interim analyses are presented descriptively. Of those receiving ≥ 1 PHL in the 12 months prior to survey, pts receiving frequent PHL were defined as ≥ 3 in 6 months or ≥ 5 in 12 months; all other pts were classified as receiving infrequent PHL. Uncontrolled HCT was defined as any HCT ≥ 45% within the prior 12 months. **Results:** Twenty-seven physicians provided data for 143 pts; 86 (60%) received ≥ 1 PHL in the prior 12 months; median (interquartile range (IQR)) age was 65.0 (52.0-70.0) years, 77% were male, median (IQR) time since PV diagnosis was 11.0 (4.0-33.5) months, and 62% were high risk (defined as ≥ 60 years old or history of thrombosis). Half experienced ≥ 1 barrier to receiving PHL, including care coordination challenges (22%), lack of resources (12%), travel time burden (12%) and vein access challenges (10%). In prior 12 months, physicians reported that 38% of pts were not fully adherent to PHL (attended PHL appointments as recommended <90% of the time). At the most recent consultation, 51% of pts were receiving cytoreductive therapy in addition to PHL. Frequent PHL occurred in 24% of pts and infrequent in 76% of pts. Overall, 90% (75/83) had uncontrolled HCT: 89% for frequent (17/19) vs 91% for infrequent PHL (58/64). Since their PV diagnosis, 13% (11/86) of pts had experienced a thromboembolism (TE), and of these 11 pts, 45% (5/11) had experienced a TE within the 12 months prior to survey. For all pts who had ever experienced a TE, the median (IQR) time since their most recent TE was 20.0 (2.5-32.0) months. **Conclusions:** Within this study, pts receiving PHL for PV commonly experienced access and logistical barriers, and incomplete PHL adherence. Nearly all pts had evidence of uncontrolled HCT in the 12 months prior to survey, including both frequent and infrequent PHL groups, and TEs were observed despite PHL treatment. These findings highlight the need for more effective and sustainable approaches to prevent consequences, such as TEs, commonly associated with uncontrolled HCT, while also reducing pt burden. Multimodal immunotherapy for high-risk acute myeloid leukemia and myelodysplastic syndrome. First Author: Parveen Shiraz, Stanford University, Stanford, CA

Background: CD117 is highly expressed on myeloid leukemia cells (MLC) with limited expression on normal tissues. Our group has developed an anti-CD117 monoclonal antibody and demonstrated its safety in a phase 1 clinical trial for myelodysplastic syndrome (MDS). To potentiate engagement with MLC and immune effector cells, we engineered bispecific antibodies (bsAb) to bind CD117 and CD33 or CD38 and recruit natural killer (NK) cells using an active Fc and CD16 (CM1/3/16/16) and/or NKp46 scFv (CM1/3/16/17). NK cell cytotoxicity against MLC increases several-fold when activated by IL2, IL15 or IL21. We studied the *in vitro* and *in vivo* efficacy of bsAbs with fresh NK cells or IL2, IL15 and IL21 (IL21521) activated NK cells (cNK) to deplete MLC. **Methods:** *In vitro* cytotoxicity assays were performed on Kasumi-1 (CD117 high) and MOLM-13 (CD117 negative) acute myeloid leukemia (AML) cell lines and a primary AML sample (CD117 low) with bsAb and NK or cNK cells. cNK were exposed to IL21521 for 7 days. To mimic *in vivo* exposure, cNK were removed from IL21521 for 24, 48 and 72 hours prior to cytotoxicity assays. Using immune deficient NBSGW mice and primary patient sample of high risk (HR)-MDS transformed to AML (MDS/AML), a patient derived xenograft (PDX) model of HR-MDS/AML was created and allowed to progress to >80% CD45+ human leukemia chimerism (HLC) before treatment. Treatment groups included CM1/3/16/16 at 1mg and/or 2e6 NK or cNK given as a single dose per animal. Weekly blood HLC and a terminal 4-week blood, marrow and spleen HLC were performed. **Results:** In *in vitro* cytotoxicity assays, among the bsAbs, CM1/3/16/16 at 100nM with NK cells at 1:1 target:effector (TE) ratio produced the highest cytotoxicity against Kasumi-1 (70%) and MOLM13 (50%). cNK cells alone produced >90% cytotoxicity of Kasumi-1 cells at 1:1 TE ratio even at 72 hours after IL21521 washout. In the HR-MDS/AML PDX advanced leukemia model, the group receiving CM1/3/16/16 with cNK demonstrated the highest depletion of MLC, with 70% reduction of HLC seen at 4 weeks post-treatment. Mice in this treatment group had 100% survival at 4 weeks at which time they were euthanized for analysis. **Conclusions:** Both CM1/3/16/16 and cNK cells independently killed MLC with high efficacy *in vitro*. A single dose of CM1/3/16/16 combined with cNK cells depleted human MLC in PDX model of HR-MDS/AML with advanced leukemia. Further clinical investigation of this bsAb with allogeneic donor cNK cells in HR-MDS/AML is warranted. Research Sponsor: California Institute of Regenerative Medicine; Edward P Evans Foundation.

Whole genome sequencing to identify novel, clinically relevant findings missed by standard of care for patients with myelodysplastic syndrome. First Author: Alex Bataller, Leukemia Department, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Genomic analysis is critical for accurate diagnosis and risk stratification for patients with myeloid malignancies. Whole genome sequencing (WGS) has the ability to capture a breadth of alterations and has the potential to complement or replace current genomic profiling techniques. We sought to validate the molecular findings from Tempus xH, a WGS based assay, with standard of care [SOC] results from a major academic institution (MDACC). **Methods:** We retrospectively sequenced 43 patient samples from MDACC using the Tempus xH WGS assay. SOC data from cytogenetics (karyotype +/- FISH), 81-gene panel sequencing, and/or optical genome mapping OGM (n=10), was regarded as the source of truth. We performed a two-part study: an initial unblinded analysis (n=10) comparing WGS to SOC, followed by a blinded unbiased comparative review (n=33). Clinically relevant alterations were compared between the SOC and xH reportable range workflows. We excluded mutations with <= 10% VAF and filtered copy number alterations (CNAs) < 5Mb, and combined OGM and cytogenetics (10>= metaphases). Structural variants (SVs) were included if they overlapped orthogonal truth or were recurrent myeloid fusions. **Results:** In the unblinded analysis (n=10), WGS detected 53 clinically reported alterations, yielding 94% sensitivity. Single nucleotide variants (SNVs) had 100% sensitivity, and 18/20 CNA events and 6/7 SVs were detected. The single missed SV event was a derivative chromosome (chr), between chr1 and chr20, identified by cytogenetics with breakpoints over the masked centromere region of the WGS. However, WGS detected CNAs in chr arms of 1 and 20, signalling the event was captured yet not resolved as a derivative chr. Two copy losses on chr 19 (complete loss and p-arm) and an *ASXL1* frameshift were detected by WGS but not by SOC. In the blinded study (n=33), WGS detected 143 events, including 124 true positives and no alterations from SOC went undetected by WGS demonstrating 100% sensitivity. WGS identified 24/24 of the CNAs detected by cytogenetics. Among all specimens, 21 novel, high confidence variants were identified in 11 specimens (39%) by WGS that were not detected by SOC; including 14 CNAs, two SNVs, and five SVs, including diagnostically and/or prognostically critical alterations: 2 *MECOM* rearrangements, 1 *KMT2A*-PTD, an 11MB deletion in chr 17p (*TP53* locus), and a focal *RUNX1* deletion highlighting the potential clinical benefit of WGS. **Conclusions:** WGS accurately recapitulates results from targeted NGS panels, OGM and cytogenetics and advances our understanding of MDS biology. xH WGS uncovered a significant number of novel, clinically relevant and potentially targetable findings undetected by SOC. WGS provides a complementary view of the genome, identifying actionable and prognostic markers helping clinicians make more informed treatment decisions. Research Sponsor: None.

Multi-modal AI foundation models approach for diagnosis of myelodysplastic syndromes across whole bone marrow aspirate and biopsy slides. First Author: Palak Dave, Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Morphologic diagnosis of myelodysplastic syndromes (MDS) from bone marrow aspirates and biopsies is subjective and error prone. Compared to narrow/specific predictive AI methods used in the literature, recently developed pathology foundation models pretrained on large, diverse histopathology corpora have the potential to improve generalizability while reducing task-specific annotation requirements. Here, we evaluate and compare multiple pretrained foundation models across bone marrow aspirate and biopsy whole-slide images (WSI), incorporate a cell-level bag-of-cells (BoC) foundation model, and assess tri-modal ensemble strategies. **Methods:** Digitized bone marrow aspirate (Asp) and biopsy (Bx) WSIs from patients with MDS and non-MDS cytopenias were analyzed using four pretrained pathology foundation models (GigaPath, H-Optimus-0, Virchow2-CLS, MUSK) for tile-level feature extraction. Cell-level features from aspirate-derived BoCs were extracted using DinoBloom-B, a foundation model pretrained for hematologic cell representations. Tile- or cell-level features were aggregated using attention-based multiple instance learning (ABMIL). Models were evaluated on 645 patients (319 MDS, 326 non-MDS) from the NHLBI MDS Natural History Study (NCT02775383) using 5-fold cross-validation (CV) and a held-out test set (n=129). For each modality, the best-performing model was selected based on test performance. Predictions were evaluated individually and combined using soft-probability ensembles. An oracle ensemble estimated the upper bound of multimodal complementarity. **Results:** Performance of the foundation models is summarized in Table 1. A soft-vote tri-modal ensemble of the selected models improved performance beyond any single modality (AUC 0.83; accuracy 0.73). Error analysis demonstrated partially non-overlapping failure modes across modalities, and an oracle ensemble achieved substantially higher accuracy (0.94), indicating unrealized multimodal complementarity. **Conclusions:** Foundation models enable robust AI-based diagnosis of MDS across bone marrow specimen types. Tri-modal ensembling improves diagnostic performance, while oracle analysis motivates TriPath, a unified framework for joint modeling of aspirate, biopsy, and cellular morphology to support standardized and generalizable MDS diagnosis. Research Sponsor: Edward P. Evans Foundation; The National MDS Natural History, NIH/NHLBI/NCI.

Characterizing the genomic landscape of Langerhans cell histiocytosis using the AACR Project GENIE database. First Author: Amber Chang, University of South Florida, Morsani College of Medicine, Tampa, FL

Background: Langerhans cell histiocytosis (LCH) is a rare neoplasm characterized by the abnormal clonal proliferation of bone marrow-derived Langerhans cells and occurs predominantly in pediatric patients. Clinical manifestations range from localized bone lesions to multisystem involvement. Given the high frequency of MAPK pathway mutations, particularly BRAF V600E, next-generation sequencing is recommended for LCH patients to identify actionable targets. This study utilizes the American Association for Cancer Research (AACR) Project Genomic Evidence Neoplasia Information Exchange (GENIE) database to address existing gaps in the genomic profiling of LCH, aiming to inform long-term risk stratification, uncover prognostic markers, and guide avenues for targeted therapy. **Methods:** AACR Project GENIE was accessed via cBioPortal (v18.0-public) on November 18, 2025 to identify all LCH patients. Gene mutations and demographic variables were tabulated, and statistical correlations were assessed using two-sided t-tests and non-parametric analyses with Benjamini–Hochberg false discovery rate correction. Entries with unknown values were excluded from analysis; discrepancies in percentage reflect unreported data. **Results:** This study identified 326 LCH samples from 290 patients, of whom 140 (48.3%) were female and 139 (47.9%) were male. By race, 140 (48.3%) identified as White, 9 (3.1%) as Black, and 9 (3.1%) as Asian. Of the samples, 152 (46.6%) originated from primary tumors and 20 (6.1%) were from metastatic tumors. The cohort included samples from 113 pediatric patients (34.7%) and 212 (65.0%) adults. Frequent mutations included *BRAF* (n=126; 38.7%), *MAP2K1* (n=57; 17.5%), *TET2* (n=17; 5.2%), and *FAT1* (n=8; 2.5%). No significant difference was identified between the genomic profiles of males and females ($p>0.05$), although comparisons by race revealed several unique somatic point mutations in Asian and Black patients. Among Asian patients, mutations in *MUTYH*, *PDGFRB*, and *TERT* were significantly enriched, while *BORCS8-MEF2B*, *BRCA1*, and *DDR2* mutations were enriched in Black patients. Within this cohort, pediatric patients were more likely to present with *PTEN* mutations, while adults ≥34 years old were more likely to have *VTI1A* or *ATM* mutations. *BRAF* mutations were mutually exclusive with *MAP2K1* mutations (n=124/124; $p<0.001$), while *TET2* mutations frequently co-occurred with *ASXL1* mutations (n=2/18, $p<0.05$). There were no significant differences in mutations between primary and metastatic samples ($p>0.05$). **Conclusions:** Our findings support the classification of *BRAF* and *MAP2K1* mutations as key driver mutations and identify several additional mutations that are significantly enriched across demographic groups. Further research into these genomic associations is crucial to address existing knowledge gaps and translate into novel treatment modalities for patients with LCH. Research Sponsor: None.

6573 **Poster Session**

Updated analysis of overall survival (OS) with imetelstat (IME) in relapsed/refractory (R/R) myelofibrosis (MF) versus real-world (RW) data, and assessment of RW treatment (tx) patterns. First Author: Andrew Tucker Kuykendall, Moffitt Cancer Center, Tampa, FL

Background: IME showed significantly longer median OS (mOS) in patients (pts) with Janus kinase inhibitor (JAKi) R/R intermediate-2–risk or high-risk MF in the IMbark trial (NCT02426086) vs closely matched RW pts treated with best available therapy (BAT) after ruxolitinib (RUX; HR, 0.35; *P*=.0019). The MF tx landscape changed considerably in recent years, potentially impacting OS. We present an updated OS analysis of IMbark pts vs a larger RW pt cohort after extended follow-up. **Methods:** The updated RW dataset included 126 pts who discontinued RUX and were subsequently treated with BAT at Moffitt Cancer Center between 2010 and 2025. To assess changes in RW tx patterns, baseline/disease characteristics and OS of pts diagnosed before/after 2016 and 2019 were compared. To update the IMbark vs RW OS analysis, a closely matched cohort was identified using IMbark eligibility criteria, including pts diagnosed before 2016 who received RUX but were R/R. The mOS was measured from time of JAKi discontinuation to death or censored at last follow-up. Propensity score approaches using average tx effect for overlap population (ATO) or stabilized inverse probability tx weighting (sIPTW) were implemented to adjust for baseline covariates/prognostic factors that may impact outcomes. **Results:** The RW tx pattern assessment included 96 pts. Time from diagnosis to start of RUX and duration of RUX tx were significantly shorter after 2016 vs before (Table). Similar changes were observed after 2019 vs before. The mOS in pts diagnosed after 2016 and 2019 was significantly longer vs before. The updated mOS analysis included 59 IMbark pts and 54 closely matched RW pts. With a median follow-up of 46.2 mo for IMbark pts and 48.2 mo for RW pts, mOS (95% CI) was 30.7 mo (25.5-36.9) with IME in IMbark vs 15.4 mo (13.1-30.5) with BAT in RW (HR, 0.512; *P*=.003) per the unweighted analysis. Propensity-weighted analyses (ATO, sIPTW) had similar results. **Conclusions:** This updated post hoc analysis confirms a significantly more favorable OS benefit with IME vs BAT in pts with R/R MF and poor prognosis consistent with the previous report (Kuykendall 2021). A significant improvement in OS in RW pts over the last decade was also demonstrated, potentially due to shorter time from diagnosis to start of RUX and earlier switch to next-line JAKi or clinical trial. Evolving tx patterns are key considerations for interpreting future clinical trial outcomes. Clinical trial information: NCT02426086. Research Sponsor: This study was funded by Geron Corporation. All authors contributed to and approved the abstract; writing and editorial assistance were provided by Casandra M. Monzon, PhD, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by Geron Corporation.

Updated RW data by time of diagnosis.

	Before 2016 (N=54)	After 2016 (N=42)	Before 2019 (N=69)	After 2019 (N=27)
Time from diagnosis to RUX start (mean), mo	46.7	10.5	39.7	8.2
RUX duration (mean), mo	30.4	13.5	26.1	15.0
Transplant, n (%)	3 (5.6)	4 (9.5)	5 (7.2)	2 (7.4)
mOS (95% CI), mo	15.4 (13.1-30.5)	34.2 (24.2-NA)	16.6 (14.2-30.0)	39.8 (34.2-NA)

Pregnancy outcomes in women with myeloproliferative neoplasms: A multicenter real-world analysis. First Author: Maryam Naser, Virginia Commonwealth University - Massey Comprehensive Cancer Center, Richmond, VA

Background: Pregnancy in women with myeloproliferative neoplasms (MPNs) is associated with increased thrombotic and obstetric risk, yet contemporary real-world data describing maternal and fetal outcomes remain limited. We evaluated pregnancy-related outcomes in women with MPNs and examined potential risk predictors. **Methods:** We conducted a retrospective cohort study using the TriNetX network, a federated multicenter network of de-identified electronic health records from participating healthcare organizations. Pregnant women with essential thrombocythemia (ET), polycythemia vera (PV), or myelofibrosis (MF) were identified. The primary outcome was all-cause mortality. Secondary outcomes included deep vein thrombosis (DVT), miscarriage, pre-eclampsia, eclampsia, preterm labor, and intrauterine growth restriction (IUGR). Subgroup analyses were performed using propensity score matching for age, race, ethnicity, and comorbidities to compare outcomes by Low Molecular Weight Heparin (LMWH) exposure, race, maternal age, and MPN subtype. Risk ratios (RR) with 95% confidence intervals (CI) were calculated. **Results:** A total of 1,904 pregnancies were identified (mean age 31.1±7.0 years).The cohort was predominantly non-Hispanic (66.2%) and White (59.1%). ET accounted for 90.3% of cases, followed by PV (8.0%) and MF (1.7%). Overall rates of maternal mortality and DVT were 2.8% and 2.6%, respectively. Adverse obstetric outcomes included miscarriage (9.6%), pre-eclampsia (12.4%), eclampsia (1.3%), preterm labor (9.1%), and IUGR (8.5%). In matched analyses, LMWH use was associated with a numerically lower risk of miscarriage compared with no LMWH (6.8% vs 10.4%; RR 0.66, 95% CI 0.42–1.04), without significant differences in pre-eclampsia, preterm labor, or IUGR. Outcomes were similar between White and African American patients. Advanced maternal age (>35 years) was associated with a lower risk of preterm labor (3.7% vs 9.2%; RR 0.40, 95% CI 0.21–0.75). Obstetric outcomes were comparable between ET and PV. **Conclusions:** In this real-world cohort, pregnancies in women with MPNs were associated with measurable rates of thrombotic and obstetric outcomes. LMWH use was associated with a numerically lower risk of miscarriage without statistically significant differences in other outcomes. These findings provide contemporary outcome estimates and may inform risk stratification and future prospective studies. Limitations include the retrospective design, potential misclassification due to inherent limitation of the database, limited MF representation, and inability to assess disease activity, aspirin use, or pregnancy-specific dosing strategies. Research Sponsor: None.

Treatment patterns and outcomes in pacritinib-treated patients with MF and higher platelet count: MY-PAC study. First Author: Douglas Tremblay, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Pacritinib (PAC), a JAK1-sparing JAK2/IRAK1/ACVR1 inhibitor has shown spleen volume and symptom improvement in clinical trials of in patients (pts) with myelofibrosis (MF) with similar benefits in the real-world. This analysis evaluated real-world outcomes in pts with MF and platelet counts (PLT) ≥50 x10^9/L at PAC initiation. **Methods:** This was a multisite chart review of pts with MF treated with PAC for ≥1 month between 06/01/2022 and 07/31/2024 with ≥6 months of follow-up through 01/31/2025. Pts were followed from PAC initiation (index) until the earliest of end of the study, the end of data availability for the pt, or death. Evaluated data included Pt characteristics, treatment patterns, palpable spleen length (total spleen length minus 10cm) and spleen size category based on palpation or palpable spleen length below costal margin (not palpable/minimally palpable <5 cm below costal margin; mild: 5-10 cm palpable; moderate: 11-20 cm palpable; severe: >20 cm palpable), PLT, hemoglobin (Hb), MF-related symptoms, and overall survival through Day 180. Results for pts with PTL ≥50 x10^9/L at index are described using counts and percentages, medians and interquartile range (IQR), and survival probabilities. **Results:** Of 169 pts with MF treated with PAC, 27% (45/169) had PLT ≥50 x 10^9/L at index. Median age was 67 years (IQR: 62-74) at diagnosis and median time from diagnosis to index was 6 months (IQR: 1.3-14.3). The median duration of follow-up from index was 7.6 months (IQR: 6.7-11.0) and 82% of pts (n=37) were still on PAC at end of follow-up. Of 12 pts with spleen length measured by ultrasound at index and Day 180, median spleen length reduction (SLR) was 39% (IQR: 30.4-48.3) with 83% (10/12) achieving SLR ≥25% by Day 180. Among those with categorical spleen size based on palpation (n=5) or ultrasound (n=12), 53% (9/17) achieved a reduction in spleen size category. No pts had a worsening in spleen size category, and spleen size category remained stable for 47% (8/17) of pts. At index, all but one pt had ≥1 MF-related symptom. By Day 180, 80% (35/44) experienced a reduction in the number of symptoms, with a median reduction of 67% (IQR: 33-75). Median PLT at index was 72 x 10^9/L (IQR: 53-110) and from index to Day 180, median increase in PLT was 14% (n=38, IQR: 0-30). Among pts with PLT ≤100 x10^9/L at index 20% (6/30) achieved an increase of ≥30x10^9/L. At index, median Hb was 8.8 g/dL (IQR: 8.0-9.7). Among 29 pts with Hb <10 g/dL at index and Hb at Day 180, Hb increased by a median of 0.8 g/dL (IQR: -0.1-1.0), with 31% (9/29) achieving an increase ≥1.0 g/dL. Overall survival by the end of follow-up was 89% (40/45), and 6-month survival probability was 93% (95% confidence interval: 81, 98). **Conclusions:** Similar to clinical trials, pts with MF and higher PLT counts treated with PAC in the real-world also experienced reduction or stabilization in spleen size category, decreased MF-symptom burden, PLT stability, and improved Hb. Research Sponsor: Sobi Inc.

Integrated analysis of the ropeginterferon alfa-2b clinical program in essential thrombocythemia to demonstrate molecular and hematologic responses with safety profile information across treatment lines, ethnicities, and driver mutation types. First Author: Ruben A. Mesa, Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC

Background: Patients with essential thrombocythemia (ET) have limited disease-modifying options. This integrated analysis of 182 ET patients from 2 trials evaluated consistency the efficacy of ropeginterferon alfa-2b (ropeg, BESREMi) across treatment lines and examined the impact of ethnicity and molecular subtype on outcomes. **Methods:** Data were pooled from the phase 3 randomized SURPASS-ET study (ropeg vs anagrelide [ANA] in HU-resistant/intolerant high-risk ET) and the phase 2b single-arm EXCEED-ET study enrolling both treatment-naïve and previously treated patients in North America. Endpoints included durable modified ELN response, hematologic and molecular responses, thrombotic events, and safety. **Results:** In SURPASS-ET, ropeg achieved a significantly higher durable modified ELN response at months 9 and 12 than ANA (42.9% vs 6.0%; p<0.0001), with superior platelet and WBC control, greater *JAK2*V617F allelic burden reduction, and fewer major thrombotic events. In EXCEED-ET, durable objective modified ELN responses reached 60.2%, with ELN2009 molecular response rates of 35.0% for *JAK2*V617F, 16.0% for *CALR*, and 25.0% for *MPL*, demonstrating consistent efficacy across treatment lines and mutation subtypes (Table 1). Safety profiles were comparable between studies, with mostly low-grade, manageable AEs. In the integrated analysis across studies, grade ≥3 TEAEs occurred in 28.6% of ropeg recipients and 33.8% of ANA. TEAEs leading to discontinuation (8.8% vs 20.0%) and serious AEs (12.6% vs 30.0%) were less frequent in the ropeg group. Fatal AEs occurred only in the ANA group (3.8%). **Conclusions:** Across the two studies, consistent molecular and hematologic efficacy with a favorable and manageable safety profile was demonstrated in treatment-naïve and pretreated ET populations, across ethnicities and disease drivers. These findings support ropeg as a disease-modifying treatment option with a favorable benefit–risk profile for all ET patients regardless of ethnicity, treatment line, driver mutation status, and mutational complexity. Clinical trial information: NCT04285086, NCT05482971. Research Sponsor: PharmaEssentia Corporation.

Activating MPN patients through empowering, patient-centered education. First Author: Aicha M. Diallo, Patient Empowerment Network, Bothell, WA

Background: Patients living with myeloproliferative neoplasms (MPNs) face complex disease management, evolving treatment options, and barriers to accessing reliable, culturally relevant information. These challenges disproportionately affect underrepresented populations, including Black, Latinx, Indigenous, rural, LGBTQIA+, and veteran communities. The [ACT]IVATED MPN program was developed to improve health literacy, patient activation, and self-advocacy among individuals newly diagnosed with MPNs, while remaining relevant across all stages of disease. **Methods:** The [ACT]IVATED MPN program delivers expert-verified, multimedia educational content designed to support patient and care partner engagement in care. Program components include multilingual expert interview videos, real-world patient vignettes, downloadable health literacy tools, and a comprehensive resource guide available in English and Spanish. Content is distributed digitally and through culturally trusted community organizations to increase reach among underserved populations. Program reach and impact are assessed through digital engagement analytics and post-program participant feedback. **Results:** To date, the [ACT]IVATED MPN program has reached over 5,000 patients and care partners. Preliminary program evaluation data indicate that 100% rated their overall experience as positive or somewhat positive, with 83.3% reporting a positive experience. Following participation, 90.9% of respondents agreed or strongly agreed that the program increased their understanding of MPNs. Indicators of patient activation were high, with 100% of participants reporting increased confidence to speak up with questions about their care and 95.7% reporting greater knowledge and confidence to take an active role in treatment decisions. **Conclusions:** The [ACT]IVATED MPN program demonstrates the feasibility and value of a patient-centered, equity-focused education model in supporting health literacy, self-advocacy, and engagement in care among individuals living with MPNs. Scalable, multilingual educational interventions may complement clinical care by promoting shared decision-making and reducing disparities in access to MPN-related information and resources. Hibbard, J. H., & Greene, J. (2013). What the evidence shows about patient activation: Better health outcomes and care experiences; fewer data on costs. *Health Affairs, 32*(2), 207–214. https://doi.org/10.1377/hlthaff.2012.1061. Association of neutrophil-to-lymphocyte ratio and thrombotic events in US veterans with polycythemia vera. First Author: Mingfei Li, Bentley University, Waltham, MA

Background: Neutrophil-to-lymphocyte ratio (NLR) is a novel predictor of thrombosis in patients with Polycythemia Vera (PV), an uncommon myeloproliferative neoplasm distinguished by excessive red blood cell production within the bone marrow. However, there is no guideline-endorsed NLR cut-off that mandates cytoreduction. This study aims to assess the association of NLR and risk of thrombotic events, and evaluate the impact of different therapies based on electronic health records from the United States (US) Veterans Affairs Healthcare System (VAHS). **Methods:** Veterans with PV were identified based on either 2 outpatient codes separated by 30 or more days or 1 inpatient code in the VAHS databases (2017–2023). The first PV diagnosis was considered as the index date. Patients with myelofibrosis or leukemia diagnosis before the index date were excluded from the analysis. Veterans with at least one NLR value were examined for the occurrence of thrombotic events. Baseline characteristics were defined over the two-year period preceding the first PV diagnosis code. Treatments were defined within two years of the index date and categorized as: cytoreductive therapy (including hydroxyurea, interferons, or ruxolitinib), phlebotomy interventions, or neither. Cox proportional hazards regression was used to evaluate the associations between therapies and the risks of thrombotic events, controlled by the pre-index use of individual therapy. **Results:** A total of 11,809 Veterans with PV were identified from the VAHS, with a mean (SD) age of 67.4 (11.1) years, 96.7% male, 9.0% Black, 81.1% White, and 5.1% Hispanic. The rate of thrombotic events (per 1000 person-year) was 45 for patients treated with cytoreductive therapy, 32 for phlebotomy-treated patients, and 51 for those who received no treatment. Patients were delineated into five groups based on NLR: $<$1, 1-2.9, 3-4.9, 5-19.9, and above 19.9. The rate of thrombotic events was closely at 39% amongst each group with NLR below 5. For those with NLR at 5-19.9 and $>$19.9, thrombotic events were reported in 48% and 61% of veterans, respectively. Cytoreductive therapy and therapeutic phlebotomy were each associated with significantly lower risks of thrombotic events compared to none of these two treatments among PV patients. Adjusted risk of thrombotic events was 45% (HR: 0.55, 95%CI: 0.48-0.62, P $<$ 0.01) and 34% (HR: 0.66, 95%CI: 0.57-0.78, P: $<$ 0.01) lower for patients with cytoreductive and phlebotomy therapy compared to no treatment. **Conclusions:** The real-world evidence from VAHS yields a cut-off value of NLR at 5 to predict risks of thrombotic events among Veterans with PV. Patients receiving cytoreductive therapy or therapeutic phlebotomy had reduced risk of thrombotic events. Research Sponsor: PharmaEssentia, Inc.

Real-world outcomes of 7+3 versus azacitidine/venetoclax in CML transformed to AML. First Author: Muhammad Mujtaba Bhinder, Charleston Area Medical Center (CAMC), Charleston, WV

Background: Although tyrosine kinase inhibitors (TKIs) have markedly improved outcomes in chronic myeloid leukemia (CML), transformation to acute myeloid leukemia (AML) remains a devastating event with poor prognosis. Intensive induction chemotherapy with cytarabine and anthracycline (7+3) is standard, but many patients are older or frail and unable to tolerate intensive therapy. Azacitidine plus venetoclax (aza-ven) has emerged as a low-intensity alternative; however, real-world comparative outcome data in CML-transformed AML remain limited. We conducted a large real-world analysis to compare survival and early clinical outcomes with 7+3 versus aza-ven. **Methods:** Adult patients with CML transformed to AML who received induction therapy between January 1, 2010, and June 1, 2025, were identified using the TriNetX Research Network. Patients were classified by receipt of 7+3 or azacitidine plus venetoclax within one year before or after allogeneic hematopoietic stem cell transplantation. Overall survival (OS) was evaluated using Kaplan–Meier analysis with hazard ratios (HRs) and log-rank testing. Early clinical outcomes were compared using z-tests with risk differences (RD), risk ratios (RR), and 95% confidence intervals (CI). **Results:** A total of 280 patients were included, of whom 222 received 7+3 and 58 received azacitidine plus venetoclax (aza-ven). Patients treated with aza-ven had a higher comorbidity burden and lower baseline albumin, consistent with a frailer population. Early infectious complications within 30 days occurred in 53.2% of patients receiving 7+3 and 58.6% receiving aza-ven (risk difference [RD] −5.47%, 95% CI −19.74% to 8.81%; risk ratio [RR] 0.91, 95% CI 0.71–1.16; p=0.46). One-year overall survival was similar between groups (66.2% vs 68.1%; hazard ratio [HR] 1.03, 95% CI 0.62–1.72; log-rank p=0.91). Hospitalization within 30 days occurred less frequently with 7+3 than with aza-ven (71.6% vs 84.5%; RD −12.86%, 95% CI −23.91% to −1.82%; RR 0.85, 95% CI 0.74–0.97; p=0.046), while hospitalization between days 31–180 was identical in both groups (50.0% vs 50.0%; p=1.00). Infection between days 14–30 occurred in 34.7% versus 43.1%, respectively (RD −8.42%, 95% CI −22.62% to 5.78%; p=0.24). **Conclusions:** In this real-world cohort of patients with CML transformed to AML, azacitidine plus venetoclax achieved comparable 1-year survival and early infectious outcomes to intensive 7+3 induction despite being used in a frailer population. Larger multicenter studies are needed to confirm comparative effectiveness and refine patient selection. Research Sponsor: None.

Clinical features, management, and outcomes of adolescents and young adults with myeloproliferative neoplasms. First Author: Sandro Pino-Ascencio, Massachusetts General Hospital, Boston, MA

Background: Myeloproliferative neoplasms (MPNs)—polycythemia vera (PV), essential thrombocythemia (ET), myelofibrosis (MF)—are chronic myeloid malignancies mainly occurring in older adults. However, up to 20% of pts are diagnosed as adolescents and young adults (AYA; ages 13–39). Thus, treatment guidelines and outcome data primarily apply to older subjects, leaving clinical features, outcomes, and management of younger pts poorly defined. We describe the characteristics, risk stratification, and treatment of AYA pts at a tertiary academic center. **Methods:** We conducted a retrospective study of AYA pts with MPN treated at Mass General Brigham between 2007–2025. Pts diagnosed at ages 13–39 and meeting 2022 WHO criteria for MPN were included. Data abstracted from the electronic medical record included demographics, diagnostics, cardiovascular (CV) risk factors, thrombotic and bleeding events, risk stratification, and management. Descriptive statistics were applied. **Results:** 90 AYA pts with MPN were identified. Median age at diagnosis was 27 years (range 16–39), 53 (58.9%) were female and 64 (71.1%) were White. ET was the most frequent (65.6%), followed by PV (22.2%), MF (6.7%), and MPN-unclassified (5.6%). Most pts (73.3%) were diagnosed incidentally with abnormal blood counts. At least one CV risk factor—HTN, HL, DM, BMI $>$25, tobacco use—was present in 53 pts (58.9%). JAK2 mutation was present in 55 pts (61.1%), CALR in 26 (28.9%), MPL in 3 (3.3%), and triple-negative in 7 (7.8%). Across 18 (20.0%) pts, 23 thrombotic events occurred; arterial (n= 9) and venous (n= 14);13 in the year prior to diagnosis and 10 after; 3 pts (3.3%) experienced events in both time periods and 4 (4.4%) pts experienced more than one event. Seven (7.8%) experienced major bleeding in the year prior to diagnosis or any time after, defined by ISTH criteria. Of the 23 pts with thrombotic and/or bleeding events, 19 were subsequently cytoreduced, most often with interferon (ropeginterferon n=10; peginterferon n=3). One pt received ruxolitinib and 12 hydroxyurea. Of 71 pts classified as low-risk, 34 (47.9%) received cytoreduction. Indications included extreme thrombocytosis (32.4%), inadequate control with phlebotomy (23.5%), symptom burden (23.5%), bleeding risk/history (17.6%), and disease modification (14.7%). Median follow-up was 3.6 years (IQR 1.9-7.6), 4 (4.4%) pts progressed to MF, and 1 (1.1%) to accelerated phase MPN. Two (2.2%) of these pts have undergone allogeneic stem cell transplantation. One (1.1%) death was reported during follow-up. **Conclusions:** In this AYA MPN cohort, $>$ 20% were high-risk due to thrombotic events. CV comorbidities were common despite young age. Nearly half of low-risk pts received cytoreductive therapy, highlighting potential limitations of standard risk stratification in young pts. These findings support the need for age-specific guidelines for AYA pts with MPN. Research Sponsor: None.

Beyond haematological control: Long-term renal outcomes of imatinib therapy in chronic myeloid leukaemia. First Author: Rachana Chennamaneni, Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

Background: Imatinib has transformed outcomes in chronic myeloid leukaemia (CML), enabling long-term survival and durable molecular responses. With therapy often extending over decades, late toxicities affecting organ function have gained increasing importance. However, real-world data on long-term renal outcomes with prolonged imatinib exposure remain limited. Objectives: To evaluate long-term changes in renal function in patients with CML receiving imatinib therapy for at least 10 years. **Methods:** This retrospective observational study included patients with CML treated with imatinib for ≥10 years at a single tertiary care centre. Clinical and treatment-related data were obtained from medical records. Renal function at baseline and at latest follow-up was assessed using estimated glomerular filtration rate (eGFR) calculated by the CKD-EPI formula. Data on diabetes and hypertension were collected. Patients with pre-existing chronic kidney disease, those receiving chemotherapy, those diagnosed with a second malignancy and patients in treatment-free remission (TFR) were excluded. **Results:** A total of 440 patients were analysed. The median age at diagnosis was 36 years (range, 5–70), with a male-to-female ratio of 1.39:1. At diagnosis, 95% were in chronic phase. Sokal risk stratification classified 32%, 31%, and 37% of patients as low, intermediate, and high risk, respectively. The median duration of imatinib therapy was 15 years (range, 10–24), with a median daily dose of 400 mg (range, 200–800 mg). At last follow-up, 91% of patients had achieved major molecular response. Overall, 62 patients (14%) developed a clinically significant decline in renal function (eGFR <60 mL/min/1.73 m²). In this subgroup, median eGFR declined from 90 range, 70-122) to 44 mL/min/1.73 m² (range, 13-54); representing a median reduction of 46 mL/min over 15 years (approximately 3 mL/min/year). Comorbidities were present in 11 patients (18%). A greater decline in eGFR was observed among males ($p<0.001$), patients aged <35 years at diagnosis ($p<0.0001$), and those achieving major molecular response ($p<0.0002$). Treatment modification was undertaken in<37 patients (60%), including TFR in 13 (21%), dose reduction in 20 (32%), and switching to an alternate tyrosine kinase inhibitor in 4 (6%). Partial renal recovery was documented in 9 patients (24%). All patients in whom TFR was attempted continue to maintain TFR at last follow-up. **Conclusions:** Long-term imatinib therapy is associated with a gradual but clinically meaningful decline in renal function in a subset of patients with CML. Dose modification, switching TKIs, or attempting TFR may result in partial reversibility, without compromising disease control. These findings highlight the importance of long-term renal monitoring and treatment optimisation in patients with sustained molecular responses. Research Sponsor: None.

Durable treatment-free remission in CML beyond clinical trials: Lessons from a large single-center real-world experience. First Author: Sadashivudu Gundeti, Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India

Background: Treatment-free remission (TFR) has become a major therapeutic objective in chronic-phase chronic myeloid leukemia (CML). While clinical trials have established the feasibility of TFR, real-world data evaluating the influence of deep molecular response (DMR) duration, cumulative tyrosine kinase inhibitor (TKI) exposure, and adherence to molecular monitoring remain limited, particularly in resource-constrained settings. **Methods:** We conducted a retrospective single-centre analysis of chronic-phase CML patients who electively discontinued TKI therapy between May 2019 and October 2025 after achieving sustained DMR (BCR-ABL ≤0.01% IS). Collected variables included demographics, ELTS risk score, TKI type, duration of DMR (<5 vs ≥5 years), cumulative TKI exposure (<8 vs ≥8 years), molecular relapse (loss of major molecular response [MMR]), time to relapse, and time to MMR regain following TKI resumption. Monitoring compliance was defined as completion of at least five PCR assessments in the first year following TKI discontinuation. Relapse-free survival was analyzed using Kaplan–Meier methods. **Results:** Eighty-eight patients were included (median age 36 years; 53.4% male). Median cumulative TKI exposure prior to discontinuation was 14.5 years, and median DMR duration was 13 years. At a median follow-up of 40 months, 72 patients (81.8%) remained in sustained TFR. TFR rates were 92% at 6 months, 87% at 12 months, and 82% at 24 months. Fourteen patients (15.9%) restarted TKI therapy due to molecular relapse, one due to withdrawal symptoms, and two died from causes unrelated to CML. Median time to relapse was 4.5 months, with the majority occurring within the first six months.No patient progressed to accelerated or blast phase. All evaluable patients who resumed TKI therapy rapidly regained MMR (median 3 months). TFR rates did not differ significantly according to DMR duration (<5 vs ≥5 years; $p=0.67$), cumulative TKI exposure (<8 vs ≥8 years; $p=0.70$), or compliance with molecular monitoring (compliant vs non-compliant; $p=0.82$). Notably, 30.6% of patients were non-compliant with recommended monitoring schedules, yet high TFR rates and excellent salvage outcomes were maintained. **Conclusions:** In this large single-centre real-world cohort, over 80% of chronic-phase CML patients achieved durable TFR with predictable early relapses, excellent salvage outcomes, and no disease progression. Neither prolonged DMR duration, extended TKI exposure, nor strict adherence to intensive molecular monitoring significantly influenced relapse risk. These findings support broader, pragmatic implementation of TFR strategies and suggest that less stringent molecular monitoring may be safely adopted in carefully selected patients, particularly in resource-limited settings. Research Sponsor: None.

ASC4FIRST wk 144 analysis: Efficacy and safety and tolerability with asciminib (ASC) vs investigator-selected tyrosine kinase inhibitors (IS TKIs) in newly diagnosed (ND) chronic myeloid leukemia in chronic phase (CML-CP). First Author: Jorge E. Cortes, Department of Medicine, Georgia Cancer Center, Augusta University, Augusta, GA

Background: In ASC4FIRST (NCT04971226) primary (wk 48) (Hochhaus A et al. *N Engl J Med*. 2024) and key secondary (wk 96) (Cortes JE et al. *Blood*. 2025) analyses, ASC had superior efficacy and improved safety/tolerability vs IS TKIs. ASC was approved for ND CML-CP in numerous countries. We report the ASC4FIRST wk 144 analysis (cutoff: Sep 29, 2025). **Methods:** In this multicenter, open-label, phase 3 study, patient (pts) with ND CML-CP were randomized 1:1 to ASC 80 mg once daily or an IS TKI at label doses, stratified by ELTS risk category and prerandomization-selected TKI (imatinib [IMA] or a second generation [2G] TKI). Primary endpoints were major molecular response (MMR) rates at wk 48 with ASC vs all IS TKIs, and ASC^{IMA} vs IS TKI^{IMA}. **Results:** Pts were randomized to ASC (n=201) or IS TKIs (n=204). Median follow-up was 38.1 mo with ASC vs 37.4 mo with all IS TKIs, 36.2 mo with ASC^{IMA} vs 35.3 mo with IS TKI^{IMA}, and 39.2 mo with ASC^{2G} vs 38.5 mo with IS TKI^{2G}. At cutoff, more pts were ongoing tx with ASC vs all IS TKIs (78.6% vs 55.9%), ASC^{IMA} vs IS TKI^{IMA} (81.2% vs 50.0%), and ASC^{2G} vs IS TKI^{2G} (76.0% vs 61.8%). MMR rate at wk 144 continued to be superior with ASC vs all IS TKIs (77.1% vs 53.4%; tx difference, 23.9%; P<*.001*) and ASC^{IMA} vs IS TKI^{IMA} (79.2% vs 47.1%; tx difference, 32.6%; P<*.001*), and higher with ASC^{2G} vs IS TKI^{2G} (75.0% vs 59.8%; tx difference, 15.2%; P=*.01*). MR^4 and $MR^{4.5}$ rates at wk 144 were higher with ASC vs all IS TKIs (56% vs 36%; 42% vs 25%), ASC^{IMA} vs IS TKI^{IMA} (58% vs 33%; 44% vs 20%), and ASC^{2G} vs IS TKI^{2G} (53% vs 39%; 41% vs 29%). Long-term outcomes with ASC vs all IS TKIs, ASC^{IMA} vs IS TKI^{IMA}, and ASC^{2G} vs IS TKI^{2G} included probability of event-free survival at wk 144 post randomization (85% vs 69%; 83% vs 63%; 87% vs 75%), and estimated progression-free survival (98% vs 95%; 97% vs 93%; 99% vs 97%) and overall survival (99% vs 97%; 99% vs 96%; 99% vs 99%), at 3 yrs post randomization. No new postbaseline mutations emerged with ASC after wk 96; 1 each emerged with IMA and nilotinib. Safety/tolerability remained favorable with ASC vs IMA vs 2G TKIs including grade ≥3 AEs (49% vs 52% vs 63%), AEs leading to discontinuation (6% vs 13% vs 14%), and AEs leading to dose adjustment/interruption (37% vs 44% vs 63%); exposure-adjusted arterial occlusive event rates were 1.3, 0.5, and 1.1 cases per 100 pt-tx yr, respectively. Median exposure duration was 37.4 mo, 33.8 mo, and 37.3 mo, respectively. No deaths occurred during tx or ≤30 d after last dose. **Conclusions:** At wk 144, ASC had consistently higher molecular response rates and favorable safety/tolerability vs all IS TKIs with no new tx-emergent mutations. Together with wk 48 and 96, this analysis reinforces ASC's improved benefit-risk profile and supports ASC as a tx option for ND CML. Clinical trial information: NCT04971226. Research Sponsor: Novartis Pharma AG.

Upfront low-dose diet-modified nilotinib versus standard imatinib in Indian patients with newly diagnosed chronic-phase chronic myeloid leukemia: The NILLOW phase II randomised trial. First Author: Deepak Garg, AIIMS, New Delhi, India

Background: Upfront use of second-generation tyrosine kinase inhibitors in chronic myeloid leukemia (CML) is limited in resource-constrained settings due to cost, fasting requirements, and tolerability concerns. Food increases nilotinib bioavailability, enabling effective dose reduction. **Methods:** NILLOW was a single-center, open-label, randomized phase II study. Newly diagnosed CML-CP patients were randomized 1:1 to receive nilotinib 150 mg twice daily with meals or imatinib 400 mg once daily. The primary endpoint was EMR at 3 months (BCR-ABL1 IS ≤10%). Safety and hematologic recovery were evaluated as secondary endpoints. **Results:** EMR at 3 months was significantly higher with nilotinib compared to imatinib (73.8% vs 46.2%; absolute difference 27.6%; p=0.001). Patients receiving nilotinib demonstrated faster hemoglobin recovery during follow-up ($p<0.01$). Grade 3/4 anemia was lower with nilotinib (5.5% vs 17.8%; p=0.02). Imatinib was associated with higher rates of peripheral edema, periorbital edema, rash, pruritus, and headache (all $p<0.05$). **Conclusions:** Low-dose fed nilotinib improves early molecular response with superior tolerability compared to imatinib. This approach represents a cost-effective frontline strategy for CML in low-resource settings. Further studies as phase 3 maybe be followed up to confirm the signal. Clinical trial information: CTRI/2024/03/064707. Research Sponsor: None.

Clinical fidelity of large language models in chronic myeloid leukemia: A multimodel comparative study. First Author: Meenal Gehlawat, Desert Valley Hospital, Victorville, CA

Background: Large language models (LLMs) are emerging as promising tools for clinical decision-making. These models are increasingly investigated for their potential in diagnosis, prognosis, and personalized treatment of chronic myeloid leukemia (CML). This study evaluates the efficacy of five leading LLMs and examines the impact of incorporating up-to-date clinical guidelines into LLM prompts to enhance clinical decision-making. **Methods:** We developed fifty standardized clinical vignettes on CML, staging, tyrosine kinase inhibitor (TKI) selection, monitoring, adverse events, and treatment-free remission. Five LLMs (DeepSeek-R1, Gemini-2.5-Pro, Claude 4.0, GPT-OSS-120B, and LLAMA 4) generated responses under two distinct prompt conditions. In the baseline prompt, the clinical vignette was entered, and a response was obtained. In the guideline-augmented prompt, models were instructed to extract information from the NCCN v1.2026 and ESMO 2017 guidelines. A blinded expert panel evaluated the responses using a peer-reviewed answer key, assigning scores of 0 for incorrect, 1 for partial, and 2 for correct answers. The maximum possible score was 100. **Results:** The use of guideline-augmented prompting increased accuracy across all models, raising performance from 79.8% to 97.6% (mean difference: 17.8 percentage points, 95% CI: 3.9-31.7, p=0.024). Improvements for individual models ranged from 5 to 33 percentage points. Notably, only Gemini-2.5-Pro achieved perfect accuracy (100%). Knowledge drift was observed in four out of five models (80%), primarily due to reliance on outdated WHO classification criteria instead of current NCCN standards. This discrepancy resulted in staging errors in 32% of baseline cases. The diagnostic workup category exhibited the highest baseline accuracy (94%), whereas the treatment-free remission criteria showed the most substantial improvement following guideline integration, increasing from 72% to 96%. **Conclusions:** LLMs possess substantial medical knowledge that can facilitate clinical decision-making. However, these AI systems remain vulnerable to errors such as knowledge drift and hallucinations. This scalable framework demonstrates that mandatory compliance with guidelines, supported by structured prompting, is essential for safe LLM integration into oncology workflows. Institutions implementing LLM-based clinical decision support should require guideline integration rather than relying solely on pre-trained knowledge. Future studies should validate these findings in prospective clinical settings and evaluate mechanisms for automated guideline updating. Research Sponsor: None.

Comparative accuracy of LLM responses under baseline vs. guideline-augmented prompts.

LLM	Baseline response accuracy	Guideline augmented response accuracy	Delta
Claude 4.0	82	97	+15
DeepSeek-R1	72	97	+25
Gemini-2.5 Pro	89	100	+11
GPT-OSS-120B	90	95	+5
LLAMA-4	66	99	+33

Molecular response and outcomes in patients with myeloproliferative neoplasms treated with interferon in the real-world setting. First Author: Laneisha Maldonado Jaime, Winship Cancer Institute, Atlanta, GA

Background: Myeloproliferative neoplasms are clonal stem cell disorders driven by constitutive JAK-STAT signaling, classically via acquisition of the *JAK2* V617F mutation. *JAK2* variant allele frequency (VAF) correlates with disease phenotype and clinical risk. Interferon (IFN) therapies are immunomodulatory agents with disease-modifying potential, demonstrating reductions in *JAK2* allele burden in limited prospective trials. However, IFN therapies are underutilized in clinical practice, and molecular responses are poorly defined. Therefore, we evaluated clinical outcomes and molecular response to IFN therapy in real-world practice, emphasizing long-term *JAK2* VAF kinetics. **Methods:** We conducted a single-center, retrospective study of consecutive patients diagnosed with essential thrombocythemia (ET), polycythemia vera (PV), or pre-fibrotic myelofibrosis (pre-MF) treated with peginterferon alfa-2a or ropegintereron alfa-2b, regardless of prior therapy. Serial *JAK2* V617F was measured in peripheral blood using allele-specific PCR. Clinical outcomes, treatment persistence, and longitudinal molecular responses were evaluated. **Results:** Eighty-two patients were included (median age 50.5 years, 73% female), with diagnosis of PV (76.8%), ET (17.1%), or pre-MF (6.1%); 44 patients (53.7%) were treatment naïve. Median follow-up was 92 mos. from diagnosis and 59 mos. from IFN initiation. At 48 mos., 82% of patients remained on treatment; 12 patients (14.6%) discontinued due to intolerance. Disease progression occurred in one patient. Complete hematologic remission (CHR) was achieved in 80.5% of patients. Median baseline *JAK2* VAF was 28%, declining to a median nadir of 4.2% at 41.5 months. Median absolute and relative percent reductions were -18.7 and -81.6%, respectively. VAF reduction $\geq$50% was achieved by 79% of patients, 19.5% achieved a nadir $<$1%, and 53.2% achieved nadir $<$5%. VAF declined progressively until 48 mos. and then remained stable through 72 mos., with later increases mostly attributable to treatment discontinuation. No baseline clinical, molecular, or treatment-related variables predicted depth of molecular response. Treatment-free remission (TFR) was attempted in seven patients after a median of 45 mos. of therapy (mean VAF 0.52%), and median TFR duration was 39 mos. **Conclusions:** This real-world analysis demonstrates that interferon therapy is feasible and effective in real-world practice. Most patients achieved durable CHR with low rates of treatment discontinuation. Disease progression was exceedingly rare. IFN was associated with substantial and sustained reductions in *JAK2* allele burden, supporting its disease-modifying activity outside of the trial setting. These findings reinforce the clinical relevance of serial molecular monitoring and inform emerging approaches to treatment de-escalation in select patients. Research Sponsor: None.

6587 **Poster Session**

Timing of TP53 mutation acquisition as a determinant of outcomes in patients with myeloproliferative neoplasms and myeloproliferative neoplasms/myelodysplastic syndromes. First Author: Lauren M. Granat, Cleveland Clinic, Cleveland, OH

Background: While *TP53* mutations have been studied in MDS and AML, their clinical significance in MPN and MDS/MPN remains incompletely understood. Emerging evidence suggests that *TP53* mutations are often not present at diagnosis, acquired over the disease course, and enriched in older patients (pts). The primary objective of this study was to evaluate whether the interval between diagnosis and the detection of *TP53* mutation impacts OS and/or PFS. **Methods:** All patients with a TP53 mutation were identified via our in-house NGS panel between 2018–2024 were included (n=497). Spearman correlation, Kruskal–Wallis, and chi-square tests were used to evaluate associations between age, VAF, and the presence of co-mutations with the interval from diagnosis to *TP53* detection. The Kaplan–Meier method and Cox proportional hazards models were used to analyze OS and PFS. **Results:** A total of 54 pts, including ET (n=27), PV (n=7), MF (n=9), and CMML (n=9) were identified. The median age at diagnosis was 65.1 yrs, 56% were males (n=30), 81% Caucasian (n=44). 22% (n=12) of pts were diagnosed with their MPN or MDS/MPN at the time of *TP53* identification. 52% pts were treated with hydroxyurea prior to *TP53* identification. At the time of *TP53* detection, 13 pts had progressed to AML and 11 pts to MF. The most common co-mutations were *JAK2* (n=19), *CALR* (n=11), *TET2* (n=10) and *ASXL1* (n=9). The median time from initial diagnosis to *TP53* detection was 6.7 yrs (interquartile range [IQR], 0.8–13.4; range, 0–38 yrs). Pts were divided into 4 quartiles depending on timing of *TP53* acquisition, with 13 pts in the $<$6-mo, 15 pts in the 6 mo–7 yrs, 13 in the 7.1-14 yrs and 13 pts in the $>$14 yrs quartiles. Older pts had a significantly shorter interval between diagnosis and *TP53* detection (Spearman r = -0.61, $p < 0.0001$). In addition to older age in TP53 time $<$ 6 months (Median 74,9 vs 64.0, p=0.005), pts in the $<$6-month group also had higher VAF ($>$ median of 41: 69.2% vs 43.9%) and had higher number of co-mutations at diagnosis ($\geq$3: 53.8% vs 26.8%), although this did not reach statistical significance. Older age at *TP53* detection was associated with significantly worse OS (3.6 vs 27.2 mo; p=0.002) and PFS (3.6 vs 17.5 mo; p$<$0.001). After adjusting for age at the time of *TP53* detection, a longer interval between diagnosis and *TP53* detection was associated with worse OS (HR for the 2nd, 3rd, and 4th quartiles vs. the 1st quartile: 1.2, 2.5, and 4.3; *p for trend* = 0.002) and worse PFS (HR 1.2, 2.9, and 4.5, *p for trend* = 0.001). **Conclusions:** This study demonstrates that after adjusting for age, a longer interval between MPN or MDS/MPN diagnosis and *TP53* detection is associated with worse OS and PFS. Older age has previously been identified as an adverse prognostic factor, however our findings suggest that timing of *TP53* acquisition may also be an important predictor of clinical outcomes in pts with MPNs and MDS/MPNs. Research Sponsor: None.

One vs. 2 vs. ≥3 *TET2* mutations in chronic myelomonocytic leukemia: Co-mutation patterns and prognostic correlates. First Author: Muhammad Yousuf, Mayo Clinic Rochester, Rochester, MN

Background: *TET2* is the most frequently mutated gene in chronic myelomonocytic leukemia (CMML) and has been associated with favorable outcome, with recent studies suggesting a more pronounced prognostic impact in the presence of $\geq$2 *TET2* mutations (*Csizmar et al. leukemia 2025;39:2030; Kynning et al. Br J Haematol. 2025 Nov 25. doi: 10.1111/bjh.70264*). We sought to determine if this particular observation extended to patients with $\geq$3 *TET2* mutations ($TET2^{MUT}$) and also held true in the context of recently reiterated genetic risk factors. **Methods:** The current study was conducted under institutional review board approved minimum risk protocols allowing retrospective patient data collection and analysis. Diagnostic criteria were according to the International Consensus Classification (Arber et al. Blood 2022. 140:1200). All statistical analyses were conducted using JMP 18 software. **Results:** 536 CMML patients who underwent CLIA-approved NGS testing were stratified according to the number of $TET2^{MUT}$: 221 (41%) wild-type, 148 (28%) with one, 153 (29%) 2, and 14 (2%) $\geq$3 $TET2^{MUT}$. Co-mutation frequencies with significant differences between one vs. two $TET2^{MUT}$ included ASXL1 (46% vs. 29%; p$<$0.01), KRAS (7% vs. 14%; p=0.02) and SETBP1 (5% vs. 0.6%; p=0.02). Phenotypic comparisons revealed preponderance of prognostically favorable traits associated with wild-type *TET2* but no significant differences between one vs. two $TET2^{MUT}$. In age-adjusted univariate analysis, transplant-censored overall survival (TCOS), calculated from the time of mutation detection, was superior in patients with one (p$<$0.01; HR 0.7) or 2 (p$<$0.01; HR 0.4) but not $\geq$3 (p=0.4) $TET2^{MUT}$, vs. those with wild-type *TET2*. TCOS was also superior with 2 vs. 1 (p=0.02; HR 0.7) but not with $\geq$3 vs. 1 (p=0.7) $TET2^{MUT}$; the results were similar when TCOS was calculated from the time of diagnosis. Multivariable analysis confirmed the survival advantage of exactly two $TET2^{MUT}$ vs. wild-type *TET2* (p$<$0.01; HR 0.5), one $TET2^{MUT}$ (p$<$0.01; HR 0.6), or $\geq$3 $TET2^{MUT}$ (p$<$0.01; HR 0.4), after adjusting for age, sex, anemia, circulating blasts $\geq$2%, and leukocyte count $\geq 13\times10^9$/L. The favorable impact of exactly two $TET2^{MUT}$ persisted in CMML-MD and CMML-MP and remained independent of *TET2* VAF, mutation type, karyotype, and other prognostically relevant mutations. This association was sustained in the BLAST (p$<$0.01; HR 0.5) and CPSS-mol (p=0.02; HR 0.7) models, but not in BLAST-mol model (p=0.12). **Conclusions:** Mechanistic explanation for this novel observation includes the possibility that *TET2* mutational categories based on mutation count reflect distinct biological states rather than having a simple linear effect. The persistence of this signal despite adjustment for established molecular and genetic risk factors supports its consideration in the development of future CMML prognostic models. Phase II trial of asciminib for newly diagnosed chronic myeloid leukemia. First Author: Maria Hachem, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Asciminib is safe and effective across all lines of therapy of chronic myeloid leukemia (CML). Here, we report interim results from an investigator-initiated phase II trial of asciminib in patients (pts) with newly diagnosed (ND) CML. **Methods:** Asciminib was given at 80 mg/day in pts with ND CML in chronic phase or accelerated phase (clonal evolution only). The primary endpoint was the rate of major molecular response (MMR) by 12 months of therapy. AEs were recorded according to the CTCAE version 5.0 criteria. The data cutoff was January 20, 2026. **Results:** A total of 59 pts were treated with a median age at diagnosis of 49 years (range, 21-79); 33 (56%) were male. Sokal score was low in 29 pts (49%), intermediate in 21 (36%), and high in 9 (15%). With a median follow-up of 12 months, the cumulative best overall response was MCyR in 57 pts (97%), CCyR in 54 (92%), MMR in 40 (68%), MR4 in 21 (36%), and MR4.5 in 17 (29%). Among pts who completed at least 1 year of asciminib therapy, the MMR rate by 12 months was 71%. By 3 months, among 58 evaluable pts, 51 (88%) achieved MCyR or transcript levels below 10% on the international scale (IS), 42 (72%) CCyR or transcript levels below 1% IS, 16 (28%) MMR, 5 (9%) MR4, and 2 (3%) MR4.5. Seven pts (12%) had transcript levels above 10%. By 6 months, among 53 evaluable pts, the rate of CCyR was 85% (45/53), MMR 64% (34/53), MR4 34% (18/53), and MR4.5 26% (14/53). By 12 months, CCyR was achieved in 27 pts (87%), MMR in 22 (71%), MR4 in 13 (42%), and MR4.5 in 10 (32%). *ASXL1* mutation was detected in 3 of 41 pts (7%) evaluated for cancer gene variants. Of them, two achieved a complete molecular response and one achieved CCyR as best response but later lost it with the acquisition of *A337T* and *F497L* mutations. The most frequent adverse events related or possibly related to asciminib included elevated lipase (Grade[G]2, n=9; G3, n=3; G4, n=1) and fatigue (G1, n=7; G2, n=2); 3 pts developed pancreatitis (G2, n=1; G3, n=2). A 71-year-old pt with a previous medical history of hypertension developed G5 acute coronary syndrome after 2.5 months of asciminib therapy. Overall, 8 of 59 pts (14%) discontinued asciminib due to: 1) adverse events in 4 (including 1 fatal acute coronary syndrome); 2) loss of CCyR in 2 (one with the emergence of *A337T* and *F497L* mutations and another with *P465A* and *D381E* mutations); 3) failure to achieve CCyR in 1 patient in the setting of cytopenias and asciminib dose reduction to 40 mg/day; and 4) withdrawal of consent by 1 patient due to inability to return to clinic for treatment due to social constraints and was in MR4 at the time of asciminib discontinuation. The 12-month rates of failure-free survival, event-free survival, transformation-free survival, and overall survival were 92%, 96%, and 98%, respectively. **Conclusions:** Treatment with asciminib in ND CML showed a MMR tare of 71% by 12 months of therapy with no new safety signals. Disease resistance was associated with the emergence of myristoyl pocket mutations. Clinical trial information: NCT06236724. Research Sponsor: None.

6590 Poster Session

Thromboelastography-guided platelet transfusion and associations with utilization and outcomes in patients with hematologic malignancies. First Author: Rana Mohamed, Brody School of Medicine at East Carolina University, Greenville, NC

Background: Thromboelastography (TEG) is a viscoelastic assay assessing clot formation and global hemostasis. In patients with hematologic malignancies, transfusion support is essential, yet evidence guiding optimal transfusion strategies is limited. This study evaluated transfusion utilization and outcomes associated with TEG use in hematologic oncology patients. **Methods:** We conducted a retrospective cohort study at a tertiary care hospital (October 2022–2025) including hospitalized patients with acute and chronic leukemias or multiple myeloma who received blood product transfusions. Primary outcomes were platelet transfusion utilization (standardized units) and platelet response. Secondary outcomes included hospital length of stay (LOS) and in-hospital mortality. Welch's t-test and chi-square testing were used, with multivariable regression adjusting for demographic and clinical covariates. **Results:** Among 975 platelet transfusion episodes, 68 (5.3%) were TEG-guided. Unadjusted analyses showed slightly lower platelet utilization with TEG-guided transfusions compared with standard care (1.03 vs 1.06 units, $p<0.001$). Platelet count increments did not differ significantly (Δ 17.9 vs 16.3, p=0.57). TEG-guided patients had longer LOS (39.8 vs 31.9 days, $p<0.001$) and higher in-hospital mortality ($p<0.001$), reflecting greater illness severity. After adjustment, differences in utilization, platelet response, and LOS were no longer significant. TEG use remained strongly associated with in-hospital mortality (adjusted OR 29.8, 95% CI 8.83–100.77, $p<0.001$). **Conclusions:** TEG use in hospitalized patients with hematologic malignancies receiving platelet transfusions was uncommon and not associated with improved transfusion efficiency or platelet response. TEG-guided transfusions occurred primarily in high-acuity settings with prolonged hospitalization and increased mortality, suggesting TEG functions more as a marker of illness severity than a routine tool for optimizing platelet transfusion. Further studies are needed to clarify its role in malignant hematology care. Research Sponsor: None.

Platelet transfusion outcomes by TEG use in hematological malignancy encounters.

Outcome	TEG guided (n=68)	Non-TEG guided (n=1214)	P Value (unadjusted)	P value (adjusted)
Number of encounters	68	1214	–	–
Standardized platelet units, mean	1.03	1.06	0.14	0.34
Platelet count response (DELTA), mean	17.9	16.3	0.57	0.93
Length of stay, mean days	39.8	31.9	<0.001	0.51
In-hospital mortality, %	94.1	44.7	<0.001	0.0008

Adjusted p values from multivariable regression models including demographics, malignancy subtype, baseline platelet count, transfusion dose, care location, transfusion priority, and timing variables. DELTA = post-pre platelet count.

6591 Poster Session

Safety and efficacy of asciminib in veterans with chronic myeloid leukemia. First Author: Omar Shukri Yaghi, George Washington University, Department of Medicine, Washington, DC

Background: Asciminib was approved for use in previously treated patients with chronic myeloid leukemia (CML) in 2021. It employs a novel allosteric mechanism that can overcome resistance and intolerance to conventional tyrosine kinase inhibitors (TKIs). We assessed the efficacy and clinical outcomes of asciminib in Veterans with CML following failure of first- and second-generation TKIs. **Methods:** Utilizing the VA Informatics and Computing Infrastructure (VINCI), we reviewed all 116 Veterans nationwide with a diagnosis of CML who were treated with asciminib prior to August 2025. Demographic and clinical data collected included age at diagnosis, gender, race, prior CML treatments, and BCR-ABL transcript levels at treatment initiation and at 3 and 6 months. Safety outcomes included the development of thrombocytopenia and neutropenia. Mortality data were collected when applicable. Since more than half of the patients were still alive at the time of chart abstraction, median survival could not be reliably estimated (median 3.4 years, lower limit 2.8 years, upper limit NA). We therefore report the restricted mean survival time (RMST). **Results:** 110 Veterans were included in the analysis after excluding 6 for missing data. The median age at diagnosis was 65 years (IQR, 52–71) and 95% of participants were male (Table 1). 70% of participants received a first-generation TKI as first-line therapy; in the second-line setting, 12% received a first-generation TKI and 83% received a second-generation TKI. The median BCR-ABL level at asciminib initiation was 1.03 (IQR, 0.08–29.95) and decreased to 0.05 (IQR, 0–0.69) at 6 months. 11 patients developed thrombocytopenia and 3 developed neutropenia. Assuming 5 years of follow-up from the start of asciminib, RMST is 3.3 years (standard error, 0.23 years). **Conclusions:** Asciminib demonstrated clinically meaningful activity in a heavily pretreated Veteran population with CML. By 6 months, the median BCR-ABL level was 0.05%, consistent with major molecular response (MMR; BCR-ABL ≤0.1%), a well-established positive prognostic indicator. Despite prior exposure to multiple therapies, overall survival (using RMST) remained favorable at a mean of 3.3 years following treatment initiation. Rates of any-grade neutropenia and thrombocytopenia were low, supporting a favorable safety profile. Research Sponsor: None.

Patient characteristics and outcomes.

Characteristic	Total (N = 110)
Age at diagnosis, median (IQR)	65 (52–71)
Gender, n (%)	
Male	105 (95%)
Female	5 (4.5%)
Race	
Black	19 (17%)
White	85 (77%)
American Indian or Alaska Native	1 (0.9%)
Unspecified	5 (4.5%)
Treatment Exposure	
First-line therapy	
1st generation TKI	77 (70%)
2nd generation TKI	33 (30%)
Second-line therapy	
1st generation TKI	13 (11.8%)
2nd generation TKI	91 (82.7%)
3rd generation TKI (ponatinib)	6 (5.5%)
Outcomes	
Thrombocytopenia	11 (10%)
Neutropenia	3 (2.7%)
RMST (5 years), years	3.3 (95% CI, 2.9–3.8)

Glucagon-like peptide-1 receptor agonist (GLP-1 RA) and hematologic cancer risk among older adults with type 2 diabetes. First Author: Wei-Han Chen, Department of Pharmaceutical Outcomes & Policy, College of Pharmacy, University of Florida, Gainesville, FL

Background: Recent preclinical and clinical evidence suggests that glucagon-like peptide-1 receptor agonists (GLP-1 RA) may reduce cancer risk through inflammation modulation. However, comparative effectiveness research evaluating hematologic malignancy risks of GLP-1 RAs remain limited in real-world populations. **Methods:** Using 15% random samples of Medicare Part D beneficiaries from 2013 to 2022, we identified older adults with type 2 diabetes who initiated GLP-1 RA or DPP-4i. The primary outcomes included myelodysplastic syndromes (MDS), lymphoma, and leukemia. We performed 1:1 propensity score matching for confounding control. We estimated the hazard ratios (HR) and 95% confidence intervals (CI) with Cox proportional hazard model. We examined the heterogeneity in treatment effects by pre-specified patient demographic and baseline factors. Subgroup analyses were conducted for: a) age (≥75 vs. <75 years), b) sex (female vs. male), c) race/ethnicity (non-Hispanic Black vs. non-Hispanic White vs. Hispanic ethnicity), d) obesity status (overweight vs. obese vs. severe obesity), and e) specific GLP-1 RA class (e.g., liraglutide, dulaglutide, and semaglutide). In the sensitivity analysis, we used cause-specific Cox model to account for death as a competing risk and calculated E-values to examine the potential influence of unmeasured confounders. **Results:** After propensity score matching, there were 29,212 patients included in the cohort (14,606 GLP-1 RA users and 14,606 DPP-4i users). Of the cohort, mean (SD) age was 77.3 (7.4) years; 53.9% were female, 69.9% were non-Hispanic White, 11.1% were non-Hispanic Black, and 3.9% were Hispanic. Compared to DPP4i, GLP-1 RA showed reduced risks in MDS (HR: 0.70, 95% CI [0.53-0.94]), lymphoma (0.71 [0.57-0.89]), and leukemia (0.85 [0.74-0.99]). Overall, no statistically significant heterogeneity of treatment effect was detected in subgroup analyses. After accounting for death as a competing event, the hazard ratios are consistent with the conventional Cox models except monocytic leukemia (HR: 1.4 [0.45-4.56], p=0.48). E-values suggest moderate robustness to potential unmeasured confounding. **Conclusions:** GLP-1 RA initiation was associated with a reduced risk of hematologic malignancies compared with DPP-4i use among real-world patients with type 2 diabetes. These findings suggest a potential protective effect of GLP-1 RAs on hematologic cancer risk and warrant further mechanistic and prospective investigation. Research Sponsor: None.

Clinical and genetic landscape of individuals evaluated in a CHIP cardiology clinic: A single-center experience, 2020 to 2025. First Author: Ohad Oren, Cleveland Clinic, Cleveland, OH

Background: Despite growing observational data linking clonal hematopoiesis of indeterminate potential (CHIP) to adverse cardiovascular outcomes, the cardiovascular evaluation and management of individuals with clonal hematopoiesis remain undefined. We report the experience of a dedicated CHIP Cardiology Clinic. **Methods:** We conducted a retrospective review of patients evaluated in the CHIP Cardiology Clinic at the Brigham and Women's Hospital. Baseline demographics, comorbidities, medication use, and treatment interventions were extracted from the electronic medical record. **Results:** Fifty-three patients were evaluated between 2020 and 2025, of whom 39 (73.6%) had clonal hematopoiesis (CH), out of which 12 (30.8%) met criteria for CHIP. Among individuals with CH, the most frequently identified mutations were D N M T 3 A (30, 76.9%), T E T 2 (23, 59.0%), and A S X L 1 (6, 15.4%). The mean age was 65.9 years (range 40-81), and 23 (58.9%) were male. Hypertension and dyslipidemia were each present in 23 (59.0%) patients. Existing cardiovascular diseases included coronary artery disease (7, 18.0%) and arrhythmias (3, 7.7%). Following evaluation in the CHIP Clinic, and shared decision-making discussion in view of the dearth of evidence regarding outcome improvement in those with CHIP, lipid-lowering therapies were initiated or increased in 28 (71.8%) patients, with statins initiated or dose escalated in 21 (53.8%) and ezetimibe in 11 (28.2%). Blood pressure medications were initiated or intensified in 5 (12.8%) patients. Ischemic evaluation was performed in 3 (7.7%) patients due to suggestive symptoms. We developed a "patient page" to acquaint the patients and families with CHIP. (https://doi.org/10.1001/jamacardio.2024.3773). **Conclusions:** In this first longitudinal report from a dedicated CHIP Cardiology Clinic, a substantial proportion of patients harbored somatic mutations associated with elevated cardiovascular risk. Institution of preventive cardiovascular medications, in particular lipid-lowering therapies, was a frequent intervention. These findings support the feasibility of CHIP-focused cardiovascular care but underscore the need for prospective trials to evaluate the impact of targeted preventive strategies in this population. Research Sponsor: None.

Clinical outcomes in *TP53*-mutated clonal hematopoiesis: Single-center retrospective study. First Author: Jacob Edward Herstein, Department of Internal Medicine, University of Texas Health Science Center at Houston, Houston, TX

Background: Clonal hematopoiesis (CH), including CH of indeterminate potential (CHIP) and clonal cytopenia of undetermined significance (CCUS), is defined by myeloid neoplasm (MN)-associated somatic mutations in the absence of known hematologic malignancy and may precede MNs, such as myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). *TP53*-mutated (*TP53*m) CH has been assumed to be high risk, but clinical outcomes are poorly characterized. **Methods:** We retrospectively evaluated patients (pts) with *TP53*m CH seen at a tertiary cancer center. Inclusion required pathogenic or likely pathogenic *TP53* mutations of presumed hematopoietic origin identified on bone marrow, peripheral blood, or plasma next-generation sequencing. **Results:** 62 pts with *TP53*m CH were included; 26 (42%) CHIP and 36 (58%) CCUS. Median age was 68 years (range, 23–81) with 30 male pts (48%). History of tobacco, alcohol, and illicit drug use was noted in 30 (48%), 31 (50%), and 7 (11%) pts, respectively. Common comorbidities included cardiovascular disease (n=51, 82%), diabetes (n=17, 27%), and rheumatologic disorders (n=13, 21%). 53 pts (85%) had a history of non-myeloid malignancy, with 41 (77%) receiving prior cytotoxic chemotherapy, 20 radiation (32%), and 13 (21%) stem cell transplant/cellular therapy (SCTCT). By CH Risk Score (CHRS), 4 (7%), 38 (61%), and 20 (32%) pts were considered low-, intermediate-, and high-risk of myeloid transformation. The 36 CCUS pts were classified as 10 (28%) low, 9 (25%) intermediate, and 17 (47%) high risk by Clonal Cytopenia Risk Score (CCRS). Median *TP53* VAF was 5% (range, 1–54), and 30 pts (46%) had additional somatic mutations. 12 pts (19%) were *TP53* double-hit. Median time from prior malignancy to CH detection was 42.3 months (mo; range, 0.2–365.0). With a median follow-up time of 60.1 mo (95% confidence interval [CI], 43.0–70.5), median overall survival (mOS) from CH detection was 67.5 mo (95% CI, 59.0–not estimable [NE]). A total of 15 pts (24%) progressed to MNs (12 MDS [80%], 3 AML [20%]) with a median time to transformation of 20.2 mo (95% CI: 6.8–53.9). mOS from time of MN diagnosis was 20.1 mo (95% CI, 7.3–NE) for MDS and 0.3 mo (95% CI, 0.3–NE) for AML pts. Pts who transformed to MNs were more likely to have had tobacco (p=0.026) or illicit drug use (p=0.031), higher comorbidity burdens (p=0.031), rheumatologic disorders (p=0.016), previous SCTCT (p=0.042), and CCUS (p=0.035). No differences were observed by *TP53* VAF. Of those who transformed, 7 (47%) were intermediate- and 8 (53%) high-risk by CHRS. CCRS showed low, intermediate, and high risk in 4 (33%), 1 (9%), and 7 (58%) of the 12 *TP53*m CCUS pts who progressed to MNs, respectively. **Conclusions:** *TP53*m CH is associated with significant comorbidity burdens and oncologic history. Existing risk stratification tools poorly predict myeloid transformation in these pts. Further clinicopathologic characterization of *TP53*m CH is warranted. Research Sponsor: None.

Genomic landscape and precision therapeutics in polycythemia vera: Insights from the AACR Project GENIE. First Author: Alena Gagnon, Santa Clara University, Santa Clara, CA

Background: Polycythemia vera (PV) is a myeloproliferative neoplasm associated with blood thickening and increased risk of life-threatening blood clots and bleeding. PV is rare and affects roughly 50 per 100,000 people in the US. PV is most commonly associated with a somatic mutation in the *JAK2* gene and the mean age of diagnosis is 60. The *JAK2* gene is critical for cell signaling, and cell maturation. Treatments for PV include immunotherapy, radiation and chemotherapy but this can only slow growth, underscoring the need to define molecular drivers for targeted therapies. Using the AACR GENIE database, this study characterizes the mutational landscape of PV to identify genetic markers and therapeutic targets. **Methods:** The American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) database was accessed from cBioPortal (v18.1-public) on November 20, 2025 to identify all patients with PV. The most common gene mutations, demographic correlations, and mutual exclusivities were analyzed using a two-sided T-test and non-parametric tests, with Benjamini-Hochberg false discovery rate (FDR) correction. **Results:** The cohort comprised 491 PV samples from 341 patients. The patient population consisted of adults(19-88 years old, n=341,100%). Males (n=171, 50.1%) were represented as equally as females (n=163, 47.8%), with some unknown cases (n=7, 2.1%). By race, the cohort consisted primarily of White (n=236, 69.2%), Black (n=13, 3.8%), and Asian (n=17, 5.0) patients, with the remaining patients (n=75, 22.0%) categorized as having an unspecified or other race. Of the samples derived from 90 tumors which were classified as primary (n=80, 16.3%) or metastatic (n=10, 2.0%), the most frequent somatic mutations were observed in *JAK2* (87.17%, n=428), *TERT2* (18.53%, n=91), *DNMT3A* (14.87%, n=73), *ASXL1* (5.50%, n=27), and *TP53* (3.05%, n=15). When stratified by sex, sex-associated mutational variability was observed. Specifically, mutations in *NF1* (n=13, $p < 0.001$) were detected only in females. *DNMT3A* mutations occurred at a higher frequency in females compared to males (n=48 v. n=23; $p < 0.001$). *AXSL1* mutations occur at a higher frequency in males compared to females (n=23 v. n=4; $p < 0.001$). **Conclusions:** To the best of our knowledge, this is the first GENIE database analysis of polycythemia vera, thus addressing a significant research gap regarding its genomic landscape. The predominance of *JAK2* and *TERT2* align with earlier descriptions in prior genetic profiling studies. Sex specific mutations underscore the importance of demographic-specific molecular features. Collectively, these findings suggest that *JAK2* and *TERT2* could serve as key genomic targets for the development of novel precision therapeutics. Further research is needed to validate these genomic associations and advance precision medicine approaches for patients with PV. Research Sponsor: None.

Universal adipogenic and immunologic remodeling in the recurrent myeloid leukemia microenvironment of recurrent versus primary myeloid leukemias: An age-stratified analysis. First Author: Karen Dong-Tran, Renown Health/University of Nevada Reno School of Medicine, Reno, NV

Background: Disease recurrence is the primary cause of mortality in myeloid leukemias. While molecular studies suggest leukemic cells actively reprogram marrow stroma to create a self-reinforcing niche, natural age-related adiposity confounds whether this remodeling is disease-intrinsic or a byproduct of aging. We sought to validate the "disease-intrinsic" hypothesis by delineating the landscape of recurrent disease across a large-scale transcriptomic cohort, rigorously distinguishing leukemic reprogramming from physiologic aging. **Methods:** We analyzed 2,378 myeloid leukemia samples (2,007 primary, 371 recurrent) from NCI genomic datasets via xCell computational deconvolution. To control for ontogenic marrow changes, the cohort was stratified into Pediatric (<18 years, n = 2,071) and Adult (≥ 18 years, n = 307) subgroups. Demographic analysis confirmed balanced gender and race distributions ($p > 0.05$); age disparity was explicitly corrected via the stratified design. Differences in tumor microenvironment (TME) composition were assessed using Mann-Whitney U tests, with Bonferroni-corrected p-values (Padj) calculated to ensure statistical rigor. **Results:** Recurrent tumors exhibited a profound, convergent stromal remodeling independent of age. The 'adipogenic shift' via Preadipocyte enrichment was observed in both Pediatric ($P < 10^{-48}$) and Adult ($P < 10^{-4}$) recurrences. Conversely, vascular collapse was universal, characterized by a significant reduction of Pericytes in both Pediatric ($P < 10^{-72}$) and Adult ($P < 10^{-8}$) cohorts. Immunologically, CD4+ Memory T cells were consistently enriched in both Pediatric ($P < 10^{-26}$) and Adult ($P < 10^{-4}$) groups, suggesting a convergent mechanism of adaptive immune persistence in the relapsed setting. **Conclusions:** We demonstrate that recurrent myeloid leukemia drives a convergent microenvironmental evolution characterized by vascular collapse, pathologic adiposity, and immune persistence, independent of patient age. These findings corroborate that stromal remodeling is a dominant, disease-intrinsic program actively driven by leukemic cells rather than a passive reflection of aging. Validating this "adipogenic shift" as a universal resistance mechanism identifies the adipogenic and vascular niches as priority targets for therapeutic intervention across the spectrum of myeloid malignancies. Research Sponsor: None.

Differential enrichment of microenvironmental populations in recurrent vs. primary myeloid neoplasms.

Cohort	Cell Type	Direction	Mean Diff (Rec - Pri)	Padj
Pediatric (<18y)	Preadipocytes	Recurrence- High	+0.064	$p < 0.05$
	Pericytes	Primary- High	-0.085	$p < 0.05$
	CD4+ Memory T-cells	Recurrence- High	+0.849	$p < 0.05$
Adult (≥18y)	Preadipocytes	Recurrence- High	+0.056	$p < 0.05$
	Pericytes	Primary- High	-0.078	$p < 0.05$
	CD4+ Memory T-cells	Recurrence- High	+1.184	$p < 0.05$

Molecular characteristics of therapy-related myeloid neoplasms in PARP inhibitor–treated patients. First Author: Tamanna Haque, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Poly ADP-ribose polymerase inhibitors (PARPi) are part of standard therapy in solid tumors, and is associated with development of therapy-related myeloid neoplasm (t-MN), including myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). The contribution of pre-existing clonal hematopoiesis (CH) in t-MN with PARPi exposure is unknown. We report outcomes of a real-world cohort of t-MN patients following PARPi therapy. **Methods:** We performed a retrospective single-center analysis of 23 patients with solid tumors treated with PARPi (olaparib, rucaparib, niraparib, talazoparib) who subsequently developed t-MN. Chart review was performed to collect clinical data. Blood samples collected as a somatic control prior to the first chemotherapy or radiation for targeted next-generation sequencing (NGS) using the MSK-IMPACT platform were analyzed for pre-existing CH in a subset of evaluable patients (n=17). CH was defined as a somatic mutation with variant allelic frequency of 2% or more in peripheral blood. **Results:** Median age was 63 years at initial solid tumor diagnosis and 68 years at t-MN diagnosis. Primary malignancies included Ovarian/Fallopian Tube (83%, n=19), Breast (17%, n=4), Prostate (9%, n=2), and Esophageal (n=1) cancer. 3 patients had a history of both Breast and Ovarian cancer. Germline BRCA1/2 mutations were present in 48% (n=11) and 1 patient had Li-Fraumeni. Median time from PARPi initiation to t-MN diagnosis was 23.7 months (range: 1.6–45.3 months). At t-MN diagnosis, 52% (12/23) presented with MDS (including one case of clonal cytopenias of undetermined significance) and 48% (11/23) with AML. Genomic profiling of t-MN showed 78% (18/23) of patients had *TP53* mutations, and 65% (15/23) had complex karyotype. 90% of evaluable AML cases were classified as adverse risk by ELN 2022 and most MDS cases (9/11) had High/Very High risk by IPSS-R. Median overall survival in this cohort was 6 months from t-MN diagnosis. Among 17 patients with evaluable baseline blood samples, 41% (7/17) had detectable CH prior to t-MN, while 59% (10/17) did not. Of those with pre-existing CH, 57% (4/7) harbored mutations in DNA damage response genes (2 with *TP53*, 2 with *PPM1D*). Other mutations included *DNMT3A* (N=2), *ASXL1* (N=1), *SRSF2* (N=1), and *JAK2* (N=1). 43% (3/7) had a single CH mutation, while 57% (4/7) had 2 or more CH mutations. 6/7 of those with pre-existing CH had molecular testing at t-MN diagnosis, all of which (6/6) had a detectable *TP53* mutation at t-MN diagnosis, even when not previously detected. Cytogenetic features of t-MN for those with and without pre-existing detectable CH were similar. **Conclusions:** This is the largest single center cohort of post-PARPi t-MN with molecular characteristics described to date. Further study on the effect of PARPi therapy in the pathogenesis of t-MN is needed. Research Sponsor: None.

Outcomes and responsiveness of standard tyrosine kinase inhibitor dose versus dose de-escalation in chronic myeloid leukemia: A single-center retrospective study. First Author: Mark Pusung, Division of Hematologic Malignancies, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background: Treatment with tyrosine kinase inhibitors (TKIs) enables patients with chronic myeloid leukemia (CML) to achieve durable remission and a normal life expectancy. Despite this success, chronic TKI therapy is associated with cumulative toxicities. Although TKI dose de-escalation can be implemented to mitigate adverse events, its impact on the attainment and durability of response milestones is not completely defined. This study explored the impact of dose de-escalation of TKIs on clinical response milestones and treatment-free remission (TFR) outcomes. **Methods:** We retrospectively analyzed 407 adult CML patients treated with TKIs at Oregon Health & Science University. Outcomes of interest were TFR and achievement of undetectable *BCR::ABL1* transcripts. Odds ratios (OR) or Cox proportional hazards regression hazard ratios (HR) were used to analyze covariates and predictors. **Results:** Overall, the median age at diagnosis was 48 years (range: 18-91) and 1st-line therapies included: imatinib (n=252; 62%), dasatinib (n=95; 23%), nilotinib (n=42; 10%), and bosutinib (n=10; 2%); the remaining 2% of patients were treated with 3rd generation or later TKIs. Median follow-up since diagnosis was 11.3 years (0.2-35.8); 189 patients (46%) remained on their initial TKI, while 218 patients (54%) received $\geq$2 TKIs. Only 13 patients (3.2%) received a bone marrow transplant. With respect to the primary outcome of TFR, 133 patients attempted TFR and were further analyzed with respect to de-escalation of dose. Fifty-two patients (39%) remained on standard dose while 81 patients (61%) underwent dose de-escalation prior to the 1st TFR attempt. TFR rates were not significantly different between patients receiving standard dose vs de-escalated dose TKI (HR: 1.07 (95% CI: 0.59-1.96); p=0.818) at either 1 year (77% vs 74%) or 2 years (69% vs 69%). At the last follow-up, 89 patients remained in TFR, 62% of which had undergone dose de-escalation. Among the remaining 274 patients who have yet to attempt TFR, 162 (59%) continued treatment with their initial TKI: 98 (60%) on imatinib, 39 (24%) on dasatinib, 17 (10%) on nilotinib, 5 (3%) on bosutinib, 2 (1%) on ponatinib, 1 (1%) on asciminib. Among these patients, 56 (34%) had dose reduction, 9 (16%) of whom achieved undetectable disease. For the 106 patients on standard doses, only 5 (5%) had undetectable disease (OR: 3.83 (95% CI: 1.08-15.40); p=0.020).More importantly, dose de-escalation led to significant reduction of adverse events. **Conclusions:** Our results show that patients who underwent dose de-escalation did not have significant differences in TFR duration and rate and are more likely to achieve undetectable diseases when compared with patients on standard doses. These findings support rational dose de-escalation as a strategy that preserves achievement of clinical outcomes while reducing adverse events. Research Sponsor: None.

TPS6599 **Poster Session**

A phase I study of HPB-092, a dual FLT3/IRAK4 inhibitor, in relapsed or refractory acute myeloid leukemia. First Author: Mingyuan Sun, State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Disease, Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China

Background: Fms-like tyrosine kinase 3 (FLT3) is a clinically validated oncogenic driver in acute myeloid leukemia (AML). While FLT3 kinase inhibitors have been approved for AML patients with FLT3 mutations, resistance remains a significant challenge. Interleukin-1 receptor–associated kinase 4 (IRAK4) has emerged as a key signaling node in treatment-induced resistance. Moreover, a subset of AML patient population harbors mutations in RNA splicing factors U2AF1 or SF3B1. These mutations result in expression of an oncogenic long form of IRAK4. Therefore, co-targeting FLT3 and IRAK4 can potentially both address resistance and treat a broader population in AML. HPB-092 is a highly selective dual-target small-molecule kinase inhibitor designed to target mutant FLT3 and IRAK4. HPB-092 demonstrated robust potency against FLT3-ITD (IC_{50} = 0.24 nM), FLT3-D835Y (IC_{50} = 0.18 nM), and IRAK4 (IC_{50} = 3.1 nM). In vivo, HPB-092 elicited dose-dependent regression of the MV4-11 tumor model. HPB-092 received IND clearance in both China and the US, showing a favorable safety profile with no significant genotoxicity or hERG inhibition, supporting its clinical evaluation. **Methods:** This ongoing, first-in-human, phase 1 study evaluates oral HPB-092 monotherapy in adults with RR-AML. The primary objectives are to evaluate safety, tolerability, pharmacokinetics (PK), and to determine the recommended phase II dose (RP2D). Secondary objectives include preliminary antileukemic activity (ORR, DOR) and exploratory biomarkers analyses. Part A is a dose-escalation phase spanning five dose levels (30–200 mg), utilizing an accelerated titration design followed by a 3+3 scheme in patients with R/R AML, regardless of FLT3, U2AF1 or SF3B1 mutation status. The study initiates with a single-dose administration on cycle 1 day 1 for SAD-PK assessment, followed by multiple ascending doses administered twice daily for MAD-PK and dose-limiting toxicities (DLTs) over a 28-day observation window. Part B is a randomized dose-expansion phase to evaluate selected dose levels in patients with FLT3-mutant AML and those with U2AF1 or SF3B1 mutations. Correlative pharmacodynamic and biomarker analyses are planned. No formal hypothesis testing or sample size calculation was performed. Safety, PK, and efficacy analyses will be descriptive in patients receiving at least one dose of HPB-092. AEs will be graded according to NCI CTCAE v5.0. PK parameters will be derived using noncompartmental methods. Time-to-event endpoints will be estimated using Kaplan–Meier methods, where applicable. Site initiation is complete; enrollment is initiated and ongoing, with the first patient anticipated in Q1 2026. Clinical trial information: NCT07137637. Research Sponsor: None.

TPS6600 **Poster Session**

A phase 3 study of revumenib plus venetoclax/azacitidine in adults with newly diagnosed *NPM1*-mutated or *KMT2A*-rearranged acute myeloid leukemia ineligible for intensive chemotherapy (EVOLVE-2/HO177/AMLSG35-24/ACT-HOV-AML-002). First Author: Geert Abraham Huls, University Medical Center Groningen, University of Groningen, Groningen, Netherlands

Background: Optimal treatment for patients (pts) with acute myeloid leukemia (AML) unfit for intensive chemotherapy (IC) remains challenging and depends on pt and disease characteristics and pt preference. In AML with a nucleophosmin-1 mutation (*NPM1*m) or lysine methyltransferase 2A (*KMT2A*) rearrangement (*KMT2A*r), menin-KMT2A fusion proteins upregulate *HOX/MEIS* gene expression, resulting in hematopoietic differentiation arrest and leukemogenesis. Revumenib is a first-in-class, oral, potent, and selective inhibitor of the menin-KMT2A interaction. In the phase 1/2 AUGMENT-101 study (NCT04065399), revumenib monotherapy demonstrated clinically meaningful response rates and was generally well tolerated in pts with relapsed/refractory *NPM1*m AML or *KMT2A*r acute leukemia. To further improve outcomes, combination regimens are being studied as front-line therapy for newly diagnosed (ND) pts. In the phase 1b Beat AML study (NCT03013998), revumenib plus venetoclax/azacitidine (VEN/AZA) demonstrated deep responses in pts $\geq$60 years (y) of age with ND *NPM1*m or *KMT2A*r AML. EVOLVE-2 will assess whether revumenib plus VEN/AZA prolongs overall survival (OS) and improves complete remission (CR) rates in pts with ND *NPM1*m or *KMT2A*r AML ineligible for IC. **Methods:** EVOLVE-2 is a phase 3, multicenter, randomized, double-blind, placebo-controlled trial (NCT06652438/EU-CT 2024-512733-32-00). Eligible pts are $\geq$75 y of age (18–74 y with comorbidities), have ND AML with centrally confirmed *NPM1*m or *KMT2A*r (excluding *KMT2A* partial tandem duplications/deletions), are ineligible for IC, and are AML treatment-naive. Pts will be randomized 1:1 to revumenib or placebo in combination with VEN/AZA and stratified by age ($<$75 vs $\geq$75 y), genotype (*NPM1*m vs *KMT2A*r), and region (Europe vs Australia vs United States). In Cycle (C) 1, VEN is given daily on Days (D) 1–28 and AZA daily on D1–7, $\pm$ revumenib twice daily on D1–28. In C2+, responders (per 2022 European LeukemiaNet criteria) may adjust VEN based on remission status/count recovery. Treatment continues until disease progression, unacceptable toxicity, pt withdrawal, or death. The dual primary endpoints are OS and CR rate. Key secondary endpoints include event-free survival and rate of CR/CR with partial hematologic recovery (CRh). Other endpoints include rates of CRh and CR/CR with incomplete hematologic recovery (CRi), measurable residual disease (MRD) negativity (CR, CR/CRh, CR/CRi with MRD negativity), time to/duration of response, adverse events, time to hematopoietic recovery, and incidence of platelet and red blood cell transfusions. Overall, 448 pts will be enrolled. As of January 27, 2026, the study is open to enrollment. Clinical trial information: NCT06652438. Research Sponsor: Syndax Pharmaceuticals, Inc.

TPS6601 **Poster Session**

Phase 1, open-label, multi-center trial of RPT1G in patients with relapsed/refractory acute myeloid leukemia and higher-risk myelodysplastic syndromes/neoplasms. First Author: Dennise De Jesus Diaz, Remedy Plan Therapeutics, Gaithersburg, MD

Background: Nicotinamide phosphoribosyltransferase (NAMPT), the rate limiting enzyme in the NAD salvage pathway, regulates cellular energy metabolism and is overexpressed in blood cancers. Because cancer cells depend on elevated NAD-flux, they are highly sensitive to NAMPT inhibition. Since normal cells also require NAD for survival, prior clinical trials of complete NAMPT inhibitors lead to dose-limiting toxicities. We developed RPT1G, a novel hyperbolic inhibitor with an improved therapeutic window that enables therapeutically effective NAD depletion in malignant cells while sparing normal tissues (Crimmins, ASH 2023). A first-in-human, Phase 1, randomized, double-blind, placebo-controlled, SAD and MAD study in healthy volunteers of RPT1G showed that oral administration of RPT1G is safe and well-tolerated with a favorable pharmacokinetics (PK) profile. Target engagement results showed that RPT1G inhibits NAMPT at doses predicted to be therapeutically relevant. **Methods:** RPT1G is being investigated in a Phase 1, multi-center, open-label clinical trial (NCT07107126) for treatment of Relapsed/Refractory Acute Myeloid Leukemia (R/R AML) and Higher-Risk Myelodysplastic Syndromes/Neoplasms (HR-MDS). It is the first NAMPT hyperbolic inhibitor to be studied for the treatment of R/R-AML and HR-MDS patients. With a standard 3+3 design, this study explores escalating oral doses of RPT1G, given twice daily in 28-day cycles. Other dosing schedules will be studied based on observed PK, PK/pharmacodynamic relationships, safety, and tolerability to identify the maximum tolerated dose or presumptive biologically effective dose and select the recommended phase 2 dose (RP2D). The starting dose of 120 mg BID was active in healthy adults. Primary objectives include: 1) defining safety and tolerability; 2) determining the RP2D, optimal schedule and/or BED. Key secondary objectives include: 1) evaluating PK; 2) assessing preliminary efficacy by European LeukemiaNet 2022, including overall response rate, duration of response, and hematologic improvement, and clinical benefit by transfusion independence and the International Working Group 2023 HR-MDS response criteria. Enrollment criteria: adults $\geq$ 18 years old, with a histological confirmation of R/R-AML (ELN 2022 criteria) or HR-MDS (International Consortium for MDS 2023 criteria) that have received appropriate standard of care therapy(s) or declined receipt of these. Adequate organ function is required. Exclusion criteria: ongoing AEs from prior therapies; received radiation $<$ 14 days from the first RPT1G dose; known active infections; or have uncontrolled cardiac issues, or other medical comorbidities that preclude safety evaluation. Clinical trial information: NCT07107126. Research Sponsor: None.

TPS6602 **Poster Session**

A phase 3 study of revumenib in combination with intensive chemotherapy in patients with newly diagnosed *NPM1*-mutated acute myeloid leukemia (REVEAL-ND NPM1). First Author: Eytan Stein, Memorial Sloan Kettering Cancer Center, New York, NY

Background: There are currently no approved targeted therapies for newly diagnosed (ND) acute myeloid leukemia (AML) harboring a nucleophosmin-1 mutation (*NPM1*m), which occurs in ~30% of ND adult AML cases. In *NPM1*m AML, the NPM1m/XPO1 protein complex binds to DNA to sustain the interaction of menin and wild-type KMT2A that drives upregulation of *HOX*/*MEIS* gene expression, resulting in hematopoietic differentiation arrest and leukemogenesis. Revumenib is a first-in-class, oral, potent, and selective inhibitor of the menin-KMT2A interaction. In the phase 1/2 AUGMENT-101 study (NCT04065399), revumenib monotherapy demonstrated clinically meaningful response rates and was generally well tolerated in relapsed/refractory *NPM1*m AML, leading to US Food and Drug Administration approval for that patient population on October 24, 2025. Standard AML treatment for younger, non-frail adults is based on intensive chemotherapy (IC) regimens and hematopoietic stem cell transplant (HSCT). The addition of revumenib to standard IC may further improve treatment responses specifically in the ND setting. This study is designed to assess the safety and efficacy of revumenib in combination with IC in patients with ND *NPM1*m AML. **Methods:** REVEAL-ND NPM1 is a phase 3, multicenter, randomized, double-blind, placebo-controlled trial (NCT07211958). Eligible patients are $\geq$12 years of age, weigh $\geq$40 kg, and have treatment-naive ND AML with locally determined (centrally confirmed) *NPM1*m. Patients will be randomized 1:1 to revumenib or placebo in combination with IC. Induction consists of 1 to 2 cycles of revumenib or placebo (dosed orally) alongside IC with cytarabine and daunorubicin or idarubicin (dosed intravenously). Consolidation consists of 1 to 3 cycles of revumenib or placebo plus cytarabine. HSCT may be performed after initial induction or consolidation. Treatment with revumenib or placebo monotherapy will continue for up to 2 years, with long-term follow-up until death, withdrawal of consent, or study closure. The dual primary endpoints are event-free survival and measurable residual disease-negative complete remission (CR) in the bone marrow, both assessed by independent reviewers. A key secondary endpoint is overall survival. Additional investigator-assessed endpoints include CR rate, composite complete remission (CRc) rate, overall response rate, duration of response (CR, CRc), safety, and quality of life. Overall, ~468 patients will be enrolled. As of January 27, 2026, the study is open to enrollment. Clinical trial information: NCT07211958. Research Sponsor: Syndax Pharmaceuticals, Inc.

TPS6603 **Poster Session**

A phase 2 study of olutasidenib in combination with azacitidine followed by olutasidenib maintenance after venetoclax plus a hypomethylating agent regimen for *IDH1*-mutated acute myeloid leukemia (University of California Hematologic Malignancies Consortium Study 2441). First Author: Brian Andrew Jonas, Division of Malignant Hematology/Cellular Therapy and Transplantation, Department of Internal Medicine, University of California Davis School of Medicine, Sacramento, CA

Background: Acute myeloid leukemia (AML) with isocitrate dehydrogenase-1 (IDH1) mutations represents a subset of up to approximately 7-14% of patients. For patients with IDH1m AML ineligible for first line intensive induction, the combination of a hypomethylating agent (HMA) and venetoclax (VEN) is a standard of care based on the VIALE-A study. In patients with IDH1m, the HMA azacitidine (AZA) plus VEN regimen leads to a complete remission (CR) plus CR with incomplete count recovery (CRi) rate of 66.7%, duration of remission (DoR) 21.9 months, and median overall survival (OS) of 15.2 months. However, one of the limiting features of HMA-VEN is myelosuppression, leading to dose delays and reductions, and adverse events (AEs) led to discontinuation in up to 30% of patients on the VIALE-A study. Approaches to increase tolerability and improve outcomes are of interest. Olutasidenib (OLU) is a potent, oral and selective small-molecule IDH1m inhibitor currently approved for relapsed/refractory AML patients with an IDH1 mutation, based on the pivotal cohort of a Phase 1/2 study. Overall, this study showed that OLU alone or in combination with AZA in patients with IDH1m AML was well-tolerated and showed meaningful clinical activity, including in those with prior VEN treatment. We hypothesize that, after achieving a response on HMA-VEN, de-escalating and switching maintenance from HMA-VEN to OLU-AZA followed by OLU monotherapy will lead to improved outcomes for patients with IDH1m AML. **Methods:** This multicenter investigator-initiated study through the University of California Hematologic Malignancies Consortium (UCHMC) is a phase II single-arm study evaluating the combination of OLU in combination with AZA followed by OLU monotherapy as a switch maintenance approach after HMA-VEN for patients with IDH1m AML. Key eligibility criteria include a diagnosis of IDH1m AML, achievement of CR or CRi to first-line HMA-VEN with no more than 4 cycles of HMA-VEN at the time of enrollment, IDH1m inhibitor naïve, age 18+, and performance status 0-2. The primary endpoint is treatment failure, defined as AML-related death, relapse, or treatment discontinuation due to AE within 12 months from the time of CR/CRi. Secondary endpoints include treatment-related AE, time to treatment failure, relapse-free survival, DoR, OS, and rate of allotransplant. Patients will receive OLU 150mg BID in combination with standard AZA during the first 4 cycles followed by OLU 150mg BID monotherapy until any discontinuation criteria are met. Disease assessments will be performed at baseline, following cycles 4, 8, and 12, and then as clinically indicated. The trial will enroll up to 28 patients across the UCHMC. The trial is currently enrolling. Clinicaltrials.gov ID is NCT07304011. Clinical trial information: NCT07304011. Research Sponsor: Rigel.

TPS6604 **Poster Session**

Updated protocol: IMPROVEMF, a phase 1b trial of imetelstat (IME)+ ruxolitinib (RUX) in patients (pts) with intermediate (INT)-1/2 or high-risk (HR) myelofibrosis (MF). First Author: John Mascarenhas, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: In preclinical evaluations, sequential treatment (tx) with RUX, a Janus kinase inhibitor (JAKi), and IME, a telomerase inhibitor, selectively reduced MF hematopoietic stem cells (HSC) and progenitor cells. In the Phase 2 IMbark trial (NCT02426086), IME monotherapy showed clinical activity and disease-modifying potential in pts with INT-2 or HR MF relapsed/refractory to JAKi. These findings, and the nonoverlapping mechanisms of action, supported the evaluation of IME+RUX in frontline MF. IMproveMF (NCT05371964) is an open-label study of IME+RUX in pts with INT-1/INT-2/HR MF. In Phase 1 (dose finding), IME+RUX was generally well tolerated, with no dose-limiting toxicities at any dose, and a safety profile consistent with reports from other IME trials. Notably, a dose-dependent signal of clinical activity was observed. The pharmacokinetics for the combination were similar to those of previous monotherapy studies. Thus, the recommended Phase 1b dose of 8.9 mg/kg IME active dose (equivalent to 9.4 mg/kg IME sodium) was chosen. **Methods:** Phase 1b (dose confirmation and expansion) will enroll adult pts with INT-1/INT-2/HR MF with an Eastern Cooperative Oncology Group performance status $\leq$2 and peripheral blood and bone marrow blasts $<$10%, $\geq$2 active symptoms with a score of $\geq$3, or a total score of $\geq$10 on the MF Symptom Assessment Form v4.0, an absolute neutrophil count of $\geq 1.5\times10^9$/L independent of growth factor support and platelets of $\geq 75\times10^9$/L (updated criterion), no active systemic hepatitis infection, acute or chronic liver disease unrelated to underlying MF, and no prior history of HSC transplantation. The study was planned to evaluate 2 cohorts. In cohort A (JAKi-naive pts), upon enrollment, pts will start RUX for $\geq$12 weeks (24 weeks max); once the RUX dose is stable for 4 weeks, 8.9 mg/kg IME intravenously (IV) every 4 weeks will be added. Per the updated protocol (November 2025), the study will no longer recruit pts into cohort A. Existing enrollees will continue in the study per schedule. In cohort B, ~15 pts will be enrolled who are currently on first-line RUX per standard of care for $\geq$12 weeks, with $\geq$4 weeks at a stable dose, and will begin 8.9 mg/kg IME IV every 4 weeks after enrollment. Tx will continue until toxicity, disease progression, or withdrawal. The primary endpoint includes safety and symptom response rate at week 24 (proportion of pts with $\geq$50% reduction in total symptom score [TSS] at week 24 from start of IME+RUX tx). Secondary endpoints include absolute change in TSS at week 24, average absolute change in TSS over 24 weeks, spleen response ($\geq$35% spleen volume reduction) at week 24, and progression-free survival. The primary analysis is planned ~6 months after the last pt's first dose of IME+RUX; the final analysis will occur after the study ends. Cohort B is actively enrolling. Clinical trial information: NCT05371964. Research Sponsor: This study was funded by Geron Corporation. All authors contributed to and approved the abstract; writing and editorial assistance were provided by Mohamed Abdelmegeed, MD, PhD, CMPP, of The Lockwood Group (Stamford, CT, USA), funded by Geron Corporation.

TPS6605 **Poster Session**

A phase 2 study to assess the safety and efficacy of bomedemstat (IMG-7289) in combination with momelotinib in patients with myelofibrosis. First Author: Ciro Roberto Rinaldi, United Lincolnshire Teaching Hospital and University of Lincoln, Lincoln, United Kingdom

Background: Myelofibrosis (MF) is a chronic myeloproliferative neoplasm characterized by splenomegaly, cytopenias, inflammatory symptoms, and progressive marrow fibrosis. Momelotinib, a JAK1/JAK2 and ACVR1 inhibitor, improves splenomegaly and anemia; however, a substantial proportion of patients experience inadequate spleen, symptom, or hematologic responses. Bomedemstat (IMG-7289), an oral irreversible inhibitor of lysine-specific demethylase 1 (LSD1), has demonstrated disease-modifying activity in MF, including effects on megakaryopoiesis, inflammatory signaling, and fibrosis. Preclinical and clinical data support complementary mechanisms between JAK inhibition and LSD1 inhibition. **Methods:** This is an open-label, single-arm, multicenter phase 2 study enrolling approximately 50–60 adults with primary or secondary MF (post–polycythemia vera or post–essential thrombocythemia) with intermediate-2 or high-risk disease. All patients receive momelotinib 200 mg orally once daily. After 12 weeks of momelotinib monotherapy, patients with protocol-defined suboptimal response—based on spleen volume reduction, symptom improvement, hematologic parameters, or transfusion requirements—initiate combination therapy with bomedemstat 50 mg orally once daily, with dose titration per MF-specific guidelines, through week 24. Two cohorts are included: (1) patients previously treated with momelotinib who demonstrate suboptimal response after ≥12 weeks of therapy, and (2) patients with baseline cytopenias initiating momelotinib within the study who demonstrate suboptimal response at week 12. The primary endpoint is the proportion of patients achieving ≥35% spleen volume reduction at week 24 by MRI or CT. Secondary endpoints include ≥50% reduction in total symptom score, changes in symptom burden, transfusion independence, hematologic responses, overall response rate, duration of response, progression-free survival, overall survival, and safety and tolerability. Exploratory endpoints include molecular and biomarker analyses assessing changes in driver mutation allele burden, inflammatory cytokines, and markers of differentiation and fibrosis. The study will run in 5 Countries (UK, France, Spain, Dubai, USA), for a total of 20 Sites. Enrollment expected to start in September 2026. Clinical trial information: ISRCTN98283910. Research Sponsor: MSD; MISP 103465.

TPS6606 **Poster Session**

ASC4Kids-2: Asciminib in pediatric chronic myeloid leukemia with or without T315I. First Author: Nobuko Hijiya, Columbia University Irving Medical Center, New York, NY

Background: Adenosine triphosphate (ATP)-competitive tyrosine kinase inhibitors (TKIs), including imatinib, dasatinib, nilotinib, and bosutinib, are the standard of care for pediatric patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP), with efficacy and safety profiles generally comparable to those observed in adults. However, TKIs can cause long-term adverse effects in pediatric pts, including delayed growth and development. Effective therapies that minimize long-term adverse effects in pediatric pts are needed. No TKI is approved for pediatric pts with the T315I mutation, which is linked with lower progression-free and overall survival. Asciminib represents an alternative to ATP-competitive TKIs that works by Specifically Targeting the ABL Myristoyl Pocket (STAMP). Asciminib is approved for adults with newly diagnosed and previously treated CML-CP (at 80 mg daily), and those harboring T315I (at 200 mg twice daily). In ASC4Kids (NCT04925479), asciminib was well-tolerated and efficacious in pediatric pts resistant or intolerant (R/I) to 1 prior TKI without T315I. Here, we describe ASC4Kids-2 (NCT07354074), a phase 2 study evaluating asciminib in pediatric pts with CML-CP. **Methods:** Approximately 50 pediatric pts aged 1 to <18 years with Philadelphia chromosome positive (Ph+) CML-CP who are (1) newly diagnosed without known T315I, (2) R/I to ≥1 prior TKI without known T315I, or (3) with T315I irrespective of prior TKIs, will be enrolled in this multicenter, open-label, single-arm study. Asciminib will be administered at 80 mg once daily, or at 200 mg twice daily for pts with T315I using the adult formulation under fasting conditions, or as a body weight–based pediatric formulation (2.6 mg/kg once daily or 6.5 mg/kg twice daily for pts with T315I, rounded to the nearest 5 mg) in the fed state. ASC4Kids-2 consists of a 22-day screening period followed by a treatment period with visits at weeks 1, 2, 4, 8, 12, 24, 36, and 48, then every 12 weeks. A posttreatment follow-up period includes a 30-day safety follow-up call and survival assessments every 12 weeks until study end, which is 240 weeks after the last pt receives the first dose. The primary objective is to assess treatment efficacy via MMR at week 48 (defined as the proportion of pts who meet MMR criteria at week 48, excluding those who discontinued earlier or lost response at/before week 48). Secondary endpoints include MMR at week 96; hematologic, cytogenetic, and molecular responses at and by scheduled time points; time to response, progression, or treatment failure; duration of response; event-free and overall survival; growth and sexual maturation (assessed via height, weight, bone age measured by x-ray, and Tanner staging); safety; and pharmacokinetic parameters. Clinical trial information: NCT04925479. Research Sponsor: Novartis Pharma AG.

TPS6607 **Poster Session**

Phase Ib study of momelotinib during and following hematopoietic stem cell transplantation for patients with primary or secondary myelofibrosis. First Author: Gabriela Hobbs, Massachusetts General Hospital, Boston, MA

Background: Despite progress in the treatment of myelofibrosis (MF) with multiple approved JAK inhibitors (JAKi), the only curative therapy is allogeneic hematopoietic cell transplantation (HCT). Discontinuation of JAKi's before HCT is challenging as patients experience return of symptoms, moreover, hematopoietic recovery post-HCT is challenging as fibrosis takes many months to resolve. Although we have shown that ruxolitinib can be safely used during and after HCT with excellent survival, low rates of GVHD, and no adverse impact on engraftment (Hobbs et al., JCO Advances 2025), important unmet needs persist: better prevention of GVHD and improved management of post-transplant anemia and residual symptoms. Momelotinib is a JAK1/JAK2, ROCK2 and ACVR1 inhibitor that may help prevent GVHD via JAK1 and ROCK2 inhibition, which play key roles in immune cell function and inflammatory signaling. Moreover, in addition to momelotinib's efficacy in spleen and symptom control, this agent improves anemia through ACVR1 inhibition. Thus, we aim to conduct a phase Ib study to determine the safety and tolerability of momelotinib in the peri/post-HCT period along with its impact on reducing transfusion needs. **Methods:** This is a phase Ib, single institution study investigating momelotinib given pre-, during- and for 1-year post-HCT for patients with primary or secondary MF (NCT 07104799). The primary endpoint is 1-year GVHD-free, relapse-free survival (GRFS). Secondary endpoints include overall (OS) and progression free survival (PFS), engraftment, and incidence of acute and chronic GVHD. Patients will be treated with reduced intensity conditioning with fludarabine (30mg/m^2/d x 5 days) and melphalan (100 or 140mg/m^2 x 1). Patients will receive peripheral blood stem cell grafts from either 7/8 or 8/8 HLA-matched donors. GVHD prophylaxis will consist of standard tacrolimus and methotrexate. We will conduct a 3+3 dose escalation of momelotinib starting on day -7 of HCT through engraftment to test the safety of momelotinib at 100 mg, 150 mg and 200 mg during the peri and early post-HCT period. Once patients achieve engraftment, dose escalation to the approved dose of 200 mg daily will be allowed and continued for one-year post-HCT. We will collect samples for correlative analysis at baseline, day +100 and 1 year post-HCT. This study is the first to test momelotinib use pre-, during- and post-HCT in patients with MF. We have demonstrated that ruxolitinib use during and after-HCT leads to excellent GRFS and OS, however, post-HCT cytopenias remain an issue. Moreover, as more JAKi become available, it is important to evaluate the safety and efficacy of different JAKi during the time of HCT. This trial is open to accrual as of January of 2026. Funding and Product for this study is provided by GSK. Clinical trial information: NCT 07104799. Clinical trial information: NCT 07104799. Research Sponsor: GlaxoSmithKline LLC.

TPS6608 **Poster Session**

A phase 3 study of olverembatinib (HQP1351) in patients with chronic-phase chronic myeloid leukemia: POLARIS-2 trial in progress. First Author: Elias Jabbour, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Chronic myeloid leukemia (CML) is driven by the BCR::ABL1 oncogenic fusion protein. Although tyrosine kinase inhibitors (TKIs) have transformed CML management, normalizing life expectancy for many patients, treatment resistance and intolerance remain significant clinical challenges. Olverembatinib is a novel third-generation BCR::ABL1 TKI with activity against wild-type BCR::ABL1, multiple resistance-conferring mutations including T315I, and challenging compound mutations. The POLARIS-2 study evaluates olverembatinib efficacy and safety in patients with relapsed/refractory chronic phase CML (CP-CML). **Methods:** This global, multicenter, open-label, randomized phase 3 registrational study includes two patient cohorts based on T315I mutation status (ClinicalTrials.gov identifier: NCT06423911; internal study number: HQP1351CG301). Part A randomly allocates patients with CP-CML previously treated with at least two approved TKIs to receive either olverembatinib or bosutinib (2:1 randomization). The primary endpoint is major molecular response (MMR) rate at 24 weeks. Part B is a single-arm study evaluating olverembatinib in patients with CP-CML with the T315I mutation at screening, and the primary endpoint is MMR rate by 24 weeks. Key inclusion criteria include age ≥18 years, diagnosis of CP-CML, Eastern Cooperative Oncology Group performance status ≤ 2, and adequate organ function. Key exclusion criteria include prior hypersensitivity to study drugs and pregnancy or lactation. Patients in Part A receiving bosutinib who do not achieve MMR by 24 weeks are eligible to cross over to olverembatinib. The study hypothesis posits that olverembatinib will demonstrate superior MMR compared to bosutinib in Part A and provide clinical benefit in T315I-positive patients in Part B. Clinical trial information: NCT06423911. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

LBA7000 **Oral Abstract Session**

frontMIND: Phase 3 study of tafasitamab (Tafa) plus lenalidomide (Len) and R-CHOP for patients (pts) with newly diagnosed diffuse large B-cell lymphoma (DLBCL). First Author: Georg Lenz, University Hospital Münster, Department of Medicine A for Hematology, Oncology and Pneumology, Münster, Germany

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

7001 **Oral Abstract Session**

Integrating BTK inhibition into R-da-EPOCH for HIV-related DLBCL. First Author: Ida Wong-Sefidan, University of California, San Diego, San Diego, CA

Background: Human immunodeficiency virus (HIV)-related diffuse large B-cell lymphomas (DLBCL) are heterogeneous in nature, clinically, & molecularly. R-da-EPOCH is accepted as a standard of care in HIV+DLBCL. Classifying tumors with respect to immunophenotype & genomic features may facilitate personalized therapy to improve outcomes in this diverse disease. The Bruton's tyrosine kinase (BTK) inhibitor, ibrutinib (ibr), also inhibits inducible T cell kinase (ITK). As HIV hijacks host ITK during replication, ibr may have additional clinical benefits in HIV+DLBCL. This trial added ibr to R-da-EPOCH in HIV+DLBCL, with an attempt to enrich for non-germinal center B-cell (non-GCB) subtype, to evaluate safety, feasibility & activity, impact on T cells, & correlate lymphoma cell of origin (COO) with response. **Methods:** This multi-center study included a 3+3 dose de-escalation cohort followed by dose-expansion at recommended phase 2 dose (RP2D). Participants (pts) age 18-64 years (y) with stage II-IV HIV-DLBCL were untreated or received 1 cycle (cy) R-da-EPOCH/CHOP off-study. CD4 $<$100 & asymptomatic leptomeningeal disease were allowed. Ibr was dosed daily days 1-21 & R-da-EPOCH administered as previously published (PMID 32430507) for 6 total cy. Moderate/strong CYP3A4 inhibitors were excluded, due to effects on ibr and chemotherapy. **Results:** 43 pts were evaluable for toxicity & 37 evaluable for response. 41/43 (95%) pts tolerated $\geq$2 cy; median cy of study therapy (tx) received = 5. At baseline median age was 52y (24-64) & CD4 count 204 (21-757); 9 pts had CD4 $<$100. 81% were male, 42% White & 49% Black. 86% were stage III/IV, 40% non-GCB, & 88% had ECOG 0-1. Ibr RP2D was 560mg daily. Noting PET was optional, overall response rate was 100% with 57% (21/37) complete (CR) & 43% (16/37) partial responses (PR). Relapse/progression occurred in 16% (6/37; 1CR, 5PR) during a median follow-up of 4.2y (95%CI = 2.3 to 4.87); median duration of response = 2.8y. 3y event-free (EFS) & overall survival (OS) were 83 & 81% respectively (GCB: 88 & 87%, non-GCB: 76 & 63%). Among 679 treatment-related adverse events (TRAE), the most frequent were (total, % grade (gr) 3+) anemia (105, 50%), thrombocytopenia (81, 41%), neutropenia (60, 88%) & lymphopenia (60, 68%). Non-hematologic AEs (total TRAE, # max gr) included diarrhea (22, 2 gr3), nausea (21, 1 g3), hypokalemia (20, 4 gr3), fatigue (17, 17 gr1), & sepsis (1 gr4). Reasons for tx discontinuation: 1 progression, 4 withdrawal, 4 TRAE, 1 lost to follow up. **Conclusions:** Incorporating ibrutinib 560mg daily with R-da-EPOCH in HIV-related DLBCL treatment resulted in manageable toxicities typical of R-da-EPOCH. Although lower confirmed CR, 3y EFS & OS are comparable or higher than prior studies of HIV+DLBCL R-da-EPOCH. Ongoing studies to be updated at the meeting include impact on T cell subsets, & correlations of response & survival with circulating tumor DNA & lymphoma features (EBV, MYC, BCL2, BCL6 & genomic determinations of COO). Clinical trial information: NCI-2017-01240. Research Sponsor: None.

7002 **Oral Abstract Session**

Phase 2 trial of epcoritamab in combination with rituximab-mini CVP for older unfit/frail or anthracycline-ineligible adult patients with newly diagnosed diffuse large B-cell lymphoma: Interim futility analysis. First Author: Dai Chihara, Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The median age at diagnosis of diffuse large B-cell lymphoma (DLBCL) is approximately 65 years, with nearly one third of patients in the US diagnosed at age $>$75 years. This older unfit/frail population is particularly vulnerable to treatment-related toxicity due to comorbidities and limited cardiac reserve, frequently leading to treatment discontinuation, and outcomes with standard attenuated anthracycline-based chemo-immunotherapy remain suboptimal. There is therefore a critical unmet need for effective, better-tolerated non-anthracycline treatments. We hypothesize that epcoritamab combined with non-anthracycline chemotherapy (R-miniCVP) can achieve high and durable CR rates. **Methods:** This is an open-label, single-arm phase 2 trial conducted at MD Anderson Cancer Center (NCT06045247). Eligible patients have histologically confirmed DLBCL and are unfit/frail per FIL simplified geriatric assessment, or not eligible for anthracycline due to reduced ejection function ($<$50%), or prior anthracycline exposure therapy. Patients receive one cycle of R-miniCVP for debulking, followed by epcoritamab added from cycle 2 using step-up dosing, then 48 mg on day 1 of each subsequent cycle. After 6 cycles, patients achieving CR complete treatment, while patients with PR continue epcoritamab to 12 cycles. The primary endpoint is CR rate after 6 cycles. **Results:** We plan to enroll 40 patients. At the data cutoff, 22 patients have completed six cycles of therapy. The median age of 22 patients was 80 years (range, 71-87); 27% had PS 2, and 86% had an IPI $\geq$3. All patients completed planned treatment. The CR rate after 6 cycles was 86% (95% CI, 65-97%). Two patients achieved PR and continue on epcoritamab. One patient achieved PR after cycle 3 but progressed after cycle 6 and subsequently died of progressive lymphoma following 2 additional lines of therapy. With a median follow-up of 11 months (range: 5-23 months), the 1-year progression-free survival was 94.7% (95% CI, 68-99%). Cytokine release syndrome occurred in 12 patients (55%), all grade 1 and occurred around C2D15, which fully resolved in 1-2 days in all patients. Four of them received tocilizumab. One patient developed grade 2 neurotoxicity after C2D15, which resolved within 24 hours after switching prednisone to dexamethasone. The trial protocol was amended to change prophylactic steroid from prednisone to dexamethasone, after which no further neurotoxicity was observed. **Conclusions:** The combination of epcoritamab with R-mini-CVP demonstrated encouraging efficacy with a favorable tolerability profile in older, unfit or frail patients who may be unable to tolerate full-dose chemotherapy. Based on these promising early-phase results, the study is planned for expansion into a multicenter trial with a larger patient cohort. Clinical trial information: NCT06045247. Research Sponsor: None.

7003 **Oral Abstract Session**

A phase 1 study of the PRMT5 inhibitor AZD3470 in patients with relapsed/refractory classic Hodgkin lymphoma (PRIMAVERA). First Author: Enrico Derenzini, Instituto Europeo Di Oncologia SRL, Milano, Italy

Background: The epigenetic enzyme protein arginine methyltransferase 5 (PRMT5) plays a critical role in cell proliferation and differentiation; PRMT5 dysregulation is associated with cancer development. Methylthioadenosine (MTA) is an endogenous partial inhibitor of PRMT5 that accumulates in cancer cells deficient in MTA phosphorylase (MTAP). In classic Hodgkin lymphoma (cHL), we previously reported that $>$80% of primary patient (pt) tumor samples are MTAP deficient (Urosevic J, ASH 2023). The MTA-cooperative PRMT5 inhibitor AZD3470 preferentially binds to the MTA-bound state of PRMT5, increasing its target engagement to MTAP-deficient cancer cells. Here, we present safety and preliminary efficacy of AZD3470 from a first-in-human Phase 1 study in relapsed/refractory (r/r) cHL (NCT06137144). **Methods:** Eligible pts were $\geq$18 years with r/r cHL after $\geq$3 prior lines of therapy (including brentuximab vedotin (BV) and anti-PD-1). In dose escalation, pts received oral AZD3470 monotherapy QD in ascending dose levels (DLs) using an mTPI-2 design. Primary endpoints were incidence and severity of treatment-emergent adverse events (TEAEs) and dose-limiting toxicity (DLT). Secondary endpoints were overall response rate (ORR) and complete response rate (CRR) per Lugano 2014 criteria. **Results:** As of Nov 25, 2025, 39 pts had received AZD3470 at DLs ranging from 1 to 8. Most pts were male (62%) with stage IV disease (77%) and a median age of 42 (range 25–78) years. Pts had received a median of 6 prior lines of anticancer therapy (range 3–14); all had had prior BV and anti-PD1 treatments, and 20 (51%) and 5 (13%) pts had had prior autologous and allogeneic hematopoietic stem cell transplantation, respectively. All patients evaluable for MTAP protein expression were MTAP deficient. Median duration of exposure was 15 weeks (range 0.1–45.1), with treatment ongoing in 16 pts (41%). TEAEs occurred in 85% of pts, predominantly grades 1 or 2. The most common TEAEs (any grade) were anemia (28%) and nausea (15%), followed by asthenia, constipation, fatigue, and neutropenia (13% each). Grade $\geq$3 TEAEs occurred in 28% of pts, most commonly neutropenia (related) and hypokalemia (n=2 each). Serious TEAEs occurred in 5 (13%) pts. Two pts had dose reductions due to TEAEs (grade 4 hypertriglyceridemia and grade 3 esophagitis). No DLTs, treatment discontinuations nor deaths due to TEAEs were reported. Of the 31 pts evaluable for efficacy, 14 had an objective response, with responses at doses $\geq$DL4. The highest response rate was observed at doses $\geq$DL7 (n=10) with an ORR of 80% and CRR of 50%. **Conclusions:** AZD3470 monotherapy was well tolerated up to DL8, with no DLTs and mainly low-grade AEs. Incidences of grade $\geq$3 AEs and SAEs were low. Importantly, both the ORR and CRR were dose-dependent and notably high in this heavily pretreated cHL population. Dose optimization is ongoing and further safety and efficacy will be reported. Clinical trial information: NCT06137144. Research Sponsor: AstraZeneca.

7004 Oral Abstract Session

Linperlisib plus CHOP for newly diagnosed peripheral T-cell lymphoma: A single-arm, phase Ib/II study (LINCH trial). First Author: Qingqing Cai, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Peripheral T-cell lymphoma (PTCL) is a heterogeneous type of aggressive non-Hodgkin lymphoma with poor prognosis. CHOP-based regimens are most widely used for PTCL yet response rates and long-term survival remain unsatisfactory. Linperlisib, a selective PI3Kδ inhibitor, has shown encouraging antitumor activity with manageable safety profile in relapsed or refractory PTCL. This study aimed to evaluate the efficacy and safety of linperlisib plus CHOP (L-CHOP) as first-line treatment for newly diagnosed PTCL. **Methods:** The LINCH trial (NCT05949944), a multi-center, single-arm phase Ib/II study, enrolled patients aged ≥ 18 years with newly diagnosed PTCL. In phase Ib, 6 patients received 6 cycles of L-CHOP to determine the recommended phase II dose (RP2D). In phase II, patients received L-CHOP at the RP2D. Following 6 cycles, patients achieving complete response (CR) or partial response (PR) continued linperlisib maintenance until progression or intolerable toxicity or up to 24 months. The primary endpoints were the DLTs incidence (phase Ib) and the CR rate after 6 cycles of L-CHOP (phase II). Preliminary results were reported. **Results:** From August 15, 2023 to November 15, 2025, 44 patients were enrolled, including 6 patients in phase Ib. The median age was 57 years (range 18–77); 28 patients were males (63.6%). Most patients (n = 35, 79.5%) had stage III-IV disease, and 17 (38.6%) had an IPI score of 3–5. In phase Ib, one DLT (grade 3 febrile neutropenia) occurred in cycle 1, confirming linperlisib 80 mg once daily as RP2D. At the data cutoff on December 30, 2025, efficacy was evaluable in 34 patients (26 completed six cycles; 8 discontinued early), with 10 still receiving induction therapy. After six cycles of combination therapy, 19 patients (55.9%) achieved CR and four achieved PR, resulting in an objective response rate (ORR) of 67.6%. Treatment-emergent adverse events (TEAEs) occurred in 32 patients (94.1%); hematologic toxicity were common: neutropenia (n = 24, 70.6%), leukopenia (n = 21, 61.8%), anemia (n =14, 41.2%). Grade ≥ 3 TEAEs occurred in 19 patients (55.9%), most frequently neutropenia (n = 13, 38.2%), leukopenia (n = 10, 29.4%) and pneumonia (n = 4, 11.8%). **Conclusions:** Preliminary results from LINCH study suggest that linperlisib combined with CHOP as first-line treatment for PTCL achieved promising efficacy and manageable safety. A randomized controlled trial evaluating linperlisib plus CHOP versus CHOP in patients with newly diagnosed PTCL has been initiated (NCT06548347). Clinical trial information: NCT05949944. Research Sponsor: None.

7005 Oral Abstract Session

Impact of VT-EBV-N on disease-free survival as post-remission therapy in EBV-positive extranodal NK/T-cell lymphoma: A randomized, double-blind, placebo-controlled phase 2 study. First Author: Youngwoo Jeon, Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea

Background: Extranodal NK/T-cell lymphoma (ENKL) is an aggressive EBV-associated malignancy. Although complete remission (CR) can be achieved with intensive therapy, patients with high-risk features remain at substantial risk of relapse, and no standard post-remission therapy exists. VT-EBV-N is an autologous EBV-specific cytotoxic T lymphocyte (EBV-CTL) therapy designed to eliminate residual EBV-infected malignant cells. This phase 2 study evaluated the efficacy and safety of VT-EBV-N as post-remission therapy in patients with EBV-positive ENKL. **Methods:** This randomized, double-blind, placebo-controlled phase 2 trial enrolled patients with EBV-positive ENKL who had achieved CR within 6 months prior to enrollment and had at least one predefined high-risk factor for relapse. Patients were randomly assigned (1:1) to receive VT-EBV-N or autologous peripheral blood mononuclear cells (PBMC) as control. Treatment was administered IV weekly for 4 weeks, followed by a 4-week rest, and then once weekly for an additional 4 weeks (total 8 doses). The primary endpoint was 2-year disease-free survival (DFS). Secondary endpoints included overall survival (OS) and safety. Efficacy was analyzed in the full analysis set (FAS), and safety was assessed in the safety set. **Results:** A total of 50 patients were randomized, and 46 patients (VT-EBV-N, n=21; control, n=25) were included in the FAS. Baseline characteristics and distributions of high-risk features were generally balanced between groups. At 2 years, VT-EBV-N demonstrated a clinically meaningful and significant improvement in DFS compared with control (95.0% vs 77.6%). DFS events occurred in 1/21 patients (4.8%) in the VT-EBV-N group and 8/25 patients (32.0%) in the control group. Stratified log-rank analysis confirmed a significant DFS benefit with VT-EBV-N (p=0.0347). No deaths occurred in the VT-EBV-N group, whereas 4 deaths (16.0%) were observed in the control group; the difference in OS did not reach statistical significance (p=0.0580). VT-EBV-N was generally well tolerated. Most adverse events (AEs) were grade 1–2. Grade ≥3 AEs (CTCAE) occurred in 2/21 patients (9.52%) in the VT-EBV-N group and 4/25 patients (16.00%) in the control group. No treatment-related deaths were reported. **Conclusions:** VT-EBV-N demonstrated a clinically meaningful improvement in disease-free survival with a favorable safety profile in patients with EBV-positive ENKL in complete remission and at high risk of relapse. These findings support VT-EBV-N as a promising post-remission therapeutic option for this rare and aggressive lymphoma. Clinical trial information: KCT0003592. Research Sponsor: ViGenCell Inc.

Key efficacy and safety outcomes.

Outcome	VT-EBV-N	Control (PBMC)
Patients analyzed (FAS), n	21	25
2-year DFS, %	95.0	77.6
DFS events, n (%)	1 (4.8)	8 (32.0)
Deaths, n (%)	0 (0.0)	4 (16.0)
Grade ≥3 AEs, n (%)	2 (9.52)	4 (16.00)

7006 Oral Abstract Session

Fixed-duration glofitamab monotherapy in relapsed/refractory (R/R) mantle cell lymphoma (MCL) with/without prior Bruton's tyrosine kinase inhibitor (BTKi) exposure: Updated data after a 3.5-year follow-up. First Author: Yasmin Karimi, Division of Hematology/Oncology, University of Michigan, Ann Arbor, MN

Background: Patients (pts) with advanced R/R MCL have poor outcomes, especially pts with high-risk features or those progressing after BTKi therapies. Glofitamab is a CD20xCD3 2:1 bispecific antibody that redirects T cells to eliminate malignant B cells. A Phase 1/2 trial (NCT03075696) evaluated glofitamab monotherapy, given with step-up dosing (SUD) after obinutuzumab pretreatment (Gpt), in pts with R/R MCL. Prior analyses showed high response rates and manageable safety, regardless of prior BTKi exposure (Phillips, et al. ASCO 2024). We report longer follow-up data from this MCL cohort. **Methods:** Pts with R/R MCL after ≥1 prior line of systemic therapy received Gpt (single 1000 mg dose or 2000 mg split over 2 days, as needed) on cycle (C)1 day (D)1. Glofitamab SUD was given on C1D8 (2.5 mg) and C1D15 (10 mg), then the target dose of 16 or 30 mg every 3 weeks on D1 of C2–12. Efficacy endpoints included investigator-assessed complete response (CR) rate, overall response rate (ORR), duration of CR (DoCR), duration of response (DoR), progression free survival (PFS), and overall survival (OS). **Results:** As of Sept 8, 2025, 61 pts with R/R MCL were enrolled (Gpt: 1000 mg, n=17; 2000 mg, n=44); 60 pts were treated. The median number of prior lines of therapy was 2 (range 1–5), median age was 72.0 years (range 41–86), 86.9% of pts had Ann Arbor stage III/IV, and 26.3% had a simplified MCL International Prognostic Index score of ≧6. Pts had high-risk disease features such as Ki-67 proliferation index ≥30% (62.3%), blastoid/pleomorphic variants (9.8%), and *TP53* mutation (19.7%). The median number of glofitamab cycles received was 12 (range 1–13). With a median OS follow-up of 41.5 months (mo; 95% CI: 37.4–48.7), the ORR and CR rate were 82% and 77%, respectively. Median DoCR was 40.8 mo (95% CI: 14.1–NE); 48.9% of pts had ongoing CRs at the data cut-off. Estimated 33-mo DoCR and DoR rates were 50.5% and 47.4%, respectively. Median (95% CI) PFS was 18 mo (11.3–42.8) and OS was NE (26.9–NE). For pts who received prior BTKi therapy (n=34 [55.7%]), the ORR and CR rate were 73.5% and 70.6%, respectively. Median (95% CI) DoCR was 15.4 mo (8.3–NE), PFS was 11.3 mo (5.1–32.6), and OS was 29.9 mo (11.3–NE). Estimated 33-mo DoCR and DoR rates were 42.7% and 41.0%, respectively. No new safety signals were observed. Cytokine release syndrome remained the most common adverse event (n=42/60, 70%; Grade 1–2, 58.3%; Grade 3–4, 11.6%), with lower rates in the 2000 mg (n=28/44, 63.6%) vs 1000 mg (n=14/16, 87.5%) Gpt cohorts. **Conclusions:** Updated data on fixed-duration glofitamab monotherapy in heavily pretreated pts with R/R MCL show robust efficacy and manageable safety, including in BTKi-exposed pts. Glofitamab monotherapy is a suitable treatment for pts with R/R MCL in need of rapid disease control and is under investigation in the Phase 3 GLOBRYTE trial. Clinical trial information: NCT03075696. Research Sponsor: F. Hoffmann-La Roche Ltd.

7007 Oral Abstract Session

Mosunetuzumab plus polatuzumab vedotin (Mosun-Pola) versus rituximab, gemcitabine and oxaliplatin (R-GemOx) in patients with relapsed/refractory large B-cell lymphoma (R/R LBCL): Updated efficacy and safety from the phase 3 SUNMO study including in second-line (2L) versus third-line plus (3L+) patient subgroups. First Author: Wonseog Kim, Samsung Medical Center, Seoul, South Korea

Background: At the primary analysis, Mosun-Pola demonstrated superior efficacy versus R-GemOx, with infrequent cytokine release syndrome (CRS) events and manageable safety in patients (pts) with R/R LBCL in the Phase 3 SUNMO trial (NCT05171647; Budde et al. 2025). We report updated efficacy and safety, including in the 2L setting. **Methods:** Pts with R/R LBCL ineligible for autologous stem-cell transplant (ASCT) were randomized 2:1 to Mosun (subcutaneous)-Pola or R-GemOx. Dual primary endpoints were IRC-assessed progression-free survival (PFS) and objective response rate (ORR); secondary endpoints included complete response (CR) rate, duration of response (DOR), duration of CR (DOCR), and safety. Overall survival (OS) was not assessed as the data cut-off was prior to the pre-defined final OS analysis. **Results:** At data cut-off (August 8, 2025), 138 and 70 pts were assigned to Mosun-Pola or R-GemOx, respectively. Overall, 91 pts had 1 prior line of therapy (LOT; 2L; Mosun-Pola, n=61; R-GemOx, n=30) and 117 had ≥2 prior LOT (3L+; Mosun-Pola, n=77; R-GemOx, n=40). With a median follow-up of 28.3 months (mos), Mosun-Pola continued to demonstrate superior PFS benefits over R-GemOx (HR, 0.41; 95% CI: 0.28–0.60; Table). ORRs with Mosun-Pola were 70.3% vs 40.0% with R-GemOx. The observed PFS benefit of Mosun-Pola over R-GemOx was similar in 2L (HR, 0.38; 95% CI: 0.22–0.67) and 3L+ (HR, 0.48; 95% CI: 0.29–0.81) subgroups. With Mosun-Pola vs R-GemOx in 2L, the 2-year PFS rates were 40.3% vs 20.1%, and the 2-year DOCR estimates were 60.8% vs 37.5%, respectively. Median DOCR was not reached with Mosun-Pola in 2L and 3L+ subgroups. ORRs with Mosun-Pola vs R-GemOx were 75.4% vs 36.7% in 2L pts, and 66.2% vs 42.5% in 3L+ pts, respectively. The safety profile was unchanged since the primary analysis. Grade (Gr) ≥2 CRS occurred in 4% of Mosun-Pola-treated pts and no ICANS events occurred. The safety profile was consistent in 2L pts: Gr 2 CRS occurred in 3% of Mosun-Pola-treated pts, with no Gr ≥3 CRS events. **Conclusions:** Mosun-Pola continues to show notable efficacy with manageable safety in pts with ASCT-ineligible R/R LBCL, particularly in the 2L setting. Clinical trial information: NCT05171647. Research Sponsor: F. Hoffmann-La Roche Ltd.

Mediterranean CD19 genetic variations and potential influence on CAR T-cell therapy efficacy: Implications for population-tailored immunotherapy. First Author: Osama Alsmadi, King Hussein Cancer Center, Amman, Jordan

Background: CAR T-cell therapy has transformed the treatment of B-cell malignancies. However, relapse due to CD19 antigen escape remain a major challenge, often driven by genetic variants affecting CD19 structure, leading to CAR-T resistance. Mediterranean populations including Arabs, remain underrepresented in genomic studies. The Arabian prevalence and functional impact of CD19 variants is unknown. **Methods:** We analyzed and annotated *CD19* NGS data from a Mediterranean cohort comprised of 1,305 Arabian individuals. The overall allele frequencies were compared to global databases. Clinically reported resistance mutations were prioritized based on published CAR T-cell studies. Hardy-Weinberg Equilibrium (HWE) was also assessed. **Results:** This study characterizes functionally significant CD19 polymorphisms in a Mediterranean population, with particular focus on the clinically relevant L174V (rs2904880) variant known to associate with CAR-T therapy resistance. 174V was seen in this cohort with a Minor Allele Frequency (MAF) of 76.3%., and a variant allele homozygosity (V/V) of 65.2%. **Conclusions:** Our cohort displayed elevated V174 homozygosity compared to other populations, including Europeans, Americans, and South Asians, potentially predisposing to diminished CAR-T efficacy. These findings indorse population-adjusted CAR-T product development, and implementation of pre-therapy CD19 genotyping protocols to identify at-risk patients. Development of CARs targeting conserved CD19-epitopes, or combinatorial antigen approaches is warranted to mitigate resistance. Research Sponsor: None.

First-line odronextamab (Odro) plus chemotherapy (CHOP) in diffuse large B-cell lymphoma (DLBCL): OLYMPIA-3 Part 1B results. First Author: Matthew Matasar, Rutgers Cancer Institute, New Brunswick, NJ

Background: Approximately 25% of patients (pts) treated with rituximab + CHOP do not have a complete response (CR), and those with refractory/relapsed disease or high-risk features have poor outcomes. To address this unmet need, bispecific antibody combinations are being evaluated. In Part 1A (dose escalation) of the Phase 3 OLYMPIA-3 study (NCT06091865), odronextamab (Odro)-CHOP demonstrated generally manageable safety (most common treatment-emergent adverse events [TEAE] were neutropenia [81.8%] and cytokine release syndrome [CRS; 54.5%]) and encouraging preliminary efficacy in pts with previously untreated DLBCL, with CR rates of 100% on PET/CT (160 mg dose level, selected for Part 1B dose optimization). Here, we report Part 1B results. **Methods:** Part 1B included pts aged ≥18 years with untreated CD20+ DLBCL not otherwise specified or high-grade B-cell lymphoma with at least 1 high-risk feature. Odro-CHOP was administered in 6 × 21-day cycles, with Odro 0.7/4/20 mg step-up dosing from Cycle 1 Day 8. Pts were randomized 1:1 to receive Odro 160 mg QW/320 mg Q2W (Regimen [R] 1) or Odro 160 mg QW/160 mg Q3W (R2) with CHOP. Primary endpoint was safety. Secondary endpoints included investigator-assessed objective response rate (ORR) and CR rate per 2014 Lugano criteria. **Results:** At data cut-off (August 19, 2025), 40 pts were enrolled in Part 1B (20 per regimen). Median age was 67.5 years, 60.0% of pts were male, and 75.0% had an IPI score of 3–5. Median duration of treatment exposure was 18.1 weeks (R1) and 16.6 weeks (R2); 67.5% of pts completed 6 treatment cycles. Median relative dose intensity ranged from 90.1 to 100% for Odro and 92.7 to 100% for CHOP. The safety profile of Odro-CHOP was similar across regimens. TEAEs led to dose interruption/delay in 70.0% vs 50.0% of pts and to CHOP dose reduction in 10.0% vs 5.0% of pts with R1 vs R2, respectively. No TEAEs led to Odro dose reduction and 1 led to treatment discontinuation (Grade 4 neutropenic sepsis, R2). The most common TEAEs were neutropenia (57.5%), CRS (55.0%), and anemia (42.5%). CRS rates were consistent with Part 1A, predominantly Grade 1 (42.5% of pts). ICANS occurred in 3 pts (all Grade 1) and resolved completely. All enrolled pts were analyzed including 3 pts who discontinued treatment prior to tumor imaging assessment. With a median follow-up of 2.3 months in both regimens, ORRs were 95.0% (R1) and 90.0% (R2), and CR rates were 85.0% (both regimens). **Conclusions:** In Part 1B of OLYMPIA-3, the safety profile of Odro-CHOP was generally manageable and preliminary efficacy was encouraging with no meaningful differences between regimens, and combination with Odro did not impact the delivery of CHOP. Given these results, the less frequent Odro dosing regimen (R2) with CHOP was selected as the recommended Phase 3 dose for Part 2 (randomized controlled trial). Biomarker data will be presented. Clinical trial information: NCT06091865. Research Sponsor: Regeneron Pharmaceuticals, Inc.

7010 **Rapid Oral Abstract Session**

Real-world outcomes of bispecific antibodies in relapsed/refractory (R/R) follicular lymphoma (FL). First Author: Jessica Allen, University of Utah/Huntsman Cancer Institute, Salt Lake City, UT

Background: Mosunetuzumab (mosun) and epcoritamab (epco) are bispecific antibodies (BsAbs) approved for R/R FL, with pivotal trials (n=90-128) initially demonstrating 60-63% complete response rate (CRR), 80-82% overall response rate (ORR), and 1-year progression-free survival (PFS) rate of 58-66%. Real-world outcomes remain limited. We report the real-world efficacy and safety outcomes of BsAbs for patients (pts) with R/R FL treated in the Collaborative United States Bispecifics Consortium (CUBIC). **Methods:** This is a multicenter retrospective study of adult pts with R/R FL treated with standard of care mosun or epco between 2/2023 and 9/2025 at eight CUBIC centers. Efficacy outcomes included ORR, CRR, PFS, and overall survival (OS). PFS and OS were estimated using the Kaplan-Meier method. Safety outcomes included incidence and grade (G) of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). **Results:** A total of 99 pts with R/R FL were treated with BsAb, with 92% receiving mosun (n=91) and 8% (n=8) receiving epco. Median age was 68 years (range 33-101), 61% were ≥65 years (n=60), 63% were male (n=62), 8% Hispanic (n=8), 92% (n=79) had ECOG performance status (PS) of 0-1, 51% (n=42) had FLIPI ≥3, and 31% (n=30) had elevated LDH. Median prior lines of therapy were 3 (range 1-14), and 15% (n=15) had prior CAR-T. Among 96 pts with complete response data, the ORR was 87% and CRR was 72%. Median time to best response was 2.9 months (mo) (range 1.2-12.7). Response rates were not significantly associated with BsAb, ECOG PS, FLIPI, elevated LDH, or prior CAR-T. At median follow-up of 16.9 mo, the one-yr and 18 mo PFS rates were 72% (95%CI 62-83%) and 56% (95%CI 45-70%). One-yr and 18 mo OS rates were 94% (95%CI 90-99%) and 92% (95%CI 86-99%), respectively. Hispanic pts had better PFS than non-Hispanic pts (2-yr PFS 100% vs 42%, p=0.02). PFS was not significantly influenced by BsAb product, elevated LDH, ECOG PS, FLIPI, or prior CAR-T. Patients with ECOG of 2 had inferior OS than pts with ECOG of 0-1 (2-yr OS 43% vs 89%, p=0.02). Male sex was associated with inferior OS compared to female sex (2-yr OS 76% vs 100%, p=0.02). No differences in ORR, CRR, PFS, or OS were observed between pts <65 vs ≥65 yrs or <80 vs ≥80 yrs. Of 96 pts with complete safety data, CRS occurred in 34% of pts (G1 26%; G2 6%), with no ≥G3 events. ICANS occurred in 3% of pts (n=3), all G1 events. The incidence of CRS or ICANS was not significantly associated with age, LDH, ECOG, FLIPI, or prior CAR-T. **Conclusions:** In this diverse, heavily pretreated real-world cohort, 61% of patients were aged ≥65 years. Bispecific antibodies for R/R FL demonstrated high response rates, favorable survival outcomes, lower rates of cytokine release syndrome—primarily due to fewer grade ≥2 events—and ICANS rates comparable to those observed in pivotal clinical trials, supporting their use across heterogeneous populations, including very elderly patients. Research Sponsor: None.

7011 **Rapid Oral Abstract Session**

Golcadomide (GOLCA), a potential, first-in-class, oral CELMoD, + Pola-RCHP in patients (pts) with newly diagnosed aggressive B-cell lymphoma (a-BCL): Safety and 12-month (mo) efficacy results. First Author: Marc S. Hoffmann, The University of Kansas Cancer Center, Kansas City, KS

Background: Up to 40% of pts with diffuse large B-cell lymphoma (DLBCL) will relapse or have refractory disease following 1L treatment (Tx) with SOC chemoimmunotherapy regimens R-CHOP or Pola-RCHP. High risk (HR) populations include those with International Prognostic Index (IPI) score 3–5 and IPI 1–2 with either ≥1 lesion ≥7 cm or baseline LDH >1.3×ULN. GOLCA is a potential, first-in-class, oral CELMoD designed for the Tx of lymphoma, with preferential distribution to lymphoid organs and enhanced activity in lymphoma cell lines. GOLCA induces rapid and deep degradation of Ikaros and Aiolos, leading to direct cell killing and immunomodulatory activity. GOLCA 0.4 mg + R-CHOP has shown promising safety, a ≥90% minimal residual disease (MRD) negativity rate, and durable efficacy (24-mo PFS, 79%) in 1L a-BCL (Nowakowski et al, ASH 2025, 476) and is being evaluated in the Phase (Ph) 3 study GOLSEEK-1 (NCT06356129). We report initial Ph1b results with GOLCA + Pola-RCHP in 1L a-BCL. **Methods:** Pts aged ≥18 y with ECOG PS ≤2, IPI 0–5 (Part 2A) or 2–5 (Part 2B), and newly diagnosed a-BCL with measurable tumorous disease were included. Pts were treated with GOLCA + Pola-RCHP for six 21-day (D) cycles or until disease progression/unacceptable toxicity/study withdrawal. In dose escalation, GOLCA was dosed at 0.2 and 0.4 mg D1–7. In dose expansion, pts were randomized 1:1 to Pola-RCHP + GOLCA 0.2 or 0.4 mg. Primary endpoint: safety; efficacy was a secondary endpoint. **Results:** At data cutoff, 57 pts were treated with GOLCA + Pola-RCHP (0.2 mg, n=28; 0.4 mg, n=29). Median age was 63 y. Most pts had HR disease (86%) and DLBCL not otherwise specified histology (84%). For known cell of origin (COO), 47% were germinal center B cell (GCB) and 39% non-GCB by Hans algorithm. Forty-seven pts (83%) completed Tx and 52 (91%) entered the follow-up (f/u) period. Grade 3/4 Tx-emergent adverse events occurred in 95% of pts, most frequently neutropenia (86%; an on-target side effect of GOLCA) and anemia (39%). Median relative dose intensity for GOLCA and Pola-RCHP components was >95%. At 15.5 mo median f/u, end of Tx (EOT) complete metabolic response (CMR) rate was 69% at 0.2 mg, 82% at 0.4 mg, and similar across COO subtypes. EOT CMR was consistent in HR pts (65% at 0.2 mg, 83% at 0.4 mg). The 12-mo DOR and PFS rates were 92% and 88% at 0.2 mg, and 96% and 96% at 0.4 mg. In pts with both pre-Tx and EOT ctDNA analysis, 65% and 83% at 0.2 and 0.4 mg achieved MRD negativity (PhasED-Seq) at EOT. **Conclusions:** GOLCA + Pola-RCHP demonstrated a predictable and manageable safety profile, and addition of GOLCA did not compromise median dose intensity of Pola-RCHP. GOLCA 0.4 mg + Pola-RCHP resulted in a high rate of durable CMRs, high rate of MRD negativity, and a promising 12-mo PFS rate. These data continue to show that GOLCA + SOC regimens R-CHOP and Pola-RCHP has potential to improve outcomes in 1L HR a-BCL. Clinical trial information: NCT04884035. Research Sponsor: Bristol Myers Squibb.

7012 **Rapid Oral Abstract Session**

Safety and efficacy of Azer-cel, an allogeneic CD19 CAR T for the treatment of patients with relapsed/refractory non-Hodgkin lymphoma and chronic lymphocytic leukemia not previously exposed to autologous CAR T therapy. First Author: Danielle Nicole Blunt, Royal Adelaide Hospital, Department of Radiation Oncology, Adelaide, SA, Australia

Background: Azer-cel (azercabtagene zapreleucel) is an allogeneic, off-the-shelf, CD19-directed, chimeric antigen receptor (CAR) T-cell therapy derived from healthy donor T cells. We report the outcomes of patients treated with azer-cel plus low-dose interleukin-2 (IL-2) who enrolled in a Phase 1b dose expansion cohort for patients with r/r NHL and CLL and were naive to prior autologous CAR T-cell therapy (NCT03666000). **Methods:** Eligible patients with an aggressive B-cell CD19+ disease included those with diffuse large B-cell lymphoma (DLBCL, not otherwise specified or transformed), high-grade B-cell lymphoma, follicular lymphoma (FL, Grade1-3a), marginal zone lymphoma (MZL), Waldenstrom macroglobulinemia (WM), primary central nervous system lymphoma (PCNSL), and CLL/small lymphocytic lymphoma. Patients must have had at least 1-2 prior lines of therapy, depending on histological subtype, and no prior treatment with an autologous CAR T-cell therapy. Prior autologous stem cell transplant (ASCT) and bispecific antibodies were allowed. Patients received lymphodepletion with fludarabine (30 mg/m^2/day) and cyclophosphamide (750 mg/m^2/day) (Aug/Cy) for 3 days, followed by azer-cel infusion (500×10^6 cells) on Day 0 and subcutaneous low-dose IL-2 (1 million IU daily) for 14 days. Peripheral blood was collected at multiple timepoints, and levels of azer-cel transgene were quantified using qPCR. **Results:** Nineteen patients received azer-cel with low-dose IL-2. Median age was 59 years (range: 56-73). Disease subtypes included: DLBCL (5), MZL (5), CLL (4), PCNSL (3), FL (1), and WM (1). Of these, 4 (21%) had received ≥4 prior therapies, 3 (16%) had prior bispecific antibodies, and 2 (11%) had prior ASCT. Primary refractory disease was present in 6 (32%) patients. Median tumor burden was 36 cm^2 (range: 5.5-125). The overall response rate was 81% (13/16), with a complete response (CR) rate of 31% (5/16). Objective response by subtype included: DLBCL, 60% (1 CR, 2 partial responses [PRs]); MZL, 100% (3 CRs, 1 PR); CLL, 100% (3 PRs); PCNSL, 50% (1 PR); FL, 100% (1 CR); and WM, 100% (1 PR). Pharmacokinetic analysis (n=16) showed a mean CAR T-cell peak expansion of 1.7×10^5 copies/μg genomic DNA (SEM: 0.6×10^5), AUC_{0-28} of 9.5×10^5 copies/μg genomic DNA (SEM: 3.4×10^5), and time to peak expansion 5.9 days (SEM: 0.63). ICANS occurred in 7 patients (37%), with 3 Grade 1-2 events, 3 Grade 3 events, and 1 Grade 4 event. CRS was observed in 15 patients (79%), with no Grade ≥3 events. **Conclusions:** Azer-cel in autologous CAR T-naïve patients demonstrates promising clinical activity across a broad range of CD19+ B-cell malignancies, including MZL and CLL. Encouraging response rates, robust CAR T-cell expansion, and a manageable safety profile support further investigation. Clinical trial information: NCT03666000. Research Sponsor: None.

7013 **Rapid Oral Abstract Session**

REVO-U: A next-generation, gene-editing–free universal CAR-T platform to enable ultra–high-yield manufacturing and identification of early clinical activity in relapsed/refractory DLBCL. First Author: Di Wu, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: We previously invented autologous CAR-T product ciltacabtagene autoleucel (Carvykti) for multiple myeloma, with robust efficacy. However, its personalized nature incurs high costs and limits scalability. Conventional universal CAR-Ts rely on complex gene editing, yielding 50-100 doses/batch, yet to be commercially approved. We created REVO-U, a gene-editing-free universal CAR-T platform using proprietary technologies, initiating explorations in hematologic and solid tumors. It enables >3,000 doses/single batch from healthy donor cells, reducing costs and potentially eliminating capacity constraints in cell therapy. **Methods:** REVO-U uses protein-directed degradation to mitigate GvHD without gene editing. In a single-arm, open-label exploratory study, CD19-targeted REVO-UWD19 was given post-lymphodepletion (fludarabine/cyclophosphamide) with short-term oral mycophenolate sodium (EC-MPS) in relapsed/refractory DLBCL patients. **Results:** Four subjects treated (see Table for details). Subject 1 (Flu 30/Cy 300 mg/m² + 100e6 cells; EC-MPS 1440 mg BID x5 days, MPA average AUC 22.12 mg·h/L): PK Cmax 4.3k copies/mL, Transient fever (38.5°C, grade 0 CRS); ≥PR ongoing >10 months. Subject 2 (Flu 30/Cy 400 mg/m² + 200e6 cells; EC-MPS 1440 mg BID x11 days, MPA average AUC 71.44 mg·h/L): Cmax 173.9 k copies/mL, grade 1 CRS, CMR by PET-CT (PFS 4 months). Subject 3 (73y, high burden; Flu 30/Cy 500 mg/m² + 200e6 cells; EC-MPS x14 days, MPA average AUC 71.23 mg·h/L): REVO-U CAR-T expansion was highly significant. Cmax reached 19,057.6 k copies/mL, grade 3 CRS/HLH (controlled), followed by prolonged neutropenia and a fatal infection; PR, unconfirmed CR. Subject 4 (post-DLT: Flu 30/Cy 400 mg/m² + 50e6 cells; EC-MPS x22 days, MPA average AUC 15.21 mg·h/L): Cmax 2.01 k copies/mL, No CRS, PD. No GvHD in any patient. The target effective MPA AUC is >30 mg·h/L. Only Subjects 2 and 3 achieved this threshold on average MPA exposure. **Conclusions:** REVO-U enables ultra-scalable manufacturing like biologic drugs. Early DLBCL data show no GvHD, with expansion, CRS and responses influenced by lymphodepletion, dose & MPA exposure. Timely EC-MPS adjustment per MPA AUC may be needed for efficacy assurance. Promising PK expansion, persistence post-EC-MPS withdrawal, and efficacy signals have also emerged in solid tumor target explorations. We will report updated data on this innovative universal platform across malignancies at future conferences. Clinical trial information: NCT06662227. Research Sponsor: Wondercel Therapeutics; The First Affiliated Hospital of Xi'an Jiaotong University.

Summary of lymphodepletion, cell dosing, MPA exposure, pharmacokinetic, safety, and efficacy.

Subject #	Flu/CTX (mg/m^2)	Dose (million cells)	EC-MPS (Day used)	MPA-mAUC (mg*h/L)	PK Cmax (k Copies/mL)	CRS (Grade)	DLT	Efficacy (30 days)	PFS (months)
1	30/300	100	5	22.12	4.3	0	-	PR (CR?)	>10
2	30/400	200	11	71.44	173.9	1	-	CMR	3

7014 **Rapid Oral Abstract Session**

First-in-human in vivo CAR T-cell generation using a CD8-targeted lipid nanoparticle platform in relapsed/refractory B-cell lymphoma. First Author: Xi Zhang, Xinqiao Hospital of Army Medical University, Chongqing, China

Background: R/R B-cell lymphomas remain challenging despite advances in ex vivo CAR T-cell therapies, which are limited by complex logistics, manufacturing delays, and cost. In vivo CAR T-cell generation using targeted delivery offers a paradigm shift. We report the first-in-human study of a CD8-targeted lipid nanoparticle (CD8-tLNP) platform to generate functional CD19 CAR T cells *in vivo*. **Methods:** The CD8-tLNP was constructed by conjugating an anti-CD8 VHH to the surface of LNP encapsulating mRNA coding a CD19-directed chimeric antigen receptor, Safety, pharmacodynamics, and tolerability were first evaluated in non-human primates following intravenous administration. Subsequently, 4 patients with R/R CD19$^+$ B-cell lymphoma received four intravenous doses of CD19-CD8-tLNPs. Peripheral blood was collected at serial time points to assess CAR$^+$ CD8$^+$ T cells, B-cell depletion, cytokine levels, and clinical laboratory parameters. Antitumor activity was evaluated by PET-CT imaging, and adverse events were graded according to standard criteria. **Results:** The platform showed favorable safety and PD in monkeys. To date, seven patients with relapsed or refractory CD19$^+$ B-cell lymphoma have been treated. Among the evaluable patients, two patients achieved PR with decreased tumor lesions, one maintained SD by day 28; four patient remains pending efficacy evaluation. Following *i.v.* administration, CAR gene and surface expression in peripheral blood CD8$^+$ T cells peaked within 4–6 hours and declined thereafter, consistent with transient in vivo CAR T-cell generation. This was accompanied by rapid and near-complete peripheral B-cell clearance, with complete depletion (<1 B cell/μL) observed between 12 hours and day 3. Three booster doses administered at 3-day intervals sustained complete B-cell depletion and CAR T-cell activity. The treatment was generally well tolerated. No cytokine release syndrome of grade ≥2 was observed. Transient increases in CRP and ferritin were observed and were clinically manageable, without significant elevations in liver enzymes or prolonged cytopenias. Two patients showed naïve B-cell reconstitution by day 32 or 47. **Conclusions:** This first-in-human study demonstrates the feasibility and early clinical activity of in vivo CAR T-cell generation using a CD8-targeted LNP platform in patients with relapsed or refractory B-cell lymphoma. The approach enables rapid, transient CAR T-cell expression, repeatable dosing, and a favorable safety profile without lymphocyte clearance and complex manufacturing in *ex vivo* CAR T-cell. These findings provide clinical proof of concept for a scalable, off-the-shelf CAR T-cell therapy and support further clinical evaluation in hematologic malignancies. Clinical trial information: 2025-02-02. Research Sponsor: None.

7015 **Rapid Oral Abstract Session**

First-in-human novel bispecific epitope anti-CD5 nanobody CAR-T cells for refractory or relapsed T-cell malignancies. First Author: Lu Haiyang, Ruijin Hospital, Shanghai, China

Background: Refractory/relapse (r/r) aggressive T-cell lymphomas have poor prognosis with 5-year PFS of 20~30%, meanwhile CAR-T therapy brings new hope to this progressive disease. We previously reported allogeneic humanized CD5 CAR-T (huCD5 CAR) therapy achieved 100% ORR in r/r acute T lymphoblastic leukemia/lymphoma (T-ALL) patients. However, huCD5 CAR-T exhibit insufficient expansion activity, necessitating the optimization of CAR-T structure. Here, we developed a llama-derived nanobody-based bispecific epitope anti-CD5 CAR (NbCD5 CAR) construct, and evaluated its efficacy and safety in r/r T-ALL and T-cell non-Hodgkin's Lymphoma (T-NHL). **Methods:** llama-derived nanobody library was utilized to screen for CD5-specific nanobodies. The efficacy was then examined in NSG mice inoculated with Jurkat cell line. Tumor burden was assessed by flow cytometry and bioluminescent imaging. Finally, the efficacy and safety of the NbCAR vector were evaluated in the trials of r/r T-ALL (NCT07070323) and r/r T-NHL (NCT07022964). **Results:** We selected the NbCD5 CAR-T cells with superior cytotoxicity against T-cell lines compared to huCD5 CAR-T constructs. Then we determined its efficacy in NSG mice inoculated with Jurkat cell line. On day 7 post-tumor inoculation, mice received either Mock-T, huCD5 CAR-T or NbCD5 CAR-T cells. We observed that the NbCD5 CAR completely controlled tumor burden in mice and showed superior efficacy compared to huCD5 CAR. Then we proceed to the clinical trials containing 5 cases of T-ALL and 9 cases of T-NHL. In the T-ALL cohort, 3 patients have history of allo SCT, 4 patients received prior CD7 CAR-T therapy. All patients have infused 1.0×10^6/kg NbCD5 CAR-T cells. The adverse events (AEs) included grade 1 CRS (5/5), grade 2 ICANS (1/5), and grade 1~2 GVHD (2/5). All patients achieved CR at day 30 evaluation. In the median follow-up time of 80 days, 2 patients bridged to allo SCT, 1 patient relapsed at day 45 and died shortly thereafter. In the T-NHL cohort, 9 patients aged 30 to 64 have failed of at least 2 lines of chemotherapy, and 1 patient had history of auto SCT. The patients have received 1.0×10^6/kg NbCD5 CAR-T cells. All patients had grade 1-2 CRS, no ICANS was reported. Notably, EBV reactivation (5/9) was observed, including Grade 3-5 EBV reactivation (3/9). The ORR was 66.7% at day 30, 2 patients failed to respond for CAR-T expansion failure or weak CD5 expression. The CAR-T expansion was reached its peak at day 12 (range: 11-17), with the clearance of CD5$^+$ T cells in blood. In the median follow-up time of 94 days, 5 patients bridged to allo SCT. **Conclusions:** We optimized the nanobody NbCD5 CAR construct and showed superior cytotoxicity *in vitro* and *in vivo*. We also got preliminary safety and efficacy profiles in r/r T-ALL and T-NHL. This clinical trial is still ongoing, and long-term efficacy and clinical complication of CD5 CAR-T cell therapy still require further investigation. Clinical trial information: NCT07070323, NCT07022964. Research Sponsor: None.

7016 **Rapid Oral Abstract Session**

Genetic signatures of CNS relapse in DLBCL patients profiled with next-generation sequencing (NGS). First Author: Jackson Thomas Bowers, Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA

Background: CNS relapse of DLBCL is a devastating event with median survival <6 months. While the overall incidence is low (~5%), various factors impact the risk of CNS relapse including CNS-IPI, cell-of-origin (COO), and *MYC* rearrangement. Recent studies using NGS have defined DLBCL genetic subgroups with distinct biology. The MCD and C5 subgroups, defined by LymphGen and DLBc*lass*, respectively, have a shared genetic signature characterized by MYD88 L265P and CD79B mutations, immune evasion, and extranodal tropism with enrichment in CNS lymphomas. We investigated the impact of MCD/C5 signature on the risk of CNS relapse in a large cohort of DLBCL patients (pts) profiled with NGS. **Methods:** We performed a retrospective analysis of 155 DLBCL pts treated with chemoimmunotherapy and profiled with the UCSF500 NGS panel, which includes 529 genes and copy number data. FISH was performed to evaluate for *MYC*, *BCL2* and *BCL6* rearrangements. Pts with CNS involvement at diagnosis were excluded. Data were extracted from medical records including demographics, WHO-HAEM5 diagnosis, COO per Hans algorithm, CNS-IPI, and treatment history. LymphGen and DLBc*lass* subtypes were determined using online classifiers incorporating NGS and FISH data. We identified LymphGen and DLBc*lass* subtypes enriched in pts with CNS relapse. We performed univariable and multivariable analysis (MVA) (Cox proportional hazards model) to assess the impact of COO, CNS-IPI, and genetic signature on the cumulative incidence (CI) of CNS relapse. **Results:** The median age was 61. 60% were male, 57% non-Hispanic white, 21% Asian, 16% Hispanic, and 3% Black. DLBCL subgroups included DLBCL-NOS (60%), transformed DLBCL (15%), Richter transformation (8%), high-grade B-cell lymphoma (HGBCL)-double hit (5%), primary mediastinal LBCL (4%), DLBCL, post-transplant (3%), HGBCL-NOS (3%), and T-cell histiocyte-rich LBCL (2%). 67% were stage III-IV, 51% non-GCB type, and 21% high-risk CNS-IPI. LymphGen subtypes included EZB-MYC- (26%), ST2 (12%), MCD (9%), EZB-MYC+ (7%), BN2 (7%), N1 (3%), and composite cases (3%); 34% were unclassifiable. DLBc*lass* subtypes included C1 (13%), C2 (3%), C3 (52%), C4 (8%), and C5 (11%); 14% were not classified given <50% confidence in assignment. Median follow-up was 30 months. 18 pts experienced CNS relapse; these cases were enriched for MCD and C5 subtypes (28% each). The 2-year CI of CNS relapse in pts with MCD and/or C5 subtypes (N=21) was 20.4% vs. 6.4% in non-MCD/C5 cases (HR 3.46, p=0.007). Notably, 3 MCD/C5 pts had late CNS relapse (>3 years from diagnosis). In MVA, MCD/C5 signature was an independent risk factor for CNS relapse (HR 4.51, 95% CI 1.42-14.32, p=0.011) along with *MYC* rearrangement (p=0.036) and non-GCB COO (p=0.028). **Conclusions:** In this heterogeneous DLBCL cohort, MCD/C5 genetic signature was an independent risk factor for CNS relapse. Incorporation of CNS-active agents should be prioritized for this subgroup. Research Sponsor: UCSF Clinical and Translational Science Institute.

Outcomes by LymphoMAP archetypes in untreated diffuse large B-cell lymphoma from the POLARIX trial. First Author: R. Andrew Harkins, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Single cell multiomics helped identify three tumor microenvironment archetypes: FMAC, high tumor-associated fibroblasts and macrophages; LN, high naive and memory T cells; TEX, high exhausted $CD8^+$ T cells (Li, et al, Cancer Cell 2025) with FMAC associated with inferior outcomes with 1L R-CHOP. The POLARIX study showed sustained and significant 5-year PFS/DFS benefits favoring Pola-R-CHP (Morschhauser et al, JCO 2025) supporting use as a standard of care for pts with untreated intermediate/high-risk LBCL. In this post hoc exploratory analysis, we investigated the clinical outcomes of LymphoMAP subtypes in POLARIX. **Methods:** LymphoMAP subtypes were determined from global gene expression patterns (GEP) using the LymphoMapR classifier. Cell of origin (COO) status was determined by NanoString. Hazard ratios (HR) were adjusted for IPI score (2 vs 3–5), age (≤ 60 vs > 60 years) and COO. All statistics are descriptive. **Results:** GEP data were available for 669 pts (Pola-R-CHP, n=331; R-CHOP, n=338; baseline characteristics comparable with ITT); among which 244 (33.5%), 229 (34.2%), 196 (29.3%) were FMAC, LN, and TEX respectively (Table). Balanced baseline clinical characteristics seen across subtypes, except lower proportion of LN with high IPI (3–5) and higher proportion of TEX as ABC-DLBCL (Table). With a median follow-up 61 months, the adjusted HRs for PFS favored Pola-R-CHP compared with R-CHOP in all subtypes and were 0.66 (95% CI: 0.43–1.01) for FMAC, 0.79 (95% CI: 0.51–1.23) for LN, and 0.81 (95% CI: 0.50–1.32) for TEX. The 5-yr PFS estimates (95% CI) were 66.0 (57.1–76.2)%, 64.6 (55.4–75.4)%, 68.8 (59.7–79.4)% for FMAC, LN, and TEX respectively in the Pola-R-CHP arm, and 56.9 (47.6-68.0)%, 61.2 (52.8–70.9)%, 56.6 (45.8–69.9)% for FMAC, LN, and TEX respectively in the R-CHOP arm. A similar trend of OS improvement was observed in the FMAC subtype with 5-yr OS estimates of 82.5 (76.3–89.3)% vs 72.0 (63.8–81.2)% with Pola-R-CHP vs R-CHOP (HR 0.64; 95% CI: 0.37–1.10). Trends of PFS and OS improvements of Pola-R-CHP over R-CHOP were observed in ABC-DLBCL pts across all LymphoMAP subtypes. For GCB-DLBCL pts, no benefit was observed with Pola-R-CHP vs R-CHOP in the TEX subtype. **Conclusions:** In this exploratory analysis, Pola-R-CHP demonstrated PFS/OS improvement trends over R-CHOP in all three LymphoMAP subtypes, especially for the FMAC subtype. Future prospective validation is required. Research Sponsor: F. Hoffmann-La Roche Ltd.

Epigenetic profiling to identify aggressiveness markers in non-Hodgkin lymphoma via a targeted methylation-based multi-cancer early detection (MCED) blood test. First Author: Xiang-Yu Zhao, Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Non-Hodgkin lymphoma (NHL) encompasses a broad spectrum of malignancies, ranging from highly indolent to highly aggressive subtypes, each requiring distinct clinical management strategies. We developed a targeted methylation-based MCED test, and our prior work showed aggressive solid tumors exhibit elevated cell-free DNA (cfDNA) tumor fractions and distinct methylation signatures characterized by high methylated-to-unmethylated (M/U) ratios. This study focused on NHL subtypes to systematically compare epigenetic biomarkers (cfDNA tumor fraction and methylation signatures) for reliable differentiation of indolent and aggressive NHL. **Methods:** Pretreatment blood samples from NHL patients enrolled in a MCED study were analyzed using the targeted methylation assay. Patients were stratified into aggressive (diffuse large B-cell lymphoma [DLBCL], n=134; mantle cell lymphoma [MCL], n=18; other aggressive NHL, n=2) and indolent subgroups (follicular lymphoma [FL], n=58; marginal zone lymphoma [MZL], n=38; other indolent NHL, n=16). cfDNA tumor fraction was quantified via a zero-inflated negative binomial model, based on the distribution of methylation signal intensities. Methylation profiles were assessed by computing M/U ratios between subgroups. Intergroup comparisons of these biomarkers were conducted using the Mann-Whitney *U* test, with adjustments for multiple testing. Additional subgroup analyses were stratified by clinical stage to mitigate confounding factors. **Results:** MCED testing showed higher sensitivity in identifying aggressive NHL subtypes (78.06% vs 67.54% in indolent subtypes), even in stage I-II cases (62.50% vs 46.34% in indolent subtypes). Aggressive subtypes exhibited significantly higher cfDNA tumor fractions than indolent subtypes (Wilcoxon rank-sum test, $p=1.27e^{-06}$). A total of 31,075 methylation markers (71.66% hypomethylated) showed elevated M/U ratios in aggressive subtypes. These differences in cfDNA tumor fractions and M/U ratios persisted after clinical stage stratification. **Conclusions:** The MCED assay's superior sensitivity for aggressive NHL suggests preferential detection of aggressive NHL while minimizing indolent NHL overdiagnosis. Aggressive NHL is characterized by elevated cfDNA tumor fractions and distinct methylation profiles with high M/U ratios. These findings demonstrate cfDNA methylation patterns are promising epigenetic biomarkers, enabling aggressiveness differentiation in both solid tumors and NHL. Collectively, this study establishes a potential non-invasive strategy for NHL risk stratification and optimized clinical management. Research Sponsor: Shanghai Xiaohe Medical Laboratory Co. Ltd.

Fragmentia AI—Lymphoma: A cfDNA language model for lymphoma detection using ultra-low-pass WGS. First Author: Rui Liu, Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Despite the potential of cfDNA liquid biopsy for non-invasive cancer monitoring, its clinical utility is often limited by high sequencing costs and a reliance on detectable driver mutations. To address these barriers, we introduce Fragmentia AI – Lymphoma, a novel transformer-based cfDNA language model designed for lymphoma detection using cost-effective ultra-low-pass whole genome sequencing (ULP-WGS). **Methods:** Trained on a cohort of 389 samples (189 lymphoma and 200 healthy), the architecture integrates genomic language model backbone with gated attention-based multiple instance learning. Fragmentia AI – lymphoma learned to identify malignancy-associated, mutation-independent signals directly from raw cfDNA sequences. We validated performance on an independent test cohort of 190 lymphoma patients and 200 healthy controls. Additionally, to evaluate clinical scalability, we conducted a read-depth titration analysis to test the minimum input requirements for sustained model performance. **Results:** Fragmentia AI – lymphoma achieved an AUC of 0.943 in the training cohort and 0.944 in the testing cohort. At 95% specificity, the model demonstrated a sensitivity of 0.889 (F1 score: 0.913). Notably, diagnostic performance remained robust even with a threefold reduction in sequencing reads (AUC > 0.94), significantly lowering the required depth compared to standard somatic mutation calling. Feature attribution analysis revealed that model's decision-making was predominantly anchored in pathognomonic fragmentomic signatures, specifically GC-content biases and aberrant fragment-size distributions characteristic of malignant cfDNA. **Conclusions:** Our model effectively identified mutation-independent diagnostic signals from low coverage sequencing data, providing a scalable and cost-effective approach for lymphoma screening and monitoring. Early corticosteroid dosing after anti-CD19 CAR-T therapy for large B-cell lymphoma: Multicenter associations with neurotoxicity, cytokine release syndrome, and survival. First Author: Randa Elzein, Upstate Medical University, Syracuse, NY

Background: Corticosteroids are key to CAR-T toxicity management, but the impact of early dosing remains unclear. Over-treatment may blunt efficacy; under-treatment risks severe neurotoxicity. We evaluated early corticosteroid strategies after anti-CD19 CAR-T for large B-cell lymphoma (LBCL). **Methods:** Multicenter retrospective cohort across 22 U.S. programs (2019–2024). Adults receiving commercial anti-CD19 CAR-T for LBCL were included. Early steroid strategies: (1) Moderate (≤48 h from first fever or grade 1–2 ICANS; 0.5–1 mg/kg for ≤3 days, taper ≤5 days); (2) High-dose (≥1.5 mg/kg or ≥5 days); (3) None within 48 h. Primary endpoint: 12-month overall survival (OS). Secondary endpoints: grade ≥3 ICANS/CRS (Fine-Gray models), ICU admission, hospital stay (LOS), 6-month relapse, and day-30 response. Multivariable Cox/logistic models adjusted for key clinical covariates and center effects. Sensitivity analyses used inverse-probability weighting and time-dependent exposure. **Results:** N = 2,186; median age 62. Strategies: Moderate 34 %, High-dose 22 %, None 44 %. Versus None, Moderate dosing reduced grade ≥3 ICANS (sub-hazard ratio [sHR] 0.62, 95 % CI 0.50–0.78; p < 0.001) with no OS change (adjusted hazard ratio [aHR] 0.96, 0.84–1.10; p = 0.55). High-dose was linked to worse OS (aHR 1.22, 1.05–1.41) and more early relapse (aHR 1.28, 1.06–1.54) despite similar CRS rates. ICU admission was lower with Moderate vs None (adjusted odds ratio [aOR] 0.78, 0.64–0.95) and LOS shorter (−1.2 days, 95 % CI −2.0 to −0.4). Findings were consistent across age ≥65 and high-risk groups. **Conclusions:** A moderate, time-limited early steroid approach after anti-CD19 CAR-T reduced severe ICANS without loss of efficacy, whereas high-dose/prolonged use correlated with poorer survival and earlier relapse. Results support adopting standardized moderate early dosing and avoiding routine high-dose regimens. Research Sponsor: None.

Clinical outcomes by early corticosteroid strategy after anti-CD19 CAR-T.

Outcome	None (n=963)	Moderate (n=742)	High-dose (n=481)	Adjusted effect vs None (95 % CI)	P value
12-mo OS (%)	61	62	55	aHR 0.96 (0.84–1.10); 1.22 (1.05–1.41)	0.55; 0.009

Overcoming resistance to prior CAR-T therapy: Efficacy and safety of a sequential, multi-antigen targeted CAR T-cell strategy in B-cell NHL. First Author: Guoai Su, Beijing GoBroad Boren Hospital, Beijing, China

Background: Relapse following CAR T-cell therapy is a significant unmet need for patients with B-cell non-Hodgkin lymphoma (B-NHL). Strategies to effectively salvage these patients are urgently required. We report the results of a prospective study evaluating a novel approach of sequential CAR T-cell administration, often with alternative antigen targeting, in this heavily pre-treated population. **Methods:** In this single-center, Phase I/II investigator-initiated trial, we enrolled patients with R/R B-NHL who had progressed after at least one prior CAR T-cell infusion. Patients received a second autologous CAR T-cell product targeting a different (e.g., CD20, CD22, CD79b) or re-challenging the same antigen with a different construct. The primary endpoints were safety and overall response rate (ORR). The cohort included high-risk subtypes such as primary central nervous system lymphoma (PCNSL). **Results:** As of the data cut-off, 26 patients with R/R B-NHL (DLBCL, n=18; PCNSL, n=6; Burkitt, n=2) were infused. The median number of prior therapies was 5 (range 3-8). All patients had failed a prior CAR-T therapy. With a median follow-up of 10.2 months, the ORR was 88.5% (23/26), with an outstanding CR rate of 73.1% (19/26). Efficacy was profound even in the most challenging histologies; in the cohort of 6 patients with R/R PCNSL, the CR rate was an unprecedented 83.3% (5/6). The safety profile was highly encouraging. Cytokine release syndrome (CRS) occurred in 92.3% (24/26) of patients, with the majority being Grade 1 (61.5%) or Grade 2 (30.8%). No Grade ≥3 CRS was observed. Immune effector cell-associated neurotoxicity syndrome (ICANS) was rare and mild, with only Grade 1 events reported in 19.2% (5/26) of patients; no Grade ≥2 ICANS occurred. Hematologic toxicities were manageable and reversible. **Conclusions:** Sequential CAR T-cell therapy is a highly effective and safe strategy that can induce high rates of durable complete responses in B-NHL patients who have relapsed after initial CAR-T treatment. The exceptional activity observed in PCNSL suggests this approach can overcome the blood-brain barrier and address a critical unmet need. These results support the integration of sequential CAR T-cell therapy as a new standard of care for this patient population. Clinical trial information: ChiCTR1900025419. Research Sponsor: None.

Late infectious complications after CD19-directed chimeric antigen receptor T-cell (CAR-T) therapy for large B-cell lymphomas (LCBL): Real-world predictors and outcomes. First Author: Daniel E. Goyco Vera, UT Southwestern Medical Center, Dallas, TX

Background: CD19-directed CAR-T therapy is a curative option for patients (pts) with relapsed/refractory (R/R) LBCL. Infectious complications are a major source of morbidity and non-relapse mortality (NRM). While early infections are attributed to lymphodepleting chemotherapy and management of immune-related toxicities, real-world data defining predictors of late infections after CAR-T remain limited. **Methods:** We performed a single-center retrospective study of adult pts with R/R LBCL, including transformed indolent lymphomas, treated with anti-CD19 CAR-T. Infectious events were defined by compatible clinical features supported by laboratory, microbiologic, or radiographic evidence. Early infections were defined as ≤30 days post-infusion and late infections as >30 days. Logistic regression assessed associations with late infection risk. Multivariable models included a priori selected clinically relevant covariates. Stepwise logistic regression was performed as a sensitivity analysis. **Results:** Ninety-five pts were included (median age 65 years; median follow-up 32 months). Most pts received axi-cel (88%); 10% received liso-cel and 2% tisa-cel. Salvage and/or bridging therapy prior to CAR-T was administered in 59% of pts. Early infections occurred in 16% of pts, while 63% experienced late infectious complications. Among patients with late infections, 53% were in remission post CAR-T; 43% had both viral and bacterial infections over time, 33% viral only, 22% bacterial only, and 2% fungal overall. Hypogammaglobulinemia (IgG <400 mg/dL at day +30 and/or +90) occurred in 48%, and grade 4 neutropenia between days +30 and +90 in 31%. Five-year NRM was 12%, with infections contributing to 80% of deaths. On univariate analysis, hypogammaglobulinemia was associated with higher infection risk (OR 2.38, 95% CI 1.00–5.85; p=0.053). After adjustment for prespecified covariates, the association was attenuated but directionally consistent (p=0.082) and remained the only variable retained on stepwise regression. **Conclusions:** Infectious complications are common following anti-CD19 CAR-T therapy for R/R LBCL and occur predominantly beyond 30 days post-infusion. Hypogammaglobulinemia showed a consistent association with infection risk across multiple modeling strategies. Ongoing prospective studies will clarify the role of immunoglobulin replacement in mitigating late infectious complications in CAR-T recipients. Research Sponsor: None.

7023 Poster Session

Real-world patient characteristics, outcomes, and resource utilization of chimeric antigen receptor (CAR) T cell therapy across Foundation for the Accreditation of Cellular Therapy (FACT) and non-FACT treatment centers in large B-cell lymphoma (LBCL). First Author: Renju V. Raj, University of Tennessee Knoxville Medical Center, Knoxville, TN

Background: CAR T cell therapy has transformed the LBCL treatment landscape and is now being offered in some non-FACT accredited centers. We evaluated clinical characteristics, AEs, time to next treatment (TTNT), and health care resource utilization (HCRU) of patients with LBCL who received CAR T cell therapy from FACT versus non-FACT centers. **Methods:** This retrospective cohort study used the Komodo Health Claims Database (01/2015–08/2025). Adults with LBCL receiving CAR T cell therapy were identified via International Classification of Diseases, Ninth/Tenth Revision, diagnosis and procedure codes. Centers were classified as FACT or non-FACT based on public records. Cytokine release syndrome (CRS), immune effector cell–associated neurotoxicity syndrome (ICANS), and infections were assessed within 15 and 30 days after infusion. TTNT was estimated using KM methods. All-cause HCRU was reported as per patient per month (PPPM) to adjust for variation in follow-up duration; inpatient utilization was assessed by length of stay (LOS). Comparisons used chi-square test. **Results:** Among 6857 CAR T cell therapy—treated eligible patients with LBCL (FACT, n = 6748; non-FACT, n = 109), demographics and characteristics were comparable between cohorts; mean Charlson Comorbidity Index score was 4.6 versus 4.9, respectively. Significantly more patients treated at FACT sites traveled > 50 miles compared with those treated at non-FACT sites (43% vs 31%; $P < 0.05$); median distance traveled was 34 versus 17 miles, respectively. Rates of CRS (44% vs 40%), ICANS (21% vs 24%), and infections (39% vs 36%) within 15 days after infusion were similar between cohorts (FACT vs non-FACT, respectively); rates were also comparable within 30 days. Median (95% CI) TTNT was numerically lower in the FACT-treated (23 months [21–25]) versus non-FACT–treated cohort but not statistically significant (42 months [18–not estimable]; $P = 0.20$; estimates limited by small sample size); 12-month TTNT rates were 58% versus 67%, respectively. Excluding infusion visits, FACT-treated patients had marginally higher post-infusion HCRU (PPPM) over 1 year, including inpatient (0.93 vs 0.61; $P = 0.52$), outpatient (3.84 vs 3.16; $P < 0.05$), and ICU visits (0.13 vs 0.07; $P < 0.05$). Standardized 1-year inpatient LOS was 18.4 versus 15.9 days, respectively ($P = 0.58$). Among patients treated in an inpatient setting, HCRU including infusion visit exhibited a similar trend. **Conclusions:** In this real-world LBCL cohort, clinical characteristics, safety, TTNT, and HCRU were generally comparable between FACT- and non-FACT– accredited centers. Despite the non-FACT sample size and claims-based limitations, these findings suggest patients have similar outcomes across both types of authorized treatment centers. Research Sponsor: This study was funded by Bristol Myers Squibb.

7024 **Poster Session**

Real-world outcomes of lisocabtagene maraleucel (liso-cel) in patients (pt) with relapsed or refractory (R/R) chronic lymphocytic leukemia (CLL): First results from CIBMTR. First Author: Emily Tomasulo, University of Pennsylvania, Philadelphia, PA

Background: Liso-cel is an autologous, CD19-directed CAR T cell product with established efficacy and safety across B-cell malignancies. In TRANSCEND CLL 004 (NCT03331198), liso-cel demonstrated promising efficacy and manageable safety in pts with R/R CLL, including those previously exposed to Bruton tyrosine kinase inhibitor (BTKi) and B-cell lymphoma 2 inhibitor (BCL2i). Here, we report real-world effectiveness and safety of liso-cel in pts with R/R CLL. **Methods:** This observational study evaluated US pts with R/R CLL who received commercial liso-cel (05/2024–09/2025) and had ≥ 1 postinfusion assessment reported to CIBMTR. Effectiveness outcomes were ORR, CR rate, duration of response (DOR), PFS and OS; safety outcomes included AEs of special interest, nonrelapse mortality (NRM) and death. Results are descriptive. **Results:** Of 45 eligible pts, 64% were male; median age was 62 y (range, 44–83; ≥ 65 y, 44%). In pts with available data, all had ECOG PS 0–1 (43/43) and 57% (21/37) had ≥ 1 comorbidity, most commonly (> 10%) cardiac (24%) or pulmonary (16%). Elevated LDH was observed in 35% (15/43) and unmutated IGHV in 91%. Pts had a median of 6 (range, 1–10) prior therapies and 71% received liso-cel as fifth-line or later treatment (tx). Most pts (84%) were previously exposed to covalent BTKi and BCL2i, and nearly half (47%) had prior pirtobrutinib tx. Bridging therapy was used in 48% (21/44) of pts. At a median (95% CI) follow-up of 6.0 mo (5.4–7.1), ORR was 84% (70–93), and CR rate was 55% (39–70); 81% (13/16) of pts in CR with available data were MRD negative. Median (95% CI) DOR, PFS, and OS were not reached. Among responders (n = 36), 6-mo DOR was 89% (70–96.5); 6-mo PFS and OS were 77% (60–87) and 87% (72–95), respectively. Among pts with any-grade (gr) cytokine release syndrome (80%; gr ≥ 3, 4%) or immune effector cell–associated neurotoxicity syndrome (36%; gr ≥ 3, 13%), no gr 5 events occurred. Clinically significant infections were reported in 40% of pts, and at 30 d after infusion, 18% had persistent gr 4 thrombocytopenia and/or neutropenia. Rates were low of HLH/MAS (7%), second primary malignancies (2%; 1 case of basal cell carcinoma 34 d postinfusion), tumor lysis syndrome (7%), and gr 3/4 organ toxicity (9%). Of the 5 deaths, 2 each were due to relapse/progression or infection, and 1 pt had multiple causes reported; 6-mo NRM was 5% (95% CI, 0.8–14). Among the 49% of pts intended for outpatient infusion, 55% (12/22) were hospitalized postinfusion, with a median (range) time to hospitalization of 5.5 d (1–20) and a stay of 5.5 d (1–26). **Conclusions:** In routine clinical practice, liso-cel demonstrated response rates higher than in clinical trials, with a consistent safety profile. These real-world data support liso-cel as an effective option for pts with R/R CLL, including heavily pretreated or high-risk pts, and the potential for outpatient administration. Research Sponsor: This study was funded by Bristol Myers Squibb.

Measurable residual disease (MRD) by circulating tumor (ct) DNA in patients (pt) with R/R follicular lymphoma (FL) treated with lisocabtagene maraleucel (liso-cel) in TRANSCEND FL. First Author: Ariel Avilion, Bristol Myers Squibb, Seattle, WA

Background: ctDNA is a minimally invasive method for detecting MRD in various malignancies. MRD negativity (MRD^{neg}) has been linked to improved PFS and durable disease control, including after liso-cel treatment in R/R large B-cell lymphoma. The prognostic value of MRD after chimeric antigen receptor (CAR) T cell therapy in R/R FL has not been established. We report an exploratory MRD analysis from TRANSCEND FL (NCT04245839), in which pts had high rates of deep and durable responses after liso-cel. **Methods:** Of 103 efficacy-evaluable pts with third-line or later (3L+) FL, 89 (86%) had ctDNA samples, of whom 90% (80/89) had evaluable ctDNA and efficacy data after liso-cel infusion. Tumor-derived phased variants were primarily identified from screening (baseline) plasma or tumor tissue when plasma was insufficient, using PhasED-Seq. Post-treatment ctDNA-MRD was assessed at months (M) 1 and 3 after infusion for all pts, and at M24 for ongoing responders. MRD positivity (MRD^{pos}) was defined as ctDNA above the assay detection threshold (lower limit of detection of 0.7 parts per million, with sample-specific sensitivity dependent on DNA input). **Results:** MRD^{neg} was achieved by 89% (71/80) of evaluable pts from TRANSCEND FL. Among pts with a best overall response of CR, 93% (71/76) of them achieved MRD^{neg}. ctDNA clearance increased over time, with MRD^{neg} rates of 68% (52/76) at M1, 83% (63/67) at M3, and 97% (57/59) at M24. In contrast, pts with PR, SD, or PD (n=4) never achieved MRD^{neg}. Baseline ctDNA levels were not associated with PFS after liso-cel treatment. MRD^{neg} after infusion was associated with longer PFS compared with MRD^{pos} ($P<0.001$). In addition, MRD status at M3 (HR, 7.0 [95% CI, 3.0–16.2]) showed a stronger correlation with PFS than at M1 (HR, 3.0 [95% CI, 1.3–6.8]), with 36-M PFS rates of 80% for MRD^{neg} (n=63) versus 38% for MRD^{pos} (n=13) pts. Multivariate analysis controlling for PET findings confirmed the independent prognostic value of MRD for PFS. Importantly, PFS was longer for pts with both CR by PET and MRD^{neg} at M3 (n=62) compared to pts with CR and MRD^{pos} (n=9; HR, 5.0, [95% CI, 1.8-13.4]), with 36-M PFS rates of 81% versus 56%, respectively, suggesting that combining MRD with PET may provide additional prognostic information for long-term outcomes. **Conclusions:** Liso-cel induced deep molecular responses in pts with 3L+ FL with most pts (89%) achieving MRD^{neg} after infusion. Although baseline ctDNA levels were not associated with PFS, MRD^{neg} after infusion was significantly associated with improved PFS, highlighting the therapeutic benefit of liso-cel regardless of tumor burden before treatment. These findings support the potential of ctDNA-based MRD as a prognostic biomarker in FL and underscore that liso-cel is a key treatment option capable of inducing MRD^{neg} and durable clinical outcomes in pts with 3L+ R/R FL. Clinical trial information: NCT04245839. Research Sponsor: This study was funded by Bristol Myers Squibb.

7026 **Poster Session**

Outcomes of lisocabtagene maraleucel (liso-cel) in patients (pt) with relapsed or refractory (R/R) mantle cell lymphoma (MCL): First real-world data from the CIBMTR. First Author: Jennifer Jing Huang, Fred Hutchinson Cancer Center, University of Washington, Seattle, WA

Background: Liso-cel, an autologous, CD19-directed CAR T cell product, demonstrated deep, durable responses with manageable safety in pts with R/R MCL in the MCL cohort of TRANSCEND NHL 001 (NCT02631044). In this study, we present the first report of real-world outcomes for pts with R/R MCL who received liso-cel, using data from CIBMTR. **Methods:** This retrospective study included pts in the US with R/R MCL who received commercial liso-cel from 05/2024 to 09/2025 with ≥ 1 postinfusion assessment reported to CIBMTR. Effectiveness outcomes included ORR, CR rate, duration of response (DOR), PFS, and OS. Safety outcomes included AEs of special interest, nonrelapse mortality (NRM), and death. Results are descriptive. **Results:** A total of 94 pts were eligible. Median age was 73 y (range, 46–85), 74% were male, 4% (4/92) had ECOG PS ≥ 2, and 65% (53/81) had ≥ 1 clinically significant comorbidity, with cardiac (31%), pulmonary (31%), and obesity (17%) being most common (> 10%). Largest nodal mass > 10 cm, indicative of bulky disease, was observed in 15% of pts (9/60), 31% had ≥ 2 extranodal involvement, and 5% had CNS involvement. Data on *TP53* mutation status and Ki-67 score were limited. Median number of prior lines of therapy (including HSCT/cell therapy) was 4 (range, 2–12); 69% of pts (62/90) had refractory disease and 72% (67/93) received bridging therapy. At a median follow-up of 6.0 mo (95% CI, 5.9–6.2), ORR was 88% (95% CI, 80–94) with CR rate of 80% (95% CI, 70–87). Median DOR, PFS, and OS were not reached; 6-month DOR, PFS, and OS rates were 79% (95% CI, 55–91), 79% (95% CI, 68–87), and 92% (95% CI, 83–96.5), respectively. Any-grade (gr) cytokine release syndrome and immune effector cell–associated neurotoxicity syndrome were reported in 65% (gr ≥ 3, 2%) and 37% (gr ≥ 3, 12%) of pts, respectively, with no gr 5 events. Clinically significant infections were reported in 23% of pts, gr 4 thrombocytopenia and/or neutropenia persistent at 30 days after infusion in 18%, and second primary malignancies in 5%, with skin malignancies being the most common. Gr 3/4 organ toxicity occurred in 1 (1%) pt, and none had tumor lysis syndrome. Nine (10%) pts died, including 6 (6%) due to PD. The NRM rate at 6 mo was 1% (95% CI, 0.1–5.4). Of the 36% of pts planned for outpatient infusion, 59% (20/34) were reported as being hospitalized postinfusion with a median (range) time to hospitalization and stay of 5.5 days (1–35) and 4.5 days (2–32), respectively. **Conclusions:** These results show that liso-cel is associated with high response rates in a broad population of heavily pretreated pts with R/R MCL with early signs of durable benefit and safety profile consistent with TRANSCEND NHL 001. While longer follow-up is needed, this supports the potential of liso-cel to address critical gaps for pts with limited treatment options, providing strong effectiveness and manageable safety. Efficacy of tocilizumab in resolving chimeric antigen receptor T-cell (CAR T)–induced cytokine release syndrome (CRS): A pooled clinical trial (CT) analysis of patients (pts) with B-cell lymphoma (BCL). First Author: Soon Jye Kho, Medidata Solutions, a Dassault Systèmes Company, New York, NY

Background: CAR T therapy offers significant efficacy in the treatment of relapsed/refractory hematologic malignancies but is also associated with developing immune-mediated toxicity, such as CRS. Tocilizumab, an interleukin-6 receptor antagonist, is the only FDA-approved treatment for CAR T-induced CRS, but its efficacy in large pt populations remains limited. This study aims to evaluate the efficacy of tocilizumab by assessing complete response (CR) rates and median time-to-CR in pts with BCL experiencing CAR T-induced CRS, using pooled clinical trial data. **Methods:** We pooled aggregated, anonymized data made available through Medidata Clinical Cloud across <10 multinational CTs, comprising 2,304 patients. Inclusion criteria required a BCL diagnosis, who developed CAR T-induced CRS and were treated with tocilizumab. The index date was defined as the initiation of tocilizumab. CR was defined as CRS resolution within 14 days of the index date without meeting any failure to respond criteria. Non-response was defined as requiring>2 doses of tocilizumab, rescue therapy with siltuximab, CRS grade escalation after 2 tocilizumab doses, or CRS recurrence after 2 tocilizumab doses. The CRS events were graded using Lee's Criteria 2014. CR rate was described as a proportion, and time-to-CR was estimated using the Kaplan-Meier method. **Results:** Of the 2,304 pts included in the database, 680 met the inclusion criteria (37% aged ≥ 65 yrs; 63% male; 80% white; 47% Diffuse Large BCL, 14% Follicular Lymphoma & 13% Mantle Cell Lymphoma; 49% Eastern Cooperative Oncology Group (ECOG) performance score=0 & 49% ECOG=1; 48% Ann Arbor Stage IV; 27% had bulky disease; 65% without bridging therapy; 73% received CD28 costimulatory domain-targeted CAR T-infusion, 27% received 41bb costimulatory domain-targeted CAR T-infusion; 72% with grade 1 CRS at the time of onset). The median time from CAR-T infusion to CRS onset was 2 days (IQR: 1 - 4), and the median time from CRS onset to the first dose of tocilizumab was 2 days (IQR: 1 - 3). The CR rate was 66% (95% CI: 62.5% - 69.6%) and the median time to CR was 4 days (95% CI: 3 - 4), with 35% achieving CR in ≤ 2 days and 80% in ≤ 7 days. **Conclusions:** This large-sample pt-level study of pooled CT data showed significant efficacy of tocilizumab in resolving CAR T-induced CRS among pts with BCL, with two-thirds of pts achieving CR. The rapid median time-to-CR (4 days) underscores the role of tocilizumab as a first-line intervention. However, the 34% of pts who did not meet the CR criteria suggest a need for further investigation into other treatment strategies. Research Sponsor: None.

Long-term real-world outcomes of axicabtagene ciloleucel (axi-cel) in relapsed/refractory (R/R) large B-cell lymphoma (LBCL). First Author: Caron Alyce Jacobson, Dana-Farber Cancer Institute, Boston, MA

Background: Axi-cel, autologous anti-CD19 CAR T-cell therapy, showed long-term survival and curative potential in R/R LBCL (ZUMA-1; Neelapu et al. *Blood*. 2023). Few studies have examined long-term outcomes beyond clinical trials. Here we report long-term real-world outcomes of axi-cel in R/R LBCL using large-sample CIBMTR data. **Methods:** A total of 1500 adults from 79 US centers receiving commercial axi-cel after ≥2 LOT for LBCL from Oct 2017-Aug 2020 were enrolled in a post-marketing requirement study. A protocol was developed prior to the study's implementation, reviewed by Kite and CIBMTR. This is a secondary analysis of said study. Key outcomes were progression-free survival (PFS), overall survival (OS), time to next therapy (TTNT), disease-specific mortality (competing risks were non-relapse deaths), subsequent malignancies, and non-relapse mortality (NRM). Outcomes were analyzed descriptively. Cases with missing data were excluded separately for each endpoint. **Results:** As of Aug 2025, 1446 patients (pts) were included in the analysis. Median age at infusion was 62.2 y (range, 19.6-90.8: 38% of pts ≥65 y); 65% were male. Five percent of pts had ECOG PS ≥2 and 16% had high-grade lymphoma. Pts had a median of 3 (range, 2-4) prior LOT, 28% had prior autologous hematopoietic cell transplantation, and 50% received bridging therapy. At 59.7 mo median follow-up, median PFS (95% CI) was 7.9 mo (6.3-10.9) and 5-y PFS was 30% (27-32). The median OS was 25.7 mo (21.6-30.2); 5-y OS was 38% (35-41). The 5-y cumulative incidence of disease-specific mortality was 51%. Among pts who were progression-free at 2, 3, 4, or 5 y post-infusion, the OS at 6 y (95% CI) was 73% (68-78), 81% (76-86), 90% (84-94), and 94% (89-97), respectively. The median duration of response (DOR) was 25.3 mo (95% CI, 20.7-32.8) and 5-y DOR was 38% (35-41). The median TTNT was 12.2 mo and 30% did not need additional LOT at 5 y. Of pts who received subsequent salvage therapy, 12 (2%) received cell therapy, 39 (7%) received hematopoietic cell transplant, and 475 (90%) received other therapy. The 1, 2, 3, 4, and 5-y cumulative incidence of relapse (95% CI) was 49% (46-51), 52% (50-55), 54% (52-57), 55% (53-58), and 56% (53-59), respectively. No new safety signals were observed. The primary causes of death (n=864; 60%) were primary disease (540; 63%), infection (111; 13%), and organ failure (57; 7%). The 5-y cumulative incidence of NRM was 16% (95% CI, 14-18). At 5 y, 11% (95% CI, 10-13) had subsequent malignancies, mostly therapy-related myeloid neoplasms (6%) and non-melanoma skin cancer (3%); none were directly attributed to axi-cel. **Conclusions:** This real-world study showed sustained survival at 5 y among pts with R/R LBCL treated with axi-cel after ≥2 LOT, consistent with ZUMA-1. Infection and organ failure were common causes of NRM. These results continue to support the use of axi-cel with curative intent in R/R LBCL. Research Sponsor: Kite, a Gilead Company.

Fixed-duration subcutaneous (SC) mosunetuzumab (Mosun) in elderly/unfit patients with previously untreated diffuse large B-cell lymphoma (DLBCL): Interim analysis and patient-reported outcomes (PROs) from the phase 2 MorningSun study. First Author: Ian W. Flinn, Tennessee Oncology and OneOncology, Nashville, TN

Background: Mosun, a CD20xCD3 T-cell engaging bispecific antibody, is approved for relapsed/refractory follicular lymphoma after ≥2 prior lines of therapy. We report an interim analysis and PROs with Mosun SC in elderly/unfit patients with previously untreated DLBCL. **Methods:** MorningSun (NCT05207670) is a Phase 2, basket study of Mosun SC in patients with B-cell non-Hodgkin lymphoma. In the DLBCL cohort, eligible patients (aged ≥80 years, or 65–79 years and ineligible for chemoimmunotherapy) received outpatient Mosun SC: Day (D) 1 (5 mg), D8 (45 mg) and D15 (45 mg) of Cycle (C) 1, then 45 mg on D1 for up to 17 21-day cycles. Primary endpoint was progression-free survival (PFS) rate at 24 months. Other endpoints included overall survival (OS), objective response rate (ORR), complete response (CR) rate, change from baseline (CfB) in lymphoma symptoms as assessed by the Functional Assessment of Cancer Therapy-Lymphoma subscale (FACT-Lym LYMS; higher scores indicate improvement, a ≥3-point increase is considered clinically meaningful) and safety. **Results:** Forty-nine patients were enrolled, primarily from community sites (n=34). Median age was 83 years (range: 71–101). International Prognostic Index was 3–5 in 53.1% patients and 18.4% of patients had bulky disease. As of February 10, 2025, the median duration of follow-up was 12.5 months (range: 1.4–30.8). PFS and OS rates at 12 months were 71.3% (95% confidence interval [CI]: 54.8–82.7) and 74.7% (95% CI: 58.5–85.4), respectively. ORR was 73.5% and CR rate was 59.2%. Completion rates for FACT-Lym LYMS were ≥95% at baseline and remained ≥87% at each subsequent timepoint. Patients reported improvement in health-related quality of life (HRQoL) over time, demonstrated by increased mean CfB (standard deviation [SD]) in FACT-Lym LYMS scores: C4D1, 5.1 (9.8); C9D1, 5.6 (11.8); C17D1, 9.8 (11.4). Clinically meaningful improvements in lymphoma symptoms were observed in 53.1% (95% CI: 38.3–67.5) of patients. The most common any-grade adverse event (AE) was injection site reaction (53.1%; all Grade [Gr] 1/2). Gr 3/4 AEs were reported in 65.3% of patients and 8.2% experienced a Gr 5 AE (no Gr 5 AEs were Mosun related, per investigator assessment). Serious AEs occurred in 42.9% of patients. Infection AEs occurred in 49.0% of patients (Gr 1: 4.1%; Gr 2: 28.6%; Gr 3: 16.3%) and resolved in 91.7%. Cytokine release syndrome occurred in 12.2% of patients (Gr 1: 10.2%; Gr 2: 2.0%; all resolved). Updated data with around one additional year of follow-up will be presented. **Conclusions:** Mosun SC showed promising efficacy with manageable safety in elderly/unfit patients with previously untreated DLBCL in an outpatient setting. Clinically meaningful improvements in lymphoma symptoms suggest that Mosun SC improves aspects of HRQoL in this population. Clinical trial information: NCT05207670. Research Sponsor: Genentech, Inc.

Pre-lymphodepletion CRP and ferritin risk stratification as a predictor of early immune toxicities and hematologic complications after CAR-T therapy: A propensity-matched cohort study. First Author: Fayaz Aijaz Ahmed Khan, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Inflammation before CAR-T has been linked to higher rates of immune effector cell-associated toxicities and worse outcomes. A pragmatic pre-lymphodepletion risk stratification using C-reactive protein (CRP) and ferritin has been proposed to identify patients at elevated risk. We used the TriNetX Network to evaluate whether CRP/ferritin risk groups predict clinically relevant early outcomes following CAR-T in a real-world setting. **Methods:** We performed a retrospective study using TriNetX Network. Adults (≥18 years) treated with CAR-T (day 0) were included if CRP & ferritin were available in the pre-lymphodepletion window (day −20 to −5). Patients were classified as low risk (CRP <4 and ferritin <400), intermediate risk (CRP ≥4 with ferritin <400 or CRP <4 with ferritin ≥400), and high risk (CRP ≥4 and ferritin ≥400). Propensity score matching was performed using demographics, comorbidities, transplant status, malignancy diagnoses & lymphodepletion therapy. Outcomes were assessed from day 0 to +30. We analyzed outcomes using odds ratio (OR) with 95% confidence interval (CI) and time-to-event comparison using log-rank p-value. **Results:** After propensity matching, high vs low risk cohorts included 246 patients per group. For intermediate vs low risk, cohorts included 298 per group. High-risk patients had higher odds of cytokine release syndrome (CRS) (OR 1.56, 95% CI 1.1–2.2; p=0.04) and immune effector cell-associated neurotoxicity syndrome (ICANS) (OR 1.86, 95% CI 1.1–3.1; p=0.01) versus low risk. In intermediate vs low risk, ICANS remained increased (OR 1.69, 95% CI 1.1–2.7; p=0.02), while CRS showed a nonsignificant trend (OR 1.36, 95% CI 0.98–1.9; p=0.06). High risk cohort was associated with greater supportive care utilization, including higher odds of G-CSF use (OR 2.93, 95% CI 1.5–5.8; p<0.01) and blood transfusion (OR 2.65, 95% CI 1.2–5.9; p=0.01) versus low risk. High vs low-risk was associated with higher odds of platelets <50 (OR 3.59, 95% CI 1.98–6.5; p<0.01) and hemoglobin <8 (OR 2.81, 95% CI 1.3–5.9; p<0.01). Neutropenia (ANC <500) was not significantly different. In intermediate vs low risk, cytopenia-related endpoints were not significantly different. All-cause mortality analysis was not performed due to low event rates. **Conclusions:** In a TriNetX propensity-matched real-world cohort, a simple pre-lymphodepletion CRP and ferritin stratification identified CAR-T recipients at significantly higher risk for early immune toxicities (CRS, ICANS) and clinically meaningful hematotoxicities (severe thrombocytopenia and anemia) within 30 days, along with increased need for G-CSF & transfusion support. These findings support using simple pre-infusion inflammatory biomarkers to guide counseling, risk-adapted monitoring, and proactive supportive care strategies in routine practice. Research Sponsor: None.

Longitudinal safety of lisocabtagene maraleucel (liso-cel) in patients (pt) with second-line or later (2L+) large B-cell lymphoma (LBCL). First Author: Manali Kirtikumar Kamdar, University of Colorado Cancer Center, Aurora, CO

Background: Liso-cel has shown favorable efficacy and a manageable, consistent safety profile across B-cell malignancies, including R/R LBCL. Here, we present pooled longitudinal safety results in pts who received liso-cel as 2L+ treatment for LBCL in 3 pivotal clinical trials. **Methods:** Data from liso-cel–treated pts in the TRANSFORM (2L transplant-eligible LBCL, NCT03575351), PILOT (2L transplant-noneligible LBCL, NCT03483103), and TRANSCEND NHL 001 (third-line or later LBCL, NCT02631044) trials were pooled. Incidences of infections, laboratory parameters, and concomitant medication/procedure use were assessed from Day (D) 0–15, D16–30, Month (M) 2–3, M4–6, M7–9, M10–12, M13–18, M19–24, and M25 to end of study (EOS). Incidences were calculated as pts with ≥ 1 event divided by ongoing pts during that period. **Results:** A total of 420 pts were included. Incidence of grade (gr) ≥ 3 neutropenia was highest from D0–15 (Table), decreased sharply after M6, then remained low. Overall, 62% of pts received growth factors for neutropenia, with highest use from D0–15 and minimal use after M3. Rate of gr ≥ 3 anemia was highest from D0–15, declined by M9, then remained low. A total of 49% of pts received red blood cell (RBC) transfusions at any point with highest use from D0–15 and minimal use after M3. Incidence of gr ≥ 3 thrombocytopenia was highest from D0–M3, declined by M9, then remained low. Platelet transfusions were received by 31% of pts at any point with highest use from D0–M3 and minimal use after M3. Use of erythropoiesis- and thrombopoiesis-stimulating agents was rare (1% and 2% at any point, respectively). Incidence of gr ≥ 3 infections was 15% overall and remained low in all periods (Table). Hypogammaglobulinemia (serum immunoglobulin < 500 mg/dL) ranged from 43% to 63% across periods with IVIG use in 20% of pts at any point on study. B-cell aplasia declined over time from 99% from D0–15 to 73% by M12 and < 50% beyond M18. The overall incidence of second primary malignancies was 6%. **Conclusions:** In these longitudinal analyses in liso-cel–treated pts with 2L+ LBCL, gr ≥ 3 cytopenias and concomitant medication use decreased over time with minimal needs for growth factors or transfusions after M3. Gr ≥ 3 infections remained low in the short- and long-term periods despite persistent hypogammaglobulinemia and B-cell aplasia in most pts at M12. These data underscore the favorable long-term safety of liso-cel in pts with 2L+ LBCL, reinforcing the feasibility of outpatient management and the potential for low health care resource utilization in clinical practice. Clinical trial information: NCT03575351, NCT03483103, and NCT02631044. Research Sponsor: This study was funded by Bristol Myers Squibb.

Period	Gr ≥ 3 neutropenia, %	Growth factor for neutropenia, %	Gr ≥ 3 anemia, %	RBC transfusion,%	Gr ≥ 3 thrombo-cytopenia, %	Platelet transfusion, %	Gr ≥ 3 infection, %
D0–15	87	42	29	35	23	12	6
D16–30	36	18	12	19	35	22	2

Long-term cognitive impairment after CAR-T therapy compared with autologous stem cell transplantation. First Author: Andrea Yun-En Sun, College of Medicine, National Yang Ming Chiao Tung University, Taipei City, Taiwan

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has transformed the management of relapsed and refractory hematologic malignancies, challenging the established role of autologous stem cell transplantation (ASCT). However, the chronic neurocognitive effects of CAR-T therapy remain unclear. This study compares the long-term risk of cognitive impairment between CAR-T and ASCT therapy recipients. **Methods:** We conducted a retrospective cohort study using US hospital data from the TriNetX research network. Patients exclusively receiving either CAR-T therapy or ASCT were propensity score-matched 1:1 and adjusted for age, sex, primary cancer diagnosis, major comorbidities, neuropsychiatric comorbidities, dexamethasone use, and laboratory values (BMI, LDH if available). Participants with prior cognitive impairment diagnosis within 1 year before index or who received multiple treatment modalities during the study period were excluded. The primary endpoint was time-to-event cognitive impairment, defined by ICD-10 codes for mild cognitive impairment, memory loss, and difficulty with concentration. Secondary outcomes included time to neurological dysfunction (delirium, encephalopathy, seizures), mood and stress-related disorders (depression, anxiety, sleep disorder), fall-related injuries, mobility impairment, and secondary malignancies. **Results:** After propensity score matching, 3,067 CAR-T patients were compared with 3,067 ASCT patients. CAR-T recipients demonstrated a 58% higher risk of cognitive impairment (HR 1.583; 95% CI 1.390-1.80) and a 57% higher risk of neurological dysfunction (HR 1.567; 95% CI 1.403-1.751) compared to ASCT patients. Encephalopathy was the most prominent individual complication, with CAR-T patients showing a 2-fold higher hazard compared to ASCT patients (HR 2.035; 95% CI 1.727-2.398). To account for acute ICANS, events occurring within the first 7 days were excluded, and CAR-T patients maintained higher hazard of cognitive impairment (HR 1.695; 95% CI 1.466-1.959). The risk was highest within the first 30 days (HR 4.224; 95% CI 3.227-5.528) and remained persistently elevated throughout the follow-up period, even at 2500 days (HR 1.761; 95% CI 1.535- 2.021). Among CAR-T products, ciltacabtagene autoleucel showed the highest hazard (HR 2.013; 95% CI 1.092-3.708), while tisagenlecleucel showed the lowest (HR 1.530; 95% CI 1.030-2.271). All $p<0.001$. **Conclusions:** Compared to ASCT, CAR-T cell therapy was associated with a significantly increased risk of long-term cognitive impairment and neurological dysfunction. These findings have important implications for incorporating neurocognitive assessment into treatment discussion, informed consent, and the need for long-term monitoring. Research Sponsor: None.

Real-world toxicity of bispecific antibodies versus CAR-T cell therapy in diffuse large B-cell lymphoma and follicular lymphoma. First Author: Nanda Krishnan Siva, West Virginia University School of Medicine, Department of Internal Medicine, Morgantown, WV

Background: CAR-T cell therapy and bispecific antibodies (BsAbs) have transformed treatment of relapsed or refractory B-cell lymphomas. While CAR-T toxicities are well characterized, real-world comparative safety data for newer BsAbs remain limited. We compared early and delayed toxicities of CAR-T versus BsAbs in diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL). **Methods:** Using the TriNetX Research Network, we conducted a retrospective cohort study of adults with DLBCL or FL treated with BsAbs or CAR-T therapy. 1:1 propensity score matching was performed for demographics, comorbidities, laboratory values, and prior lines of chemotherapy. Outcomes included cytokine release syndrome (CRS) at 14 and 30 days; immune effector cell–associated neurotoxicity syndrome (ICANS) at 30 and 60 days; ICU admission within 90 days; infections within 90 days; hypogammaglobulinemia within 180 days; neutropenia within 90 days; and treatment-related mortality at 90 days. Analyses used Kaplan–Meier methods, hazard ratios (HR), risk ratios (RR), and 95% confidence intervals (CI). **Results:** A total of 1,110 CAR-T–treated and 897 BsAb-treated patients met inclusion criteria. After matching, 384 patients were included per cohort. Compared with CAR-T, BsAbs were associated with lower CRS at 14 days (RR 0.45, 95% CI 0.37–0.55) and 30 days (RR 0.52, 95% CI 0.44–0.62), and lower ICANS at 30 days (RR 0.30, 95% CI 0.20–0.47) and 60 days (RR 0.36, 95% CI 0.25–0.51). ICU admission within 90 days occurred less frequently with BsAbs (RR 0.56, 95% CI 0.40–0.78). Infection rates at 90 days (RR 1.06, 95% CI 0.87–1.30) and hypogammaglobulinemia at 180 days (RR 0.81, 95% CI 0.65–1.01) were similar between groups. Neutropenia within 90 days was lower with BsAbs (RR 0.55, 95% CI 0.49–0.61). 90-day overall survival was lower with BsAbs (HR 2.99, 95% CI 1.89–4.73), likely driven by treatment selection bias, as BsAbs are frequently used in patients ineligible for CAR-T due to poor performance status, comorbidities, or aggressive disease. **Conclusions:** In this real-world cohort of DLBCL and FL, BsAbs were associated with substantially lower early immune-mediated toxicity and healthcare utilization compared with CAR-T therapy, while infectious and delayed immune complications were similar. These findings provide important safety data for newer bispecific agents. Research Sponsor: None.

Outcome	Bispecific Antibodies (n = 384)	CAR-T (n = 384)	HR/RR [95% CI]
CRS (0–14 days)	25.3%	56.3%	0.45 [0.37-0.55]
CRS (0–60 days)	31.8%	59.6%	0.53 [0.45-0.63]
ICANS (0–30 days)	8.1%	22.4%	0.30 [0.20-0.47]
ICANS (0–60 days)	9.4%	26.0%	0.36 [0.25-0.51]
ICU admission (0–90 days)	12.0%	21.4%	0.56 [0.40-0.78]
Infections (0–90 days)	34.6%	32.6%	1.06 [0.87-1.30]
Neutropenia (0–90 days)	49.2%	89.6%	0.55 [0.49-0.61]
Hypogammaglobulinemia (0–180 days)	27.1%	33.6%	0.81 [0.65-1.01]
Overall Survival (0–90 days)	81.4%	93.2%	2.99 [1.89 – 4.73]

The influence of advanced age on outcomes in patients with diffuse large B-cell lymphoma treated with CAR-T therapy. First Author: Muqtasid Aftab Khan, University of Alabama at Birmingham Heersink School of Medicine - Huntsville, Department of Internal Medicine, Huntsville, AL

Background: Chimeric antigen receptor T-Cell (CAR-T) has emerged as a potentially curative treatment for diffuse large B-Cell lymphoma (DLBCL). The median age at DLBCL diagnosis is 66 years with nearly 30% of patients diagnosed at ≥75 years. Studies have examined outcomes of CAR-T therapy in DLBCL, with elderly patients (≥ 65 years) included in analyses; however, clinical trial populations have underrepresented the true age distribution of the disease. This study evaluates the impact of advanced age on survival and toxicity outcomes in patients with DLBCL treated with CAR-T therapy. **Methods:** A multicenter retrospective cohort study was conducted using TriNetX, a federated database of over 159 million de-identified electronic health record and claims data. Patients aged ≥75 years with DLBCL treated with CD19-directed CAR-T therapy were compared with a 1:1 propensity score–matched cohort of patients aged 18–65. Propensity score matching was performed based on demographics, comorbidities, and baseline laboratory values. Primary outcomes included 1-year and 3-year overall survival (OS), as well as the development of cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), and infection within 100 days following CAR-T infusion. Outcomes were assessed using Kaplan–Meier survival analyses, hazard ratios (HR), risk ratios (RR), and 95% confidence intervals (CI). **Results:** Prior to PSM, there were 326 patients ≥ 75 years and 816 patients aged 18-65 years who were treated with CD-19 directed CAR-T for DLBCL. After PSM, there were 241 patients in each cohort. There was no statistically significant difference in one-year or three-year overall survival between patients ≥ 75 years vs. 18-65 years (1-year HR: 0.89, 95% CI [0.63-1.26]; 3-year HR: 1.00, 95% CI [0.74-1.36]). Interestingly, patients ≥ 75 years were at a lower risk for the development of CRS compared younger patients (RR: 0.84, 95% CI [0.72, 0.98]). There was no statistically significant difference in the risk for development of ICANS (RR: 0.98, 95% CI [0.70–1.38]). Risk of infection at 100 days post-CAR-T infusion was lower in patients ≥ 75 years (RR: 0.75, 95% CI [0.58–0.95]). **Conclusions:** In this large multicenter real-world analysis, patients aged ≥75 years experienced comparable overall survival and no increased toxicity following CAR-T therapy for DLBCL. These findings suggest that advanced age alone should not preclude CAR-T eligibility and support broader consideration of CAR-T therapy in appropriately selected older adults. Research Sponsor: None.

Outcome	Age ≥75 (n=241)	Age 18-65 (n=241)	HR/RR [95% CI]
1-year OS	71.6%	68.6%	0.89 [0.63-1.26]
3-year OS	47.3%	53.7%	1.00 [0.74-1.36]
CRS	**52.3%**	**62.2%**	**0.84 [0.72–0.98]**
ICANS	21.6%	22.0%	0.98 [0.70–1.38]
Infection (≤100 days)	**30.3%**	**40.7%**	**0.75 [0.58–0.95]**

Immune priming with the EZH2 inhibitor tazemetostat in B-cell lymphomas receiving CAR T-cell therapy. First Author: Samuel Yamshon, Weill Cornell Medicine, New York, NY

Background: While chimeric antigen receptor (CAR) T cells have shown efficacy in B cell lymphomas, most patients (pts) still relapse. Preclinical studies have shown that inhibiting histone methyltransferase EZH2 prevents T cell exhaustion, promotes a T-cell memory phenotype, and sensitizes immune-based approaches. **Methods:** We administered the EZH2 inhibitor tazemetostat in pts receiving standard-of-care CART for diffuse large B cell, follicular, or mantle cell lymphoma (DLBCL, FL, MCL). Pts received tazemetostat for ≥7 days prior to apheresis and continued to lymphodepletion. Following CART, pts resumed tazemetostat at count recovery and continued for up to 12 mo (6 mo in pts with complete remission [CR]). Peripheral blood mononuclear cells were collected Day -24 and Day -5. To evaluate the immunomodulatory effects of priming, high parameter flow cytometry, RNA-seq with cell deconvolution, differential gene expression patterning, and functional gene signature scoring using ssGSEA were compared. **Results:** 13 pts enrolled (7 DLBCL, 5 FL, 1 MCL). Median prior lines of therapy were 2 (1-4), and 85% were refractory to the last therapy. *EZH2* mutations were present in 2 pts. 4 pts had *TP53* mutation or deletion, 4/7 DLBCL pts had *MYC* translocation and 3 had transformed disease. Five pts received axi-cel, 5 liso-cel, 2 tisa-cel, and 1 brexu-cel. All successfully completed CART manufacturing. The ORR was 100%, including 77% in CR (DLBCL 71%, FL 100%). At a median follow up of 18 months, 54% remain progression-free, and 77% remain alive. Ten pts (77%) experienced CRS, with 1 grade 3 CRS. 6 pts had transient grade 1-2 ICANS. Grade 3+ neutropenia was seen in 77%. Three pts experienced grade 3 infections. The most common AEs were gastrointestinal and almost exclusively grade 1-2. Comparing baseline and pre-CART samples, pts experienced a 14% and 20% increase in NK cells and CD16+ monocytes ($p < 0.03$) and a 14% and 53% decrease in Tregs and CD14+ monocytes ($p < 0.02$). Increases in the expression of functional gene signatures associated with MHC-I antigen presentation (p = 0.010), antigen-specific T cell activation (p = 0.019), and cellular cytotoxicity (p = 0.043) were also observed. Parallel reductions in signatures associated with tolerogenic dendritic cells (p = 0.011), myeloid suppression (p = 0.043), and coagulation (p = 0.030) were also seen. There was no observed negative impact on CART transduction efficiency, activation, or expansion. **Conclusions:** Addition of the EZH2 inhibitor tazemetostat is associated with high clinical efficacy and peripheral immune remodeling. Increases in lymphocyte activation and cytotoxicity along with decreases in myeloid tolerogenicity and immunosuppression could potentially augment CART expansion and persistence. Additional immune correlates are ongoing, and randomized studies are planned to validate this approach. Clinical trial information: NCT05934838. Research Sponsor: Ipsen.

Predictors of low- and high-grade ICANS after CAR-T: A nationwide analysis. First Author: Ashish Nepal, WellSpan York Hospital, York, PA

Background: Immune effector cell-associated neurotoxicity syndrome (ICANS) is a leading cause of morbidity following chimeric antigen receptor T-cell (CAR-T) therapy. However, the real-world predictors of severity remain incompletely defined. We evaluated whether ICANS risk differs between multiple myeloma (MM) and other CAR-T indications. **Methods:** CAR-T hospitalizations were identified using ICD-10-PCS procedure codes. ICANS was identified using ICD-10-CM grade-specific codes (G92.00–G92.05) and severity was graded as none, low-grade (1–2), or high-grade (3–5). The 2022–2023 Healthcare Cost and Utilization Project National Inpatient Sample (HCUP NIS) with discharge weights was used for this analysis. Multivariable multinomial (nominal) regression (reference outcome: no ICANS) estimated adjusted odds ratios (aORs) for low- and high-grade ICANS. Cancer type was modeled with MM as a reference and compared with lymphomas, leukemias, solid/metastatic malignancies, and unspecified/other malignancies, adjusting for prespecified comorbidities including dementia, diabetes, and substance use diagnoses. **Results:** Among 10,105 weighted CAR-T hospitalizations, the risk of high-grade ICANS varied significantly by cancer type. Relative to MM, high-grade ICANS was significantly higher in leukemia (aOR 5.23 (95% CI 3.81–7.16), $p < 0.001$); lymphoma (aOR 3.91 (95% CI 3.07–5.00), $p < 0.001$); solid/metastatic malignancy (aOR 1.92 (95% CI 1.30–2.83), p = 0.001); and unspecified/other malignancy (aOR 6.34, 95% CI 4.98–8.07, $p < 0.001$). For low-grade ICANS, lymphoma was associated with increased odds compared with MM (aOR 1.53, 95% CI 1.31–1.78; $p<0.001$). Comorbidity signals were dominated by baseline neurologic vulnerability and metabolic disease. Dementia was the strongest predictor of high-grade ICANS (aOR 7.54, 95% CI 4.13–13.78; $p<0.001$). Drug abuse was associated with increased odds of low-grade ICANS (aOR 2.68, 95% CI 1.45–4.97; p=0.002). Diabetes with complications was associated with both low-grade (aOR 1.49, 95% CI 1.24–1.79; $p<0.001$) and high-grade ICANS (aOR 1.63, 95% CI 1.33–1.99; $p<0.001$). **Conclusions:** In a nationally representative inpatient cohort, multiple myeloma (MM) was associated with significantly lower odds of high-grade ICANS compared with other CAR-T indications, especially leukemia and lymphoma. Dementia and complicated diabetes were highly predictive of high-grade ICANS across all cancer types. These findings identify a clinically actionable risk profile that may inform future risk-stratified monitoring and early intervention strategies as CAR-T use expands. Limitations include reliance on administrative ICD-10 coding, which may misclassify ICANS severity, the possibility of clinical confounding, and a lack of product-specific and other clinical granularity. Real-world outcomes of epcoritamab vs glofitamab in relapsed/refractory diffuse large B-cell lymphoma: A TriNetX retrospective study. First Author: Juhi Ardeshna-Chovatiya, University of California Riverside, Riverside, CA

Background: Glofitamab and epcoritamab are CD20-directed bispecific antibodies that engage CD3-positive T cells and are approved for relapsed/refractory diffuse large B-cell lymphoma (R/R DLBCL). While trials reported high response rates, real-world comparative data on survival, safety, and treatment complications are limited. We conducted a propensity score-matched analysis to compare the effectiveness and safety of glofitamab and epcoritamab in R/R DLBCL. **Methods:** We conducted a retrospective cohort study of adult relapsed/refractory diffuse large B-cell lymphoma patients treated with glofitamab or epcoritamab through January 2026 using the TriNetX network. Eligible patients had confirmed R/R DLBCL, $\geq$2 prior systemic therapies and $\geq$30 days follow-up. Data from 134 million patients across 70 US healthcare organizations were analyzed. Propensity-score matching was done for age, sex, race, comorbidities, prior CAR T, and prior therapies. Outcomes included overall survival, all-cause mortality, hematologic adverse events, CRS, ICANS, infections, and ICU admissions. **Results:** A total of 369 epcoritamab and 337 glofitamab patients met the inclusion criteria. After 1:1 propensity-score matching, 205 patients were included in each cohort. Median age was 68 years for glofitamab and 67.8 years for epcoritamab, with 62.9% vs 64.9% male. Median follow-up was 6.8 months vs 5.8 months. At 6 months, mortality was 29.3% versus 39.0% (RR 0.75, 95% CI 0.57-0.99; p=0.037), with estimated overall survival 68.1% versus 55.8% (HR 0.68, 95% CI 0.49-0.95; p=0.023). This benefit persisted at 12 and 24 months (estimated overall survival 54.0% vs 43.8% and 37.5% vs 33.3%, HR 0.73-0.75), though fixed-time risk differences were not significant. Any-grade CRS occurred in 22.4% vs 30.2% (RR 0.74, 95% CI 0.53-1.03; p=0.073), with grade $\geq$3 CRS not significantly different between cohorts. ICANS occurred in 7.3% vs 11.7% (RR 0.63, 95% CI 0.34-1.16; p=0.130), and tocilizumab use was comparable (20.0% vs 22.0%). Hematologic adverse events, including neutropenia (21.5% vs 26.8%), thrombocytopenia (34.1% vs 35.1%), anemia (35.1% vs 40.0%), and ICU admissions (19.0% vs 25.4%), were comparable and not significantly different. Infections were significantly lower with glofitamab (38.0% vs 48.8%, RR 0.78, 95% CI 0.62-0.98; p=0.028), supporting a favorable safety profile. **Conclusions:** In this real-world analysis, glofitamab and epcoritamab had similar safety profiles, with glofitamab showing lower early mortality and higher overall survival. Hematologic adverse events, CRS, ICANS, and ICU admissions were comparable, while infections were significantly lower with glofitamab. The selection of CD20$\times$CD3 bispecific antibodies should consider infection risk and early survival outcomes until longer follow-up clarifies durability and late toxicities. Research Sponsor: None.

Baseline phosphoproteomic signatures in peripheral blood and prediction of durable response to CAR T-cell therapy in B-cell malignancies. First Author: Christian A. Gordillo, Columbia University Irving Medical Center, New York, NY

Background: Despite the success of Chimeric Antigen Receptor (CAR) T-cell therapy, most patients fail to achieve durable remission. T-cell "fitness" is a critical, yet undercharacterized, determinant of efficacy. Standard immune and transcriptomic profiling do not measure the dynamic signaling networks driving cellular function. We hypothesized that baseline phosphoproteomic signatures in peripheral blood mononuclear cells (PBMCs) prior to CAR T-cell could serve as functional biomarkers for T-cell fitness, predicting durable response. **Methods:** We performed unbiased LC-MS/MS-based phosphoproteomics (KScan) on baseline PBMCs from 59 patients (39 Aggressive Lymphoma [DLBCL], 20 Multiple Myeloma [MM]) treated with CD19- or BCMA-directed CAR-T. Kinase Substrate Enrichment Analysis (KSEA) inferred upstream kinase activity. The primary endpoint was Complete Response (CR) at 6 months. We also analyzed a subset of DLBCL patients (n=6) who achieved CR at Day 30 but progressed (POD) by Month 6 ("early relapse") to identify markers of transient versus durable response. **Results:** We quantified 7,602 phosphopeptides. In the DLBCL cohort (20 CR, 17 POD), distinct phosphorylation in kinase signaling networks separated durable responders from non-responders, specifically implicating dysregulated stress response and MAPK signaling in resistance. KSEA revealed dysregulation in the MAPK/ERK, Casein Kinase (e.g., CSNK1E), and Cyclin-Dependent Kinase activity, linking baseline proliferative potential to long-term efficacy. Notably, the "early relapse" group (Day 30 CR / Month 6 POD) exhibited a unique profile, characterized by differential phosphorylation of proteins involved in apoptotic regulation and chromatin remodeling (e.g., FADD, ARID1A, ACIN1, KMT2A), suggesting these intrinsic defects may limit CAR T-cell persistence. Correlation analysis further integrated these signaling features with CD3+, CD4+, and CD8+ T-cell counts, validating their biological relevance. In the MM cohort, the signaling landscape was heavily dominated by immune cell composition. KSEA revealed that kinase activity in CR patients strongly correlated with the CD4:CD8 ratio and absolute CD3+ counts, validating that the captured phosphoproteomic variance reflects the underlying T-cell phenotype required for successful expansion and cytotoxicity. **Conclusions:** Baseline PBMC phosphoproteomics is a powerful tool for predicting CAR T-cell efficacy. We identified specific signatures—distinct from broad immune cell counts—that differentiate durable responders from patients at risk of primary refractory disease or early relapse. These targets highlight avenues for pharmacological conditioning to enhance T-cell fitness. These data support integrating functional proteomic biomarkers into patient stratification strategies to optimize outcomes. Research Sponsor: None.

Clonal hematopoiesis as a predictor of immune toxicity and efficacy after chimeric antigen receptor T-cell therapy: A systematic review and meta-analysis. First Author: Adam Bowen, McLaren Greater Lansing, Lansing, MI

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is associated with age-related inflammation and may influence immune toxicity and efficacy after CAR T-cell therapy, although reported associations are inconsistent. We performed a systematic review and meta-analysis to quantify CHIP associations with CAR-T toxicities and response. **Methods:** We conducted a systematic review and meta-analysis of comparative studies reporting CAR-T outcomes by sequencing-defined CHIP status. PubMed, Embase, Cochrane Central, and Web of Science were searched through 2025; nine observational studies were included from 3,529 records. The evidence comprised nine retrospective cohorts (n=869) of adults receiving commercial CD19 CAR-T for B-cell malignancies (mainly aggressive lymphoma/LBCL, B-ALL) or BCMA CAR-T for multiple myeloma. CHIP was identified from pre-infusion blood-derived samples using targeted myeloid sequencing, typically at VAF $\geq$2% (range $>$0.3%–$\geq$2%; one study $\geq$1%), with prevalence 16–56%. Primary endpoints were ASTCT grade $\geq$3 CRS and ICANS; secondary endpoints included CRS $\geq$2, any-grade ICANS, ORR, and CR. Risk ratios were pooled using random-effects Mantel–Haenszel models with prespecified subgroup and sensitivity analyses by CAR target/disease; risk of bias was assessed with ROBINS-I. **Results:** Four cohorts (n=360; 2 CD19, 1 BCMA, 1 mixed) contributed to primary toxicity analyses. CHIP was not associated with severe CRS (ASTCT $\geq$3; 8/172 vs 14/188; RR 0.72, 95% CI 0.24–2.13; I^2=31%) or severe ICANS (RR 1.16, 95% CI 0.48–2.81; I^2=39%), with wide confidence intervals reflecting low event counts. A CD19-restricted sensitivity analysis demonstrated higher risk of severe ICANS among CHIP-positive patients (RR 1.66, 95% CI 1.03–2.65; I^2=0%). For moderate-to-severe CRS (ASTCT $\geq$2), five cohorts (n=456) showed no association (RR 1.04, 95% CI 0.73–1.48; I^2=59%); exclusion of a mixed cohort reduced heterogeneity and remained null (RR 1.02, 95% CI 0.79–1.32; I^2=18%). Any-grade ICANS was not increased (six cohorts, n=440; RR 1.10, 95% CI 0.85–1.41; I^2=1%). Efficacy was preserved: ORR was modestly higher in CHIP-positive patients in full-text cohorts (n=347; RR 1.14, 95% CI 1.02–1.27; I^2=0%), with similar estimates when including abstract-only data (RR 1.10, 95% CI 1.01–1.21). CR showed a small overall increase (n=385; RR 1.24, 95% CI 1.01–1.52; I^2=15%) that was not robust on sensitivity analysis (RR 1.23, 95% CI 0.90–1.67). **Conclusions:** CHIP was not consistently associated with CRS severity or overall ICANS incidence after CAR-T therapy, although severe ICANS may be higher in CD19 CAR-T lymphoma. Efficacy was preserved in CHIP-positive patients, with no evidence of impaired ORR or CR, and observed response differences should be interpreted cautiously given observational design and heterogeneous definitions. Research Sponsor: None.

The impact of COVID-19 mRNA vaccination on bispecific antibody outcomes in hematologic malignancies: A retrospective multicenter cohort study. First Author: Mostafa Eysha, Texas Tech University Health Sciences Center El Paso, El Paso, TX

Background: Bispecific antibody (BsAb) therapies are universally available, off-the-shelf therapies and are increasingly being used in hematologic malignancies. However, long term efficacy, durability and survival data are lacking. Furthermore, widespread expansion is limited by immune-mediated toxicities, including cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), and infections. The real-world impact of mRNA SARS-CoV-2 vaccines on outcomes in patients receiving BsAb therapies remain unknown. **Methods:** We conducted a retrospective, propensity score-matched cohort study using the TriNetX federated electronic health record network. Adult patients with hematologic malignancies who received BsAb therapy were included and stratified by receipt of mRNA SARS-CoV-2 vaccines. Patients with documented COVID-19 infection or post-COVID-19 conditions were excluded. Cohorts were matched 1:1 on baseline demographic and clinical characteristics, yielding 238 patients per group, and followed longitudinally. Outcomes included all-cause mortality, any-grade CRS grade, and ICANS, graded per the ASTCT criteria. Associations were assessed using risk estimates and time-to-event analyses with Kaplan-Meier methods and Cox proportional hazards models. Event burden was evaluated by the number of events per patient among those experiencing CRS or ICANS. **Results:** All-cause mortality was lower in the vaccinated cohort compared with the unvaccinated cohort (21.4% vs 29.0%; p=0.057), with significantly improved survival on time-to-event analysis (hazard ratio [HR] 0.55; 95% CI, 0.38-0.79; log-rank p=0.001). The incidence of CRS grade 1/2 was similar between cohorts (25.2% vs 24.0%), with no difference in time to first CRS event (HR 0.98; 95% CI, 0.68-1.41). ICANS incidence was also comparable (10.9% vs 11.3%), with no significant difference in time-to-event (HR 0.87; 95% CI, 0.51-1.50). Among patients who developed ICANS, the vaccinated cohort experienced a higher mean number of ICANS episodes (2.58 vs 1.67; p=0.036) see (table1). **Conclusions:** In this propensity score-matched real-world analysis, mRNA SARS-CoV-2 vaccination was associated with significantly reduced all-cause mortality (HR, 0.55) among patients receiving BsAb therapy, without an increased risk of CRS grade 1/2 or ICANS. These findings support the safety of mRNA vaccination in this high-risk population and suggest a potential survival benefit necessitating prospective validation. Research Sponsor: None.

Outcome	Vaccinated (n=238)	Unvaccinated (n=238)	Key Effect
All-cause mortality	21.4%	29.0%	HR 0.55 (95% CI 0.38-0.79)
CRS grade 1/2	25.2%	24.0%	HR 0.98 (95% CI 0.68-1.41)
CRS grade 1/2 episodes (mean)	2.98	2.35	P=0.16
ICANS	10.9%	11.3%	HR 0.87 (95% CI 0.51-1.50)
ICANS episodes (mean)	2.58	1.67	p=0.036

Early toxicity, healthcare utilization, and survival after CAR T-cell therapy versus bispecific antibodies in DLBCL: A propensity-matched real-world analysis. First Author: Jatin Thukral, New York Medical College, Landmark Medical Center, Woonsocket, RI

Background: CD20×CD3 bispecific antibodies and CD19-directed CAR T-cell therapies are increasingly used in relapsed/refractory DLBCL. CAR T therapy is associated with higher rates of CRS,ICANS, and cytopenias, whereas bispecific antibodies are often perceived as less toxic and more outpatient-friendly. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. Adult patients with DLBCL treated with bispecific antibodies (glofitamab, epcoritamab) were compared with those receiving commercial CAR T-cell therapy (tisa, liso, axi). Propensity score matching was performed on demographics, comorbidities, baseline laboratory values, and corticosteroid exposure, yielding 468 patients per cohort. Outcomes included CRS, ICANS, severe neutropenia (ANC $<500/\mu L$), and thrombocytopenia (platelets $<50\times10^3/\mu L$), as well as hospitalization and ICU admission at 1, 3, 6, and 12 months. Overall survival (OS) was assessed using Kaplan–Meier analysis with log-rank testing. **Results:** After matching, CAR T therapy was associated with significantly higher immune-mediated toxicity. CRS occurred more frequently with CAR T at 1 month (37.4% vs 22.4%), 3 months (39.3% vs 27.6%), 6 months (40.6% vs 28.8%), and 12 months (41.2% vs 29.7%) (all $p<0.001$). ICANS was also more common with CAR T across all timepoints (1 month: 10.5% vs 4.9%; 12 months: 12.6% vs 7.5%). Severe neutropenia and thrombocytopenia were markedly more frequent in the CAR T cohort, with neutropenia affecting 66.7% vs 12.8% at 1 month and 71.6% vs 32.7% at 12 months (all $p<0.001$). Despite higher toxicity, healthcare utilization was comparable. Hospitalization rates were similar between groups at 1 and 3 months (61.8% vs 66.7% and 67.1% vs 75.9%), and ICU admission rates did not differ meaningfully at any timepoint. Importantly, overall survival consistently favored CAR T therapy. Survival differences emerged early and persisted over time, with lower mortality in the CAR T cohort at 1 month (2.1% vs 9.0%), 3 months (7.7% vs 18.6%), 6 months (15.8% vs 26.7%), and 12 months (26.5% vs 35.3%), corresponding to significantly improved OS by log-rank testing at all timepoints ($p<0.001$). **Conclusions:** In this large, real-world, propensity-matched analysis of relapsed/refractory DLBCL, CAR T-cell therapy was associated with substantially higher rates of CRS, ICANS, and severe cytopenias compared with bispecific antibodies. However, these toxicities did not translate into higher hospitalization or ICU utilization. Despite a less favorable early toxicity profile, CAR T therapy conferred a consistent and clinically meaningful survival advantage from early to late follow-up. Early toxicity alone should not preclude CAR T referral in appropriate candidates, underscoring the need for optimized patient selection, sequencing strategies, and supportive care. Research Sponsor: None.

Real-world impact of atrial fibrillation (AFib) on cardiovascular (CV) outcomes and healthcare resource utilization (HCRU) in patients with chronic lymphocytic leukemia (CLL). First Author: Michael Fradley, University of Pennsylvania School of Medicine, Philadelphia, PA

Background: While the association between AFib and CLL has been reported, real-world evidence on its clinical and economic impact is limited. This study evaluated impact of AFib on CV outcomes (stroke, bleeding, heart failure) and HCRU in patients (pts) with CLL overall, by age, and by Bruton tyrosine kinase inhibitor (BTKi) therapy. **Methods:** This retrospective observational study used the US Symphony database to identify adults newly diagnosed with CLL (2014-2024). Pts were followed for 1 year after CLL diagnosis to assess incidence of AFib. Subsequent CV outcomes (stroke, bleeding, heart failure) and HCRU (inpt, outpt, other services) were compared in CLL pts with and without AFib. Multivariate regression analyses assessed associations between AFib and outcomes. Subgroup analyses were conducted in elderly pts aged ≥65 years. Exploratory analyses compared first-line (1L) BTKi use (ibrutinib, acalabrutinib, or zanubrutinib). **Results:** In 233,362 newly diagnosed CLL pts, 13.1% had AFib within 1 year of CLL diagnosis. A significantly greater proportion of CLL pts with AFib had ≥1 inpt visit within 1 year of CLL diagnosis than those without AFib (54.9% vs 23.2%, $P<.0001$), as well as a higher likelihood to incur inpt service (OR: 2.28, 95%CI [2.21, 2.35], $P<.0001$). Significantly higher proportions of CLL pts with AFib had subsequent stroke (14.3% vs 8.9%), bleeding (27.9% vs 19.1%), and heart failure (54.5% vs 18.9%) than those without AFib ($P<.0001$). Age ≥65, male, non-white, and AFib were associated with subsequent stroke, bleeding, or heart failure ($P<.01$). Results were consistent in pts aged ≥65 years. In pts initiating 1L BTKi, AFib rate within 1 year of treatment for 1L zanubrutinib vs acalabrutinib vs ibrutinib was 11% vs 13% vs 16%, respectively; $P<.0001$. Compared to 1L ibrutinib and 1L acalabrutinib, a lower proportion of CLL pts with AFib treated with 1L zanubrutinib had subsequent stroke (12.2% vs 9.4% vs 4.8%, respectively), bleeding (27.4% vs 21.5% vs 17.4%), and heart failure (50.9% vs 45.6% vs 39.6%) ($P<.002$). CLL pts with AFib treated with 1L zanubrutinib had less inpt services than 1L ibrutinib and 1L acalabrutinib within 1 year of BTKi treatment (46.4% vs 51.5% vs 60.4%; $P<.0001$). In multivariate regression, 1L acalabrutinib pts had 29% higher odds than 1L zanubrutinib pts (OR: 1.29, 95% CI [1.12, 1.50], $P=.0005$); 1L ibrutinib pts had 69% higher odds than 1L zanubrutinib pts (OR: 1.69, 95% CI [1.48, 1.93], $P<.0001$) to incur inpt service within 1 year after initiating BTKi treatment. **Conclusions:** Findings highlight significant real-world CV and HCRU burden incurred by CLL pts with AFib. Exploratory analyses suggested 1L zanubrutinib may offer potentially favorable outcomes over other BTKi in lessening AFib and related clinical and HCRU complications. Future studies with longer follow-up are warranted to confirm these findings. Research Sponsor: BeOne Medicines, Ltd.

7043 **Poster Session**

Effect of first-line treatment of CLL/SLL with the all-oral combination of sonrotoclax (sonro) and zanubrutinib (zanu) on minimal residual disease (uMRD) rates, including in patients with del(17p)/TP53. First Author: Constantine Si Lun Tam, Alfred Hospital and Monash University, Melbourne, VIC, Australia

Background: Oral, fixed-duration BTKi-BCL2i combinations are effective and convenient options for first-line treatment of CLL. However, all current regimens, including those using second-generation BTKi, are limited by low uMRD rates of 29-47%. We hypothesize that upgrading the BCL2i component of BTKi-BCL2i with sonro, a next generation BCL2i with ~14x pharmacological potency compared with venetoclax, may lead to improved uMRD rates. Here, we report updated safety and efficacy results in patients with treatment-naive CLL/SLL treated with zanu+sonro (320 mg cohort) in a phase 1/1b study (NCT04277637), with a median follow-up of 30.9 months (range, 3.1-41.9 months). **Methods:** Study treatment consisted of lead-in zanu 320 mg QD for 8-12 weeks, after which sonro was added with a ramp-up to the target dose of 320 mg QD. Patients were treated until progression, unacceptable toxicity, or protocol-defined elective discontinuation after 96 weeks of combination treatment at target dose. Primary endpoint was safety per NCI-CTCAE v5.0. Secondary endpoints included overall response rate (ORR). Exploratory endpoints included uMRD4 rates in peripheral blood per flow cytometry and next generation-sequencing (NGS). **Results:** Of the 86 patients enrolled in the sonro 320 mg cohort, 45 (52%) remained on treatment at data cut-off, and 40 (47%) discontinued sonro, most due to protocol-defined elective discontinuation (85%; n=34). The most common (≥30%) any-grade treatment-emergent adverse events (TEAEs) were neutropenia (38%), contusion (38%), COVID-19 (33%), and upper respiratory tract infection (30%). Neutropenia was the most common grade ≥3 TEAE (29%). No TLS occurred, and no AEs led to death. In 84 efficacy-evaluable patients, the ORR was 100%, with 46 (55%) achieving complete response. Median time to response was 2.6 months (range, 1.5-9.1 months). No patients in the 320 mg cohort experienced progression with an estimated 30-month PFS of 100%. The best uMRD4 rate assessed by flow cytometry was 99% (83/84) and 100% (10/10) in patients with *TP53*/del(17p) mutations. Median time from reaching sonro target dose to uMRD was 3.0 months (range, 2.3-27.4 months), and the best uMRD4 rates by weeks 24, 48 and 96 were 81% (69/85), 91% (63/69) and 98% (55/56), respectively. No patient with uMRD4 reverted to MRD4+. In the NGS evaluable set, best uMRD5 ($<10^{-5}$) was 86% (66/77). Updated results will be presented. **Conclusions:** Sonro+zanu was well tolerated and achieved uMRD rates of >90%, including in patients with high-risk cytogenetics. The depth and kinetics of uMRD achieved with sonro+zanu highlights the improved potency and differentiated profile of this combination vs available combination therapies in first-line CLL. Sonro+zanu is being evaluated in two phase 3 clinical trials (NCT06073821, NCT07277231). Clinical trial information: NCT04277637. Research Sponsor: BeOne Medicines, Ltd.

Pirtobrutinib in treatment-naïve patients with CLL/SLL: Pooled results from BRUIN CLL-313 and BRUIN CLL-314. First Author: William G. Wierda, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Pirtobrutinib, a highly selective, non-covalent Bruton tyrosine kinase inhibitor (BTKi), is approved globally for patients (pts) with chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) previously treated with a covalent BTKi. BRUIN CLL-313 and BRUIN CLL-314 are open-label, randomized phase 3 studies evaluating pirtobrutinib for therapy of pts with CLL/SLL, including in the treatment-naïve (TN) setting [versus bendamustine plus rituximab (BendaR; CLL-313, NCT05023980) and versus ibrutinib (CLL-314, NCT05254743)]. **Methods:** Pooled data from TN CLL pts randomized to receive pirtobrutinib from CLL-313 and CLL-314 were used to assess efficacy [overall response rate (ORR), progression-free survival (PFS) and overall survival (OS)] and safety. PFS and OS estimates were calculated by the Kaplan-Meier method. All pts (253) randomized within each study to receive pirtobrutinib are included in efficacy analyses and all pts (252) who received pirtobrutinib treatment are included in safety analyses. **Results:** A total of 253 TN pts, median age of 66 yrs, were assigned to receive pirtobrutinib (CLL-313 n=141; CLL-314 n=112); all but one received treatment. Among pts with evaluable samples 134/233 (58%) had unmutated IGHV, 14/253 (6%) had del(17p) and 21/220 (10%) had mutated TP53. Efficacy was consistent between the two studies (Table). Overall, ORR was 93.3%. Median PFS was not reached; the 24-month PFS rate was 93.2% (95%CI, 89.1-95.8). Median OS was also not reached; the 24-month OS rate was 97.5% (95%CI, 94.6-98.9). Median duration of therapy was 29.1 months. Treatment discontinuation due to TEAEs occurred in 4.8% of pts with 1.6% treatment related. Any-grade infection occurred in 59.9% of pts; neutropenia in 18.3% and grade ≥3 bleeding in 2.4%. Any-grade hypertension occurred in 10.7% of pts and atrial fibrillation/flutter was reported in 2.8%. **Conclusions:** In 253 TN pts with CLL randomized on two phase 3 studies, pirtobrutinib showed a high ORR and favorable 24-month PFS and OS rates. The safety profile was consistent with prior studies using pirtobrutinib in more heavily treated pts, with low rates of atrial fibrillation/flutter, hypertension and TEAE-related discontinuations. These findings reinforce the potential of pirtobrutinib as a meaningful and clinically relevant treatment option for pts with TN disease. Clinical trial information: NCT05023980 and NCT05254743. Research Sponsor: Eli Lilly and Company.

Efficacy of pirtobrutinib in TN patients with CLL/SLL.

	Parameter	CLL-313 N = 141	CLL-314 N = 112	Pooled TN pts N=253
ORR	ORR, % (95% CI)	94.3 (89.1, 97.5)	92.0 (85.3, 96.3)	93.3 (89.5, 96.0)
PFS	24-month PFS rates, % (95% CI)	92.7 (86.8, 96.0)	94.3 (87.8, 97.4)	93.2 (89.1-95.8)
	Median FU, months	28.1	22.4	27.7
OS	24-month OS rates, % (95% CI)	97.8 (93.3, 99.3)	97.2 (91.5, 99.1)	97.5 (94.6-98.9)
	Median FU, months	32.7	26.7	29.5

ORR includes a best response of partial response or better.

Real-world treatment and survival outcomes for zanubrutinib (zanu) and acalabrutinib (acala) monotherapy among treatment-naive patients with chronic lymphocytic leukemia (CLL) in the United States. First Author: Ryan Jacobs, Atrium Health Levine Cancer Institute, Wake Forest University School of Medicine, Charlotte, NC

Background: Bruton tyrosine kinase (BTK) inhibitors are central to the management of CLL/SLL (hereafter referred to as CLL). Acala was approved for CLL in the US in 2019, followed by zanu in 2023. Despite their widespread use, real-world evidence comparing therapy effectiveness is limited. This US-based study compared the real-world effectiveness of zanu and acala monotherapy as first-line treatment for patients with CLL based on overall survival (OS) and time to next treatment (TTNT). **Methods:** This retrospective analysis utilized the Komodo claims database between January 2015 and August 2025. Eligible patients were adults (aged ≥18 years) in the US with ≥2 diagnoses of CLL or SLL, who were treatment naive for CLL and had an index claim for monotherapy with zanu (January 2023 to August 2025) or acala (November 2019 to August 2025). The index date was defined as the date of the first observed claim for the respective therapy. Patients were required to have continuous enrollment or activities within 1 year prior to and 3 months after the index date. Patients with evidence of clinical trial participation, prior CLL/SLL treatment, or two diagnoses of mantle cell lymphoma between January 2015 and the index date were excluded. Outcomes included OS (measured from index claim to all-cause mortality), and TTNT (measured from index claim to initiation of subsequent therapy or death). If death did not occur, patients were censored at the date of last activity or the enrollment end date. For OS analysis, Komodo data captured the death date, but not the cause of mortality. Survival analyses were conducted using Kaplan-Meier estimates and Cox proportional hazards models. Inverse probability of treatment weighting (IPTW) was adjusted for age, sex, US region, treatment initiation year, and Charlson Comorbidity Index (CCI). **Results:** Among 16,788 patients (zanu, n=5819; acala, n=10,969), median age was higher in zanu (73.3 years) vs acala (71.8 years) cohorts. Most patients were male (acala, 62%; zanu, 59%), non-Hispanic white (acala, 73%; zanu, 72%), and the median CCI was 2 in both cohorts. Median follow-up was 12.8 and 16.4 months for in zanu and acala cohorts, respectively. Median TTNT and OS were not reached for either cohort. With the unadjusted model, zanu had a longer TTNT (unadjusted HR, 0.88; 95% CI, 0.79-0.97; P=.009) and OS (HR, 0.72; 95% CI, 0.62-0.82; P<.001). After IPTW adjustment, zanu was associated with a significantly improved OS (IPTW-adjusted HR, 0.75; 95% CI, 0.65-0.86; P<.001) and TTNT (IPTW-adjusted HR, 0.89; 95% CI, 0.80-0.98; P=.02) compared with acala. **Conclusions:** In this real-world analysis, zanu monotherapy demonstrated significantly longer TTNT and improved OS compared with acala monotherapy. These findings suggest that zanu may offer superior outcomes in the real-world setting. Research Sponsor: BeOne Medicines, Ltd.

7046 **Poster Session**

Subsequent therapies and time to second progression-free survival events (PFS2) in treatment-naive chronic lymphocytic leukemia/small lymphocytic lymphoma (TN CLL/SLL) previously treated with zanubrutinib (zanu) or bendamustine-rituximab (BR) in SEQUOIA. First Author: Constantine Si Lun Tam, Alfred Hospital and Monash University, Melbourne, VIC, Australia

Background: Cohort 1 of the phase 3 SEQUOIA trial assessed zanu, a next-generation BTKi, compared to BR in TN CLL/SLL without del(17p). Zanu previously demonstrated sustained superiority in progression free survival (PFS) and time to next treatment (TTNT) vs BR. However, evidence regarding outcomes on subsequent therapies (tx) after progressive disease (PD) on zanu remain limited. Here, we present results on follow-up (FU) tx after zanu, including PFS2. **Methods:** Pts without del(17p) were randomized to receive continuous zanu or six cycles of BR. Pts who received BR could crossover to receive zanu after PD. All pts were followed post-PD for details on any subsequent anti-CLL treatments. This analysis evaluated PFS, TTNT, TTNT or death (TTNT-D) and PFS2. P-values are descriptive. **Results:** In total 479 pts were randomized; 241 to zanu and 238 to BR. Baseline demographics and disease characteristics were well balanced between the arms. As of 31 October 2025, median FU was 78.7mo (range, 0.0-96.0). Sustained PFS superiority with zanu vs BR was observed (HR, 0.28; 95% CI, 0.21-0.38; P<.0001) with 78mo PFS estimates of 70.9% (95% CI, 64.2-76.6) for zanu and 28.6% (21.7-35.8) for BR. Overall, 211/241 (87.6%) of pts treated with zanu had not received subsequent tx and 34 pts had died without subsequent tx. TTNT and TTNT-D favored zanu over BR (HR, 0.23 [95% CI, 0.15- 0.35; P<.0001] and 0.37 [0.27-0.50; P<.0001], respectively). Overall, 24/241 (10.0%) zanu pts and 82/238 (34.0%) BR pts had PD after study treatment and received subsequent tx. Of the 24 zanu pts receiving subsequent tx after PD, 13 (54.2%) received BCL2i-based regimens, 8 (33.3%) received chemoimmunotherapy (CIT) (incl. anti-CD20 antibody monotherapy), and 3 (12.5%) received BTKi. Of the 82 BR pts receiving subsequent tx after PD, 77 (93.9%) received BTKi (incl. 71 crossover pts), 3 (3.7%) received BCL2i-based regimens and 2 (2.4%) received CIT. Median time from PD following first tx to initiation of next tx was 2.1mo for zanu (range 0-25.7) and 7.4mo (0.3-48.0) for BR. Zanu pts who had PD and received subsequent BCL2i-based tx had a median FU of 33.5mo from initiation of next-line tx. Among these pts, 10 remain alive and without PD, two had died, and one had PD. Overall, PFS2 significantly favored zanu over BR (HR, 0.66; 95% CI, 0.45-0.98; P<.05) with 78mo PFS2 estimates of 81.3% (95% CI, 75.6-85.8) vs 73.8% (67.2-79.3), respectively. **Conclusions:** PFS2 remained superior with zanu despite broad use of novel subsequent tx (including crossover) in BR pts. Importantly, BCL2i-based salvage after initial zanu achieved high PFS rates at almost 3 years of FU. Together, these findings support that initial zanu provides durable benefit while preserving sensitivity to effective subsequent tx. Clinical trial information: NCT03336333. Research Sponsor: BeOne Medicines, Ltd.

Real-world outcomes among Medicare beneficiaries treated with first-line (1L) Bruton tyrosine kinase inhibitors (BTKis) for chronic lymphocytic leukemia (CLL). First Author: Daniel Arthur Ermann, Huntsman Cancer Institute, University of Utah School of Medicine, Salt Lake City, UT

Background: Covalent BTKi monotherapies are standard of care for 1L CLL in the US. However, there is a lack of head-to-head BTKi trials in the 1L setting, and previous real-world studies had limited sample size and follow-up time. We used a large US database to evaluate clinical outcomes among patients (pts) treated with BTKis for 1L CLL. **Methods:** This retrospective cohort study utilized the de-identified Medicare Fee-For-Services database. Eligible pts included those with a CLL/SLL diagnosis at age ≥65 y who started 1L BTKi monotherapy between 01/01/2020 and 06/30/2025 and ≥12 months (mos) enrollment pre-1L. Outcomes included real-world overall survival (OS), time to next treatment (tx) or death (TTNT), and time to tx discontinuation or death (TTD) from 1L start. Landmark tx and survival probabilities at 12 and 24 mos were estimated using Kaplan–Meier methods. Adjusted hazard ratios (aHRs) and 95% CIs were estimated using Cox proportional hazard models, adjusting for age, sex, race/ethnicity, Charlson Comorbidity Index (CCI) and year of 1L start. Subgroup analysis was performed by age groups (65-74, 75-84, ≥85 y). **Results:** A total of 10,523 pts were included (zanubrutinib [zanu]:3006; acalabrutinib [acala]: 4309; ibrutinib [ibr]:3208). Median age at 1L was 77 y for zanu and acala, and 76 y for ibr. Most pts were male (58%), non-Hispanic White (91%), and resided in urban areas (78%). Median CCI score was 4 for zanu and acala, and 3 for ibr. At baseline, hypertension was 65% overall, and atrial fibrillation was 17% for zanu and acala, and 12% for ibru. Median follow-up was 16 mos (range: 0-61) for zanu, 21 mos (0-69) for acala and 35 mos (0-69) for ibr. Median OS was not reached (NR) for all groups. Median TTNT was NR for zanu (95% CI, 45-NR), 40 mos (38-42) for acala, and 30 mos (29-32) for ibr. Median TTD was NR (NR-NR) for zanu, 24 mos (22-25) for acala, and 14 mos (13-15) for ibr. Pts on zanu had higher probability of survival, not advancing to next line of therapy and not discontinuing tx at 12 and 24 mos, than those receiving acala and ibr (Table; with 95% CIs). After adjusting for baseline factors and year of 1L, pts on zanu had a statistically significantly lower risk of death, advancing to next line, or discontinuing tx, than those on ibr or acala. Similar results were observed across age subgroups. **Conclusions:** In this large cohort of pts aged ≥65 yrs with longest follow up to date, zanu monotherapy was associated with better survival and tx outcomes, compared to ibr and acala. Research Sponsor: BeOne Medicines, Ltd.

Targeted combination therapies for untreated chronic lymphocytic leukemia: A network meta-analysis of randomized trials. First Author: Owais Gul, United Health Services Hospitals, Johnson City, NY

Background: Treatment options for previously untreated chronic lymphocytic leukemia (CLL) have expanded to include both fixed-duration venetoclax-based combinations and continuous Bruton tyrosine kinase (BTK) inhibitor therapy. While both approaches improve outcomes compared with chemoimmunotherapy, their relative benefits and risks have not been well defined. We performed a network meta-analysis to compare the efficacy and safety of these frontline targeted strategies. **Methods:** We searched MEDLINE, Embase, PubMed, the Cochrane Library, Web of Science, and major oncology conference proceedings from inception through November 2025. Phase II–III randomized trials enrolling treatment-naïve adults with CLL and evaluating venetoclax-based combinations or continuous BTK inhibitor–based regimens were included. A frequentist random-effects network meta-analysis was conducted. Treatment effects were summarized using hazard ratios (HRs) for progression-free survival (PFS) and risk ratios (RRs) for grade $\geq$3 adverse events. **Results:** Eight randomized trials including 3,056 patients and five treatment regimens were analyzed. All targeted therapy–based regimens significantly improved PFS compared with chlorambucil plus obinutuzumab. The greatest PFS benefit was observed with ibrutinib plus obinutuzumab (HR 0.41; 95% CI, 0.29–0.59), followed by venetoclax plus ibrutinib and venetoclax plus obinutuzumab. Acalabrutinib plus obinutuzumab also significantly reduced the risk of progression (HR 0.52; 95% CI, 0.41–0.67). No significant inconsistency was detected across the treatment network. Safety outcomes varied by regimen, reflecting differences in treatment duration and mechanism of action. **Conclusions:** In previously untreated CLL, fixed-duration venetoclax-based combinations achieve PFS outcomes comparable to continuous BTK inhibitor–based therapy, with distinct safety and treatment exposure profiles. These findings support personalized frontline treatment selection based on patient comorbidities, tolerability, and preference for time-limited therapy. Research Sponsor: None.

Outcome comparison of once versus twice daily dosing of zanubrutinib. First Author: Allison Kagerer, Weill Cornell Medicine, New York, NY

Background: Zanubrutinib, a Bruton tyrosine kinase inhibitor (BTKi), approved as frontline treatment in chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), can be dosed as 320mg once daily (QD) or 160mg twice daily (BID). In phase I trials 160mg BID and 320mg QD achieved comparable BTK occupancy in peripheral blood. While most clinical trials utilized BID dosing, there is limited data evaluating outcomes between regimens. Thus, we performed a retrospective study comparing outcomes of QD vs BID dosing of zanubrutinib in frontline CLL/SLL patients (pts). **Methods:** We conducted a single center retrospective study evaluating pts with CLL/SLL treated with zanubrutinib QD vs BID at Weill Cornell Medical Center (May 1, 2020 - Feb 1, 2025). Included CLL/SLL pts were treated with frontline zanubrutinib and separated into 3 groups: 320mg QD (Group 1), 160mg BID (Group 2) and dose switch (Group 3). Pearson's Chi-squared test and Fisher's exact test were used to compare baseline characteristics. Progression-free survival (PFS) and overall survival (OS) were evaluated with Kaplan-Meier (KM) method and log-rank test was used to compare KM curves; however, few events limited statistical power and prevented formal survival comparison and are presented as descriptive only. The median follow-up time was estimated by reverse KM method. **Results:** We identified 23 pts initiated on QD dosing, 43 pts initiated on BID dosing, and 33 pts who switched groups. Thirty pts switched from BID to QD and 3 pts from QD to BID. Median follow up time was 28.4 months. Median overall age was 71 with 60% male. There were no differences in age, sex, immunoglobulin heavy chain gene (IGHV) mutational status or incidence of complex karyotype, del11q, del13q, del17p, trisomy 12 and *TP53* mutations. There was 1 death (Group 2) due to a second cancer. OS KM curves visually appeared similar (p=0.62). One pt in Group 2 and 2 pts in Group 3 progressed on zanubrutinib. PFS KM curves were visually similar (p=0.88). Twenty-two (22.2%) pts discontinued therapy due to intolerance. In Group 1, one pt (4.3%) discontinued for hypertension (HTN). In Group 2, 17/43 (39.5%) pts discontinued for rash (29.4%), infection (17.6%), bruising/bleeding (17.6%), HTN (11.7%), atrial fibrillation (11.7%) and diagnosis of second cancer (11.7%). In Group 3, 4/33 (12.1%) pts stopped for rash (50%) and HTN (50%). Zanubrutinib cessation was lower in QD vs BID ($p < 0.002$). **Conclusions:** We retrospectively compared QD vs BID dosing of zanubrutinib to evaluate impact on outcomes. While lack of progression and death limited our ability to make definitive statements on PFS or OS, we observed overlap of KM curves with 2 years of follow-up. We observed a lower treatment discontinuation rate with QD dosing. Our results suggest QD dosing in frontline CLL/SLL may improve tolerability while maintaining comparable efficacy. Further research is needed to confirm real-world non-inferiority of these safety and survival outcomes. Research Sponsor: None.

Hematologic and cardiovascular outcomes of SGLT2 inhibitors in patients with chronic lymphocytic leukemia and type 2 diabetes: A real-world TriNetX analysis. First Author: Safa Saadat Afridi, SUNY Upstate Medical University, Syracuse, NY

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) exhibit biologically plausible metabolic and immunomodulatory effects beyond glycemic control that may be relevant in chronic lymphocytic leukemia (CLL), by reducing insulin resistance, activating AMPK signaling, suppressing downstream PI3K/AKT/mTOR activity, and improving cellular metabolic homeostasis. SGLT2i also decrease systemic and adipose-derived inflammation by inhibiting the NLRP3 inflammasome, reducing IL-6 and TNF-α levels, and mitigating oxidative stress. Improved mitochondrial efficiency and modulation of HIF-1α signaling may influence leukemic cell survival and immune exhaustion, suggesting a plausible role for SGLT2i in reducing infection risk, cardiovascular events, and survival outcomes in patients with CLL. However, real-world clinical evidence remains limited. **Methods:** We conducted a retrospective cohort study using the TriNetX Analytics Network to evaluate outcomes associated with SGLT-2i use in adults with CLL and type 2 diabetes mellitus. SGLT-2-exposed and non-exposed cohorts were compared for infectious complications, hematological outcomes like cytopenias, cardiovascular (CV), and all-cause mortality. Propensity score matching minimized confounding due to contemporary CLL therapies, baseline demographics, comorbidities, and treatment-related outcomes. Time-to-event outcomes were analyzed using Kaplan-Meier and Cox models. **Results:** After propensity score matching, with comparable mean short and long term follow durations (60-821 days), SGLT2 inhibitor use was associated with a significantly lower risk of pneumonia (5.4% vs 8.0%; HR 0.70, 95% CI 0.56-0.89) and CV mortality (13.9%, vs 21.9%) with improved survival on KM analysis ($p<0.001$; HR-0.70, 95% CI 0.59-0.83). A modest reduction in sepsis was observed in SGLT2i users (4.7% vs 6.0%), but did not reach statistical significance (HR 0.82, 95% CI 0.65-1.05). All-cause mortality was numerically lower in the SGLT2 cohort (7.4% vs 8.5%), but no significant difference in survival was observed (HR 0.91, 95% CI 0.76-1.10). The SGLT2i group showed lower thrombocytopenia risk and a similar rare risk of AIHA between the two cohorts, with no significant difference in time-to-event analysis, suggesting that SGLT2 inhibitors may preferentially reduce selective infectious complications and CV mortality without significant improvement in overall mortality. **Conclusions:** SGLTI might have biologically plausible cardioprotective, metabolic, and immunomodulatory effects that may improve outcomes related to inflammation and infection, and reduce CV mortality in CLL, without a demonstrable short-term overall mortality benefit. Longer follow-up and prospective studies are needed to define the durability of these effects and their impact on survival. Research Sponsor: None.

Impact of SGLT2 inhibitors on clinical outcomes in diabetic patients with CLL receiving BTK inhibitors: A global propensity-matched study. First Author: Angimar Uriepero-Palma, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Diabetic patients with chronic lymphocytic leukemia (CLL) receiving Bruton's tyrosine kinase inhibitors (BTKi) face intersecting challenges of metabolic dysfunction, immune dysregulation, and treatment-related toxicities, including cardiovascular complications and increased susceptibility to infections. Sodium–glucose cotransporter 2 inhibitors (SGLT2i), have emerged as a pleiotropic cardio-renal-metabolic therapeutic class with benefits extending beyond glycemic control. We hypothesize that early initiation of SGLT2i in diabetic patients with CLL may mitigate BTKi–associated toxicities and improve long-term treatment tolerability and clinical outcomes. **Methods:** We used the TriNetX Global Collaborative Network to identify patients with CLL (C91.1, C83.00) and diabetes (E08–E13) treated with BTK inhibitors (ibrutinib, acalabrutinib, or zanubrutinib), comparing those with and without SGLT2 inhibitor exposure. Propensity score matching adjusted for demographic, metabolic, cardiovascular, and renal confounders, as well as hypoglycemic and cardiovascular medications. After matching, 1,102 patients (551 per cohort) were included. Outcomes were assessed within 3 years of the index event, and hazard ratios (HRs) with 95% confidence intervals were estimated. **Results:** The 3-year all-cause mortality was significantly lower with concurrent BTKi and SGLT2i compared with BTKi alone (HR 0.50, 0.38–0.66), corresponding to a 3-year overall survival of 77% versus 62% ($p < 0.0001$). Hematologic toxicity was also significantly lower in the SGLT2i cohort, including grade 3 thrombocytopenia (HR 0.632, 0.461–0.866), grade 3 anemia (HR 0.532, 0.422–0.671), and neutropenia (HR 0.618, 0.419–0.911). Infectious complications were less frequent in the SGLT2i group, with a significant decrease in neutropenic fever (HR 0.393, 0.221–0.698), sepsis (HR 0.686, 0.504–0.934), and pneumonia (HR 0.65, 0.506–0.835). Likewise, a lower incidence of Deep vein thrombosis and pulmonary embolism was found in the SGLT2i cohort (0.555, 0.35–0.879). Surprisingly, cardiovascular outcomes were not significantly different between groups, including hypertension (HR 1.10, 0.961–1.278), atrial fibrillation (HR 1.073, 0.86–1.339), and heart failure (HR 1.128, 0.919–1.385). **Conclusions:** SGLT2i use was associated with significantly longer 3-year overall survival and lower hazards of severe cytopenias and serious infections in diabetic patients with CLL receiving BTK inhibitors, with no meaningful differences in major cardiovascular outcomes. The mechanisms underlying these associations is unclear; however, emerging evidence suggests that SGLT2i may exert immunomodulatory effects and have been shown to reduce tumor cell proliferation in breast cancer models. Further studies are warranted to confirm the role of SGLT2i in diabetic CLL patients. Research Sponsor: None.

Real-world overall survival outcomes of BTK inhibitors vs. venetoclax-based therapy as second-line treatment for chronic lymphocytic leukemia. First Author: Mariah Black, Texas Tech University Health Sciences Center El Paso, El Paso, TX

Background: Chronic lymphocytic leukemia (CLL) is a B-cell malignancy with highly variable clinical behavior. The treatment landscape has shifted from chemo-immunotherapy to targeted agents, specifically Bruton's tyrosine kinase inhibitors (BTKi) and venetoclax (BCL-2 inhibitor). While both are established first-line options, the optimal treatment sequence to maximize long-term survival remains undefined. This real-world analysis evaluates overall survival (OS) when utilizing BTKi or venetoclax-based therapy as second-line (2L) treatment. **Methods:** This retrospective, propensity-matched cohort study utilized de-identified electronic medical record data from the TriNetX network (through Jan. 2026), covering 189 million patients. Adult patients with CLL (ICD-10: C91.1) were identified based on treatment sequencing of 1L BTKis followed by 2L Venetoclax or vice-versa. The index event was the initiation of 2L therapy with either a BTKi or venetoclax. Patients receiving traditional chemotherapy were excluded from analysis. To minimize confounding, 1:1 Propensity Score Matching (PSM) was performed using a greedy nearest-neighbor algorithm based on demographics (age, sex, race/ethnicity) and comorbidities (hypertension, ischemic heart disease, diabetes, CKD, COPD, obesity). Standardized mean differences (<0.1) confirmed covariate balance. The primary endpoint was OS through 10 years. **Results:** A total of 5,841 patients met inclusion criteria (BTKi n=2,589; venetoclax n=2,892). After PSM, 1,959 patients were included per cohort. Ten-year OS was significantly higher in patients receiving BTKi as 2L therapy compared to venetoclax (71.5% vs. 68.0%; HR 0.651, 95% CI 0.55-0.77; $p<0.0001$). Median follow-up duration was longer for the BTKi group (1,287 days) than the venetoclax group (639 days). **Conclusions:** In this real-world analysis, treatment sequence with Venetoclax (1L) and BTKis (2L) was associated with a significant long-term survival advantage compared to venetoclax. The observed reduction in mortality risk (HR 0.651) suggests that treatment sequencing of immunotherapy with Venetoclax followed by a BTKi may offer superior clinical outcomes for treatment of CLL. While these results support preferential sequencing of BTKis after venetoclax, additional prospective studies are needed for further evaluation and confirmation. Research Sponsor: None.

Modern Hodgkin lymphoma treatments to reduce second cancer risks: Influence of risk-adapted screening. First Author: Aislinn Macklin-Doherty, Institute of Cancer Research / Royal Marsden Hospital, London, United Kingdom

Background: Second primary malignancies (SPMs) are the leading cause of long-term treatment-related mortality in Hodgkin Lymphoma (HL). Although substantial improvements have been made to treatments over recent decades, few studies have demonstrated reduced SPM risk, particularly following modern treatments, and how risks should inform screening. **Methods:** We assembled a national cohort of 7,428 women treated for HL aged <36 across England & Wales 1954-2010, with 99% complete follow-up until 2018. We analyzed SPM incidence from national cancer registry linkage. Treatment data were collated from >250 treatment centers. Standardized incidence ratios (SIRs) and Absolute Excess Risks (AERs) for SPMs were calculated, and multivariable analyses (Hazard Ratios, HR) were undertaken to assess the impact of changes in treatment and assess changing incidence trends over time. **Results:** Twelve hundred women (16%) developed 1,467 SPMs with mean follow-up of 22 years (range 0-62 years). Overall SIR to develop any SPM was 3.3 (95% CI 3.1-3.5), with breast cancer contributing the greatest excess risk (AER 30.8 95% CI 27.7-34.1). Radiotherapy use halved from 1954-1980 to 2000-2010 (98% to 47%) and mean dose dropped from 48Gy to 33Gy. Conversely chemotherapy use doubled from 55% to 97%, with anthracyclines used in 94% and classic alkylators in 31% of treatments in the most recent period compared with 6% and 48% respectively pre-1980. Radiotherapy conferred the greatest treatment-specific risk factor for SPMs, (SIR 3.5 95% 3.3-3.7), with a strong dose-response relationship trend (HR 1.01/Gy $p<0.001$), and highest relative risks seen in those treated with radiotherapy aged <15years (SIR 7.4 (95% CI 5.7-9.1). There was a 25% reduction in SPM risk from the earliest treatment period (<1990) to most recent (2000-2010) and 34% reduction in solid SPM risk (Table). The decrease in risk for SPMs became smaller and non-significant after adjusting for reduced radiotherapy use and dose (HR 0.89, p_{trend} 0.11). There was no attenuation after adjustment for chemotherapy. Despite declining risks, risks remained significantly elevated beyond 40 years after treatment. **Conclusions:** Modern HL treatments are associated with a substantial reduction in SPM risks, which appears to be largely attributable to decreased radiotherapy use and dose. However large persistent excess risks, particularly for breast and lung cancers, underscore the need for targeted screening in high-risk survivors treated in more recent eras. Research Sponsor: National Institute of Health Research Biomedical Research Centre - Royal Marsden Hospital / Institute of Cancer Research; Breast Cancer Now; Cancer Research UK.

Invasive-field radiotherapy plus rituximab versus rituximab alone after response to immunochemotherapy in stage III follicular lymphoma: An open-label, multicenter, randomized clinical study. First Author: Tongyu Lin, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China

Background: Stage III follicular lymphoma (FL) remains incurable with immunochemotherapy followed by rituximab maintenance. Radiotherapy plays a critical role in the curative treatment of early-stage FL; however, its role in the management of stage III disease remains undefined. **Methods:** In this open-label, multicenter, randomized clinical trial, patients with stage III FL, who demonstrated complete or partial response without bulky after induction immunochemotherapy were enrolled. Eligible patients randomly assigned (1:1) to receive invasive field consolidation radiotherapy (IFRT) combined rituximab maintenance (IFRT+R arm) or rituximab maintenance alone (R arm). The dose of IFRT was 30Gy. The primary endpoint was 5-year progression-free survival (PFS), and the secondary endpoint was 5-year overall survival (OS). This study is registered with Chinese ClinicalTrials.gov, number ChiCTR2000032550. **Results:** Between January 2015 to January 2021, 152 eligible patients were randomly assigned to receive IFRT+R (n=74) or R alone (n=78). Baseline characteristics showed no significant differences between the two arms. After a median follow-up of 82 months, the 5-year PFS was 88.9% in IFRT+R group and 66.7% in R alone group (HR, 0.32; 95% CI, 0.16-0.66, P = 0.002). The 5-year OS was 97.3% in IFRT+R group versus 84.4% in R group (HR, 0.23; 95% CI, 0.07-0.81, P = 0.02). Treatment-related adverse events were more frequent in the IFRT+R arm than in the R arm (58% vs 38%), predominantly consisting of acute hematologic toxicities, including neutropenia (33% vs 26%) and leukopenia (34% vs 28%). Grade 3-4 toxicities were more common in the IFRT+R arm (27% vs 18%), and no treatment-related deaths were observed. **Conclusions:** Involved-field radiotherapy after effective systemic therapy significantly improved PFS and OS with manageable toxicity, highlighting its potential role in the management of stage III FL. Clinical trial information: ChiCTR2000032550. Research Sponsor: National Natural Science Foundation of China; U24A20679 and 82470237.

Single-cell analysis and functional profiling of galectin-3 in the tumor immune microenvironment in transformed follicular lymphoma. First Author: Xiaohui Wang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Histological transformation of follicular lymphoma (tFL) represents an aggressive subtype characterized by a complex and immunosuppressive tumor immune microenvironment (TIME). Therefore, it is urgent to investigate the characteristics of TIME and develop more effective immunotherapy strategies for tFL patients. **Methods:** Using single-cell RNA sequencing, a high-resolution landscape of the entire TIME ecosystem of follicular lymphoma (FL) and tFL patients is depicted. Findings were validated by multiplex immunofluorescence (mIF) staining, in vitro assays, and a mouse model. **Results:** Compared to FL patients, tFL patients exhibited a higher proportion of exhausted CD8+T cells expressing checkpoint receptors such as LAG3, CTLA4, PD-1, and HAVCR2. Notably, Galectin-3 expression was acquired by tumor cells after transformation, leading to enhanced Galectin-3–LAG3 interactions with $CD8^+$ T cells, as confirmed by mIF staining. In co-culture experiments, Galectin-3-overexpressing tumor cells impaired $CD8^+$ T cell proliferation and cytotoxicity, inducing an exhausted phenotype. Treatment with the Galectin-3 inhibitor GB1107 rescued T cell function. Similar T cell dysfunction and GB1107 response were observed in Galectin-3-overexpressing mouse xenograft model. Additionally, we identified an accumulation of MDSC-like monocytes and M2-like macrophages in tFL patients, further contributing to immune suppression. **Conclusions:** Galectin-3 drives T cell exhaustion and reshapes the immune microenvironment in tFL patients, promoting immune evasion and disease progression. Targeting Galectin-3 may represent a promising immunotherapeutic strategy for tFL patients. Research Sponsor: None.

Diagnostic yield after pre-biopsy steroid administration in primary CNS high-grade B-cell lymphoma. First Author: Charmi Trivedi, Brown University Health, Providence, RI

Background: Primary central nervous system high-grade B-cell lymphoma (PCNSL) is typically diagnosed via brain biopsy. Corticosteroids are often administered pre-biopsy to reduce vasogenic edema, but are hypothesized to decrease diagnostic yield by inducing lymphocyte apoptosis. This study aims to evaluate whether steroid administration prior to biopsy affects the likelihood of obtaining a diagnostic result in pts with PCNSL. **Methods:** A retrospective chart review of Brown University Health pts (2015-2024) with PCNSL, including primary CNS diffuse large B cell lymphoma (DLBCL), was conducted. Collected variables included demographics (age, sex, ECOG), steroid dose, biopsy type (excisional, incisional, or stereotactic needle biopsy) and outcome of biopsy (diagnostic vs. undiagnostic). Statistical analysis comparing pre-biopsy steroid (PBS) group with steroid naive group was conducted using Chi-squared, Wilcoxon rank sum and Fisher's Exact test. **Results:** A total of 59 pts were found to have biopsy proven PCNSL and were included in statistical analysis. 53 pts had DLBCL and 6 had high grade PCNSL. Baseline demographics and biopsy types did not significantly differ between PBS group and steroid-naive pts ($p>0.05$). Among pts that received PBS, 35/35 (100%) had a diagnostic biopsy compared with 22/24 (92%) in pts who did not receive steroids. Pre-biopsy steroid use was not associated with a statistically significant difference in diagnostic yield, (Fisher's Exact p=0.16). As there were no non-diagnostic biopsies in the PBS group, the odds ratio was infinite and the upper confidence bound could not be estimated. Median dose of steroids was 213mg (prednisone equivalents; Q1 93mg, Q3 307mg). As all pts in the PBS group had diagnostic biopsies no analysis based on steroid dose could be conducted. All pts who received steroids had documented concern for vasogenic edema and steroids were not used for empiric treatment. **Conclusions:** In our cohort, pre-biopsy corticosteroid administration did not appear to affect diagnostic yield. There was no difference in the rate of diagnostic first biopsies between the PBS and steroid naive group. Among pts receiving steroids, all biopsies were diagnostic regardless of timing relative to biopsy or total steroid dose. Due to the small sample size and the universal diagnostic success, statistical comparisons were limited. These findings suggest that steroids may not compromise the diagnostic yield of PCNSL biopsies. Research Sponsor: None.

Chemotherapy use and survival by demographic and socioeconomic factors in primary central nervous system lymphoma: A population-based SEER analysis. First Author: Kevin Cheng Liang Wu, Zucker School of Medicine at Hofstra/Northwell, Staten Island University Hospital, Staten Island, NY

Background: Primary central nervous system lymphoma (PCNSL) is a rare non-Hodgkin lymphoma confined to the brain and spinal cord. Despite the introduction of rituximab to modern systemic therapy, previous population-based studies suggest that survival disparities by race and socioeconomic status persist. This study uses chemotherapy utilization modeling and contemporary 2000–2022 data to quantify the real-world survival impact of chemotherapy underuse across ethnic and neighborhood income strata in adults with PCNSL. **Methods:** Adults (≥20 years) with histologically confirmed PCNSL diagnosed from 2000–2022 were identified from SEER 21 registries. Patients with concurrent systemic lymphoma were excluded. Chemotherapy receipt was coded as yes vs no/unknown; with blank fields excluded. Binary logistic regression estimated odds of receiving chemotherapy by demographics. Multivariable Cox proportional hazards models evaluated associations of age, sex, race, neighborhood median household income (MHI), rural–urban residence, and chemotherapy with cause-specific survival. MHI was categorized into quintiles derived from the cohort distribution (approximately equal case counts per band). Kaplan–Meier methods estimated cause-specific survival and median survival times. **Results:** A total of 9,533 adults met the inclusion criteria. Compared with Whites, Black (OR 0.42, 95% CI 0.35–0.49) and Hispanic patients (OR 0.75, 95% CI 0.66–0.84) were less likely to receive chemotherapy; patients from neighborhoods with MHI < $65k also had reduced chemotherapy use versus ≥$100k (OR 0.53, 95% CI 0.45–0.62). Median survival was 64 months for patients receiving chemotherapy versus 3 months for those with no/unknown chemotherapy. Median survival by race was 17 months in Black patients, 25 months in Whites, and 38 months in Hispanics. Median survival was 14 months in the lowest MHI band (<$65k) and 46 months in the highest (≥$100k). In Cox models, lack of chemotherapy was associated with more than twice the hazard of lymphoma-specific death (HR 2.29, 95% CI 2.17–2.44). After adjustment for age, sex, race, MHI, residence, and chemotherapy; Black patients had higher mortality than Whites (HR 1.22, 95% CI 1.10–1.36), female gender had improved survival than males (HR 0.88, 95% CI 0.833-0.929), and MHI < $65k was associated with worse survival versus ≥$100k (HR 1.20, 95% CI 1.09–1.32). **Conclusions:** In this cohort of adults with PCNSL, chemotherapy use, race, neighborhood income, and age were powerful independent determinants of cause-specific survival. Chemotherapy underuse was concentrated among Black, Hispanic, and lower-income patients and was associated with a dramatic survival penalty, indicating that inequities in access to systemic therapy are likely major drivers of persistent racial and socioeconomic survival gaps in PCNSL. Research Sponsor: None.

Navigating the post–covalent bruton tyrosine kinase inhibitor (cBTKi) landscape in mantle cell lymphoma (MCL): Real-world insights on treatment patterns, discontinuation, and healthcare resource utilization (HCRU). First Author: Alvaro Jose Alencar, University of Miami/Sylvester Comprehensive Cancer Center, Miami, FL

Background: cBTKis have become standard therapy for relapsed/refractory MCL and are rapidly advancing to the first-line setting. However, real-world evidence on clinical and economic outcomes following cBTKi therapy is limited. Treatment patterns, time to treatment discontinuation (TTD), and HCRU were evaluated among patients (pts) with MCL previously treated with cBTKis. **Methods:** This retrospective observational study used claims data from the Symphony Integrated Dataverse (Jan 2020-Aug 2025) to identify adults with MCL who received a cBTKi in any line of therapy (LOT) and, following discontinuation, initiated another treatment. Post-cBTKi regimens were categorized as B-cell lymphoma 2 inhibitor (BCL2i), cBTKi, noncovalent BTKi (ncBTKi), chimeric antigen receptor T-cell therapy (CAR-T), chemo±immunotherapy (C±IT), and other. TTD and HCRU (outpatient/inpatient/other medical, reported per-patient-per-month [PPPM]), were assessed for regimens received post cBTKi. **Results:** Of 10,519 total US pts with MCL, 571 were previously treated with cBTKis and received a subsequent therapy (median age, 72.0 years; ≥65 years, 77%; male, 74%; White non-Hispanic, 67%; Medicare, 62%). Regimens received in a subsequent LOT after cBTKi included cBTKis (38%), ncBTKis (32%), C±IT (11%), BCL2is (9%; monotherapy 7%), CAR-T (2%), and other (8%). Median TTD was longest with cBTKis (365 days), followed by ncBTKis (206 days), and shortest with BCL2is (140 days). Mean HCRU PPPM was lowest with cBTKis (outpatient, 1.21; inpatient, 0.20; other medical, 1.07) and highest with CAR-T (outpatient, 10.63; inpatient, 1.89; other medical, 1.55). **Conclusions:** In this real-world analysis, pts with MCL who previously received cBTKis were most frequently re-treated with cBTKis, highlighting the need for novel treatment options in the post-cBTKi setting. TTD was greatest in pts who received cBTKis or ncBTKis and shortest in those treated with BCL2is. HCRU burden was lowest for pts who received cBTKis and highest for those treated with CAR-T. Further research, including an understanding of the reasons for re-exposure to cBTKis, is warranted to confirm these findings. Research Sponsor: BeOne Medicines, Ltd.

Efficacy, safety, and genetic analysis of orelabrutinib combined with rituximab as first-line systemic treatment for marginal zone lymphoma. First Author: Xian Li, The Second Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China

Background: Marginal zone lymphoma (MZL) is a heterogeneous B-cell malignancy that is often managed with chemoimmunotherapy in the first-line setting, but chemotherapy entails considerable toxicity. Orelabrutinib, a novel oral BTK inhibitor which offers improved target selectivity and fewer off-target effects. This study evaluates the chemo-free combination of orelabrutinib plus rituximab in untreated MZL. **Methods:** This is a prospective, single-arm, multicenter phase II clinical trial (NCT07022223). Patients with untreated MZL who met ECOG criteria of 0–2 and were in need of treatment, or who had failed local, were eligible. All participants will receive induction therapy with the orelabrutinib and rituximab regimen. The treatment cycle is 28 days, with a total of 4~6 cycles. The induction treatment period is as follows: Cycle 1: Rituximab, 375 mg/m², on day 1. Cycles 2-6: Orelabrutinib, 150 mg, once daily orally, from day 1-28, plus rituximab 375 mg/m² on day 1. Patients who achieve a partial response (PR) or better will enter a 2-year maintenance period with orelabrutinib. The primary endpoint is the overall response rate (ORR). Secondary endpoints include complete response (CR) rate, PR rate, progression-free survival (PFS), and overall survival (OS). Safety is assessed by monitoring adverse events (AEs). **Results:** From March 2025 to December 2025, a total of 40 patients with MZL (32 MALT, 6 NMZL, 2 SMZL) were enrolled. The median age at diagnosis was 68 years (range 44–84), and 82.5 % of patients were older than 60 years. 21 (52.5%) were female. Most patients had an ECOG score of 0-1 (28/40), Ann Arbor Stage III-IV disease (35/40). Twelve patients had an MZL-International Prognostic Index score of ≥2. Thirteen patients had failed prior local therapy, the majority of whom had undergone surgical resection. After three cycles, 25 patients were evaluable, with an ORR of 80 % (20/25) and a CRR of 24 %. Following six cycles, 13 patients were evaluable, achieving an ORR of 100 % (13/13) and a CRR of 62 % (8/13). The median time to response was 72 days. With a median follow-up of 5.7 months (range, 5.1-6.8), the median PFS and OS were not reached, the 1-year PFS rates were 97.2% and the 1-year OS rates were 100%. Next-generation sequencing (NGS) was performed on 16 patients, a total of 158 mutated genes were identified, with missense mutations predominating (62.7%). The most frequently mutated genes were NOTCH2, FAT4, LRP1B, PCLO, and SYNE1, all at 31.2 %. Treatment was generally well tolerated, only 13 patients experienced adverse events, the most common adverse events were anemia (15 %), infection (12.5 %) and neutropenia (10 %). Notably, BTK inhibitor–associated atrial fibrillation (0 %) and bradycardia (0 %) were absent. **Conclusions:** The combination of orelaburtinib and rituximab shows significant activity in MZL, with a manageable toxicity profile. Clinical trial information: NCT07022223. Research Sponsor: None.

Diagnostic accuracy of circulating tumor DNA for post-remission surveillance in diffuse large B-cell lymphoma: A systematic review and meta-analysis. First Author: Mohammad Ahsen Soomro, Internal Medicine, The Wright Center for Graduate Medical Education, Scranton, PA

Background: Relapse after complete remission remains a major cause of treatment failure in Diffuse Large B-Cell Lymphoma (DLBCL). Standard surveillance using clinical assessment and imaging often detects recurrence after substantial tumor regrowth. Circulating tumor DNA (ctDNA) has emerged as a promising biomarker for minimal residual disease detection; however, its diagnostic accuracy for relapse surveillance in DLBCL has not been systematically quantified. **Methods:** A systematic review and meta-analysis was performed per a prespecified PROSPERO protocol (CRD420251179858). MEDLINE, Embase, CENTRAL, and major conference proceedings were searched through October 2025. Following systematic screening of B-cell non-Hodgkin lymphoma studies, those eligible for quantitative synthesis enrolled adults with DLBCL in complete remission undergoing post-treatment ctDNA surveillance, with clinically or radiologically confirmed relapse as the reference standard. Studies were included if sufficient data were available to construct 2×2 contingency tables. Pooled sensitivity and specificity were estimated using a bivariate random-effects logistic regression model with a logit link, accounting for between-study heterogeneity. A continuity correction of 0.5 was applied to all cells in studies with zero counts prior to model fitting. **Results:** Three studies (N=157) comprising patients in complete remission after first-line therapy were included in the quantitative synthesis. Using a bivariate random-effects model, the pooled sensitivity of ctDNA for detection of clinical relapse was 58.6% (95% CI 32.2–80.8%), while pooled specificity was 93.9% (95% CI 83.6–97.9%), indicating high specificity but moderate sensitivity during surveillance. Specificity was consistently high, supporting strong rule-in performance. Sensitivity varied across studies (range: 31%–88%), likely reflecting differences primarily in sampling density, as well as assay platforms (tumor-informed Ig-HTS vs. targeted NGS). Across included cohorts, ctDNA positivity generally preceded or coincided with clinically detected relapse, while ctDNA negativity was associated with durable remission during follow-up. **Conclusions:** In patients with DLBCL in complete remission after first-line therapy, ctDNA surveillance demonstrates very high specificity but only moderate sensitivity for detection of clinical relapse. These findings support ctDNA as a highly specific rule-in biomarker for relapse during surveillance, potentially resolving ambiguity in equivocal imaging findings. However, its moderate sensitivity limits its standalone ability to detect relapse. Prospective validation of standardized testing intervals and assay harmonization are needed to optimize sensitivity before integration with standard monitoring strategies. Research Sponsor: None.

Epcoritamab (epcor) + chemoimmunotherapy (CIT) in patients (pts) with relapsed/refractory large B-cell lymphoma (R/R LBCL) eligible for autologous stem cell transplant (ASCT): Pooled results from arms 4 and 10 of EPCORE NHL-2. First Author: Yasmin Karimi, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI

Background: Pts with R/R LBCL can have inadequate response to salvage treatment (tx), precluding ASCT. While CAR T therapies are standard of care in the 2L setting for pts with early relapse (< 12 mo of 1L tx), their use is limited by eligibility, accessibility, or cost. Regimens that enhance salvage tx response rates enabling pts to proceed to ASCT are needed. In Arms 4 and 10 of the phase 1b/2 EPCORE NHL-2 trial (NCT04663347), epcor + CIT showed high response rates in ASCT-eligible R/R LBCL. A pooled analysis of these data is reported. **Methods:** ASCT-eligible pts received epcor + rituximab, dexamethasone, cytarabine, and oxaliplatin/carboplatin (R-DHAX/C) (Arm 4) or epcor + rituximab, ifosfamide, carboplatin, and etoposide (R-ICE) (Arm 10). After salvage tx, pts could proceed to ASCT or remain on epcor mono tx. ORR per investigator, DOCR, PFS, OS, and safety are reported. **Results:** The analysis included 63 pts (Arm 4: n = 29; Arm 10: n = 34). Baseline characteristics: median age 61 y (range 28–77), 68% male, 71% stage III/IV, 13% (8/33 assessed) high-grade B-cell lymphoma with *MYC* and *BCL2* and/or *BCL6* translocations (central lab), 8% prior CAR T. 79% (n = 50) were receiving 2L tx; 57% (n = 36) were receiving 2L tx and were refractory or had early relapse to 1L tx. Median relative CIT dose intensity was ≥ 80%. At 18.3 mo median follow-up, ORR and CR rates were 84% and 67% (Table). 57% (n = 36) proceeded to ASCT; 16% (n = 10) remained on epcor mono tx due to pt/physician decision. Median DOCR, PFS, and OS were not reached in pts who proceeded to ASCT or who remained on epcor. Similar outcomes were seen in 2L pts and across 2L pts with early and late relapse. Overall, the most common any-grade TEAEs were anemia (68%), thrombocytopenia (68%), and neutropenia (62%). CRS occurred in 48% of pts and ICANS in 3%; all events were grade 1–2. Serious infections occurred in 17%. TEAEs led to tx discontinuation in 11%. There were no fatal TEAEs. **Conclusions:** In this pooled analysis of ASCT-eligible pts with R/R LBCL, tx with epcor + salvage CIT resulted in high CR rates, enabling a large proportion of pts to proceed to ASCT. Deep, durable responses were seen in pts who underwent ASCT and those who continued epcor mono tx. A high CR rate was also observed in 2L pts with early relapse. Safety was consistent with prior reports. Dose intensity of CIT was not impacted. These findings support epcor-based combination salvage strategies to increase response depth and facilitate higher ASCT rates and possible cure in ASCT-eligible pts with DLBCL. Clinical trial information: NCT04663347. Research Sponsor: Genmab A/S and AbbVie.

	All pts (N = 63)	2L (n = 50)	2L with early relapse[a] (n = 36)	Proceeded to ASCT (n = 36)	Remained on epcor mono (n = 10)
ORR/CR, %	84/67	84/68	81/61	100/94	100/80
DOCR, 18-mo rate, %	79	80	81	83	64
PFS, 18-mo rate, %	62	62	58	80	67
OS, 18-mo rate, %	82	82	77	93	100

A real-world comparison of treatment and survival outcomes with zanubrutinib (zanu) and acalabrutinib (acala) monotherapy among patients with relapsed or refractory (R/R) mantle cell lymphoma (MCL) in the United States. First Author: Yucai Wang, Mayo Clinic Rochester, Rochester, MN

Background: MCL is a rare and aggressive subtype of B-cell non-Hodgkin lymphoma that remains incurable. Bruton tyrosine kinase (BTK) inhibitors are an established standard of care for R/R MCL. However, comparative effectiveness data for different BTK inhibitors for R/R MCL are limited. This study evaluated the real-world effectiveness of zanu and acala in US patients with R/R MCL based on overall survival (OS) and time to next treatment (TTNT). **Methods:** A retrospective cohort study was conducted using Komodo health administrative claims data. Eligible patients were adults (aged ≥18 years) with ≥2 MCL diagnoses and continuous enrollment or activities within 1 year prior to and 3 months following the index date. Patients were required to initiate monotherapy with zanu (index period: November 2019 to August 2025) or acala (index period: October 2017 to August 2025) as a second-line or later (2L+) treatment, with index date defined as the first observed claim for zanu or acala. Patients with evidence of clinical trial participation, end stage renal disease or prior stem cell transplant were excluded. Outcomes included OS (time from index date to all-cause mortality) and TTNT (time from index date to subsequent therapy with an allowable gap of 120 days). If an outcome was not observed, patients were censored at the date of last activity or enrollment end date. Survival analyses were conducted using Kaplan-Meier estimates and Cox proportional hazards models. Inverse probability of treatment weighting (IPTW) was adjusted for age, sex, US region, treatment initiation year and Charlson Comorbidity Index (CCI). **Results:** In total, 2219 patients (zanu, n=931; acala, n=1288) were eligible and included in the study. The mean age was higher in the zanu (72.3 years; SD, 9.4) vs acala cohort (71.4 years; SD, 9.7). Most patients were male (zanu, 71%; acala, 75%), non-Hispanic white (zanu, 73%; acala, 74%), and the mean CCI was 3.5 (SD, 3.2) and 3.6 (SD, 3.1) in the zanu and acala cohorts, respectively. Median follow-up was 14.8 and 18.2 months in zanu and acala cohorts, respectively. Median TTNT was 26.7 months for zanu and 20.8 months for acala. Median OS was not reached for zanu and was 60.6 months for acala. In the unadjusted model, zanu had a longer TTNT (HR, 0.86; 95% CI, 0.76-0.97; *P*=.012) and OS (HR, 0.74; 95% CI, 0.62-0.88; *P*<.001). After IPTW adjustment, TTNT and OS favored zanu treatment (TTNT: IPTW-adjusted HR, 0.86; 95% CI, 0.76-0.98; *P*=.025; OS: IPTW-adjusted HR, 0.81; 95% CI, 0.68-0.98; *P*=.03). **Conclusions:** In this real-world analysis of US health claims data, zanu monotherapy demonstrated significantly longer TTNT and improved OS compared with acala in patients receiving 2L+ therapy for MCL. These findings support zanu as an effective BTK inhibitor for R/R MCL. Research Sponsor: BeOne Medicines, Ltd.

Signatures of biological heterogeneity associated with treatment outcome in diffuse large B-cell lymphoma. First Author: Boya Wang, Lymphoid Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: Genetic subtypes of diffuse large B-cell lymphoma (DLBCL) capture biological differences between tumors that influence the response to immunochemotherapy (Schmitz et al., NEJM 2018). However, nearly 40% of DLBCL cases remain unclassified. The addition of gene expression signatures can accelerate classification and inform therapeutic intervention. **Methods:** We generated single-cell RNA sequencing of 103 DLBCL patient biopsies from Weill Cornell Medicine, New York Presbyterian Hospital, and the National Institutes of Health. We also utilized bulk genomic data from a discovery cohort (n=311, Ennishi et al., J Clin Oncol 2019) and a validation cohort (n=574, Schmitz et al., NEJM 2018). **Results:** Single cell sequencing allowed us to isolate the malignant B cells and develop genetic subtype signatures. The MCD signature was associated with poor overall survival ($p<10^{-6}$), as was the BN2 signature within ABC tumors ($p<10^{-3}$). When applied to unclassified tumors, the subtype signatures identified characteristic genetic alterations including SLC1A5 mutations in MCD ($p<10^{-5}$), UBE2A mutations in BN2 ($p<10^{-13}$), C10orf12 truncations and copy number loss in EZB ($p<10^{-6}$), and SGK1 mutations in ST2 ($p<10^{-7}$). Moreover, we discovered that most DLBCL tumors (80%) contained two or more genetic subclones (median 2, range 1-5) based on DNA copy number differences. The genetic subclones had distinct phenotypes based on expression of six recurrent gene expression metasignatures, herein termed themes. The germinal center (GC) B cell, memory B cell, plasma cell, and pan-B cell themes reflect B cell differentiation whereas two other themes – cell cycle and cell growth – reflect proliferative and metabolic states that are independent of the differentiation states. Surprisingly, 23% of DLBCL (24/103) harbored genetic subclones expressing B cell differentiation themes that distinguished them from other malignant cells in the same tumor. The GC B cell theme was associated with a favorable response to R-CHOP chemotherapy ($p<0.02$), as expected, while the cell growth theme (but not the cell cycle theme) was associated with adverse survival ($p<0.02$). **Conclusions:** Our study revealed that genetic subtypes have distinct gene expression signatures. We further demonstrated a role for tumor subclones in generating intra-tumoral biological diversity. We developed signatures of inter and intra-tumoral heterogeneity that are associated with overall survival. Research Sponsor: U.S. National Institutes of Health.

Differential clinical and economic signatures of CAR T-cell therapy in DLBCL across demographic and payer strata: A national analysis. First Author: Karnav Modi, University of Missouri Kansas City, Kansas City, MO

Background: Chimeric antigen receptor (CAR) T cell therapy has revolutionized care for relapsed/refractory diffuse large B cell lymphoma (DLBCL), yet granular delineation of real-world immune effector toxicities, organ-specific sequelae and economic burden across demographic and socioeconomic strata requires further exploration. **Methods:** Using the National Inpatient Sample (2017–2022), we identified adult DLBCL hospitalizations receiving CAR T through ICD-10-PCS codes. Cytokine release syndrome (CRS) [all grades - 2021–2022], immune effector cell–associated neurotoxicity syndrome (ICANS) [all grades – 2022], infections, cardiac events and acute kidney injury (AKI) were identified through ICD-10 codes. Age was stratified into 21-40, 41-60, 61-80 and >81 years. Payer groups were Medicare, Medicaid, Private and Uninsured. Races were White, African American, Hispanic and others [Pacific Islanders, Native Indians, Asians]. Chi-square analysis was performed, and multivariate regression adjusted for demographics, comorbidities, and hospital characteristics. **Results:** Across >11,000 weighted hospitalizations, inpatient mortality, all-grade CRS and ICANS were comparable across age, race, and payer groups ($p>0.05$). Inpatient mortality was numerically higher in other minor races (6.6%) vs White (3.3%), African American (3.1%), and Hispanic (0.9%; p=0.230). Any grade CRS was numerically higher in other minor races (72.5%) than in White (62.3%) and African American (60.6%; p=0.614). Any grade ICANS dispersion included 29.5% (White), 39.1% (African American), 22.5% (Hispanic) and 11.1% (Other; p=0.204). A race-specific signal for ICANS grade 5 (p=0.030) was seen, but numbers were small. Among cardiac events, arrhythmias rose from 7.6% (age 21–40 years) to 57.1% (age ≥81 years) ($p<0.001$). By payer, arrhythmias were highest in Medicare (31.2%; $p<0.001$). Other cardiac events including myocardial infarction, stroke and cardiogenic shock were similar across groups. Pneumonia rates varied by payer, peaking in the Uninsured (23.8%; p=0.010). Sepsis and septic shock rates showed no differences. AKI (p=0.007) rates showed differences but attenuated after adjustment. Hispanic and other minor races had lower adjusted costs than White (Odds ratio [OR] 0.9, p=0.046; OR 0.8, p=0.006), while ages 61–80 had higher adjusted costs vs 21–40 (OR 1.2, p=0.023). **Conclusions:** In this national cohort, CRS, ICANS and mortality were similar across demographic and payer strata, indicating consistent immune effector safety. Cardiac arrhythmia rates were higher among the elderly and Medicare beneficiaries. There were lower expenditures among minor race groups and higher costs in elderly. These findings highlight discrete domains of variability and suggest intensified cardiac surveillance in elderly and equitable resource allocation to optimize outcomes with CAR-T. Frontline intensified vs standard immunochemotherapy in high-risk diffuse large B-cell lymphoma: A systematic review and meta-analysis. First Author: Lauren Scarpetti, Department of Medicine, NYU Langone Health, New York, NY

Background: While the phase III CALGB 50303 trial comparing frontline REPOCH vs standard RCHOP for diffuse large B-cell lymphoma (DLBCL) showed comparable outcomes overall, it suggested a potential benefit of intensified therapy in high-risk patients, including high-grade (HG) and double/triple-expressor (DE/TE) disease. Subsequent studies evaluating REPOCH in HG and DE/TE DLBCL have been small, retrospective and non-randomized, with conflicting results. Despite limited evidence and greater toxicity, REPOCH is commonly used in these cohorts. We conducted a systematic review and meta-analysis to assess outcomes after frontline REPOCH vs RCHOP in HG and DE/TE DLBCL, comprising the largest high-risk cohort to date. **Methods:** Original research studies evaluating outcomes after frontline REPOCH or RCHOP in HG or DE/TE DLBCL from 2009 to 2025 were included. HG was defined by *MYC* translocation, including double/triple-hit (DH/TH; *MYC* and *BCL2* and/or *BCL6* translocation). DE/TE was defined by *MYC* and *BCL2* and/or *BCL6* by IHC. Studies were excluded if they had <10 subjects or used agents in addition to the RCHOP or REPOCH backbones. RCHOP-like regimens with comparative substitutions were included (e.g., RCOMP). We used random effects models to calculate pooled response rates and survival outcomes. **Results:** 69 studies were included with 3979 total patients (1818 HG; 2161 DE/TE). 2698 patients (68%) were treated with RCHOP, and 1281 (32%) with REPOCH. Limited reporting of patient characteristics in HG or DE/TE cohorts precluded multivariable analysis of prognostic factors. While overall response rate (ORR) did not differ between treatment groups (relative risk [RR] 1.04, CI 0.92-1.19), patients treated with REPOCH were more likely to achieve complete response (CRR; RR 1.12, CI 1.01-1.23). This difference was especially notable in the HG subgroup (RR 1.4, CI 1.21-1.61), but there was no difference in the DE/TE subgroup (RR 1.04, CI 0.93-1.17). Across all patients, REPOCH was associated with significantly improved progression-free survival (PFS; hazard ratio [HR] 0.5, CI 0.39-0.65) and overall survival (OS; HR 0.59, CI 0.43-0.82). Landmark 2-year PFS (65% vs 52%, p = 0.013) and OS (75% vs 50%, $p < 0.0001$) were significantly higher for REPOCH. Subgroup analysis showed significantly improved 2-year OS with REPOCH in both HG (72% vs 47%, $p < 0.0001$) and DE/TE (67% vs 51%, p = 0.032) disease. **Conclusions:** In this large cohort, REPOCH was associated with significantly improved CRR, PFS and OS relative to RCHOP in HG and DE/TE DLBCL. Reported patient characteristics were limited, and the REPOCH arm may have preferentially included younger patients with better performance status. Nevertheless, our analysis provides evidence in an area lacking randomized trial data. While not definitive, our findings support the common clinical practice of treating select high-risk patients with REPOCH. Research Sponsor: None.

Differences in outcomes for elderly patients with DLBCL treated at academic vs community programs: A 10-year survival analysis. First Author: Carolina Velez-Mejia, Virginia Commonwealth University - Mays Cancer Center, Richmond, VA

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive B-cell malignancy that primarily affects older adults. Optimal treatment management in the geriatric population is challenging due to the high-risk disease biology and their age-specific vulnerabilities. Combination chemotherapy is effective, however, due to frailty often a dose-reduced regimen is administered. This large population real-world study compares demographic, clinical and survival characteristics of patients older than 75 years and compares Academic Cancer Programs (ACP) vs Community Cancer Programs (CCP). **Methods:** A retrospective analysis using the National Cancer Database was conducted on 103,671 patients (ACP: 51,848; CCP: 51,823) diagnosed with DLBCL between 2004 and 2022 was carried out. ACP included academic and National Cancer Institute-designated research centers; CCP included community, comprehensive community, and integrated network cancer programs. Kaplan-Meier and Cox regression models were used to compare overall survival (OS), adjusting for: age, race/ethnicity, insurance status, Charlson-Deyo comorbidity score, and distance from treating facility. **Results:** Patients in ACP and CCP were mostly females with a median age of 81 years. For both cohorts the majority were non-Hispanics and Whites; however, for ACP it was noted a higher rate of Hispanics (6% vs 5%) and Blacks (5% vs 3%) compared to CCP. Most of the patients in both groups were from the Metropolitan area, but the median distance in miles for ACP was 9.0 vs 7.4 in CCP. Treatment rates were higher for ACP vs community settings (63% vs 59%, $p<0.001$), with more patients presenting at Stage IV (36% vs 33%, $p<0.001$). Better OS was noted in elderly patients treated at ACP, $p<0.001$. The median OS for ACP was of 1.79 years vs 1.50 years at CCP, which was consistent with a longer median follow up time of 17.7 months vs 14.1, $p<0.001$. This survival advantage remained consistent throughout long-term observation, with 2-year OS rates of 49% at ACP [CI: 0.48,0.49] vs 46% at CCP [CI: 0.459,0.468], 5-year OS of 34% [CI: 0.336,0.346] vs 32% [CI: 0.317,0.327], and 10-year OS of 16% [CI: 0.154,0.164] vs 15% [CI: 0.142,0.151], respectively. **Conclusions:** Among patients aged ≥75 years with DLBCL, OS differed by treatment facility type, with a statistically significant but modest survival advantage observed among patients treated at ACP compared with CCP (log-rank $p<0.001$). This difference occurred in the context of higher treatment rates and greater disease severity at presentation. Given the relatively small absolute survival differences, these findings suggest that care for older adults with DLBCL is largely standardized across practice settings; however, this highlights an opportunity to optimize treatment delivery and intensity, supportive care, and geriatric-focused management in both academic and community programs. Research Sponsor: None.

Efficacy and tolerability of duvelisib in relapsed/refractory peripheral T-cell lymphoma: A multicenter real-world analysis. First Author: Priyanka Pullarkat, Washington University School of Medicine, St. Louis, MO

Background: Relapsed/refractory (R/R) peripheral T-cell lymphomas (PTCL) are a rare group of non-Hodgkin lymphomas with median survival at relapse of 6-10 months and few treatment options. Duvelisib is a g/Δ phosphatidylinositol 3-kinase inhibitor approved in CLL and NCCN compendium listed in PTCL. In indolent lymphomas, concerns for cumulative duvelisib toxicity limit its use. In contrast, studies in R/R PTCL show duvelisib to be well-tolerated. Therefore, we sought to assess the efficacy and tolerability of duvelisib in a real world setting in R/R PTCL. **Methods:** We conducted a retrospective analysis of patients with R/R PTCL treated with duvelisib from 2012-2025 at 12 centers. **Results:** We identified 207 patients with PTCL: nodal PTCL with TFH phenotype (n=106, 51%), PTCL-NOS (n=78, 38%), ALCL (n=16, 8%), enteropathy associated T-cell lymphoma (n=4, 2%), NK/T-cell lymphoma (n=2, 1%), adult T-cell leukemia/lymphoma (n=1, 0.5%). 90 patients (43%) were female. Median age was 64; median International Prognostic Index score 3. Median prior lines of therapy was 2 (range 1-9). 26% received frontline transplant (23% auto, 3% allo). 118 patients received single agent duvelisib; 89 patients received duvelisib in combination with other agents (66 romidepsin, 12 bortezomib, 4 azacitadine, 3 ruxolitinib, 4 other). Of patients with response data, ORR was 51% (94/186; 31% CR, 17% PR) with median OS 12 months. ORR in patients with TFH-phenotype vs. non-TFH phenotype was 60% and 41% respectively. ORR in patients treated with single agent duvelisib and duvelisib combinations was 46% (46/99; 29% CR, 17% PR) and 55% (48/87; 39% CR, 16% PR), respectively with no difference in OS. Median duration of therapy was 84 days; the most common reason for discontinuation was progression (41%, 76/186). 13% (25/196) underwent allo-SCT after duvelisib therapy. Toxicity data is summarized in our table. In patients receiving single agent duvelisib therapy, rates of cytopenia were lower (7% vs. 34%, $p<0.001$) and rates of colitis were higher (17% vs. 7%, p= 0.03). **Conclusions:** In this real world, multicenter analysis of patients with R/R PTCL treated with duvelisib-based regimens, the ORR of 51% was consistent with published trials. Duvelisib therapy was well tolerated and a minority required hospitalization for toxicity. This suggests that duvelisib is safe in patients with R/R PTCL who have poor prognosis and limited treatment options. Research Sponsor: None.

Comparative safety and efficacy of obinutuzumab versus rituximab in combination with chemotherapy for follicular lymphoma: A systematic review and meta-analysis. First Author: Abdul Rafae Faisal, CMH Multan Institute of Medical Sciences, Multan, Pakistan

Background: Follicular lymphoma is one of the most common non-Hodgkin lymphoma subtypes, typically presenting with advanced-stage disease and a relapsing-remitting course. Over the past two decades, anti-CD20 monoclonal antibodies combined with chemotherapy have significantly improved outcomes. Rituximab, a first-generation anti-CD20 antibody, has been the standard of care since approval. Obinutuzumab, a type II glycoengineered anti-CD20 antibody with enhanced antibody-dependent cellular cytotoxicity and direct cell death mechanisms, is a newer option with potential efficacy advantages. While individual randomized trials have shown promising results with obinutuzumab, comparative data on safety and efficacy remain limited. **Methods:** A systematic search of PubMed, ClinicalTrials.gov, Scopus, Embase, and Cochrane CENTRAL identified relevant English-language randomized controlled trials and observational studies. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using fixed- or random-effects models based on heterogeneity. Statistical significance was set at $p<0.05$, and heterogeneity was assessed using the I^2 statistic. Analyses were performed using Review Manager version 5.3, following PRISMA guidelines. **Results:** Three studies met inclusion criteria, including two retrospective observational studies (Claustre et al., 2023; Berger et al., 2023) and one randomized controlled trial (Marcus et al., 2017). The pooled sample included 1,482 patients, of whom 53% were female. Compared with rituximab, obinutuzumab was associated with higher partial response rates (OR=0.66; 95% CI: 0.50–0.89; p=0.006) and improved disease progression outcomes (OR=0.64; 95% CI: 0.49–0.86; p=0.002). No significant differences were observed in overall response rate (OR=1.18; 95% CI: 0.84–1.65; p=0.34) or complete response (OR=0.82; 95% CI: 0.63–1.06; p=0.13). Obinutuzumab was associated with a higher incidence of adverse events during induction (OR=1.56; 95% CI: 1.04–2.33; p=0.03) and maintenance (OR=1.48; 95% CI: 1.13–1.93; p=0.004). Treatment discontinuation, dose reduction, or interruption due to adverse events occurred more frequently with obinutuzumab (OR=1.65; 95% CI: 1.13–2.42; p=0.01), as did neutropenia (OR=1.38; 95% CI: 1.12–1.71; p=0.002). **Conclusions:** This meta-analysis demonstrates that obinutuzumab provides improved efficacy, including higher partial response rates and reduced disease progression, compared with rituximab in follicular lymphoma. However, this benefit is accompanied by increased toxicity. Treatment selection should balance efficacy gains against safety risks. Research Sponsor: None.

Survival and socioeconomic disparities in the elderly population with mycosis fungoides and Sézary syndrome: A comparative analysis of 2,690 patients by facility type. First Author: Oscar Hinojosa, Department of Hematology Oncology, The University of Texas Health Science Center, San Antonio, TX

Background: Mycosis fungoides (MF) and Sézary syndrome (SS) are rare T-cell malignancies (0.26 and 0.36/100,000 person-years, respectively), that predominantly affect elderly patients, a population frequently underrepresented in clinical trials and with limited access to specialized care. While population-level outcomes are known, the impact of facility type on management and survival remains poorly studied. We utilized the National Cancer Database (NCDB) to conduct the largest retrospective cohort analysis comparing patient demographics, treatment patterns, and survival (OS) between Academic Cancer Programs (ACPs) and Community Cancer Programs (CCPs). **Methods:** Patients ≥75 years old diagnosed with MF/SS in the US from 2000 to 2020 were identified. Facilities were categorized as ACPs (Academic/research programs) and CCPs (Comprehensive community/integrated network programs). Demographic and clinical variables were compared. Overall survival (OS) was estimated using Kaplan–Meier methods, with Cox proportional hazards models performed to assess associations between facility type and survival. **Results:** A total of 2690 patients were identified (ACPs: 2176;CCPs: 514). Both cohorts showed male predominance (ACPs: 58%;CCPs: 64%) and were primarily White (ACPs: 84%;CCPs: 92%). Socioeconomic analysis revealed that ACP patients were more likely to belong to the highest income quartiles compare to CCP patients across all periods (2000: 43% vs 32%; 2008–2012: 36% vs 26%; 2012–2016: 39% vs 29%; and 2016–2020: 40% vs 30%; all $p < 0.01$). Notably, ACP patients were more likely to receive systemic treatment (71% vs 65%; $p<0.05$) and experienced shorter median times to treatment initiation (37 vs 48 days; $p<0.05$). Conversely, radiotherapy was utilized more frequently at CCPs (29% vs 15.2%; $p<0.01$). With a longer median follow-up at ACPs (37 vs 31 months; $p< 0.05$), a higher proportion of patients remained alive at the end of the study (42% vs 30%). OS was superior among patients treated at ACPs, with higher 2-, 5-, and 10-year survival rates and a longer median OS (4.9 vs 3.0 years; log-rank p=0.001). **Conclusions:** In elderly patients with mycosis fungoides and Sézary syndrome, management at an Academic Cancer Program was associated with a statistically significant and clinically meaningful overall survival advantage compared with Community Cancer Programs. This survival difference occurred alongside more frequent use of systemic therapies, expedited treatment initiation, and distinct socioeconomic differences between care settings. These findings highlight important system-level disparities and underscore the critical need to strengthen referral pathways and academic–community partnerships to improve access to specialized care and optimize outcomes for this vulnerable population. Exploring improved prognostication using PET/CT radiomics in relapsed/refractory, TP53-aberrant diffuse large B-cell lymphoma (DLBCL). First Author: Vincenzo Pizzuti, University of Colorado Department of Medicine, Aurora, CO

Background: Patients (pts) with TP53-aberrant DLBCL have inferior progression-free survival (PFS) and overall survival (OS) compared to pts with wild type disease, and outcomes are worse for those with R/R disease. Improved prognostics are needed to identify those at risk for inferior outcomes to guide enhanced surveillance and early initiation of subsequent therapy. **Methods:** Retrospective data from pts with R/R, TP53-aberrant DLBCL treated at the University of Colorado system with 2 distinct PET/CT scans at time of R/R diagnosis and post-treatment between 2016 and 2025 were included in this analysis. PET/CT measurements were conducted by two nuclear medicine physicians blinded to outcomes and included SUVmax, total metabolic tumor volume (TMTV) by 41% SUVmax method, and total lesional glycolysis (TLG). Receiver operator curves (ROC) were constructed to determine the optimal cutoff points for PFS at 1 year using Youden's J statistic. Survival analysis was conducted using Kaplan-Meier and Cox analyses. **Results:** The 22 pts had a median age of 66.9 years (44-83), median follow-up of 18.7 months (mos.), and a median OS of 28.7 mos. (95% CI 19.0 – 53.8) from R/R diagnosis. 17/22 (77%) pts had primary refractory disease, 7/22 (32%) had bulky disease, 13/22 were GCB, and 8/22 (36%) had double-hit lymphoma. 17/22 pts received CAR-T therapy as next line of therapy, and OS was not associated with therapy type or line by Cox regression. ROC analysis for PET/CT interval changes from R/R diagnosis to post-treatment identified cutoffs of 86.7% for ΔSUVmax, 93.43% for ΔTMTV, and 97.98% for ΔTLG. The known prognostic ΔSUVmax >70% was associated with better OS with hazard ratio (HR) of 0.307 (p=0.025). Each radiomic metric was independently associated with superior PFS (Table 1). R-IPI >3 at progression was not associated with differences in PFS or OS (p=0.751 and p=0.655, respectively). Pts with 2 or more high-risk PET/CT radiomic features (any combination of 2+ makers less than the cutoffs) was associated with inferior PFS (Table 1), OS (HR=0.265, p=0.009), and had a median PFS of 3.5 months and OS of 19.0 months. **Conclusions:** PET/CT radiomic metrics were independently associated with PFS and OS in R/R, TP53-aberrant DLBCL pts. Pts with 2 or more high-risk PET/CT features were at high risk for progression and inferior OS compared to those with ≤ 1, and this 2-component model significantly outperformed R-IPI for predicting PFS and OS in this exploratory analysis, which warrants validation in future study. Research Sponsor: None.

	Median PFS	Median OS	HR for PFS (95% CI, p-value)
Δ SUVmax ≥ 86.7%	NR	50.1 months	0.259 (0.078-0.861, p=0.0164)
Δ TMTV ≥ 93.43%	NR	46.3 months	0.294 (0.085-1.03, p=0.0223)
Δ TLG ≥ 97.98%	NR	46.4 months	0.223 (0.066-0.758, p=0.0071)
≥2 high-risk PET/CT features	3.5 months	19.0 months	0.181 (0.055-0.591, p=0.0012)
High-risk IPI (3 or higher)	36.7 months	28.6 months	1.207 (0.341-4.279, p=0.751)

Conditional survival by primary extranodal site in diffuse large B-cell lymphoma: A population-based landmark analysis. First Author: Muhammad Dawood Amir Sheikh, University of South Alabama, Mobile, AL

Background: Diffuse large B-cell lymphoma (DLBCL) frequently presents with extranodal involvement. Prior population-based studies report site-specific survival differences from diagnosis, but these estimates are influenced by early mortality and may not reflect prognosis among longer-term survivors. We therefore evaluated conditional survival by primary site using landmark analyses. **Methods:** Adolescents and adults (≥15 years) with primary extranodal DLBCL diagnosed in the Surveillance, Epidemiology, and End Results (SEER) database (2002–2022) were identified. Overall survival was assessed using multivariable Cox models adjusted for age, sex, race/ethnicity, and era. Landmark Cox models at 12 and 24 months estimated survival among patients alive at each timepoint. Gastrointestinal (GI) tract served as the reference site. **Results:** Among 30,963 patients, survival differed significantly by primary site ($p<0.001$). From diagnosis, CNS/brain involvement was associated with markedly worse survival compared with GI disease (HR 2.09, 95% CI 2.00–2.19), while several sites appeared favorable at diagnosis. Among 12-month survivors (n=20,497), excess risk for CNS persisted (HR 2.46). In contrast, early advantages for bone/bone marrow and head/neck diminished, and breast, skin/soft tissue, and testis were associated with higher subsequent hazards (HR ~1.2 each). At 24 months (n=17,614), increased risk remained for CNS (HR 2.47), lung/pleura (HR 1.41), breast (HR 1.35), skin/soft tissue (HR 1.23), and testis (HR 1.26), while most other differences were small or no longer significant. **Conclusions:** Prognostic differences by primary site change after conditioning on early survival. CNS involvement remains high risk, while several sites that appear favorable at diagnosis lose this advantage over time. Landmark analyses provide more meaningful risk estimates for survivors but cannot account for site-specific treatment differences in SEER. Research Sponsor: None.

Adjusted hazard ratios for overall survival by primary extranodal site among 12- and 24-month survivors.

Site (ref: GI)	12m HR (95% CI)	24m HR (95% CI)	Site (ref: GI)	12m HR (95% CI)	24m HR (95% CI)
Bone/Bone marrow	1.01 (0.93–1.11)	0.96 (0.87–1.07)	Breast	1.24 (1.09–1.42)	1.35 (1.17–1.55)
CNS/Brain	2.46 (2.29–2.65)	2.47 (2.27–2.68)	Head/Neck	1.03 (0.96–1.11)	1.08 (1.00–1.17)
Hepatobiliary/ Pancreas	1.18 (1.04–1.34)	1.12 (0.97–1.29)	Kidney/Adrenal	1.26 (1.07–1.48)	1.07 (0.88–1.29)
Lung/Pleura	1.39 (1.26–1.54)	1.41 (1.26–1.58)	Skin/Soft tissue	1.23 (1.14–1.33)	1.23 (1.13–1.34)
Spleen	0.91 (0.80–1.04)	0.92 (0.80–1.06)	Testis	1.23 (1.11–1.37)	1.26 (1.12–1.41)

Adjusted for age, sex, race/ethnicity, and diagnosis era. Landmark Cox models among patients alive at 12 and 24 months.

Deep learning–based PET/CT radiomics-clinical model for prognostic stratification and immunotherapy exploration in natural killer/T-cell lymphoma. First Author: Tongyu Lin, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China

Background: Natural killer/T-cell lymphoma (NKTCL) is a highly aggressive malignancy with substantial heterogeneity. The value of deep learning on PET/CT-based radiomics for risk stratification in NKTCL remains to be defined. **Methods:** In this retrospective multicenter study, 425 consecutive NKTCL patients from four hospitals were randomly assigned to training or validation cohorts. Radiomics features extracted from pre-treatment PET/CT images were used to construct prognostic models with multiple deep learning algorithms. The best model was integrated with established clinical prognostic factors, and its performance in informing treatment decisions was tested in another independent immunochemotherapy cohort. **Results:** The XGBoost-based radiomics model achieved the highest prognostic accuracy for progression-free survival (PFS) and overall survival (OS) across cohorts. Integration with clinical factors yielded the Radiomic-Clinical Prognostic Model (RCPM), which further improved prediction (training cohort AUC: PFS 0.977, OS 0.946; validation cohort AUC: PFS 0.834, OS 0.814) and effectively stratified patients into high- and low-risk groups with distinct PFS and OS (all $P < 0.001$). In another exploratory treatment cohort, high-risk patients derived significant benefit from PD-1 inhibitor therapy (3-year PFS: 67.7% vs. 21.7%, 3-year OS: 81.7% vs. 39.6%; both $P < 0.001$), whereas low-risk patients did not. **Conclusions:** In conclusion, the RCPM demonstrated strong prognostic value and may help identify patients who could potentially benefit from immunotherapy in NKTCL. Research Sponsor: National Natural Science Foundation of China; U24A20679 and 82470237.

Efficacy and safety of mesutoclax (ICP-248) in combination with orelabrutinib in patients with B-cell malignancies: A pooled analysis. First Author: Zhiming Li, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Mesutoclax (ICP-248) is a next-generation BCL2 inhibitor, and orelabrutinib is a marketed BTK inhibitor for CLL/SLL, MCL, and MZL. However, the clinical activity of their combination in these malignancies remains undefined. This analysis evaluated the combination of mesutoclax and orelabrutinib across B-cell malignancies. **Methods:** Patients with relapsed and refractory (R/R) MCL, MZL were enrolled in a phase 1 study (NCT05728658), and treatment-naive (TN) CLL/SLL were enrolled in a phase 2 study (NCT06378138). R/R MCL and MZL patients received continuous daily mesutoclax (125 mg) and orelabrutinib (150mg) from cycle 1 day 1 continuously until disease progression or unacceptable toxicity. For CLL/SLL patients, induction therapy with orelabrutinib (150 mg QD, Cycles 1-17) was administered first, followed by mesutoclax (100 mg or 125 mg QD, Cycles 3-14). The orelabrutinib treatment continued beyond cycle 17 if the uMRD ($\leq$10-4) was not achieved. Mesutoclax was implemented with a ramp-up schedule in all patients to mitigate the risk of TLS. **Results:** As of 05 Jan 2026, 60 patients were enrolled and treated in the studies: 8 R/R MCL, 10 R/R MZL, and 42 TN CLL/SLL (mesutoclax 100 mg, n=21; 125 mg, n=21). In R/R patients, the median number of prior lines of therapy was 1 (1-4). 6 (33.3%) were refractory to the last line of therapy. For TN CLL/SLL, 76.2% (32/42) of patients had moderate or high TLS risk, and 14.3% (6/42) had TP53 mutation or del (17p). Among 5 MCL and 8 MZL patients who had at least one disease evaluation, the overall response rate (ORR) was 100%, with CRR of 100% and 50%, respectively. Five patients (38.5%) achieved peripheral blood (PB) uMRD. In the 21 CLL/SLL patients receiving mesutoclax 125 mg, the ORR was 100% and the CRR was 38.1%, and the peripheral blood uMRD rate at 36-week was 65%. The median time to CR was 3.7 months in R/R group and 7.1 months in TN group. The 12-month PFS rate was 100% in CLL/SLL, while data for MCL and MZL are immature due to short follow-up. As the safety data cutoff (31 Dec 2025), the combination of mesutoclax and orelabrutinib was well tolerated with a favorable safety profile, and no new safety signals were identified compared to either agent as monotherapy. Most TEAEs were grade 1-2, with no TEAEs leading to drug discontinuation or death reported. The most common grade $\geq$3 TEAEs include neutrophil count decreased (35%), platelet count decreased (11.7%). Notably, no grade $\geq$3 anemia was reported. No clinical or laboratory TLS occurred. **Conclusions:** Mesutoclax in combination with orelabrutinib demonstrated a tolerable safety profile across B cell malignancy subtypes (MCL, MZL, CLL/SLL). Significant 100% ORR and deep response were observed in patients receiving mesutoclax 125mg combined with orelabrutinib. This all oral, chemo-free regimen has the potential to establish a novel therapeutic option for B-NHLs. Clinical trial information: NCT05728658. Research Sponsor: None.

Effect of FDG-PET–based bone marrow assessment on prognostic accuracy compared to conventional histologic evaluation in patients with follicular lymphoma: A subanalysis of the FIL FOLL12 trial. First Author: Stefano Luminari, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

Background: Bone marrow biopsy (BMB) is an invasive staging procedure for follicular lymphoma (FL) and its results are needed to calculate FLIPI2 and PRIMA-PI scores. Beyond conventional biopsy bone marrow can also be assessed through FDG-PET bone staging (PETb). We report preliminary data on a comparison of BMB and PETb in assessing BM involvement among FL patients enrolled in the FIL-FOLL12 trial. **Methods:** Untreated stage II–IV FL patients requiring therapy were included. Patients were balanced according to treatment received and arm. BMBs were assessed by morphology and immunohistochemistry. PET/CT scans were reviewed by two expert nuclear medicine physicians. Pathological bone uptake (PETb+) was defined as mono- or multifocal, or diffuse FDG uptake in bone segments higher than liver activity (SUVmax). **Results:** This analysis included 179 patients; no significant differences in disease characteristics were observed between the revised cohort and the remaining patients enrolled in the FOLL12 trial. High-risk FLIPI2 was noted in 35.4%, and β2-microglobulin was increased in 53% of patients. BMB involvement was present in 58.5% (median infiltration 30%, range 0.5–95%). PETb was positive in 38 cases (21%), including 14% with focal or multifocal involvement and 7% with diffuse increased uptake. Concordant results between BMB and PETb were observed in 53.6%: among 103 BMB+ patients, 30 were PETb+ (29%). PETb identified BM involvement in 8 cases missed by BMB. While BMB+ was not associated with a different risk of PFS compared to BMB-, we observed a significant impact of PETb+ on PFS: PETb+ had 41% 5-year PFS (CI 25-72, p=0.003), while BMB+/PETb- showed 74% (CI 62-83, p=0.27) and BMB-/PETb- 66%(CI 52-72, reference).We then calculated FLIPI2 and PRIMA-PI using either conventional BMB or PETb to define BM involvement. The agreement between BMB and PETb scores was 87% for FLIPI2 and 67% for PRIMA-PI and the main disagreement was due to reallocation to lower risk groups; FLIPI2 0-2 patients raised from 65% to 74.3% according to FLIPI2-PET. FLIPI2 was confirmed prognostic for PFS and its c-Harrel increased from 0.582 to 0.602 when BMB was substituted with PETb (Table 1), with a 52% (CI 39-64) 5-Year PFS for conventional high risk FLIPI2 shifting to 41% (CI26-56) for high risk FLIPI2-PET. **Conclusions:** Although BMB detects marrow involvement in most patients, this does not uniformly translate into adverse prognosis. PETb, while less sensitive, identifies metabolically active and prognostically relevant bone disease. A FDG-PET-based assessment of bone involvement could refine risk stratification in FL and spare BMB in most patients Research Sponsor: None.

Score	HR for High risk	CI	c-Harrell
FLIPI2	2.03	1.25-3.31	0.582
FLIPI2-PET	2.58	1.57-4.26	0.602
PRIMA-PI	1.23	0.67-2.23	0.537
PRIMA-PI-PET	1.47	0.85-2.54	0.550

Defining APOBEC-like signature in diffuse large B-cell lymphoma and demonstration of distinct transcriptomic profile. First Author: Adam Albitar, Genomic Testing Cooperative LCA, Lake Forest, CA

Background: APOBEC (apolipoprotein B mRNA editing enzyme, catalytic polypeptide-like) mutational signatures are uncommon in hematologic malignancies compared with solid tumors. This signature is characterized by C>T and C>G substitutions and clustered chromosomal abnormalities and is typically defined using whole-genome or whole-exome sequencing. Data on APOBEC signatures detected by targeted gene panels are limited. We interrogated a database of diffuse large B-cell lymphoma (DLBCL) cases sequenced between 2023 and 2025 using a targeted panel. Cases with >30 mutations were classified as "APOBEC-like," and their molecular and expression features were analyzed. **Methods:** DNA and RNA were extracted from FFPE samples and sequenced by next-generation sequencing. DNA sequencing used a 302-gene panel and RNA sequencing a 1,600-gene panel. Hybrid-capture libraries were sequenced on an Illumina NovaSeq 6000. **Results:** Among 670 DLBCL cases, 39 (6%) demonstrated an APOBEC-like signature. A striking feature was the presence of multiple mutations within the same gene. One case harbored 20 distinct SOCS1 mutations, and 20 of 39 cases (51%) had at least one gene with $\geq$10 mutations. Cell of origin was germinal center B-cell in 21 cases (54%). All APOBEC-like cases showed numerous chromosomal abnormalities, most commonly 6q deletion/monosomy 6 (23 cases, 59%). Deletion of 17p was rare (2 cases). TP53 mutations were detected in 12 cases (31%), PIM1 in 23 (58%), and SOCS1 in 18 (46%). Gene expression profiling revealed significant differences between APOBEC-like and average DLBCL cases. TRAF3, TRAF5, and TRAF2 expression was significantly lower in APOBEC-like cases (log10 FDR < -12), while NAMPT, PRPF8, SF3A1, NFYC, LUC7L2-MCM3AP, and SMAD5 were significantly overexpressed (log10 FDR < -7). Despite the limited cohort size, random forest modeling demonstrated that expression profiling could distinguish APOBEC-like cases, with 20 genes achieving an AUC of 0.904 in a testing set. **Conclusions:** APOBEC-like mutational signatures can be identified in approximately 6% of DLBCL cases using targeted gene panels and are characterized by extreme intragenic hypermutation, recurrent chromosomal abnormalities, and a distinct expression profile that enables accurate classification by machine-learning approaches. Research Sponsor: None.

Aberrant somatic hypermutation in large B-cell lymphomas and its relationship to mutational signatures, including a novel haloalkane pattern. First Author: Nicholas J. Dcunha, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Diffuse large B cell lymphoma (DLBCL) is a genetically complex disease, often characterized by the simultaneous occurrence of multiple mutations within single driver genes. Here, while activation-induced cytidine deaminase (AID)-driven aberrant somatic hypermutation (aSHM) is recognized as a major contributor to mutation, many genes could be heavily mutated due to other mechanisms. In this study, we evaluate clinical DLBCL samples identified as hypermutated, to assess the presence of AID driven mutation and the contribution of other defined mutational signatures which may contribute to clinicopathologic heterogeneity. **Methods:** Clinical samples of DLBCL tested by a hybrid-capture next-generation sequencing (NGS) panel targeting up to 468 genes, were identified. Hypermutated cases were selected based on the qualifying criteria of having three or more co-occurring mutations in at least 1 gene. Based on the mutational position from transcriptional start site and inter-mutational distance, cases were initially classified as having aSHM or Kataegis. Mutational signature analysis was performed using all high-confidence somatic single-base substitutions (SBS) identified and interpreted according to COSMIC SBS signatures v3.5. A predominant signature was defined when >40% of the mutations were attributed to the signature. Wherever possible, correlation between the morphological type, molecular subtype, and mutational signatures was performed. **Results:** Out of the 216 samples identified as hypermutated, most (n=172, 79.6%) were classified as having aSHM, 9.3% (n=20) as Kataegis and 11.1% (n=24) were unclassifiable. The 3 most common genes targeted by aSHM were PIM1(n=66), SOCS1(n=55) and BCL2(n=35). By contrast, SGK1(n=16), MYC(n=12), GNA13(n=6) and ITPKB(n=6) were the common targets of Kataegis. The most frequent dominant molecular signatures included AID (n=82) and Clock-like aging(n=48), followed by Haloalkane (n=24), MMR deficiency (n=17) and the SBS39 (n=14) signature of unknown etiology. Based on morphology and immunophenotype, cases were primarily stratified as either Germinal Center B-cell like (GCB; n=86) or Non-GCB (n=87), with lower representation of Primary mediastinal B cell lymphomas (n=21), High grade B cell lymphomas with MYC and BCL2 translocations (n=18), and DLBCL special subtypes (n=4). The same top 3 molecular signatures were identified across all subtypes, except in GCB, where MMR deficiency constituted the 3rd most frequent signature. **Conclusions:** In DLBCL, mutational signatures are primarily driven by endogenous processes, namely AID and Aging. The identification of a haloalkane signature in a small proportion of cases is a novel finding, raising suspicion for the role of exogenous influences, either environmental or therapeutic in origin. Further studies are needed to better define this cohort. Research Sponsor: None.

An exploratory study to assess the safety, immunogenicity, and preliminary anti-tumor activity of the EBV mRNA vaccine (WGc-043 injection) combined with PD-1 antibody in patients with relapsed or refractory ENKTL. First Author: Xingchen Peng, Cancer Center and State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, China

Background: Extranodal NK/T cell lymphoma (ENKTL) is a rare and aggressive lymphoma associated with Epstein-Barr virus (EBV) infection and requires novel therapeutic strategies. WGc-043, a therapeutic mRNA vaccine, showed promise against ENKTL patients alone by targeting EBV-driven oncogenesis in our previous study. This study evaluates the safety, immunogenicity, and preliminary anti-tumor activity of WGc-043 combined with PD-1 antibody in patients with relapsed or refractory ENKTL (r/r ENKTL). **Methods:** This single-center, open-label, exploratory study enrolled 5 patients with EBER1/2 positive r/r ENKTL. The primary inclusion criteria were patients with an ECOG of 0-2 who have failed an asparaginase-based regimen. WGc-043 was administered intramuscularly, including 5 doses of base immunization followed by optional personalized treatment. The base immunization was given at week 1, 2, 3, 4 and 7. Tislelizumab (PD-1 antibody) was administered every three weeks until disease progression, for a maximum of two years. The primary endpoint is safety. Secondary endpoints include immunogenicity, ORR and DCR. The exploratory analysis focuses on immune biomarkers predictive of therapeutic response. **Results:** WGc-043 combined with PD-1 antibody (Tislelizumab) demonstrated a favorable safety and efficacy in patients with r/r ENKTL. It was well tolerated with only grade 1 adverse events. The most common adverse events were injection site reactions (100%, 4/4) , hemoglobin decreased (50%, 2/4), TSH elevated (50%, 2/4), fever (25%, 1/4), weakness (25%, 1/4) and lymphopenia (25%, 1/4). Importantly, this combo showed good, durable responses, with 2 patients achieving CR in 4 evaluable patients, and both remained CR status on the Jan 11, 2026. This result indicates that the combination of WGc-043 and PD-1 antibody is promising as part of the therapeutic strategy for this challenging lymphoma. **Conclusions:** WGc-043 combined with PD-1 antibody is well tolerated with a safety profile and yields encouraging CR rate and durable responses. Further investigations are warranted to validate these findings and to explore the full potential of this regimen in larger studies. Clinical trial information: 2200065962. Research Sponsor: None.

Safety and efficacy of GT719, an off-the-shelf CAR-NKT therapy, in adults with relapsed or refractory CD19-positive B-cell malignancies. First Author: Yarong Liu, Grit Biotechnology, Shanghai, China

Background: GT719 is an off-the-shelf CAR-NKT therapy derived from umbilical cord blood hematopoietic stem cells and genetically engineered to co-express an anti-CD19 CAR, an invariant natural killer T (NKT)-specific TCR, and secreted interleukin-15 (IL-15). This design enables CD19-targeted tumor killing, avoids risk of graft-versus-host disease (GVHD), and enhanced cellular expansion, persistence, and immune function through IL-15 signaling. We report clinical data from 7 adults with relapsed or refractory (R/R) CD19-positive B-cell hematologic malignancies enrolled in two open-label, single-arm studies (NCT06948981, NCT07131254) evaluating the safety and preliminary efficacy. **Methods:** The primary endpoint was safety, including treatment-emergent adverse events (TEAEs), graded per CTCAE v5.0. Secondary endpoints included 3-month overall response rate (ORR), best overall response (BOR), duration of response (DOR), progression-free survival (PFS), and overall survival (OS). Efficacy was assessed using Lugano 2014 criteria and the 2024 Chinese guidelines for adult acute lymphoblastic leukemia. **Results:** As of December 31, 2025, 7 patients were treated (median age 51 years; median two prior therapies), including 3 with B-ALL and 4 with B-NHL. Following FC lymphodepletion, all patients received a single GT719 infusion (5×10^7 to 1×10^9 viable cells). Most adverse events (AEs) were Grade 1-2. Grade ≥3 AEs were limited to lymphodepletion-related cytopenia and resolved or improved to Grade ≤2 within 14 days, excluding disease-related cytopenia. One patient experienced Grade 1 cytokine release syndrome that resolved within 1 day. No ICANS, neurotoxicity, or GVHD, severe infections, or serious TEAEs were observed. Efficacy was evaluable in all patients across B-ALL, follicular lymphoma (FL, grade 3a), and diffuse large B-cell lymphoma (DLBCL). The 3-month ORR was 50% (3/6), with all responders achieving CR; one patient was excluded due to insufficient follow-up. The disease control rate (DCR) was 71.4% (5/7). Two of 3 FL patients achieved CR, while one had a PR and remained under follow-up. One of three B-ALL patients achieved stringent complete remission, maintained through 24 weeks of relapse-free follow-up. CAR transgene analysis demonstrated robust in vivo expansion, with peak levels occurring between Days 7-10 in B-ALL and within two months in FL. GT719 persistence was observed for up to six months post-infusion. **Conclusions:** GT719 demonstrated a favorable safety profile and encouraging antitumor activity in adults with R/R CD19-positive B-cell malignancies. The absence of severe GT719-related toxicities and evidence of durable cellular persistence support further clinical investigation of this off-the-shelf CAR-NKT therapy. Clinical trial information: NCT06948981, NCT07131254. Research Sponsor: Grit Biotechnology. Research Sponsor: None.

First-in-human study of in vivo CAR-T therapy GT801 in adults with relapsed or refractory CD19-positive B-cell hematologic malignancies. First Author: Yarong Liu, Vivacta Biotechnology, Shanghai, China

Background: Despite high initial cure rates, patients with B-cell hematologic malignancies, including B-ALL and B-NHL, experience substantial relapse, with markedly reduced disease-free and overall survival after second-line therapy. GT801 is a first-in-human, in vivo CAR-T therapy that uses antibody-displayed lipid nanoparticle (LNP) to deliver CD19 CAR mRNA directly to T cells, enabling in vivo reprogramming without ex vivo cell manufacturing or lymphodepletion. We report initial safety and efficacy data from an open-label, single-arm phase I study (NCT07205315). **Methods:** GT801 was evaluated using a modified 3+3 dose-escalation design across three dose levels (0.5, 1.5, and 3.0 mg). Patients received up to 4 treatment cycles, each consisting of a single intravenous administration of GT801 on Day 1 of a 7-day cycle. The primary endpoint was safety, including treatment-emergent adverse events (TEAEs), graded per CTCAE v5.0. Secondary endpoints included 3-month overall response rate (ORR), best overall response (BOR), duration of response (DOR), progression-free survival (PFS), and overall survival (OS), assessed per Lugano 2014 criteria. **Results:** As of January 13, 2026, 3 patients were enrolled (median age 60 years; median three prior therapies). One patient received 3 doses at 0.5 mg, and two patients received 4 doses at 1.5 mg. All patients had B-NHL. Premedication included dexamethasone, NSAIDs, antihistamines. Most AEs were Grade 1-2. Common TEAEs included cytokine release syndrome (CRS), cytopenia, and transient liver enzyme elevations. Grade ≥3 events were hematologic toxicities and CRS. No neurotoxicity or organ failure was observed. At Week 4, all patients demonstrated a treatment response. Peripheral blood flow cytometry showed rapid CAR-T generation, with $CD8^+$ CAR-T cells detectable within 4 hours post-infusion and peak levels on Day 1. Reprogramming efficiency reached up to 93% and was maintained with repeat dosing. Minimal off-target CAR expression was detected in monocytes. Complete peripheral B-cell depletion occurred within 4 hours after the first dose and was sustained for at least 7 days; after the third dose, B-cell depletion and CAR-T detection were observed in both peripheral blood and bone marrow. **Conclusions:** GT801 demonstrated a manageable safety profile and early signs of antitumor activity in heavily pretreated B-NHL patients. The ability to generate functional CAR-T cells in vivo without lymphodepletion supports further clinical evaluation of GT801 as a promising therapeutic approach. Clinical trial information: NCT07205315. Research sponsor: Vivacta Biotechnology (Shanghai) Co., Ltd. Research Sponsor: None.

7080 Poster Session

Zanubrutinib plus rituximab as front-line treatment for mucosa-associated lymphoid tissue (MALT) lymphoma: A single-arm, phase II study (ZAMA). First Author: Yi Xia, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Guangzhou, China

Background: Mucosa-associated lymphoid tissue (MALT) lymphoma is the most common subtype of marginal zone lymphoma and follows an indolent clinical course. For patients with advanced-stage disease with an indication for treatment, rituximab-based immunochemotherapy is recommended as frontline therapy; however, toxicity and tolerability remain concerns. Zanubrutinib, a next-generation Bruton tyrosine kinase inhibitor, has shown promising antitumor activity with a manageable safety profile in marginal zone lymphoma. This study aimed to evaluate zanubrutinib plus rituximab as frontline treatment for MALT lymphoma. **Methods:** The ZAMA study (NCT06647732), a multicenter, single-arm, phase II trial, enrolled patients aged ≥18 years with histologically confirmed CD20-positive MALT lymphoma. Eligible patients had newly diagnosed advanced-stage disease or relapsed disease after prior local therapy, had not received prior systemic treatment, and had at least one measurable lesion. Patients received rituximab (375 mg/m^2) plus zanubrutinib (160 mg twice daily) in 28-day cycles. Treatment was administered for six cycles, after which patients achieving complete response (CR) entered observation, while those with partial response or stable disease received two additional cycles. The primary endpoint was the CR rate as best response. **Results:** From October 30, 2024 to December 12, 2025, 39 patients were enrolled. At the data cutoff of January 10, 2026, 23 patients had completed protocol-specified treatment, including 14 patients who received six cycles and 9 patients who received eight cycles. The median age was 58 years (range 24–75); 7 patients were males (30.4%). Most patients (n = 21, 91.3%) had an ECOG performance status of 0–1, and 21 patients (91.3%) had Ann Arbor stage III–IV disease; two patients had relapsed disease after prior local therapy. Eighteen patients (78.2%) achieved CR, and the remaining five patients achieved PR. Treatment-emergent adverse events (TEAEs) occurred in 20 patients (87.0%); hematologic toxicity were most common: neutropenia (n = 2, 8.7%), and thrombocytopenia (n = 2, 8.7%). Grade ≥ 3 TEAEs occurred in 4 patients (17.4%), most frequently neutropenia (n = 2, 8.7%), and thrombocytopenia (n = 2, 8.7%). **Conclusions:** Preliminary results from the ZAMA study show that frontline zanubrutinib plus rituximab provides encouraging efficacy with manageable safety in MALT lymphoma. The study is ongoing, and patient enrollment is continuing. Clinical trial information: NCT06647732. Research Sponsor: None.

Brentuximab vedotin plus cyclophosphamide, doxorubicin, etoposide, and prednisone (CHEPA) in newly diagnosed CD30-positive peripheral T-cell lymphomas with integrated ctDNA analysis: Results of the phase 2 CHEPA trial. First Author: Marek Trněný, Charles University, 1st Fac Medicine, General Hospital, Prague, Czech Republic

Background: Peripheral T-cell lymphomas (PTCLs) are aggressive malignancies associated with poor outcomes. While adding brentuximab vedotin (BV) to CHP has improved results in CD30+ PTCL, relapses remain common. Given the suggested benefit of etoposide (CHOEP) in younger patients, the prospective multicenter single-arm Phase 2 CHEPA study (NCT05006664) was conducted to evaluate the efficacy and safety of CHEPA (BV-CHEP) induction combined with circulating tumor DNA (ctDNA) analysis. **Methods:** Patients with previously untreated CD30+ PTCL eligible for autologous stem cell transplantation (ASCT) were enrolled. Treatment consisted of 6 cycles of CHEPA (D1: BV 1.8 mg/kg, cyclophosphamide 750 mg/m², doxorubicin 50 mg/m²; D1–3: etoposide 100 mg/m²; D1–5: prednisone 100 mg/d) every 21 days. The primary endpoint was the complete metabolic response (CMR) rate at the end of treatment (EOT). Secondary endpoints included safety, PFS, OS, ORR, and exploratory ctDNA analysis. Plasma cfDNA was profiled using CAPP-Seq (259 genes) and clonotypic VDJ sequencing at all TCR loci via SABER. **Results:** Between 05/2022 and 09/2025, 40 patients were screened; 33 met eligibility criteria and initiated therapy. The cohort included 14 (42%) ALCL and 19 (58%) non-ALCL cases (median age 57 years, range 26–69). Baseline characteristics showed a predominance of males (67%), advanced-stage disease (79%), elevated LDH (58%), and bone marrow involvement (30%); all pts had an ECOG PS of 0–1. All 33 pts completed 6 cycles of CHEPA. At EOT, 25/33 (76%) achieved CMR, meeting the primary endpoint. The ORR was 91% for the entire cohort (CMR: 86% for ALCL, 68% for non-ALCL). ASCT was preplanned in 21/33 pts and has been performed to date in 14 pts. At a median follow-up of 19 months, the 18-month PFS and OS probabilities were 75% and 92%, resp. Specifically, PFS was 100% for ALCL vs. 59% for non-ALCL, while OS was 100% vs. 87%. Age and bone marrow involvement were the only baseline variables significantly associated with CMR. Baseline ctDNA burden was significantly correlated with total metabolic tumor volume (r=0.68, p<0.001), LDH level (r=0.48, p=0.03), and PIT (p<0.05). Grade 3–4 adverse events occurred in 82% of pts, primarily hematological: neutropenia (79%), thrombocytopenia (18%), febrile neutropenia (15%), and anemia (15%). No grade 3–4 peripheral neuropathy or grade 5 events were reported. **Conclusions:** The CHEPA study met its primary endpoint with a 76% CMR rate. Despite limited follow-up and high non-ALCL prevalence of our cohort, PFS and OS results are promising. Toxicity was manageable with no treatment-related deaths even though 33% of patients were >60 years old, supporting the safety of adding etoposide to the BV-CHP backbone. Further investigation of outcomes based on EOT MRD by ctDNA is ongoing. Clinical trial information: NCT05006664. Research Sponsor: AZV NW26-03-00462; Prchal Foundation; BBMRI_CZ LM2023033.

Chidamide in combination with CHOP in previously untreated peripheral T-cell lymphoma with T follicular helper phenotype: Results of the phase II SWIFT trial. First Author: Qingqing Cai, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Peripheral T-Cell Lymphoma with T-follicular helper phenotype (PTCL-TFH), which mainly includes angioimmunoblastic T-cell lymphoma (AITL), is a biologically distinct subtype characterized by frequent epigenetic alterations. Chidamide is an oral, histone deacetylase (HDAC) inhibitor that targets HDAC subtypes 1, 2, 3, and 10, has shown encouraging activity in R/R PTCL-TFH. This study aimed to evaluate the efficacy and safety of chidamide in combination with CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisone) in previously untreated PTCL-TFH patients. **Methods:** This is a multicenter, open-label, single-arm phase II study (NCT05572983). Patients with previously untreated PTCL-TFH were enrolled and received chidamide (20 mg, oral, biweekly) combined with CHOP regimen for up to six induction cycles. Patients achieving complete response (CR) after induction entered a maintenance phase with chidamide for up to two years. The primary endpoint was CR rate. Secondary endpoints included overall response rate (ORR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between May 2023 and July 2025, a total of 47 patients were enrolled, and enrollment was completed. All patients had the AITL subtype. The median age was 62 years (IQR, 54–67), and 25.5% were female. Advanced-stage disease (stage III–IV) was present in 85.0% of patients, and 48.9% had extranodal involvement. The median number of induction cycles was 5 (range, 1–6), with 33 patients completing six cycles of induction therapy. Among 35 patients who underwent post-treatment PET/CT evaluation, the best CR rate during the induction phase was 85.2% (30/35), with an ORR of 100%. At the end of induction therapy, the CR rate was 87.9% (29/33), and the ORR remained 100%. As of October 2025, disease progression was observed in 10 patients. The most common grade 3–4 adverse events were neutropenia (42.6%), thrombocytopenia (19.1%), infections (17.0%), anemia (6.4%), and elevated transaminases (2.1%). **Conclusions:** Chidamide in combination with CHOP demonstrated promising efficacy with a manageable safety profile in previously untreated PTCL-TFH patients. A randomized controlled trial is currently ongoing to further validate these findings (NCT06947967). Clinical trial information: NCT05572983. Research Sponsor: None.

Prognostic impact of comorbidity burden on overall survival in patients with Waldenström macroglobulinemia in the United States. First Author: Gaelle Haddad, Cleveland Clinic, Weston, FL

Background: Waldenström macroglobulinemia (WM), also known as lymphoplasmacytic lymphoma (LPL), is a rare indolent Non-Hodgkin B-cell lymphoma affecting approximately 1500 patients annually in the US. Existing prognostic models: IPSS-WM, revised IPSS-WM, and MSS-WM focus primarily on disease specific factors including age, albumin, hemoglobin, platelet count, β2-microglobulin, LDH, and monoclonal IgM at diagnosis, and were derived from small cohorts. However, comorbidity burden is not included in these models, despite data showing that mortality is frequently attributed to comorbidities unrelated to lymphoma. We conducted this analysis to identify prognostic factors with emphasis on the impact of comorbidity burden on overall survival in WM. **Methods:** In this IRB approved retrospective study, we analyzed 17130 patients with histologically confirmed WM (ICD-O-3 9761/3) from the NCDB (2004–2023). Univariable and multivariable Cox regression identified independent prognostic factors for overall survival. Age stratified sub-analysis assessed the prognostic impact of comorbidity within each age group. Analyses were performed using SAS 9.4. **Results:** On multivariable Cox regression with backward elimination, Charlson comorbidity score (CC) ≥1 emerged as a significant independent predictor of mortality (HR 1.7 95% CI 1.58–1.75 p < 0.0001). Age-stratified analysis confirmed CC ≥1 significance in all age groups (HR 1.52-2.07, p<0.0001). Seven additional prognostic factors were identified: advanced age was associated with progressively worse survival (55≤age<65: HR 1.7; 65≤age<75: HR 2.3; age≥75: HR 5.5; all p<0.0001), while female sex was protective (HR 0.86; p<0.0001). Lower median household income was associated with worse outcomes (<$40,227: HR 1.38; $40,227–$50,353: HR 1.26; $50,354–$63,332: HR 1.1; all p<0.0001). Private insurance was associated with better OS compared with uninsured (HR 1.7; p<0.0001) and governmental insurance (HR 1.3; p<0.0001). Treatment at non-academic facilities (HR 1.13; p<0.0001) and multiple primary malignancies (HR 1.19; p<0.0001) were associated with inferior survival. No difference was observed between multi- and single-agent chemotherapy (HR 1.0; p=0.96), while patients not requiring chemotherapy had superior survival (HR 0.80; p<0.0001). **Conclusions:** In the largest WM cohort to date, we identified several prognostic factors impacting survival WM patients in the US. Among these factors, CC ≥1 was a strong independent predictor of mortality. Given that half of deaths in WM patients are due to comorbidities, comorbidity assessment is essential for accurate prognostication and individualized treatment planning. Managing comorbidities may be as important as treating the disease itself. CC or equivalent should be integrated into future prognostic models to improve clinical decision-making in WM. Research Sponsor: None.

Age and HIV status as survival predictors in HHV8-positive diffuse large B-cell lymphoma: The largest population-based analysis to date. First Author: Gaelle Haddad, Cleveland Clinic, Weston, FL

Background: HHV8-positive Diffuse Large B Cell Lymphoma (HHV8+ DLBCL) is a rare and aggressive subtype of Non-Hodgkin Lymphoma that is frequently associated with HHV8-positive Multicentric Castleman Disease (MCD). Due to its rarity, population-based studies have been limited to small cohorts or have focused primarily on demographic features without survival analysis. This study explores demographic features, treatment pattern and prognostic factors affecting survival in patients diagnosed with (HHV8+ DLBCL) in the United States. **Methods:** Following IRB approval, we analyzed the largest cohort of HHV8+ DLBCL to date (n=262) using the National Cancer Database (NCDB) (2010-2023). Patients with histologically confirmed HHV8+ DLBCL (ICD-O-3 9738/3) were included. Univariable Cox regression identified factors associated with survival; significant variables were included in multivariable cox regression with backward elimination ($p<0.05$). Data was analyzed using SAS version 9.4. **Results:** Among 262 patients with HHV8+ DLBCL, (mean age 52.6 years), 65.6% were <60 years, 76.7% were male, and 66.0% were white. Primary site was predominantly nodal (78.6%), with extranodal involvement in 21.4%. 19.2% were HIV-positive, and 63.3% had no comorbidities (Charlson-Deyo score 0). The majority received systemic therapy (84.6%). Among treated patients, 62.2% received chemotherapy and 43.1% received immunotherapy. Median overall survival was 133 months, with 1-, 3- and 5-year survival rates of 68.2%, 63.1%, and 59.9%, respectively. On multivariable Cox regression analysis, age $\geq$60 years (HR 2.20, p=0.0004), higher Charlson-Deyo score (HR 1.67, p=0.0090), HIV-positive status (HR 2.56, p=0.0026), and absence of systemic treatment (HR 2.16, p=0.0016) was independently associated with worse overall survival. **Conclusions:** In conclusion, HHV8+ DLBCL is a rare and aggressive lymphoma with poor long-term survival, frequently associated with multicentric Castleman disease, mainly affecting males with nodal involvement. Age $\geq$60 years, higher Charlson-Deyo score, HIV-positive status, and lack of systemic treatment independently predicted worse survival. Our study provides the largest cohort analysis of HHV8+ DLBCL to date. Nevertheless, further prospective studies with larger sample sizes are necessary to gain deeper insight into the pathogenesis and optimize treatment of this rare lymphoma. Research Sponsor: None.

Genomic profiling of Burkitt lymphoma in adults: Novel molecular insights and implications for outcomes. First Author: Manju Sengar, Tata Memorial Hospital, Mumbai, India

Background: The real-world treatment outcomes of Burkitt lymphoma (BL) from low-middle income countries appear to be inferior ($<$60%). Delays in diagnosis, treatment interruptions and toxicities are often attributed as the reasons for poor outcomes. However, biological differences could also explain the observed differences. However, there is limited information on the molecular profile of adult BL from developing countries. **Methods:** We evaluated a cohort of adult BL (histopathologically confirmed) who received treatment at our centre between 2012-2019. The data on demography, stage, HIV status, treatment type, response and survival was recorded. The formalin-fixed paraffin blocks were subjected to targeted next-generation sequencing using the hybrid capture based targeted panel- SOPHiA Lymphoma Solution which identifies single nucleotide variants (SNVs), indels from 73 genes and gene amplification events in 68 genes. **Results:** Among a total of 165 patients, the adequate quality DNA was extracted from 76 patients(83% males). Median age was 34 years ;67% patients had stage III/IV disease,10% were HIV positive. Treatment regimen were high-dose methotrexate based-74 %, 24%- DA-EPOCH. Rituximab was given to 83% of patients. Complete response was seen in 69% of patients. 67 cases (88.2%) harboured at least one somatic variant, while no variants were detected in 9 cases (11.8%) within the genes covered by the targeted panel. A total of 712 somatic variants were identified across the cohort. Based on ACMG/AMP classification, 88 variants (12.4%) were categorized as oncogenic and 318 variants (44.7%) as likely oncogenic. This indicates a substantial mutational burden in Burkitt lymphoma, despite its classical characterization as a MYC-driven malignancy. Considering only oncogenic and likely oncogenic variants, the most recurrently mutated genes were *KMT2D, CREBBP, ARID1A, EP300* and *TP53*. *TP53* showed the highest number of confirmed oncogenic variants (22 variants) and also accounted for the largest number of missense mutations (16 out of 158 missense variants). Mutations in *PTPRD* and *ITPKB* were mutually exclusive (p = 0.051), as were mutations in *CCND3* and *KMT2D* (p = 0.053). These patterns suggest possible distinct molecular subsets of Burkitt lymphoma, potentially reflecting alternative oncogenic pathways driven either by aberrant cell cycle regulation (*CCND3*) or by epigenetic dysregulation *(KMT2D*). **Conclusions:** Our data suggests that histopathologically confirmed BL have complex mutational landscape characterized by frequent alterations in epigenetic regulators, tumour suppressor genes, and key signalling molecules which can lead to inferior outcomes. Research Sponsor: None.

iMARIX for primary and secondary central nervous system lymphomas. First Author: Ekin Kırcalı, Medicana International Ankara, Ankara, Turkey

Background: The Bruton tyrosine kinase inhibitor (BTKi) ibrutinib is used in relapsed/resistant central nervous system (CNS) lymphoma because it can cross the blood-brain barrier and is effective as a single drug. Its efficacy has been demonstrated in combination with rituximab and high-dose methotrexate. CNS lymphomas are aggressive lymphomas, and responses to single-agent therapies are generally poor or insufficient. Also, even well-established agents used in lymphoma treatment may sometimes be unavailable worldwide, and drug restrictions may be experienced worldwide. Thiotepa is one of these agents. In this case series, we summarized the iMARIX treatment in which we used ibrutinib in combination with high-dose methotrexate, cytarabine and rituximab instead of thiotepa for the treatment of primary/secondary CNS lymphomas. **Methods:** The participants diagnosed with primary/secondary CNS lymphoma and treated between August 2022 and December 2025, received rituximab 375 mg/ m2 (one day), 3.5 g/m2 methotrexate (one day), 2x2 g/ m2 cytarabine (two days), and ibrutinib 560 mg/day in each course. Ibrutinib was continued provided that platelet count is over 30.000/ mm3 and neutrophil count is over 500/ mm3. Patient data were collected retrospectively. **Results:** 17 patients were treated with iMARIX protocol during the study course. Male/ female ratio was 8 (47%)/ 9 (53%) and the median age was 53 (21- 71). 8 (47 %) of the participants had primary whereas 9 (53 %) had secondary CNS lymphoma. 4 (23.5%) participants died of either relapse or sepsis during the study period. The median overall survival was 16.3 months (4- 31.6). 13 (76,5 %) patients underwent consolidative autologous stem cell transplantation (ASCT). One patient experienced atrial fibrillation due to ibrutinib use. One patient experienced relapse after ASCT and was further treated with allogeneic stem cell transplantation. **Conclusions:** Although our patient series is small, the results suggest that the combination of ibrutinib with high-dose methotrexate, rituximab and cytarabine is a combination that may yield good clinical results with an acceptable tolerance and adverse effect profile. Evaluating the incidence and predictors of chronic opioid use in early survivorship for patients with diffuse large B-cell lymphoma. First Author: Mithunan Ravindran, Department of Medicine, University of Toronto, Toronto, ON, Canada

Background: Exposure to opioids during cancer treatment is common and may lead to new persistent opioid use (NPOU) in a subset of patients in survivorship. There are limited data on the incidence and predictors of NPOU in a diffuse large B-cell lymphoma (DLBCL) cohort. **Methods:** We conducted a population-based cohort study utilizing health administrative datasets from Ontario, Canada. We included patients $\geq$18 years old with DLBCL who received first-line rituximab-based chemoimmunotherapy from 2014 to 2021 and survived $>$365 days after treatment. We considered patients to be opioid exposed if they filled $\geq$1 opioid prescriptions from 90 days prior to and 180 days after first rituximab-based chemoimmunotherapy (the exposure window). The primary outcome was NPOU defined as filling $\geq$1 opioid prescriptions in each of the two half-years of follow up after the exposure window (i.e. within both 0-180 days and 181-365 days). We used a multivariable Poisson regression model with robust error variance to assess the relative risk (RR) of NPOU while controlling for covariates. **Results:** Our cohort consisted of 4,988 patients with DLBCL. The median age was 66 years and 32.3% had relapsed/refractory disease. Opioid exposure occurred in 55.0% of the entire cohort. Of the entire cohort, 6.7% fulfilled criteria for NPOU including 10.4% of exposed patients compared to 2.4% of unexposed patients. In the multivariable analysis, exposed patients were four times more likely to develop NPOU (RR 3.81, 95% CI 2.85-5.07). After adjustment, other statistically significant predictors of NPOU included palliative care use in follow-up (RR 2.77, 95% CI 2.21-3.47), relapsed/refractory disease (RR 1.63, 95% CI 1.33-1.99), comorbid disease burden (RR 1.50, 95% CI 1.01-2.23), and prior mental health diagnoses (RR 1.27, CI 1.01-1.58). **Conclusions:** Over 1 in 2 DLBCL patients were exposed to opioids during treatment and 1 in 10 exposed patients developed NPOU. Exposed patients were four times more likely to develop NPOU. Our study identified several clinically relevant predictors of NPOU in DLBCL, which may enable clinicians to identify high-risk patients who would benefit from early intervention. Survival outcomes of plasmablastic lymphoma according to immune status. First Author: Hien Lau, Department of Medicine, University of Southern California (USC), Los Angeles, CA

Background: Plasmablastic lymphoma (PBL) is a rare, aggressive subtype of NHL associated with HIV, but also reported in other immunosuppressed states. Outcomes of PBL patients with non–HIV-related immunosuppression remain poorly defined. We compared clinicopathological features and survival outcomes among patients with HIV-associated immunosuppression (IS-HIV), and non–HIV-related immunosuppression (IS) and those without HIV or history of immunosuppression (IC). **Methods:** We retrospectively analyzed 35 patients with pathologically confirmed PBL, including 14 IC, 16 IS-HIV, and 5 IS patients. Associations between immune status and clinical characteristics were assessed using chi-square analysis. Progression-free survival (PFS) and overall survival (OS) were evaluated using Kaplan–Meier analysis with log-rank testing and multivariable Cox proportional hazards regression. **Results:** Median ages were 49, 45, and 56 years for IC, IS-HIV, and IS groups, with male predominance across all groups (71.4%, 93.8%, and 100%), respectively. Epstein–Barr virus positivity was significantly higher in IS-HIV (93.8%) and IS (40.0%) compared with IC patients (14.3%; $p< 0.01$). IS patients had lower rates of extranodal involvement than IC and IS-HIV patients (80.0% vs 100%; $p= 0.04$). Immune status was not associated with age, sex, ethnicity, ECOG performance status, stage, IPI score, radiation therapy, CNS prophylaxis, or autologous stem cell transplantation. Rates of primary refractory disease and relapse did not differ significantly among IC (14.3%, 21.4%), IS-HIV (31.3%, 12.5%), and IS (40.0%, 0%) groups (p = .42 and p = .48, respectively). Response rates following first-line therapy were numerically lower in IS patients but did not differ significantly ($p= 0.23$). Median follow-up was 30, 21, and 4 months for IC, IS-HIV, and IS groups, respectively. Median PFS was 60.5 months, not reached, and 4 months for IC, IS-HIV, and IS groups, respectively ($p= 0.03$). One- and two-year OS rates were 78.6% and 64.3% (IC), 74.0% and 65.8% (IS-HIV), and 0% and 0% (IS; $p= 0.02$). On multivariable analysis, IS status was associated with inferior PFS (HR 3.6, $p= 0.03$) and OS (HR 3.9, $p= 0.03$), whereas IS-HIV was not. **Conclusions:** PBL patients with non–HIV-related immunosuppression experienced significantly inferior PFS and OS compared with IC and IS-HIV patients. Although lower response rates and higher primary refractory disease were observed in IS patients, these differences did not reach statistical significance, likely due to small sample size. Consistent with prior reports, HIV-associated immunosuppression was not associated with worse survival. Larger studies are needed to better define disease biology and optimize therapeutic strategies for this high-risk population. Research Sponsor: None.

Survival of hematologic malignancy in patients with early-stage chronic kidney disease (SHIP-CKD). First Author: Songphol Tungjitviboonkun, University of California, San Francisco, San Francisco, CA

Background: Chronic kidney disease (CKD) is a common comorbidity among cancer patients and may influence treatment options and outcomes. However, the independent effect of CKD in patients with hematologic malignancies remains unclear. **Methods:** We conducted a retrospective cohort study using electronic medical records, including 1,238 adult patients diagnosed with hematologic malignancies between 2015 and 2019. Patients with CKD stages 1–3A were compared to those without CKD. The primary outcome was 5-year all-cause mortality. We used stratified Cox proportional hazards models adjusted for age, sex, and comorbidities (HIV, diabetes, hypertension, and COPD) and performed 1:1 propensity score matching without replacement. Subgroup analyses by cancer subtypes were performed. **Results:** Among 1,238 patients, 529 (42.7%) had CKD. CKD patients were older (67 vs. 55 years), with higher rates of hypertension (66.0% vs. 48.0%). Five-year mortality was higher in the CKD group (24.4% vs. 17.8%, p=0.006). In adjusted Cox models, CKD was not significantly associated with mortality (HR 1.08; 95% CI: 0.82–1.43). Subgroups by stages showed no significant risk: stage 1 (HR 1.27; 95% CI: 0.76–2.13), stage 2 (HR 1.05; 95% CI: 0.77–1.43), stage 3A (HR 1.03; 95% CI: 0.60–1.78). In matched analysis (n=758), CKD remained non-significant (HR 1.04; 95% CI: 0.77–1.41). **Conclusions:** Early-stage CKD was common and linked to higher unadjusted mortality, but not with increased mortality after adjusting for covariates. These findings suggest that early-stage CKD may not independently impact survival among patients with hematologic malignancies. Research Sponsor: None.

Comparative effectiveness of CAR-T and bispecific antibodies in relapsed/refractory large B-cell lymphoma: A network meta-analysis of phase III trials. First Author: Aniqa Baloch, The Wright Center for GME, Scranton, PA

Background: Second-line and later-line cellular therapies and bispecific antibodies have transformed the management of relapsed/refractory large B-cell lymphoma (LBCL), yet comparative efficacy across platforms remains uncertain due to the absence of head-to-head trials. We conducted a network meta-analysis (NMA) to compare disease control and overall survival (OS) across contemporary randomized phase III studies, representing the first synthesis of contemporary CAR-T and bispecific antibody phase III data. **Methods:** A frequentist graph-theoretical NMA was performed using trial-level hazard ratios (HRs) extracted from five randomized phase III trials (ZUMA-7, TRANSFORM, BELINDA, STARGLO, SUNMO). Treatments included axicabtagene ciloleucel, lisocabtagene maraleucel, tisagenlecleucel, glofitamab-GemOx, mosunetuzumab-polatuzumab, and chemoimmunotherapy as the reference. Outcomes were disease control (EFS/PFS) and OS. Random-effects models were applied, and P-scores were used to rank treatment hierarchy. **Results:** Five trials encompassing approximately 2,000 patients were included. For disease control, lisocabtagene maraleucel (HR 0.35, 95% CI 0.23–0.53), axicabtagene ciloleucel (HR 0.40, 95% CI 0.31–0.51), glofitamab-GemOx (HR 0.40, 95% CI 0.28–0.57), and mosunetuzumab-polatuzumab (HR 0.41, 95% CI 0.29–0.58) each significantly improved outcomes, whereas tisagenlecleucel did not (HR 1.07, 95% CI 0.82–1.40). Ranking favored lisocabtagene maraleucel (P-score 0.82), followed by axicabtagene ciloleucel (0.67), glofitamab-GemOx (0.67), and mosunetuzumab-polatuzumab (0.64). For OS, lisocabtagene maraleucel (HR 0.59, 95% CI 0.40–0.87), glofitamab-GemOx (HR 0.62, 95% CI 0.43–0.89), and axicabtagene ciloleucel (HR 0.73, 95% CI 0.55–0.97) significantly improved survival, while mosunetuzumab-polatuzumab showed a non-significant favorable trend (HR 0.80, 95% CI 0.52–1.24). Tisagenlecleucel did not improve OS (HR 1.24, 95% CI 0.83–1.85). OS rankings again favored lisocabtagene maraleucel (P-score 0.84), followed by glofitamab-GemOx (0.80) and axicabtagene ciloleucel (0.61). **Conclusions:** Across randomized phase III evidence, lisocabtagene maraleucel demonstrated the highest probability of being the most effective therapy for both disease control and overall survival in relapsed/refractory LBCL, followed closely by glofitamab-GemOx and axicabtagene ciloleucel, while tisagenlecleucel consistently ranked lowest. Although limited by cross-trial heterogeneity inherent to indirect comparisons, these findings highlight meaningful differences across platforms and may inform treatment sequencing while prospective head-to-head studies mature. Utility of a modified geriatric assessment to identify impairments in adults of all ages with lymphoma: A prospective observational cohort study. First Author: Christopher Edward Jensen, Lineberger Comprehensive Cancer Center, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Performance status assessments may overlook important health vulnerabilities in adults with cancer. While geriatric assessment (GA) systematically evaluates multiple domains including physical function, cognition, psychological health, comorbidity, and nutrition, it has been predominantly studied in older adults. We evaluated the prevalence and patterns of GA-identified deficits among adults of all ages initiating systemic therapy for lymphoma. **Methods:** Adults with lymphoma enrolled in a prospective registry at an academic cancer center from 2018-2025 completed a modified Cancer and Aging Research Group (CARG) GA at treatment initiation. The assessment included validated measures across eight domains: mobility (Timed Up and Go), falls history, instrumental activities of daily living (IADLs), medication burden, comorbidities, weight loss, cognition (Blessed Orientation-Memory-Concentration test), and psychological health (Mental Health Index-13). Karnofsky Performance Status (KPS) was documented. Prevalence of deficits was compared between adults <65 and ≥65 years. **Results:** Among 97 participants (mean age 57 years, range 22-84; 39% ≥65 years), 94% had normal KPS (≥80). Despite preserved performance status, 56% had multiple (≥2) GA-identified deficits, and only 21% had zero deficits. The most common deficit was unintentional weight loss (43% overall). Among younger adults (<65 years), substantial proportions reported weight loss (34%), falls (27%), IADL impairment (27%), and anxiety or depression (45%). Most deficits did not differ significantly between age groups, though weight loss, multimorbidity (≥4 comorbidities), and severe polypharmacy (≥10 medications) were more prevalent in older adults. **Conclusions:** GA reveals high prevalence of health-related deficits across multiple domains in adults with lymphoma regardless of age, despite preserved performance status. These findings support a shift toward needs-based rather than age-based approaches to identify individuals who may benefit from supportive care interventions. Research Sponsor: None.

Functional measures among adults treated for lymphoma, stratified by age.

Deficit Domain	Full Cohort % (95% CI)	Age < 65 % (95% CI)	Age ≥ 65 % (95% CI)	p**
Weight Loss	43 (33-53)	34 (23-47)	57 (41-71)	**0.035**

Temporal trends in ischemic heart disease mortality among lymphoma patients in the United States, 1999–2023: A 25-year nationwide analysis. First Author: Prithvi Raghavan, Sinai Hospital of Baltimore, Baltimore, MD

Background: Enhanced lymphoma survival has transitioned clinical priorities toward non-malignant late effects, particularly cardiovascular morbidity. Although life-extending therapies like radiation and anthracyclines are effective, their cardiotoxic profiles significantly increase Ischemic Heart Disease (IHD) risk. Despite this, longitudinal trends and demographic disparities in lymphoma-IHD mortality remain under-investigated. This study analyzes 24 years of data to characterize mortality shifts and identify vulnerable populations, aiming to optimize integrated cardio-oncology management. **Methods:** We conducted a population-based retrospective analysis using the CDC WONDER Multiple Cause of Death database from 1999 to 2023. Deaths among individuals with lymphoma were identified using ICD-10 codes C81–C85, and IHD-related deaths were identified using ICD-10 codes I20–I25. Age-adjusted mortality rates (AAMRs) per 100,000 persons were calculated and stratified by sex, race/ethnicity, geographic region, urbanization status, and place of death. Temporal trends were analyzed using Joinpoint regression to estimate annual percent change (APC) and average annual percent change (AAPC). **Results:** Between 1999 and 2023, a total of 61,480 deaths were reported among individuals with both lymphoma and IHD in the United States. The overall AAMR declined from 0.93 in 1999 to 0.62 in 2023. Females had a lower overall AAMR compared with males (0.43 vs 1.13). By race/ethnicity, Non-Hispanic individuals had a higher AAMR than Hispanic individuals (0.74 vs 0.46). Regionally, the Midwest had the highest overall AAMR (0.84), while the South had the lowest (0.64). A higher AAMR was observed in non-metropolitan compared with metropolitan areas (0.84 vs 0.69). Most deaths occurred in inpatient medical facilities (22,633 deaths; 36.8%), followed by deaths at home (18,922 deaths; 30.8%). **Conclusions:** While mortality has declined overall, continued excess risk among males, rural residents, and Midwestern populations highlights inequities in care delivery. Expanding integrated cardio-oncology programs in non-metropolitan areas may further reduce national mortality. Research Sponsor: None.

Comparative analysis of age-adjusted mortality rates (AAMR) for comorbid lymphoma and ischemic heart disease by demographic and geographic subgroups (1999–2023).

Category	Group with Highest AAMR	Group with Lowest AAMR
Sex	Males (1.13)	Females (0.43)
Ethnicity	Non-Hispanic (0.74)	Hispanic (0.46)
Region	Midwest (0.84)	South (0.64)
Urbanicity	Non-metropolitan (0.84)	Metropolitan (0.69)

Multivariable analyses (MVAs) of overall survival (OS) in the phase 3 SUNMO, STARGLO, and POLARGO trials in relapsed/refractory large B-cell lymphoma (LBCL). First Author: Matthew Matasar, Rutgers Cancer Institute, New Brunswick, NJ

Background: Phase 3 trials, notably SUNMO (NCT05171647), STARGLO (NCT04408638) and POLARGO (NCT04182204), have shown superior efficacy of combination treatments over rituximab (R) + gemcitabine and oxaliplatin (GemOx) in second line or later LBCL. However, baseline imbalances may impact the robustness of efficacy results, even with stratified randomization. We conducted MVAs of SUNMO, STARGLO and POLARGO to assess OS. As the target number of OS events was not reached at the SUNMO interim OS analysis, to increase the sample size we also conducted a pooled analysis of mosunetuzumab (Mosun) + polatuzumab vedotin (Pola; data from SUNMO and GO40516 [Phase 2; NCT03671018]) vs R-GemOx (comparators from SUNMO, STARGLO and POLARGO). **Methods:** A multivariable Cox regression model was used to estimate treatment effect while adjusting for potential confounding factors selected by a systematic process involving: 1) univariable analysis of prespecified baseline factors; 2) multicollinearity assessment of pairwise correlation among selected factors; 3) MVA of the experimental arm (SUNMO: Mosun-Pola; STARGLO: glofitamab [Glofit]-GemOx; POLARGO: Pola-R-GemOx) vs the control arm (R-GemOx) and selected non-collinear prognostic baseline factors from steps 1 and 2. **Results:** In SUNMO, patients treated with Mosun-Pola had more high-risk features, such as a higher ECOG performance status and greater bulky disease, vs those treated with R-GemOx. The MVA-adjusted hazard ratio (HR, 0.65 [95% confidence interval [CI]: 0.41–1.02]) was more favorable than the unadjusted interim OS HR (0.80 [95% CI: 0.54–1.20]) for Mosun-Pola vs R-GemOx. The MVA-adjusted HR for POLARGO was also more favorable than the unadjusted HR; the HR for STARGLO remained largely unchanged (Table). A pooled MVA was used to increase the sample size, noting baseline differences between trials (e.g. $\geq$2 prior lines of therapy: SUNMO, 56%; STARGLO, 37%; POLARGO, 35%). In this pooled analysis, OS HRs favored Mosun-Pola vs R-GemOx in the unadjusted (HR, 0.62 [95% CI: 0.48–0.81]) and MVA-adjusted (HR, 0.59 [95% CI: 0.44–0.81]) models, with lower HRs and narrower 95% CIs vs the MVA of SUNMO alone. **Conclusions:** The MVAs support favorable OS benefits in SUNMO, STARGLO and POLARGO, all with an MVA-adjusted OS HR $\leq$0.65 vs R-GemOx. The pooled MVA further supports the OS benefit of Mosun-Pola vs R-GemOx. Overall, the MVAs show that baseline imbalances can influence OS estimates, thus multivariable adjustment is important when interpreting pooled or cross-trial comparisons. Clinical trial information: NCT05171647, NCT04408638, NCT04182204, NCT03671018. Research Sponsor: F. Hoffmann-La Roche Ltd.

	SUNMO n=208	STARGLO n=274	POLARGO n=255	Pooled Mosun-Pola vs R-GemOx n=465
Median follow-up, months (range)	23.2 (0–32)	20.7 (0–36)	24.6 (0–34)	–
MVA-adjusted OS HR (95% CI)	0.65 (0.41–1.02)	0.63 (0.44–0.90)	0.52 (0.36–0.74)	0.59 (0.44–0.81)
Unadjusted OS HR (95% CI)	0.80 (0.54–1.20)	0.62 (0.43–0.88)	0.60 (0.43–0.83)	0.62 (0.48–0.81)

Iopofosine I-131 after BTK inhibitors in Waldenström macroglobulinemia: CLOVER-WaM subgroup efficacy and safety. First Author: Jarrod Longcor, Cellectar Biosciences, Inc, Florham Park, NJ

Background: Waldenström Macroglobulinemia (WM) remains incurable with current available therapeutic options. Treatment options for relapsed/refractory pts are limited and often continuous, underscoring the need for new agents with novel mechanisms of action and pt-centered, fixed duration therapy. Iopofosine I 131 is a novel radiopharmaceutical compound composed of a lipid raft-targeting phospholipid ether covalently bound to ^{131}I, a beta emitting radioisotope. Here, we report preliminary sub-group results of the CLOVER-WaM study [NCT02952508] in WM pts treated with a Bruton's Tyrosine Kinase inhibitor (BTKi) immediately prior to iopofosine. **Methods:** Eligible WM pts had received >2 prior therapies and had symptomatic disease requiring therapy according to consensus recommendations for WM. Treatment consisted of 2 cycles of iopofosine I 131 administered at 15 mCi/m^2 on days 1 and 15 of each 57-day cycle. The primary efficacy endpoint was major response rate (MRR; partial response or better, as determined by the modified IWWM-VI). Secondary and exploratory endpoints included overall response rate (ORR), treatment-free survival (TFS), progression free survival (PFS), duration of response (DOR), and clinical benefit rate (CBR; stable disease or better). Herein, efficacy endpoints were assessed in the modified intent-to-treat (mITT) population (all pts who received $\geq$60 mCi total administered dose of iopofosine I 131), and whose treatment regimen prior to iopofosine included a BTKi. Safety was evaluated using CTCAE v4.03 in pts who received $\geq$1 dose of iopofosine. Data cut off for this analysis was Jan. 16, 2026. **Results:** As previously reported, 65 pts were dosed and 55 are included in the mITT population. Of those, 22 (40%) had received a BTKi containing regimen immediately prior to iopofosine; and 11 who previously received at least 2 regimens utilizing BTKis and 12 who were refractory to rituximab. In this subgroup, median age was 70.5 (range 55-88), 17 (77%) were male, and 5 (23%) were female. The median number of prior therapies was 3 (range 2-7), 15/22 (68%) were MYD88 mutated and 18/22 (82%) were TP53 wildtype. The MRR was 15/22 (68.2%), ORR was 19/22 (86.4%) and CBR was 100%, median PFS was 12 months (range 1.6 to 28.0) and median TFS was 19.1 months (range 2.5-34.4). Grade $\geq$ 3, related treatment emergent adverse events (TEAE) occurring in > 10% of pts included anemia (41%), leukopenia (41%), neutropenia (58%), and thrombocytopenia (86%). **Conclusions:** Iopofosine I 131 demonstrated significant efficacy; 100% CBR, 86.4% ORR and 68.2% MRR with a median PFS of 12 months (range: 1.6 – 28.0 months) in a pt population with no current standard of care therapy. The treatment was well-tolerated with a manageable toxicity profile with cytopenias as the only Grade 3 or greater TEAE. Based on the results of this pivotal trial, iopofosine I 131 could be a promising novel treatment for WM pts after BTKi therapy. Clinical trial information: NCT02952508. Research Sponsor: None.

Analysis of sex-based differences in tumor microenvironments within hematopoietic and reticuloendothelial system malignancies. First Author: Vera Vaz, Renown Health/University of Nevada Reno School of Medicine, Reno, NV

Background: While sex-specific disease incidence, genomic profiles, and survival outcomes are widely recognized in hematologic malignancies, the biological mechanisms and tumor microenvironment (TME) factors driving these sex-based disparities remain largely undefined, particularly at the level of the TME, which plays a key role in immune surveillance, therapeutic response, and disease progression. This meta-analysis investigates whether significant differences exist in the abundance of various cell types between males and females within lymphoid and myeloid leukemias, plasma cell tumors, mature B-cell lymphomas, and acute lymphoblastic leukemia. Characterizing these variations is essential for developing tailored therapeutic strategies that optimize clinical outcomes for both sexes. **Methods:** Computational meta-analysis was performed on the TCGA National Database, using xCell enrichment scores across transcriptomic samples from hematopoietic and reticuloendothelial system tumors, comparing males (n= 3,829) and females (n= 2,995). Mann-Whitney U testing with Bonferroni correction identified cell populations with differential enrichment (padj$<$0.05). Cohorts were balanced for age, race, and tumor type (primary, recurrence, metastatic) (all p$>$0.05). **Results:** Of the 64 cell types screened, 12 exhibited a significant difference in abundance between males and females. Nine of these were female-enriched populations (padj $<$0.01). These included erythrocytes (Mean Difference [Male-Female]: -0.5192), neutrophils (-0.4343), eosinophils (-0.4147), GMP (-0.1345), platelets (-0.1097), common myeloid progenitors (CMP) (-0.0917), mast cells (-0.0640), MPP (-0.0556), and megakaryocytes (-0.0131) indicating higher relative enrichment in females. Conversely, the male-enriched populations (padj $<$0.02) consisted of DC (0.2210), Th2 cells (0.0761), and Th1 cells (0.0634). **Conclusions:** This study demonstrates sex-based differences in TME cellular abundance in hematopoietic and reticuloendothelial tumors. Females exhibited a higher presence of early-stage progenitor populations, such as MPP and CMP, and innate immune cells, including neutrophils and eosinophils, potentially due to hormonal influences, differences in myelopoiesis, or sex-linked immune polarization. In contrast, males had a higher presence of DC and Th cells. Among all cell types analyzed, erythrocytes exhibited the greatest magnitude of difference in abundance between sexes, showing potential distinctions in metabolic and oxygenation profiles. These findings highlight biologically meaningful sex specific variations in the TME, underscoring the need for further mechanistic studies linking sex-specific TME compositions to therapeutic responses and incorporating biological sex as a critical variable in immunotherapy trial design. Research Sponsor: None.

Real-world outcomes of mogamulizumab retreatment in cutaneous T-cell lymphoma: A single-center retrospective study. First Author: Shahzeem Bhayani, Washington Univeristy in St. Louis, St. Louis, MO

Background: Mogamulizumab, monoclonal antibody against CCR4, is approved for relapsed/refractory cutaneous T cell lymphoma (CTCL), with an overall response rate of 28%in CTCL. The most common toxicity is mogamulizumab-associated rash (MAR), occurring in ~24% of patients and reported in up to 88% of responders, frequently leading to treatment discontinuation. Given the limited therapeutic options in CTCL, retreatment with mogamulizumab is clinically appealing but not well described. We report a single center experience with mogamulizumab retreatment in patients with CTCL. **Methods:** We conducted a single-center retrospective study of all adult patients with CTCL treated with mogamulizumab from 2013 to 2025. Retreatment was defined as reinitiation after a >90-day treatment-free interval. Disease status, patient characteristics, response and toxicity to therapy was collected. **Results:** Among 54 CTCL patients treated with mogamulizumab, 13 (24%) (MF=7, SS=6) underwent retreatment. Median age at diagnosis was 67 years (range, 44 - 84) and mostly male (69%). Patients had a median of 5 prior systemic therapy lines (range, 3–9). The median interval from initial mogamulizumab discontinuation to retreatment was 11.4 months (range 3.1-40.2). During initial mogamulizumab exposure, ORR 92.3% (12/13, 8 CR, 4 PR).11 discontinued mogamulizumab due to rash, 1 due to clinical response and 1 with PD. Retreatment dosing schedules included weekly administration in 2 patients (15%), every-2-week dosing in 8 (62%), and every-4-week dosing in 3 (23%). On retreatment, ORR was 38.5% (5/13) with CR in 2 patients and PR in 3, SD in 3 and progressive disease (PD) in 5. Median number of doses on retreatment was 5 (range 1-44). Among retreatment responders (CR/PR; n=5), median DOR was 15.0 months (range, 6.2–28.0). Median PFS from retreatment initiation was 4.0 months (range, 0.0–40.7) and estimated 2 -year OS was 84.6%. Both deaths were unrelated to CTCL progression or mogamulizumab-related toxicity. MAR occurred in 10/13 (76.9%) patients on retreatment. Rechallenge strategies included temporary treatment interruption until resolution of MAR (n=7) and increasing dosing intervals (n=3). Rash was predominantly maculopapular or morbilliform, most commonly involving the trunk and extremities. All MAR events were CTCAE grade 1-2. MAR was managed with topical steroids (n=9), oral steroids (n=1), and cessation of mogamulizumab (n=9). **Conclusions:** In this real-world, heavily pretreated CTCL cohort, mogamulizumab retreatment demonstrated meaningful clinical activity with durable responses in patients despite prior exposure. Although rash was common, it was most often low to moderate grade, responsive to standard management, and retreatment or rechallenge after resolution was feasible. Research Sponsor: None.

TPS7097 **Poster Session**

Lisocabtagene maraleucel (liso-cel) as first-line (1L) therapy for transplant-ineligible patients (pt) with primary central nervous system lymphoma (PCNSL): The CAROLYN study. First Author: Allison Marie Winter, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: Treatment of PCNSL is based on high-dose methotrexate (HD-MTX) induction chemotherapy, followed by consolidative autologous stem cell transplantation (ASCT) in eligible pts. Those deemed transplant ineligible have a high risk of relapse and are a population with a significant unmet therapeutic need. Liso-cel, an autologous, CD19-directed chimeric antigen receptor (CAR) T cell product, demonstrated promising results in secondary CNS lymphoma. In a phase 2 study (NCT03484702), 4 of 5 pts with PCNSL treated with liso-cel after failure of 1L high-dose chemotherapy and ASCT achieved a CR. Here, we report the study design of the CAROLYN study (NCT07015242; currently enrolling), which is evaluating efficacy and safety of liso-cel as 1L therapy in transplant-ineligible pts with PCNSL. **Methods:** This open-label, single-arm, multicenter, phase 2 study will enroll approximately 65 pts. The primary endpoint is investigator-determined 12-month PFS rate (from infusion date). Secondary endpoints include additional efficacy assessments (PFS, event-free survival, and OS from enrollment; CR rate, ORR, and duration of response), safety (AEs, serious AEs, and AEs of special interest), and health-related quality of life. Key inclusion criteria are newly diagnosed PCNSL confirmed by local pathology, receipt of $\geq$ 2 cycles of standard-of-care regimens, transplant ineligibility (defined by investigator assessment and either age $\geq$ 65 years or hematopoietic stem cell transplantation-specific comorbidity index score $\geq$ 3), MTX-sensitive disease (CR or PR), and ECOG PS $\leq$ 2. Key exclusion criteria include diagnosis of secondary CNS lymphoma, primary intraocular lymphoma, primary vitreoretinal lymphoma, and isolated cerebrospinal fluid involvement. Enrolled pts can receive optional holding therapy with a HD-MTX–based regimen while awaiting leukapheresis. After leukapheresis, bridging therapy with a HD-MTX–based regimen is permitted during liso-cel manufacturing. Before liso-cel infusion, pts receive lymphodepleting chemotherapy consisting of fludarabine (30 mg/m^2/day for 3 days) and cyclophosphamide (300 mg/m^2/day for 3 days). Pts then receive a single infusion of liso-cel at a target dose of 100 $\times$ 10^6 CAR$^+$ T cells. After infusion, pts remain in the treatment period for 90 days and then transition to follow-up for 2 years from enrollment. The total study duration is expected to be 3 years; pts who receive liso-cel can enroll in a separate 15-year long-term follow-up (NCT03435796). Clinical trial information: NCT07015242. Research Sponsor: This study was funded by Juno Therapeutics, a Bristol-Myers Squibb Company.

TPS7098 **Poster Session**

KITE-753: A phase 2 study of an autologous anti-CD19/CD20 CAR T-cell therapy in CAR-naive patients with relapsed/refractory (R/R) large B-cell lymphoma (LBCL). First Author: Saurabh Dahiya, Stanford University, Stanford, CA

Background: CD19-directed CAR T-cell therapy has become the standard of care for R/R LBCL; however, some patients are refractory to CD19 CAR T-cell therapy and a subset of responders relapse (Eyre et al. *Ann Oncol*. 2025, Westin et al. *N Engl J Med*. 2023). KITE-753 is an investigational, bicistronic, CD19/CD20 CAR T-cell therapy with a parallel CAR design to optimally engage two tumor antigens, synergistic CD28/4-1BB costimulation to enhance T-cell function, and a rapid manufacturing process that preserves naive and stem cell memory T cells. It is designed to improve cure rates while limiting toxicity for patients with R/R LBCL. In vitro, KITE-753 demonstrated potent antitumor activity at a dose >25-fold lower than an identical product manufactured with a traditional ex vivo expansion period (Murakami et al. ASH 2024). Phase 1 assessment of KITE-753 showed very low rates of immune effector cell-associated neurotoxicity syndrome (ICANS) and no high-grade cytokine release syndrome or ICANS in patients with R/R LBCL at the intended pivotal dose level. Furthermore, high response rates were observed with 79% of patients achieving complete response (CR). CAR T-cell expansion was comparable to KITE-363 and axi-cel despite a 10-fold lower dose (Dahiya et al. ASH 2025, Dahiya et al. ASCO 2025). Based on Phase 1 outcomes, the Phase 2 dose was established as 2$\times$10^5 CAR T cells/kg. This Phase 2 study will evaluate the safety and efficacy of KITE-753 in CAR-naive patients with R/R LBCL. **Methods:** In this open-label, multicenter, single-arm study, patients will undergo leukapheresis and receive optional bridging therapy, followed by lymphodepleting chemotherapy (cyclophosphamide [300 mg/m^2/day] and fludarabine [30 mg/m^2/day]) from Day -5 to Day -3, and infusion of KITE-753 at a target dose of 2$\times$10^5 CAR T cells/kg on Day 0. The primary endpoint is objective response rate (CR rate + partial response rate) assessed by central review per Lugano Classification (Cheson et al. *J Clin Oncol*. 2014). Secondary outcomes include CR rate, duration of response, progression-free survival, overall survival, and safety. The target enrollment is 80 patients. Eligible adults have histologically confirmed R/R LBCL (including transformation of indolent lymphomas and primary mediastinal B cell lymphoma) after $\geq$2 prior lines of systemic therapy (including anti-CD20 mAb or bispecific antibody + anthracycline). Other key inclusion criteria are adequate bone marrow and organ function and ECOG performance status $\leq$2. Key exclusion criteria are prior CAR T-cell therapy or active central nervous system involvement from lymphoma. This study is currently open and actively accruing patients (NCT04989803). Clinical trial information: NCT04989803. Research Sponsor: Kite, a Gilead Company.

TPS7099 **Poster Session**

Sonrotoclax (BGB-11417) + zanubrutinib (SZ) vs venetoclax + acalabrutinib (AV) in treatment-naive chronic lymphocytic leukemia (TN CLL): A phase 3 randomized trial design (CELESTIAL-TNCLL-2). First Author: Mazyar Shadman, Fred Hutchinson Cancer Center, University of Washington, Seattle, WA

Background: Inhibition of B-cell lymphoma 2 (BCL2) and Bruton tyrosine kinase (BTK) has emerged as an effective fixed-duration treatment (tx) strategy that can induce high rates of undetectable minimal residual disease (uMRD) in patients (pts) with TN CLL. AV is approved in the EU as a first-line fixed-duration tx for TN CLL. Sonrotoclax, a next-generation BCL2 inhibitor, is a more selective and pharmacologically potent inhibitor of BCL2 than venetoclax, with a shorter half-life and no drug accumulation. Zanubrutinib is a highly potent next-generation BTK inhibitor that is approved in the US/EU for CLL. In an ongoing phase 1/1b trial (NCT04277637), SZ has had promising efficacy, with a 100% ORR (n=135) and high rates of blood uMRD at 10^{-4} sensitivity (uMRD4) in pts with TN CLL, including those with high-risk disease features. SZ is generally well tolerated, with neutropenia as the most common grade $\geq$3 TEAE and no laboratory or clinical TLS events occurred. The phase 3 trial BGB-11417-304 (NCT07277231) was designed to directly compare fixed-duration SZ vs AV in TN CLL to investigate whether SZ compared with AV, may improve efficacy in terms of achieved uMRD rate after completing treatment and PFS and potentially improve tolerability and safety. **Methods:** BGB-11417-304 is a global phase 3, open-label, randomized study. Eligible adults have a confirmed diagnosis of previously untreated CLL requiring tx per iwCLL 2018 criteria, adequate hematologic and organ function, ECOG PS 0-2, and measurable disease confirmed by CT/MRI. Exclusion criteria include prior systemic tx for CLL; diagnosis of prolymphocytic leukemia or Richter transformation; known central nervous system involvement; history of confirmed progressive multifocal leukoencephalopathy; or uncontrolled hypertension or clinically significant cardiovascular disease. Approximately 500 pts will be enrolled and randomized 1:1 to arm A (3 lead-in cycles of oral zanubrutinib monotherapy followed by 12 cycles of oral SZ) or arm B (2 lead-in cycles of oral acalabrutinib monotherapy followed by 12 cycles of oral AV). Randomization will be stratified by age (<65 y vs $\geq$65 y), IGHV mutation status, and presence of del(17p) and/or *TP53* mutations. The primary endpoint is PFS in arm A vs arm B, as determined by independent review committee (IRC), with an intermediate endpoint of uMRD4 rate in blood and bone marrow in arm A vs arm B, assessed by next-generation sequencing (clonoSEQ) at the first post-tx follow-up visit. Key secondary endpoints are PFS-IRC in high-risk subgroups and OS. Other secondary endpoints are ORR and complete response assessed by IRC and investigator (INV), uMRD5 rate (clonoSEQ), PFS-INV, duration of response by IRC and INV, time to next tx, pt-reported outcomes, and safety/tolerability. Enrollment in BGB-11417-304 is currently ongoing. Clinical trial information: NCT04277637. Research Sponsor: BeOne Medicines, Ltd.

TPS7100 **Poster Session**

ROCKET-CLL: A randomized, open-label, multicenter, phase 3 study of rocbrutinib (LP-168) versus pirtobrutinib in covalent BTK inhibitor (cBTKi) in pretreated relapsed or refractory (R/R) chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL). First Author: Anna Chen, Newave Pharmaceutical Inc, Pleasanton, CA

Background: Bruton tyrosine kinase covalent inhibitors (cBTKi) have been transformative in CLL treatment. Despite achieving extended remissions, in most patients disease still relapses despite cBTKi therapy, often associated with *BTK* C481 mutations. Non-covalent BTKi (ncBTKi), including pirtobrutinib, can overcome this resistance (Sharman et al. *ASCO*. 2025). Pirtobrutinib received FDA approval in Dec 2025, for R/R CLL/CLL patients pretreated with cBTKi. Rocbrutinib (LP-168) is a highly selective next-generation BTKi that can covalently bind wild-type and gatekeeper mutations (T474X, commonly seen in patients relapsed after pirtobrutinib) and non-covalently target C481-mutated *BTK*, with preclinical efficacy in treatment-naïve and BTKi-resistant CLL (Gordon et al. *IWCLL*. 2025). In the rocbrutinib phase 1 trial (NCT04775745), encouraging safety and efficacy have been observed in CLL patients with prior exposure to BTKi and/or BCL2 inhibitor (BCL2i) (Woyach et al. *Blood*. 2025). Presented here is the design of a phase 3 trial aiming to compare the efficacy of rocbrutinib versus pirtobrutinib in cBTKi-pretreated R/R CLL/SLL patients. **Methods:** ROCKET-CLL (NCT07342478) is a randomized, open-label, multicenter, phase 3 study comparing rocbrutinib (Arm 1) to pirtobrutinib (Arm 2) in R/R CLL/SLL subjects who previously received treatments including covalent BTKi. Eligible subjects must require treatment per 2018 iwCLL criteria, have measurable lesions by CT, an ECOG performance score of 0-2, and adequate hematologic and other organ functions. About 306 subjects will be randomized 1:1 based on stratification factors such as 17p deletion/*TP53* mutation presence, reasons for discontinuing prior cBTKi, prior BCL2i treatment, and geographic region. Participants assigned to each arm will receive rocbrutinib (200 mg QD) or pirtobrutinib (200 mg QD) tablets continuously until disease progression, unacceptable toxicity, withdrawal, or other study discontinuation criteria are met. The primary endpoint is progression-free survival (PFS), assessed by an independent review committee (IRC) per iwCLL 2018 criteria with CLL (Hallek et al. 2018) and Lugano 2014 criteria with SLL (Cheson et al. 2014). Important secondary endpoints include overall survival (OS), time to next treatment (TTNT), event-free survival (EFS), overall response rate (ORR), duration of response (DOR), PFS assessed by investigator (INV), concordance between IRC and INV PFS, safety and tolerability, and population PK. Exploratory endpoints include health-related quality of life and biomarker assessment. Recruitment is ongoing. Clinical trial information: NCT07342478. Research Sponsor: None.

TPS7101 **Poster Session**

A global multicenter, open-label, randomized, phase 3 registrational study of lisaftoclax (APG-2575) in previously treated chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL): GLORA trial in progress. First Author: Matthew Steven Davids, Dana-Farber Cancer Institute, Boston, MA

Background: Patients with high-risk CLL/SLL not achieving a complete response (CR) after ≥ 12 months of BTK inhibitor (BTKi) monotherapy remain at risk for early progression due to residual disease and BTKi resistance. A BCL-2 inhibitor (BCL-2i) introduces a complementary, BCR-independent apoptotic mechanism that may deepen responses and prolong progression-free survival (PFS). Lisaftoclax, a selective oral BCL-2i with a short half-life (4-6 h), enables once-daily dosing and is approved in China as second-line CLL therapy. Lisaftoclax monotherapy has demonstrated overall response rates (ORRs) of 67% in relapsed/refractory CLL and 62.5% in BTKi-refractory disease, including del(17p)/*TP53*-mutated cases. Lisaftoclax combined with acalabrutinib achieved ORRs >97% with favorable tolerability. This study evaluates whether lisaftoclax plus BTKi (acalabrutinib, zanubrutinib, or ibrutinib) improves PFS and/or overall survival (OS) (vs continued BTKi monotherapy) in patients with CLL/SLL and residual disease after prolonged BTKi treatment. **Methods:** This study will enroll approximately 440 patients randomly allocated to receive lisaftoclax plus BTKi or BTKi alone. Eligible patients have CLL/SLL and, after ≥12 months of BTKi monotherapy (lines 1-3), have achieved neither CR nor progressive disease (PD). Randomization is stratified by del(17p)/*TP53* status. Key inclusion criteria include age ≥18 years, ECOG PS 0-2, and residual disease with either high-risk features (del(17p)/*TP53* mutation, unmutated *IGHV*, or complex karyotype [≥5 abnormalities]), or measurable residual disease with lymph nodes ≥2.5 cm in the absence of high-risk features. Exclusion criteria include prior BCL-2i therapy or Richter transformation. Patients in the investigational arm will undergo a 5-day oral lisaftoclax ramp-up to 400 mg once daily plus physician's choice of BTKi in 28-day cycles until progression or toxicity. Control patients continue their current BTKi monotherapy. Safety and disease assessments (CT/MRI) will occur regularly. The primary endpoint is PFS by independent review committee (iwCLL 2018); key secondary endpoint OS; and other secondary endpoints, PFS by investigator, ORR, duration of response, MRD negativity, and safety. Enrollment is ongoing across 126 sites in 18 countries (ClinicalTrials.gov ID: NCT06104566). Clinical trial information: NCT06104566. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

TPS7102 **Poster Session**

Golcadomide (GOLCA), a potential, first-in-class, oral CELMoD, plus rituximab (R) versus investigator's choice (IC) in patients (pts) with relapsed/refractory follicular lymphoma (R/R FL) who have received ≥ 1 line of systemic therapy: GOLSEEK-4, a phase (Ph) 3, randomized study. First Author: Clémentine Sarkozy, Institut Curie, Hôpital Saint-Cloud, Université de Versailles, Saint-Quentin, France

Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (NHL), typically presenting as advanced-stage at diagnosis. With current SOC (chemoimmunotherapy [CIT] and maintenance), many pts can achieve remission; however, FL remains incurable, with shorter remissions and overall survival (OS) following relapses. Treatments for R/R FL, including CIT or R-lenalidomide (R^2), offer limited long-term benefit. T-cell-redirecting therapies in ≥ 3L provide better efficacy but are limited by tolerability and logistical challenges. An unmet need persists for effective, well-tolerated, convenient options for R/R FL pts after ≥1L of systemic therapy. GOLCA is a potential, first-in-class, oral CELMoD designed for the treatment of lymphoma, with preferential distribution to lymphoid organs and enhanced activity in lymphoma cell lines. GOLCA induces rapid and deep degradation of Ikaros and Aiolos, leading to direct cell killing and immunomodulatory activity. GOLCA 0.4 mg + R was studied in heavily pre-treated R/R FL pts (including those given lenalidomide [LEN] and T-cell redirecting therapies) in the Ph 1/2 CC-99282-NHL-001 study, resulting in objective response rate 97%, complete response rate 78% and tolerable safety, suggesting benefit vs SOC (Chavez et al., ASH 2025, #1006). As a result, the Ph 3 study, GOLSEEK-4 (NCT06911502) was initiated. **Methods:** GOLSEEK-4 is a global, randomized, Ph 3 study evaluating fixed-duration, chemo-free GOLCA + R vs IC (R^2 or R-chemo) in R/R FL after ≥1 prior lines of therapy. Included: adults (≥18 yr) with grade 1-3A R/R FL or cFL, PET-positive disease with measurable lesions (Lugano criteria), ECOG 0–2 (or 3 if due to lymphoma), require treatment based on modified GELF, and ≥1 prior regimen, including anti-CD20 + alkylating agent. Prior T-cell-redirecting therapy allowed. Excluded: composite DLBCL/FL, transformed NHL, CNS involvement, those who are R/R or intolerant to all options in IC arm. Approximately 400 pts will be randomized 1:1 to GOLCA (0.4 mg QD, Days 1–14 per 28-day cycle) + R for 5 cycles, then GOLCA monotherapy for 7 cycles (12 cycles total) or IC (R^2 for 5 cycles then LEN monotherapy for 7 cycles, or R-CHOP or R-Bendamustine for 6 cycles). Randomization will be stratified by disease progression within 24 months (mo) vs >24 mo from initial CIT, prior lines (2L vs 3L+), and IC regimen. Pts will be followed for at least 5 yrs. Recruitment began July 2025. Primary endpoint: progression-free survival (IRAC). Secondary endpoints: overall response rate (IRAC), OS, complete metabolic response, minimal residual disease, time to next therapy, duration of response. Safety is exploratory. Acknowledgement: BMS ChatGPT4 used to revise existing text with human author input (Jan 26). Clinical trial information: NCT06911502. Research Sponsor: Bristol Myers Squibb.

TPS7103 **Poster Session**

Phase 1 study of ARV-393, a PROTAC BCL6 degrader, as monotherapy in patients with advanced non-Hodgkin lymphoma (NHL) or combined with glofitamab in patients with diffuse large B-cell lymphoma (DLBCL). First Author: Martin Hutchings, Rigshospitalet and University of Copenhagen, Copenhagen, Denmark

Background: Despite recent advancements in NHL therapies, many patients experience disease progression or relapse. Agents with novel mechanisms of action and combination strategies are needed to improve clinical outcomes. B-cell lymphoma 6 (BCL6) is a master transcriptional regulator of immune cells, particularly of germinal center B cells, and an established oncogenic driver in NHL. ARV-393 is an oral PROteolysis TArgeting Chimera (PROTAC) BCL6 degrader that binds an E3 ubiquitin ligase and BCL6 to induce ubiquitination of BCL6 and its subsequent proteasomal degradation. ARV-393 monotherapy potently inhibited tumor growth and induced tumor regressions across NHL cell-derived xenograft (CDX) and patient-derived xenograft models, including models of DLBCL, transformed follicular lymphoma, and nodal T-follicular helper cell lymphoma (nTFHL). Furthermore, administration of ARV-393 with a CD20×CD3 bispecific antibody, glofitamab, demonstrated combinatorial antitumor activity in a humanized high-grade B-cell lymphoma CDX model, inducing deeper tumor growth inhibition and increased tumor regressions vs either monotherapy. These preclinical findings demonstrated single-agent ARV-393 antitumor activity across NHL subtypes and suggested mechanistic synergy with glofitamab, supporting clinical investigation of monotherapy in NHL and this chemotherapy-free combination in patients with DLBCL. **Methods:** This global, multicenter, open-label, first-in-human, phase 1 dose escalation and optimization/expansion study (NCT06393738) is evaluating the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity of ARV-393 as monotherapy in relapsed or refractory (R/R) NHL or in combination with glofitamab in R/R DLBCL, with a primary objective of determining provisional doses for further exploration. Patients eligible for ARV-393 monotherapy are adults with confirmed R/R B-cell NHL who previously received ≥2 lines of systemic therapy (including rituximab), or nTFHL who previously received standard of care therapy. Patients eligible for ARV-393 in combination with glofitamab are adults with pathologically confirmed R/R DLBCL, DLBCL not otherwise specified, or large B-cell lymphoma arising from follicular lymphoma who were treated with ≥2 prior lines of systemic therapy. ARV-393 will be administered orally once daily in 28-day cycles alone or in combination with intravenous glofitamab during 21-day cycles. Approximately 255 patients will be enrolled across study cohorts. As of January 2026, enrollment is ongoing. Copyright © 2026 AACR. Originally presented at AACR 2026. Reprinted with permission. Clinical trial information: NCT06393738. Research Sponsor: Arvinas Operations Inc.

TPS7104 **Poster Session**

waveLINE-011: Zilovertamab vedotin plus R-CHP versus polatuzumab vedotin plus R-CHP as first-line therapy in germinal center B-cell–like (GCB) diffuse large B-cell lymphoma (DLBCL). First Author: Max S. Topp, University of Würzburg, Würzburg, Germany

Background: DLBCL is a heterogeneous malignancy broadly categorized into 3 subtypes: activated B-cell–like (ABC) DLBCL, GCB DLBCL, and unclassified DLBCL. The standard-of-care first-line treatment option for DLBCL regardless of subtype is polatuzumab vedotin plus rituximab, cyclophosphamide, doxorubicin, and prednisone (R-CHP). However, while polatuzumab plus R-CHP prolongs PFS compared with R-CHOP in ABC DLBCL, it provides no benefit over R-CHOP in GCB DLBCL. Alternative first-line treatment options for GCB DLBCL are needed. Receptor tyrosine kinase–like orphan receptor 1 (ROR1) is an oncofetal transmembrane protein that is overexpressed in DLBCL, making it an attractive therapeutic target. Zilovertamab vedotin is an antibody-drug conjugate comprising an anti-ROR1 antibody with a proteolytically cleavable linker and the cytotoxic antimicrotubule agent MMAE. In the phase 1 waveLINE-001 study, zilovertamab vedotin was shown to have antitumor activity in heavily pretreated lymphoid cancers and promising efficacy and manageable safety in combination with R-CHP as first-line treatment for DLBCL. The randomized, open-label, phase 2 waveLINE-011 study (NCT06890884) has been designed to evaluate the efficacy and safety of zilovertamab vedotin plus R-CHP versus polatuzumab vedotin plus R-CHP in participants with previously untreated GCB DLBCL. **Methods:** Key eligibility criteria include age ≥18 years, previously untreated histologically confirmed GCB DLBCL (including but not limited to: DLBCL not otherwise specified GCB type and high-grade B-cell lymphoma [HGBL] GCB subtype), PET-positive disease at screening, an ECOG performance status score of 0 to 2, and an International Prognostic Index (IPI) score of 2 to 5. Participants with a history of transformation of indolent disease to DLBCL or with primary mediastinal B-cell lymphoma or gray zone lymphoma are excluded. All participants will be randomly assigned (1:1) to zilovertamab vedotin 1.75 mg/kg plus R-CHP or polatuzumab vedotin 1.8 mg/kg plus R-CHP on day 1 of every 3-week cycle for 6 cycles. Randomization will be stratified by geographic region (Western Europe vs US vs rest of world), IPI score (2 vs 3-5), bulky disease (<7.5 cm vs ≥7.5 cm), and histopathology (HGBL vs others). The primary end point is CR rate at the end of therapy per Lugano criteria by BICR. Secondary end points include PFS, EFS, duration of CR, OS, safety, and change in PROs. Response assessments (CT/FDG-PET) will be performed after cycle 4 day 1 but on or before cycle 5 day 1, and at 12 weeks after the cycle 4 scan. Follow-up efficacy assessments will be completed every 24 weeks for 2 years from the end of treatment assessment, then every year for 3 years. Adverse events will be graded per NCI CTCAE v5.0. Approximately 594 participants will be enrolled. Recruitment is ongoing. Clinical trial information: NCT06890884. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS7105 **Poster Session**

AQUARIUS: A longitudinal multi-center molecular biomarker discovery registry for patients with hematologic malignancies. First Author: Michael A. Thompson, Tempus AI, Inc., Chicago, IL

Background: Despite therapeutic innovations over the past decade in hematologic malignancies, there remains a significant unmet need in understanding disease progression, identifying progression and resistance biomarkers, and accurately predicting responses to various treatments. Identifying new therapeutic targets by moving deeper into the molecular and genetic architecture of the tumor is key to overcoming resistance and tailoring interventions to the unique biological profile of each individual. For example, follicular lymphoma (FL) demonstrates heterogeneous clinical behavior ranging from not requiring therapy (active observation), with not as yet well-defined high risk features for early progression, to patients who relapse early after initial therapy (POD24) and the ongoing risk of transformation to aggressive histology. Registry studies, in particular, provide insights into tumor heterogeneity, progression patterns, and clinical behaviors, which are essential for designing effective clinical trials and developing targeted therapies. The Tempus AQUARIUS hematologic biomarker discovery registry (NCT07154823) is a non-interventional, multi-center registry study aiming to create a robust dataset of molecular and clinical data from patients with hematologic malignancies to facilitate clinician-led research using whole genome sequencing (WGS) to generate hypotheses for predictive biomarkers, identify potential resistance mechanisms, and guide therapy selection. **Methods:** AQUARIUS is designed as a master protocol with multiple real world (rw) cohorts continuously added as future research questions emerge. The first cohort is on patients with FL, followed by additional cohorts in 2026. The FL cohort will encompass the following populations: newly diagnosed active observation (n: 100), newly diagnosed high risk (n: 150), relapsed/refractory high risk POD24 (n: 125), and transformed FL (n: 125), aiming to enroll 500 patients in total. Lymph node tissue or bone marrow aspirate and blood samples are collected during routine standard of care visits, with blood samples collected at all follow-up timepoints. Clinical data is collected—including demographics, medical history, treatment, and outcomes—at all timepoints, along with standard of care images. The emerging DNA WGS assay (Tempus xH) and existing RNA whole transcriptome sequencing assay (Tempus xR) will be performed at screening and progression/primary refractory disease to capture specific molecular alterations and potential genomic variants. Multimodal molecular profiling data will be generated prospectively. The following endpoints will be assessed: rw Overall Survival (OS), rw Progression Free Survival (PFS), rw Time to Next Treatment (TTNT), rw Time to Discontinuation (TTD), and changes in biomarkers over time. The study is open and actively enrolling. Clinical trial information: NCT07154823. Research Sponsor: None.

TPS7106 **Poster Session**

ROCK-2: An ongoing open-label, randomized, multicenter phase 2 study of rocbrutinib versus investigator's choice of therapy in patients with R/R non-GCB DLBCL. First Author: Peng Liu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common type of lymphoma. Aberrant activation of the Bruton's tyrosine kinase (BTK)-related signaling pathway is present in the non-GCB subtype of DLBCL (Davis et al. Nature 2010). Multiple BTK inhibitors (BTKi) have demonstrated efficacy in relapsed or refractory (R/R) non-GCB DLBCL (Strati et al. Haematologica. 2021; Wilson et al. Nat Med. 2015; Yang et al. Blood Adv. 2022), however, there remains room for further improvement. Rocbrutinib is a novel, highly selective, the fourth generation covalent (irreversible) and non-covalent (reversible) BTKi. Phase 1 study showed that in 45 patients with R/R non-GCB DLBCL who had received ≥2 prior lines of systemic therapy, rocbrutinib monotherapy achieved an overall response rate (ORR) of 57.8% and a complete response (CR) rate of 31.3%(Song et al. CSCO. 2025). This article describes the design and progress of a phase 2 pivotal study aimed at comparing the efficacy and safety of rocbrutinib versus investigator's choice of therapy in patients with R/R non-GCB DLBCL. **Methods:** ROCK-2 (NCT07189065; CTR20253693) is an open-label, randomized, multicenter phase 2 study conducted in China. Eligible patients must have non-GCB DLBCL, not otherwise specified (NOS) per the 2017 WHO classification, received ≥2 prior lines of systemic therapy. Additionally, patients must have measurable disease, an ECOG performance status of 0-2, and adequate hematologic and organ function. Key exclusion criteria include central nervous system involvement, DLBCL transformed from indolent lymphoma, prior refractoriness to BTK-targeting agents, uncontrolled systemic diseases, active infection. Approximately 150 eligible subjects will be randomized 1:1 to receive either rocbrutinib or BR/R^2, stratified by the number of prior lines of therapy (2 vs ≥3) and International Prognostic Index (IPI) score (0-2 vs 3-5). Subjects in the experimental group will receive rocbrutinib [200 mg once daily (QD)] until disease progression or unacceptable toxicity. Subjects in the control group will receive either BR or R^2 according to the investigator's choice. The BR regimen consists 6 cycles of rituximab (375 mg/m² on day 1) plus bendamustine (90 mg/m²/d on days 1-2). The R^2 regimen consists of rituximab (375 mg/m² on day 1 of cycles 1-6) plus lenalidomide (20 mg QD on days 1-21 of each 28d-cycle until disease progression or unacceptable toxicity). The primary endpoint is ORR assessed by Independent Review Committee (IRC) according to the 2014 Lugano criteria. Secondary endpoints include ORR assessed by investigator (INV), and CR rate, progression-free survival (PFS), duration of response (DOR), time to response (TTR), overall survival (OS) assessed by IRC or INV. The first subject was enrolled on Nov 27th,2025. Recruitment is ongoing. Clinical trial information: NCT07189065. Research Sponsor: Guangzhou Lupeng Pharmaceutical Company Ltd.

TPS7107 **Poster Session**

Phase 2 trial of lisocabtagene maraleucel for minimal residual disease in patients with large B-cell lymphoma. First Author: Dai Chihara, Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with relapsed/refractory large B-cell lymphoma (LBCL) have a poor prognosis. Identifying patients at high risk of recurrence after completion of first line (1L) treatment is crucial to enable early intervention with further treatments that may improve outcomes. Recent studies have shown that detectable minimal residual disease (MRD) by circulating tumor DNA (ctDNA) assay after 1L chemoimmunotherapy is prognostic for risk of recurrence. We hypothesize that lisocabtagene maraleucel (liso-cel) will eradicate the MRD in patients with LBCL who have detectable ctDNA at the end of 1L treatment will lead to improved long-term outcomes relative to historical results with liso-cel in second line treatment for patients with radiologically-detected disease. **Methods:** This is an open-label, phase 2, single-arm, multicenter, investigator-sponsored trial designed to evaluate the efficacy and safety of lisocabtagene maraleucel (liso-cel) in patients with LBCL who have achieved a response to 1L standard-of-care therapy but have detectable MRD. The trial will enroll 50 evaluable patients. Eligible participants are adults with LBCL, including DLBCL-NOS and HGBCL, who received 1L anthracycline-based chemoimmunotherapy (R-CHOP, DA-EPOCH-R, or polatuzumab-R-CHP) for six cycles, with or without an additional two cycles of rituximab, for previously untreated disease. Patients must have achieved a CR, or a PR with a negative biopsy or biopsy not feasible, and must demonstrate detectable MRD as assessed by the Foresight CLARITY ctDNA-MRD assay following completion of 1L therapy. The primary endpoint is event-free survival rate at 12 months, and secondary endpoints include rate of undetectable MRD. Correlative studies are designed to build a holistic model for understanding the tumor-intrinsic and immune features that contribute to response, as well as treatment-associated toxicities following liso-cel in patients with LBCL and detectable MD, a population at high risk of recurrence. Enrolment to the trial is planned at five centers in the US: MD Anderson Cancer Center, Memorial Sloan Kettering Cancer Center, Fred Hutchinson Cancer Center, City of Hope and Massachusetts General Hospital (NCT07316010). Clinical trial information: NCT07316010. Research Sponsor: None.

7500 **Oral Abstract Session**

Safety and efficacy of elranatamab as early intervention in patients with high-risk smoldering myeloma: First results from the phase 2 ERASMM (EMN34) study. First Author: Cyrille Touzeau, University Hospital of Nantes, Nantes, France

Background: Early intervention with lenalidomide or daratumumab significantly delays disease progression to active disease in high-risk (HR) smoldering multiple myeloma (SMM) patients (pts). The BCMAxCD3 bispecific antibody elranatamab (Elra) demonstrated strong anti-MM activity with favorable safety profile in relapsed MM. Using T-cell engagers in the early stage of the disease, with a potentially less exhausted immune system, may lead to improved efficacy. Here we report initial efficacy and safety results of Elra monotherapy in HR SMM pts enrolled in the phase 2 ERASMM Study (EMN34; NCT06183489). **Methods:** ERASMM is an international open-label multicenter phase 2 study of Elra as single agent in adult pts with HR SMM, defined as the presence of ≥2 Mayo 2018 "20-2-20" criteria. Treatment consisted of a fixed duration (2 years) of single-agent SC Elra with priming doses of 12 mg (C1D1) and 32 mg (C1D4), followed by 76 mg on days 8 and 15 during cycle 1, 1 and 15 during cycles 2–3, and 1 during cycles 4–24 (28-day cycle). The primary objective was the rate of complete response (CR). Safety was a key secondary endpoint. Other secondary objectives included overall response rate (ORR), measurable residual disease (MRD), progression-free survival (PFS), PFS2, time to active MM, and overall survival (OS). **Results:** Fifty pts with previously untreated HR SMM were included from May 2024 to September 2025 in 17 centers collaborating with the European Myeloma Network. Median age was 65 years (range 58–71). All pts had HR SMM, including M-spike >20 g/L in 42 (84%), bone marrow plasma cells >20% in 36 (72%), or free-light chain ratio >20 in 33 (66%). As of December 4, 2025, the median follow-up was 10 months (range 2.3–18.23). Thirty-four (68%) patients experienced a cytokine release syndrome event, all grade 1–2, except for grade 3 events in 2 pts. No ICANS events were observed. Infections occurred in 25 (50%) pts, including 14% grade 3–4. Other common (≥20%) non-hematologic adverse events (AEs) were skin rash (34%), diarrhea (26%), AST/ALT increase (28%), fatigue (20%), and peripheral neuropathy (20%), mostly grade 1–2. Four patients discontinued treatment due to AEs, including AST/ALT increase (n=1), Guillain–Barré syndrome (n=1), and infections (n=2). The ORR was 92%, including a very good partial response or better (≥VGPR) in 82% of pts, and a complete response or better (≥CR) in 45%. The 9-month PFS and OS rates were 95% and 100%, respectively. **Conclusions:** In HR SMM pts, single-agent Elra was highly active, with a 92% ORR, 45% of pts achieving ≥CR, and a favorable safety profile. Data on safety and efficacy (response, MRD, PFS) will be updated for the meeting. These data support further investigation of Elra as a therapeutic option for HR SMM. Clinical trial information: NCT06183489. Research Sponsor: Pfizer.

7501 **Oral Abstract Session**

Phase 3 randomized trial to evaluate the impact of anselamimab on all-cause mortality in κ light-chain amyloidosis. First Author: Ashutosh D. Wechalekar, University College London Hospitals and National Amyloidosis Center, Royal Free London NHS Trust, London, United Kingdom

Background: AL amyloidosis is a plasma cell dyscrasia (PCD) characterized by κ or λ Ig light chain amyloid fibrils that deposit in vital organs. Anselamimab is an investigational mAb designed to complement anti-PCD therapy through accelerated removal of amyloid fibrils. Cardiac Amyloid Reaching for Extended Survival (CARES) studies (NCT04512235 and NCT04504825) investigated the efficacy and safety of anselamimab compared with placebo, in addition to anti-PCD therapy. **Methods:** Alongside anti-PCD therapy with CyBorD (daratumumab was permitted) newly diagnosed patients with European modification of Mayo stage IIIa or IIIb AL amyloidosis were randomized 2:1 to receive anselamimab (1000 mg/m^2) or placebo (normal saline) IV every 7 days for 4 weeks followed by every 14 days for the remainder of the blinded study (18 months after the last participant enrolled). The primary endpoint was a hierarchical combination of time to all-cause mortality (ACM) and frequency of adjudicated cardiovascular hospitalizations (CVH) using the Finkelstein-Schoenfeld test and win-ratio in the combined study population. Subgroup analysis by involved κ or λ free light chain (iFLC) was prespecified. **Results:** 271 patients were randomized to receive anselamimab and 135 placebo. Baseline characteristics were similar between treatment arms. The median duration of treatment was 21.4 months and 21.1 in the anselamimab and placebo arms, respectively. Daratumumab was used in 79.3% and 83.7% of the anselamimab and placebo arms, respectively. Results of the primary efficacy analyses are shown in the table. Anselamimab-treated patients with κ iFLC had a 62% reduction in ACM (HR = 0.38; 95% CI, 0.17, 0.86; nominal P = 0.012) and a 71% reduction in risk for CVH (estimated CVH rate ratio = 0.29; 95% CI, 0.10, 0.87; nominal P = 0.028). Patients with λ iFLC had a 10% reduction in risk for CVH; none in ACM. Safety data were comparable between both treatment arms. In anselamimab-treated patients, safety findings were similar between κ subgroup and full population. **Conclusions:** Anselamimab, a κ light chain–directed anti-fibril monoclonal antibody used alongside standard of care chemotherapy, offers a first-in-class, new therapeutic option for patients with newly diagnosed κ AL amyloidosis. Clinical trial information: NCT04512235 and NCT04504825. Research Sponsor: Alexion, AstraZeneca Rare Disease.

7502 **Oral Abstract Session**

First results from the phase 1/2 LINKER-AL2 trial of linvoseltamab (LINVO) in patients (pts) with relapsed or refractory (RR) systemic light chain (AL) amyloidosis. First Author: Ashutosh D. Wechalekar, University College London Hospitals and National Amyloidosis Center, Royal Free London NHS Trust, London, United Kingdom

Background: Systemic AL amyloidosis is caused by deposition of misfolded amyloid fibrils produced by clonal plasma cells in vital organs. With no currently approved therapies, there is a need for new targeted agents eliciting rapid normalization of involved free light chain (iFLC), which is linked to improved organ function recovery and overall survival. Here are the first results of LINVO (human BCMA×CD3 bispecific antibody) in RR systemic AL amyloidosis from the Phase 1 portion of the Phase 1/2 LINKER-AL2 trial (NCT06292780). **Methods:** Eligible adults with RR systemic AL amyloidosis and ≥1 prior therapy received intravenous step-up doses of LINVO 5 mg and 25 mg (Cycle [C] 0 Days 1 and 8, respectively) followed by 28-day cycles of full subcutaneous (SC) doses of 80 mg or 240 mg administered once weekly in C1–C2 and then once every 4 weeks in C3–C12. The Phase 1 primary endpoint was incidence of dose-limiting toxicities (DLTs) within 28 days after the first full dose. Key secondary endpoints were rates of hematologic complete response (hCR; by FLC ratio and absence of AL), very good partial response or better (≥hVGPR), objective response (hOR), time to hCR, and safety. **Results:** As of data cut-off (DCO) August 25, 2025, 20 pts (median age, 64 years; prior daratumumab therapy, 60.0%) received LINVO 80 mg (n=7) or 240 mg (n=13), with a median follow-up of 9.6 (range 1.1–25.0) weeks. No DLTs or ICANS occurred. All pts had ≥1 treatment-emergent adverse event (TEAE; Grade (Gr) ≥3, 55.0%). One pt with prior cardiac disorder discontinued (Gr 5 ventricular fibrillation, unrelated to LINVO). Most common TEAEs were CRS (50.0%; Gr 1, 35.0%; Gr 2, 15.0%) and infusion-related reactions (45.0%; Gr 1, 25.0%; Gr 2, 20.0%), most during step-up dosing. LINVO elicited rapid responses (Table): hOR rates were 100% (80 mg: ≥hCR, 57.1%) and 92.3% (240 mg: ≥hCR, 38.5%), which are expected to deepen with longer follow-up. Most pts reached iFLC <20 mg/L (80 mg: 100%; 240 mg: 84.6%). **Conclusions:** LINVO demonstrated generally manageable safety and rapid, meaningful clinical activity, with most pts achieving hOR and iFLC <20 mg/L. These results support continued evaluation of LINVO in RR systemic AL amyloidosis. Longer follow-up data, including organ responses, are being evaluated. Clinical trial information: NCT06292780. Research Sponsor: Regeneron Pharmaceuticals Inc.

7503 **Oral Abstract Session**

DREAMM-9 final analysis: Belantamab mafodotin (belamaf), bortezomib, lenalidomide, and dexamethasone (BVRd) for transplant-ineligible (TI) newly diagnosed multiple myeloma (NDMM). First Author: Saad Z. Usmani, Memorial Sloan Kettering Cancer Center, New York, NY

Background: DREAMM-9 (NCT04091126) was a phase 1 dose and schedule evaluation study of BVRd in adults with TI NDMM. **Methods:** Patients (pts) received BVRd in 1 of 8 belamaf dosing cohorts at an induction/maintenance schedule of Q3/4W (SHORT: 1.9, 1.4, 1.0 mg/kg), Q6/8W (STRETCH: 1.9, 1.4 mg/kg), Q9/12W (step-down [S/D]: 1.9 for 1 dose then 1.4 mg/kg; 1.4 for 1 dose then 1.0 mg/kg), or Q12W (1.0 mg/kg). The primary endpoint was safety. Responses, minimal residual disease negativity (MRD[-]) in complete response or better (CR+), and pt-reported outcomes (PROs) were assessed. Median dose intensities (mDIs) were calculated as mg/kg/21 days in induction and mg/kg/28 days in maintenance. **Results:** As of June 2, 2025, 118 pts were enrolled (intention-to-treat population). Median duration of follow-up was 15.9–47.1 months. Induction mDI generally decreased as planned dosing intervals increased and was lowest in S/D Q9/12W or Q12W cohorts. Maintenance mDI was similar across cohorts due to dose modifications. Overall response rates were ≥83% across cohorts. Cohorts with higher induction mDI had the deepest responses (CR+/MRD[-] 75/55% for pooled SHORT+STRETCH and 59/43% for pooled Q9/12W+Q12W). Grade (Gr) ≥2 ophthalmic exam findings (OEFs; best-corrected visual acuity changes/slit lamp findings [Keratopathy and Visual Acuity scale]) were 90% for pooled SHORT+STRETCH/69% for pooled Q9/12W+Q12W, while Gr 3/4 OEF rates were higher with higher induction mDI (79%/35%). Most cohorts (5/8) had no belamaf discontinuations due to Gr ≥3 OEFs, which occurred only in SHORT cohorts (n = 1 each). First Gr ≥2 OEFs resolved prior to end of treatment in 83–100% across cohorts. The long-interval group (Q9/12W and Q12W dosing schedules) remained largely below the vision-related function (VRF) deterioration threshold (12.5 points per Ocular Surface Disease Index) across most timepoints, suggesting a favorable VRF profile vs the SHORT interval group. **Conclusions:** BVRd had high response rates across all cohorts (≥83%), highlighting the promising efficacy of the regimen. Regimens with higher belamaf induction mDI had the deepest responses, while those with lower induction mDI had milder OEFs. Belamaf dosing with a higher induction DI is optimal to achieve deeper responses, and a lower maintenance DI (i.e., using longer schedules) improves tolerability, PROs, and maintains responses. Clinical trial information: NCT04091126. Research Sponsor: GSK.

7504 **Oral Abstract Session**

Impact of sustained MRD negativity for up to 5 years on long-term outcome of transplant-eligible newly diagnosed multiple myeloma patients enrolled in the randomized phase 2 FORTE trial. First Author: Mattia D'Agostino, Division of Hematology, AOU Città della Salute e della Scienza di Torino, University of Torino and Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy

Background: Novel combinations induce high rates of minimal residual disease (MRD) negativity (neg) in multiple myeloma (MM) patients (pts). However, the optimal duration of MRD negative status to predict long term outcomes remains a matter of debate. We analyzed the impact of different sustained (sust) MRD neg cut-offs on progression free survival (PFS) and overall survival (OS) in transplant eligible Newly Diagnosed MM pts treated in the randomized phase 2 FORTE trial (NCT02203643). **Methods:** We included all pts enrolled in the trial who were randomized to maintenance. MRD was assessed in the bone marrow in pts with ≥very good partial response by multiparameter flow cytometry (sensitivity of 10^{-5}) at premaintenance and every 6 months thereafter. SustMRD neg was defined as consecutive MRD-negative evaluations for at least 1, 2, 3, 4 or 5 years without intercurrent MRD-positive results. The primary aim of the analysis was the impact of different SustMRD neg durations on PFS. A subgroup analysis according to a modified Consensus Genomic Staging (mCGS as described in Avet-Loiseau et al JCO 2025 without the use of molecular data), and the presence of an MGUS-like profile at diagnosis (Burgos et al JCO 2023) was performed. **Results:** 356 pts were randomized to maintenance according to study protocol. After a median follow-up of 85 months from maintenance randomization, 77% of pts have > 1 MRD negative evaluation. The rate of at least 1, 2, 3, 4, 5-years sustMRD neg was 53%, 42%, 36%, 28% and 20% respectively. Compared to MRD positive patients (n=83), MRD neg lasting <1 year (HR 0.72; 95% CI 0.47-1.09), 1 year (HR 0.40; 95% CI 0.22-0.72), 2 years (HR 0.36; 95% CI 0.19-0.66), 3 years (HR 0.17; 95% CI 0.07-0.40), 4 years (HR 0.15; 95% CI 0.06-0.35) and 5 years (HR 0.06; 95% CI 0.03-0.15) significantly and progressively improved pts' PFS. In pts with ≥ 3-years sustMRD neg vs < 3-year sustMRD, 7-years PFS rates were 84.7% vs 35.4% (HR 0.16, 95% CI 0.10-0.27) and 7-years OS rates were 97% vs 69% (HR 0.08, 95% CI 0.02-0.27). Stratifying patients according to mCGS and 3-years sustMRD neg, 7-years PFS rates were 84% for mCGS standard risk with ≥ 3-y sustMRD, 83% for mCGS high risk and ≥ 3-y sustMRD, 43% for mCGS standard risk with < 3-y sustMRD, 23% for mCGS high risk with < 3-y sustMRD. Among patients with < 3-years sustMRD neg, the presence of an MGUS-like profile predicted a significantly better PFS and OS compared to non MGUS-like pts (7-years PFS 67% vs 33%, HR 0.37 95% CI 0.17-0.85; 7-years OS 93% vs 66%, HR 0.15 95% CI 0.02-1.08). **Conclusions:** SustMRD neg for more than 3 years significantly improved PFS and OS of NDMM pts, with pts with at least 5-year SustMRD neg having a 7-year PFS of 91%. Reaching > 3-y sustMRD neg is mandatory in high-risk pts to achieve long term remissions, while MGUS-like pts may have good outcomes despite the absence of 3-y sustMRD neg. Clinical trial information: NCT02203643. Research Sponsor: Amgen; Celgene/Bristol Myers Squibb.

7505 **Oral Abstract Session**

New IMS/IMWG risk criteria by next-generation sequencing (NGS): Analysis of daratumumab benefit in both high- and standard-risk patients (pts) in the PERSEUS study. First Author: Luca Bertamini, Department of Hematology Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: IMS/IMWG recently proposed novel Consensus Genomic Staging (CGS) high-risk criteria for newly diagnosed multiple myeloma (NDMM), including genetic alterations not identifiable by fluorescence in situ hybridization (FISH) but by NGS (eg, *TP53* mutations). PERSEUS/EMN017 (NCT03710603) evaluated the addition of daratumumab to VRd induction/consolidation and to R maintenance (DVRd arm) vs VRd+R (VRd arm) in transplant-eligible (TE) pts. PERSEUS previously reported that DVRd significantly improved progression-free survival (PFS) regardless of cytogenetic risk as defined by previous criteria. **Methods:** 709 pts with NDMM were randomized 1:1 to DVRd vs VRd. Unique molecular assay (UMA)-NGS target panel was used on DNA extracted from CD138+ bone marrow (BM) cells. Of 664 pts from whom BM was collected, 434 patient DNA samples were available for NGS testing. Per the new IMS/IMWG CGS criteria, high risk was defined post-hoc by the presence of del17p/*TP53* mutations; t(4;14) or t(14;16) or t(14;20) with additional amp1q or del1p; amp1q and del1p; biallelic del1p; and high β2 microglobulin with normal renal function. Classic FISH high risk was defined per-protocol by the presence of del17p, t(14;16), and/or t(4;14). Minimal residual disease negativity (MRD neg) was assessed by NGS (Adaptive) in pts with complete response or better. **Results:** Of 434 pts evaluated, 152 (35%) were high risk by CGS. The most common genetic lesions were del17p/*TP53* (n=59, 14%), IgH translocation with amp1q/del1p (12%), and del1p with amp1q (9%); 2% had biallelic focal del1p. Using CGS criteria, 17% of pts were reclassified from standard risk to high risk; additionally, 4% of pts previously classified as high risk were reclassified as standard risk. DVRd was associated with increased MRD neg rates at 10^{-6} compared to VRd in both CGS standard-risk (67% vs 39%, *P*=0.0001) and high-risk pts (56% vs 26%, *P*=0.0003). Sustained MRD neg (10^{-6}) rates for ≥12 months (+/-1 mo) were higher with DVRd vs VRd for both CGS standard-risk (57% vs 24%; *P*<0.0001) and high-risk pts (41% vs 19%; *P*<0.0001), and pts who achieved sustained MRD negativity (10^{-6}) had superior PFS outcomes versus those who did not, regardless of CGS risk status (*P*<0.0001). DVRd led to improved PFS in both CGS standard-risk (HR 0.38, 95% CI 0.20–0.73; *P*=0.001) and high-risk pts (HR 0.54, 95% CI 0.31–0.95; *P*=0.039), adjusting for ISS, lactate dehydrogenase, and age (>65 years). **Conclusions:** DVRd improved MRD negativity and PFS over VRd in both the new IMS/IMWG CGS high-risk and standard-risk subgroups. UMA-NGS panel successfully stratified risk according to CGS criteria, identifying nearly twice as many high-risk pts in the PERSEUS study. These data further support DVRd induction/consolidation and DR maintenance as standard of care for TE-NDMM, regardless of cytogenetic risk. Clinical trial information: NCT03710603. Research Sponsor: Johnson & Johnson.

Mezigdomide, carfilzomib, and dexamethasone (MeziKd) vs carfilzomib and dexamethasone (Kd) in relapsed/refractory multiple myeloma (RRMM): Results from the phase 3 SUCCESSOR-2 trial. First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

7507 **Oral Abstract Session**

MajesTEC-9: A phase 3 randomized study of teclistamab monotherapy vs investigator's choice of pomalidomide, bortezomib, and dexamethasone or carfilzomib and dexamethasone (PVd/Kd) in patients (pts) with relapsed refractory multiple myeloma (RRMM). First Author: Roberto Mina, Winship Cancer Institute, Emory University; Division of Hematology, Department of Molecular Biotechnology and Health Sciences, AOU Città della Salute e della Scienza di Torino, University of Torino, Torino, Italy

Background: Triplet and quadruplet regimens have greatly improved outcomes in newly diagnosed multiple myeloma, yet a high unmet need remains for more effective, broadly accessible treatments for anti-CD38- and lenalidomide- (Len) exposed/refractory RRMM. Teclistamab (Tec) is the most widely used BCMA×CD3 BsAb in heavily pretreated RRMM, with improved outcomes in earlier lines of therapy (LOTs). In MajesTEC-3, the synergistic Tec-daratumumab combination significantly improved progression-free and overall survival (PFS/OS) as early as first relapse. MajesTEC-9 (NCT05572515) is the first phase 3 study of Tec monotherapy in pts with 1–3 prior LOTs. **Methods:** Pts with RRMM and 1–3 prior LOTs including anti-CD38 and Len were randomized 1:1 to receive 28-day cycles (C) of Tec (C1–2: 2 step-up doses then 1.5 mg/kg QW; C3–6: 3 mg/kg Q2W or Q4W depending on response; C7+: 3 mg/kg Q4W) or investigator's choice of PVd/Kd (21/28-day C). Primary endpoint was PFS by IRC; secondary endpoints included OS, complete response or better (≥CR), and safety. **Results:** 593 pts were randomized (Tec, n=296; PVd/Kd, n=297). Median (range) age: 70 (34–86) yrs; number of prior LOTs: 2 (1–3); Len refractory: 80%; anti-CD38 refractory: 85%; refractory to last LOT: 92%. With 17.3-mo median follow-up, Tec significantly improved PFS vs PVd/Kd (HR, 0.29; 95% CI, 0.23–0.38; *P*<0.0001); mPFS: NR vs 8.2 mo; 18-mo PFS rate: 69.8% vs 26.9%. OS was significantly improved with Tec vs PVd/Kd (HR, 0.60; 95% CI, 0.43–0.83; *P*=0.0020). Of 174 PVd/Kd pts who received subsequent treatment, 68.4% received BsAb or CAR-T. PFS favored Tec across all prespecified subgroups, including anti-CD38-refractory pts and Len-refractory pts. ≥CR rate was significantly higher with Tec vs PVd/Kd (65.9% vs 16.8%; OR, 10.42; 95% CI, 6.89–15.76; *P*<0.0001). At data cutoff, 65.3% of pts remained on Tec vs 24.0% on PVd/Kd (safety set: Tec, n=291; PVd/Kd, n=283). TEAEs were similar for Tec and PVd/Kd (99.7% vs 97.9%). Grade (Gr) 3/4 TEAEs (84.9% vs 76.3%) and Gr 5 TEAEs (6.5% vs 3.5%) were higher with Tec vs PVd/Kd, noting the median treatment duration was nearly doubled with Tec (13.1 vs 7.0 mo). Treatment discontinuation due to TEAEs was lower with Tec vs PVd/Kd (10.7% vs 13.1%). Gr 3/4 infections were higher with Tec vs PVd/Kd (41.6% vs 29.0%). Any-onset Gr ≥3 infections decreased over time. CRS occurred in 66.0% of pts with Tec (Gr 1/2: 48.8%/16.5%) and ICANS in 4.1% (Gr 1/2: 2.4%/1.4%). **Conclusions:** Tec monotherapy significantly improved PFS/OS vs standard of care (SoC) in this high unmet need population. CRS and infections were managed with established protocols. Results of phase 3 studies support Tec-based regimens as a SoC as early as second line, across all treatment settings and regardless of prior anti-CD38/Len exposure. Clinical trial information: NCT05572515. Research Sponsor: Johnson & Johnson.

7508 Oral Abstract Session

Etentamig in patients (pts) with relapsed/refractory multiple myeloma (RRMM) with prior exposure to B-cell maturation antigen (BCMA)—targeted therapy. First Author: Saurabh Chhabra, Mayo Clinic Arizona, Phoenix, AZ

Background: Data on response to BCMA-targeted therapies among BCMA-exposed pts with RRMM are limited. Outcomes after sequential/subsequent anti-BCMA bispecific T-cell engagers (Bs-TCE) are vital to evaluate. Etentamig is a next-generation differentiated BCMA x CD3 Bs-TCE composed of a bivalent BCMA-binding domain with a high-avidity, low-affinity CD3-binding domain potentially reducing cytokine release syndrome (CRS), and a silenced Fc tail for extended half-life and convenient monthly (Q4W) dosing. Phase 1 results of etentamig in RRMM showed robust efficacy and potential best-in-class safety. **Methods:** Arm B of the open-label, Phase 1b MOVISO study (NCT05650632) evaluated etentamig in pts with RRMM with ≥2 prior lines of therapy (PLT), including triple-class and prior BCMA exposure (antibody-drug conjugate [ADC] >30 days or CAR-T >6 months [mo] after last exposure). Primary safety endpoints were CRS and immune effector cell-associated neurotoxicity syndrome (ICANS); efficacy endpoints included objective response rate (ORR; IMWG 2016), duration of response (DoR), and progression-free survival (PFS). Pts received etentamig (60 mg IV; no step-up dosing [SUD]) on Cycle 1 Day 1 and Q4W thereafter. **Results:** At cutoff (June 11, 2025), 41 prior BCMA-exposed pts (CAR-T, n=24; ADC, n=17) had been treated; 24 (57%) were male, 38 (93%) were White, median (mdn) (range) age was 68 (43–89) years, 37 (88%) had ECOG PS ≤1, and 34 (81%) were triple-class refractory. Mdn (range) PLT was 6 (3–15). For 21 (51%) pts, the last PLT was BCMA directed; 23 (56%) had previously responded to anti-BCMA therapy (17/24 [71%] for CAR-T and 6/17 [35%] for ADC). Mdn (range) time from last prior CAR-T or ADC to first dose of etentamig was 15 (1–30) and 4 (1–45) mo, respectively. Mdn (range) follow-up was 5.5 (0.2–17.1) mo. Despite no SUD, CRS and ICANS were reported in 24 (57%) and 3 (7%) pts, respectively; all G1/2 events, except 1 G3 ICANS. G3/4 neutropenia and infections were reported in 15 (36%) and 17 (41%) pts, respectively. Efficacy outcomes are detailed in the Table (NE, not estimable). For pts whose last PLT was BCMA directed, MRD negativity (clonoSEQ, 10^{-5}) was seen in 2/3 (67%) evaluable pts, along with robust peak activation and proliferation of CD8+ T cells. **Conclusions:** Pts treated with etentamig achieved durable responses; rates were higher in pts who received CAR-T as last line. No new safety signals were observed; only low-grade CRS was seen despite no SUD. Clinical trial information: NCT05650632. Research Sponsor: AbbVie Inc.

7509 Rapid Oral Abstract Session

Updated results from inMMyCAR, the ongoing first-in-human phase 1 study of KLN-1010 in patients (pts) with relapsed and refractory multiple myeloma (RRMM). First Author: P. Joy Ho, Royal Prince Alfred Hospital and University of Sydney, Camperdown, NSW, Australia

Background: KLN-1010 is a modified lentiviral vector generating a novel, fully human anti-BCMA CAR-T cell *in vivo* when administered intravenously without preparative chemotherapy to pts with RRMM. Here, we report updated findings from inMMyCAR, the first sponsored, multicenter study of an *in vivo* CAR-T therapy for pts with RRMM. **Methods:** Eligibility required RRMM with measurable disease, adequate end-organ and bone marrow (BM) function, and ≥3 prior lines of therapy, including a proteosome inhibitor, an immunomodulatory drug, and an anti-CD38 monoclonal antibody. **Results:** To date, 6 pts were infused across two dose levels (6×10^6 and 2×10^7 IU/kg). Pts ranged in age from 61-72 and had received 3-5 prior lines of therapy. 5 pts had high-risk cytogenetics. BM plasma cell involvement ranged from <5% to 80%. 1 pt had extramedullary disease (EMD). Median time from consent to infusion was 13.5 days. All pts experienced treatment-emergent adverse events. Infusion-related reactions (IRR) occurring in 3 pts (2 at 2×10^7 IU/kg, 1 at 6×10^6 IU/kg) were manageable and resolved within 6-48 hrs. Cytokine release syndrome (CRS) was observed in 4 pts, with median onset on day 11 and median duration of 3.5 days; all events were Gr 2 and were managed with tocilizumab and corticosteroids. No immune effector cell–associated neurotoxicity syndrome (ICANS) or delayed neurotoxicity were observed. Peak absolute lymphocyte counts occurred between days 13-22, with median counts of 6.9×10^9/L (range 2.3-43.1$\times10^9$/L) and no associated clinical sequelae. CAR-T cells were detectable in peripheral blood through 4 months follow-up and were predominantly memory-phenotype by month 3 (M3). All 6 pts achieved minimal residual disease (MRD) negativity (5 at 10^{-6} and 1 at 10^{-5} sensitivity) at M1 in the BM. MRD negativity was maintained through M6 (10^{-6} sensitivity) in the pt with the longest follow-up. All pts achieved a response by IMWG criteria, and responses deepened over time. The pt with EMD showed complete resolution by M1. **Conclusions:** Results from inMMyCAR continue to demonstrate compelling early clinical activity. All pts achieved early MRD-negative responses and deepening of IMWG response over time. The pt with the longest follow-up remains MRD-negative with a stringent CR at M6. Activity was also observed in EMD, with radiologic resolution within 1 month. KLN-1010 was generally well-tolerated, with manageable toxicities related to IRR and CRS, supporting potential feasibility for outpatient administration. No ICANS or delayed neurotoxicity were observed. The study remains ongoing; updated results will be presented. Clinical trial information: NCT07075185. Research Sponsor: Kelonia Therapeutics, Inc.

7510 Rapid Oral Abstract Session

Optec/Optal: A phase 2 study to evaluate outpatient (OP), step-up administration of teclistamab (Tec) or talquetamab (Tal) with prophylactic tocilizumab (prophyToci) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). First Author: Peter Forsberg, Colorado Blood Cancer Institute, Denver, CO

Background: Tec, a B-cell maturation antigen x CD3 bispecific antibody (bsAb), and Tal, a G protein-coupled receptor class C group 5 member D x CD3 bsAb, are approved for the treatment of pts with triple-class exposed (TCE) RRMM. Cytokine release syndrome (CRS) is a common adverse event associated with T-cell therapies. CRS occurred in 72% and 73-79% of pts in the MajesTEC-1 (TEC-1) and MonumenTAL-1 (TAL-1) studies, respectively. One cohort of pts in TEC-1 received prophyToci, resulting in a lower rate of CRS (26%) without negatively impacting safety or efficacy. A cohort of pts in TAL-1 received prophyToci, with 18% experiencing CRS; safety and efficacy were comparable to the overall TAL-1 population. **Methods:** This nonrandomized, multicenter, prospective study evaluates prophyToci in RRMM pts treated with Tec (Arm A) or Tal (Arm B) using the approved step-up dose (SUD) schedule in the OP setting. ProphyToci 8 mg/kg was administered before SUD 1 of either Tec or Tal. Specific recommendations (home monitoring, IV immunoglobulin [IVIG] for IgG levels <400 mg/dL) and restrictions (caregiver requirements and travel distance) are also provided for pt safety. Primary endpoint is incidence of any grade CRS in cycles 1-2. Secondary endpoints include safety and efficacy measures. Safety parameters encompass incidence of Grade ≥2 CRS, any grade recurrent CRS, any grade infections, neurotoxicity (NT), and neutropenia throughout the study. Efficacy endpoints include overall response rate (ORR), best overall response (BOR) and progression-free survival (PFS). **Results:** As of 06 January 2026, 43 pts enrolled in Arm A, and 7, in Arm B. In Arm A, the CRS rate was 5%, all G1. In Arm B, G1 CRS occurred in 14% of pts. Adverse events G≥3 included neutropenia (G3, n=4; G4, n=6), anemia (G3, n=1), and febrile neutropenia (G3, n=1). Twenty pts (47%) in Arm A experienced infections, with 19% ≥G3. Among Arm A patients who experienced infections, 10 (50%) exhibited IgG levels <400 mg/dL, of whom 2 (20%) received IVIG. In Arm B, 4 pts (57%) experienced infections, with 29% (n=2) ≥G3. BOR in Arm A included 3 stringent complete responses (sCRs), 6 CRs, 11 very good partial responses (VGPR), 8 PRs, 1 stable disease, 5 progressive disease (PD), and 9 non-evaluable pts. Among the 34 evaluable pts in Arm A, the ORR was 82%. BOR in Arm B included 1 sCR and 6 non-evaluable pts. After a median follow-up of 11.8 months, 74.4% of pts (n=32) in Arm A did not experience progression. **Conclusions:** A single dose of prophyToci before SUD 1 of Tec or Tal reduced the incidence of CRS, with no impact on safety or efficacy, and supports administration of these bsAbs in the OP setting. The protocol was amended to add an arm evaluating the effect of prophylactic oral dexamethasone on CRS in pts treated with Tec (Arm C). Enrollment is ongoing (NCT05972135). Clinical trial information: NCT05972135. Research Sponsor: Johnson & Johnson Innovative Medicine; Sarah Cannon Research Institute.

7511 Rapid Oral Abstract Session

Survival outcomes comparing sequencing of CAR-T followed by BiTE versus BiTE followed by CAR-T in patients with relapsed multiple myeloma. First Author: Joseph OBrien, Denver Health Medical Center, Denver, CO

Background: Chimeric antigen receptor T-cell (CAR-T) therapies and bispecific T-cell engager (BiTE) antibodies for relapsed and refractory multiple myeloma (MM) are increasingly used earlier in the disease course but the optimal sequencing remains unclear. It has been hypothesized that CAR T before BiTE would lead to less T-cell exhaustion and better outcomes than BiTE before CAR T. **Methods:** A multicenter retrospective cohort study using the TriNetX Global Collaborative Network from 2021-2025 to evaluate outcomes among MM pts who received both CAR-T (idecel or ciltacel) and a BiTE (teclistamab, talquetamab, or elranatamab). Cohorts by treatment sequence: CAR-T followed by BiTE (CAR-T→BiTE) or BiTE followed by CAR-T (BiTE→CAR-T). Primary outcome: 5-yr mortality from the initiation of first advanced immunotherapy. Secondary outcomes: incidence of CRS, ICANS, infection, sepsis, ICU admission, and 1-yr mortality following each therapy. Propensity score matching included demographic variables, comorbidities, prior myeloma therapies (including prior SCTx) and baseline laboratory values. **Results:** 389 pts were included (244 CAR-T→BiTE; 145 BiTE→CAR-T); in the CAR T 1st group, 72% received ide-cel and 28% had cilta-cel, whereas in the BiTE 1st group 86% went on to receive cilta-cel as the CAR T product. Median overall survival was reached in the BiTE-first cohort (3.59 years) but not in the CAR-T–first cohort. Five-year survival was significantly higher with CAR-T–first sequencing (57.1% vs 25.5%; log-rank p = 0.045). In adjusted Cox regression, CAR-T–first sequencing was independently associated with lower 5-year mortality (hazard ratio 0.57, 95% CI 0.34–0.95). In unmatched analyses stratified by the specific BiTE (anti-BCMA vs anti-GPRC5D) used, overall survival did not differ significantly within each treatment sequence (all log-rank p > 0.05). In propensity score–matched analyses (112 patients per group), CAR-T–first pts experienced higher ICANS (all grades, 22% vs 10.7%) after first therapy but lower ICU admission (52% vs 70%), and significantly lower CRS (37% vs 56%, all grades) following second therapy. Rates of infection, sepsis, and 1-yr mortality were similar between groups. **Conclusions:** Among patients with MM who received both CAR-T and BiTE therapies, CAR-T–first sequencing was associated with significantly improved long-term survival in spite of a much higher percentage receiving the less effective CAR T product. The additional finding of a lack of survival differences by specific BiTE used also suggests that treatment order, rather than product selection, may be the primary determinant of long-term outcomes. These findings support consideration of earlier CAR-T deployment when feasible and underscore the importance of sequencing strategy in the evolving landscape of MM immunotherapy. Belantamab mafodotin with daratumumab, lenalidomide, and dexamethasone in transplant-ineligible, newly diagnosed multiple myeloma patients: Phase 1/2 BelaDRd study. First Author: Evangelos Terpos, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: The MAIA trial established daratumumab with lenalidomide, dexamethasone (DRd) as standard therapy for transplant-ineligible (TI) NDMM. Belantamab mafodotin (belamaf) showed high efficacy in relapsed/refractory disease. Quadruplet regimens improved clinical outcomes, providing a strong rationale to evaluate belamaf in combination with DRd in TI NDMM. **Methods:** BelaDRd is a phase 1/2, open-label study (EUCT-2024-515634-32) evaluated this combination in TI-NDMM. Part 1 (dose-finding phase) assessed the safety and tolerability of two belamaf doses (1.9/1.4 mg/kg Q8W) with DRd. This part established belamaf 1.9 mg/kg Q8W, extended to Q12W to account as the recommended phase 2 dose (RP2D). Part 2 (dose-expansion phase) evaluates the safety and efficacy of the RP2D in two cohorts Groups A and B, guided by ophthalmologist and hematologist (using Vision-Related Anamnestic, VRA tool), respectively. **Results:** In Part 1, 24 pts (median age: 73 years; male: 54.2%) entered the study;12.5% had high-risk cytogenetics (HRC). At a median follow-up of 34.3 months, 18 (75%) pts remained on treatment, while 6 (25%) discontinued; 3 (12.5%) death, 1 (4.2%) AE/SAE, 1 (4.2%) withdrew consent, and 1 (4.2%) due to PD. The median dose intensity (MDI) of belamaf was 0.5 mg/kg/Q4W. MRD negativity was achieved in 13 (81.3%) of evaluable patients (n=16). The ORR was 22 (91.7%). Sixteen patients (69.6%) achieved both ≥CR and ≥VGPR. In Part 2 (n=12; median age: 74 years; male: 58.3%),16.7% of pts had HRC. At a median follow-up of 17.9 months, 11 pts (91.7%) remained on treatment; 1 pt (8.3%) discontinued due to PD. Of 113 planned belamaf doses 13 doses were skipped due to OAEs. The MDI was 0.8 mg/kg/Q4W. MRD negativity was achieved in 5 (71.4%) of evaluable patients (n=7). ORR was 11 (91.7%) in evaluable pts. The median time to ≥PR was 1.1 months for both parts. At 18 months, PFS was 91.7% (95% CI 76.4-97.2) and 87.5% (95% CI 66.1-95.8) in the overall and RP2D populations, respectively; corresponding TTP rates were 97.1% (95% CI 80.9-99.6) and 95.5% (95% CI 71.9-99.4). Grade ≥3 BCVA decline was observed in 74(10.4%) of ocular assessments in part 1 and 4(3.9%) and 5(5.3%) in part 2 groups A and B, respectively. Grade ≥2/≥3 keratopathy occurred in 20.2%/0.6% of assessments in Part 1; in Part 2, rates were 6.7%/0% (Group A) and 10.6%/0% (Group B). Median ≥Grade 2 BCVA OAE/keratopathy resolution time was 1.1/1.0 months (Part 1) and 1.9/1.0 months (Part 2). **Conclusions:** BelaDRd demonstrated robust clinical activity, with rapid and deep responses. Low frequency of ≥Grade 3 OAEs was observed and were rapidly resolved. Moreover, a similar frequency of OAEs was noted when dosing was guided by haematologist vs ophthalmologist ocular assessment. The remarkable PFS supports further evaluation of this quadruplet in a phase 3 study versus other novel quadruplet combinations in NDMM. Clinical trial information: EUCT-2024-515634-32. Research Sponsor: None.

7513 **Rapid Oral Abstract Session**

Daratumumab plus bortezomib, lenalidomide, and dexamethasone (DVRd) in patients (pts) with newly diagnosed multiple myeloma (NDMM): Final analysis of transplant-ineligible (TIE) pts in the phase 3 CEPHEUS study. First Author: Saad Z. Usmani, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The phase 3 CEPHEUS study established that DVRd improved overall minimal residual disease (MRD)-negativity (neg) rates and progression-free survival (PFS) vs VRd in pts with TIE or transplant-deferred (TD) NDMM. The first analysis of the DVRd TIE subpopulation at a median follow-up of 58.7 months (mo) showed a complete response or better (≥CR) rate of 80.6% and overall MRD neg rate of 60.4%, with ~70% of pts alive and progression free. This final analysis of the CEPHEUS TIE subpopulation describes a longer median follow-up of 76.0 mo. **Methods:** The primary endpoint of overall MRD neg rate (10^{-5} and ≥CR), and secondary endpoints, including investigator-assessed PFS and ≥CR rate, and sustained MRD neg (confirmed MRD neg ≥12 months +/- 1 mo apart without MRD positivity in between and ≥CR) were assessed in the TIE population. The study was closed at the final analysis and pts were able to continue their study treatment via post-study access. **Results:** Of 395 pts enrolled, 289 pts with TIE NDMM received either DVRd (n=144) or VRd (n=145). The overall MRD neg rate at 10^{-5} was 61.1% for DVRd and 40.0% for VRd (odds ratio [OR] 2.35; 95% CI 1.47–3.77; *P*=0.0004) and at 10^{-6} was 46.5% for DVRd vs 27.6% for VRd (OR 2.27; 95% CI 1.39–3.71; *P*=0.0010). Sustained MRD neg rate at 10^{-5} was 49.3% for DVRd and 29.0% for VRd (OR 2.40; 95% CI 1.47–3.91; *P*=0.0005) and at 10^{-6} was 37.5% for DVRd and 16.6% for VRd (OR 3.01; 95% CI 1.73–5.24; *P*<0.0001). Overall ≥CR rate was 80.6% for DVRd and 61.4% for VRd (OR 2.64; 95% CI 1.54–4.51; *P*=0.0003). Median investigator-assessed PFS was not estimable (NE; 95% CI 74.81–NE) for DVRd and was 50.20 mo (95% CI 41.95–62.95) for VRd (HR 0.55; 95% CI 0.39–0.78; *P*=0.0007), with 59.3% for DVRd vs 38.3% for VRd alive and progression free at 72 mo. OS favored DVRd over VRd (HR 0.84; 95% CI 0.57–1.24), particularly when censoring for COVID-19, which significantly impacted this study (HR 0.74; 95% CI 0.49–1.12). The treatment effect was consistent across most subgroups (Table). **Conclusions:** After median follow-up of over 6 years, the final analysis of the CEPHEUS trial demonstrated that TIE pts treated with DVRd continue to have deep and durable responses compared with those on VRd, which is crucial for patients for whom transplant is not an option. These data continue to reinforce DVRd as a standard of care in the TIE NDMM population. Clinical trial information: NCT03652064. Research Sponsor: Johnson & Johnson.

Efficacy and safety of iberdomide, daratumumab, bortezomib, and dexamethasone in patients with newly diagnosed multiple myeloma. First Author: Prashant Kapoor, Mayo Clinic Rochester, Rochester, MN

Background: Iberdomide (Iber) is a CELMoD that binds with greater specificity & affinity to the cereblon protein of the E3 ligase complex than a traditional IMiD. Both transplant-eligible (TE) & ineligible (TIE) patients (pts) with newly diagnosed multiple myeloma (NDMM) are currently treated with quadruplet induction, consisting of an anti-CD38 monoclonal antibody, a proteasome inhibitor, an IMiD & dexamethasone (dex). We conducted a clinical trial (NCT05392946, IDEAL) to examine the efficacy of a novel finite-duration approach, using Iber, daratumumab, bortezomib & dex (Iber-DVd) quadruplet induction followed by Iber monotherapy maintenance. **Methods:** Both TE and TIE pts with NDMM were enrolled in this Phase 1 (3+3 design)/Phase 2 (single stage) trial. The primary goal was to assess the ≥complete response (CR) rate — utilizing the more sensitive serum MASS-FIX assay in lieu of serum immunofixation — during induction. Treatment involved twelve 28-day cycles of induction with Iber, given PO at the recommended phase 2 dose (RP2D), days 1-21, daratumumab 1800mg SQ, weekly for 2 cycles, every other week during Cycles 3-6, & every 4 weeks thereafter, bortezomib 1.3 mg/m^2 SQ, weekly & dex 40 mg, weekly, followed by Iber monotherapy (24 cycles). Growth factor was not allowed during the dose-limiting toxicity (DLT) assessment period (Cycle 1). **Results:** Among 47 pts enrolled, 9 pts were in Phase 1 portion which assessed the maximum tolerated dose (MTD), with Iber starting at 1 mg/day dose, days 1-21 [Dose Level (DL) 1]. DLT (all grade 4 neutropenia) was noted in 3 pts, 2 at DL 1 & 1 at DL -1. This analysis includes 44 pts who received Iber at the RP2D (0.75 mg/day, days 1-21), including 6 pts from the Dose Confirmation Cohort (Phase 1, DL -1), dosed at MTD, & 38 pts in the Dose Expansion Cohort. The median age at registration was 65 years (range 36-86 years), & 23 pts (52.3%) were deemed high-risk. At data cut-off, pts had received a median of 15 cycles (range 3-36) of therapy. Overall response rate was 100%; ≥CR rate, 36.4% (95% CI: 22.4, 52.2) during induction & 52.3% (95% CI: 36.7, 67.5), overall, including the maintenance phase. The marrow flow-based (10^{-5}) MRD negative rate was 29.5% during induction & 47.7% overall. At a median follow-up (FU) 18.3 mos, 2 pts have died (one during FU due to progressive disease & the other on-treatment due to COVID-19). 12- (& 18-) month progression-free survival & overall survival rates were 91% (88%) & 97% (94%), respectively. Most common toxicities at RP2D were lymphopenia, neutropenia (leading 27% of pts to require pegfilgrastim support), rash, peripheral neuropathy, diarrhea, & infections. Cases of high-grade fatigue were low (<5%). Updated data will be presented at the meeting. **Conclusions:** Iber-DVd is an active and safe regimen for both TE and TIE pts with NDMM, leading to high response rates which improved over time, with nearly one-half of the pts achieving MRD negative state. Clinical trial information: NCT05392946. Research Sponsor: Bristol Myers Squibb (BMS).

7515 **Rapid Oral Abstract Session**

Long-term outcomes with sustained minimal residual disease (MRD) negativity in belantamab mafodotin–treated patients (pts) with relapsed/refractory multiple myeloma (RRMM): An update from DREAMM-8. First Author: Suzanne Trudel, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: B-cell maturation antigen (BCMA)–directed therapies have changed the RRMM treatment landscape. In the phase 3 DREAMM-8 trial (NCT04484623), BCMA-directed antibody-drug conjugate (ADC) belantamab mafodotin + pomalidomide and dexamethasone (BPd) demonstrated significant progression-free survival (PFS) benefit and higher rates of complete response (CR)–based MRD negativity vs triplet pomalidomide, bortezomib, dexamethasone (PVd) in pts with RRMM and ≥1 prior line of therapy (LOT). As MRD negativity predicts improved survival in MM, this long-term, postbaseline update describes clinical outcomes and characteristics of pts with sustained MRD negativity. **Methods:** Pts with ≥1 prior LOT including lenalidomide were randomized 1:1 to BPd or PVd. The primary endpoint was PFS (independent review committee assessed); PFS2 was investigator assessed. CR-based sustained MRD negativity (≥12 mo) was an exploratory endpoint. Pts with ≥ CR were tested for MRD negativity by next-generation sequencing (10^{-5} sensitivity). **Results:** At data cutoff (7/7/2025), with median follow-up of 35.8 mo overall, the intention-to-treat population of BPd (n=155) vs PVd (n=147) was >4× more likely to achieve ≥ CR + MRD negativity (27.7% vs 6.1%) and sustained MRD negativity (15.5% vs 2.7%). In pts with ≥ CR (BPd, n = 67; PVd, n = 25), rates of MRD negativity were also higher with BPd vs PVd (64.2% vs 36.0%), as were rates of sustained MRD negativity (55.8% vs 44.4%) among all ≥ CR + MRD negative pts. Pts with sustained MRD negativity had durable PFS in both arms; 1 of 24 and 0 of 4 pts experienced PFS events with BPd and PVd, respectively. In pts without sustained MRD negativity, median PFS was 21.1 mo with BPd (HR vs sustained MRD negative, 0.04; 95% CI, 0.01-0.32) and 10.2 mo with PVd (HR vs sustained MRD negative, not estimable [NE]). Sustained MRD negativity was also associated with durable PFS2 in both arms; 2 of 25 and 0 of 4 pts experienced PFS2 events with BPd and PVd, respectively. In pts without sustained MRD negativity, median PFS2 was 20.2 mo with BPd (HR vs sustained MRD negative, 0.08; 95% CI, 0.02-0.33) and 9.3 mo with PVd (HR vs sustained MRD negative, NE). Findings were similar in pts with vs without ≥ CR + MRD negativity. Of BPd-treated pts, those with MRD negativity (n=43) received 1-3 prior LOT, of which most (74.4%) had 1. MRD-positive pts (n=112) received up to 6 prior LOT, of which 44.6% received 1 and 17.0% received >3. Almost 40% of pts with CR-based MRD negativity had high-risk cytogenetics. **Conclusions:** Pts receiving BPd vs PVd were >4× more likely to achieve sustained MRD negativity, which was associated with improved PFS and PFS2. MRD negative vs positive pts in the BPd arm more often had 1 prior LOT. These findings further support BPd, a BCMA-directed ADC regimen, in earlier LOTs for RRMM, including in pts with high-risk cytogenetics. Clinical trial information: NCT04484623. Isatuximab plus pomalidomide-dexamethasone in relapsed/refractory multiple myeloma: Subgroup analysis by prior anti-CD38 exposure from the phase 3 IRAKLIA trial. First Author: Albert Oriol Rocafiguera, Institut Català d'Oncologia and Josep Carreras Research Institute, Hospital Germans Trias i Pujol, Barcelona, Spain

Background: With the growing use of anti-CD38 therapies in early multiple myeloma (MM) management, there is a need for data in patients previously exposed to anti-CD38 therapy to guide decision making. In the Phase 3 IRAKLIA trial (NCT05405166), patients with relapsed/refractory MM (RRMM) received the anti-CD38 monoclonal antibody isatuximab (Isa) subcutaneously (SC) delivered via an innovative on-body injector (OBI) or intravenously (IV), with pomalidomide and dexamethasone (Pd). In this post hoc analysis, we examined outcomes in IRAKLIA patients with vs without prior anti-CD38 exposure. **Methods:** RRMM patients ≥18 years with ≥1 prior line of therapy including lenalidomide and a proteasome inhibitor were randomized to receive Isa SC (n=263) or IV (n=268) weekly in Cycle 1, then every 2 weeks, with Pd. Patients with prior anti-CD38 exposure <9 months (mos) before randomization or intolerance to anti-CD38 were excluded. Refractory patients were defined as those who failed to achieve minimal response on treatment or had progression within 60 days after last dose. Patients receiving Isa SC or IV were pooled. **Results:** Overall, 67 patients (12.6%) had prior anti-CD38 exposure with a median washout period of 20.2 mos, of which 26 (38.8%) were anti-CD38 refractory. Baseline characteristics were largely consistent between patients with or without prior anti-CD38 exposure; the median follow-up for the overall population was 12 mos. Patients with prior anti-CD38 exposure had an overall response rate (ORR) of 52.2%, 12-mo progression-free survival (PFS) rate of 40.6%, and median PFS of 8.5 mos. In patients without prior exposure, an ORR of 73.5%, 12-mo PFS of 68.8%, and non-estimable (NE) median PFS were reported. Anti-CD38 non-refractory vs refractory patients had an ORR of 48.8% vs 57.7%, 12-mo PFS of 38.9% vs 42.2%, and median PFS of 9.0 vs 7.5 mos. Patients with a longer washout period (>median of 20.2 mos) had an ORR of 63.6%, 12-mo PFS of 61.8% and NE median PFS, whereas patients whose prior anti-CD38 therapy ended more recently (≤median of 20.2 mos) had an ORR of 41.2%, 12-mo PFS of 19.2%, and median PFS of 6.7 mos. The safety profile of Isa + Pd was similar in patients with vs without prior anti-CD38 exposure. **Conclusions:** Isa + Pd demonstrated clinical benefit across anti-CD38–naïve, anti-CD38–exposed, and anti-CD38–refractory patients. A washout period >median of 20.2 mos resulted in outcomes comparable to those in anti-CD38–naïve patients, and outcomes were consistent between anti-CD38–exposed and anti-CD38–refractory patients after a >9-mo washout period. Efficacy of Isa + Pd in patients with prior anti-CD38 exposure from the IRAKLIA trial presents an opportunity to address an unmet need in a difficult-to-treat patient population. Clinical trial information: NCT05405166. Research Sponsor: Sanofi.

Final analysis of daratumumab, carfilzomib, pomalidomide, and dexamethasone in relapsed/refractory multiple myeloma. First Author: Jennifer H. Cooperrider, University of Chicago, Department of Medicine, Chicago, IL

Background: Frontline therapy for patients with multiple myeloma (MM) has mainly consisted of a proteasome inhibitor and an immunomodulatory imide drug (IMiD). Anti-CD38 monoclonal antibodies are fast becoming incorporated into frontline regimens, but many patients experiencing relapse today remain naïve to this drug class. While quadruplet therapies have become a standard-of-care in the newly diagnosed setting, they have not been well studied in patients with relapsed/refractory MM (RRMM). Here, we report the final analysis of a phase 2 Multiple Myeloma Research Consortium study of daratumumab combined with carfilzomib, pomalidomide, and dexamethasone in RRMM (NCT01665794). **Methods:** Eligible patients had documented MM with 1-3 prior lines of therapy, including a proteasome inhibitor and an immunomodulatory drug. Prior exposure to a CD38-directed monoclonal antibody was exclusionary. Dose and frequency were described previously. The primary endpoint was the rate of near complete response (nCR) after 4 cycles of DaraKPd; secondary endpoints included progression-free survival (PFS) and overall survival (OS). **Results:** A total of 28 patients were treated with DaraKPd. Patients had received a median of 1 prior line of therapy (range 1-3), including 24 (85.7%) with prior autologous stem cell transplant, and 82% that were refractory to lenalidomide. The study reached the statistical threshold for efficacy (nCR of 39%; 95% CI 22-59%), and the study was stopped early as a result. At a median follow-up of 70.2 months, the median progression-free survival (mPFS) was 38.3 months (95 % CI 18.4 mo-not reached [NR]) and median OS (mOS) was not reached. The 36-month PFS and OS were 54% (95% CI 35-70%) and 75% (95% CI 57-87%), respectively. High-risk cytogenetics, as defined by the presence of t(4;14), t(14;16), t(14;20), deletion 17p, and 1q gain or amplification, were present in 18 (64%) patients. The mPFS in the high risk group was 42.8 mo (18.4-NR) and mOS was not reached. For patients with standard-risk cytogenetics, neither the mPFS nor mOS were reached. Of the 26 patients evaluable for MRD negativity by flow cytometry (limit of detection 10^{-5}), 17 (65%) achieved MRD-negativity and 11 (42%) had sustained MRD negativity for ≥1 year. Among patients with MRD-negativity as best response, mPFS was 69.4 mo (18.9-NR) compared to 14.0 mo (1.2-NR) in patients with MRD positivity (p = 0.002). There were no new safety signals or treatment-related deaths. **Conclusions:** With nearly 6 years of follow-up, DaraKPd in lenalidomide-exposed and anti-CD38 monoclonal antibody-naïve RRMM showed deep and durable responses, with a mPFS of 38.3 months and 36-month OS of 75%. These long-term follow-up data support DaraKPd as a safe and effective treatment in patients with RRMM. Clinical trial information: NCT01665794. Research Sponsor: Multiple Myeloma Research Consortium; Amgen; Bristol Myers Squibb.

Prediction of progression in MGUS using transformer-based survival time-series modeling. First Author: Vaishnavi Kumbhar, Division of Hematology, Mayo Clinic Rochester, Rochester, MN

Background: Monoclonal gammopathy of undetermined significance (MGUS) is common, yet only a minority progress to malignant plasma-cell disorders. Mayo risk stratification uses baseline factors and is commonly implemented/validated in a Cox proportional hazards (CoxPH) framework, which may miss prognostic longitudinal patterns. **Methods:** We assembled 15,158 MGUS patients with longitudinal laboratory data and progression outcomes (smoldering multiple myeloma, multiple myeloma, AL amyloidosis, or Waldenström macroglobulinemia). We compared a Mayo-factor Cox proportional hazards (CoxPH) baseline versus STRaTS, a transformer-based survival model, to predict progression risk at 3-, 5-, and 10-year horizons. STRaTS leveraged longitudinal trajectories of routine labs including hemoglobin, platelets, differential counts (neutrophils/lymphocytes/monocytes), immunoglobulins (IgG/IgA/IgM), free light chains (kappa/lambda), M-spike, and creatinine. To minimize bias, we used laboratory results collected from 1–3 years after diagnosis and started follow-up at year 3; patients progressing before year 3 or lacking follow-up beyond year 3 were excluded. A total of 7,305 patients met eligibility and were split into train/validation/test cohorts of 4,383/1,461/1,461. Discrimination was assessed by concordance index (C-index). Clinical operating performance was evaluated on a held-out test cohort by comparing sensitivity and specificity at the same proportion of patients selected for intensified surveillance (same workload). **Results:** Among MGUS patients with complete baseline Mayo factors(N=3,388), Kaplan–Meier–estimated 3-/5-/10-year cumulative progression risk was 0.1/0.4/3.4% (Low), 3.0/4.3/7.9% (Low-Intermediate), 4.4/6.4/14.1% (High-Intermediate), and 8.9/12.5/16.9% (High). On a held-out test cohort, STRaTS demonstrated superior discrimination versus the Mayo-factor CoxPH (C-index 0.75 vs 0.538; p<0.0001). Both models were trained and evaluated on identical train/test splits. At the same surveillance workload, STRaTS achieved higher sensitivity with comparable specificity; when 40.3% of patients were selected for closer surveillance, 3-year sensitivity was 81.0% for STRaTS versus 47.6% for CoxPH (Table). **Conclusions:** Among MGUS patients who remain progression-free at 3 years, transformer-based survival modeling of longitudinal laboratory trajectories provides more accurate individualized conditional progression risk estimates and improved workload-matched identification of progressors compared with the conventional Mayo/Cox approach. Research Sponsor: None.

Sensitivity/specificity (%).

Early detection of multiple myeloma and MGUS progression risk using artificial intelligence and routine laboratory data. First Author: Ciro Roberto Rinaldi, United Lincolnshire Teaching Hospital and University of Lincoln, Lincoln, United Kingdom

Background: Multiple myeloma (MM) is a malignant plasma cell disorder that often presents with non-specific symptoms, resulting in delayed diagnosis and poorer outcomes. While artificial intelligence (AI) models using routine laboratory data have shown promise for MM detection, their ability to distinguish monoclonal gammopathy of undetermined significance (MGUS) from early MM and to identify patients at risk of progression remains limited. **Methods:** We conducted a retrospective study using routinely collected clinical and laboratory data from 89 patients evaluated at the Lincolnshire Hospital Group between 2003 and 2025. The cohort included confirmed MM cases, MGUS patients, and non-myeloma controls. Predictive features included hemoglobin, serum creatinine, calcium, albumin, immunoglobulin levels, paraprotein concentration, and derived laboratory indices. After rigorous data cleaning and preprocessing, eight supervised machine learning models were trained using a training–testing split. These included six machine learning algorithms (Lasso, gradient boosting, random forest, elastic-net, ridge regression, and support vector) and two baseline algorithms (Naïve (Mean) and Seasonal-Naïve). The training set included 69 patients (82%), and the test set included 20 patients (18%). Model performance was evaluated using precision, recall, F1 score, and regression evaluation metrics such as R^2 (R-squared) and MAE (Mean Absolute Error), with a specific focus on MGUS–MM differentiation. **Results:** The developed AI models demonstrated reliable performance in distinguishing MM from non-myeloma controls and showed improved discriminatory ability between MGUS and MM compared with standard laboratory threshold-based assessment. Specific laboratory feature patterns were associated with progression-consistent phenotypes, enabling risk stratification within the MGUS population. The best-performing model, Lasso Regression, achieved 0.01 MAE (months) and a nearly perfect score of 1.00 for R^2. This meant the best prediction done by the model had a 0.47 months error, i.e. 14 days difference from the actual transformation date. Gradient Boosting and Random Forest achieved 1.04 and 1.15 MAE, and 0.90 and 0.95 R^2, respectively. The results were implemented as a prototype clinical decision-support tool capable of generating rapid risk predictions using routinely available laboratory data. **Conclusions:** This study advances existing AI-based diagnostic approaches by addressing the clinically important challenge of early MM detection and MGUS risk stratification. AI-driven analysis of routine laboratory data may support earlier identification of patients at risk of progression, enabling improved monitoring, timely referral, and enhanced clinical decision-making. Research Sponsor: None.

Artificial intelligence predicted natural killer cell fitness to guide daratumumab and transplant strategies in newly diagnosed multiple myeloma. First Author: Arjun Raj Rajanna, Sylvester Myeloma Institute, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL

Background: Daratumumab (Dara) requires CD16-expressing natural killer (NK) cells for anti-myeloma activity. The use of bone marrow transplant (ASCT) results in prolonged immunosuppression, including lower levels of NK-cells. We evaluated if artificial intelligence (AI) predicted CD16 from routine hematoxylin and eosin (H&E) stained bone marrow biopsy slides could be used to guide Dara and transplant treatment strategies. **Methods:** We analyzed 212 newly diagnosed patients from the HealthTree registry treated with VRd (n=135; median follow-up 24.5 months (mo)) and D-VRd (n=77; 16.6 mo). H&E slides were processed using GigaTIME, a foundation model via zero-shot inference. Patients were dichotomized at median predicted CD16 and stratified by ASCT status. Subgroups: transplant-eligible (TE: age$<$65, ASCT; n=53), deferred (TD: age$<$70, no ASCT; n=34), and ineligible (TI: age$\geq$70; n=17). Primary endpoint: time to next treatment (TTNT). Multivariate Cox regression adjusted for age, cytogenetic risk tested interaction between CD16, treatment and ASCT. **Results:** D-VRd achieved superior outcomes vs VRd (23.4% event rate vs 74.8%, p$<$0.001) despite lower ASCT use among D-VRd treated patients (50.6% vs 71.1%, p=0.005). In the VRd group, AI-predicted CD16 was highly prognostic in non-transplanted patients: High-CD16 achieved median TTNT 33.1 vs 5.1 mo for Low-CD16 (p=0.0053). ASCT rescued Low-CD16 patients (median 5.1 to 26.7 mo, p$<$0.001). Conversely, in D-VRd, CD16 did not stratify outcomes (p=0.48), indicating that Dara can rescue low-immune-fitness disease. Specifically, Dara rescued low CD16 non-transplanted patients from progression (86.8% 18-mo event-free survival for D-VRd versus 28.6% 18-mo event-free survival for VRd; p$<$0.001). High CD16 patients on D-VRd without ASCT achieved 86.3% event-free survival, non-inferior to ASCT (82.2%, p=0.21), supporting transplant deferral. The CD16$\times$treatment$\times$ASCT interaction was significant (HR 0.06, p=0.045). Among transplant-deferred patients, D-VRd improved 18-mo event-free rates vs VRd (70.5% vs 40%, p=0.029), with the largest benefit in Low CD16 (p=0.016). TI patients on D-VRd achieved 100% event-free at 18 mo vs 38.2% on VRd (p=0.011). **Conclusions:** We validated that AI-quantified CD16 from routine H&E guides Dara and transplant strategies in NDMM (n=212). The CD16$\times$treatment$\times$ASCT interaction (HR=0.06, p=0.045) confirms that CD16 predicts treatment benefit, not just prognosis. In VRd, low CD16 identifies a high-risk group (median TTNT 5.1 mo) needing intensification. D-VRd rescues low-immune-fitness patients (18-mo event-free survival: 86.8% vs 28.6% with VRd, p$<$0.001) and enables safe transplant deferral in high-fitness patients (82.2% with ASCT vs 86.3% without, p=0.21). This novel strategy enables precision medicine using standard H&E slides, with immediate clinical implications. Research Sponsor: None.

AI-enabled multimodal adjudication of revised IMWG progression after BCMA CAR-T. First Author: David Kaldas, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Real-world ascertainment of clinically meaningful relapse after BCMA CAR-T is challenging because progression signals are distributed across laboratories, imaging, pathology, and clinician actions and are frequently embedded in unstructured external reports. The revised IMWG criteria (Kumar et al., IMS 2025) provide standardized definitions for imaging-based progression (PET/CT and WB-MRI) enabling automated recognition of radiologic and serologic progression thresholds. We developed an AI-enabled multimodal framework to automate real-time derivation of recognized IMWG progression across fragmented care settings. **Methods:** We analyzed 183 BCMA CAR-T treatment episodes with longitudinal routine laboratory data and independent dual-reviewer adjudication of progression dates. Automated detection evaluated every M-protein and FLC measurement longitudinally in a continuous IMWG rules engine, in addition to flagging new hypercalcemia. In addition, initiation of a new line of therapy (considered a progression event), together with large-language-model extraction of radiologic progression from PET/CT, WB-MRI, CT, X-ray, and MRI brain/spine reports. Performance was assessed using accuracy and specificity. **Results:** Serologic progression from real-world lab feeds was detected with high reproducibility, with FLC and M-protein achieving high accuracy (96.5% and 98.5%, respectively) and specificity ($>$97%), indicating minimal premature triggering across serial measurements. Hypercalcemia was rare but highly specific for progression. Radiology-based AI extraction achieved high accuracy (91%) and specificity (92.1%), enabling reliable identification of imaging-defined relapse. Initiation of a new line of therapy occasionally occurred before formal serologic IMWG thresholds were met, reflecting clinician-recognized relapse or that driven by non-serologic disease. Notably, 19% of adjudicated relapses were triggered by radiologic or marrow criteria when serologic IMWG thresholds were absent or lagging, including 12.5% radiology-only and 5.8% marrow-only events, aligned with our published data for post CART relapses (Abuhelwa et al Front. Oncol 2025). **Conclusions:** Automated lab-only approaches systematically underestimate true IMWG progression after BCMA CAR-T. An AI-enabled multimodal adjudication framework aligned with the revised IMWG criteria enables scalable, real-time, and reproducible progression capture for clinical trials and real-world datasets, supporting rapid endpoint determination, regulatory-grade retrospective analyses, and biologically faithful reconstruction of relapse patterns after CAR-T. Research Sponsor: None.

Echo cancer advisor: A modular AI framework for interpretable, patient-specific oncology decision support. First Author: Ariosto Siqueira Silva, H. Lee Moffitt Cancer Center, Tampa, FL

Background: Oncology increasingly relies on large, heterogeneous datasets spanning genomics, clinical records, imaging, and treatment history. Large language models (LLMs) show promise for synthesizing such information, yet currently suffer from limited transparency, hallucination risk, and poor alignment with real-world clinical reasoning. There is a critical need for AI systems that can integrate multimodal data while preserving interpretability, traceability, and clinician control. **Methods:** We developed a modular AI decision-support system to assist oncologists in complex clinical reasoning tasks. Unlike monolithic LLM approaches, it decomposes clinical questions into atomic sub-tasks that are executed through structured, auditable pipelines, while integrating curated clinical data (EHR, genomics, pathology), external knowledge bases, and computational analyses via a function-oriented architecture. Each step is independently validated, logged, and audited to ensure correctness. It uses a hybrid local/cloud architecture and was evaluated on real-world oncology use cases in Moffitt Cancer Center's Multiple Myeloma (MM) cohort, which contains three data modalities: clinical, molecular, and pre-clinical. Clinical data resides in a PHI-compliant Snowflake data warehouse (Moffitt Cancer Analytics Platform, MCAP), including longitudinally-resolved treatment and outcome information from clinical notes, labs, pathology and radiology reports. CD138-enriched bone marrow samples from 1,260 MM patients were molecularly profiled using RNA-seq (n=1,376 biopsies) and whole exome sequencing (WES, n=1,427), whereas 549 tumor samples from MM patients were tested for ex vivo drug sensitivity. **Results:** This system successfully decomposed complex clinical questions into atomic sub-questions and generated appropriate database queries and software tool calls to retrieve relevant information across heterogeneous data sources. Independently, the system integrated clinical data—including physician notes, pathology reports, laboratory values and pharmacy records—to reconstruct longitudinal patient histories achieving 80% concordance with expert manual abstraction, while reducing case synthesis time from hours to minutes. Importantly, the system preserved transparency by explicitly exposing intermediate reasoning steps and highlighting missing or ambiguous data requiring clinician judgment. **Conclusions:** We propose a shift from generative AI toward structured, interpretable clinical reasoning systems. By emphasizing modularity, auditability, and human-in-the-loop design, we offer a scalable path toward trustworthy AI deployment in oncology. This framework supports precision medicine not by replacing clinical judgment, but by amplifying it—providing clinicians with transparent, reproducible, and context-aware decision support. Research Sponsor: None.

Identifying high-risk cytogenetic subgroups in multiple myeloma using large language artificial intelligence models. First Author: John Culnan, Massachusetts Veterans Epidemiology Research and Information Center, Department of Veterans Affairs Healthcare System, Boston, MA

Background: The Revised International Staging System (R-ISS) is the clinical standard for risk stratification in multiple myeloma (MM) and is central to treatment selection and prognostication. However, the cytogenetic abnormalities on which the R-ISS is predicated are typically reported in unstructured formats within bone marrow biopsy reports and clinical notes. Despite the critical importance and relevance of obtaining cytogenetic abnormalities in MM, this information is often missing from large clinical databases, limiting their availability for large scale research and real-world analyses. Here, we created a large language model (LLM)-based algorithm to identify cytogenetic abnormalities from unstructured text and evaluated our model's adaptability by comparing its performance across definitions of high-risk abnormalities. **Methods:** We extracted oncology notes and pathology reports within 2 years of diagnosis from the EHR of adult patients with MM registered within the Department of Veterans Affairs (VA) Cancer Registry System between 2000 and 2024. Two physician reviewers iteratively annotated 1600-character snippets from these texts for abnormalities and their type (gain, deletion, translocation) plus normal cytogenetics. From these annotations we identified items with high-risk cytogenetic abnormalities per current guidelines (del(17p) in $>$ 20% plasma cells; TP53 mutation; gain(1q) and/or del(1p32) plus t(4;14), t(14;16), or t(14;20); monoallelic del(1p32) plus gain(1q); biallelic del(1p32)) and previous guidelines (t(4;14), t(14;16), t(14;20), del TP53/17p, del(1p), gain(1q)). We used few-shot prompting with GPT-OSS 120B to extract cytogenetic results and validated our model on a test set of 985 snippets representing 773 patients at 98 VA centers. **Results:** The test set contained 81 snippets with normal cytogenetics and 464 with abnormalities; 58 were high-risk per current guidelines and 144 per previous guidelines. Our model successfully identified high-risk cytogenetics per current (P: 88.9%, R: 82.8%, F1: 85.7%) and previous guidelines (P: 86.7%, R: 90.3%, F1: 88.4%), as well as type of cytogenetic abnormality (weighted averages; P: 92.3%, R: 92.2%, F1: 92.4%), demonstrating its utility and flexibility for the task as standards change. Applied to a cohort of 7250 unlabeled notes, our model identified high-risk cytogenetics in 501 (6.9%) and any cytogenetic information in 5385 (74.3%). **Conclusions:** Our model demonstrated the successful capture of cytogenetic information across multiple definitions of high-risk cytogenetic abnormalities, providing a fast, adaptable framework for extraction that traditionally required repeated large-scale human efforts. Leveraging an LLM for this task enables scalable MM risk stratification while reducing clinician burden and supporting rapid adaptation to evolving cytogenetic risk definitions. Research Sponsor: VA Office of Research and Development.

RP2R dose selection of Tal + Tec for the treatment of EMD patients in the RedirecTT-1 study. First Author: Nicholas Au, Johnson & Johnson, Spring House, PA

Background: Talquetamab (Tal, anti-GPRC5D) and Teclistamab (Tec, anti-BCMA) are first-in-class bispecific antibodies approved as monotherapies for triple-class exposed relapsed/refractory multiple myeloma (RRMM). Extramedullary disease (EMD) is an aggressive MM subtype with poor outcomes and high unmet need. RedirecTT-1 (NCT04586426) is a Phase 1b/2 dose escalation/expansion study evaluating Tal + Tec in RRMM patients (pts) including EMD. We present data supporting selection of the recommended Phase 2 regimen (RP2R) for treatment of EMD pts, based on efficacy, safety, and exposure-response (E-R) analyses from Phase 1. Phase 2 allowed switching to a Q4W regimen after cycle 6 or cycle 4 if the response was ≥VGPR. **Methods:** Phase 1 evaluated 6 dose regimens of Tal (0.2–0.4 mg/kg QW, 0.8 mg/kg Q2W, 0.8 mg/kg Q4W) + Tec (0.75-1.5 mg/kg QW, 1.5-3 mg/kg Q2W, 3 mg/kg Q4W). Responses were investigator-assessed per IMWG criteria. CRS and ICANS were graded by ASTCT criteria; all other adverse events were graded by CTCAE v5.0. Model-based E-R analyses for efficacy were conducted with reported efficacy endpoints (ORR, ≥VGPR, ≥CR). First cycle PK metrics (C_{avgC1}, $C_{troughC1}$) were used due to time-varying clearance of Tal and Tec. **Results:** At the clinical cutoff for this analysis (18 March 2025), Phase 1 enrolled 114 pts (38 EMD) with a median follow-up of 31.6 months. EMD pts treated with QW regimens of Tal 0.2-0.4 mg/kg + Tec 0.75-1.5 mg/kg (n=13), which comprised of multiple dose levels (1-9 pts per cohort), achieved an ORR of 33-100% (≥CR, 0-22.2%). EMD pts treated with the Q2W regimen using Tal 0.8 mg/kg and Tec 1.5 mg/kg (n=4) achieved an ORR of 50% (≥CR, 25%), while EMD pts treated with the Q2W regimen including Tal 0.8 mg/kg + Tec 3.0 mg/kg (RP2R, n=18) demonstrated high and deep response rates (ORR, 61.1%, ≥CR, 44.4%) with a manageable safety profile. EMD pts treated with the Q4W regimen of Tal 0.8 mg/kg + Tec 3.0 mg/kg (n=3) achieved an ORR of 100%, where 2 achieved ≥VGPR, but none achieved ≥CR. The RP2R generally provided higher and deeper responses in EMD pts compared to non-RP2R regimens. The efficacy E-R analysis for EMD pts showed a positive E-R relationship between exposure (C_{avgC1} and $C_{troughC1}$) and ≥CR. Pts with exposures above the median for both Tal and Tec showed higher CR rates. At RP2R, C_{avgC1} and C_{trC1} exceeded median exposures across all Phase 1 dose regimens for both antibodies. The overall safety profile of Tal + Tec at the RP2R was manageable and consistent with each agent as monotherapy, while enabling deeper and more durable responses than observed across non-RP2R regimens. **Conclusions:** The totality of efficacy, safety and E-R analyses support advancement of a Tal + Tec regimen for further clinical development in RRMM pts with EMD who have received a PI, an IMiD, and an anti-CD38 mAb, and offers flexibility of switching to Q4W for responders. Clinical trial information: NCT04586426. Research Sponsor: Johnson & Johnson.

7525 **Poster Session**

An integrated population pharmacokinetic/pharmacodynamic (popPK/PD) model to select the linvoseltamab (LINVO) dosing regimen in patients with high-risk smoldering multiple myeloma (HR-SMM). First Author: Brett Matzuka, Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Background: LINVO is a BCMA×CD3 bispecific antibody approved for triple-class exposed relapsed/refractory (RR) multiple myeloma (MM) after ≥3 therapies (EU) or ≥4 prior lines of therapy (USA). LINVO 200 mg was approved based on the deep and durable responses and manageable safety profile observed in the LINKER-MM1 study (objective response rate [ORR] 71%; NCT03761108). LINVO 200 mg demonstrated promising efficacy and a generally manageable safety profile as an early intervention in HR-SMM (ORR 100%; Phase [Ph] 2 LINKER-SMM1 NCT05955508; IMS 2025 OA-68) and as frontline therapy in newly diagnosed (ND) MM (ORR 86%; Ph 1/2 LINKER-MM4 NCT05828511; ASH 2025 #697). We present results from a semi-mechanistic popPK/PD model of LINVO integrating data from pts with RRMM, NDMM, and HR-SMM, to support full dose selection for a Ph 3 HR-SMM study. **Methods:** A popPK/PD model was developed from LINKER-MM1 RRMM data to predict LINVO concentration (conc) and disease burden dynamics (soluble BCMA, total [involved + uninvolved] free light chain [FLC] conc). Free LINVO conc was a strong predictor of ORR and progression-free survival in the LINKER-MM1 model. The model was updated with data from LINVO administration in pts with NDMM and HR-SMM. Based on baseline disease characteristics in pts with HR-SMM, the model was used to predict free and total LINVO conc for regimens with full doses of 50, 100, and 200 mg in a clinical trial simulation setting. The model assumed that T-cell–mediated tumor killing was dependent on free LINVO forming the T-cell + drug + MM cell complex. The variability in observed response rates across studies was presumed to arise due to differences in disease burden, MM plasma cell proliferation, and T-cell fitness, with the killing rate expected to be more similar between HR-SMM and NDMM than between HR-SMM and RRMM. **Results:** The dose regimen chosen for evaluation in a Ph 3 HR-SMM study comprised a 200 mg dose given weekly in cycle (C) 1 with the frequency decreasing to every 2 weeks after C1, every 4 weeks after C6, and every 8 weeks after C13. Following initial weekly dosing in this regimen, the free LINVO conc predicted in HR-SMM matched the free LINVO conc predicted in the higher efficacy arm of LINKER-MM4 and the higher efficacy arm in Ph 2 of LINKER-MM1. The model predicted that the 200 mg dose regimen would achieve deep responses (measured by substantial reduction in FLC conc) as rapidly as Week 8, and continue through Week 30, despite the reduced dosing frequency. **Conclusions:** The totality of evidence, including efficacy and safety data in pts with SMM, dose-ranging data (PK/PD, safety, and efficacy) in pts with NDMM and RRMM, and exploratory analyses integrating exposure and response markers across studies, supports selection of the less intensive LINVO 200 mg dose regimen (compared with NDMM and RRMM) in the Ph 3 HR-SMM study. Clinical trial information: NCT03761108; NCT05828511; NCT05955508. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Comparative efficacy of linvoseltamab versus teclistamab in triple-class exposed (TCE) relapsed/refractory multiple myeloma (RRMM): Updated matching-adjusted indirect comparison (MAIC) with longer follow-up. First Author: Hans C. Lee, Sarah Cannon Research Institute, Nashville, TN

Background: Linvoseltamab and teclistamab are anti-B-cell maturation antigen (BCMA)×CD3 bispecific antibodies evaluated in the LINKER-MM1 and MajesTEC-1 trials, respectively, and approved for TCE RRMM. In the absence of head-to-head trials, a previous MAIC assessed their relative efficacy at ~14-month median follow-up (mFU). We present updated results with longer follow-up for both trials. **Methods:** After excluding 10 patients (pts) with prior BCMA antibody–drug conjugate exposure from LINKER-MM1 to align with MajesTEC-1 eligibility, pt-level data from LINKER-MM1 (linvoseltamab 200 mg, N=107; data cut-off [DCO] July 2024; mFU 21.3 months) and aggregate data from MajesTEC-1 (N=165; DCO August 2023; mFU 30.4 months) were used. LINKER-MM1 pts were weighted to match MajesTEC-1 using prespecified prognostic factors, as described previously (Lee et al., *Clin Lymphoma Myeloma Leuk* 2025;25:897–909). MAICs were rerun for objective response rate (ORR), very good partial response or better (≥VGPR) rate, complete response or better (≥CR) rate, duration of response (DOR), progression-free survival (PFS), overall survival (OS) and time to next treatment (TTNT). Treatment effects were estimated using odds ratios (ORs) and hazard ratios (HRs) with 95% confidence intervals (CIs). Restricted mean survival time (RMST) was evaluated at 30 months. **Results:** In both unadjusted comparisons and MAICs adjusted for 6 key prognostic factors (cytogenetic risk, age, refractory status, ISS stage, ECOG score, extramedullary disease/plasmacytoma status; effective sample size 82.5), linvoseltamab showed numerically higher ORR, ≥VGPR, and ≥CR rates and significantly longer DOR, PFS, OS, and TTNT vs teclistamab (Table). Compared with prior MAICs with shorter follow-up, adjusted HRs for DOR and TTNT further decreased in favor of linvoseltamab, while other results remained stable. **Conclusions:** With longer follow-up, linvoseltamab continued to demonstrate comparative efficacy advantages vs teclistamab, reinforcing its potential as an effective treatment option for TCE RRMM. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Outcome, linvoseltamab vs teclistamab	Unadjusted	Adjusted for 6 key prognostic factors
	OR (95% CI)	*OR (95% CI)*
ORR	1.44 (0.97–2.13)	1.50 (0.97–2.32)
≥VGPR	1.19 (0.83–1.72)	1.17 (0.79–1.74)
≥CR	1.29 (0.91–1.82)	1.21 (0.83–1.76)
	HR (95% CI); RMST difference, months (95% CI)	*HR (95% CI); RMST difference, months (95% CI)*
DOR	0.58 (0.36–0.96)*; 3.66 (0.77–6.55)*	0.54 (0.31–0.92)*; 4.06 (1.13–6.98)*
PFS	0.57 (0.40–0.82)*; 5.13 (2.01–8.25)*	0.55 (0.36–0.82)*; 5.43 (2.04–8.81)*
OS	0.68 (0.47–0.98)*; 2.99 (0.22–5.75)*	0.64 (0.43–0.97)*; 3.06 (0.08–6.04)*
TTNT	0.42 (0.28–0.62)*; 7.10 (4.27–9.94)*	0.41 (0.27–0.64)*; 7.12 (4.15–10.09)*

*p<0.05. OR >1, HR <1, or RMST >0 indicate better efficacy with linvoseltamab vs teclistamab.

Updated two-year overall survival and toxicity outcomes of BCMA CAR-T therapy compared with teclistamab in multiple myeloma. First Author: Junmin Song, Department of Medicine, Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY

Background: B-cell maturation antigen (BCMA) targeted chimeric antigen receptor T-cell therapy (CAR-T) and bispecific antibodies have transformed the treatment landscape for relapsed or refractory multiple myeloma. In a prior real-world study, CAR-T therapy was associated with improved short-term overall survival compared with teclistamab; however, follow-up was limited to less than one year. Longer-term comparative outcomes between these modalities remain insufficiently characterized. This sequel study evaluates the updated two-year overall survival and toxicity outcomes. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, comprising data from over 70 healthcare institutions in the United States, to identify patients with multiple myeloma treated between 2021 and 2023 with either CAR-T therapy (ciltacabtagene autoleucel [cilta-cel] or idecabtagene vicleucel [ide-cel]) or teclistamab. Patients who received other bispecific antibodies, including elranatamab, talquetamab, or linvoseltamab, were excluded. Two mutually exclusive cohorts were defined: patients who received CAR-T therapy without prior or subsequent teclistamab and patients who received teclistamab without prior or subsequent CAR-T therapy. Propensity score matching was performed to balance baseline demographics, comorbidities, prior therapies, and laboratory values. HR and 95% CI were estimated using Cox proportional hazards models for two-year overall survival, cytokine release syndrome (CRS), and immune effector cell-associated neurotoxicity syndrome (ICANS). **Results:** A total of 351 CAR-T cell therapy recipients and 507 teclistamab recipients were included. After propensity score matching, 227 patients were retained in each cohort, with well-balanced baseline characteristics, including demographics (mean age: 65 years, White: 74%, male: 53%), comorbidities, and prior multiple myeloma treatments, including immunomodulatory drugs, proteasome inhibitors, dexamethasone, and anti-CD38 antibodies. Mean follow-up durations were comparable between the CAR-T and teclistamab cohorts at 524 and 438 days, respectively. CAR-T therapy was associated with significantly improved two-year overall survival compared with teclistamab (HR: 0.61, 95% CI: 0.43-0.87, p=0.005). In contrast, CAR-T therapy was associated with higher risks of CRS (HR: 1.48, 95% CI: 1.12-1.96, p=0.003) and ICANS (HR: 2.02, 95% CI: 1.20-3.41, p=0.007). **Conclusions:** In this extended two-year real-world analysis, CAR-T therapy was associated with superior overall survival compared with teclistamab, albeit with increased immune-mediated toxicities. These findings build upon prior short-term data and underscore the need for prospective studies directly comparing BCMA-targeted treatment strategies across longer follow-up intervals. Research Sponsor: None.

Iberdomide (Iber) maintenance following upfront autologous stem cell transplant (ASCT) in multiple myeloma (MM). First Author: Tanya Marya Wildes, University of Nebraska Medical Center, Omaha, NE

Background: Lenalidomide (Len) maintenance after ASCT has been a standard of care for patients (pts) with MM. Historically, ~30% of pts discontinue Len within 1 year (yr) due to toxicity and there is a need for more effective and better tolerated maintenance strategies. Iber is a potent, oral cereblon E3 ligase modulator under evaluation in the relapsed/refractory and newly diagnosed settings. We report the results of the primary analysis of a Phase II trial of Iber maintenance following upfront ASCT. **Methods:** Pts ≥ 19 yrs of age with MM, within 1-yr of initiation of induction therapy and in a ≥ partial response (PR) at day 80-110 post-ASCT, were accrued. Iber was administered 1.0 mg orally days 1-21 of a 28-day cycle, continued until progressive disease (PD) or toxicity. Up to 2 dose reductions (0.75 mg/day then 0.6 mg/day) were allowed. Growth factor support was not permitted. Minimal residual disease (MRD) assessment by flow cytometry (10^{-5}) was performed at registration, post-cycle 12 and post-cycle 24. An optimal Simon two-stage design with type I and II errors of 0.1 was chosen to test whether the proportion of pts who are progression-free and on treatment at 1 yr is <60% against the alternative of ≥ 80%. If ≥ 27 out of 38 pts were progression-free (by 2016 IMWG criteria) and on treatment at 1 yr, Iber would be considered to have promising activity. **Results:** 38 pts (55% males, median age 61 yrs (range: 41-77)) received Iber. R-ISS at diagnosis was stage I (34%), II (39%), III (8%) and unknown (18%), with 34% having high-risk disease per 2025 IMS/IMWG criteria. All pts received triplet or quadruplet induction therapy, with 97% receiving Len and 84% receiving daratumumab. At day 80-110 post-ASCT, all pts had ≥ very good PR, with 22 (58%) ≥ complete response (CR) and 33 (87%) MRD-negative (neg). The median number of administered treatment cycles is 18 (range: 1-45), with 18 (47%) pts having ≥ 1 dose reduction, most commonly due to neutropenia (n=12). The most common grade (gr) 3/4 adverse event was neutropenia (gr 3 (n=19), gr 4 (n=5)). Within yr 1, 29% (11/38) discontinued Iber due to neutropenia (n=5), rash (n=1), infection (n=1), pt choice (n=1), or PD (n=3). After 1 yr, 6 pts discontinued due to neutropenia (n=4) and PD (n=2). While on Iber, 19 pts had deepening of response to stringent CR and 3 pts converted from MRD-positive to MRD-neg. The post-cycle 12 and 24 MRD-neg rates are 85% (23/27) and 100% (14/14), respectively. **Conclusions:** Iber demonstrated promising activity with dose reductions/discontinuations mainly due to neutropenia. Strategies including lower starting dose, growth factor support and more flexible management of neutropenia may enable more pts to remain on treatment. Longer follow-up will permit evaluation of sustained MRD-negativity and PFS, but overall, these results provide rationale for further exploration of Iber-based post-ASCT maintenance strategies. Clinical trial information: NCT05177536. Research Sponsor: Bristol Myers Squibb.

Association between survival outcomes in patients with multiple myeloma and treatment facility volume. First Author: Carl Ola Landgren, Sylvester Myeloma Institute, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL

Background: Oncology research previously demonstrated a volume-outcome relationship, where patients treated at healthcare centers with higher (vs lower) treatment volumes have improved survival. In multiple myeloma (MM), evidence supporting this association remains limited. Most patients with MM are treated at lower volume centers; it is important to recognize and prioritize partnerships between higher and low-volume centers. **Methods:** Adults (≥18 years) receiving ≥1 active MM therapy—IMiD, PI, anti-CD38 mAb, CAR-T, ASCT—from 2017 - 2023 with ≥6-month pre-index enrollment were identified in Komodo Health's Healthcare Map. Patients lacking facility data or treated outside their diagnosing site were excluded. Facilities were segmented based on volume, defined as the average number of new patients with MM per year: ≤1 (very low), 1–5 (low), >5–10 (medium volume), >10 (higher volume). Outcomes included overall survival (OS) and event-free survival (EFS), the latter separately defined as time to 1) therapy change and 2) first symptomatic progression (based on CRAB criteria). Multivariable mixed-effects Cox models were adjusted for diagnosis year, demographics, comorbidities, payer type and treatment exposure. Subgroup analysis of patients initiating 2L therapy was also conducted. **Results:** 18,646 MM patients and 2,049 facilities were identified. Volume distribution was highly skewed: 81.0% were treated at very low volume centers and ~1.9% were treated at higher volume centers. Higher volume centers had the highest use of ASCT (63.7%) and CAR-T (2.1%). Among all patients, use of IMiD-, PI-, and anti-CD38–based regimens were 51.42%, 63.55% and 35.69%, respectively. Although median OS was not reached for any of the segments, higher volume centers had the highest unadjusted median EFS using therapy-based (771 days) and CRAB-defined progression (213 days) definitions (p<.001 vs all other segments). After adjustment, lower-volume segments (very low, low and medium volume centers) had shorter median OS (HRs: 1.03-1.26, 95% CI 0.88-1.46) than higher volume centers. However, compared with higher volume centers, median EFS was similar in lower-volume segments (HRs: 0.97-1.09, 95% CI 0.86-1.23). Among 2L patients, OS models and CRAB-defined EFS showed similar volume-related patterns compared with adjusted overall results. **Conclusions:** Higher-volume centers had more experience with novel therapies and combination of therapies. Experience from high volume centers can effectively be used to partner with smaller volume centers to advance MM care and be able to improve outcomes for patients. Research Sponsor: Pfizer, Inc.

Adjusted EFS and OS hazard ratios by treatment facility segment.

	Change in Therapy EFS		OS

Gaps in access to chimeric antigen receptor T-cell (CAR-T) therapy post leukapheresis: Waiting time and post-leukapheresis treatment patterns in relapsed/refractory multiple myeloma (RRMM)—Real-world evidence from U.S. claims. First Author: Sikander Ailawadhi, Division of Hematology/Oncology, Department of Medicine, Mayo Clinic Florida, Jacksonville, FL

Background: B-cell maturation antigen (BCMA)-directed CAR-T therapy is a highly effective treatment with potential for long-term remission of RRMM with improved outcomes vs daratumumab-based regimens. CAR-T suitability may be limited by delays/manufacturing failure and changes in pt condition, financial situation, or access to specialized treatment centers. We characterized pts with RRMM who underwent leukapheresis to prepare for CAR-T and pt treatment waiting time, to understand the delays incurred prior to CAR-T infusion. **Methods:** A real-world study in the US using the PharMetrics Plus claims database (July 2020–September 2024) was performed. Eligible pts were aged ≥18 years with RRMM, had their first leukapheresis claim (index date) during the index period (March 2021–August 2024), were continuously enrolled in medical/pharmacy benefits for ≥180 days prior to and ≥30 days after index date, and were not clinical trial participants. Pt characteristics, rate of CAR-T receipt, and time to CAR-T receipt were assessed during the variable follow-up. **Results:** Overall, 337 pts who received leukapheresis were identified. Median (interquartile range) age was 62 (55–67) years, and 59.1% of pts were male. Mean National Cancer Institute (NCI) comorbidity index was 0.52. Most pts received care in the Midwest (31.8%) or Northeast (24.6%) regions. Most pts (95.9%) received leukapheresis in an outpatient setting. Median available follow-up time was 255 days (mean 337 days). During follow-up, 183 pts (54.3%) did not receive CAR-T after leukapheresis. Among pts who had ≥12 months of follow-up (n=143), the proportion of pts who did not receive CAR-T was similar at 53.1% (n=76). Among pts who received CAR-T during the follow-up (n=154; 45.7%), the median waiting time was 54.0 days (mean 56.7 days). The cohort of pts who did not receive CAR-T had a higher proportion of females (48.6%/31.8%), were more likely to have Medicaid (29.5%/7.8%), had higher NCI comorbidity index (scores 0.55/0.47), and most commonly received care in the Northeast (35.5%/11.7%) while pts who received CAR-T most commonly received care in the Midwest (23.0%/42.2%). The most common first classes of multiple myeloma medications after leukapheresis but prior to CAR-T infusion in pts who did/did not receive CAR-T were an alkylating agent (65.6%/36.1%), proteasome inhibitor (40.3%/30.6%), steroid (38.3%/39.3%), immunomodulatory drug (22.7%/27.3%), anti-CD38 (20.8%/20.8%), and stem cell transplant (0%/17.5%). **Conclusions:** Over half of pts receiving leukapheresis did not receive CAR-T infusion, highlighting a persistent gap between eligibility and treatment delivery. These data emphasize an urgent need for broadly accessible BCMA-targeted therapies that provide deep and durable responses. Research Sponsor: GSK.

Targeting cfDNA and NETs with DNAse I to augment CAR T-cell function and antitumor efficacy. First Author: Alexey Stepanov, Scripps Research, La Jolla, CA

Background: Chimeric antigen receptor (CAR) T-cell therapy induces high initial response rates in B-cell malignancies; however, limited persistence and early relapse remain major clinical challenges. Accumulation of cell-free DNA (cfDNA) and neutrophil extracellular traps (NETs) within the tumor microenvironment represents a potential mechanism of CAR T-cell dysfunction through induction of exhaustion, immunosuppression and impaired expansion. We hypothesized that enzymatic degradation of extracellular DNA using DNase I could enhance CAR T-cell persistence and antitumor efficacy. **Methods:** The effects of cfDNA and NETs on human CD19 CAR T-cell function were evaluated using sequential killing assays, proliferation assays, and flow cytometry–based phenotyping. DNase I was assessed for its ability to reverse cfDNA/NET-mediated suppression and prevent exhaustion. In vivo efficacy, expansion, and persistence of CAR T cells were studied in xenogeneic B-cell acute lymphoblastic leukemia (Nalm-6) and Burkitt lymphoma (Raji) mouse models. Longitudinal in vivo tracking of CAR T-cell expansion was performed using bioluminescence imaging and serial peripheral blood analysis. Translational relevance was further explored through compassionate-use administration of DNase I in combination with CAR T-cell therapy in a pediatric patient with relapsed/refractory Burkitt lymphoma. **Results:** cfDNA and NETs suppressed CAR T-cell proliferation and cytotoxicity while promoting upregulation of exhaustion markers, including PD-1, LAG-3, and TIM-3. DNase I efficiently degraded extracellular DNA, preserved CAR T-cell effector function, improved CD8:CD4 ratios, and reduced exhaustion across multiple rounds of tumor rechallenge in vitro. In vivo, DNase I significantly enhanced CAR T-cell expansion and persistence following infusion, as demonstrated by longitudinal tracking studies. Combination therapy resulted in improved tumor control, delayed relapse upon rechallenge, and prolonged survival in both NALM-6 and Raji xenograft models. In a single pediatric patient with highly refractory Burkitt lymphoma, DNase I co-administration was associated with marked CAR T-cell expansion and progressive reduction in tumor burden after prior CAR T-cell failure. **Conclusions:** Extracellular DNA and NETs constitute a critical barrier to durable CAR T-cell efficacy. DNase I enhances CAR T-cell persistence and antitumor activity by eliminating cfDNA/NET-driven immunosuppression, supporting further clinical evaluation of DNase I as a combinatorial strategy to improve CAR T-cell therapy outcomes. Evaluating the impact of a statewide intervention on multiple myeloma bispecific T-cell engaging antibody (BsAb) therapy uptake in Florida (FL). First Author: Maen A. Hussein, Florida Cancer Specialists & Research Institute, Lady Lake, FL

Background: BsAbs are highly effective, off-the-shelf T-cell engagers recently approved for relapsed/refractory multiple myeloma (MM) but remain underutilized in real-world settings. In partnership with the Florida Society of Clinical Oncology (FLASCO), a statewide initiative was launched to expand BsAb access through peer-led regional discussions focused on operational barriers, care transitions, and therapy management strategies. This study assessed the real-world impact of these interventions on BsAb utilization in FL. **Methods:** Multidisciplinary discussion forums were held in 4 FL metropolitan areas (Jan-Apr 2024). We conducted single and controlled interrupted time series (ITS) analyses using IQVIA eLAAD claims data (Apr 2023 - Sep 2025) including adult patients with a diagnosis of MM, evidence of claim activity, and provider state information. Fifth line or later (5L+) status was estimated as 3.3% of MM prevalence (Nikolaou et al.) BsAb utilization (% of MM 5L+ patients receiving a BsAb) was evaluated using segmented regression to estimate pre- and post-intervention trends, excluding the intervention period. We reported BsAb utilization by comparing FL with all other states, between community versus academic settings, and assessing the number of sites administering BsAb. **Results:** Before the intervention, BsAb utilization among MM 5L+ patients in FL rose from 8.2% (Apr 2023) to 11.2% (Dec 2023) (0.3 pp/mo; p=0.23), compared with a rise from 6.7% to 16.3% (1.3 pp/mo; $p<0.0001$) across all other states over the same time period. Post-intervention, BsAb utilization in FL increased from 22.8% (May 2024) to 35.9% (Sep 2025), reflecting a 7.0% immediate increase and 0.8 pp/mo sustained growth, exceeding the post-intervention trend observed across all other states (23.5% to 30.3%; 0.5 pp/mo). Overall, although pre-intervention BsAb utilization in FL was lower than all other states, FL demonstrated a 1.2 pp/month higher post-intervention utilization trend ($p<0.001$; Table). Post-intervention, FL community sites showed a 0.13 pp/mo higher BsAb utilization trend than academic sites, and the number of community sites administrating BsAb increased from 5 to 9, with no change among academic sites. **Conclusions:** This study suggests that the FLASCO-led, collaborative model increased BsAb utilization in FL community oncology sites and offers a framework for broader community adoption across other states. Research Sponsor: Pfizer.

Immune effector cell–associated enterocolitis (IEC-EC) incidence and characterization in cilta-cel–treated patients with RRMM in CARTITUDE clinical studies. First Author: Yi Lin, Mayo Clinic Rochester, Rochester, MN

Background: Ciltacabtagene autoleucel (cilta-cel) shows benefit for patients (pts) with relapsed/refractory multiple myeloma (RRMM). A recently recognized uncommon adverse reaction, IEC-EC is characterized by severe/persistent diarrhea typically 1–3 months post CAR-T cell infusion. Here we summarize incidence and features of IEC-EC in clinical trials of cilta-cel for RRMM. **Methods:** 483 pts across RRMM studies (CARTITUDE-1, -2, -4, and CARTIFAN-1) were evaluated for evidence of IEC-EC. The clinical picture and nomenclature for IEC-EC were described in the real-world setting after infusion of most pts. As such, retrospective analysis was performed to identify cases consistent with IEC-EC, defined as prolonged (≥3 weeks) and severe (≥grade 3) diarrhea after cilta-cel infusion, without clear infectious etiology. Correlative biomarker analyses included peripheral CAR-T cell expansion/persistence, immune cell composition, and cytokines/inflammatory markers. Centralized pathomorphological review and immunohistochemical analysis of available biopsies was conducted. **Results:** Across RRMM studies, 6/483 (1.2%) pts demonstrated the clinical picture of IEC-EC, presenting 12–214 days after receiving cilta-cel (median onset 67 days post infusion). Best response was CR/sCR for all subjects. Pts received therapies including steroids (4/6). Four pts experienced symptom resolution within 123–227 days; 2 had persistent symptoms until death (causes: multiorgan failure and COVID19). Pts with IEC-EC had lower levels of B cells and higher levels of CAR+ T cells and inflammatory cytokines (eg, IL-6) at onset compared to a GI symptom-free control group at comparable time; while all cilta-cel–treated pts experienced B cell depletion, pts with IEC-EC had more prolonged deficiency. Histological analyses of GI biopsies from 5 pts with IEC-EC revealed plasma cells, normally present in the GI tract, were absent. CAR-T cells were detected and localized to the lamina propria and were not observed juxtaposed with epithelia, making it unlikely direct damage to epithelia was caused by CAR-T cells. Histologic damage was greater in the small intestine (predominantly duodenum) than the colon. **Conclusions:** Retrospective analysis of cilta-cel trials identified a low IEC-EC incidence (1.2%). Findings support a reactive mechanism involving plasma cell depletion and immune dysregulation rather than direct CAR-T cell cytotoxicity and highlight the importance of upper endoscopy to identify injury patterns in the small intestine that may be less pronounced in the colon. Although the pathophysiology is not fully defined, increased awareness and earlier diagnosis may improve understanding of management and enhance likelihood of IEC-EC reversibility. Influence of genomic and clinical high-risk features on outcomes after BCMA-directed bispecific antibody therapy in relapsed/refractory multiple myeloma. First Author: Stefan Longobardi, University of Arkansas for Medical Sciences, Little Rock, AR

Background: The definition of high-risk (HR) multiple myeloma (MM) is broad and encompasses established molecular features such as gain(1q) and del(17p), and the presence of extramedullary disease (EMD), plasma cell leukemia (PCL), and focal lesions (FLs), particularly when located in the humeri and femora. While the prognostic relevance of these factors has been widely studied, most data were generated in the pre–T-cell–redirecting therapy era. Their role in patients treated with bispecific antibodies (bsAb) remains poorly defined. Here, we investigated the prognostic value of FL and other high-risk features in relapsed/refractory (RR) MM patients receiving BCMA-directed bsAB therapy. **Methods:** We included 152 RRMM patients (59% male) with a median age of 72 years at bsAb initiation, and a median of 5 (2-12) prior lines of therapy. All patients received at least one full cycle of BCMA targeting bsAb therapy. Functional imaging (PET and/or DWI) was performed within 3 months of bsAb initiation. HR status was defined according to the IMS/IMWG consensus. Progression free (PFS) and overall survival (OS) were estimated using Kaplan Meier analysis. To address the combined impact of prognostic factors, we calculated conditional inference trees. **Results:** Patients with FLs involving the appendicular skeleton (humeri/femora/ribs/shoulders, n=85) showed a trend toward shorter median PFS (20 months, p=0.061) and significantly shorter median OS (20 months, p=0.01), compared to patients without FLs (n=54) or with FLs confined to the spine and/or pelvis (n=13, median PFS and OS not reached [NR]). EMD and PCL were observed in 41 (27%) and 10 (7%) patients, respectively. Patients with PCL had the poorest outcomes, with both median PFS and OS <2 months. EMD was also strongly prognostic, with significantly shorter PFS (11 vs 28 months) and OS (17 months vs NR) compared to patients without EMD. Similarly, HR disease as defined by IMS/IMWG criteria was associated with worse outcomes (PFS 14 months, OS 19 months). Conditional inference tree analyses for PFS identified PCL, EMD and del(17p) as the most relevant prognostic variables. For OS, PCL again emerged as the strongest predictor, whereas EMD was only prognostic in the presence of gain(1q). Notably, gain(1q) also modified the impact of other clinical parameters: both a higher number of prior therapy lines (>5) and prior BCMA exposure were prognostic only in patients without gain(1q). **Conclusions:** Here, we show that EMD, PCL, and FLs of the appendicular skeleton are associated with inferior outcomes in RRMM patients treated with BCMA-directed bsAbs. Notably, the prognostic impact of these tumor growth patterns appears to be strongly influenced by the presence of genomic HR features, underscoring the central role of chromosomal aberrations as key modifiers of clinical risk even in the era of T-cell–redirecting immunotherapies. Age-stratified late outcomes following bispecific antibody therapy in multiple myeloma: A real-world 6-month landmark analysis. First Author: Madhu Bhargavi Chandra, Wellstar Spalding Regional Hospital, Griffin, GA

Background: Multiple myeloma (MM) predominantly affects older adults, with a median age at diagnosis of 69 years. Underrepresentation of older adults in clinical trials of Bispecific antibodies (BsAbs) and limited statistical power preclude definitive conclusions about treatment outcomes in this demographic. Some real-world studies report comparable outcomes for BsAbs in older and frail patients, but these are small and heterogeneous. Consequently, limited data exist on the safety and efficacy of BsAbs in older MM patients, especially late outcomes. To address this gap, we conducted a retrospective study comparing the post-6-month outcomes of BsAbs in older adults (≥65 years) with those in younger patients. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. We identified MM patients (ICD-10-CM: C90) aged ≥18 years who received any BsAbs (teclistamab, elranatamab, talquetamab, blinatumomab, epcoritamab, mosunetuzumab), stratified by age into two cohorts: (1) age ≥ 65 years (N =1913), and (2) age between 18 and 64 years (N =948). The index event was date of initial administration of BsAbs. Outcomes were analysed within a time window starting 180 days after index event, and patients with outcomes outside the window were excluded. Compared outcomes using Kaplan-Meier survival analysis. Calculated hazard ratios (HRs) and log-rank p-values. **Results:** After propensity score matching (1:1), each cohort had 736 patients. Median age was 75 years (maximum age 90 years) in cohort 1 vs 57 years in cohort 2. Female (41.7% vs 43.2%), White (60.6% vs 58.6%), African American (22.6% vs 23.4%). All comorbidities and prior therapies, including stem cell transplant (35.2% vs 35.1%), ide-cel CAR-T (6.3% vs 6.7%), and cilta-cel CAR-T (1.4% vs 1.4%), were balanced between groups. Median follow-up was 305.5 days in cohort 1 and 316 days in cohort 2. All-cause mortality did not differ significantly between groups (HR = 1.212, p = 0.229). ER visits (HR = 1.345), neutropenia (HR = 1.311), thrombocytopenia (HR = 1.559), sepsis (HR = 1.398), pneumonia (HR = 1.122), and opportunistic infections (HR = 1.119) were slightly higher, in contrast, anemia (HR = 0.841), blood transfusion (HR = 0.812), and hypogammaglobulinemia (HR = 0.927) were lower in the older cohort but none were statistically significant ($p > 0.05$). **Conclusions:** In this large, real-world study, outcomes of BsAbs among patients aged ≥ 65 years were comparable to those of younger patients, without a significant increase in mortality or toxicities. Our findings, although retrospective, suggest that BsAbs can be safely administered in select patients aged ≥65 years, and advanced age should not, in itself, preclude treatment. Careful assessment and optimization of comorbidities and performance status could ensure that these patients benefit from effective treatments with minimal toxicity. Research Sponsor: None.

Ciltacabtagene autoleucel in lenalidomide-refractory multiple myeloma responding to bridging therapy: CARTITUDE-4 cytogenetic subgroup analysis. First Author: Roberto Mina, Winship Cancer Institute, Emory University, Atlanta, GA

Background: CARTITUDE-4 (NCT04181827) showed significant overall (OS) and progression-free survival (PFS) benefits of ciltacabtagene autoleucel (cilta-cel) in patients with lenalidomide-refractory multiple myeloma (MM) after 1–3 lines of therapy. Emerging data underscore the importance of successful bridging therapy (BT); deeper responses (partial response or better, ≥PR) during BT were associated with better survival and safety outcomes in patients treated with cilta-cel. Here, we present efficacy and safety in patients who received cilta-cel as study treatment with high- and standard-risk cytogenetics who responded to BT. **Methods:** CARTITUDE-4 as-treated set comprised patients who received a single cilta-cel infusion as study treatment after apheresis, ≥1 BT cycle, and lymphodepletion. High-risk cytogenetics were defined as positivity for del(17)p, t(14;16), t(4;14) or gain/amp(1q); standard-risk patients were negative for these mutations. Responses to BT were assessed based on International Myeloma Working Group criteria. Efficacy and safety from as-treated patients with ≥PR to BT were analyzed in high- and standard-risk cytogenetics subgroups. **Results:** Of 176 patients who received cilta-cel as study treatment (median follow-up, 33.6 months), 64 patients had high-risk cytogenetics and achieved ≥PR to BT. In these patients, median PFS and OS were not reached; 30-month PFS and OS rates were 65.1% (95% CI, 51.4–75.8) and 87.2% (95% CI, 76.1–93.4), respectively. In 40 patients with standard-risk cytogenetics and ≥PR to BT, median PFS and OS were not reached; 30-month PFS and OS rates were 85.0% (95% CI, 69.6–93.0) and 92.5% (95% CI, 78.5–97.5), respectively. Safety analysis included 64 patients with high-risk and 40 with standard-risk cytogenetics. In the high-risk subgroup, cytokine release syndrome was reported in 73.4% of patients, serious nonhematological adverse events in 64.1%, grade 3/4 infections in 43.8%, and immune effector cell-associated neurotoxicity syndrome in 7.8%. Corresponding rates in the standard-risk subgroup were 70.0%, 57.5%, 30.0%, and 0. Nonrelapse mortality (NRM) occurred in 9 patients (high-risk, 7; standard-risk, 2); there were 4 infection-related deaths in the high-risk population. No cases of immune effector cell (IEC)-parkinsonism were reported in high- and standard-risk subgroups. **Conclusions:** This analysis showed survival and response benefits of cilta-cel in patients with high- and standard-risk cytogenetics who had achieved ≥PR to BT, with >85% of patients alive at 30 months. No patients had IEC-parkinsonism, and infections were a key cause of NRM. These data highlight the profound benefit that cilta-cel can provide to patients with high- and standard-risk cytogenetics when MM is well controlled at time of infusion. Clinical trial information: NCT04181827. Research Sponsor: Johnson & Johnson; Legend Biotech USA Inc.

7537 Poster Session

CAR T-cell detection and clonality assessment in immune effector cell–associated enterocolitis following ciltacabtagene autoleucel. First Author: Eric Matthew Jurgens, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Ciltacabtagene autoleucel (cilta-cel) is an FDA approved chimeric antigen receptor (CAR) T cell therapy for relapsed/refractory multiple myeloma (RRMM). Cilta-cel is associated with gastrointestinal (GI) toxicities including immune effector cell (IEC)-associated enterocolitis. The pathophysiology of IEC-associated enterocolitis is poorly understood and may represent a clonal CAR T cell lymphoproliferative disorder. **Methods:** Retrospective review of patients with RRMM treated with standard of care (SOC) cilta-cel at a single center between 07/21/2022-10/31/2025. Baseline characteristics, outcomes, and GI toxicities were collected. CAR transgene was detected via digital droplet polymerase chain reaction (ddPCR) in GI tissue and peripheral blood samples. CAR T cell clonality was assessed via T cell receptor (TCR) fragment analysis and TCR Beta Constant Region 1 (TRBC1) assessment via IHC or flow cytometry. **Results:** In total 201 patients were included of whom 20 (10%) exhibited GI toxicity. Diarrhea accounted for most cases (15/20). CAR T cells were detected in 5/20 (25%) GI biopsies (Table 1). A clonal CAR T-cell lymphoproliferative disorder affected predominantly the duodenum, evidenced by TRBC1-restricted CD4- or CD8-positive T cells in lamina propria. The cells were positive for CD3 and TCRalpha while negative for CD103 and TCRdelta. MUM1, CD138 and BCMA demonstrated absence of plasma cells in all samples. TCR fragment analysis identified clonal TCR rearrangements in 3/5 evaluable cases. The remaining 2 cases showed equivocal fragment analysis with prominent but subthreshold peaks, likely reflecting low tumor burden. Symptoms resolved in 13/15 patients without detectable CAR T cells compared to 1/5 patients with detectable CAR T cells. Of the remaining 4/5 patients, 2 died and 2 had ongoing symptoms at time of last follow-up. **Conclusions:** GI toxicity was observed in 10% of patients treated with cilta-cel. CAR T-cell infiltration, predominantly duodenal, was detected in 25% of symptomatic patients consistent with IEC-associated enterocolitis. TRBC1-restricted CAR T cell populations were detected in all cases supporting the presence of a clonal CAR T cell lymphoproliferative disorder. At the meeting we will present additional translational studies from GI and peripheral blood CAR T cells including whole genome sequencing, spectral flow cytometry, and single cell RNA sequencing. Research Sponsor: None.

Clinical and pathologic features of IEC-associated enterocolitis.

How long is long enough? Outcomes with finite-duration bispecific antibody therapy in multiple myeloma. First Author: Eva Duvalyan, Department of Medicine, University of California, San Francisco, San Francisco, CA

Background: Bispecific antibodies (BsAbs) have shown unprecedented efficacy in relapsed/refractory multiple myeloma (RRMM), and finite-duration therapy is an increasingly common yet poorly studied strategy. We aimed to analyze outcomes in MM patients (pts) treated with finite-duration teclistamab (tec) or talquetamab (tal). **Methods:** This single-institution retrospective cohort study included pts treated with tec or tal monotherapy at UCSF from 7/2021 to 1/2025 for RRMM, excluding pts with prior BsAb exposure and pts receiving BsAbs as a bridge to CAR-T. Patient-, disease-, and treatment-related characteristics were collected and summarized descriptively. To assess the impact of treatment duration while mitigating immortal time bias, we conducted 6- and 9-month landmark analyses of PFS, comparing pts who discontinued treatment before the landmark with pts still on treatment. Patients with PD or death before the landmark were excluded. Multivariate analyses (MVA) of survival outcomes used Cox regression with the following covariates: age, IMS-IMWG risk, ISS stage, extramedullary disease (EMD), ECOG score, and prior BCMA exposure. **Results:** In total, 120 consecutive pts were included with median follow-up 13.7 mos. Forty stopped therapy early for reasons other than PD (finite) and 80 did not (non-finite). Among finite pts, median treatment duration was 4.7 mos (range 0.2-32.4), 24 stopped due to toxicity, and 16 due to sustained remission. Clinical characteristics including age, ISS, IMS-IMWG risk, and ECOG were balanced between groups, but finite pts had less EMD (7.5% vs 25.0%, p=0.03) and triple-class refractory status (52.5% vs 73.8%, p=0.03) than non-finite pts. ORR was 97.5% (60% CR+) and 73.4% (29.1% CR+) in finite and non-finite pts, respectively. For finite, non-finite, and all pts, respectively, median PFS was not reached (NR) with 24-mo PFS 63%, 7.9 mos, and 16.53 mos, while median OS was NR, 24.8 mos, and NR. For landmark analysis of patients alive and progression-free at 6 mos, 22 were off therapy and 55 pts remained on therapy at 6 mos and median PFS was NR and 29.5 mos, respectively (univariate regression HR 0.71 [0.32-1.57], p=0.4). On MVA, the hazard ratio also favored the on-therapy group (HR 0.51 [0.21-1.22], p=0.13). At the 9-month landmark, 20 pts were off therapy and 42 pts were on, with univariate regression HR 1.71 (0.58-5.11, p=0.3) and MVA HR 1.1 (0.32-3.76, p=0.87). **Conclusions:** Finite-duration BsAb therapy was associated with durable responses in selected patients, although this group had more favorable baseline disease characteristics. In adjusted landmark analyses, early discontinuation before 6 months was associated with numerically shorter PFS without statistical significance, while PFS was comparable at the 9-month landmark. Randomized-controlled trials are required to define optimal treatment duration. Research Sponsor: None.

Clinical outcomes following CAR T-cell therapy in relapsed or refractory multiple myeloma patients with baseline renal dysfunction: A TriNetX analysis. First Author: Preetinder Singh Manshahia, Rochester General Hospital, Rochester, NY

Background: Renal dysfunction is common in relapsed or refractory multiple myeloma (RRMM) and has historically limited eligibility for chimeric antigen receptor T-cell (CAR-T) therapy. However, real world data evaluating early complications and long-term outcomes in this population remains limited. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network, including adult RRMM patients treated with idecabtagene vicleucel or ciltacabtagene autoleucel. Patients with baseline renal dysfunction (creatinine ≥ 2.0 mg/dl, not on dialysis) were compared with those with preserved renal function (creatinine ≤ 1.0 mg/dl) after propensity matching. Early post-CAR-T complications: cytokine release syndrome (CRS) and disseminated intravascular coagulation (DIC) were assessed from day 0 to 15 post CAR-T therapy. Mortality was evaluated at 6 months, 1 year and 3 years. A secondary exploratory analysis assessed renal recovery at 90 days in patients with renal dysfunction following CART-cell infusion using creatinine based (≤ 1.9 mg/dl) and eGFR based (≥50 mL/min/1.73 m²) definitions. **Results:** 84/777 (10.8%) RRMM patients who received CAR T-cell therapy had baseline renal dysfunction. After propensity matching, 79 patients were included in each cohort, demographics in Table 1. 0-15 day CRS incidence was similar in patients with and without renal dysfunction (36.5% vs 33.3%), and no patients developed DIC or required dialysis at any point of time. Mortality was significantly higher in patients with renal dysfunction at 6 months (40% vs 13.2%), 1 year (45.3% vs 15.8%), and 3 years (52% vs 21.1%). Among patients with baseline renal dysfunction and available 90 day follow-up (61/79); renal recovery occurred in 48/61 (78.7%) by creatinine and in 38/61 (62.3%) by eGFR criteria. **Conclusions:** Baseline renal dysfunction was not associated with increased CRS incidence or progression of renal disease needing dialysis but was associated with higher long-term mortality, likely reflecting greater myeloma burden. Most patients with baseline renal dysfunction demonstrated renal recovery within 90 days, though they remain underrepresented among CAR-T recipients, highlighting a potential treatment gap. Research Sponsor: None.

Baseline characteristics of both cohorts.

Demographic parameter	Baseline renal dysfunction cohort, N=79(n, %)	Preserved renal dysfunction cohort, N=79, (n, %)

Expansion of a highly activated (HLA-DR+/CD38+) CAR T cell population after mezigdomide exposure post–idecabtagene vicleucel infusion in relapsed multiple myeloma. First Author: Lawrence W. Liu, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Herein, we report CAR T subsets from peripheral blood (PB) mononuclear cell (PBMC) samples from the NCT06048250 Phase 1 trial of mezigdomide (mezi) post ide-cabtagene vicleucel (ide-cel) in patients with RRMM. Prior studies used PCR for CAR T quantification but have not directly immunoprofiled CAR T. Additionally, we identified a highly activated CAR T cell subpopulation with HLA-DR and CD38 expression. These HLA-DR+/CD38+ T cells correlate with inflammation and disease activity in HLH and viral infections but have not been characterized in CAR T. **Methods:** Mezi was given orally on 21/28 day cycles after ide-cel infusion until disease progression, intolerance, or 12 cycles, whichever comes first. Immunoprofiling of PBMCs were performed at baseline (within two weeks prior to mezi start day of cycle 1 day 1 [C1D1]), C1D8 (early), and cycle 3 day 1 (C3D1; late) using Cytek Aurora spectral flow cytometry with 29-markers in 6 patients (3 in the DL-1 cohort receiving 0.3 mg and 3 in the DL-2 cohort receiving 0.6 mg). Changes in cell populations were measured as frequencies. The parent population was CD3+ BCMA CAR T+ cell for CAR T subsets, CD8+ T cells for CD8 subsets, CD3+ cells for the remainder of the T cell subsets, CD3- CD19+ cells for the B cell subsets, CD3-CD19-CD33+ for the monocyte subsets, and CD3- CD19-CD56+ for the NK cell subsets. Comparisons between groups were assessed using the Wilcoxon test. Mezi was started between D+60 to D+120 post ide-cel. Herein, we report the early translational data for this cohort. **Results:** As of 12/29/25, we enrolled 7 patients: 6 patients had evaluable PB immunoprofiling data. Median age was 81 years old (range: 38-85 years) and a median 5 prior lines of therapy (range 4-7). The median time from CAR T to mezi C1D1 was 108 days (range: 48-112). There was a trend towards increased BCMA CAR T cells at C1D8 (P=0.22) and increased BCMA CAR T % was associated with ³ CR (P=0.04). Early increases in HLA-DR+/CD38+ T cells (P=0.03) and HLA-DR+/CD38+ CAR T cells (P=0.02), CD8+ effector memory cells (P=0.03), BTLA+ T cells (P=0.03), CTLA-4+ T cells (P=0.02), monocytes (parent: PBMCs; P=0.04; higher in the DL-2 cohort, P=0.03), and activated B cells (P=0.04) compared to baseline were noted. Early decreases in CD8+ TEMRA (P=0.02), TIGIT+ T cells (P=0.04), monocyte-myeloid-derived suppressor cells (M-MDSCs; P=0.02), total B cells ($P<0.05$), memory B cells ($P<0.05$), and naïve B cells ($P<0.05$) were noted. The DL-2 cohort had higher increases in helper T cells (P=0.007) and CD4:CD8 ratio (P=0.03) at C1D8. **Conclusions:** Preliminary results show that mezi induced a decrease in suppressive cells, a shift in T- cells from exhausted to activated phenotype, and expansion of highly activated HLA-DR+/CD38+ CAR T cells. Future studies should investigate whether it is correlated with efficacy. FP and MJ contributed equally to this work. Clinical trial information: NCT06048250. Research Sponsor: Bristol-Myers Squibb; American Society of Clinical Oncology and Conquer Cancer; 2024YIA-1400257601.

7541 **Poster Session**

CAR-T in the older adults: Real-world survival and toxicity in patients ≥ 75 years with relapsed/refractory multiple myeloma. First Author: Jayasree Krishnan, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: CAR-T cell therapy targeting BCMA has transformed the treatment landscape for relapsed/refractory multiple myeloma (RRMM). However, pivotal clinical trials have limited representation of patients aged ≥75 years, leaving the safety and effectiveness of CAR-T therapy in this older population undercharacterized. In this study, we sought to evaluate the real-world outcomes of CAR-T therapy in patients aged ≥75 years with RRMM. **Methods:** A retrospective cohort study was conducted using the TriNetX database, which includes data from a large network of healthcare institutions in the US. Adult patients with RRMM who received CAR-T therapy were identified and stratified into two age based cohorts: ≥75 years and <75 years. Propensity score matching (1:1) was performed based on race, gender, comorbidities, and high risk cytogenetics if available. Outcomes included incidence of immune effector cell-associated neurotoxicity syndrome (ICANS), cytokine release syndrome (CRS), tocilizumab (Toci) use, sepsis, 30-day intensive care unit (ICU) admission rates, 90-day mortality rate, and 1 and 3-year overall survival (OS). Cox proportional hazards multivariate analysis was used to assess the impact of age on OS, controlling for confounders. **Results:** A total of 1,392 patients met study criteria, of which 198 patients were aged ≥75 yrs at the time of infusion. The mean age was 62.6 vs. 77.5 yrs in the younger and older cohort, respectively. Prior to propensity score matching (PSM), there were no significant differences in the rates of CRS, ICANS, Toci, sepsis, or 30-day ICU admissions rate post-infusion. Grade 3 or higher CRS/ICANS were infrequent in both cohorts. Additionally, the 90-day mortality rate did not differ significantly between the older and younger cohorts. Following PSM, these findings remained consistent (Table 1). While there was no significant difference in 1-year OS, the 3-year OS was lower in the ≥75 cohort (69% vs. 55.4%, log rank p=0.51), although the difference was not statistically significant. Cox proportional hazards multivariate analysis, controlling for race, gender, and comorbidities, revealed that age ≥75 was not independently associated with OS (hazard ratio [HR] = 1.04, 95%CI 0.65-1.65, p = 0.87). **Conclusions:** In this real-world cohort of RRMM patients receiving CAR-T therapy, age ≥75 years was not associated with differences in risks of CRS, ICANS, sepsis, 90-day mortality, or 1-year overall survival. While 3-year overall survival was lower in patients ≥75 years, possibly due to competing mortality risks, these findings overall suggest that age alone should not preclude BCMA-directed CAR T-cell therapy in select older patients. Research Sponsor: None.

Outcome	<75 years (n=197)	≥75 yrs (n=197)	p-value
CRS	53%	46%	0.27
ICANS	12%	8%	0.22
TOCI use	53%	51%	0.82
ICU admission	3.8%	5.1%	0.39
Sepsis	6%	7.9%	0.36
90 day mortality	3.9%	5%	0.28
1-yr OS	86.2%	86.6%	0.86
3-yr OS	69%	55.4%	0.51

Dynamic changes in immune checkpoint and cell populations following lymphodepletion and CAR-T therapy in hematologic malignancies. First Author: Zarina Brune, Dartmouth Hitchcock Medical Center, Lebanon, NH

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has significantly improved outcomes in relapsed and refractory hematologic malignancies; however, durable remissions remain limited in patients with high-risk features, including early progression to ≥2 extranodal sites, high tumor burden, and elevated serum lactate dehydrogenase. Proposed mechanisms of resistance include CAR-T cell exhaustion, impaired expansion and cytotoxicity, antigen loss or downregulation, and inadequate tumor infiltration. In addition, immunosuppressive interactions among myeloid-derived suppressor cells (MDSCs), regulatory T cells, tumor-associated macrophages, and inhibitory immune checkpoints such as PD-1, PD-L1, LAG-3, TIM-3, and VISTA may further limit CAR-T efficacy. Lymphodepleting chemotherapy alters immune homeostasis by affecting T-, B-, and NK-cell populations, modulating co-stimulatory signaling, reducing regulatory populations, and reshaping cytokine networks, influencing both response and toxicity. **Methods:** We conducted a pilot study (n = 10) to characterize peripheral immune alterations in patients receiving lymphodepleting chemotherapy followed by CAR-T therapy. Serial peripheral blood samples were collected at predefined time points before and after lymphodepletion and CAR-T infusion (D -5, D0 and D28+/-2). Flow cytometry was used to quantify immune cell subsets and evaluate immune checkpoint expression, including PD-1, PD-L1, LAG-3, and VISTA. **Results:** Lymphodepleting chemotherapy resulted in a marked reduction in T cells, B cells, and MDSCs. By D28, most immune populations recovered to pre-lymphodepletion levels; however, granulocytic MDSCs remained relatively suppressed. Preliminary molecular analyses demonstrated trends in both VISTA and LAG-3 expressions on T cells in multiple myeloma patients following lymphodepletion, without significant changes in overall circulating immune cell frequencies. Among patients who experienced disease recurrence (n = 3), a trend toward decreased $CD45^+CD3^+$ and $CD45^+CD4^+$ T-cell frequencies on D28 compared with D0 was observed relative to patients achieving complete remission (n = 7). **Conclusions:** These preliminary data suggest that lymphodepleting chemotherapy and CAR-T therapy induce dynamic peripheral immune remodeling, including sustained suppression of select myeloid populations and differential immune checkpoint expression. Interpretation is limited by the small sample size and pilot nature of the study. Nonetheless, observed trends in post-infusion T-cell dynamics associated with disease recurrence support further investigation. Larger, longitudinal studies are needed to validate these findings, elucidate mechanisms of resistance, and identify immune biomarkers predictive of response, toxicity, and durable remission following CAR-T therapy. Research Sponsor: None.

Impact of prophylactic cyclophosphamide on ALC and delayed neurotoxicity after cilta-cel. First Author: Melinda Tan, Mayo Clinic Rochester, Rochester, MN

Background: Delayed neurotoxicity (DNT) after ciltacabtagene autoleucel (cilta-cel) is associated with severe morbidity and mortality occurring in 10-15% of patients. A high post-infusion peak absolute lymphocyte count (ALCpeak ≥$3x10^9$/L; ALC^{hi}) is correlated with an increased risk of DNT (25-30%). We previously examined prophylactic dexamethasone (PPX DEX) administered for 3 days when ALC^{hi} was reached and found no reduction in ALC expansion, DNT incidence or severity. Here, we report the use of prophylactic cyclophosphamide (PPX CTX) on ALC kinetics and DNT. **Methods:** We conducted a retrospective analysis of patients (pts) treated with cilta-cel at Mayo Clinic (09-12/2025; n =60). Pts with ALC^{hi} received CTX 500 mg IV/PO once (n = 22). Outcomes and ALC kinetics including ALCpeak, ALC D28 (ALC_{D28}), and area under the curve D1-D28 (ALC_{AUC}) were compared with PPX DEX cohort (12/2024-08/2025; n =50) and a historical cohort without PPX (04/2022-11/2024; n =116). **Results:** Pre-lymphodepletion (LD) demographics were similar across historical ALC^{hi}, PPX DEX, and PPX CTX groups. Pre-LD CRP was higher in the historical ALC^{hi} cohort; however, baseline ferritin, CRS, and ICANS, and disease burden did not differ significantly between groups. There were no statistically significant differences in time to ALCpeak or ALC kinetics among the 3 cohorts. Among pts with ALC $< 3\times10^9$/L treated during the PPX CTX study period, 2 developed cranial nerve palsy (IEC-CNP; 2/38, 5%). Both presented with unilateral facial nerve palsy and were treated with corticosteroids. One pt resolved symptoms by one month, while the second had persistent symptoms at 2 weeks and remains on follow-up. Among ALC^{hi} patients in the PPX CTX cohort, DNT occurred in 4/22 pts (18%), including 1 case of IEC-CNP (5%) and 3 with parkinsonism (IEC-PKS, 14%). Within the PPX CTX cohort, baseline characteristics and post-infusion CRS or laboratory parameters did not differ between patients with and without DNT. Among patients who developed DNT, ALC kinetics were similar across PPX CTX, PPX DEX, and historical cohorts. PPX CTX was well tolerated, with 2 cases of grade 1 nausea reported. The incidence of DNT did not differ significantly between the PPX DEX (14/61, 23%) and PPX CTX (4/22, 18%) cohorts. However, DNT presentations in the PPX CTX cohort appeared milder and were responsive to treatment. Two of three patients (67%) presented with mild symptoms (one with dynamic dysphasia; second with flat affect) that responded to DEX. A third patient presented with typical parkinsonian features (hypomimia, bradykinesia, rigidity) and demonstrated clinical improvement following high-dose CTX. **Conclusions:** PPX CTX was well tolerated. While it did not significantly impact ALC expansion kinetics or DNT rates, first few cases of IEC-PKS suggest that the presentation may be milder and amenable to less toxic treatment. Larger cohorts are needed to refine optimal prophylactic strategies. Research Sponsor: None.

Efficacy and hematopoietic recovery of high-dose melphalan with stem cell rescue as bridging to CAR-T compared with non-intensive bridging in relapsed/refractory multiple myeloma. First Author: Eli Zolotov, Hackensack University Medical Center, Hackensack, NJ

Background: Bridging therapy is required for disease control in relapsed/refractory multiple myeloma (RRMM) patients awaiting CAR-T. Recent data suggest intensive cytotoxic bridging impairs post-CAR-T hematopoietic recovery. We compared melphalan-based therapy with stem cell rescue (MBT) versus talquetamab (T), a GPRC5D-directed bispecific antibody. **Methods:** We performed a retrospective single-center study of RRMM patients bridged with MBT or T prior to CAR-T (June 2021–December 2024) post apheresis. Cytopenias were graded per CTCAE v5.0 during early (within 30 days of CAR-T) and late (beyond 30 days of CAR-T) periods. Kaplan Meier analysis was performed to evaluate survival outcomes. **Results:** Of 242 CAR-T recipients, 34 received bridging either with T (n = 21, 62%) or MBT (n = 13, 38%). MBT patients were younger (61.9 vs 67.2 years; P = 0.08); high-risk cytogenetics by FISH were similar (92% vs 85%; P = 0.58). Bridging response rates were comparable (92% vs 82%; P = 0.36).At 20 months, 64% MBT and 58.7% T patients remained progression-free. Early grade 3–4 neutropenia for MBT vs T: 92% vs 95% (P = 0.37); late: 46% vs 33% (P = 0.84). Early grade 3–4 thrombocytopenia MBT vs T: 31% vs 24% (P = 0.28); late: 15% vs 14% (P = 0.40). Early grade 3 anemia MBT vs T: 69% vs 38% (P = 0.18); late grade 3–4: 17% vs 10% (P = 0.35). Median recovery times (MBT vs T): ANC 10 vs 5 days early (P = 0.28), 19 vs 17 days late (P = 0.11); platelets 7 vs 7.5 days early (P = 0.30), 12 vs 49 days late (P = 0.20); hemoglobin 13.5 vs 9 days early (P = 0.49), 35 vs 93 days late (P = 0.65). CRS rates were comparable: 53.8% vs 63.6% (P = 0.57). ICANS occurred only in the T cohort (13.6%) (p = 0.08). **Conclusions:** MBT yielded hematopoietic recovery, toxicity, and outcomes comparable to bispecific antibody bridging. These findings contrast with prior studies showing impaired recovery after intensive cytotoxic bridging, likely because stem cell rescue improves hematopoietic reserve. Prospective studies are warranted. Research Sponsor: None.

Racial disparities in utilization of bispecific T-cell engager therapy for relapsed/refractory multiple myeloma: A TriNetX study. First Author: Emmanuel Ekpenyong, Mobile Infirmary Medical Center, Mobile, AL

Background: There have been remarkable advancements in the treatment of multiple myeloma over the past few decades. With the advent of cell redirecting immunotherapies, such as bispecific T-cell engagers (BiTEs), we have significantly improved rates of progression-free survival. As a result, physicians now prefer early utilization of these therapies in Relapsed/Refractory Multiple Myeloma (RRMM) due to their efficacy. This study aims to investigate the utilization and clinical outcomes of bispecific therapy based on race using a real-world database. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, including adult patients (≥18 years) with RRMM treated with teclistamab, talquetamab, elranatamab, or linvoseltamab. Outcomes were assessed from 30 days to 5 years following the index diagnosis of RRMM. Propensity score matching (1:1) was performed to balance demographics, comorbidities, prior therapies, transplant status, medications, and laboratory parameters. Kaplan–Meier analyses were used to assess overall survival. Outcomes included hospitalization, overall survival, cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) rates. **Results:** A total of 25,225 patients with RRMM were identified. 67.3% were White, 19.5% were Black, and the remainder were classified as other races, including Asian or unknown. Among 1,889 patients treated with bispecific antibodies, 1,256 (66.5%) were White and 403 (21.3%) were Black patients. The median follow-up was 854 days for White patients and 785 days for Black patients. In the unadjusted analysis, mortality was similar between Black and White patients (21.7% vs 23.7%, p = 0.43), with no difference in overall survival (HR 0.98; log-rank p = 0.88). Hospitalization rates (34.6% vs 39.0%), CRS and ICANS were comparable. After propensity score matching, outcomes remained consistent. Mortality was numerically lower among Black patients (20.3% vs 25.4%), though not statistically significant (p = 0.11). Hospitalization, CRS and ICANS did not differ significantly between cohorts. **Conclusions:** Our findings showed no significant difference in mortality or five-year survival probability between Black and White patients. The incidence of multiple myeloma is more than twice as high among Black vs. White people (14 vs. 6.1 per 100,000). Despite this, White patients are disproportionately more likely to receive BiTE therapy than Black patients. This highlights the impact that lack of access has on myeloma outcomes for Black patients, likely driven by systemic inequities such as socioeconomic status, geographic barriers to access therapy, the requirement of a full-time caregiver and lack of knowledge about newer therapies available. Future efforts should focus on expanding access to BiTE therapy to promote equitable care for Black patients. Research Sponsor: None.

cfDNA WGS vs plasma proteomics for minimally invasive MRD assessment in multiple myeloma. First Author: Dor Abelman, University of Toronto, Department of Medical Biophysics, Toronto, ON, Canada

Background: MRD assessment informs relapse risk in MM but is typically bone marrow-based and invasive. We therefore compared two minimally invasive MRD assays: BM-informed cfDNA whole-genome sequencing (cfWGS) and plasma proteomic MRD (EasyM). **Methods:** 71 longitudinal plasma samples (22 diagnosis, 49 follow-up) from 22 newly diagnosed MM patients across 8 Canadian sites (TFRIM4) had paired cfWGS and EasyM (Rapid Novor Inc). cfWGS MRD used patient-specific mutation lists from diagnostic BM WGS (Abelman et al., medRxiv 2025). EasyM used mass spectrometry to quantify residual M-protein from baseline. The primary endpoint was progression-free survival (PFS). **Results:** Among 22 MM patients (8 male, 14 female; median age at diagnosis 62 years), 8 progressed at a median follow-up of 52.6 months (range: 10-79 months). At 1-year maintenance (n = 18 available), cfWGS MRD+ (6/18) predicted inferior PFS (HR 20.12, 95% CI 2.23-181.60, p = 0.007). EasyM any-detect positivity was frequent (16/18, reflecting delayed clearance) and not prognostic (p = 0.99), with poor agreement vs cfWGS (44.4%, κ = 0.118). An exploratory EasyM clearance threshold of 0.93% (hypothesis-generating) classified 5/18 patients as MRD+ and stratified PFS (HR 8.78, 95% CI 1.55-49.82, p = 0.004), improving agreement with cfWGS (17/18, 94.4%, κ = 0.870). Progression clustered in cfWGS+/EasyM-high patients (EasyM >0.93%; 4/5; median 11.9 months post-collection [1.9–22.8]) and occurred once in cfWGS−/EasyM-low patients (1/12, 27.6 months). The only discordant case (cfWGS+/EasyM−) progressed 8.7 months after collection. Higher quantitative MRD burden was associated with inferior PFS (cfWGS: HR 2.92 per 1 SD, 95% CI 1.29-6.59, p = 0.01; EasyM: HR 5.48 per 1 SD, 95% CI 0.79-37.90, p = 0.085). At ~100 days post-autologous stem cell transplantation (ASCT; n = 16 available), EasyM was uniformly MRD+ (16/16) while cfWGS was MRD+ in 7/16 patients. Applying an EasyM clearance threshold (2.13%; 9 cleared vs 7 residual) improved agreement with cfWGS (14/16; 87.5%; κ = 0.746). Of two discordant cases, one cfWGS+/EasyM-cleared patient relapsed 38.6 months post-collection and one cfWGS−/EasyM-residual patient remained progression-free at last follow-up. At post-ASCT, both assays showed consistent but underpowered associations with PFS (cfWGS HR 6.32, 95% CI 0.70–56.76, p = 0.100; EasyM-clearance HR 2.36, 95% CI 0.39–14.18, p = 0.335). Across all post-treatment samples (n = 49), continuous cfWGS burden correlated with EasyM residual M-protein (rho = 0.535, p < 0.001). **Conclusions:** BM-informed cfWGS MRD strongly stratified PFS, whereas EasyM required a clearance definition due to near-universal early positivity. Concordant plasma burdens support complementary MRD information. Future work will validate these findings in larger cohorts and quantify the incremental value of combined cfWGS and proteomic MRD for early relapse prediction. Current threshold of measurable disease in AL amyloidosis clinical trials. First Author: Eugene Brailovski, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Eligibility for clinical trials in AL amyloidosis requires measurable disease to ensure that the hematologic response can be adequately assessed, usually set at 5mg/dL. However, there are validated response criteria in low burden disease (dFLC 2-5mg/dL) that correlate with clinical outcomes in the upfront setting (Milani, 2017). Despite validated criteria in low burden disease, most trials maintain a dFLC of 5mg/dL as measurable disease. Shorter survival is seen in patients with high-risk dFLC progression, defined as dFLC >2mg/dL, >20% of baseline value and >50% increase from nadir (Palladini, 2018). Patients with organ progression also have poor outcomes. We examined patients who were excluded from clinical trials to determine if the current measurable disease criteria adequately capture patients who require salvage therapy. **Methods:** We reviewed patients screened for three clinical trials enrolling patients with relapsed/refractory AL amyloidosis: phase I/II trial of carfilzomib (NCT01789242), phase III trial of ixazomib/dexamethasone versus physician's choice (NCT01659658) and phase I trial of etentamig (NCT06158854) to identify patients who failed screening. All clinical trials required measurable disease, defined as dFLC at least 5mg/dL. High-risk dFLC progression (Palladini, 2018) and organ progression (Palladini, 2012/2014) were evaluated at the time of screen failure. **Results:** Among 47 patients screened, 14 (30%) were enrolled: 7 for carfilzomib, 6 on the ixazomib trial, 1 for etentamig (Figure 1). Of 33 excluded patients, 18 (54%) were due to dFLC < 5mg/dL. Among 18 patients excluded due to insufficient dFLC at the time of screening, 6 met criteria for organ progression (cardiac (n=4), renal (n=2)), 6 had high-risk dFLC progression (as defined in background) and 2 had both (Table 1), indicating 10 patients were at high risk of poor outcomes. Four patients were lost to follow-up within 6 months of screening. In the remaining 14 patients, 5 received alternative commercially available therapy within 6 months of screening, 5 enrolled in trials with lower dFLC eligibility, and 1 progressed to dFLC > 5, was rescreened and enrolled on the carfilzomib trial. Among the other 3 patients, none achieved a dFLC of 5mg/dL: 1 died within 12 months, 1 was treated after 12 months and one remains off treatment at 8 months. **Conclusions:** Two thirds of patients with AL amyloidosis failed screening with >50% due to dFLC<5mg/dL. Among those with dFLC<5mg/dL, the majority met criteria for high-risk dFLC progression or organ progression and were treated within 6 months. The current dFLC threshold for measurable disease excludes AL amyloidosis patients requiring therapy from clinical trials and results in trial patients not being representative of real-world practice. In the era of highly effective T cell redirecting therapies, we advocate a lower dFLC inclusion (>2mg/dL) to enable participation of patients with low-burden disease. Real-world outcomes comparing the use of GLP-1 agonists in patients with multiple myeloma and comorbid obesity: A propensity score–matched analysis from a global federated health research network. First Author: Arshi Syal, Mayo Clinic Florida, Jacksonville, FL

Background: Glucagon-like peptide-1 (GLP-1) receptor agonists are widely used for the treatment of type 2 diabetes and obesity, and emerging evidence suggests their benefits beyond glycemic control, including cardiovascular effects and potential anti-inflammatory and anti-proliferative properties. Therapeutic advances in multiple myeloma (MM) have improved the overall life-expectancy in our patients. However, metabolic comorbidities remain common, likely driven by disease burden, functional decline, ongoing inflammation, and treatment related effects. Our study evaluates the impact of GLP-1 receptor agonists on outcomes in patients with MM, exploring potential interactions between metabolic modulation and disease outcomes. **Methods:** We conducted a real-world retrospective cohort study using the TriNetX Global Collaborative Network, covering January 2000 to December 2025, encompassing data from 168 global healthcare organizations. Patients aged 18 and above with multiple myeloma were identified and then stratified into two groups based on treatment with GLP-1 agonists or not. The two groups were then propensity-matched based on age, sex, race, and various comorbidities. We assessed outcomes including overall mortality, myocardial infarction (MI), ischemic stroke, sepsis, anemia, pancreatitis, venous thromboembolism (VTE), and ED visits. Time-to-event analyses were performed using Kaplan-Meier methods and Cox proportional hazards models. **Results:** We identified 1716 patients with MM and obesity who received GLP-1 receptor agonists, and 13,491 patients with MM and obesity who did not receive GLP-1 therapy. After propensity matching, each cohort consisted of 1712 patients with well-balanced baseline characteristics. We followed these patients for 5 years from treatment initiation. Patients with MM who received GLP-1 had a significantly lower risk of overall mortality (Hazard Ratio [HR]: 0.423, 95% CI: 0.351-0.509, p-value $<$0.001), MI (Risk Difference [RD]: -3.6 %, 95% CI: -5.4 % to -1.7 %, p-value $<$0.001), ischemic stroke (RD: -1.7 %, 95% CI: -3.3 % to -0.1 %, p-value = 0.04), sepsis with and without shock (RD: -3.0 %, 95% CI: -4.9 % to -1.1 %, p-value = 0.002), and anemia (RD: -9.6 %, 95% CI: -12.9 % to -6.4 %, p-value $<$0.001). There was no statistically significant difference in the rates of VTE, ED visits, and pancreatitis between the two cohorts. **Conclusions:** Our study revealed that patients with MM with obesity who received GLP-1 therapy had significantly lower rates of overall mortality, MI, ischemic stroke, sepsis with and without shock, and anemia. Additional longitudinal cohort studies are required to explore the associations between these agents and inform clinical practice guidelines in these patients. Research Sponsor: None.

Duffy-null status and cytopenias following BCMA-directed CAR T therapy in multiple myeloma. First Author: Christen Marie Dillard, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Anti-BCMA chimeric antigen receptor T-cell (CAR T) therapies are highly effective in relapsed or refractory multiple myeloma (RRMM). The Duffy null phenotype, common among individuals of African ancestry and associated with lower baseline neutrophil counts, may influence hematologic toxicity following CAR T therapy. We evaluated outcomes of anti-BCMA CAR T by Duffy antigen status. **Methods:** We performed a retrospective analysis of 173 RRMM patients receiving ciltacabtagene autoleucel (cilta-cel; n=83) or idecabtagene vicleucel (ide-cel; n=90) between July 2021 and May 2025. Primary endpoints were PFS, OS, and response rate. Secondary endpoints included cytopenias and infections. Analyses were stratified by Duffy status and race/ethnicity and adjusted for age, prior therapies, and baseline ANC. **Results:** Cilta-cel: Duffy null patients (n=11, 13.3%) had comparable baseline characteristics to Duffy positive patients, except lower ANC (1.71 vs 2.44, p=0.01). Duffy null status was associated with prolonged neutropenia, with lower median ANC at day 30 (0.56 vs 1.77, p=0.005) and day 90 (1.06 vs 2.45, p=0.0002), and persistent grade $\geq$3 neutropenia at day 90 in 44.4% vs 4.3% (p=0.002). Infection rates were similar between groups (36.4% vs 41.7%, p=1.0). Response rates were high in both groups (100% vs 92%) and PFS did not differ significantly (HR 0.54, 95% CI 0.12–2.43, p=0.42), with a nonsignificant trend toward improved PFS among Duffy null patients after adjustment (HR 0.38, p=0.24). There were no significant differences in OS. Ide-cel: Duffy null status (n=16, 17.8%) was not associated with delayed cytopenia recovery (day 90 grade $\geq$3 neutropenia 33.3% vs 16.4%, p=0.2). Duffy null patients had higher infection rates (68.8% vs 39.2%, p=0.03) and a trend toward inferior OS (median 19.1 vs 40.4 months, log-rank p=0.11). These patients were more heavily pretreated (median 7 vs 5 prior lines, p=0.04); in multivariable analysis, prior lines of therapy predicted OS (HR 1.13, p=0.046) while Duffy status did not (HR 1.63, p=0.30). Response rates and PFS were similar between groups. Race/ethnicity alone was not associated with cytopenia recovery, infection rates, or survival. **Conclusions:** Duffy null status predicts severe, prolonged cytopenias following cilta-cel, without compromising efficacy or survival. Despite profound neutropenia, similar infection rates suggest benign cytopenia rather than true immunosuppression. Pre–CAR T Duffy phenotyping may prevent unnecessary neutropenia-directed interventions such as growth factors or stem cell boost. In ide-cel recipients, higher infection rates and inferior survival trends likely reflect heavier pretreatment and diminished marrow reserve. Future studies should evaluate Duffy status in earlier treatment lines and assess post-CAR T supportive care utilization by phenotype. Christen Dillard and Erneisha Brown contributed equally to this work. Research Sponsor: None.

The future mortality trends in multiple myeloma (SEER analysis 2000–2030). First Author: Muhammad Talha Shaukat, King Edward Medical University, Lahore, Pakistan

Background: Novel therapies have transformed Multiple Myeloma (MM) from a rapidly fatal diagnosis into a chronic condition. However, this extended survival exposes patients to a new set of competing risks. We utilized the SEER database to quantify the evolving burden of cause-specific mortality in the modern era and project future mortality trends. **Methods:** We identified 129,837 patients diagnosed with MM from 2000–2022 using SEER-17 registries. Patients were stratified by era: Pre-Novel (2000–06), Early-Novel (2007–14), and Modern (2015+). Median overall survival (mOS) and cumulative incidence function of death (CIF) were analyzed using Kaplan-Meier estimates and Gray's test, respectively. Fine-Gray competing risk regression was used to estimate sub-distribution hazard ratios (sHR) for non-cancer death. Non-cancer mortality burden was projected from 2021-2030 using linear regression models based on 2010–2021 trends. **Results:** Median Overall Survival (mOS) improved from 32 months (Pre-Novel era) to 49 months (Early-Novel era) and 63 months (Modern era) (p$<$0.001). Modern-era patients had lower odds of dying from MM compared to the Pre-Novel era (OR 0.68, 95% CI 0.66–0.71, p$<$0.001). The 5-year CIF of MM-specific death decreased from 46.5% (Pre-Novel) to 28.0% (Modern) while the non-cancer death remained stable (20.2% vs 20.7%). Among 82,585 total deaths recorded, Myeloma remained the primary cause (62.5%), while non-cancer causes accounted for 37.5%. Cardiovascular disease was the most common specific non-cancer cause, accounting for 11.4% (n=9,383) of all deaths. Early decedents ($<$3 years) had significantly higher odds of dying from Myeloma compared to late survivors (65.1% vs 58.5%; OR 1.32, p$<$0.001). In contrast, late survivors ($\geq$3 years) had significantly higher odds of death from cardiovascular disease (OR 1.16, 95% CI 1.11–1.21, p$<$0.001) and Infections (OR 1.16, 95% CI 1.05–1.28, p=0.003) as compared to early decedents. In Fine-Gray competing risk models, the modern era was associated with a reduced relative hazard of non-cancer death (sHR 0.80, p$<$0.001). The population of MM is projected to grow by 34.5% (from ~47,200 to ~63,500) between 2022 and 2030 and annual Myeloma-specific deaths are projected to increase by 6.1% (~2,980) by 2030, annual non-Cancer deaths are projected to rise by 38.8% (~3,600). **Conclusions:** Novel therapies have nearly doubled median survival in MM, narrowing the "mortality gap" as non-cancer causes as now approach half of annual deaths. Despite reduced relative hazards, the absolute non-cancer burden is projected to rise 49% by 2030. This necessitates the need for comprehensive survivorship care for the management of MM. Research Sponsor: None.

Machine learning to identify racial and socioeconomic disparities in the onset and tumor distribution of second primary malignancies in multiple myeloma. First Author: Muhammad Talha Shaukat, King Edward Medical University, Lahore, Pakistan

Background: As survival in Multiple Myeloma (MM) improved with novel therapies, the burden of second primary malignancies (SPM) has emerged as a significant competing risk. While racial disparities in MM outcomes are established, it remains unclear whether the the timing and type of SPM differ by race or socioeconomic status. **Methods:** We analyzed 7,513 MM survivors from the SEER Research database (2000–2022) who developed a confirmed, invasive SPM (excluding non-melanoma skin cancers). To account for the shorter follow-up duration in the modern era, latency drivers were assessed using Fine-Gray competing risk models which adjust for censoring. Racial and socioeconomic differences were quantified using logistic regression adjusted for age, sex, and median household income. Random Survival Forests were used to identify predictors of SPM latency with variable importance (VIMP) indicating the contributor for each factor. **Results:** The mean time-to-SPM decreased from 5.18 years (2000–2010) to 2.61 years (2011–2022) ($p < 0.001$). Black patients developed SPMs earlier than White patients (Average Direct Effect: -0.33 years, $p < 0.001$) and at a younger mean age for secondary Prostate cancer (68.5 vs. 71.6 years, $p < 0.001$). In Random Survival Forest modeling, biological age (VIMP=0.15) was the primary predictor of latency, followed by Stem Cell Transplant and Radiation utilization (VIMP=0.03). Multivariable linear regression indicated that patients with low household income ($<$\$60k) developed SPMs 0.34 years faster than wealthier peers ($p = 0.009$). Black patients had significantly lower odds of therapy-related hematologic malignancies (OR 0.62, 95% CI 0.49–0.77; $p < 0.001$) but higher odds of solid tumors (OR 1.62, 95% CI 1.30–2.04; $p < 0.001$). This solid tumor disparity persisted after adjusting for age and income ($p=0.27$) and was driven by Prostate (OR 1.79, 95% CI 1.54–2.09) and Breast cancer (OR 1.31, 95% CI 1.06–1.62). Post-SPM mortality hazard was higher in Black patients compared to White patients (HR 1.15, $p < 0.001$). **Conclusions:** Our findings showed racial and socioeconomic factors impact both the timing and type of SPM in MM survivors. Black and low-income patients develop SPM earlier and are more likely to develop solid tumors, especially prostate and breast. These findings suggests need for surveillance strategies and earlier focused screening for high risk populations to address disparities in MM survivorship. Research Sponsor: None.

Impact of human immunodeficiency virus on in-hospital outcomes among patients hospitalized with multiple myeloma: A National Inpatient Sample study, 2016–2022. First Author: Sophio Kakabadze, Ascension Saint Joseph Chicago, Chicago, IL

Background: Outcomes among hospitalized patients with multiple myeloma (MM) and concomitant human immunodeficiency virus (HIV) infection remain incompletely characterized at a national level. We evaluated the association of HIV infection with in-hospital outcomes among MM hospitalizations in the United States. **Methods:** We analyzed 161,303 MM hospitalizations and identified HIV infection using ICD-10 diagnosis codes (B20–B24, Z21). To improve comparability, we restricted analyses to hospitalizations with length of stay (LOS) $<$ 30 days and complete covariate data, then performed 1:1 propensity score matching using demographics, hospital characteristics, Charlson comorbidity category, and key comorbidities. Primary outcome was in-hospital mortality. Secondary outcomes included LOS, total hospital charges, and inpatient complications. **Results:** Of 161,303 MM hospitalizations, 0.4% (n = 681) had HIV infection. After applying analytic restrictions, 458 HIV-positive hospitalizations were matched to 458 HIV-negative hospitalizations with good covariate balance; mean age was 60.0 years. HIV infection was not associated with higher in-hospital mortality (OR 0.68, 95% CI 0.37–1.21; p = 0.191). Median LOS was similar between groups (5 days in both); however, on log-transformed analysis HIV infection was associated with shorter LOS (LOS ratio 0.90; p = 0.033). HIV infection was associated with a nonsignificant trend toward lower total hospital charges (cost ratio 0.88, 95% CI 0.77–1.01; p = 0.061). HIV infection showed nonsignificant trends toward increased venous thromboembolism, including pulmonary embolism (OR 4.05; p = 0.078) and deep vein thrombosis (OR 1.88; p = 0.085). No significant differences were observed for mechanical ventilation or cerebrovascular accident. **Conclusions:** In matched analyses of MM hospitalizations, HIV infection was not associated with increased in-hospital mortality and was associated with shorter LOS despite similar median LOS. Total charges were not significantly different, though a trend toward lower charges was observed. Signals for increased venous thromboembolism warrant further study in larger cohorts. Single-cell analysis of plasma cell–centered inflammatory–immunosuppressive niches and response to daratumumab in primary light-chain amyloidosis. First Author: Xuezhu Wang, Department of Hematology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Primary light-chain amyloidosis (pAL) is a plasma cell disease in which clonal plasma cells produce misfolded immunoglobulin light chains that lead to progressive organ dysfunction. Daratumumab (Dara), an anti-CD38 monoclonal antibody, is the backbone of first-line regimens for pAL; however, ~10–30% of treated patients fail to achieve ≥VGPR. Currently, there remains an unmet need to delineate the immune microenvironmental mechanisms underlying Dara resistance in pAL to enable the identification of predictive biomarkers and therapeutic targets, particularly for patients who lack prognostic cytogenetic markers such as 1q21 gain. **Methods:** We profiled 630,111 single cells obtained from a prospective observational cohort of 30 patients treated with a frontline Dara–bortezomib–dexamethasone regimen, including 11 paired samples collected pre-treatment and post-treatment. Overall, 37.0% of patients showed suboptimal responses (≤PR) before cycle 6 or initiation of next-line therapy. Plasma cells enriched with $CD138^+$ magnetic beads and whole bone marrow were profiled with single-cell RNA-seq. **Results:** At cohort baseline, 93.3% of the patients were Mayo 2004 stage I–IIIa, 46.7% harbored the t(11;14) translocation, and 20.0% had 1q21 gain. Suboptimal responders showed two plasma cell-centered immune processes already upregulated at baseline: (i) an inflammatory axis with elevated PTGES2/PTGES3 (PGE_2)–EP2/EP4 (BH-adjusted Wilcoxon $p < 0.05$) signaling between plasma cells and myeloid, NK, and T cells, possibly driven by upstream PTGS2-expressing myeloid-derived suppressor cell-like $CD38^-$ $CD14^+$ monocytes that expanded during treatment; and (ii) an immunosuppressive axis in which non-classical MHC class I on plasma cells increased inhibitory interactions mainly with NK and T cells (including HLA-E–KLRK1, HLA-G–LILRB1, and HLA-F–LILRB1) (BH-adjusted Wilcoxon $p < 0.05$). Compared with patients with 1q21 gain, patients with t(11;14) were associated with higher non-classical MHC class I and PTGES3-dependent prostaglandin signaling and lower PTGES2-dependent prostaglandin signaling. Possibly driven by this microenvironment, myeloid cells downregulated phagocytosis and endocytosis, NK cells showed impaired effector functions, and T cells upregulated exhaustion, accompanied by an enhanced interferon response in suboptimal versus good responders (BH-adjusted Wilcoxon $p < 0.05$). **Conclusions:** This single-cell cohort revealed a baseline inflammatory–immunosuppressive niche in pAL that underpins suboptimal hematologic responses to Dara, characterized by up-regulated non-classical MHC class I and prostaglandin signaling between plasma cells and immune cells and associated with impaired immune effector functions during Dara treatment. Copy number aberration profiling using shallow whole-genome sequencing-based LeukoPrint in multiple myeloma. First Author: Li Gao, Xinqiao Hospital of Army Medical University, Chongqing, China

Background: Multiple myeloma (MM) is a clonal plasma cell malignancy in which cytogenetic abnormalities are central to prognosis and therapy. Karyotyping is limited by low plasma cell proliferation, and FISH provides only targeted, costly detection. LeukoPrint, a shallow whole-genome sequencing–based assay, enables genome-wide CNA profiling. Supported by prior validation, we launched a prospective multicenter trial (ChiCTR2300077768) to assess the clinical relevance of LeukoPrint-detected CNAs in MM, and report interim results from the first 102 patients. **Methods:** This multicenter, prospective trial aims to enroll 396 newly diagnosed active multiple myeloma patients per IMWG 2014 criteria. As of June 12, 2025, 102 patients from seven hospitals in China were enrolled. LeukoPrint was used to profile CNAs ($>$1 Mb) from paired bone marrow $CD138^+$ plasma cell gDNA and peripheral blood cfDNA collected at diagnosis, post-induction, and relapse. Karyotyping and FISH were performed in parallel when available and compared with LeukoPrint. Risk stratification followed mSMART criteria. **Results:** LeukoPrint identified 863 CNAs (379 chromosomal and 484 sub-chromosomal) in 91 of 102 patients (89.2%). Hyperdiploidy was observed in 33 patients, non-hyperdiploidy in 58, and normal karyotype in 11. The most frequent alterations were 1q gain (53%) and chromosome 13 deletion (50%). Odd-numbered trisomies, often co-occurring, were detected in 51.0% of patients, predominantly in hyperdiploid cases, whereas del(13) was evenly distributed across ploidy groups. Subdiploidy was common (54%) and hyperdiploidy rare (13%) among IGH-translocated cases, suggesting mutual exclusivity of hyperdiploidy and IGH-translocation. LeukoPrint showed 88.4% concordance with FISH for four key prognostic CNAs (1p32-, 1q21+, 13q14-, 17p13-) but detected substantially more abnormalities, including in 80% of FISH-negative patients. It also markedly outperformed karyotyping (90.1% vs. 8.8%), consistent with the limited sensitivity of karyotyping due to the low proliferative activity of plasma cells in MM. Blood-based ctDNA analysis showed good concordance with bone marrow results (81.9%), and CNA dynamics tracked closely with clinical remission, supporting LeukoPrint as a robust tool for diagnosis and treatment monitoring in MM. **Conclusions:** LeukoPrint outperforms FISH and karyotyping, providing a cost-effective, genome-wide CNA platform in MM and demonstrating utility in ctDNA-based liquid biopsy. These results support LeukoPrint as a complementary, and potentially alternative approach to conventional cytogenetics. Clinical trial information: ChiCTR2300077768. Research Sponsor: None.

Extrachromosomal DNA as a shaper of aggressive transcriptional states in multiple myeloma. First Author: Hyunsoo Cho, Seoul National University Hospital, Seoul, Seoul, South Korea

Background: Extrachromosomal DNA (ecDNA) is increasingly recognized as a key driver of oncogene amplification, intratumoral heterogeneity, and poor clinical outcomes across solid tumors. However, its significance in multiple myeloma remains largely unexplored. Multiple myeloma is characterized by marked genomic instability including hyperdiploidy or IgH translocations, and widespread structural rearrangements that underlie biological heterogeneity and therapy resistance. Defining whether ecDNA contributes an additional layer of genomic complexity in this disease therefore represents an important unmet need. **Methods:** Whole-genome sequencing (WGS) BAM files of primary myeloma cells from the Multiple Myeloma Research Foundation (MMRF) CoMMpass study were analyzed using the AmpliconSuite pipeline to identify circularized DNA amplicons indicative of ecDNA. Matched transcriptome (RNA-seq) data and clinical metadata from the same cohort were integrated to evaluate the prognostic impact of gene expression associated with ecDNA-harboring loci. Gene Set Enrichment Analysis (GSEA) was performed using the *clusterProfiler* R package to assess pathway-level biological signatures linked to ecDNA-positive tumors. **Results:** We identified ecDNA in 28 of 904 patients (3.1%) from the MMRF CoMMpass dataset. Despite the low prevalence, ecDNA-positive myeloma patients exhibited significantly inferior survival compared with patients without ecDNA. Frequently amplified ecDNA loci contained oncogenes such as *MYC, TNFRSF17 (BCMA),* and *SNX29,* as well as pro-tumoral lncRNAs including *CASC11* and *PVT1.* GSEA revealed strong enrichment of MYC and E2F targets, oxidative phosphorylation, and PI3K–AKT–mTOR and mTORC1 signaling in ecDNA-positive tumors, highlighting transcriptional addiction and metabolic activation. These pathways align with known mechanisms of proliferation, metabolic rewiring, and treatment resistance in multiple myeloma. **Conclusions:** ecDNA-positive myeloma represents a biologically aggressive subset characterized by oncogene-enriched circular amplicons and hyperactivated proliferative and metabolic programs. Myeloma patients with ecDNA showed significantly worse survival, supporting ecDNA as a previously underrecognized high-risk feature. These findings highlight ecDNA as potential therapeutic vulnerabilities in myeloma and warrants further investigation. Research Sponsor: Korea Health Industry Development Institute.

Enabling blood-based mass spectrometry MRD detection in multiple myeloma without archived serum samples. First Author: Daniel Jesus Groso, Uni-University of Miami Miller School of Medicine, Miami, FL

Background: Minimal residual disease (MRD) assessment in multiple myeloma (MM) relies almost exclusively on bone marrow (BM) biopsy, an invasive, costly, and spatially limited procedure that is poorly suited for frequent longitudinal monitoring and may miss focal or extramedullary disease. Blood-based MRD strategies offer a less invasive, lower-cost alternative that could enable more frequent surveillance and earlier detection of disease progression. Mass spectrometry (MS)-based detection of monoclonal immunoglobulin peptides in peripheral blood is a promising MRD approach; however, current methods typically require prior identification of circulating M-protein amino acid sequences from archived serum, limiting applicability in patients without banked samples. We sought to determine whether patient-specific immunoglobulin V(D)J sequences could be reconstructed from BM-derived DNA or RNA, or from peripheral blood RNA, to enable blood-based MRD detection. **Methods:** We analyzed RNA-seq and whole exome sequencing (WES) from BM plasma cells and RNA-seq from peripheral blood mononuclear cells in 75 patients with MM, all of whom had abnormal plasma cells identified by flow cytometry. Immunoglobulin heavy chain (IGH) V(D)J sequences were reconstructed using MiXCR, and the dominant productive clonotype in the BM was selected per patient. Variable-region sequences containing complementarity-determining region 3 (CDR3) and adjacent framework regions were extracted when available. Peripheral blood RNA-seq was evaluated for clonotype recovery without BM sampling. In silico proteolytic digestion was performed to identify peptides compatible with standard MS detection. **Results:** Across 75 patients, dominant IGH clonotypes were reconstructed from 100% of BM sequencing data. From these clonotypes, a mean of 7 RNA-seq–derived peptides and 6 WES-derived peptides per patient were identified, with a mean of 2 peptides shared between platforms. Fifty patients (67%) generated ≥10 MS-compatible peptides, and 33 patients (44%) had at least one peptide shared between RNA-seq and WES. Among 51 patients with paired tumor and peripheral blood RNA-seq, dominant clonotypes were detectable in peripheral blood by CDR3 matching in 30 patients (58.8%). **Conclusions:** Patient-specific immunoglobulin clonotypes can be reliably reconstructed from prior BM sequencing data, yielding MS-compatible peptide targets for downstream analysis. In selected patients, clonotype discovery is feasible directly from peripheral blood, potentially reducing the need for invasive BM sampling. This approach overcomes a key limitation of existing MS-based MRD assays by enabling peptide target discovery in patients without archived serum but with available BM sequencing. Additional studies are required to validate MS detection of these peptides and establish a scalable, minimally invasive blood-based MRD platform. Research Sponsor: None.

Circulating tumor DNA *NRAS* and *TP53* mutations to identify ultra-high-risk primary refractory myeloma patients. First Author: Sridurga Mithraprabhu, Alfred Hospital / Monash University, Melbourne, Australia

Background: Approximately 5% of newly diagnosed multiple myeloma (MM) patients progress on bortezomib-containing first-line (1L) therapies and develop primary refractory disease (1REF). These patients have unacceptably poor outcomes. Underlying drivers of 1REF remain unclear. We hypothesized that circulating tumour DNA (ctDNA) profiling would identify the genetic drivers of 1REF. **Methods:** We analyzed plasma ctDNA, bone marrow (BM) MM cells from 89 patients, comprising 33 1REF and 56 contemporaneous 1L-responsive (RES) patients. ctDNA was available for all patients; BM was available for 63% (18 1REF and 38 RES). Ultra-deep targeted sequencing used a 21-gene panel enriched for MM drivers. High-confidence pathogenic variants were defined as variant allele frequency ≥1% with ≥15 supporting reads. Genomic enrichment analyses used Fisher's exact test. Survival outcomes (progression-free survival, PFS and overall survival, OS) were available for 27 1REF patients and analyzed using Kaplan–Meier methods. **Results:** Interrogation of BM showed more mutations in 1REF versus RES (67% vs 34%; p=0.04) with *RAS/RAF* predominating (67% vs 26%; p=0.007). Mutation patterns in 1REF versus (vs) RES comprised predominantly *KRAS* (44% vs 21%), followed by *NRAS* (22% vs 8%). *BRAF* was detected exclusively in 1REF (17% vs 0%) and *TP53* showed no difference (6% vs 8%). ctDNA profiling revealed pathogenic variants in 18% of patients, enriched in 1REF vs RES (30% vs 11%; p=0.02), with *RAS/RAF* pathway mutations predominating (24% vs 2%; p=0.001), in line with BM observations. However, ctDNA *RAS/RAF* mutation patterns differed strikingly from BM. In 1REF vs RES, these comprised mainly *NRAS* (12% vs 0%; p=0.01) and *BRAF* (9% vs 0%; p=0.04), detected exclusively in 1REF, and *KRAS* (6% vs 2%). *TP53* did not co-occur with *RAS/RAF* and were comparable across both cohorts (6% vs 5%). Mutation-survival associations in 1REF patients also revealed differences between BM and ctDNA. BM mutations lacked prognostic value while ctDNA mutations predicted survival, suggesting ctDNA captures treatment-resistant systemic disease. Patients with any ctDNA mutations had significantly shorter PFS and OS compared to those without (PFS: 8.5 months vs not reached [NR], p=0.0005; OS: 12.0 months vs NR, p=0.004). Patients with *NRAS* mutations showed consistently poor outcomes, while the impact of *BRAF* varied. The worst outcome was seen in an ultra-high-risk subset (15%, 4/27) with *TP53* or *NRAS*, with all patients demonstrating an early fatal outcome (PFS 5.3 and OS 5.6 months; both p<0.0001). **Conclusions:** ctDNA *TP53* or *NRAS* identify a high-risk subset of 1REF patients with exceptionally poor outcomes, demonstrating that liquid biopsy, not BM evaluation, captures treatment-resistant systemic biology. These findings establish ctDNA as superior for risk stratification in 1REF MM and highlight an urgent need for alternative therapies in these patients. Research Sponsor: None.

A machine learning (ML)—based six-gene signature for risk stratification and therapeutic target identification in multiple myeloma. First Author: Sriram Subramanian, Langley High School, Mclean, VA

Background: Multiple myeloma(MM) accounts for 10-15% of hematologic malignancies with significant heterogeneity. Current risk stratification relies on clinical variables (ISS, sex, race, age, cytogenetics) but has limited prognostic accuracy (C-index ~0.63).TP53mt MM has worse outcomes, present in only 5% of newly diagnosed patients and increase to 25% at progression. **Methods:** We performed differential gene expression (DGE) and gene set enrichment analysis (GSEA) between TP53mt (36) and TP53wt (717) MM from (MMRF CoMMpass). Intersection of DGE and GSEA identified 46 genes, which along with clinical variables were modeled using Cox regression and 4 ML algorithms: LASSO, CoxBoost, XGBoost and Random Forest. Models were trained on 70% and tested on 30% of data, with external validation on GSE24080 (n=559).The final 6-gene signature was functionally evaluated in drug sensitivity data from 16 MM cell lines (DepMap). Performance was assessed using concordance index (C-index) and hazard ratios (HR). **Results:** CoxBoost model 6-gene signature (UBE2C, STMN1, TK1, DSCC1, PTTG1, CENPF) outperformed all other models. Combined with clinical variables, it achieved C-index 0.742 in discovery (95% CI: 0.708-0.776) versus 0.629 for clinical variables alone (+18.0% improvement, p<0.001).Minimal overfitting was observed (training: 0.748, test: 0.742, gap: 0.006). In multivariable Cox analysis, the CoxBoost risk score remained highly significant (HR 1.95, 95%CI:1.51-2.52,p<0.001) independent of ISS stage (HR 2.89, p<0.001) and age (HR 1.39 per decade, p<0.001).External validation on GSE24080 showed improved performance (C-index 0.683,+6.8% over clinical variables).The signature showed 50% gene overlap with LASSO (3/6 genes) and outperformed UAMS-70 (C-index 0.742 vs 0.631).Drug sensitivity analysis identified three compounds (MACIMORELIN, MW-150, BROFAROMINE) with selective activity against high-risk MM cells (p<0.001),validated across 16 cell lines. **Conclusions:** TP53 and its downstream pathways are central to MM progression. CoxBoost modeling produced a 6-gene signature that improved MM risk stratification over clinical variables, identifies therapeutic vulnerabilities, and is computationally efficient model suitable for clinical deployment, warranting prospective validation in MM treatment stratification. Research Sponsor: None.

SATMM: A systems genetic network analysis—based risk stratification tool validated across the disease trajectory of relapsed/refractory multiple myeloma. First Author: Carl Murie, Institute of Systems Biology, Seattle, WA

Background: Precision medicine in multiple myeloma (MM) requires risk stratification tools that account for the patient-specific impact of cytogenetic abnormalities on disease progression. We developed SATMM (SYGNAL Analytics Tests for MM) based on each patient's chromosomal abnormality subtype using the previously developed mmSYGNAL network. While originally validated in newly diagnosed (ND) cohorts, this study provides updated validation of SATMM in the relapsed/refractory (RR) setting. **Methods:** SATMM performance was evaluated in a new RR cohort from the Moffitt Cancer Center, stratified into Early RR (ERR; 1–3 prior events, n=258) and Late RR (LRR; > 3 prior events, n=251). Predictive accuracy was assessed via ROC analysis (AUC) and Kaplan-Meier (KM) survival curves to determine Median Progression-Free Survival (mPFS) and Cox Hazard Ratios (HR). SATMM was benchmarked against the established GEP70 and SKY92 gene panels. **Results:** As detailed in the accompanying table, SATMM demonstrated robust and superior predictive performance compared to existing panels throughout the RR disease trajectory: Prognostic Accuracy: SATMM achieved superior overall accuracy in both ERR (0.61) and LRR (0.55) groups compared to GEP70 (0.52 and 0.37) and SKY92 (0.54 and 0.43). Early-Stage Performance: In the ERR group, SATMM provided the most significant clinical separation with a Δ mPFS of 10.7 months (KM *p*=1.60e-05), outperforming GEP70 (8.9 months, KM *p*=0.00053) and SKY92 (4.4 months, non-significant). Late-Stage Performance: In the heavily pre-treated LRR group, SATMM maintained significant stratification (KM *p*=0.0068, HR *p*=0.0078) with an AUC of 0.62, GEP70 showed lesser performance (KM *p*=0.021, HR *p*=0.021) while SKY92 failed to provide accurate risk prognosis (AUC=0.43). High-Risk Patient Detection: SATMM identified a larger proportion of high-risk patients (ERR n=93 sen = 0.47; LRR n=117, sen = 0.51) with higher sensitivity (sen) compared to GEP70 (ERR n=25, sen =0.13; LRR n=46, sen = 0.20) and SKY92 (ERR n=59, sen = 0.27; LRR n=111, sen = 0.41). **Conclusions:** SATMM is a patient-specific prognostic test that effectively stratifies risk based on the unique patient genomic profile compared to current gene panels. These data confirm that SATMM not only accurately predicts progression in ND patients but maintains its high performance across the entire disease trajectory, offering superior accuracy and sensitivity for high-risk detection for RR patients. Research Sponsor: Andy Hill Care Foundation.

Method	Disease status	AUC	Δ Median PFS	KM pvalue	High risk n	Cox HR	Cox HR pvalue	Accuracy	Sensitivity
SATMM	ERR	0.65	10.7	1.6E-05	93	0.512	1.3E-04	0.609	0.47

A common gene expression signature across multiple myeloma disease stages to identify high-risk of disease progression. First Author: Claudio Cerchione, Hematology Unit, Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS, Meldola, Italy

Background: An accurate and timely identification of high-risk (HR) disease is crucial to maximize therapeutic opportunities nowadays available for multiple myeloma patients. **Methods:** In this study, 105 consecutive patients with smoldering (SMM = 33), newly diagnosed (NDMM = 42) and relapse/refractory (RRMM = 30) myeloma were enrolled. Bone marrow samples were processed by SKY92 assay (Skyline Dx) to detect HR gene expression (GE) signature and cytogenetics according with manufacturer guidelines. Statistics were performed using GraphPad Prism 8 and R (v4.4.2). Two-sided statistical tests were used, with significance of $P < 0.05$ and Benjamini–Hochberg method for false discovery rate (FDR) correction. **Results:** Based on SKY92 quality requirements, this test was feasible in the 81.1% of SMM, 92.8% of NDMM and 80.0% of RRMM cases, showing an increased detection of HR SKY92 signature frequency from SMM (18%) toward NDMM (43.5%) and RRMM (67%, P= 0.0018). By comparing SKY92 virtual FISH with available standard FISH data we observed a high performance of t(4;14), t(14;16/20) and gain1q detection with an accuracy [95%(CI)] of 97.9 (93.9-100), 85.2 (71.8-98.6) and 87.2 (77.7-96.8) respectively, decreasing to 66.7 (49.8-83.5) for del17p suggesting that this chromosomal aberrancy can be less likely recapitulated by GE-based projections. NDMM HR SKY92 patients showed a worst overall survival compared to patients with SKY92 standard risk (SR, P= 0.0079), a trend maintained in RRMM with a nearly significant statistics due to the cohort sample size (P= 0.093). These results suggested that HR patients could share a transcriptional trademark across disease stages. This hypothesis was tested by comparing SKY92 HR NDMM and RRMM versus SR GE data with the following observations: *(i)* relative risk-related clusterization by a principal component analysis (PCA) and *(ii)* modulation of canonical pathways frequently altered in cancer by a gene set enrichment analysis (GSEA). To test the predictivity of GE-based approaches in the asymptomatic phase of myeloma we projected GE data of SMM on the PCA bi-dimensional space previously generated with NDMM and RRMM data and we observed a partial overlap of samples based on SKY92 risk profiles across MM stages. Interestingly, a GSEA comparing SKY92 HR vs SR SMM outlined deregulated gene pathways associated with inflammation and aggressive disease. Consistently, available follow up data show a progression rate of 60% for HR SKY92 SMM compared with 0% of the SR group (P = 0.173). **Conclusions:** Our findings support the use of GE-based tools for MM patient's risk profiling and HR-related cytogenetic detection if FISH is not available. Furthermore, it provides evidence that HR patients share transcriptional traits across asymptomatic and symptomatic phases consistent with recent findings underlying common genomic features shared by a portion of SMM with MM. Research Sponsor: None.

Comparative analysis of subcutaneous Isa VRd (ISASOCUT) and intravenous Isa VRd (IMROZ) in transplant-ineligible newly diagnosed multiple myeloma across age groups. First Author: Arthur Bobin, Centre Hospitalier Universitaire de Poitiers, Poitiers, France

Background: Intravenous (IV) isatuximab (Isa) plus bortezomib, lenalidomide, and dexamethasone (VRd) significantly improved PFS in patients (pts) with transplant-ineligible newly diagnosed multiple myeloma (Ti NDMM) in the IMROZ randomized Phase (Ph) 3 study (NCT03319667). Efficacy and safety of subcutaneous (SC) Isa VRd, using an innovative on-body injector (OBI), has been demonstrated previously, including in Ti NDMM pts in the ISASOCUT Ph2 study (NCT05889221). Bortezomib was administered twice weekly (BIW) in IMROZ vs weekly in ISASOCUT. Here, safety and efficacy of Isa OBI VRd (ISASOCUT) and Isa IV VRd (IMROZ) are evaluated at 8 months (mos) follow-up. **Methods:** This analysis included 74 pts from ISASOCUT (Isa OBI VRd) and 265 from IMROZ (Isa IV VRd). Isa OBI VRd pts received Isa 1400 mg (weekly cycle [C]1, then every 2 weeks [Q2W] up to C12, and Q4W thereafter); each cycle lasted 28 days. SC bortezomib (1.3 mg/m^2) was given BIW in C1 and weekly thereafter. Isa IV VRd pts received Isa 10 mg/kg weekly in C1, then Q2W, followed by Q4W from C18 onwards. SC bortezomib (1.3 mg/m^2) was given BIW from C1-4. C1-4 lasted 42 days, with the remainder lasting 28 days each. This comparative analysis evaluated safety and efficacy at 8 mos follow-up by baseline age group ($<$75 yrs, $\geq$75 yrs). **Results:** Baseline demographic and disease characteristics were similar between Isa OBI VRd and Isa IV VRd pts. Incidence of serious TEAEs were similar between groups (35.1% and 42.2% for Isa OBI VRd and Isa IV VRd, respectively) and across age groups. The rate of systemic infusion reaction was lower with Isa OBI VRd vs Isa IV VRd (4 [5%] vs 60 [22.8%]). Grade (G) $\geq$3 neutropenic complications occurred in 2.7% Isa SC OBI pts and 3.8% Isa IV pts and were similar across age groups ($<$75 yrs, 2% vs 4.1%; $\geq$75 yrs, 4% vs 2.9%). Study discontinuation due to TEAEs occurred in 2.7% Isa SC OBI pts and 8.7% Isa IV pts, with lower rates in Isa SC OBI ($<$75 yrs, 0% vs 8.2%; $\geq$75 yrs, 8% vs 10.3%). Across both age groups, a lower incidence of G2 peripheral neuropathy (PN) was observed with Isa OBI VRd (weekly V) vs Isa IV VRd (BIW V) ($<$75 yrs, 20.4% vs 28.7%; $\geq$75 yrs, 20% vs 35.3%) as well as G$\geq$3 PN ($<$75 yrs, 2% vs 9.2%; $\geq$75 yrs, 0% vs 7.4%). Isa OBI VRd (weekly V) was associated with less bortezomib dose reduction due to nervous system disorders (Isa OBI VRd [weekly V] vs Isa IV VRd [BIW V]: $<$75 yrs, 14.3% vs 37.4%; $\geq$75 yrs, 28.0% vs 35.3%). $\geq$VGPR rates for Isa OBI VRd and Isa IV VRd were 87.8% and 83.2%, respectively (RR: 1.055; 95% CI: 0.934-1.192), in pts aged $<$75 yrs and 80.0% and 82.6%, respectively (RR: 0.968; 95% CI: 0.774-1.211), in pts aged $\geq$75 yrs. **Conclusions:** In this comparative analysis, Isa OBI VRd with weekly bortezomib (ISASOCUT) is more tolerable for pts regarding PN than the BIW schedule (IMROZ). Both groups maintained similar $\geq$VGPR rates across age groups. These findings support the efficacy and safety of the Isa SC OBI with weekly bortezomib. Clinical trial information: NCT05889221 and NCT03319667. Research Sponsor: Sanofi.

ISABELA: A phase 2 study of isatuximab, belantamab mafodotin, pomalidomide, and dexamethasone in relapsed/refractory multiple myeloma. First Author: Andrew J. Yee, Mass General Brigham Cancer Institute, Boston, MA

Background: Combination therapies form the backbone of multiple myeloma (MM) care, and therapies targeting BCMA are now a cornerstone of treatment. We evaluated ISABELA, a phase 2 study that combines an established regimen of isatuximab (isa), pomalidomide (pom), and dexamethasone (dex) with the recently approved anti-BCMA antibody drug conjugate belantamab mafodotin (belamaf) in relapsed/refractory (RR) MM. **Methods:** ISABELA is an investigator-initiated study (NCT05922501) enrolling up to 50 patients (pts) with RRMM who have received at least 1 prior line of therapy including lenalidomide and a proteasome inhibitor. We gave belamaf 1.9 mg/kg iv q8 weeks; isa 10 mg/kg iv weekly for cycle 1 and then days 1 and 15 for cycle 2 onward; pom 4 mg on days 1-21, and dex 40 mg weekly divided over two days. Each cycle was 28 days. Treatment was until progression or unacceptable toxicity. **Results:** At data cutoff, the trial had enrolled 17 pts with a median follow-up of 9.6 months. Median age was 72 (range 55-91); 65% were male. ISS at study entry: I (59%), II (24%), III (18%). Median number of prior regimens was 2 (range 1-12). All pts were refractory to their last line of therapy and were previously treated with lenalidomide and a proteasome inhibitor. Prior therapies included pom (59%), bortezomib (82%), carfilzomib (41%), ixazomib (35%), CD38 antibody (59%) [daratumumab, 59%; isa 12%], and auto SCT (24%). Prior exposure to newer therapies included drugs that target BCMA (24%) [teclistamab 6%, elranatamab 18%, CAR T-cells 12%]; GPRC5D (12%) [talquetamab]; and cereblon (29%) [mezigdomide, 29%; cemsidomide, 12%]. Soft tissue plasmacytomas were present in 18%. The overall response rate (ORR) was 86% (12/14, not evaluable (NE) 3), $\geq$VGPR 43%, CR 7%, and 16-month PFS was 73% (95% CI 0.5-1). In CD38-antibody-naïve patients, ORR was 84% (5/6, NE 1) and 16-month PFS was 67% (95% CI 0.38-1). In triple-class exposed (BCMA naïve) pts, ORR was 75% (3/4, NE 2), and 12-month-PFS was 86% (95% CI 0.63-1). In quad-class exposed pts (including BCMA) (N=4), ORR was 100% and 12-month PFS was 75% (95% CI 0.43-1). Grade 3-4 hematologic adverse events (AEs) included neutropenia (53%), thrombocytopenia (29%), and anemia (12%). Common non-hematologic AEs (all; grade 3-4) included blurred vision (65%; 6%); fatigue (65%; 0%); hypertension (59%; 6%); diarrhea (53%; 0%); and AST/ALT increase (47%; 6%). Infections occurred in 35% with no grade $\geq$3 events. Ocular AEs by keratopathy visual acuity scale included grade 1 (14%), grade 2 (29%), grade 3 (36%). No patients discontinued treatment for AEs or ocular toxicity. **Conclusions:** This is the first report in RRMM for the combination of belamaf with a CD38 monoclonal antibody. The ISABELA regimen shows promising preliminary activity in RRMM with an ORR of 86% and 16-month PFS of 73%, including quad-class-exposed pts treated with anti-BCMA therapy, with manageable, reversible AEs. Clinical trial information: NCT05922501. Research Sponsor: GSK; Sanofi.

Safety and reliability of isatuximab subcutaneous on-body injector: Results across the phase 3 IRAKLIA, phase 2 IZALCO and phase 1b TCD15484 trials. First Author: Xavier P. Leleu, University Hospital, Poitiers, France

Background: Subcutaneous (SC) drug delivery options have become more widely available in multiple myeloma (MM). SC delivery of isatuximab (Isa), an anti-CD38 monoclonal antibody, has been investigated across clinical trials via a novel hands-free on-body injector (OBI). Isa SC OBI features a small, retractable needle, establishing the first device-enabled delivery of an oncologic treatment. The Phase 3 IRAKLIA, Phase 2 IZALCO, and Phase 1b (TCD15484) trials consistently demonstrated similar efficacy and safety of Isa SC OBI vs Isa IV in relapsed/refractory MM (RRMM) patients (pts). Here, we present a cross-trial analysis exploring safety and reliability of Isa SC OBI in RRMM pts. **Methods:** Pts with RRMM in IRAKLIA (N=263) and the Phase 1b expansion cohort (N=22) received 1400 mg Isa SC OBI plus pomalidomide and dexamethasone (d). In IZALCO, RRMM pts (N=64) received 1400 mg Isa SC OBI + carfilzomib (K)-d. Pts were monitored for 4 hrs (IRAKLIA) or 1-2 hrs (IZALCO) following first administration and for 1 hr for the following cycle (C) 1 administrations to assess local tolerability. Pre-infusion medications included montelukast (C1), steroids, acetaminophen and H1 antihistamines. Pts without systemic infusion-related reactions (IRRs) after 4 consecutive administrations of Isa SC OBI had subsequent pre-medication reassessed at investigator's discretion. Safety and device performance explored in this cross-trial analysis of company sponsored studies were assessed in the Isa SC OBI cohorts by the duration of injection, IRRs, local injection-site reactions (ISRs), and injection/device success, which were defined similarly across all trials. **Results:** The median duration of Isa SC OBI injection was 13 mins in IRAKLIA, 12 mins in IZALCO, and 10 mins in the Phase 1b trial (6426 total injections, N=349 pts). IRRs across trials occurred in 6/6426 (0.09%) injections and 4/349 (1.15%) pts. IRRs were mostly grade 1 (G; 3/6426, 0.05%) with 1 G3 (0.02%); none leading to discontinuation. In IRAKLIA, 80/263 (30.4%) pts did not require premedication (931/5145 injections, 18.1%); no IRRs occurred in this group. Across trials, ISRs occurred in 21/349 (6.02%) pts resulting in 35 (0.54%) ISR events. Most ISRs were G1 (33, 0.51%), the remaining were G2 (2, 0.03%) and generally occurred on the day of injection. 99.9% (6421/6426) of injections in 98.6% (344/349) pts were successful (completed without interruption) across all trials. **Conclusions:** These findings support overall low, self-limiting rates of IRRs and ISRs across trials, with $>$6000 (99.9%) Isa SC OBI injections successfully delivered. Isa SC OBI shows reproducible safety and reliability in IRAKLIA, IZALCO and Phase 1b trials, supporting it as a novel administration option for MM pts and its potential for future exploration in at-home administration. Clinical trial information: NCT04045795, NCT05405166, and NCT05704049. Research Sponsor: Sanofi.

Updated results from the phase 2 IZALCO study: Efficacy and safety of isatuximab subcutaneous plus carfilzomib and dexamethasone in relapsed/refractory multiple myeloma. First Author: Marcelo Capra, Centro Integrado de Hematologia e Oncologia, Hospital Mãe de Deus, Porto Alegre, Brazil

Background: In combination with conventional doublet and triplet therapy, isatuximab (Isa) provides significant benefit to patients (pts) across the multiple myeloma (MM) spectrum. Subcutaneous (SC) administration of Isa could be a more convenient option for pts and caregivers. The Phase (Ph)3 IRAKLIA trial in relapsed/refractory MM (RRMM) pts demonstrated non-inferiority in efficacy and pharmacokinetics of Isa SC delivered via a wearable on-body injector (OBI) in combination with pomalidomide and dexamethasone (Pd) vs Isa IV Pd. The Ph2 IZALCO study (NCT05704049) also showed efficacy and safety of Isa SC plus carfilzomib and dexamethasone (Kd), either by manual or OBI injections, in RRMM pts. Following exposure to both methods, pts showed higher preference for OBI vs manual SC injection. Here we present updated efficacy and safety results from IZALCO. **Methods:** Isa SC 1400 mg was given weekly in Cycle (C)1 then biweekly. In Part 1, pts received Isa injected SC manually. In Part 2, pts were randomized to Isa administered SC via OBI (Isa SC OBI; C1-C3) followed by manual SC injection (C4-C6), or to manual SC injection (C1-C3) followed by Isa SC OBI (C4-C6). Starting at C7, pts could choose either treatment method. All pts were treated with carfilzomib (20 mg/m^2 on Day [D]1-2 then 56 mg/m^2 on D8-9, 15-16 at C1, then D1-2, 8-9, and 15-16) and dexamethasone (20 mg on D1-2, 8-9, 15-16, and 22-23). **Results:** A total of 74 RRMM pts were enrolled (8 in Part 1; 66 in the randomized cohort, Part 2). At the data cut-off of November 10, 2025, 59 pts remained on study. At study entry, pts had median age of 65 (44-85) years, median weight of 75.9 (40.0-129.0) kg, and median of 1 prior line of therapy (1-5), and 56.8% had ISS stage I. The median duration of Isa SC OBI administration was 12 mins and manual SC injection was 6 mins. None of the Isa SC injections, manual or OBI, were interrupted. Median time to best response was 5.3 months (mos) (95% CI: 3.25-6.24). At median follow-up of 21.9 mos, median PFS was not reached (NR) (95% CI: 16.23-NR). PFS at 18 mos was 61.5% (95% CI: 48.7–72.0). OS at 18 mos was 80.8% (95% CI: 69.8-88.2); median OS was not reached (95% CI: NR-NR). Overall, grade (G) ≥3 TEAEs occurred in 66.2%, and serious TEAEs in 51.4% pts. Infusion reaction (IR) on C1D1 occurred in 2 pts (2.7%) with manual SC injections; no IRs occurred with OBI. Six (8.1%) pts had 13 injection-site reactions (ISR), all G1, in 2425 (0.54%) manual or OBI injections. Only 1 ISR was deemed related to OBI. Pt satisfaction with injection method remained consistently high with Isa SC OBI up to C25D15. **Conclusions:** Updated results of the IZALCO study continue to show the efficacy and safety of Isa SC plus Kd delivered either by manual injection or Isa SC OBI, while demonstrating high pt satisfaction and preference for Isa SC OBI. These findings are consistent with those reported in the Ph3 IKEMA study (Isa IV plus Kd). Clinical trial information: NCT05704049. Research Sponsor: Sanofi.

Durable clinical benefit with B-cell maturation antigen (BCMA)–directed therapy, belantamab mafodotin plus pomalidomide and dexamethasone (BPd) in relapsed/refractory multiple myeloma (RRMM): DREAMM-8 long-term responder (LTR) analysis. First Author: Meletios A. Dimopoulos, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece; Department of Medicine, Korea University, Seoul, South Korea

Background: BCMA–directed therapies have changed the RRMM treatment landscape. In the phase 3, open-label, randomized DREAMM-8 trial (NCT04484623), BPd demonstrated significant progression-free survival (PFS) benefit compared with pomalidomide, bortezomib, and dexamethasone (PVd) in patients (pts) with RRMM who received ≥1 prior line of therapy (LOT). This post hoc analysis examined the characteristics of and outcomes in pts achieving sustained clinical benefit with BPd. **Methods:** DREAMM-8 is an ongoing, phase 3, open label study evaluating BPd and PVd in pts with RRMM with ≥1 prior LOT, including lenalidomide. Pts were randomized 1:1 and treatment continued until disease progression, unacceptable toxicity, withdrawal of consent, or death, whichever occurred first. The primary endpoint was PFS; secondary endpoints included minimal residual disease (MRD) negativity (10^{-5}), PFS2, response rates, and safety. LTRs were pts with PFS ≥30 months (data cutoff: July 7, 2025; median follow up 36 months in both arms). **Results:** Of the 302 pts in DREAMM-8 (BPd, n=155; PVd, n=147), 81 were LTRs. The BPd arm had more than twice the proportion of LTRs (n=59 [38%]) as the PVd arm (n=22 [15%]). Baseline characteristics between treatment arms were generally well balanced. In LTRs, median PFS potentially favored BPd (not reached [NR]; 95% CI, NR-NR) vs PVd (NR; 95% CI, 42.7 months-NR), with a hazard ratio (HR) of 0.72 (95% CI, 0.20-2.53). BPd LTRs continued to demonstrate potential benefits after the first subsequent therapy, with median PFS2 (95% CI) of NR (NR-NR) in the BPd LTR arm and NR (44.2 months-NR) in the PVd LTR arm (HR, 0.33; 95% CI, 0.07-1.69). LTRs treated with BPd vs PVd had deeper responses: 76% vs 59% had complete response or better (≥ CR), 56% vs 32% had MRD negativity plus ≥ CR overall (73% vs 54% of pts with ≥ CR), and 39% vs 18% had sustained MRD negativity for ≥12 months, respectively. A higher proportion of pts with high-risk cytogenetics (ie, ≥1 of t[4;14], t[14;16], or del[17p13]) treated with BPd vs PVd achieved long-term response (27% vs 11%). The safety profile in LTRs was generally consistent with that previously reported. **Conclusions:** More than one-third of pts treated with BPd achieved LTR status, representing a 2.5-fold higher rate than with PVd, with similar rates in pts with high-risk cytogenetics; median PFS with BPd remains unreached. These findings suggest that this broadly accessible BCMA-targeted regimen delivers potential durable clinical benefit, characterized by deep and sustained disease-free survival. Clinical trial information: NCT04484623. Research Sponsor: Sponsored by GSK. Editorial support provided by Nucleus Global, an Inizio company and funded by GSK (study ID 207499). Drug linker technology licensed from Seagen Inc.; monoclonal antibody produced using POTELLIGENT Technology licensed from Biowa.

PFS2 outcomes by prior therapy from DREAMM-8: A phase 3 study assessing belantamab mafodotin (belamaf), pomalidomide, and dexamethasone (BPd) vs pomalidomide, bortezomib, and dexamethasone (PVd) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). First Author: Güldane Cengiz Seval, Department of Hematology, Ankara University, Ankara, Turkey

Background: B-cell maturation antigen (BCMA)–directed therapies have transformed the treatment landscape in RRMM. Belamaf, a BCMA-targeting antibody-drug conjugate, in combination with Pd significantly improved progression-free survival (PFS) vs PVd (hazard ratio [HR], 0.52; 95% CI, 0.37-0.73; $P<0.001$) in pts with RRMM in DREAMM-8 (median follow-up, 22 mo). This PFS benefit was maintained with extended follow-up (HR, 0.49; 95% CI, 0.36-0.67; median follow-up 36 mo); median PFS2 also favored BPd vs PVd (47.1 vs 21.7 mo, respectively; HR, 0.52; 95% CI, 0.38-0.70), indicating sustained clinical benefit over time. We report PFS2 outcomes from DREAMM-8 in subgroups based on prior therapy to further understand the long-term impact of BPd and inform treatment sequencing. **Methods:** DREAMM-8 (NCT04484623) is a phase 3, randomized, open-label study evaluating BPd vs PVd in pts with RRMM with ≥1 prior line of therapy including lenalidomide (LEN). Pts could not have received prior BMCA-targeted therapy. PFS2 was defined as time from randomization to disease progression after initiation of subsequent antimyeloma therapy or death. PFS2 was assessed based on prior-treatment subgroups. **Results:** In the BPd arm (DCO: Jul 7, 2025; median follow-up, 36 mo), PFS2 benefit was maintained in all subgroups, including pts who were LEN refractory and anti-CD38 exposed/refractory. In LEN-refractory pts, BPd treatment led to almost a 3-fold median PFS2 improvement vs PVd (41.7 vs 15.0 mo). A total of 56/155 pts (36%) in the BPd arm and 93/147 (63%) in the PVd arm received any first subsequent therapy (FST) at data cutoff. Across both arms, 36% of pts received steroids, 28% received anti-CD38 therapies (>50% of pts with any subsequent therapy in each arm), and 23% received proteasome inhibitors as FST. A total of 21 pts (7%) received novel therapies (BPd, n=6 [4%]; PVd, n=15 [10%]) as FST, including BCMA-targeted bispecific antibodies (bsAbs), non-BCMA bsAbs, CELMoDs, venetoclax, and belamaf. Improved median PFS2 was observed in patients who had novel therapies as FST (n=21) vs non-novel agents (n=128) (26.0 vs 20.1 mo; HR, 0.61; 95% CI, 0.34-1.09). **Conclusions:** BCMA-directed therapy, BPd, resulted in improved PFS2 outcomes vs PVd, demonstrating sustained clinical benefit beyond initial belamaf therapy. This benefit was seen regardless of prior treatment, with LEN-refractory pts experiencing almost a 3-fold PFS2 benefit, and despite a higher proportion of pts receiving novel therapies as FST in the PVd arm. PFS2 benefit with high use of subsequent anti-CD38 agents supports sequencing of belamaf combinations early in the treatment paradigm prior to anti-CD38 agents. Research Sponsor: Sponsored by GSK. Editorial support provided by Nucleus Global, an Inizio company and funded by GSK (study ID 207499). Drug linker technology licensed from Seagen Inc.; monoclonal antibody produced using POTELLIGENT Technology licensed from Biowa.

Real-world one-year comparative outcomes of quadruplet and triplet induction regimens in older, transplant-ineligible multiple myeloma patients. First Author: Okan Cetin, Boston Medical Center, Boston, MA

Background: Older patients with newly diagnosed multiple myeloma (MM) frequently experience early treatment discontinuation due to toxicity, comorbidities, and frailty. Although randomized trials support anti-CD38-based induction regimens, real-world comparative data evaluating early clinical outcomes in older, transplant-ineligible patients remain limited. **Methods:** We conducted a retrospective, multi-institutional cohort study using TriNetX, including adults aged ≥70 years with newly diagnosed MM after 2019 who initiated treatment within two months of diagnosis and did not undergo autologous stem cell transplantation. We performed two matched comparative analyses: Dara-RVd versus RVd and Dara-RVd versus Dara-Rd. We first assessed the proportion of patients initiating second-line therapy at 12 and 24 months. Analyses were then restricted to patients who remained on first-line therapy for at least one year to evaluate early clinical outcomes, including all-cause mortality and healthcare utilization (emergency department [ED] visits, ICU admissions, and bacterial infection or sepsis). Matching included demographics, comorbidities, presence of extramedullary plasmacytoma, and baseline laboratory values (LDH, albumin, β2 microglobulin, creatinine, and hemoglobin), BMI and recent hospitalization. Hazard ratio (HR) and risk ratio (RR) with 95% confidence intervals (CI) were reported. **Results:** Compared with RVd, Dara-RVd showed similar second-line initiation within 12 months (13% vs 14%; p=0.857) and 24 months (14% vs 19%; p=0.086). Among 768 matched patients per group who remained on first-line therapy at one year (mean age 75 years), Dara-RVd was associated with lower 1-year all-cause mortality (12% vs 17%; HR 0.70; 95% CI 0.55–0.90) and reduced healthcare utilization, including ≥1 ED visit (30% vs 36%; RR 0.85; 95% CI 0.73–0.98) and ICU admission (8% vs 12%; RR 0.70; 95% CI 0.52–0.95), while infection rates were similar. Compared with Dara-Rd, Dara-RVd showed comparable second-line initiation within 12 months (13% vs 10%; p=0.126) and 24 months (15% vs 11%; p=0.218). Among 511 matched patients per group who remained on first-line therapy at one year (mean age 76 years), no significant differences were observed in 1-year all-cause mortality or healthcare utilization outcomes. **Conclusions:** In older, transplant-ineligible patients with newly diagnosed MM who remained on therapy at one year, Dara-RVd was associated with improved early survival and lower healthcare utilization compared with RVd, while outcomes were comparable to Dara-Rd. Despite the retrospective design and potential unmeasured confounding, these findings support daratumumab-based regimens in older patients. Prospective studies incorporating frailty and early treatment discontinuation are needed to better define optimal induction strategies. Research Sponsor: None.

Comparative efficacy of belantamab mafodotin plus bortezomib and dexamethasone (BVd) vs standard of care in patients with relapsed/refractory multiple myeloma (RRMM). First Author: Joshua Ryan Richter, Mount Sinai, New York, NY

Background: BVd is approved in the United States as a third-line or later (3L+) option for patients with RRMM based on the DREAMM-7 study of BVd vs daratumumab (D) plus bortezomib (V) and dexamethasone (d; DVd). This study aimed to compare the relative efficacy of BVd vs pomalidomide (P) plus Vd (PVd), elotuzumab plus Pd (EPd), isatuximab plus Pd (IsaPd), and idecabtagene vicleucel (ide-cel) in adults with 3L+ RRMM who received a proteasome inhibitor and an immunomodulatory drug. In the absence of head-to-head trials, indirect treatment comparisons (ITCs) can inform on the relative efficacy of regimens. **Methods:** ITCs of progression-free survival (PFS) and overall survival (OS) were conducted using the eligible study populations (only patients with ≥2 prior lines of therapy [LOT]) from the DREAMM-7 (BVd), DREAMM-8 (PVd), ELOQUENT-3 (EPd), ICARIA-MM (IsaPd), and KarMMA-3 (ide-cel) trials. Individual pt data (IPD) were available for patients treated with BVd and PVd, while only published summary data were available for patients treated with EPd, IsaPd, and ide-cel. In base-case analyses, study populations were weighted (using inverse probability of treatment weighting to compare to PVd and matching adjusted indirect comparison for the other treatments) to match in terms of age, prior exposure to bortezomib, prior exposure to lenalidomide, refractoriness to lenalidomide, number of prior LOT, and cytogenetic risk. Weighting was done separately for each comparator treatment. Weighted Cox regression was then performed to compare outcomes of patients treated with BVd to each respective comparator treatment. **Results:** In the base-case models, weighting yielded very good balance for all matched covariates (standardized mean difference <0.25 for each covariate across each comparison, and <0.10 in all cases except for age, prior bortezomib, and >4 prior LOT in the PVd comparison). Hazard ratios for BVd vs EPd, IsaPd, and ide-cel for PFS and OS significantly favored BVd (Table). For BVd vs PVd, PFS significantly favored BVd and OS numerically favored BVd. **Conclusions:** In DREAMM-7, direct comparison of BVd vs DVd showed PFS and OS improvements with BVd. This indirect comparison of patients in the 3L+ setting further showed that BVd improved PFS and OS vs PVd, EPd, IsaPd, and ide-cel. Research Sponsor: GSK.

Age and frailty analyses of transplant-ineligible (TIE) patients (pts) with newly diagnosed multiple myeloma (NDMM) in the phase 3 MAIA and CEPHEUS trials of daratumumab + lenalidomide-dexamethasone (Rd) and bortezomib-Rd (VRd). First Author: Christopher P. Venner, Cross Cancer Institute, University of Alberta, Edmonton, and BC Cancer – Vancouver Centre, University of British Columbia, Vancouver, BC, Canada

Background: MAIA and CEPHEUS trials demonstrated that daratumumab (Dara) with standard of care (SOC) VRd or Rd significantly improved clinical outcomes versus SOC in TIE NDMM. Here we describe efficacy and safety in TIE pts from both trials by age and baseline (BL) frailty using the latest data cuts. **Methods:** Pts were randomized 1:1 to DRd (n=368) or Rd (n=369) in MAIA and 1:1 to DVRd (n=144) or VRd (n=145) in CEPHEUS. Progression-free survival (PFS), complete response or better (≥CR), overall MRD negativity (neg) at 10^{-5} with ≥CR, sustained MRD neg with ≥CR (confirmed MRD neg ≥12 ± 1 months [mo] apart without MRD positivity in between), and safety were assessed by age (<70, 70–<75, or ≥75 years [y]) and BL frailty (assessed by IFM simplified frailty score: 0–1, non-frail; ≥2, frail). **Results:** Median follow-up was 64.5 mo in MAIA and 76.0 mo in CEPHEUS. In MAIA, 155 (21%) pts were <70 y, 261 (35%) 70–<75 y, and 321 (44%) ≥75 y; 341 (46%) pts were frail, 88.0 % of whom were ≥70 y. In CEPHEUS TIE pts, 70 (24%) pts were <70 y, 133 (46%) 70–<75 y, and 86 (30%) ≥75 y; 83 (29%) pts were frail, 86% of whom were ≥70 y. DRd or DVRd improved PFS, MRD neg rates, sustained MRD neg rates, and ≥CR rates vs Rd or VRd arms across age and frailty subgroups in both trials (Table). Safety was consistent with established individual drug profiles, and adverse event rates were generally comparable across treatment arms and subgroups within both trials. Additional data on patient-specific factors relevant to these subgroups will be presented. **Conclusions:** Dara-based regimens improved efficacy outcomes across subgroups in MAIA and CEPHEUS trials, reinforcing Dara-based regimens as SOC in TIE NDMM regardless of age or frailty. These data offer clinically relevant insights to help guide treatment selection for TIE pts. Clinical trial information: NCT03652064; NCT02252172. Research Sponsor: Johnson & Johnson.

Minimal residual disease dynamics in newly diagnosed multiple myeloma and impact on progression-free survival: A cohort study. First Author: Panagiotis Malandrakis, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Minimal residual disease (MRD) is a sensitive tool for evaluating treatment response in multiple myeloma (MM) and is a surrogate marker of progression-free survival (PFS) and overall survival (OS). Consecutive MRD evaluations offer important information regarding the depth and the duration of response to treatment and can be used to guide the patients' management. **Methods:** This single center, retrospective study included patients with newly diagnosed MM (NDMM), who were evaluated with at least 3 consecutive MRD tests. Four subgroups of patients were identified: sustained MRD positive (sMRDpos), sustained MRD negative (sMRDneg), converted to MRD negative (conMRDneg) and converted to MRD positive (conMRDpos). The aim of the study was to compare PFS between groups. **Results:** Overall, 335 NDMM patients were included in the analysis. The median age at diagnosis was 59 years (range 35-89), and the median number of assessments was 5 (range 3-14). Regarding risk stratification, 56 (16.7%) were ISS-3, and 52 (15.5%) were labeled as high-risk per the novel IMS/IMWG HRMM criteria. The median number of MRD evaluations in each patient was 5 (range 3-13). One third received quadruplet regimen. The median follow-up of the cohort was 6.1 years. Patient distribution according to MRD status was as follows: 191 (57%) sustained negativity, 40 (12%) sustained positivity, 53 (15.8%) converted to negative, whereas 51 (15.2%) converted to positive. Median PFS and OS were not achieved in any of the MRD subgroups. Sustained MRD negativity was associated with superior PFS compared to all the other subgroups (HR=0.21, 95% CI: 0.10 – 0.42, p<0.001). Sustained MRD positivity was associated with significantly inferior PFS compared to sMRDneg (HR=4.84; 95% CI: 1.91 – 12.30, p<0.001) and conMRDpos had also inferior PFS compared to the sMRDneg (HR= 6.04, 95% CI: 2.74 – 13.31, p<0.001). Furthermore, the presence of at least one MRD positive, at any time-point, was associated with inferior PFS compared to the sMRDneg (HR= 4.29, 95% CI: 2.05 – 8.99, p<0.001). Among the sustained MRD negative patients, high risk cytogenetics yielded a trend towards worse PFS (HR= 1.42. 95% CI: 0.30 - 6.69, p=0.659), possibly suggesting that sMRDneg overrides high risk cytogenetics. Finally, among the 165 patients who sustained MRD negativity, the median number of MRD tests were 5 (range 3-14). Among these patients with more than 5 tests had superior PFS, compared to less than 5, with a HR= 0.04, 95% CI: 0.01 – 0.33, p=0.003 signaling no further need of additional consecutive MRD testing in such patients. **Conclusions:** In patients with NDMM in the real-world setting, sustained MRD negativity is associated with prolonged PFS, even in HR patients, whereas the presence of even one MRD positive result impacted PFS. Research Sponsor: None.

Exploratory associations between incretin-based therapies and plasma cell disorders in patients with type 2 diabetes: A real-world study. First Author: Yousef Ateiwi, University of Jordan, Amman, Jordan

Background: Incretin-based therapies, including dipeptidyl peptidase-4 inhibitors (DPP-4i) and glucagon-like peptide-1 receptor agonists (GLP-1RAs), are widely used in the management of type 2 diabetes mellitus (T2DM). Experimental and clinical data suggest that metabolic and immune pathways may influence plasma cell dyscrasia development, yet the relationship between incretin-based therapies and monoclonal gammopathy of undetermined significance (MGUS) or multiple myeloma (MM) remains unclear. In this study, we aimed to evaluate the association between incretin-based therapy exposure and the risk of MGUS and MM. **Methods:** A multicenter, retrospective cohort study was conducted using the TriNetX Global Collaborative Network, a federated electronic health record database, between January 1, 2015, and December 31, 2025. Adult patients with T2DM were categorized into six exposure cohorts. Individuals treated with GLP-1RAs with a minimum of one year of therapy were compared with patients initiating sodium–glucose cotransporter-2 inhibitors (SGLT2i), sulfonylureas (SU), and thiazolidinediones (TZDs). The same cohort design was applied to DPP-4i users. A 1:1 propensity score matching (PSM) model was applied to minimize confounding by balancing baseline demographics, clinical comorbidities, laboratory parameters, and concurrent medication use. Individuals with a prior cancer diagnosis were excluded. The primary endpoint was progression to MM, and the secondary endpoint was the development of MGUS. Statistical analyses were performed within the TriNetX platform. **Results:** After 1:1 PSM, GLP-1RA therapy was associated with a significantly lower risk of both MGUS and MM compared with SU (n = 141,225 per group; MGUS RR 0.59, 95% CI 0.50–0.69; MM RR 0.84, 95% CI 0.77–0.92) and SGLT2i (n = 57,919 per group; MGUS RR 0.75, 95% CI 0.65–0.86; MM RR 0.62, 95% CI 0.49–0.79). No significant differences in MGUS or MM risk were observed when GLP-1RAs were compared with TZDs. In contrast, DPP-4i use was associated with aincreased risk of MM compared with TZDs (n = 29,462 per group; RR 1.93, 95% CI 1.40–2.66) and SGLT2i (n = 68,481 per group; RR 1.44, 95% CI 1.19–1.74).No significant associations were observed for MGUS across comparators, and no significant differences in MGUS or MM risk were seen between DPP-4i and SU (Table 1). **Conclusions:** In patients with T2DM, GLP-1RA exposure were associated with differential rates of MGUS and MM diagnosis across antihyperglycemic drug classes. GLP-1RA was associated with a lower rates of MGUS and MM compared with SU and SGLT2i, whereas DPP-4i use was associated with higher MM rates when compared with SGLT2i and TZDs. While these findings are clinically promising, prospective studies are needed to confirm causality and clarify underlying mechanisms. Research Sponsor: None.

Incretin-based therapies and all-cause mortality and progression to multiple myeloma in patients with MGUS and type 2 diabetes: A real-world cohort study. First Author: Yousef Ateiwi, University of Jordan, Amman, Jordan

Background: Monoclonal gammopathy of undetermined significance (MGUS) progresses to multiple myeloma (MM) at an estimated rate of approximately 1–2% per year. Emerging evidence suggests metabolic dysfunction, including type 2 diabetes mellitus (T2DM) may influence the trajectory of progression to MM.Incretin based therapies have immunomodulatory and metabolic effects that could modify outcomes in patients with plasma cell dyscrasias. We conducted this study to evaluate the association between incretin-based therapies and the risk of progression to MM and all-cause mortality among patients with MGUS and T2DM. **Methods:** A multicenter, retrospective cohort study was conducted using the TriNetX Global Collaborative Network, a federated electronic health record database, from January 1, 2015, to December 31, 2025. Adult patients with T2DM and MGUS who had at least one year of treatment exposure to incretin-based therapies both before and after MGUS diagnosis were included. Patients were categorized into six exposure cohorts. Outcomes among glucagon-like peptide-1 receptor agonist (GLP-1RA) and dipeptidyl peptidase-4 inhibitor (DPP-4i) users were compared with matched cohorts receiving sulfonylureas (SU), sodium–glucose cotransporter-2 inhibitors (SGLT2i), and thiazolidinediones (TZDs). Individuals with a prior cancer diagnosis were excluded. A 1:1 propensity score matching (PSM) approach was applied to balance demographics, comorbidities, laboratory parameters, and concurrent medication use. The primary outcome was all-cause mortality, and the secondary outcome was progression to MM. All statistical analyses were performed within the TriNetX platform. **Results:** After 1:1 PSM, GLP-1RA use was associated with lower all-cause mortality compared with SU (n = 393 per group; RR 0.35, 95% CI 0.25–0.49). No significant differences were observed in all-cause mortality or progression to MM when GLP-1RAs were compared with SGLT2i or TZDs. In contrast, DPP-4i use was associated with significantly higher all-cause mortality compared with SGLT2i (n = 315 per group; RR 2.53, 95% CI 1.77–3.62) and TZDs (n = 120 per group; RR 2.37, 95% CI 1.27–4.44). DPP-4i exposure was not significantly associated with progression to MM across any comparator group. **Conclusions:** Among patients with T2DM and MGUS, GLP-1RA use was associated with significantly lower all-cause mortality compared with SU, whereas DPP-4i use was associated with increased mortality compared with SGLT2i and TZDs, with no significant effect on progression to MM. These findings suggest a clinically meaningful survival differences across antihyperglycemic therapies and should be validated in future prospective studies. Research Sponsor: None.

Early intravenous immunoglobulin use in multiple myeloma patients treated with talquetamab: Effect on risk of infections and mortality. First Author: Joseph OBrien, Denver Health Medical Center, Denver, CO

Background: Bispecific T-cell–engaging (BiTE) antibodies have transformed the treatment of relapsed or refractory multiple myeloma (MM) but are associated with high rates of infectious complications. Talquetamab, a GPRC5D-directed BiTE, induces immune dysfunction but has been shown to be associated with less infection risk than anti-BCMA BiTEs. Although there is evidence supporting prophylactic intravenous immunoglobulin (IVIG) use for pts receiving anti-BCMA BiTEs, there is limited data assessing the benefit of early IVIG use in patients treated with talquetamab. **Methods:** A retrospective multicenter cohort study using the TriNetX Research Network to evaluate outcomes among adults with MM treated with talquetamab. Patients who received IVIG within 4 weeks of talquetamab initiation were compared to those who did not receive IVIG within 4 weeks. Propensity score matching was performed which included comorbidities, demographics, prior therapies (PIs, ImIDs, anti-CD38 abs, other BiTEs, belantamab, SCTx and CAR T), lab markers of disease severity, IgG levels, EM disease and plasma cell leukemia. Primary outcomes were 1-year all-cause mortality and infection incidence. Secondary outcomes included infection subtypes and ICU admission. Multivariable Cox proportional hazards models were used to identify independent associations. **Results:** Among 834 pts treated with talquetamab, 305 received IVIG within 4 wks of initiation. After propensity score matching, 271 patients remained in each cohort with balanced baseline characteristics. Early IVIG use was associated with lower 1-year mortality (14.8% vs. 26.7%; OR, 0.48; 95% CI, 0.31–0.74) and fewer infections of any type (41.7% vs. 55.0%; OR, 0.59; 95% CI, 0.42–0.82). Reductions were most pronounced for respiratory and bloodstream infections. In multivariable analysis, early IVIG remained independently associated with lower hazard of mortality (HR, 0.52; 95% CI, 0.37–0.73). In addition, a sub-analysis comparing early IVIG with no IVIG exposure within 1 year found similar findings. **Conclusions:** Early IVIG administration following talquetamab initiation was associated with reduced infection risk and improved survival in a large real-world cohort. These findings support consideration of early IVIG as part of routine supportive care for patients receiving talquetamab. Research Sponsor: None.

Outcome (after propensity matching)	IVIG within 4 weeks (n=271)	No IVIG within 4 weeks (n=271)	OR	95% CI	P-value
1-year mortality	40 (14.8)	72 (26.7)	0.48	0.31–0.74	0.0008
Any infection	113 (41.7)	149 (55.0)	0.59	0.42–0.82	0.002
Respiratory infections	37 (13.6)	55 (20.3)	0.62	0.39–0.98	0.04
Bloodstream infections	39 (14.4)	61 (22.5)	0.58	0.37–0.90	0.016
Opportunistic infections	13 (4.8)	10 (3.6)	1.31	0.57–3.05	>0.2
Skin & Soft Tissue infections	12 (4.4)	10 (3.6)	1.21	0.51–2.85	>0.2
Urinary tract infections	12 (4.4)	13 (4.8)	0.92	0.41–2.05	>0.2

Comparative safety and efficacy of DKRd versus DVRd regimens in multiple myeloma: A systematic review and meta-analysis. First Author: M. Bakri Hammami, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: The addition of anti-CD38 monoclonal antibodies to proteasome inhibitor–based triplet regimens, such as bortezomib-lenalidomide-dexamethasone (VRd) and carfilzomib-lenalidomide-dexamethasone (KRd), has improved depth of response, minimal residual disease (MRD) negativity, and survival in newly diagnosed multiple myeloma (NDMM). Comparative data on the efficacy and safety of daratumumab-KRd (DKRd) versus daratumumab-VRd (DVRd) are limited. We performed a systematic review and meta-analysis to evaluate these regimens in patients with NDMM. **Methods:** Following PRISMA guidelines, we searched PubMed, Scopus, Web of Science, and Embase from inception to November 2025 for clinical trials and observational studies of patients with NDMM treated with DVRd or DKRd. Outcomes included progression-free survival (PFS), overall survival (OS), MRD negativity, tumor response, and safety. Two independent reviewers screened studies and extracted data from each included article. Meta-analyses were done using R version 4.3.0. Heterogeneity was assessed using Cochrane's Q-test and I2. **Results:** Sixteen studies involving 2114 patients were included. Two-year OS was comparable between regimens (DKRd: 94.12%; DVRd 94.17%; p=0.979) while two-year PFS favored DVRd (92.76% vs 85.04%; p<0.001). At 10-5 sensitivity, post-induction MRD negativity was higher with DKRd (57.10% vs 28.60%; p=0.004). DVRd achieved superior post-induction (98.94% vs 94.62%; p<0.001) and best overall responses (98.96% vs 95.10%; p=0.019). Safety outcomes generally favored DKRd, with fewer serious adverse events (32.79% vs 60.51%; p<0.001) and grade ≥3 adverse events (77.78% vs 90.34%; p<0.001). Grade ≥3 neutropenia (50.78% vs 30.90%; p<0.001) and thrombocytopenia (25.51% versus 9.62%; p=0.005) were more common with DVRd. Treatment discontinuation rates favored DKRd (1.94% versus 8.23%; p=0.015). Mortality remained low in both arms (1.41% versus 3.00%; p=0.403). **Conclusions:** In NDMM, DKRd achieved deeper early MRD responses and better tolerability, whereas DVRd provided superior two-year PFS and overall response rates. Treatment selection should balance efficacy against toxicity. Research Sponsor: None.

Plasma exchange in myeloma-associated acute kidney injury: A multicenter propensity-matched cohort study. First Author: Jarred Madison Boone, Division of Hematology and Oncology, University Hospitals Seidman Cancer Center, Cleveland, OH

Background: Acute kidney injury (AKI) in newly diagnosed multiple myeloma (MM) is frequently driven by light chain cast nephropathy and associated with dialysis dependence and early mortality. Plasmapheresis or plasma exchange (either one referred to here as PLEX) have been used to accelerate free light chain (FLC) removal, despite inconsistent evidence of clinical benefit. Whether PLEX improves renal or survival outcomes in the modern treatment era remains uncertain. **Methods:** A retrospective multicenter cohort study using the TriNetX Research Network identified newly diagnosed MM pts from 2014-2024 presenting with AKI (an ICD-10 code for acute renal failure or Cr > / = 3.0 mg/dL and a 6 mo prior Cr < 1.5) and laboratory evidence of light chain cast nephropathy (defined as a free light chain concentration > 1,500 mg/L). Pts were included if they received PLEX within 7d of diagnosis, and were compared to those who did not receive PLEX. Pts were excluded if they had pre-existing end stage renal disease. Propensity score matching included demographics, comorbidities, myeloma therapies and laboratory values (Cr, calcium, albumin, hgb). **Results:** Among 5,454 eligible pts, 251 (4.6%) received PLEX (81% were plasma exchange and 19% were plasmapheresis). After propensity score matching, 248 pts were included in each group with well-balanced baseline characteristics (ex: ave Cr 4.1 and 4.2 in the PLEX vs no PLEX groups, respectively; 38% received PIs in each group). PLEX was not associated with reduced dialysis dependence at 90 days (16.1% vs 18.1%; odds ratio [OR] 0.87, 95% confidence interval [CI] 0.54–1.39) or 180 days (18.5% vs 20.2%; OR 0.90, 95% CI 0.58–1.41). Mortality at 90 (17.7% vs 15%) and 180 days (23.4% vs 23.9%) and ICU admission rates (20% vs 21%) were similar between groups. Dialysis-free survival over 180 days did not differ. Findings were consistent across all prespecified sensitivity analyses, including pts receiving early PI-based therapy and those with extreme free light chain burden (FLC > 5000mg/L, 28% of total cases), with no differences in dialysis dependence or survival. Patients treated with PLEX were numerically more likely to achieve creatinine < 2.0 mg/dL at both 90 days (83.9% vs 77.4%; OR 1.81, 95% CI 0.97–2.38; p = 0.07) and 180 days (86.3% vs 79.8%; OR 1.59, 95% CI 0.98–2.56; p = 0.06), but these differences did not reach statistical significance, except for those with FLC > 5000 (at 90d: 77% vs 63%, p = 0.02; and at 180d: 83% vs 66%, p = 0.006). **Conclusions:** In this large, contemporary, real-world retrospective cohort, PLEX was not associated with significantly improved renal recovery, dialysis-free survival, or mortality among patients with newly diagnosed myeloma-associated AKI due to light chain nephropathy. These results support current guidelines emphasizing rapid initiation of effective anti-myeloma therapy rather than routine extracorporeal light chain removal. Research Sponsor: None.

Trends in frontline treatment patterns for multiple myeloma among US veterans, 1999–2025. First Author: Byron Seiya Sigel, Washington University School of Medicine, St. Louis, MO

Background: Frontline treatment for multiple myeloma (MM) has evolved substantially, transitioning from alkylating therapy to newer therapeutic classes, including immunomodulatory drugs, proteasome inhibitors, and monoclonal antibodies. Despite these advances, real-world treatment patterns remain heterogeneous, and MM therapies carry substantial toxicity and costs. Using nationwide Veterans Health Administration (VHA) data, an integrated health system with longitudinal follow-up, we characterized frontline treatment patterns for MM among US Veterans from 1999 to 2025. **Methods:** We identified Veterans diagnosed with MM in the VHA from 1999 to 2025. Diagnoses were confirmed using a published and validated natural language processing (NLP) algorithm, with the index date defined as the first MM-specific treatment, excluding dexamethasone alone. Patients receiving no MM-specific therapy or dexamethasone alone were excluded. Frontline treatments were defined as treatments initiated within 30 days of the index date. Treatments were captured using VA inpatient and outpatient pharmacy files, inpatient and outpatient procedure records for injectable agents, Fee Basis and Community Care data, and CMS Medicare Part D claims. Because the VHA does not require insurance approval, a 30-day window was used to define frontline treatment. Hematopoietic stem cell transplant was excluded to focus on trends in frontline treatments. MM-specific treatments were defined using a clinician-reviewed list of medications and relevant Current Procedural Terminology (CPT) codes. **Results:** We identified 4,738 Veterans with MM from 1999 to 2025. Median age was 72.1 years (IQR 65.1-78.1), and 96.7% were men. Non-Hispanic Black accounted for 20.1%, non-Hispanic White 55.6%, Hispanic 3.0%, and other races 1.5%. Median BMI was 27.6 (IQR 24.3-31.8), and 63.3% lived in urban areas. Melphalan predominated in 1999 (85.3%) but steadily declined. Cyclophosphamide use increased from 10.5% in 1999 to a peak of 29.2% in 2015, followed by a decline to 10.4% in 2024. Thalidomide use peaked in 2005 (61.8%) and declined to near zero by 2017. Lenalidomide use increased after 2006, reaching 78.1% in 2024. Bortezomib increased from 1.2% in 2004, peaking at 49.4% in 2015 and remaining common, whereas carfilzomib and ixazomib were infrequently used ($<$ 6%). Monoclonal antibody use expanded after 2019 with daratumumab, reaching 45.5% in 2024. **Conclusions:** Using national VHA data from 1999 to 2025, we describe real-world frontline MM treatment patterns among US Veterans, illustrating temporal shifts in therapeutic class use, including increasing adoption of monoclonal antibodies within an integrated, longitudinal health system. Research Sponsor: None.

QUINTESSENTIAL-2: A phase 3 study of arlocabtagene autoleucel versus standard of care in adult patients with relapsed and refractory multiple myeloma (RRMM) exposed to lenalidomide. First Author: Eyal Lebel, Hadassah Medical Center, Jerusalem, Israel

Background: Despite advances in multiple myeloma (MM) treatment, most patients (pts) will relapse, highlighting the need for new drug classes in RRMM. Further, with the extensive use of lenalidomide (LEN), an immunomodulatory drug (IMiD), in frontline and maintenance therapies, LEN-refractoriness has become increasingly common and poses an additional challenge as the disease is less likely to respond to subsequent treatment. G protein-coupled receptor class C group 5 member D (GPRC5D) is a promising therapeutic target for MM as the receptor is highly expressed on malignant plasma cells; it has little to no expression on non-plasma cell immune populations and limited expression on other tissues. Arlocabtagene autoleucel (arlo-cel) is a GPRC5D-directed autologous CAR T cell therapy that has demonstrated safety and efficacy in pts with RRMM in a first-in-human phase 1 study. ORR was 94% and 91% in pts with 1-3 and $\geq$3 prior LOT (pLOT), respectively, after a single arlo-cel infusion (150×10^6 CAR T-cells); ORR was 92% in pts with $\geq$3 pLOT following a 75×10^6 CAR T cell infusion. These phase 1 study outcomes support further clinical development of arlo-cel. **Methods:** QUINTESSENTIAL-2 (NCT06615479) is a randomized, open-label, multicenter, phase 3 confirmatory study comparing the efficacy and safety of arlo-cel vs SOC in adults with RRMM and prior LEN. Key inclusion criteria were age $\geq$18 years, confirmed diagnosis of MM per IMWG criteria, 1-3 pLOT (may include a proteasome inhibitor, IMiD, anti-CD38 antibody, and BCMA-targeted therapy), be exposed to LEN ($\geq$2 consecutive cycles, unless PD was the best response to LEN-containing treatment or if there was LEN intolerance or unacceptable toxicity), have measurable disease, and ECOG PS of 0 or 1. Pts who received prior GPRC5D-targeted therapy are excluded. Eligible pts will be randomized 1:1 across 2 arms. Arm A includes leukapheresis within 3-4 days of randomization, mandatory bridging therapy $\leq$6 days of randomization with DPd (daratumumab, pomalidomide, dexamethasone) or Kd (carfilzomib, dexamethasone) per investigator choice and lymphodepleting chemotherapy prior to a single arlo-cel infusion. Arm B includes SOC of DPd or Kd per investigator choice, dosed per labeling, until PD. Primary endpoints are PFS and minimal residual disease (MRD) negativity in CR. Key secondary endpoints include OS and ORR. Other endpoints include safety, MRD-negative status, CR rate, time to response, duration of response, pharmacokinetics, and pt-reported outcomes. Pts will be followed for $\leq$5 years after the last pt is randomized, and with a long-term follow-up study ($\leq$15 years post-infusion) for pts receiving arlo-cel. Anticipated enrollment is 440 pts at ~125 sites globally. The first pt was enrolled in March 2025. ©American Society of Hematology (2025). Reused with permission. Clinical trial information: NCT06615479. Research Sponsor: Bristol Myers Squibb.

TPS7579 **Poster Session**

MOMENTUM: A phase 2, open-label, single-arm, multicenter study to evaluate the efficacy of cemsidomide + dexamethasone in subjects with relapsed/refractory multiple myeloma (RRMM). First Author: Binod Dhakal, Medical College of Wisconsin, Milwaukee, WI

Background: Cemsidomide is a novel, highly potent, cereblon-based, IKZF1/3 MonoDAC degrader, having a similar mechanism of action as BMS's IMiD or CELMoD degraders for MM. Cemsidomide displays catalytic activity enabling rapid and deep target degradation with high binding affinity to overcome resistance due to low cereblon levels. Cemsidomide binds to cereblon to facilitate the recruitment and ubiquitination of IKZF1/3 leading to the proteasomal degradation of both proteins. IKZF1/3 degradation induces multiple myeloma cell death, activation of fully differentiated T-cells which prevents T-cell exhaustion and promotes secretion of key immune stimulating cytokines. In a Phase 1 study, cemsidomide, given orally QD over 14 days with a 14 day "off" period (14/14) in combination with weekly dexamethasone in a heavily pre-treated patient population (7 median prior lines), was well tolerated and demonstrated durable anti-myeloma activity at increasing dose levels. A 53% ORR was observed as the highest dose of 100 μg QD 14/14, with a 36% ORR observed across all dose levels (Dhakal IMS 2025). **Methods:** MOMENTUM (NCT07284758) is a Phase 2 multi-center, open-label, single-arm, global study to further evaluate the anti-myeloma activity as well as safety, tolerability, and PK/PD of cemsidomide. The study will enroll ~100 patients. The patient population eligible for this study include those who have received at least 3 prior antimyeloma regimens, which must have included an IKZF1/3 degrader other than cemsidomide, a proteasome inhibitor, an anti-CD38 antibody, and a TCE or CAR-T therapy (unless not indicated). Prior TCE or CAR-T therapy may be one or more targets including but not limited to: BCMA, GPRC5D, FcRH5, and CD38. Patients must have an ECOG score of $\leq$2, and adequate organ function prior to dosing. Patients will receive cemsidomide 100 μg QD 14/14 and dexamethasone in a 28-day cycle until progressive disease, AE requiring treatment discontinuation, or withdrawal of consent. The primary endpoint of this study is ORR per IMWG response Criteria (IMS 2025) assessed by an Independent Review Committee (IRC). Secondary endpoints include assessment of DOR, PFS, and OS. Exploratory objectives include antimyeloma activity assessed by investigator, degradation of IKF1/3, quantification of protein expression, and patient QoL assessments. Exposure-response relationships between cemsidomide and relevant markers of safety and efficacy will also be analyzed. A safety review committee and an IRC will be established to oversee safety and efficacy throughout the trial. The study is open to enrollment as of December 2025. Clinical trial information: NCT07284758. Research Sponsor: C4 Therapeutics.

TPS7580 **Poster Session**

A phase 1/2 study of mRNA-2808 in participants with relapsed or refractory multiple myeloma. First Author: Hans C. Lee, Sarah Cannon Research Institute, Nashville, TN

Background: Multiple myeloma (MM) remains mostly incurable despite therapeutic advances and relapsed or refractory multiple myeloma (RRMM) remains a significant unmet need. mRNA-2808 is an intravenously (IV) administered mRNA-encoded, multiplexed T-cell engager (TCE) that delivers *in vivo* translation of three distinct TCEs targeting BCMA, GPRC5D, and FcRH5. This multiplexed approach aims to enhance immune-mediated cytotoxicity, overcome tumor heterogeneity and target-mediated resistance. Previous preclinical studies of mRNA-2808 have demonstrated efficient *in vivo* translation of TCEs, potent activity against both primary MM cells *ex vivo* and murine tumor xenografts *in vivo*, and target-cell depletion in non-human primates. Taken together, this supports the clinical evaluation of mRNA-2808. **Methods:** This ongoing, first-in-human, open-label, multicenter Phase 1/2 study evaluates the safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy of mRNA-2808 administered to participants with RRMM. Key eligibility criteria include RRMM with prior exposure to a proteasome inhibitor, an IMiD, and an anti-CD38 monoclonal antibody and are either triple-class refractory or have progressed on or within 60 days of their last line of therapy, have measurable disease including bone marrow plasma cells $>$30% or plasmacytoma $\geq$2cm in size, and ECOG PS 0-2. Prior exposure to BCMA, GPRC5D, or FcRH5 targeted therapies is allowed. The study comprises two parts: Part 1 (dose escalation) to determine the recommended Phase 2 dose(s) (RP2D) and Part 2 (dose expansion) to further assess safety and efficacy of selected RP2D(s). The dose-escalation in Part 1 will proceed in 2 phases: Accelerated Titration Phase (single participant per dose level (DL)) and Standard Titration Phase (at least 3 participants per DL). The Accelerated Titration Phase will continue until a dose limiting toxicity (DLT) or a clinically significant AE of $\geq$Grade 2 is observed. If a $\geq$Grade 2 CRS and/or $\geq$Grade 2 neurotoxicity including ICANS occurs, step-up dosing will be implemented. During the Standard Titration Phase, dosing decisions will be guided by a Bayesian Optimal Interval design based on the observed DLT rate from the current cohort and recommendations from the Safety Review Committee. During Cycle 1 (28-day cycles), mRNA-2808 will be administered IV weekly, and during Cycles 2-12 every 2 weeks. Treatment with mRNA-2808 will continue for up to 12 cycles. Participants who achieve at least a partial response by the end of Cycle 5 may transition to a 4-week dosing schedule at the Investigator's discretion. Additional exploratory endpoints will evaluate surrogates of efficacy, mechanism of action, and characterize exposure. Dose Levels 1 and 2 have been completed without DLT and dose escalation is ongoing (NCT07116616). Clinical trial information: NCT07116616. Research Sponsor: Moderna, Inc.

TPS7581 **Poster Session**

Initial phase 1b/2 study results of purinostat mesylate (PM) in combination with pomalidomide (POM) and low dexamethasone (DEX) in patients with RRMM. First Author: Lijuan Chen, Department of Hematology, State Key Laboratory of Biotherapy and Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: MM remains an incurable disease and resistance mechanisms are emerging. PM is a high selective HDAC I/IIb inhibitor. In phase I study, PM monotherapy had shown good tolerability and efficacy in relapsed/refractory (RR) hematologic malignancies including MM. A phase 1b/2 study is being conducted to further assess the efficacy and safety of PM combined with POM and low DEX (80mg/cycle) in RRMM. **Methods:** The ongoing phase 1b/2 study includes dose escalation followed by dose expansion. Eligible RRMM had received ≥1 prior line of therapy (LOT) including ≥1 PI and ≥1 IMiD. Cohort A (21D cycle) and Cohort B (28D cycle) of the PM combination regimens are assessed using 3+3 escalation design. Pts in Cohort A receive PM at levels of 4, 6, 8.4, 11.2 and 15mg/m^2 IV on D1,4,8,11; POM 4mg QD on D1-14; DEX 20mg on D1,4,8,11. Pts in Cohort B receive PM at same dose range to Cohort A, on D1,4,15,18; POM 4mg QD on D1-21; DEX 20mg on D1,4,15,18. Pts continue to receive PM until disease progression or unacceptable toxicity. Primary outcomes are DLT and ORR. Secondary outcomes include PFS et al. **Results:** As of Dec 23, 2025, 27 Pts were recruited including 6 in Cohort A and 21 in Cohort B. The dose had been escalated to 6mg/m^2 and 11.2mg/m^2 in Cohort A and B. Cohort A: Median age was 61.5 years, 66.7% male, 16.7% had prior ASCT. 2 (33.3%) Pts had high risk cytogenetics, including 1q21 duplication (n=1), t (4;14) (n=1) and 1p32 deletion (n=1). 6 Pts were evaluable with median 1 (1-3) prior LOT. The ORR was 50% with 1 sCR and 2 PR along with 1 MR. With a median F/U of 138 days, the median PFS was 151 days (95% CI, 21-NR). Median DOR was NR. The most common ≥ G3 TEAEs were neutropenia (83.3%), lymphocytopenia (83.3%) and thrombocytopenia (100%). No DLT was reported. Cohort B: Median age was 61.0 years, 57.1% male, 19.1% had prior ASCT and 19.1% had extramedullary disease (EMD). 7 (33.3%) Pts had high risk characteristics, including 1q21 duplication (n=7), t (4;14) (n=2) and early relapse after ASCT (n=3). Median prior LOT is 2 (1-5). Among 16 evaluable Pts, the ORR was 37.5% with 1 sCR, 1 CR, 3 VGPR and 1 PR; additional 4 Pts achieved MR. In 7 Pts given the dose of 8.4mg/m^2, the ORR was 42.9% with 3 VGPR; 3 more Pts achieved MR. With median F/U of 104 days, the median PFS and DOR were NR. The most common ≥ G3 TEAEs were neutropenia (81.0%), lymphocytopenia (61.9%) and thrombocytopenia (38.1%). 1 DLT (G4 neutropenia) was reported. Moreover, in 4 Pts with EMD, 2 achieved objective response. In 4 Pts with super high risk (Double or Triple Hit/early relapse), 1 achieved sCR and 1 achieved VGPR. 1 Pt with prior 5-line therapy including BCMA-ADC had shown VGPR after treatment. **Conclusion:** PM as a highly selective HDACi in combination with POM and low DEX shown encouraging efficacy and safety in RRMM. Complicated cases with EMD, super high-risk characteristics or heavily pretreatment can benefit from the PM triplet therapy. Clinical trial information: NCT06484829. Research Sponsor: None.

TPS7582 **Poster Session**

A phase 1b/2 study of mirdametinib in combination with sirolimus for patients with RAS-mutated relapsed/refractory multiple myeloma. First Author: Roshani Patel, National Institute of Health, Bethesda, MD

Background: Relapsed and refractory multiple myeloma (RRMM) remains a significant therapeutic challenge, particularly among patients with genomic alterations in the RAS pathway (KRAS/NRAS mutations). These mutations occur in 60-70% of RRMM and are associated with aggressive disease and poor outcomes. Preclinical evidence suggests that dual inhibition of MEK and mTOR is required to effectively suppress oncogenic signaling in RAS dependent MM. This study evaluates the combination of the MEK inhibitor mirdametinib and the mTOR inhibitor sirolimus in patients with RAS-mutated RRMM. **Methods:** This is an open-label, single center, Phase 1b/2 study in adults with RRMM who are penta-class exposed and have no remaining standard therapeutic options. Patients must have RAS dependent MM as evidenced by a KRAS or NRAS mutation. Patients will be screened for these mutations at the NIH clinical center if unknown prior to referral. The phase 1b portion uses a standard 3+3 dose-escalation design to determine the recommended phase 2 dose (RP2D) of mirdametinib in combination with sirolimus. Phase 2 is a dose-expansion cohort using a Simon two-stage design to evaluate preliminary efficacy at the RP2D by overall response rate per the IMWG. Key eligibility criteria include adults aged ≥18 years with relapsed or refractory multiple myeloma per IMWG criteria, documented KRAS or NRAS mutation, prior exposure to a proteasome inhibitor, immunomodulatory agent, and anti-CD38 monoclonal antibody, ECOG performance status 0–2, and adequate organ function. Correlative studies include serial assessment of MAPK and mTOR pathway inhibition and pharmacodynamic biomarkers in peripheral blood and bone marrow samples. The study is actively enrolling at the NIH Clinical Center (NCT06876142), with a planned total enrollment of 54 patients. Clinical trial information: NCT06876142. Research Sponsor: None.

Randomized phase III study of nivolumab after surgery and adjuvant chemotherapy in NSCLC (ECOG-ACRIN EA5142, ALCHEMIST). First Author: Jamie E. Chaft, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The NCI's ALCHEMIST program has screened thousands of patients with resected lung adenocarcinoma for mutations in *EGFR* and *ALK*. EA5142 studied the efficacy of adjuvant nivolumab after standard of care adjuvant therapy in patients with resected lung adenocarcinoma without sensitizing *EGFR* and *ALK* alterations and squamous cell carcinoma. **Methods:** Patients enrolled in the ALCHEMIST screening trial (A151216) with resected NSCLC tumors at least 4 cm and/or lymph node positive (N1/2) (for lung adenocarcinoma, without sensitizing *EGFR* and *ALK* alterations), were centrally tested for tumor cell PD-L1 expression using the DAKO 28-8 clone. After completion of all planned adjuvant therapy (chemotherapy and/or post-operative radiation) patients were randomized 1:1 to adjuvant nivolumab 480 mg IV every 4 weeks for up to 1 year or best supportive care. Patients were stratified by tumor histology, stage (AJCC 7th edition IB/IIA vs IIB/IIIA), prior adjuvant treatment, and PD-L1 status ($<$1% vs $\geq$1%). The primary study endpoints were disease free survival (DFS) in all patients and in patients with high tumor PD-L1 expression ($\geq$50%). Overall survival was powered to be tested hierarchically, if DFS was positive. **Results:** Between July 2016 and October 2019, 935 patients were randomized across 378 sites. The treatment arms were balanced for age (median 66 years), sex (52% male), smoking status (10% never smoked), histology (29% squamous), stage and PD-L1 expression (29% PD-L1 high). With a median follow-up of 72.6 months, nivolumab did not improve DFS in the intention to treat population (median DFS 71.3 months vs. 68.8 months in observation arm), hazard ratio (HR) 0.97 (95% CI 0.81-1.17, p=0.78) or the PD-L1 $\geq$50% subset (median DFS 89.8 months vs. 78.5 months in observation arm), HR 0.86 (95% CI 0.59-1.25, p=0.43). In multivariate analysis, adjusting for age, gender, and smoking history, the DFS HR was 0.99 (95% CI 0.82-1.19, p=0.89) in all randomized patients and 0.82 (95% CI 0.56-1.2, p=0.31) in the PD-L1 $\geq$50% subset. As the primary recurrence endpoint included any lung cancer, including new primaries, a sensitivity analysis was performed excluding new primary lung cancers, DFS HR 0.97 (95% CI 0.80-1.18, p=0.76) in all patients and HR 0.88 (95% CI 0.60-1.30, p=0.52 in the $\geq$50% subset. The median duration of treatment with adjuvant nivolumab was 9.4 months (range 0-12.7 months). The most common reasons for nivolumab discontinuation were adverse event (29%), patient withdrawal (11%), and disease progression while on treatment (10%). Treatment related grade 3-5 toxicities were reported in 25% of patients: Grade 3: 23%, Grade 4: 2%, Grade 5: $<$1%. **Conclusions:** In patients with resected NSCLC ($\geq$4cm or LN+, *EGFR/ALK*-) adjuvant nivolumab did not improve DFS, irrespective of tumor PD-L1 expression. Clinical trial information: NCT02595944. Research Sponsor: National Cancer Institute; U10CA180820, U10CA180794, U10CA180821, U10CA180888, U10CA180868, UG1CA189863, UG1CA189956, UG1CA189971, UG1CA233180, UG1CA233247, UG1CA233253, UG1CA233290, UG1CA233329, UG1CA233337; National Cancer Institute; UG1CA189830, UG1CA189858, UG1CA189821, UG1CA233302, UG1CA233327, UG1CA233340 and P30CA008748.

Adjuvant erlotinib versus observation after complete resection of *EGFR*-mutant NSCLC: Final overall survival results of Alliance A081105. First Author: Ramaswamy Govindan, Alvin J Siteman Cancer Center at Washington University School of Medicine in St. Louis, St. Louis, MO

Background: The ALCHEMIST clinical trial platform, launched by the National Clinical Trials Network (NCTN) in 2014, screened patients with resected non-small cell lung cancer (NSCLC) for molecular markers and tailored post-operative adjuvant therapy trials. A081105 evaluated whether adjuvant erlotinib improved overall survival (OS) following complete resection in patients with early stage *EGFR* mutated lung adenocarcinoma. **Methods:** A081105 was a randomized phase III trial enrolling patients with completely resected stage IB ($\geq$4 cm), II, or IIIA non-squamous NSCLC (per the 7th TNM staging classification) harboring *EGFR* exon 19 deletion or L858R mutations. Patients were randomized 1:1 to erlotinib 150 mg daily for up to 2 years or placebo/observation, stratified by stage, prior chemotherapy, *EGFR* mutation subtype, and ECOG performance status. The primary endpoint was OS in the per-protocol (PP) population with centrally confirmed *EGFR* mutations, designed to detect a hazard ratio (HR) of 0.67 in favor of erlotinib with a power of 86% and one sided type I error rate of 5%. Secondary endpoints included OS and disease free survival (DFS) in a modified intent-to-treat (mITT) population with local or centrally confirmed EGFR mutations, and safety. A prespecified backstop analysis was conducted after a minimum of 5 years of follow-up on all patients. **Results:** Trial enrollment was discontinued when 390 of the intended 450 patients had been enrolled due to the proven benefit of adjuvant osimertinib. Among 390 enrolled patients, the arms were balanced for age (median: 67.0 years), sex (70% female), race (70% white), stage (II: 51%, IIIA: 37%), prior chemotherapy (82%), ECOG PS 0 (60%), and exon 19 deletion (57%). Adjuvant erlotinib did not significantly improve OS compared with placebo/observation in the overall PP population (364 patients, 108 events, HR 0.89; 95% CI, 0.59–1.34; 1-sided P = 0.29) or within exon 19 deletion (HR: 0.94) or L858R mutation (HR: 0.82) subgroups. Five-year OS rates were 78.6% versus 77.9%, respectively. Results were consistent in the mITT analysis (379 patients, 113 events, HR 0.86; 95% CI, 0.58–1.28). Erlotinib improved DFS (mITT: 181 events, median: 68 vs 50 months, HR 0.74; 95% CI, 0.55–1.01). Across both arms, 11% of patients started non-protocol treatment (Osimertinib: 9%) prior to disease progression, and 9% withdrew consent for all follow-up prior to recurrence. In the erlotinib arm, 3 deaths on study were reported; grade 3 or higher adverse events were reported on 39% of patients. Median duration of treatment on Erlotinib arm was 16 months; only 37% of patients completed the planned treatment. **Conclusions:** In resected *EGFR*-mutant NSCLC, adjuvant erlotinib did not improve overall survival but improved DFS. Additional studies are exploring efficacy in selected subsets of patients using genomics and proteomic analyses. Clinical trial information: NCT02193282. Research Sponsor: NCI, USA; U10CA180821, U10CA180882.

8002 **Oral Abstract Session**

Neoadjuvant lorlatinib in stage III NSCLC harboring ALK fusion: A phase 2 multicenter study (LORIN). First Author: Chao Zhang, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China

Background: While adjuvant alectinib has established itself as the new standard for resected anaplastic lymphoma kinase (ALK) fusion non-small cell lung cancer (NSCLC), there is limited data on neoadjuvant treatment for locally advanced ALK fusion NSCLC. Given the groundbreaking efficacy of lorlatinib in advanced NSCLC, it is worth exploring its clinical feasibility as neoadjuvant treatment for stage III ALK+ NSCLC. **Methods:** This study is an open-label, phase 2 multi-center prospective trial (ClinicalTrials.gov NCT05740943) utilizing a Simon two-stage design. Patients diagnosed with potentially resectable or unresectable stage III ALK+ NSCLC were enrolled, with up to 3 cycles of lorlatinib administered, followed by optional local treatment and consolidation lorlatinib for up to 2 years. The primary endpoint was the pathological complete response (pCR) (H0$\leq$20%, H1$\geq$40%, α=0.05, β=0.2, at least 12 pCR events for 43 patients enrolled), while secondary endpoints included major pathological response (MPR), event-free survival (EFS), overall survival (OS), and safety profile. Xenium as well as spatial proteomics was performing on paired samples collected before and after lorlatinib. **Results:** As of January 1, 2026, 43 patients with stage III ALK-fusion NSCLC (19 evaluated as potentially resectable and 24 as unresectable) were consecutively enrolled and received 3 cycles neoadjuvant lorlatinib, with 32 completing surgery (including neck dissection and/or contralateral lymph node dissection), 9 continuing TKI therapy, and 2 undergoing radiotherapy. The most common treatment-related adverse events (TRAEs) included hypertriglyceridemia, hypercholesterolemia, and edema. The confirmed objective response rate (ORR) was 83.7% (36/43), without progressive disease (PD). Among patients who underwent surgery, the R0 resection rate was 96.9% (31/32) and 3 patients experiencing conversion to thoracotomy. pCR and MPR rates were 46.9% (15/32) and 81.3% (26/32), respectively, reaching the primary endpoint. Pathological nodal downstaging was seen in 90.6% (29/32) patients. For those with initially unresectable stage III disease, 75.0% (18/24) achieved conversion surgery through multidisciplinary evaluation after neoadjuvant lorlatinib, while others continued TKI or underwent radiotherapy. With a median follow-up of 13 months, the 1-year EFS rate was 97.1% (95% CI, 91.5-100) and no OS events were observed. Only 3 patients experienced local relapse (regional lymph nodes and/or intrapulmonary metastasis) without distant metastasis; all had initially presented with N3 disease and did not receive adjuvant lorlatinib after surgery. **Conclusions:** Neoadjuvant lorlatinib unveiled overwhelming pathological response and could lead to high conversion surgery for unresectable stage III disease. Further large-scale prospective trial was warranted to testified such treatment modality. Clinical trial information: NCT05740943. Research Sponsor: National Science Foundation of China; National Science Foundation of China.

8003 **Oral Abstract Session**

Pollution and progression: Air quality and stage of lung cancer diagnosis across the U.S. First Author: Raheem Bell, Northwestern University Feinberg School of Medicine, Department of Surgery, Chicago, IL

Background: Air pollution contributes to increased lung cancer incidence, but whether it accelerates tumor progression, resulting in more advanced stage at diagnosis, is not well understood. Understanding environmental and social factors influencing late-stage presentation can guide targeted prevention efforts. **Methods:** We identified primary lung cancer cases from the National Cancer Database (NCDB; 2010–2023) across 2,803 U.S. counties. Individual-level data were linked to county-level annual averages of $PM_{2.5}$ ($\mu g/m^3$) and NO_2 (ppb). Generalized estimating equation logistic models with county-level clustering assessed associations between chronic pollution exposure and odds of advanced-stage (III–IV vs. I–II) diagnosis, adjusting for median household income and educational attainment. Pollutants were z-score standardized (mean = 0, SD = 1) and summed to create a combined Pollution Burden metric. Effect modification by histology and socioeconomic status was tested. **Results:** Among 1,023,140 patients (mean age 68.5 $\pm$ 10.8 years; 51.3% female), 67.1% presented with advanced-stage disease. Each standard deviation increase in $PM_{2.5}$ was associated with 4.8% higher odds of advanced-stage diagnosis (95% CI: 3.5–6.1%; $p < 0.001$; Table 1). In multi-pollutant models, $PM_{2.5}$ remained significant (OR = 1.062, 95% CI: 1.047–1.076; $p < 0.001$), with combined pollution burden linked to a 3.1% increase in odds (95% CI: 1.5–4.7%; $p < 0.001$). Low-SES communities had higher advanced-stage rates regardless of pollution exposure (69.7% vs. 63.6%; $p < 0.001$), equating to approximately 6,100 excess annual diagnoses. Effects varied by histology, with small cell carcinoma showing the highest advanced-stage rate (91.2%), followed by adenocarcinoma (67.3%) and squamous cell carcinoma (58.6%). **Conclusions:** Higher $PM_{2.5}$ exposure and lower socioeconomic status were independently associated with later-stage lung cancer diagnosis across over 1 million cases from 2,803 U.S. counties. Low-SES communities showed 6 percentage points higher advanced-stage rates irrespective of pollution levels. These findings highlight how environmental factors that may accelerate cancer progression and social barriers to accessing care can jointly delay early-stage diagnosis. Targeted pollution control and expanded lung cancer screening in underserved communities could reduce the burden of advanced-stage disease. Research Sponsor: None.

Odds of advanced-stage lung cancer by air pollutant exposure.

Pollutant	Model	Mean $\pm$ SD	OR	95% CI Lower	95% CI Upper	P-value
$PM_{2.5}$ ($\mu g/m^3$)	Single-pollutant	8.17 $\pm$ 1.58	1.048	1.035	1.061	$<$0.001
$PM_{2.5}$ ($\mu g/m^3$)	Multi-pollutant		1.062	1.047	1.076	$<$0.001
NO_2 (ppb)	Single-pollutant	6.93 $\pm$ 3.93	1.009	0.993	1.026	0.28
NO_2 (ppb)	Multi-pollutant		0.978	0.963	0.994	0.007
Combined Burden	Z_PM2.5 + Z_NO2		1.031	1.015	1.047	$<$0.001

8004 **Oral Abstract Session**

Redefining lung cancer screening eligibility: Smoking duration vs. pack-years in a national VA cohort of nearly 1 million patients. First Author: Brendan Heiden, Division of Cardiothoracic Surgery, Department of Surgery, Washington University School of Medicine, St. Louis, MO

Background: Lung cancer is the leading cause of cancer death in the US, yet current lung cancer screening (LCS) criteria based on tobacco pack-years (TPY) miss nearly half of all cases and are difficult to capture reliably in clinical practice. Tobacco smoking duration (TSD) is a simpler, more consistently measurable metric that may better identify high-risk individuals. We evaluated whether TSD improves lung cancer risk prediction compared with TPY in a unique real-world cohort of nearly 1 million patients. **Methods:** We conducted a retrospective cohort study of Veterans aged 50–80 in the Veterans Health Administration. The primary exposure was smoking history quantified as TPY and TSD; the primary outcome was 5-year lung cancer incidence (2021-2025). We compared risk-adjusted 5-year lung cancer incidence based on 2013 USPSTF guidelines (≥30 TPY, quit within 15 years), revised 2021 USPSTF guidelines (≥20 TPY, quit within 15 years), our proposed TSD criteria (≥20 TSD), and never-smoking. We further estimated the impact of switching to TSD-based eligibility on the theoretical number of missed lung cancer diagnoses (i.e., the proportion of lung cancers diagnosed in screening-ineligible individuals) and performed subgroup analyses across race and sex. **Results:** A total of 960,770 Veterans were included in the study, with 340,312 (35.4%) currently smoking, 304,589 (31.7%) formerly smoking, and 315,869 (32.9%) never smoking. The median (SD) age was 64.9 (9.6) years old. Most participants were male (n=876,215, 91.2%) and of white race (n=677,823, 70.6%). 341,061 (35.5%) qualified for 2013 TPY criteria, 437,803 (45.6%) qualified for 2021 TPY criteria, and 571,087 (59.4%) qualified for TSD criteria. Importantly, 127,604 (22.3%) individuals who met TSD criteria did not meet 2021 TPY criteria, suggesting that TSD criteria would increase the eligible screening population by 28.8%. The 5-year incidence of lung cancer was 0.95% (1.87% among 2013 TPY criteria; 1.73% among 2021 TPY criteria; 1.48% among TSD criteria; and 0.13% among never-smoking). The proportion of missed lung cancer diagnoses was 30.3% among 2013 TPY criteria, 17.1% among 2021 TPY criteria, and 7.5% among TSD criteria. Finally, eligibility was higher for TSD vs. TPY criteria in various subgroups, including among black individuals (percent of current or former smokers eligible for screening: 34.7% 2013 TPY; 54.0% 2021 TPY; and 83.7% TSD) and females (38.5% 2013 TPY; 55.1% 2021 TPY; and 83.7% TSD). **Conclusions:** In this nationwide VA cohort consisting of nearly 1 million Veterans, smoking duration performed at least as well as TPY in predicting lung cancer risk and substantially expanded screening eligibility with fewer missed cancers. TSD criteria were also associated with improved equity. These findings support revisiting national lung cancer screening guidelines to prioritize smoking duration over pack-years. Concurrent thoracic radiotherapy (TRT), platinum/etoposide chemotherapy, and durvalumab immunotherapy in extensive-stage (ES) small cell lung cancer (SCLC): A phase III trial. First Author: Bjorn Henning Gronberg, Department of Oncology, St. Olavs hospital, Trondheim, Norway

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

8006 **Oral Abstract Session**

Intracranial efficacy of tarlatamab versus chemotherapy (CTx) as second-line (2L) treatment for small cell lung cancer (SCLC): DeLLphi-304 phase 3 post hoc analysis. First Author: Giannis S. Mountzios, Fourth Department of Medical Oncology and Clinical Trials Unit, Henry Dunant Hospital Center, Athens, Greece

Background: Brain metastases (BM) are common in patients (pts) with SCLC and are associated with poor outcomes. Tarlatamab, a bispecific T-cell engager (BiTE) immunotherapy, demonstrated superior overall survival versus CTx in pts with SCLC following progression on or after platinum-based CTx in the DeLLphi-304 study, including pts with history of BM (prior or current) at baseline (OS HR 0.45 [95% CI: 0.31–0.65]). Here we compare the intracranial efficacy of tarlatamab vs CTx. **Methods:** Pts were randomized 1:1 to receive tarlatamab or CTx (topotecan, lurbinectedin or amrubicin) as 2L treatment for SCLC. Pts with stable asymptomatic brain metastases were eligible; prior CNS treatment was required until protocol amendment 3. Baseline brain imaging by contrast enhanced MRI was mandatory for all pts at screening and repeated at all subsequent imaging assessments for pts with a history of BM at baseline. A post hoc analysis on intracranial efficacy was performed by BICR per mRANO-BM. Given that most pts had prior CNS treatment, specified outcomes were CR, non-CR/non-PD, and PD. **Results:** BM at baseline were present in 98/254 pts (39%) in the tarlatamab arm and 99/255 (39%) in the CTx arm, of whom 75/98 (77%) and 69/99 (70%) had prior CNS treatment, respectively. A CNS full analysis set (FAS) was specified to include pts who had both a baseline scan and ≥ 1 postbaseline scan (tarlatamab-67; CTx-56 pts). In pts in FAS, treatment with tarlatamab resulted in longer CNS PFS than CTx (median: 6.5 mos vs 4.2 mos; HR, 0.40 [95% CI: 0.24–0.66]; Table). CNS tumor shrinkage of ≥30% was observed in 56% of pts with tarlatamab vs 38% with CTx. CNS complete response was observed in 15% of pts with tarlatamab vs 5% with CTx, with longer CNS duration of complete response (DOCR) (not estimable [NE] vs 3.6 mo) and longer CNS duration of disease control (DODC) (8.2 vs 5.2 mo) for pts in the tarlatamab arm. Pts with BM at baseline had longer OS with tarlatamab vs CTx (median OS: 13.9 vs 6.8 mos; HR, 0.51 [95% CI: 0.34–0.74]). In pts with BM at baseline, treatment-emergent adverse events (TEAEs) of any grade (gr)/gr 3/gr 4/gr 5 occurred in 99%/38%/9%/7% for tarlatamab vs 100%/38%/40%/10% for CTx. In pts treated with tarlatamab, the incidence of CRS and ICANS was 54% and 9% in pts with BM at baseline vs 58% and 4% in pts without BM at baseline, respectively. **Conclusions:** Tarlatamab demonstrated increased intracranial efficacy with longer CNS PFS and OS vs CTx in pts with stable, treated and untreated asymptomatic BM. These results affirm tarlatamab as the 2L standard of care for SCLC, even in pts with BM. Clinical trial information: NCT05740566. Research Sponsor: Amgen Inc.

	Tarlatamab n = 67	CTx n = 56
CNS PFS, mos (95% CI)	6.5 (4.3, 13.7)	4.2 (2.9, 5.5)

8007 **Oral Abstract Session**

Efficacy and safety of ivonescimab combined with liposomal irinotecan in patients with small-cell lung cancer (SCLC) progressing after first-line chemoimmunotherapy: A multicenter, phase 2 study. First Author: Yun Fan, Department of Thoracic Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: SCLC patients (pts) progressing after first-line platinum-based chemoimmunotherapy have limited effective treatment options and poor prognosis. This study evaluated the efficacy and safety of ivonescimab combined with liposomal irinotecan in this setting. **Methods:** This phase 2, multicenter, single-arm trial enrolled SCLC pts who progressed during or after platinum-based chemoimmunotherapy. Eligible pts were required to be ≥18 years of age and have an ECOG PS of 0 or 1. Pts received ivonescimab (20 mg/kg, IV, Q3W) plus liposomal irinotecan (56.5 mg/m², IV, Q2W) until disease progression or unacceptable toxicity. The primary endpoint was 6-month progression-free survival (PFS) rate (ClinicalTrials.gov: NCT06478043). **Results:** Between October 22, 2024 and August 27, 2025, 60 pts were included in the intention-to-treat population. Median age was 62.0 years (range: 38-75), 56 (93.3%) were male, and 53 (88.3%) had ECOG PS 1. At baseline, 35.0% and 26.7% of pts had liver and brain metastases, respectively. A total of 63.3% of pts had a chemotherapy-free interval of more than 90 days. As of December 15, 2025, with a median follow-up time of 7.3 months (95% CI: 6.0-9.0), the 6-month PFS rate was 72.0% (95% CI: 57.0-82.6). Median PFS was 9.8 months (95% CI: 6.7-13.4), and median OS was not reached. The confirmed objective response rate was 61.7% (95% CI: 48.2-73.9; all partial responses) and the disease control rate was 91.7% (95% CI: 81.6-97.2). In subgroup analysis, the median PFS was 11.9 months (95% CI: 7.3-NE) for patients with a CFI ≥90 days and 7.0 months (95% CI: 4.4-NE) for those with a CFI < 90 days. Treatment-related adverse events (TRAEs) of grade ≥3 occurred in 16 pts (26.7%). The most common grade ≥3 TRAEs were decreased neutrophil count (8.3%), decreased white blood cell count (8.3%), fatigue (6.7%), and diarrhea (3.3%). TRAEs led to treatment interruption in 31.7% and chemotherapy dose reduction in 25.0% of pts. No patient discontinued all treatment drugs due to TRAEs; discontinuation of ivonescimab alone occurred in 6 pts (10%). Immune-related AEs occurred in 33.3 % of pts, with grade 3 events in 8.3%. No grade ≥4 irAEs or treatment-related deaths were reported. **Conclusions:** Ivonescimab combined with liposomal irinotecan demonstrated encouraging antitumor activity with a manageable safety profile as a second-line treatment for SCLC pts after platinum-based chemoimmunotherapy. These results support further investigation in randomized controlled trials. Clinical trial information: NCT06478043. Research Sponsor: None.

8008 Oral Abstract Session

ABBV-706 as monotherapy and in combination with budigalimab in patients with relapsed/refractory (R/R) small cell lung cancer (SCLC). First Author: Lauren Averett Byers, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: SCLC is an aggressive cancer with poor prognosis and limited treatment options. Seizure-related 6 homolog (SEZ6) is overexpressed in SCLC. ABBV-706 is a SEZ6-targeting antibody-drug conjugate with topoisomerase 1-inhibitor payload. Here we report updated data from a phase 1 study (NCT05599984) evaluating ABBV-706 in patients (pts) with R/R SCLC as monotherapy or in combination with budigalimab (Budi), an anti-PD-1 immune checkpoint inhibitor (CPI). **Methods:** The study enrolled pts ≥18 years old with R/R SCLC and Eastern Cooperative Oncology Group performance score ≤1. Pts received either ABBV-706 monotherapy every 3 weeks (Q3W), or in combination with 375 mg Budi Q3W. **Results:** As of Sept. 27, 2025, 124 pts received ABBV-706 monotherapy. Of these, 41 received the recommended phase 3 dose (1.8 mg/kg), with 17 receiving ABBV-706 as a second-line (2L) therapy. Overall, median age was 64 years, and most pts (65%) received at least 2L of prior treatment. The safety profile was comparable with previously reported data. Median follow-up (mFU) was 16.2 months, and median overall survival (mOS) overall (N=124) and among pts receiving 1.8 mg/kg as 2L (n=17) was 11.3 and 14.3 months, respectively. The 15-month OS estimates for the same cohorts were 40% and 50%, respectively. As of Sept. 27, 2025, 11 pts received ABBV-706 (1.8 mg/kg Q3W) + Budi as 2L treatment. Median age was 68 years. No new safety signals were detected as compared to monotherapy, and there were no reports of pneumonitis. Treatment-related adverse events (TRAEs) occurred in 91% of pts, most commonly gastrointestinal (64%) and hematological (64%). TRAEs grade ≥3 occurred in 46% of pts, with anemia (27%) and neutrophil count decreased (18%) being most common. TRAEs led to treatment discontinuation, interruption, or dose reduction in 0%, 64%, and 36% of pts, respectively. No treatment-related deaths were reported. mFU was 9.1 months. Detailed efficacy endpoints are shown in the Table. **Conclusions:** ABBV-706 monotherapy shows promising OS benefit in a heavily pretreated pt population with R/R SCLC and is combinable with a CPI. Clinical trial information: NCT05599984. Research Sponsor: AbbVie Inc.

Efficacy of ABBV-706 in R/R SCLC.

Complex segmentectomy versus lobectomy in small-sized peripheral non–small cell lung cancer: A post-hoc supplemental analysis of a multicenter, open-label, phase 3 trial (JCOG0802/WJOG4607L). First Author: Atsushi Kamigaichi, Hiroshima University, Hiroshima, Japan

Background: JCOG0802/WJOG4607L confirmed the superiority of segmentectomy on overall survival (OS) over lobectomy for small-sized peripheral non-small cell lung cancer (NSCLC). However, it remains unclear whether technically demanding complex segmentectomy offers therapeutic efficacy compared to lobectomy, similar to simple segmentectomy. This study therefore aimed to evaluate the oncological outcomes of complex and simple segmentectomy compared to those of lobectomy using final analysis data from JCOG0802/WJOG4607L. **Methods:** Simple segmentectomy was defined as resection of the bilateral superior division (S^6), left lingular (S^{4+5}), or superior division (S^{1-3}); all other segmentectomies were defined as complex. The primary outcome was OS, and secondary outcomes were respiratory function, relapse-free survival (RFS), cumulative incidence of locoregional relapse, and lung cancer-specific death. To ensure comparability, a location-adjusted analysis was performed, separately comparing lobectomy to simple segmentectomy in patients with tumors in the bilateral S^6, left S^{1-3}, or S^{4+5}, and to complex segmentectomy in patients with tumors in the right S^{7-10}, S^{1-3}, or left S^{8-10}, S^{1-3}. **Results:** 1106 patients were assigned to either lobectomy (n = 554) or segmentectomy (n = 552) including 318 complex and 234 simple segmentectomies. At a median follow-up of 10.5 years, the 10-year OS was 83.5% (95% CI: 78.8–87.3%), 83.5% (95% CI: 77.7–87.9%) and 79.8% (95% CI: 76.1–83.0%) for complex, simple segmentectomy, and lobectomy, respectively. In the location-adjusted analysis, the 10-year OS were 83.6% (95% CI: 78.9–87.3%) for complex segmentectomy and 79.2% (95% CI: 74.7–82.9%) for lobectomy (HR 0.839 [95% CI 0.608–1.158]). Similarly, 10-year OS were 82.9% (95% CI: 76.9–87.4%) for simple segmentectomy and 78.0% (95% CI: 72.5–82.6%) for lobectomy (HR 0.791 [95% CI 0.540–1.158]). The reduction of median forced expiratory volume in 1 second at 1 year was less after complex (−7.9%) and simple segmentectomy (−9.0%) than lobectomy (−12.0%; $p < 0.001$ and $p < 0.001$, respectively). RFS and lung cancer-specific death were not significantly different among the arms, while the cumulative incidence of locoregional relapse was higher after complex and simple segmentectomy than lobectomy (HR 2.124 [95% CI 1.327–3.339] and HR 1.817 [95% CI 1.071–3.083], respectively). Surgical margins were shorter in complex (median 2.2 cm, $p < 0.001$) and simple (2.5 cm, $p < 0.001$) segmentectomy than lobectomy (4.0 cm). **Conclusions:** Complex segmentectomy showed a trend toward improved OS compared to lobectomy in small-sized peripheral NSCLC similar to simple segmentectomy. However, due to a higher risk of locoregional relapse, complex segmentectomy should be performed with meticulous attention to securing adequate surgical margin. Perioperative toripalimab in non-small cell lung cancer: Clinical outcomes and safety from a large prospective real-world study. First Author: Pingping Song, Cancer Hospital of Shandong First Medical University (Shandong Cancer Institute, Shandong Cancer Hospital), Jinan, China

Background: The phase III NEOTORCH trial demonstrated that perioperative toripalimab significantly improved event-free survival in stage IIIA–IIIB driver-gene-negative NSCLC, along with a favorable overall survival trend. However, the generalizability of randomized controlled trial (RCT) results to broader, more heterogeneous, real-world populations is uncertain. This study aimed to evaluate the effectiveness and safety of this regimen in routine clinical practice, providing essential evidence for treatment decisions. **Methods:** This nationwide, prospective, observational study in China consecutively enrolled patients with stage II-III NSCLC planned for perioperative treatment containing toripalimab. The primary endpoint was real-world event-free survival (rwEFS). Secondary endpoints included pathological complete response (pCR) rate, major pathological response (MPR) rate, objective response rate (ORR), R0 resection rate, real-world disease-free survival (rwDFS), real-world overall survival (rwOS), and safety. **Results:** Between December 9, 2024, and January 14, 2026, 1727 patients were enrolled from 221 tertiary and secondary hospitals across 28 provinces in China. Baseline characteristics: 82.8% male; 51.4% aged ≥65 years; ECOG PS 0/1/2 in 43.2%/54.4%/2.4%. Histology: 71.4% squamous, 18.3% nonsquamous, 10.3% NSCLC not otherwise specified. Clinical stage distribution: IIA (1.7%), IIB (10.4%), IIIA (52.8%), IIIB (33.0%), IIIC (2.1%). Of all enrolled patients, 542 (31.4%) were pending preoperative assessment. Surgery was not performed in 634 patients (36.7%); reasons included: other causes (64.9%), patient refusal (15.7%), surgical ineligibility (9.3%), disease progression (8.2%), and adverse events (1.9%). Ultimately, 551 patients (31.9%) underwent resection, with 503 having postoperative pathological assessment. The MPR rate was 67.0% (337/503) and the pCR rate was 39.6% (199/503). As of the data-cutoff, investigators reported 20 (1.2%) grade ≥3 or clinically significant treatment-emergent adverse events, with hematologic toxicities being most common. Immune-related adverse events were infrequent (four events: three grade 1–2 pneumonitis, one grade 3 rash). **Conclusions:** This is the largest prospective real-world study of perioperative immunotherapy in NSCLC to date. Its extensive geographic coverage and diverse patient population-including higher proportions of elderly patients, those with ECOG PS 1, and varied histologies-validate the effectiveness and manageable safety of perioperative toripalimab in routine practice beyond RCT settings. The significant pathological response rates observed support the clinical benefit of this regimen for a broad spectrum of stage II-III NSCLC patients, providing crucial evidence for real-world decision-making. Clinical trial information: ChiCTR2400091457. Research Sponsor: the Shanghai Science and Technology Innovation Action Plan; 24SF1900100.

8011 Rapid Oral Abstract Session

LuSato-1: Phase I study of ^{177}Lu-SSO110 with ^{68}Ga-SSO120 companion imaging in patients with extensive stage small cell lung cancer (ES-SCLC) on maintenance treatment with immune checkpoint inhibition (ICI). First Author: Surein Arulananda, Monash Health, Clayton, VIC, Australia

Background: Outcomes for pts with ES-SCLC remains suboptimal despite the addition of ICIs to platinum-based chemotherapy. Somatostatin receptor 2 (SSTR2) is expressed in the majority of SCLC lesions. SSTR2 targeted radiopharmaceutical therapy (RPT) has proven safe and effective when used in other neuroendocrine tumors. The multicentre, open-label, phase I LuSato-1 (ACTRN12623000185662) study investigated the use of ^{177}Lu-satoreotide Tetraxetan (^{177}Lu-SSO110) with ^{68}Ga-Satoreotide Trizoxetan (^{68}Ga-SSO120) companion imaging in pts with ES-SCLC, who are on 1L maintenance ICIs. **Methods:** Adult pts with ES-SCLC received 1L induction therapy with carboplatin, etoposide and atezolizumab for 4 cycles. Following induction, eligible pts without PD were enrolled and received up to 4 doses of ^{177}Lu-SSO110 in 6 to 9 week intervals, with up to 3 additional treatments per investigator choice. Activities were escalated from 3.7GBq to 5.2GBq, following a BOIN design with a target DLT rate of 0.30. The primary objective was to investigate the safety and tolerability of ^{177}Lu-SSO110 with ^{68}Ga-SSO120 companion imaging in pts on maintenance ICI, with secondary objective of anti-tumor activity of the combination. Concordance between ^{68}Ga-SSO120 PET/CT and contrast-enhanced CT was an exploratory endpoint. **Results:** Of the 35 screened pts, 20 were deemed eligible (median age 65.5 years (range 47-83), 55% female, 25% brain mets). With a median 11.1 month follow up (data cut off: 08/12/25), the TEAE rate associated with ^{177}Lu-SSO110 was 0% at 3.7GBq (dose level 1), 71.4% at 4.5GBq (dose level 2), and 83.3% at 5.2GBq (dose level 3). The grade 3/4 TEAE rate associated with ^{177}Lu-SSO110 was 0% (dose level 1), 57.1% (dose level 2), and 41.7% (dose level 3). Grade 2 to 4 thrombocytopenia rate related to ^{177}Lu-SSO110 was 45%. Grade 3/4 irAEs related to ICI was 20%. There was 10% pneumonitis rate attributed to ICI. The treatment interruption rate was 50% and treatment discontinuation rate was 10% (2 attributed to ^{177}Lu-SSO110 associated thrombocytopenia). From the start of C1 induction chemoICI, the ORR was 85%, including 1 CR. From the start of maintenance ICI, median PFS was 3.7 months and median OS was 8 months. **Conclusions:** Addition of SSTR2 targeted RPT to maintenance ICI was well tolerated and demonstrated clinically meaningful anti-tumor activity. This supports further investigation of SSTR2-targeted RPT in combination with ICI in patients with ES-SCLC. Clinical trial information: ACTRN12623000185662. Preliminary results from an ongoing phase 1 study of LB2102, a dnTGFBR2-armored DLL3-targeted autologous CAR-T cell therapy, in patients with relapsed or refractory SCLC or LCNEC. First Author: Zhonglin Hao, Markey Cancer Center, Lexington, KY

Background: Delta-like ligand 3 (DLL3) is a promising target for small cell lung cancer (SCLC) and other neuroendocrine tumors. We present results from an ongoing dose-escalation study of LB2102, an autologous CAR-T cell therapy engineered to target DLL3 and armored with a TGF-β receptor blockade to overcome the immunosuppressive tumor microenvironment. **Methods:** This open-label, multicenter, phase 1 study evaluates LB2102 in patients with SCLC or large cell neuroendocrine carcinoma (LCNEC), relapsed or refractory to ≥1 prior line of therapy (LOT). Dose escalation follows an i3+3 design, with dose levels (DL) of 0.3, 1.0, 2.0, 4.0, 8.0, 12.0, and 16.0x10^6 CAR+ T cells/kg. Subjects received a single infusion of LB2102 after standard lymphodepletion (LD). The primary objectives are to assess safety and tolerability, and to determine the recommended phase 2 dose. **Results:** As of 05-JAN-2026, 20 subjects received LB2102 (DL1–DL5, n = 3 each; DL6 was skipped based on data; DL7, n = 5). Seventeen subjects had SCLC and 3 LCNEC; 13 (65%) had a history of brain metastases. Median age was 56.5 yrs (range 20–73 yrs) with median 1 prior LOT (range 1–7); 95% received bridging therapy between apheresis and LB2102. The most-common grade ≥ 3 LB2102-related adverse events (TRAEs) were hematologic and co-attributed to LD. Four subjects (20%) had cytokine-release syndrome (CRS; 3 Grade 1 and 1 Grade 2); all resolved. Two subjects developed ICANS (1 Grade 1 and 1 Grade 3); both resolved. There were no dose-limiting toxicities (DLTs) or TEAE-related deaths. Other grade ≥ 3 non-hematologic LB2102-related TEAEs were dyspnea, prolonged QT, and hypoxia (all n = 1 at DL7). Of 17 response-evaluable subjects, best overall responses per RECIST1.1 criteria were 3 partial responses (PR, one each at DL3, DL4, and DL7) and 10 stable diseases (SD, at DLs 2–7), for an objective response rate (ORR) of 3/17 (18%) and a disease control rate (DCR) of 13/17 (76%). Median DOR among patients with a PR was 208 days. CAR-T expansion in peripheral blood (measured by qPCR) was observed at DL3 (N = 3), DL4 (N = 3), DL5 (N = 3), and DL7 (N = 5; 1 patient excluded due to incomplete PK profile): median C_{max} was 694, 581, 527, and 2851 copies/μg gDNA; median T_{max} was 15, 15, 6, and 6 days, respectively. Patients with partial responses had relatively higher PK exposure (median C_{max}) compared to the PK exposure of patients with stable diseases and progressive diseases. Median tumor expression of DLL3 at baseline was 97% (n = 16, range 45%–100%) and at Day 29 post-infusion was 90% (n = 8, range 55%–100%). **Conclusions:** LB2102 demonstrated consistent CAR-T expansion and encouraging anti-tumor activity at doses ≥ 2x10^6 CAR+T cells/kg (ORR 27% and DCR 91%). LB2102 was well tolerated with no DLTs and manageable CRS and ICANs. Clinical trial information: NCT05680922. Research Sponsor: Legend Biotech USA, Inc; Novartis.

Autologous natural killer cell infusion as consolidation therapy after first-line chemoradiotherapy for limited-stage small-cell lung cancer: A randomized, controlled, open-label, single-center phase II clinical study. First Author: Jiuwei Cui, The First Hospital of Jilin University, Changchun, China

Background: Small-cell lung cancer (SCLC) grows rapidly, is aggressive, has a poor prognosis, and tends to recur after treatment. Autologous cellular immunotherapy (CIT) has demonstrated good safety and efficacy across various tumors; however, there are no prospective studies utilizing autologous natural killer (NK) cells for consolidation therapy following first-line chemoradiotherapy for SCLC. **Methods:** This study aimed to evaluate the safety and efficacy of autologous NK cell infusion (administered every 2 weeks for a total of six courses) as consolidation therapy after first-line standard treatment for limited-stage SCLC, compared to routine follow-up in a randomized, controlled, open-label, single-center phase II clinical trial. The primary endpoint was progression-free survival (PFS, assessed according to Response Evaluation Criteria in Solid Tumors version 1.1), while secondary endpoints included overall survival (OS), the 12- and 24-month PFS rate, the 24- and 36-month OS rate and safety. **Results:** Forty-three patients with limited-stage SCLC were included in the final analysis, comprising 21 patients in the treatment group who received autologous NK cell infusion after chemoradiotherapy and 22 patients in the control group who underwent routine follow-up. At 6 months, the response to initial chemoradiotherapy was maintained in 27.3% (6/22) of the control patients and 57.1% (12/21) of the treatment patients. The objective response rate (ORR) and PFS rates at 12 months for controls compared to treatment patients were 0% versus 19.0% (4/21) ($P < 0.05$) and 4.5% (1/22) versus 42.9% (9/21) ($P < 0.01$), respectively. Compared to the control group, the autologous NK cell consolidation group achieved significantly longer PFS (median 6.5 vs. 11.92 months; hazard ratio [HR] 0.38, 95% confidence intervals [CI] 0.18 to 0.79; P = 0.01) and OS (median 15.6 vs. 27.13 months; HR 0.41, 95% CI: 0.19 to 0.87, P = 0.02), with a particularly pronounced PFS benefit when calculated from the end of chemoradiotherapy (median 8.1 vs.16.3 months; HR 0.35, 95% CI 0.17 to 0.72, P = 0.01). Regarding safety, the incidence of all adverse events (AEs) due to any cause was 50.0% (11/22) in the observation group and 47.6% (10/21) in the treatment group, with most being grade 1–2 and considered unrelated to NK cell infusion. NK cell treatment exhibited good overall safety and tolerability. Additionally, we characterized changes in peripheral blood cell subsets and metabolites before and after treatment, as well as the tumor immune microenvironment characteristics in patients from the treatment group. **Conclusions:** Autologous NK cell infusion as consolidation therapy after first-line chemoradiotherapy for SCLC yielded promising preliminary PFS and OS results, with a well-tolerated safety profile. Clinical trial information: NCT03410368. Research Sponsor: National Natural Science Foundation of China; 82273191; Jilin Provincial Science and Technology Department; 20240304037SF.

8014 **Rapid Oral Abstract Session**

Transcriptomic analyses of molecular subsets and correlations with clinical outcomes from the phase 3 IMforte study of lurbinectedin (lurbi) + atezolizumab (atezo) maintenance treatment (Tx) in extensive-stage small-cell lung cancer (ES-SCLC). First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, Universidad Complutense and Ciberonc, Madrid, Spain

Background: Transcriptomic analyses of pre-Tx tumor samples from the Phase 3 IMpower133 study identified 4 molecular subtypes with distinct clinical outcomes to first-line (1L) Tx with atezo and chemotherapy (chemo). Neuroendocrine (NE) tumors with low tumor-associated macrophage (TAM)/high T-effector (T-eff) signal demonstrated longer overall survival (OS) vs non-NE tumors with high TAM/high T-eff, suggesting that TAM contributes to resistance to atezo. Lurbi, an alkylating agent that modifies the tumor microenvironment and synergizes with immune checkpoint inhibitors, could enhance atezo activity. Lurbi + atezo as 1L maintenance Tx significantly improved progression-free survival (PFS) and OS vs atezo in patients (pts) with ES-SCLC in the Phase 3 IMforte study (NCT05091567). We report exploratory biomarker analyses from IMforte. **Methods:** Adults with Tx-naïve ES-SCLC, without disease progression after induction with atezo + chemo, received maintenance Tx of either 3.2 mg/m² lurbi + 1200 mg atezo or 1200 mg atezo q3w until unacceptable toxicity or disease progression. Transcriptomic analyses were conducted on pre-induction Tx tumor samples to identify subgroups with concordance to previously reported SCLC subtypes (SCLC-A, -N, -I-NE and -I-non-NE), immune gene expression signatures (TAM, T-eff) and *SLFN11*. Post-hoc exploratory analyses were conducted for correlation with IRF-assessed PFS and OS. **Results:** Of 483 randomized pts, 303 had samples for RNA sequencing. Of 303 tissue samples analyzed, 104 (34.3%) were classified as SCLC-A, 89 (29.4%) as SCLC-N, 46 (15.2%) as SCLC-I-NE and 64 (21.1%) as SCLC-I-non-NE. Clinical outcomes in the 303 pts (median [m] PFS: 5.5 vs 2.4 months [mo], hazard ratio [HR] 0.61; mOS: 13.5 vs 11.7 mo, HR 0.72, for lurbi + atezo [n = 150] vs atezo [n = 153], respectively) were consistent with the full analysis set. PFS and OS benefit from lurbi + atezo were comparable between NE (mPFS: 5.5 vs 2.1 mo, HR 0.58; mOS: 13.5 vs 11.7 mo, HR 0.74, for lurbi + atezo [n = 115] vs atezo [n = 124], respectively) and non-NE subtypes (mPFS: 4.6 vs 2.8 mo, HR 0.73; mOS: not reached vs 12.0 mo, HR 0.68, for lurbi + atezo [n = 35] vs atezo [n = 29], respectively). Pts with high TAM/high T-eff in the atezo arm had shorter OS vs those with low TAM/high T-eff. The addition of lurbi improved OS in the high TAM/high T-eff subgroup vs atezo alone (HR 0.56). SLFN11 expression was high at baseline across subtypes and had no predictive value for lurbi + atezo clinical benefit. **Conclusions:** The prevalence of the 4 SCLC subtypes and the TAM/T-eff pre-Tx data for IMforte are consistent with findings from IMpower133. PFS and OS were longer for lurbi + atezo vs atezo irrespective of molecular subset, though numerical trends suggest that lurbi may overcome TAM-mediated resistance to atezo. Clinical trial information: NCT05091567. Research Sponsor: IMforte is sponsored by F. Hoffmann-La Roche Ltd. and co-funded by Jazz Pharmaceuticals. Third-party medical writing assistance was provided by Rachel Dobb, PhD, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

8015 **Rapid Oral Abstract Session**

Impact of neoadjuvant durvalumab (D) on tumor microenvironment (TME) features and their association with event-free survival (EFS) in patients with resectable NSCLC (R-NSCLC) from the phase 3 AEGEAN trial. First Author: John V. Heymach, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: In AEGEAN, perioperative D + neoadj CT improved EFS and pathological complete response vs neoadj CT alone in pts with R-NSCLC. Here, we report exploratory transcriptomic analyses of the TME in tumor samples collected at baseline (BL) and surgery (Sx) to investigate the impact of neoadj D on TME features and their association with EFS. **Methods:** AEGEAN is a double-blind PBO-controlled study (NCT03800134). Adults with Tx-naïve R-NSCLC (stage II–IIIB[N2]) and ECOG PS 0/1 were randomized 1:1 to neoadj platinum-based CT + D or PBO IV (Q3W, 4 cycles) before Sx followed by D or PBO IV (Q4W, 12 cycles) after Sx. EFS was evaluated by BICR (RECIST v1.1) in the modified ITT (mITT) population, which excluded pts with known *EGFR*/*ALK* aberrations. Total RNA was extracted from BL and Sx tumor samples and sequenced (Illumina NovaSeq X Plus). Unsupervised hierarchical clustering of samples was conducted based on previously reported gene signatures reflective of tumor and TME components. **Results:** Transcriptomic data were available from 366 samples in 292 mITT pts across both arms (at BL, 257 pts; at Sx, 109 pts) whose characteristics and outcomes were broadly representative of the mITT population (74 pts with paired samples). At BL, 3 distinct phenotypic clusters (C) based on TME features were identified: an immune desert (C1, 24.9% of pts), characterized by a predominance of proliferating tumor cells; immune suppressed (C2, 39.3%), by elevated levels of suppressive myeloid cells, angiogenesis, and fibroblasts; and immune activated (C3, 35.8%), by high levels of effector T cells. A higher proportion of pts with squamous vs non-squamous tumors had phenotype C1 (37.5% vs 13.9%, respectively) while a lower proportion had C3 (22.5% vs 47.4%). The addition of perioperative D improved EFS across all BL C (C1: HR, 0.43; 95% CI, 0.19–0.94; C2: HR, 0.90; 95% CI, 0.50–1.63; C3: HR, 0.41; 95% CI, 0.20–0.81), with least improvement in C2. The same clusters were detected at Sx (C1, 32.1%; C2, 33.9%; C3, 33.9%) and pts with C1 tumors had the highest risk of progression; 36-month EFS rates (95% CI) were 27.8% (12.1–46.0), 55.7% (33.7–73.0), and 77.2% (59.3–88.0) for C1, C2, and C3, respectively. Neoadj D was associated with higher proportions of pts with C2 and C3 phenotypes at Sx, such that the proportion with poor prognosis C1 tumors at Sx was 17.9% vs 47.2% in the D vs PBO arms, respectively. Among pts with C3 tumors at Sx, EFS benefit in the D vs PBO arm was striking (HR, 0.16; 95% CI, 0.03–0.79). **Conclusions:** The TME before and after neoadj Tx impacts EFS in pts with R-NSCLC, with an immune suppressed phenotype associated with reduced perioperative D benefit. The TME differs between squamous and non-squamous tumors and is influenced by neoadj D, which may promote an immune-activated phenotype associated with prolonged EFS benefit with perioperative D. Clinical trial information: NCT03800134. Research Sponsor: AstraZeneca.

Tumor-naïve multimodal cfDNA MRD assay to predict recurrence in a prospective cohort of patients undergoing curative-intent lung cancer resection. First Author: Di Lu, Department of Thoracic Surgery, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong, China

Background: Tumor-informed circulating tumor DNA (ctDNA) assays can achieve high sensitivity for minimal residual disease (MRD) detection after lung cancer resection but require tumor tissue and individualized assay design, limiting scalability and timeliness in routine practice. Tumor-naïve MRD approaches offer a practical alternative for postoperative surveillance; however, their sensitivity remains constrained. Integrating complementary cfDNA features beyond somatic mutations may enhance tumor-naïve MRD detection and postoperative risk stratification. **Methods:** A prospective cohort of 212 patients with resectable stage I–IV lung cancer, predominantly consisting of stage I disease (146 of 212), was enrolled. Postoperative plasma samples were collected at a landmark timepoint (~1 week after surgery) and longitudinally every 3–6 months for up to 3 years. MRD was assessed using ShieldingUltra, a tumor-naïve multimodal cfDNA assay integrating somatic mutations, copy number variations (CNVs), and fragmentomic features based on ultra-deep UMI-based sequencing of an integrated panel covering >2000 cancer-related genes. MRD positivity was determined from integrated multimodal cfDNA signals. Survival outcomes were evaluated using Kaplan–Meier analysis and Cox proportional hazards models, with subgroup analyses by disease stage, histology, and postoperative adjuvant therapy. **Results:** At the postsurgical landmark timepoint, MRD positivity was strongly associated with an increased risk of recurrence (hazard ratio [HR], 9.72; log-rank $p=2.06\times10^{-8}$). Longitudinal MRD monitoring further improved risk stratification, with MRD-positive patients exhibiting a markedly higher recurrence risk (HR, 16.64; log-rank $p=1.66\times10^{-9}$) while maintaining high specificity (~90%). Among the 27 patients who developed radiographically confirmed recurrence, MRD was detected prior to imaging in the majority of cases (21 of 27), providing a median lead time of 264 days. The prognostic value of MRD status was consistently observed across disease stages, histologic subtypes, and postoperative adjuvant treatment strategies, with particularly robust prognostic discrimination observed in patients with stage I disease. Multivariable analyses confirmed MRD positivity as an independent predictor of recurrence in both landmark and longitudinal settings. **Conclusions:** Tumor-naïve multimodal MRD assessment integrating mutation, CNV, and fragmentomic cfDNA features enables sensitive and clinically informative detection of residual disease after lung cancer surgery. Early and longitudinal MRD monitoring provides robust prognostic stratification and meaningful lead time over imaging, supporting its clinical utility for postoperative surveillance in resectable lung cancer. Clinical validity of ultrasensitive single-digit parts per million ctDNA detection in non–small cell lung cancer. First Author: James R.M. Black, Francis Crick Institute, London, United Kingdom, London, United Kingdom

Background: Circulating tumor DNA (ctDNA) is a promising biomarker for detecting molecular residual disease (MRD) and predicting recurrence after curative treatment in non-small cell lung cancer (NSCLC). Ultrasensitive personalized assays have demonstrated clinical validity at detection thresholds of ~80-100 parts per million (PPM). As this assay can detect ctDNA at concentrations an order of magnitude lower (below 10 PPM), we extend these analyses to explore the clinical outcomes of patients with single-digit PPM ctDNA. In the future, this may guide adjuvant treatment decision-making. **Methods:** We analyzed longitudinal plasma samples from 431 patients with stage IA–IIIB NSCLC enrolled in the TRACERx study and treated with upfront surgery. We achieved ultrasensitive MRD testing with ctDNA limits of detection as low as 1-3 PPM across 2994 plasma samples using NeXT Personal, a personalized liquid biopsy assay which tracks up to ~1,800 patient-specific somatic variants. Plasma samples were classified as preoperative, postoperative landmark (10–120 days), or longitudinal follow-up. Associations with recurrence-free survival (RFS) and overall survival (OS) were assessed. **Results:** Preoperative ctDNA detection below 10 PPM was associated with inferior recurrence-free survival (RFS) and overall survival (OS) compared to undetectable ctDNA in individuals with lung adenocarcinoma (<10 PPM vs. undetected: HR: 3.25, 95% CI 1.52-6.94, p = 0.0024 and HR: 3.49, 95% CI 1.24-9.81, p = 0.018 for RFS and OS). Postoperative ctDNA was detected in 21% of patients. Detection below 10 PPM occurred in 16.7%, 15.5%, and 11.5% of stage I, II, and III patients, respectively. ctDNA detection preceded imaging-confirmed recurrence in 120 individuals. In postoperative landmark plasma samples, 18% of ctDNA detections occurred below 10 PPM and were associated with increased risk for recurrence and death versus undetectable ctDNA (RFS: HR 3.49, 95% CI 1.70–7.17, p=0.00067; OS: HR 2.58, 95% CI 1.09–6.14, p=0.032). Within ctDNA-positive patients, <10 PPM was associated with improved outcomes compared with ≥10 PPM (HR: 0.38, 95% CI 0.19-0.78, p = 0.0086, HR: 0.37, 95% CI 0.16-0.86, p = 0.021). **Conclusions:** Sub-10 PPM ctDNA detection identifies a clinically high-risk subgroup of early-stage NSCLC patients. Notably, this included stage I patients who would not typically be classified as high-risk or considered for adjuvant therapy; ctDNA positivity in this group therefore reveals high-risk disease that would otherwise go unrecognized. Reliable detection of ctDNA at sub-10 PPM levels may refine post-surgical risk stratification beyond conventional staging and imaging, enabling earlier identification of molecular relapse and potentially guiding treatment escalation in future practice. Lung cancer stage prediction using longitudinal CT imaging compared with single-timepoint assessment. First Author: Amrik Majumdar, Westfield High School, Chantilly, VA

Background: Lung cancer staging guides treatment decisions but is based on single-timepoint imaging, treating tumors as static entities. Screening programs routinely acquire serial low-dose CTs (LD-CTs), yet this longitudinal information is not used for staging. We hypothesized that modelling temporal change would capture tumor evolutionary dynamics predictive of stage beyond volume change alone, reframing staging as a process rather than a snapshot. **Methods:** We identified 236 NLST participants with biopsy-confirmed lung cancer and three pre-treatment LD-CTs (median interval 12 months). Reference staging used AJCC 7th edition criteria, pathologic where available and otherwise clinical, for overall stage (I–IV) and T and N components. We developed a longitudinal 3D residual network with dual attention and interval-aware temporal encoding, trained using nested five-fold cross-validation. Volume doubling time (VDT) was computed to assess whether temporal features provided information beyond growth rate. The primary endpoint was macro-AUC for overall stage. Secondary endpoints included balanced accuracy, weighted κ, calibration (ECE, Brier score), and decision-curve net benefit. External validation is ongoing in NLSTseg (n = 605) and NSCLC Radiogenomics (n = 211). **Results:** The longitudinal model outperformed a single-timepoint baseline, achieving a macro-AUC of 0.86 versus 0.82, Δ +0.04, $p < 0.05$. Improvements were greatest for N-stage (Δ +0.13) and T-stage (Δ +0.11). Compared with a recent foundation model approach (DINOv2 + ABMIL), the model showed superior N-stage discrimination (AUC 0.86 vs 0.70). Temporal features remained independently predictive after adjustment for VDT, indicating capture of biological signal beyond growth rate. Attention maps consistently highlighted lesion margins and peritumoral regions across timepoints, consistent with invasive behavior. Performance was stable across sex, age, and smoking subgroups, and inference was feasible on standard CPUs. **Conclusions:** Modelling longitudinal change across serial LD-CTs captures tumor evolutionary dynamics that predict lung cancer stage independently of growth rate. This reframes staging as a dynamic, evolution-aware process and provides a practical route for integrating artificial intelligence into screening workflows where serial imaging is already available. External validation is underway. Research Sponsor: None.

Rapid multi-task intraoperative diagnosis of lung cancer via deep neural network-driven label-free femtosecond laser imaging (FLI). First Author: Yin Li, School of Medicine, Shanghai Jiao Tong University, Shanghai Chest Hospital, Shanghai, China

Background: Rapid and accurate intraoperative pathological diagnosis is critical for guiding surgical margins and preserving lung function during lung cancer surgery. Current frozen-section (FS) analysis is time-consuming and prone to artifacts. Femtosecond label-free imaging (FLI) enables high-resolution, non-destructive tissue visualization without staining or freezing, offering a promising platform for real-time assessment. **Methods:** We developed FastLung, an integrated FLI+AI platform for multi-task diagnosis. Fresh, unprocessed tissue samples (326 paired tumor-normal specimens) from surgical resections were imaged using multimodal FLI. FastLung employs a self-supervised deep learning model trained on ~4 million image patches, with formalin-fixed paraffin-embedded (FFPE) histopathology as ground truth. The system provides malignancy probability maps and categorical outputs within 5 minutes. **Results:** FastLung achieved high diagnostic performance across key intraoperative tasks: benign vs. malignant (AUC = 0.9854 $\pm$ 0.01), invasive vs. minimally invasive adenocarcinoma (AUC = 0.9573 $\pm$ 0.03), and adenocarcinoma vs. squamous cell carcinoma (AUC = 0.9892 $\pm$ 0.009). It significantly reduced diagnostic turnaround time (5–10 min vs. 20–30 min for FS, 60–80% faster) while maintaining accuracy comparable to or exceeding FS. In core needle biopsies (n = 94), accuracy reached 95.8%. The platform also demonstrated consistent performance across operators and time, supporting reliable integration into surgical workflow. **Conclusions:** FastLung combines label-free FLI with deep learning to deliver rapid, accurate, and reproducible intraoperative diagnosis of lung cancer, outperforming frozen sections in speed and multidimensional assessment. Its robust performance in both resection and biopsy specimens highlights its potential to improve surgical decision-making and extend toward pan-cancer diagnostic applications. Noninvasive imaging biomarkers for survival risk stratification with tarlatamab in ES-SCLC. First Author: Mohammadhadi Khorrami, Wallace H. Coulter Department of Biomedical Engineering, Georgia Institute of Technology and Emory University, Atlanta, GA

Background: Subsequent treatment for extensive-stage small cell lung cancer (ES-SCLC) following platinum-etoposide chemotherapy +/- an immune checkpoint inhibitor was historically limited to alternative forms of chemotherapy with relatively poor clinical outcomes. Bispecific delta-like ligand 3 (DLL3)-targeting T-cell engagers, such as tarlatamab, have since demonstrated clinically meaningful activity with notable improvements in survival. Although there was a modest improvement in median progression-free survival (PFS) with tarlatamab in the phase 3 DeLLphi-304 trial, 20% of patients remained free from disease progression at 12 months. Unfortunately, conventional clinical factors and early radiographic responses are unable to distinguish transient from sustained benefit; thus underlying the need for validated biomarkers to identify patients likely to derive a durable response from tarlatamab. **Methods:** This study sought to evaluate whether radiomic texture and quantitative vessel tortuosity (QVT) metrics derived from baseline CT imaging are associated with PFS and overall survival (OS) in patients with ES-SCLC receiving tarlatamab.50 patients from Cleveland Clinic with ES-SCLC who received tarlatamab after front-line chemoimmunotherapy were included in this study. Radiomic texture and QVT features characterizing intratumoral heterogeneity and vascular architecture were extracted from CT scans obtained before the first dose of tarlatamab (median scan-to-treatment interval: 33.5 days). A least absolute shrinkage and selection operator Cox regression model with cross-validation identified prognostic features for PFS and OS. A radiomic risk score (RRS) was computed as a weighted linear combination of selected features, and patients were stratified into high- and low-risk groups using the median RRS. Cox regression and Kaplan–Meier analyses with log-rank testing evaluated associations with PFS and OS. **Results:** On univariable analysis, RRS was significantly associated with PFS (HR = 2.3, 95% CI 1.36–3.94, *P* = 0.0019) and OS (HR = 3.9, 95% CI 1.67–9.1, *P* = 0.0016). Kaplan–Meier analyses demonstrated significantly shorter PFS and OS in the high-risk group. In multivariable models adjusting for age, sex, race, smoking history, COPD, and prior lines of therapy, RRS remained the only factor independently associated with PFS (HR = 2.1, 95% CI 1.16–4.0, *P* = 0.014) and OS (HR = 5.87, 95% CI 2.0–17.0, *P* = 0.001). **Conclusions:** Baseline CT-derived radiomic and vascular features represent noninvasive biomarkers for predicting PFS and OS in patients with ES-SCLC receiving tarlatamab. Further validation of these novel features can improve patient selection, treatment sequencing, and optimized utilization of DLL3-targeted therapy in this unique cancer population with otherwise limited treatment options. Development and validation of an artificial intelligence–based deep learning imaging model for early lung cancer detection: DAVINCI, a retrospective study of 8,962 patients. First Author: Syeda Hafsa Noor-AIN, Ayaan Institute of Medical Sciences, Srinagar, India

Background: Lung cancer is the leading cause of cancer-related mortality worldwide, primarily due to delayed diagnosis and diagnostic variability in histopathological assessment. Advances in deep learning applied to medical imaging offer the potential to enhance early detection accuracy, reduce interobserver variability, and improve diagnostic efficiency in lung cancer. **Methods:** In this retrospective study, we evaluated DAVINCI using a dataset of 8,962 patients with confirmed lung malignancies. The model utilizes a specialized architecture combining convolutional neural networks (CNNs) and residual blocks to optimize feature extraction from high-resolution pathological slides. Performance was measured via detection accuracy, recall, specificity, and Area Under the Curve (AUC). **Results:** A total of 8,962 patients were included in the analysis. The DAVINCI model correctly identified lung cancer in 93% of cases, corresponding to 8,334 of 8,962 patients, with a 95% confidence interval (CI) of 86%–100% (7,707–8,962 patients). Model specificity was also 93% (95% CI, 86%–100%), indicating a high true-negative rate. Sensitivity (recall) was 87%, with correct detection in 7,797 patients and a 95% CI of 80%–94% (7,170–8,425 patients). The model demonstrated strong discriminatory performance, achieving an area under the curve (AUC) of 0.91 (95% CI, 0.84–0.98). In comparison, active pathologists achieved a mean diagnostic accuracy of 83%, corresponding to 7,438 of 8,962 cases, with a 95% CI of 76%–90% (6,811–8,066 cases). In terms of efficiency, DAVINCI processed whole-slide images in 16–19 seconds, substantially faster than conventional manual review, which typically requires several minutes per slide. **Conclusions:** DAVINCI demonstrated superior accuracy, robust discriminatory performance, and markedly faster processing compared with human review, supporting its potential role in early lung cancer detection at scale. Research Sponsor: None.

Cross-stage validation of a multimodal machine learning model to predict pathological complete response to neoadjuvant chemotherapy or chemoimmunotherapy in resectable stage III non–small cell lung cancer. First Author: Loïc Ferrer, SOPHiA GENETICS, Pessac, France

Background: Pathological complete response (pCR) after neoadjuvant chemoimmunotherapy is associated with improved outcomes in resectable non–small cell lung cancer (NSCLC), yet reliable tools to predict treatment response before surgery are lacking. Machine learning models have shown promise in advanced disease, but their ability to generalize across disease stages remains uncertain. We evaluated the performance of a machine learning model developed in stage IV NSCLC when applied to a cohort of patients with surgically resectable stage III disease treated with neoadjuvant chemotherapy or chemoimmunotherapy. **Methods:** The DEEP-Lung-IV study (NCT04994795) developed and validated machine learning models for personalized risk prediction based on multimodal data in patients with stage IV NSCLC treated with first-line pembrolizumab and/or chemotherapy. The models incorporated multimodal clinical routine data such as clinical, biological and CT-scan images. For the present study, the trained pre-treatment model was applied without retraining to patients enrolled in the NADIM trials (NCT03081689, NCT03081689) who received neoadjuvant chemotherapy alone (CTx), or in combination with nivolumab (Nivo+CTx), followed by surgery. Model performance was assessed using the area under the ROC curve (AUC) by considering only the last chest CT-scan image before surgery, or by combining it with other multimodal data. **Results:** A total of 103 patients with available clinical, biological, imaging data and who experienced surgery was considered for validation analysis (N = 88 patients with Nivo+CTx, N = 15 patients with CTx). When applied to the stage III NADIM cohort, the stage IV–derived model demonstrated strong predictive performance for pCR, with an AUC of 0.68 (95% CI, 0.57–0.78) in all patients using the CT-scan image only, rising to 0.76 (95% CI, 0.67–0.84) when additionaly leveraging on clinical and biological data. Performance was consistent across clinically relevant subgroups, especially in the patients treated with Nivo+CTx, with AUC estimates from 0.65 (95% CI, 0.54–0.76) using CT-scan image alone to 0.72 (95% CI, 0.61–0.82) when combined with the other multimodal data. The model was capable of handling missing predictor values, and preserved predictive value despite differences in disease stage and treatment intent. **Conclusions:** A machine learning model trained in advanced-stage NSCLC accurately predicted pathological response to neoadjuvant chemo- or chemoimmuno-therapy in a resectable stage III cohort, supporting the biological continuity of treatment response across disease stages. This cross-stage generalizability highlights the potential of machine learning–based tools to guide treatment personalization in earlier-stage NSCLC and warrants prospective validation. Multimodal intraoperative diagnosis and grading system integrating macroscopic images, CT imaging, and textual reports for adenocarcinoma (MaCTex) in early-stage LUAD: A multicentric diagnostic study. First Author: Yingwei Lu, Guangdong Cardiovascular Institute, Guangzhou, Guangdong, China

Background: Intraoperative frozen section (IFS) analysis is pivotal for guiding surgical strategies in stage IA lung adenocarcinoma (LUAD), specifically the extent of resection and lymph node dissection. However, IFS is constrained by sampling errors and prolonged turnaround times, which can compromise diagnostic precision and surgical efficiency. To address these unmet needs, we developed and validated a multimodal artificial intelligence framework. By integrating preoperative chest CT imaging, unstructured radiology text reports, and intraoperative macroscopic images of resected specimens, this system aims to deliver rapid, precise intraoperative predictions, thereby mitigating reliance on traditional IFS and optimizing surgical decision-making. **Methods:** This retrospective, multicenter study enrolled patients with stage IA LUAD who underwent complete resection between June 2020 and September 2023 across three institutions (Guangdong Provincial People's Hospital, Affiliated Hospital of Guangdong Medical University, and Meizhou People's Hospital). We collected preoperative thin-slice chest CT scans and unstructured text reports within three months prior to surgery. Intraoperative macroscopic images of resected specimens were captured via smartphone under natural lighting. We developed MaCTex, a multimodal AI model, to predict the IASLC grading system (PIL, MIA, IAC G1, G2, G3). Performance was evaluated against the gold standard of postoperative paraffin pathology. The study is registered with the Chinese Clinical Trial Registry (ChiCTR2500111776). **Results:** The cohort included 1,516 patients (yielding 1,638 pulmonary nodules) with matched preoperative CT imagings/reports and 2,344 intraoperative macroscopic images. We developed four distinct models for evaluation: a CT-only model, a CT-Text model, a Gross Image model, and the comprehensive MaCTex framework. The CT-Text model achieved a diagnostic AUC of 0.857, outperforming the unimodal CT model with an AUC of 0.837. The Gross Image model achieved a performance of 0.82 in five-class prediction. Notably, the integration of unstructured CT text reports significantly enhanced model efficacy, underscoring the critical value of radiologist expertise in refining intraoperative diagnostics. **Conclusions:** We established a robust multimodal AI framework integrating radiographic data, clinical text, and macroscopic pathology that enables efficient and accurate intraoperative prediction of IASLC grading in lung adenocarcinoma. By circumventing the sampling limitations of traditional methods, MaCTex serves as a promising alternative or adjunct to intraoperative frozen sections, providing thoracic surgeons with real-time, precise decision support to optimize surgical management. Research Sponsor: None.

A deep learning model for intraoperative diagnosis of lung adenocarcinoma using frozen section whole-slide images (CryoPath): A multicentric diagnostic study. First Author: Jinqing Li, Guangzhou University of Chinese Medicine, Guangzhou, Guangdong, China

Background: Intraoperative frozen section (FS) analysis is critical for guiding surgical decision-making in lung cancer. However, its diagnostic accuracy can be limited by time constraints, sampling issues, and inter-pathologist variability. Deep learning-based analysis of whole-slide images (WSIs) offers a new paradigm for real-time, objective intraoperative diagnosis. **Methods:** We developed and validated an artificial intelligence system, CryoPath, for the intraoperative diagnosis of lung adenocarcinoma (LUAD) from FS-WSIs. The system was trained and tested using a large, multicentric, retrospectively collected cohort comprising 3000 LUAD FS-WSI cases from seven medical centers in China. The model architecture is based on attention-challenge multiple instance learning framework with vision transformer for feature extraction. CryoPath was designed for end-to-end prediction of diagnostic subtypes (pre-invasive lesions, minimally invasive adenocarcinoma and invasive adenocarcinoma) and key pathological features such as extent of invasion and lymphovascular invasion from FS-WSIs. **Results:** The study included 1,042 patients, yielding 1,139 WSI with early-stage lung adenocarcinoma from multiple centers, which comprised a total of 637 WSIs with IAC, 402 with MIA, and 100 with PIL. The CryoPath model achieved an AUC of 0.931 for discriminating IAC from PIL/MIA, which achieved a sensitivity of 0.87 and a specificity of 0.85. In clinical decision simulation, the model-assisted strategy increased surgical decision accuracy from 75% to 88%. 15 WSIs classified as PIL on FS but upgraded to IAC on permanent sections by pathologist were corrected by CryoPath and Attention heatmaps generated by the model highlighted histologically relevant regions. CryoPath model achieved an AUC of 0.92 (95% CI: 0.90–0.94) for discriminating IAC from PIL/MIA on the test set. . In clinical decision simulation, the model-assisted strategy increased surgical decision accuracy from 75% to 88. Attention heatmaps generated by the model highlighted histologically relevant regions. **Conclusions:** The CryoPath system demonstrates for the first time that large-scale deep learning-based analysis of FS-WSIs can achieve high-accuracy, real-time, and interpretable intraoperative diagnosis for LUAD. This system has the potential to serve as a powerful adjunct tool for pathologists and surgeons, potentially reducing diagnostic variability, shortening intraoperative wait times, and providing an objective foundation for precise surgical strategy. A prospective, multi-center clinical trial is being planned to further evaluate its clinical utility. Research Sponsor: None.

Intratumoral heterogeneity of *MTAP* loss by immunohistochemistry in non–small cell lung cancer: Implications for clinical outcomes. First Author: Tsuyoshi Hirata, National Cancer Center Hospital East, Kashiwa, Japan

Background: MTAP-cooperative PRMT5 inhibitors are under development for MTAP-loss solid tumors including non-small cell lung cancer (NSCLC). However, the intratumoral heterogeneity of MTAP loss in NSCLC and its potential implications for clinical outcomes remain incompletely understood. **Methods:** Tumor specimens from patients with NSCLC who underwent surgical resection between January 2019 and October 2019 in our institution were retrospectively collected. MTAP expression status was evaluated in surgically resected specimens using MTAP immunohistochemistry (IHC) 2G5 and categorized as retained (100% positive tumor cells), partial loss (1–99%), or complete loss (0%). MTAP status was confirmed by fluorescence in situ hybridization (FISH). Clinicopathological characteristics and survival outcomes were analyzed according to MTAP expression status. **Results:** MTAP expression status was successfully analyzed in 196 specimens from primary lesion of patients with NSCLC. MTAP expression status was classified as retained in 131 specimens (67%), partial loss in 43 (22%), and complete loss in 22 (11%). Of 14 specimens of which MTAP status was evaluated by FISH, the MTAP status by IHC and FISH were completely consistent. Compared to the patients with retained, the patients with complete loss showed no significant differences in the clinicopathological characteristics, but the patients with partial loss were significantly more frequently associated with adenocarcinoma histology (93% vs 74%, $P = 0.02$) and never-smoker status (51% vs 22%, $P < 0.001$). Among specimens diagnosed as adenocarcinoma, those with partial loss showed a significantly higher frequency of lepidic and papillary predominant patterns compared to those with complete loss (83% vs 50%, $P = 0.02$). Among specimens of which *EGFR* mutation status was analyzed, the frequency of EGFR mutations was significantly higher in specimens with MTAP complete/partial loss compared to MTAP retained (59% vs 30%, $P = 0.03$). There were no significant differences in the recurrence-free survival (RFS) and the overall survival (OS) among the patients with complete loss, partial loss and retained (5-year RFS rates: 82%, 83% vs 76%, 5-year OS rates: 90%, 81% vs 77%). MTAP expression status of corresponding metastatic lymph node (mLN) was evaluated in 6 patients with MTAP partial loss. MTAP expression status for corresponding mLN were consistent with predominant MTAP expression status for primary lesion in 4 patients (67%). **Conclusions:** Intratumoral heterogeneity of MTAP expression was observed in 22% of NSCLC, particularly with adenocarcinoma histology and in never-smokers. Intratumoral heterogeneity of MTAP loss may contribute to inaccurate assessment of MTAP status on small biopsy samples. MTAP expression status was not associated with the prognosis in patients with surgically resected NSCLC. Research Sponsor: None.

Cancer-related overall survival for patients on durvalumab for stage III unresectable non–small cell lung cancer with PD-L1 positive and negative tumors. First Author: Zohra Nooruddin, University of Texas Science Center at San Antonio, San Antonio, TX

Background: Durvalumab improves overall survival (OS) and progression free survival (PFS) when used as consolidation therapy for patients with stage III unresectable non-small cell lung cancer (UR-NSCLC) following chemoradiotherapy (CRT). However, it is uncertain if similar benefits are achieved for patients with PD-L1 positive (1% or greater) and negative (<1%) tumors. We previously found no difference in OS, but no study has yet compared cancer-related overall survival (OS). **Methods:** Patients with stage III UR-NSCLC on durvalumab following CRT, at any Veterans Health Administration (VHA) facility, from 1/1/17 to 6/30/20, were included. Patients were followed from durvalumab initiation through the earliest of their last VHA visit, loss to follow up, death, or end of study (6/30/25). Electronic health record data were retrospectively collected to determine durvalumab treatment course, OS, and cancer-related OS—as determined by review of each patient's chart and death certificate. Kaplan-Meier and Cox regression methods were used to compare cancer-related OS. **Results:** Of the 340 eligible patients, 221 (65%) had PD-L1 positive and 119 (35%) had PD-L1 negative tumors. Groups were similar in age, sex assigned at birth, White race, smoking status, marital status, Charlson score, ECOG 1+ status (78% overall), histology, stage, EGFR, and RAS mutations. Patients with PD-L1 positive and negative tumors had similar median (interquartile range [IQR]) number of durvalumab doses (15 [6-24] vs 13 [5-24], p=0.55), months of durvalumab (8 [3-12] vs 6 [2-12]), and months of follow-up (33 [12-69] vs 28 [11-63], p=0.22). OS was similar for patients with PD-L1 positive and negative tumors in a multivariate model accounting for ECOG 1+ status (HR 0.93, 95% CI 0.70-1.24). Likewise, cancer-related OS was similar in the multivariate model (HR 0.87, 95% CI 0.63-1.21). Median OS was 33.3 months (95% CI 29.8-47.3) for patients with PD-L1 positive tumors and 28.5 months (95% CI 21.6-39.7) for patients with PD-L1 negative tumors. Likewise, median cancer-related OS was 20.4 months (95% CI 16.0-25.4) for patients with PD-L1 positive tumors and 20.6 months (95% CI 15.4-28.5) for patients with PD-L1 negative tumors. The table depicts common causes of death. **Conclusions:** In this real-world study of VHA patients on durvalumab for stage III UR-NSCLC, OS and cancer-related OS were similar for those with PD-L1 positive and negative tumors. Research Sponsor: AstraZeneca Pharmaceuticals LP.

Chromosomal instability and integrated tumor-margin immune ecosystem remodeling as drivers of progression of pulmonary ground-glass nodules. First Author: Ruoyi Jin, Department of Thoracic Surgery, Peking University People's Hospital, Beijing, China

Background: Precise management of pulmonary ground-glass nodules (GGNs) is hindered by an incomplete understanding of the biological determinants driving the transition from indolence to aggressive progression. **Methods:** In a multicenter longitudinal study of 845 patients, we stratified GGNs into three trajectories via serial CT: Stable, ground glass opacity (GGO)-predominant progression, and solid-predominant progression. Integrative profiling was performed using WES, WGS, bulk RNA-seq, Visium HD, CosMx SMI, and imaging mass cytometry. We developed a deep learning model to predict solid-predominant progression using baseline radiographic features. **Results:** During a median follow-up of 55.8 months, our analysis indicated GGNs progression was driven predominantly by chromosomal instability rather than distinct point mutational profiles. Specifically, progressive GGNs harbored catastrophic structural variations, including chromothripsis, kataegis, and extrachromosomal DNA which were absent in stable lesions. Spatially, the immune microenvironments diverged sharply. While stable GGNs were quiescent, GGO-predominant growth lesions were significantly enriched with antigen-presenting macrophages (p = 0.00054), which facilitated the spatial aggregation of activated lymphocytes and promoted the formation of early tertiary lymphoid structure (TLS)-like niches through CCL19-CCR7 signaling. Conversely, in solid-predominant aggressive progression nodules, macrophages underwent a phenotypic shift from antigen-presenting toward SPP1+ state, accompanied by a marked reduction in CD74 and HLA-DR expression (p = 0.0019). Within the tumor core, SPP1+ macrophages suppressed T-cell effector function via SPP1-CD44 signaling. At the tumor margin, hypoxia-adapted endothelial cells exhibited significant upregulation of CD274 (PD-L1), contributing to T-cell inhibition, while activated fibroblasts deposited dense collagen matrices formed a physical barrier restricting B-cell infiltration. Together, these mechanisms established a coordinated immunosuppressive niche facilitating tumor growth. Leveraging these biological insights, we developed a deep learning model extracting radiomic features from the baseline CT nodule and an extended 2.5mm perinodular margin. This approach significantly outperformed models using the nodule alone or the nodule plus a 1mm margin ($p < 0.05$), achieving AUCs of 0.89 in the training cohort (n = 471), 0.85 in the internal test cohort (n = 202) and 0.83 in the external cohort (n = 117). **Conclusions:** Distinct radiographic progression trajectories of GGNs are underpinned by divergent chromosomal and spatial immune programs at the tumor core and margin, providing a biological foundation for margin-aware AI strategies to predict aggressive progression and guide optimal surgical intervention. PSG copy number amplification and association with poor survival in early-stage female lung adenocarcinoma patients. First Author: Jung Hun Oh, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Pregnancy-specific glycoproteins (PSGs) are essential for maintaining maternal immune tolerance by modulating innate and adaptive responses to prevent fetal rejection. Given our prior finding that increased PSG expression is associated with worse outcomes for female lung cancer patients, we aimed to investigate whether copy number alterations (CNAs) show the same sex-dependent effect on survival in early-stage disease. **Methods:** We evaluated the sex-specific impact of PSG CNAs across two lung adenocarcinoma (LUAD) cohorts: The Cancer Genome Atlas (TCGA) (n = 503; 269 females, 234 males) and MSK-IMPACT (n = 3,863; 2,450 females, 1,413 males). CNAs were retrieved from cBioPortal for the TCGA cohort and determined via the FACETS algorithm on BAM files for the MSK-IMPACT cohort. Overall survival (OS) differences between patients with and without PSG copy number amplification were analyzed using Kaplan-Meier curves along with log-rank tests. Additionally, we examined the association between tumor stage and the prognostic impact of PSG copy number amplification. **Results:** In the TCGA cohort, female patients with PSG copy number amplification exhibited significantly worse OS compared to those without (HR = 1.96, p = 0.0039), while no significant survival difference was observed in males (HR = 1.37, p = 0.1902). This sex-specific trend was further validated in the MSK-IMPACT cohort, where the association between PSG copy number amplification and poor OS was highly significant in females (HR = 1.46, p = 7.5×10^{-6}) but relatively weaker in males (HR = 1.29, p = 0.0089). Notably, the prognostic impact of PSG copy number amplification was stage-dependent; while no significant survival differences were found for either sex in Stage 4 disease across both cohorts, the effect was highly pronounced in early-stage female patients. In the TCGA cohort, female patients with early-stage disease showed increasingly significant survival disparities between patients with and without PSG copy number amplification as stage decreased (Stage $\leq$ 3: HR = 1.81, p = 0.0182; Stage $\leq$ 2: HR = 2.03, p = 0.0129; Stage 1: HR = 2.51, p = 0.0047), whereas no such associations were found in males. Similarly, in the MSK-IMPACT cohort where tumor stage was dichotomized (Stages 1–3 vs. Stage 4), female patients with Stage $\leq$ 3 disease showed a strong survival difference between patients with and without PSG copy number amplification (HR = 1.86, p = 1.79×10^{-5}), which remained significantly stronger than the association observed in the male patients (HR = 1.49, p = 0.0129). **Conclusions:** Our findings raise the question of the potential role of PSG-mediated immune modulation in promoting tumor progression in early-stage female lung cancer patients, and suggest that there may be value in sex-stratified approaches to clinical risk assessment and in therapeutic targeting. Breath analysis of volatile organic compounds with mid-infrared laser spectroscopy in a cohort of lung cancer patients and control subjects. First Author: Boshi Duan, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, China

Background: Exhaled volatile organic compounds (VOCs) represent potential non-invasive biomarkers for lung cancer detection. This study assessed a mid-infrared cavity ring-down spectroscopy (CRDS) platform for measuring key breath VOCs in a large clinical cohort including lung cancer patients across stages/histologies, carcinoma in situ, and non-cancer controls. **Methods:** This prospective single-center validation study enrolled 1,041 participants: approximately 500 with pathologically confirmed lung cancer (various stages and histologies), 25 with carcinoma in situ, healthy controls, patients with benign pulmonary diseases, and those with low- and high-risk pulmonary nodules. Breath samples were collected under standardized fasting and mouth-rinsing conditions and analyzed using a self-developed mid-infrared CRDS system targeting isoprene, acetone, and formaldehyde (detection limit $<$ 10 ppb). The primary endpoint was diagnostic accuracy for distinguishing lung cancer (including carcinoma in situ) from healthy controls, measured by area under the receiver operating characteristic curve (AUC). Sample size was powered to detect an AUC difference of $\geq$0.15 from 0.50 (null hypothesis) with $>$ 85% power at α = 0.05. Group comparisons used independent t-tests or Mann-Whitney U tests with Bonferroni correction for multiple testing. Predictive modeling employed logistic regression and machine learning (random forest and XGBoost) with 5-fold cross-validation; feature importance and SHAP values were assessed. Performance metrics included AUC, sensitivity, specificity, and 95% confidence intervals (CI). **Results:** Isoprene exhibited the most consistent group differences across comparisons ($P < 0.001$ in lung cancer vs healthy and carcinoma in situ vs healthy). Random forest and XGBoost models yielded AUC of 0.94 (95% CI, 0.92-0.96) for lung cancer vs healthy controls and 0.97 (95% CI, 0.95-0.99) for carcinoma in situ vs healthy controls. At optimal thresholds, sensitivity and specificity reached 90-96% and 92-95%, respectively, in primary analyses. Subgroup performance remained robust in non-smokers and stage I patients. Decision curve analysis demonstrated net clinical benefit across 1-20% risk thresholds compared with low-dose CT screening strategies. Acetone and formaldehyde provided supplementary contributions in pathological subtype and benign disease distinctions. **Conclusions:** Mid-infrared CRDS-based breath VOC analysis shows feasible diagnostic performance for lung cancer detection, including strong results in carcinoma in situ and early-stage disease, in this large cohort. Multi-center prospective validation is needed to confirm clinical utility and integration into screening strategies. Research Sponsor: None.

Management of pulmonary nodules across Latin America: A real-world observational study. First Author: Danilo Lopes, Astrazeneca, São Paulo, Brazil

Background: Lung cancer is the leading cause of cancer-related mortality globally, with lung cancer accounting for 6.8% of all cancer cases in Latin America and the Caribbean. Despite the availability of guidelines, lung cancer early detection and the management of pulmonary nodules across the region are inconsistent, often hindered by limited resources and fragmented health systems. This study aimed to characterize the diagnostic and treatment journey of pulmonary nodules in patients with lung cancer across Latin America. **Methods:** This was a non-interventional observational study that captured retrospective (March 2019 to July 2021) and prospective (July 2021 to March 2023) data across 16 health institutions in Latin America. Participants were followed for at least two years or until treatment initiation or withdrawal. Data were collected from patients' medical records. Patient characteristics and physicians' involvement were summarised descriptively. Median time estimates of receiving diagnostic procedure or examination from nodule identification and estimates on median time of treatment decision from lung cancer diagnosis were analysed descriptively using the Kaplan-Meier (KM) method. **Results:** Among a total of 546 participants (215 prospective; 331 retrospective), 82 were diagnosed with lung cancer during the study period, most commonly with Stage I lung cancer (5.9%). The majority of referrals to dedicated nodule clinics were made by pulmonologists (44.1%) and prompted by incidentally detected pulmonary nodules (83.9%), which were typically solid and ranged from 8mm to 3cm in size (79.5%). The median time to receiving a diagnostic procedure from nodule identification was 10.83 (prospective) and 12.47 (retrospective) months, while the median time to treatment decision post-diagnosis was 1.20 months across both cohorts. Multidisciplinary teams were involved in only 0.3% of diagnostic procedures, but were involved in at least 40% of treatment decisions across different follow-up visits. **Conclusions:** This study reveals substantial delays in diagnostic procedures and limited multidisciplinary team involvement during early patient evaluation phases in Latin America. Compared with international studies, the study population experienced considerably longer delays in receiving diagnostic procedures. These findings underscore the need for structured referral pathways and broader implementation of critical tools across the region. In addition, adherence to established guidelines is critical to improve early detection and treatment outcomes of lung cancer patients. Research Sponsor: AstraZeneca.

Prognostic stratification of early-stage NSCLC patients using preoperative circulating tumor DNA (ctDNA). First Author: Zhicheng Huang, Department of Thoracic Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Curative-intent surgery for early-stage non-small-cell lung cancer (NSCLC) is followed by relapse in approximately 20–30% of patients. We previously reported interim results of the prospective MUSETALK-Lung01 study (multiomics sequencing technique application kick-start), showing that pre-operative, ctDNA positivity predicted increased relapse risk. Here we present the final analysis of the full cohort and incorporate pathological risk factors to conduct a more comprehensive prognostic evaluation for early-stage NSCLC. **Methods:** The MUSETALK-Lung01 study is a prospective, longitudinal, observational study designed to evaluate the clinical utility of a tumor-naïve ctDNA assay in patients with early-stage NSCLC. Cell-free DNA (cfDNA) was extracted, and subjected to CanCatch Surf test as described previously. The assay algorithm reports both the ctDNA detection status (positive/negative) and the estimated ctDNA levels. Longitudinal data, including vital status, treatment, relapse, and survival status, were collected over 5 years. The study was approved by the institutional review board or ethics committee at each site, with all participants providing written informed consent. **Results:** The complete cohort of MUSETALK-Lung01 consisted of 455 early-stage NSCLC patients, among whom the median follow-up time was 63 months, with a 2-year recurrence rate of 7.0% and a presurgical ctDNA positivity rate of 6.4%. To identify clinical and biological factors associated with survival, both univariate and multivariate analyses were performed. Presurgical ctDNA positivity was strongly associated with inferior recurrence outcomes (χ^2 $p < 1 \times 10^{-9}$), indicating that tumor burden can be prognostic beyond clinical stage and pathological conditions. Specifically, among clinical stage I lung adenocarcinoma (LUAD) patients, ctDNA detection demonstrated robust prognostic stratification for recurrence risk (2-year RFS: 60% [95% CI: 40%–91%] vs. 96% [95% CI: 94%–98%]; log-rank $p < 1 \times 10^{-7}$). Similar prognostic value of ctDNA was observed in stage II-IIIA LUAD patients, albeit with reduced discriminative power (log-rank $p < 0.01$). After incorporating pathological information, the performance of prognostic stratification was further improved. **Conclusions:** By evaluating ctDNA abundance, we provide highly sensitive and specific prognostic assessments and risk stratification for early-stage NSCLC patients. The non-invasive, nature of this test enables precision peri-operative management and selection of patients who may benefit from innovative treatments, with the potential to improve survival. Pseudoprogression after neoadjuvant immunotherapy for resectable NSCLC: Incidence, PET/CT patterns, and differentiation. First Author: Li-Bo Berlin Tang, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: Neoadjuvant immunotherapy combined with chemotherapy is now the standard of care for resectable non-small cell lung cancer (NSCLC). However, evaluating treatment response remains challenging due to the unique response pattern of pseudoprogression associated with immune checkpoint inhibitors (ICIs), which may lead to unnecessary cancellation of curative surgeries. This study aimed to characterize pseudoprogression and investigate strategies for distinguishing pseudoprogression from true tumor progression in the neoadjuvant ICI setting. **Methods:** This retrospective study included 283 patients with resectable NSCLC who underwent neoadjuvant ICI therapy (n=235) or targeted therapy (n=48) between January 2021 and December 2023. PET-CT scans were acquired at baseline and before surgery. Radiological and metabolic responses were evaluated using RECIST 1.1 and EORTC criteria, respectively. Pathological responses were assessed according to IASLC guidelines. Multivariate logistic regression and receiver operating characteristic analyses were performed to identify predictors of pseudoprogression and evaluate diagnostic performance. **Results:** Among 283 patients (ICI 235, TKI 48), 9.2% (26 patients) were classified as having progressive disease (PD) by RECIST 1.1, all in the ICI cohort. According to EORTC on PET-CT, progression increased to 25.1% (71 patients). Despite radiologic progression, all 26 patients underwent R0 resection; pCR and MPR rates were 53.8% and 11.6%. Among patients without radiologic progression, pCR and MPR were 30.0% and 19.1%, with no differences in R0 rate or pathological response (p = 1.00 and 0.06). Among 71 patients with progressive metabolic disease (PMD) on PET/CT, 69 (97.2%) achieved R0 resection; 27 (38.0%) achieved pCR and 12 (16.9%) achieved MPR, with similar outcomes by PMD status (p = 1.00 and 0.53). In both the ICI cohort and overall population, primary tumor progression was associated with lower MPR rates than lymph node or distant progression (16.7%, 61.2%, and 100%; p = 0.001) and worse EFS and OS. In the TKI cohort, imaging-defined progressive or stable disease was associated with lower MPR and worse survival. Pseudoprogression occurred in 7.2% by CT, increasing to 16.2% with PET-CT, predominantly nodal. A $\geq$53.1% reduction in primary-tumor SUVmax identified pseudoprogression (AUC 0.865; sensitivity 73.8%; specificity 88.6%). A multivariable model combining ΔSUVmax, longest diameter change (%), smoking status, and histology showed excellent discrimination (AUC 0.935). **Conclusions:** Pseudoprogression is common in resectable NSCLC treated with neoadjuvant ICI therapy, presenting as nodal or distant lesions without primary tumor progression. A multifactorial model incorporating primary tumor SUVmax changes provides a robust tool for distinguishing pseudoprogression and guiding clinical decision-making. Research Sponsor: None.

Class-specific clinical and molecular features of *SMARCA4* alterations in non—small cell lung cancer. First Author: Chihiro Takemura, Department of Thoracic Surgery, National Cancer Center Hospital, Tokyo, Japan

Background: *SMARCA4* mutations occur in 5–10% of non-small cell lung cancers (NSCLCs) and are associated with poor overall survival, especially class I *SMARCA4* alterations (truncating mutations, fusions, and homozygous deletion), which often result in *SMARCA4* loss. However, the biological and clinical significance of *SMARCA4* alteration classes and their distribution among pan-cancers in Asians remain unclear. **Methods:** We analyzed pan-cancer across solid tumors patients enrolled in Center for Cancer Genomics and Advanced Therapeutics (C-CAT) database (approval number CDU2021-001N) between June 2019 and October 2025 and patients with surgically resected NSCLCs at our hospital between 1999 and 2023 (approval number 2005-109) were performed by whole exome sequencing. Somatic mutations were annotated using Annovar and OncoKB. *SMARCA4* mutations were classified into two groups: class I or class II (missense or other). Copy number alterations were detected using facets and GISTIC2. Transcriptomic differences were assessed using RNA sequencing with DESeq2 and gene set enrichment analysis (GSEA). Tumor immune cell composition was assessed using CIBERSORTx. **Results:** In the C-CAT pan-cancer dataset (N=10,155), *SMARCA4* mutations were frequently identified in NSCLC (NSCLC vs. others; 12.3% vs. 4.0%). In NSCLC, *TP53* was the most frequent co-altered gene in patients with class I and class II mutation (73.0% vs. 63.0%). Other major genes did not show clear class-associated differences. In our NSCLC cohort (N=1,166), the frequency of *SMARCA4* class I and II mutation was 2.3% (all truncating) and 2.3% (all missense), respectively. The class I *SMARCA4* alterations were associated with significantly poorer survival outcomes compared with wild- type tumors (OS: HR = 2.04, 95% CI = 1.24–3.12, p = 0.007; RFS: HR = 2.09, 95% CI = 1.28–3.20, p = 0.005), whereas class II alterations were not significantly different in survival (OS: HR =0.50, 95% CI =0.40-0.61, p =0.17; RFS: HR = 0.46, 95% CI = 0.42–0.76, p =0.12). Regarding transcriptomic analysis and genomic profiling, class I tumors showed activation of *ASCL1*-related transcriptional programs, suppression of squamous/basal lineage differentiation, increased $CD8^+$ T-cell infiltration, and recurrent copy number loss of *SMARCA2* and *CDKN2A/B* compared with wild type tumors. In contrast, class II tumors showed limited transcriptomic divergence from wild-type tumors, downregulating *SPRR2E*, *KRT5*, and *KRT13* without a significant $CD8^+$ T-cell difference. **Conclusions:** In NSCLC, class I *SMARCA4* altered tumors are associated with poor survival outcomes, and an immune-active molecular phenotype with recurrent copy number loss of *SMARCA2* and *CDKN2A/B*, whereas class II tumors lack these features and do not show adverse survival compared to wild-type tumors. This highlights the distinct clinical implications of *SMARCA4* alteration class. Research Sponsor: None.

Outcomes of atypical *EGFR* mutations in early-stage *EGFR*-mutated non-small cell lung cancer (NSCLC). First Author: Jacqueline V. Aredo, Stanford Cancer Institute, Stanford, CA

Background: Adjuvant osimertinib (osi) improves survival outcomes in patients (pts) with early-stage *EGFR*-mutated NSCLC harboring the classical *EGFR* exon 19 deletions (ex19del) or L858R mutation after surgery or chemoradiotherapy. Pts with early-stage NSCLC harboring atypical *EGFR* mutations were excluded from the respective clinical trials. Outcomes in this pt population remain unknown. **Methods:** We conducted a multi-institutional retrospective analysis of pts with stage IA-IIIC *EGFR*-mutated NSCLC (2010-2024) who were classified into two groups: those with tumors harboring classical *EGFR* mutations (c-*EGFR*: ex19del or L858R) or atypical *EGFR* mutations (a-*EGFR*: non-ex19del or L858R). Kaplan-Meier analyses compared disease-free survival (DFS), central nervous system (CNS) DFS, and overall survival (OS). Multivariable Cox regression adjusted for disease stage, definitive therapy, and adjuvant therapy. **Results:** Among 417 pts, 293 had tumors harboring c-*EGFR* and 124 had a-*EGFR* mutations. Baseline characteristics were similar between groups (Table). Median follow-up was 4 years. Among pts not treated with adjuvant osi (n = 346), a-*EGFR* was associated with a significantly lower 3-year DFS compared to c-*EGFR* (52.5% vs 71.2%; HR 1.71, 95% CI 1.21-2.42; P = 0.003). Compared to c-*EGFR*, a-*EGFR* had higher rates of recurrence to the ipsilateral lung (24% vs 14%) and bone (12% vs 6%). A-*EGFR* was associated with a significantly lower 3-year CNS DFS (81.3% vs 87.1%; P = 0.002) and 5-year OS (77.7% vs 85.6%; P = 0.007) compared to c-*EGFR*. Among pts with a-*EGFR* mutations, *EGFR* exon 20 insertions (ex20ins) were associated with a significantly reduced 3-year DFS compared to other alterations (35.9% vs 68.2%; HR 2.04, 95% CI 1.10-3.77; P = 0.013), and with a lower 3-year CNS DFS (70.9% vs 92.2%; P = 0.028) and trend towards lower 5-year OS (71.3% vs 84.4%; P = 0.141). Among pts who underwent surgery for stage IB-IIIA NSCLC (n = 209), adjuvant osi improved 3-year DFS among c-*EGFR* (84.2% with osi vs 63.4% without osi) whereas a-*EGFR* had a lower 3-year DFS (36.4%; P $<$ 0.001), which was driven by *EGFR* ex20ins compared to other alterations (19.9% vs 59.2%; P = 0.003). **Conclusions:** Atypical *EGFR* mutations are associated with inferior survival outcomes compared to classical *EGFR* mutations in early-stage NSCLC. *EGFR* ex20ins appear to drive poor outcomes among the atypical *EGFR* mutations. Novel adjuvant therapy strategies are warranted to improve definitive treatment of early-stage atypical *EGFR*-mutated NSCLC. Research Sponsor: None.

Clinical impact of genomic co-mutation profiles including TP53 in resected early-stage *EGFR*-mutated NSCLC: LC-SCRUM-Advantage. First Author: Kiyotaka Yoh, National Cancer Center Hospital East, Kashiwa, Japan

Background: Adjuvant osimertinib is the standard of care for resected stage IB–IIIA EGFR-mutated non-small cell lung cancer (NSCLC), and its benefit in stage IA2–IA3 disease is being evaluated in ADAURA2. However, the prognostic impact of genomic co-alterations, particularly TP53, in early-stage EGFR-mutated NSCLC remains unclear. This study characterized genomic co-alterations and their association with clinicopathologic features in resected early-stage EGFR-mutated NSCLC. **Methods:** LC-SCRUM-Advantage is a prospective genomic screening program for resected NSCLC. Post-operative tumor specimens were analyzed using the Oncomine Precision Assay to identify co-alterations, including TP53 and other recurrent genes, across major EGFR mutation subtypes. PD-L1 expression was assessed by immunohistochemistry. Clinico-genomic characteristics and survival outcomes were evaluated. **Results:** Among 1052 enrolled patients, 327 had EGFR-mutated adenocarcinoma (19del 42%, L858R 47%, others 11%). Among tumors with common EGFR mutations, single EGFR alterations accounted for 59%, while co-alterations were detected in 41%. Frequent co-alterations included TP53 (19%), CTNNB1 (4%), PIK3CA (4%), additional EGFR mutations (5%), and EGFR amplification (12%). Co-alteration prevalence increased with pathological stage (IA1 25%, IA2–IA3 41%, IB 53%, II 47%, III 46%), with TP53 showing a similar pattern (IA1 8%, IA2–IA3 18%, IB 19%, II 28%, III 27%). PD-L1 positivity also increased progressively with disease stage (I 37%, II 52%, III 73%; p = 0.0002). TP53-mutated tumors showed a significantly higher PD-L1 positivity rate than TP53 wild-type tumors (60% vs. 39%; p = 0.007). Co-alteration frequencies were comparable across EGFR subtypes. With limited follow-up, five recurrences were observed (IB 1, IIA 1, IIIA 2, IVA 1); three involved co-alterations (TP53, EGFR amplification, EGFR E709V). **Conclusions:** Genomic co-alterations, including TP53, were common and increased with pathological stage in early-stage EGFR-mutated NSCLC. Co-altered tumors exhibited features associated with aggressive biology, including higher PD-L1 expression. Early recurrences were frequently observed in patients with co-alterations, underscoring their potential prognostic relevance. These findings highlight substantial molecular heterogeneity within early-stage EGFR-mutated NSCLC and support incorporating co-alteration status into risk stratification and adjuvant treatment planning. Ongoing follow-up from this study will further clarify the prognostic and predictive significance of co-alterations, particularly regarding their implications for adjuvant targeted therapy. Fusion-positive early-stage and locally advanced lung cancers: A real-world analysis of event-free, disease-free, and overall survival. First Author: Sameh Nabeeh Daher, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Fusion-positive lung cancers are a distinct subset of lung cancers. While outcomes in metastatic disease are comprehensively characterized, data on survival and disease recurrence outcomes after definitive therapy in non-metastatic disease remain limited. **Methods:** This was a single institution, retrospective study, including patients (pts) with *ALK/ROS1/RET/NTRK+* early-stage/locally advanced lung cancer pts diagnosed between 2012-2025. The primary endpoint in pts who underwent curative surgery or stereotactic body radiotherapy (SBRT) was disease-free survival (DFS; time from curative therapy to disease recurrence or death). The primary endpoint in pts initially treated with neoadjuvant therapy prior to surgery or definitive chemoradiation was event-free survival (EFS; time from curative therapy to disease progression, recurrence, failure of treatment or death). Overall survival (OS) from the start of curative therapy was analyzed. **Results:** 179 pts (82 *ALK*, 38 *ROS1*, 55 *RET*, 4 *NTRK*) were identified. Median EFS across all pts for *ALK/ROS1/RET/NTRK* was 4.4yrs (95%CI: 2.8, Not Reached (NR)), 3.4yrs (95%CI: 2.0, NR), 7.4yrs (95%CI: 4.6, NR) and 3.0yrs (95%CI: 0.4, NR), respectively. Median OS for *ALK/ROS1/RET/NTRK* pts was: 13.0yrs (95%CI: 12.0, NR), 12.0yrs (95%CI: 11.0, NR), 14.0yrs (95%CI: 12.0, NR) and NR (95%CI: 5.4, NR), respectively. 132/179 (74%) of all pts were treated with surgery (128 pts) or SBRT (4 pts) first. Median EFS for pts treated with neoadjuvant treatment first (N=26) for *ALK* (n=15)/*ROS1* (n=5)/*RET* (n=6) pts was 0.9yrs (95%CI: 0.8, NR), 0.9yrs (95%CI: 0.7, NR) and NR (95%CI: 0.2, NR), respectively. Median EFS for pts treated with chemoradiation first (N=21) for *ALK* (n=7)/*ROS1* (n=5)/*RET* (n=9) pts was NR (95%CI: 0.5, NR), 0.6yrs (95%CI: 0.5, NR) and 1.0yrs (95%CI: 0.8, NR), respectively. Median DFS for pts treated with surgery/SBRT first (N=132) for *ALK* (n=60)/*ROS1* (n=28)/*RET* (n=40)/*NTRK* (n=4) pts was: 5.1yrs (95%CI: 3.8, NR), 5.2yrs (95%CI: 3.2, NR), NR (95%CI: 6.6, NR) and 3.0yrs (95%CI: 0.4, NR), respectively. **Conclusions:** This is the largest series on outcomes in fusion-positive early stage/locally advanced lung cancers treated with definitive therapy. Prolonged EFS, DFS, and OS were observed. Research Sponsor: None.

Induction chemoimmunotherapy followed by hypofractionated radiotherapy and consolidation immunotherapy for locally advanced unresectable non–small cell lung cancer: A prospective phase II study. First Author: Xiangzhi Zhu, The Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, Jiangsu, China

Background: Concurrent chemoradiotherapy followed by consolidation immunotherapy is the standard treatment for unresectable stage III LA-NSCLC; however, many patients in real-world practice are unable to complete concurrent therapy, and locoregional failure remains common. This phase II study evaluated induction chemoimmunotherapy followed by hypofractionated radiotherapy (hypo-RT) and consolidation immunotherapy to improve feasibility and disease control. **Methods:** Patients with newly diagnosed unresectable stage III NSCLC received 3-4 cycles of immune checkpoint inhibitors combined with platinum-based doublet chemotherapy. Patients without progression or grade ≥2 pneumonitis underwent eligibility assessment for hypo-RT based on anatomical suitability and organ-at-risk constraints. Eligible patients received definitive sequential hypo-RT (48–60 Gy in 12–15 fractions based on tumor regression) and consolidation immunotherapy when appropriate. The primary endpoint was progression-free survival (PFS) with secondary endpoints of safety and overall survival (OS). **Results:** Between October 2022 and October 2025, 132 patients received induction chemoimmunotherapy, and 55 underdoing hypo-RT. Median age was 70 years (range, 47–85), and 42 patients (76.4%) had squamous cell carcinoma. Programmed death-ligand 1 (PD-L1) expression ≥1% was observed in 17 patients (30.9%), with unknown PD-L1 status in 14 patients (25.5%). With a median follow-up of 20.1 (95%CI, 17.3-22.9) months, median PFS and OS were not reached. The 1- and 2-year PFS rates were 88.1% (95% CI, 78.8%–98.5%) and 58.5% (95% CI, 43.6%–77.7%), respectively; the 1- and 2-year OS rates were 100% and 77% (95% CI, 61.5%–93.7%), respectively. Isolated in-field recurrence occurred in 4 patients (7.3%). Pneumonitis was the most common acute nonhematologic toxicity, with grade 3 in 4 patients (7.3%) and grade 4 in 1 patient (1.8%). Grade 3 atelectasis occurred in 4 patients (7.3%), and grade 3 radiation esophagitis in 2 patients (3.6%). No grade 5 toxicities were observed. **Conclusions:** Induction chemoimmunotherapy followed by eligibility-adapted hypofractionated radiotherapy showed promising survival and locoregional control with acceptable toxicity in unresectable locally advanced NSCLC, supporting its feasibility as an alternative strategy for selected patients. Clinical trial information: NCT05784142. Analysis of recurrence and risk factors in resectable early-stage adenocarcinoma with uncommon *EGFR* mutations: A comprehensive cohort study in South Korea. First Author: Insu Kim, Dong-A University Hospital, Busan, South Korea

Background: This study aimed to identify clinicopathologic factors associated with recurrence in patients with surgically resected lung adenocarcinoma harboring uncommon EGFR mutations. **Methods:** We conducted a multicenter retrospective cohort study. The study included patients with stage I–III lung adenocarcinoma harboring uncommon EGFR mutations (G719X, S768I, or L861Q) who underwent curative-intent resection between 2010 and 2017 in South Korea. Recurrence-free survival (RFS) and overall survival (OS) were analyzed using Cox proportional hazards models. **Results:** A total of 48 patients were analyzed (stage I: n=33, stage II: n=6, stage III: n=9). The median age was 65 years; 56.3% were female and 66.7% were never-smokers. Mutation distribution was G719X (72.9%), S768I (16.7%), and L861Q (10.4%). Visceral pleural invasion (VPI) and lymphovascular invasion (LVI) were present in 37.5% and 16.7% of cases, respectively. During follow-up, 26 patients (54.2%) experienced recurrence and 21 (43.8%) died. Multivariable analysis identified ECOG performance status ≥1 (HR 4.55, 95% CI 1.226–16.899; P=0.024), stage III vs. I (HR 5.07, 1.181–21.771; P=0.029), and VPI (HR 3.67, 1.030–13.058; P=0.045) as independent predictors of recurrence. EGFR subtype (non-G719X vs. G719X) was not significantly associated with recurrence (P=0.428). **Conclusions:** Patients with surgically resected lung adenocarcinoma harboring uncommon EGFR mutations face a substantial risk of postoperative recurrence. Conventional clinicopathologic factors—particularly ECOG status, advanced stage, and VPI—outperform EGFR subtype as prognostic indicators. These findings support the need for risk-adapted surveillance and prospective evaluation of adjuvant strategies in these high-risk subsets. Research Sponsor: None.

Socioeconomic focus in neoadjuvant chemoimmunotherapy: An analysis of pathologic complete response and overall survival in clinical stage II-III NSCLC patients. First Author: Jack William Ibinson, Penn State College of Medicine, Hershey, PA

Background: In 2022, CheckMate 816 supported neoadjuvant chemoimmunotherapy (CTIO) as standard treatment for clinical stage II-III non-small cell lung cancer (NSCLC). Low socioeconomic status has historically been underrepresented in clinical trials, warranting further analysis of CTIO outcomes in patients from diverse socioeconomic backgrounds. This study aims to assess the role of socioeconomic factors on pathologic complete response (pCR) and overall survival (OS) after CTIO. **Methods:** Data from the National Cancer Database (NCDB) was obtained for patients diagnosed with clinical stage II-III NSCLC between 2022-2023 undergoing CTIO. Complete T, N, and M stage and post-pathologic status (ypT, ypN) were obtained. OS was available for patients diagnosed in 2022. Patients receiving neoadjuvant radiotherapy or with clinical or pathologic metastatic disease were excluded. Group comparisons were based on socioeconomic factors: age (< 75 vs ≥ 75 years), sex, race (Non-Hispanic White vs Other), primary payor at diagnosis, urban/rural, percent no high-school degree quartile, and median income quartile. Primary outcomes were pCR and OS, analyzed via logistic and cox regression models, respectively. All tests were two-sided, and a p-value of < 0.05 was statistically significant. **Results:** 2,819 patients received CTIO from 2022-2023, with 1,134 patients diagnosed in 2022. Univariate analysis showed patients in the two lowest median income quartiles ($46,277–$57,856: OR 1.40, 95% CI 1.08-1.80, p = 0.011; < $46,277: OR 1.70, 95% CI 1.30-2.23, $p < 0.001$) had significantly higher odds of pCR compared with those in the highest income quartile (≥$74,063). This effect persisted in multivariate analysis ($46,277–$57,856: OR 1.59, 95% CI 1.19-2.13, p = 0.002; < $46,277: OR 2.00, 95% CI 1.41-2.83, $p < 0.001$). Univariate analysis showed that other race (HR 0.49, 95% CI 0.29-0.81, p = 0.006) was associated with improved OS compared to Non-Hispanic White, which persisted in multivariate cox analysis (HR 0.50, 95% CI 0.30-0.85, p = 0.010). There were no significant associations for pCR and OS with age, sex, primary payor at diagnosis, urban/rural status, or percent no high school degree quartile. **Conclusions:** Our findings present promising evidence of improved outcomes of neoadjuvant chemoimmunotherapy among groups facing historical marginalization, namely low-income communities and non-white race. These effects were persistent in multivariate regression models controlling for other socioeconomic variables such as age, sex, primary payor, urban/rural, and percent no high school degree quartile. In light of these findings, further studies with diverse patient populations are warranted to examine the benefit of neoadjuvant chemoimmunotherapy on patients with NSCLC. Research Sponsor: None.

An integrated multidisciplinary analysis of pre-treatment cachexia in locally advanced non–small cell lung cancer. First Author: Ernest Nadal, Thoracic Tumors Unit, Medical Oncology, Catalan Institute of Oncology (ICO). Bellvitge Biomedical Research Institute (IDIBELL), Hospitalet De Llobregat (Barcelona), Spain

Background: Cancer-associated cachexia is underdiagnosed and not routinely captured in cancer registries, despite its negative impact on quality of life and survival. We aim to determine the prevalence of cachexia in patients with locally advanced NSCLC and to perform a multidisciplinary characterization of cachexia to inform the development of future therapeutic interventions. **Methods:** In this prospective study, 51 patients diagnosed with locally advanced unresectable NSCLC candidates to concurrent chemoradiotherapy followed by immunotherapy at the HUB-ICO Comprehensive Cancer Centre (2022-2024) were included. The primary objectives were to (1) determine the frequency of cachexia according to Fearon's criteria and (2) characterize patients before and after completing chemoradiotherapy in terms of nutritional status, metabolic parameters, body composition and circulating cytokine levels. Baseline assessment results are reported here. **Results:** Most patients were male (80%) and ever smokers (98%), with a median age of 68 years. All patients completed the planned concurrent chemoradiotherapy regimen, whereas only 43% initiated durvalumab consolidation therapy. At baseline, 27 patients met the diagnostic criteria for cachexia (53%, 95% CI 39-66) and women were more likely to have cachexia than men (80% vs 46%, respectively), although this difference was not statistically significant. Cachexia was significantly associated with more advanced tumor stage ($p < 0.001$), worse performance status (p = 0.027), lower skeletal muscle index (p = 9e-4) and reduced total adipose tissue index (p = 0.004), elevated C-Reactive Protein blood levels (p = 0.004), moderate to severe malnutrition ($p < 0.001$), reduced caloric intake (p = 0.007) and decreased physical strength (p = 0.001). Cachectic patients had lower fat intake compared with non-cachectic individuals (p = 0.006), while protein intake was similar in both subgroups. Proteomic profiling using the O-link platform identified significant differences in circulating cytokine levels between cachectic and non-cachectic patients. Cachexia was associated with significantly increased levels of CCL23, IL-6, C1QA, CSF1, motilin and agouti-related protein (AGRP), among others, which showed varying degrees of correlation with caloric intake. By contrast, GDF-15 was significantly associated with weight loss (p = 0.00014) but showed no association with caloric intake or body composition parameters. **Conclusions:** This prospective study reveals that cancer-associated cachexia is highly prevalent in patients with unresectable locally advanced NSCLC before treatment initiation. Beyond previously described inflammatory mediators, we identified several understudied cytokines, which may contribute to the progression of the cachexia phenotype and represent potential targets for future therapeutic interventions. Decomposing the co-mutational landscape of NSCLC by unsupervised learning to unveil components with impact on overall survival. First Author: Chidiebube Ugwu, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: The molecular characterization of non-small cell lung cancer (NSCLC) and targeting therapies are improving outcomes for many patients. However, about 40% remain without identifiable molecular drivers. Understanding the co-mutational landscape of NSCLC may contribute to close that gap but has not yet been sufficiently characterized beyond e.g. *TP53* co-mutations that associated with adverse outcome (Galina et al. *J. Thor. Onc*. 2024). Previously, the hierarchical Dirichlet mixture model (HDMM) provided important insight into acute leukemia biology (Papaemmanuil et al. *NEJM* 2016, Turki et al. *EHA plenary abstract* 2025), reason why we adopted this method for the first time to decompose the NSCLC genetics landscape. **Methods:** Here, we leveraged the HDMM with multinomial distribution for unsupervised learning of NSCLC genetics on the large AACR GENIE BPC NSCLC cohort (n = 1,846 patients, Choudhury et al. *Clin. Can. Res*. 2023) including 300 features for 60 genes. Preprocessing excluded columns with < 5 mutations, features duplicating information or with high rates of missingness, leaving the most relevant 85 genetic features for HDMM analysis including single mutations, gene amplifications and deletions. Within UICC stages I, II-III and IV, overall survival (OS) was analyzed with the Kaplan Meier method comparing the new components with the logrank test. **Results:** Among 1926 genetically distinct tumors of 1785 NSCLC patients with detectable genetic alterations, the HDMM identified four components assembling patients with similar landscape. Their driver patterns involved either co-mutated *TP53/KRAS*, *TP53/EGFR* or *PDGFR/KDR* and other mutations including established risk groups, i.e. with amplifications in *ALK*, *BRAFV600E*, *cMET exon 14* or single *EGFR* or *KRAS* mutations, *ROS1* or *NTRK* translocations. As expected, UICC stages I-IV stratified this cohort significantly for OS. Next, we tested whether genetic components refined outcomes within the same UICC stage. Indeed, for stage I NSCLC the genetic components associated with significant OS differences (p = 0.0065). Patients with PDGFR/KDR had the highest OS, while patients of the TP53/KRAS component had the lowest median OS with a Kaplan Meier estimate of 82.4 months as compared to 116.7 in the TP53/EGFR cluster. Also, among patients with stage II-III NSCLC, the three components associated with significant differences in OS (p = 0.023). Not taking into account other driver mutations, the components also associated with distinct OS in patients with stage IV NSCLC (p = 0.0001). **Conclusions:** This analysis of the co-mutational landscape is complementing existing genetic classes in NSCLC. We identified a new *PDGFR/KDR* component and support the relevance of previously described co-occurring *TP53/EGFR* and *TP53/KRAS*. The significantly distinct OS in resectable NSCLC may open new risk adapted treatment strategies. Research Sponsor: None.

Fraction genome altered to predict survival in early-stage non–small cell lung cancer. First Author: Mobina Shrestha, Sentara Albemarle Medical Center, USACS, Elizabeth City, NC

Background: Patients with stage I-III non-small cell lung cancer (NSCLC) often have very different outcomes, even when they share the same anatomic stage. This suggests that tumor biology plays an important role in prognosis. Fraction genome altered (FGA), a measure of chromosomal instability derived from next-generation sequencing (NGS), is already used in clinical practice but its prognostic value in early-stage NSCLC is not well established. Therefore, we evaluated whether FGA is associated with overall survival (OS) in early-stage NSCLC and whether it provides prognostic information beyond standard clinical factors and tumor mutation burden (TMB). **Methods:** We performed a retrospective analysis of 7,722 patients with NSCLC using clinical-grade targeted NGS with available copy-number data (MSK CHORD 2024). Disease stage was categorized as stage I-III versus stage IV. FGA was analyzed in quartiles, with high FGA defined as the top quartile. OS was assessed using Kaplan-Meier and multivariable Cox proportional hazards models adjusting for age, sex, smoking history, histology group, sequencing panel, stage, and log-transformed TMB. Incremental prognostic value was evaluated using concordance (C-index) and likelihood ratio testing (LRT). The results were validated using several sensitivity/statistical analysis. **Results:** After quality control, 7,722 patients were included (3,934 deaths), including 4,343 with stage I-III disease (1,559 deaths). In early-stage NSCLC, increasing FGA was associated with progressively worse OS across quartiles (log-rank $\chi^2 = 199.6$, $p < 0.0001$). 5-year OS declined from 65.6% in the lowest FGA quartile to 39.6% in the highest quartile. Patients with high FGA had significantly inferior survival compared with low-FGA patients (5-year OS 39.6% vs 63.0%, $p < 0.0001$). In multivariable models restricted to stage I-III, high FGA remained independently associated with mortality (Hazard-Ratio = 1.60, 95% CI: 1.42-1.82, $p < 0.0001$). Adding FGA to clinical models improved survival prediction (C-index = ~0.70) and overall model performance (LRT = 125.9, $p < 0.0001$), and this improvement was greater than that seen with TMB. When both biomarkers were included, FGA continued to provide strong prognostic information, whereas TMB did not improve prediction once FGA was already in the model. We found our results to be consistent across internally validated analysis. **Conclusions:** FGA was strongly associated with OS in stage I-III NSCLC. FGA identified a subgroup of early-stage patients with substantially worse outcomes despite similar anatomic stage, indicating important underlying biologic differences. Since, FGA can be obtained from routine targeted NGS already used in clinical practice, it presents a practical biomarker that may improve risk stratification beyond standard clinical factors and TMB, and help guide surveillance and perioperative trial selection. Real-world adoption of comprehensive genomic profiling in a national cohort of patients with resected stage I–III non–small cell lung cancer. First Author: Brendan Heiden, Division of Cardiothoracic Surgery, Department of Surgery, Washington University School of Medicine, St. Louis, MO

Background: Comprehensive genomic profiling (CGP) is increasingly used in the multidisciplinary management of resectable NSCLC to identify candidates for targeted adjuvant therapies and clinical trials. NCCN and Veterans Affairs (VA) guidelines recommend selective – not universal – testing in early-stage disease, yet real-world use after surgery remains poorly described. Using the VA's highly unique National Precision Oncology Program (NPOP), we evaluated trends in CGP uptake, factors associated with testing, and the biomarker landscape in early-stage NSCLC. **Methods:** We performed a retrospective cohort study of patients with resected pathologic stage I–III NSCLC (2019-2025) within the VA. CGP was defined as next-generation sequencing (NGS) of the primary tumor within 3 months of surgery. We assessed frequency of CGP and clinicodemographic factors associated with GCP via multivariable logistic regression. We also assessed the distribution of potentially actionable genomic alterations. **Results:** A total of 6,605 patients were included (4,686 [70.9%] stage I; 1,255 [19.0%] stage II; 664 [10.1%] stage III). Over the study period, 1,337 (20.2%) patients received NGS testing. CGP utilization increased over time (11.4% in 2019 to 25.8% in 2025), paralleling evolving recommendations regarding adjuvant targeted therapies. Of note, the GCP utilization rate among those with stage Ib-III NSCLC in 2025 was 54.9%. In multivariable models, factors associated with higher CGP use included former smoking status (adjusted hazard ratio [aHR] 1.19, 95% CI 1.02-1.40), never smoking status (aHR 1.31, 95% CI 1.05-1.65), robotic resection (aHR 1.82, 95% CI 1.52-2.18), higher stage (stage II: aHR 4.33, 95% CI 3.72-5.04; stage III: aHR 5.79, 95% CI 4.81-6.98), and more recent treatment year (aHR 1.25, 95% CI 1.20-1.30). Median time from surgery to CGP ordering was 25 days (IQR 10-67). Among tested tumors, key genomic alterations included EGFR exon 19 deletions (2.39%) and L858R (1.20%), ALK fusions (0.52%), KRAS G12C (10.62%), MET exon 14 skipping (2.02%), ERBB2 mutations (3.29%), BRAF V600E (1.05%), and ROS1 fusions (0.53%). **Conclusions:** In this national cohort, CGP use after resection of stage I–III NSCLC increased substantially over time, likely supported by the VA NPOP infrastructure. Testing patterns were largely guideline-concordant, with continued uptake within complex multidisciplinary pathways. These findings reinforce the real-world adoption of genomically informed decision-making in early-stage disease while highlighting opportunities to strengthen implementation and promote wide access to precision oncology. Research Sponsor: None.

Multi-center prospective study evaluating an AI-enabled clinical decision support tool to improve biomarker testing in early-stage NSCLC. First Author: Melina Elpi Marmarelis, University of Pennsylvania, Philadelphia, PA

Background: Non-adherence to guideline-concordant biomarker testing in non-small cell lung cancer (NSCLC) can limit access to targeted therapies and adversely impact survival. We evaluated an AI-enabled clinical decision support (AI-CDSS) program comprising: (1) education around baseline testing rates; (2) continuous monitoring to generate real-time alerts for eligible patients with missing biomarker testing; and (3) longitudinal feedback via dashboards. Here, we report the effectiveness of this program in identifying and closing biomarker testing gaps for patients with early-stage NSCLC. **Methods:** In this descriptive study, we analyzed patients with confirmed NSCLC across 6 geographically and socioeconomically diverse US community health systems. The AI-CDSS identified early-stage patients eligible for biomarker testing (eNSCLC as AJCC 8th edition Stg IB-IIIB (T3, N2) with planned curative intent treatment). Biomarker testing included EGFR, ALK, and PD-L1. We compared testing adherence between a baseline period (BL: 24 months through 3 months prior to the health system-specific roll-out) and a post-launch period (PL: roll-out through Oct 2025). The AI-CDSS was implemented on a rolling basis across health systems (BL from Feb 2022 - Dec 2024 and PL from Feb 2024 - Oct 2025). Testing rates were calculated as the proportion (%) of patients with testing completed within 90 days of pathologic diagnosis in each period. The improvement in test rates (absolute lift) is calculated as the difference in PL - BL testing percentages in the two periods. **Results:** A total of 662 patients with eNSCLC (270 BL and 392 PL) were included in the analysis. Patients were predominately white (85%), had a history of smoking (88%), with a median age of 70 years at diagnosis. The stage distribution was as follows: Stage III (34%), Stage II (37%), Stage IB (25%), and Stage IB or IIA [indeterminate] (5%). The absolute lift in biomarker testing within 90 days of pathologic diagnosis before vs after intervention was 18% for EGFR, 24% for ALK, and 13% for PDL1 biomarkers. Among patients with molecular testing who received adjuvant treatment, 89% were on guideline-concordant adjuvant treatment. **Conclusions:** Implementation of an AI-CDSS was associated with clinically meaningful improvements in rates of biomarker testing for eNSCLC and resulted in high concordance with guideline-directed adjuvant therapy. Appropriate and timely biomarker testing is essential for perioperative treatment planning. This study provides preliminary evidence that AI can use complex electronic health records to provide real-time interventions that can promote guideline-concordant care. Research Sponsor: None.

Testing gap results.

Biomarker	Baseline N	Baseline Test Rate	Post Launch N	Post Launch Test Rate	Absolute Lift
EGFR	264	49%	392	67%	18%
ALK	270	43%	389	67%	24%
PD-L1	270	59%	389	72%	13%

Non-surgical management and outcome of 1,113 patients with stage I-II non-small cell lung cancer (NSCLC) in a 20-year cohort. First Author: Ping Yang, Mayo Clinic Arizona, Scottsdale, AZ

Background: Surgical resection is the primary therapy for stage I-II NSCLC but not performed in a subset of patients due to comorbidities or self-election, who instead undergo radiation with or without systemic therapy (RT±ST). Little is known about the demographic, tumoral, therapeutic, and quality-of-life (QOL) characteristics of this non-surgical group. Understanding their differences from the surgical group is essential for developing precision treatment strategies and tailored survivorship guidelines. **Methods:** In a prospectively enrolled (1997-2016) and followed (through 2025) cohort of 20,951 primary lung cancer patients, 6,486 (31%) had stage I-II NSCLC, including 5,359 (83%) treated surgically (Surgical) and 1,113 (17%) otherwise (Non-surgical). Preexisting diseases were grouped into cancer, lung, and other comorbidities. QOL data were available for 40% of all patients. Descriptive analysis of demographics, tumor features, treatment patterns, and QOL metrics, as well as survival analysis (median years and overall survival [OS] rates) were conducted. QOL measures, on overall and 15 symptom and functional domains, were scored 0 (worst) to 10 (best), with 1-unit difference considered clinically and statistically meaningful. **Results:** At time of diagnosis, compared to the Surgical, the Non-surgical patients were older (median 73 v 68 years), more likely to have smoked cigarettes (91% v 83%), squamous cell and unspecified NSCLC (53% v 28%), stage IIB (19% v 12%), and preexisting lung comorbidities (71% v 58%). Non-surgical patients more frequently received RT±ST than the Surgical (70% v 21%) and had shorter median survival (2.5 v 7.8) years. Within the Non-surgical, 28% had no cancer treatment (No-Tx), 44% RT-only, 7% ST-only, and 19% both (RT+ST); their respective median diagnosis ages were 74, 76, 68, 70 years; median survival were 1.7, 2.7, 2.2, 3.2 years; 5-year OS (95%CI) at 25% (21-31), 25% (21-29), 26% (17-38), 30% (25-37); and 10-year OS at 9% (7-14), 7% (5-10), 10% (5-21), 9% (6-14), respectively. RT-only group had highest rates of comorbidities (37-84%) and the No-Tx the lowest (31-66%). Although the overall QOL scored the same for all groups, RT-only patients reported the worst scores on multiple symptoms burden, and the No-Tx reported the least pain and lung cancer symptoms but the worst on mental well-being and social activities. **Conclusions:** Non-surgically managed stage I-II NSCLC cases present clinically distinct patients with the shortest median survival in No-Tx group and highest 5-year survival in RT+ST. RT-only patients were oldest, had the most comorbidities, and reported the worst symptom burdens. These differences highlight the need for more in-depth analyses and studies (considering age, histology, comorbidity, QOL, etc.) to support tailored therapeutic strategies and survivorship care for patients who decline or are not suitable for surgery. Research Sponsor: None.

Influence of neoadjuvant spatially fractionated stereotactic body radiotherapy on antitumor immunity and pathological response to toripalimab-based immunochemotherapy in resectable stage IIA-IIIB non-small cell lung cancer. First Author: Xu Yaping, Department of Radiation Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Background: Neoadjuvant immunochemotherapy has improved outcomes in resectable non–small cell lung cancer (NSCLC); however, pathological complete response (pCR) rates remain limited, and strategies to further amplify antitumor immunity are needed. Spatially fractionated stereotactic body radiotherapy (SF-SBRT, Lattice) delivers spatially separated high-dose regions "peaks" to promote immunogenic cell death while maintaining low-dose regions "valleys" that preserve the tumor immune microenvironment (TIME). We hypothesized that integrating SF-SBRT with toripalimab-based immunochemotherapy could reprogram the TIME and enhance pathological response in resectable NSCLC. **Methods:** This prospective phase II study enrolled resectable stage IIA–IIIB NSCLC (NCT06293690). Patients received one fraction of Lattice SF-SBRT (12 Gy peak / $<$4 Gy valley) on Day 1, followed by toripalimab plus chemotherapy on Day 2, administered every 3 weeks for 2 cycles prior to surgery. The primary endpoint was major pathological response (MPR). Secondary endpoints included pCR, radiological response, nodal downstaging, event-free survival, overall survival, and safety. Single-cell RNA sequencing (scRNA-seq) was performed to characterize treatment-associated immune remodeling. **Results:** 20 patients completed neoadjuvant therapy and underwent curative-intent resection, R0 resection was achieved in all patients without treatment-related surgical delays. MPR was observed in 95.0% (19/20) of patients, including a pCR rate of 55.0% (11/20). The radiological objective response rate was 100.0%. Nodal downstaging to ypN0 occurred in 82.4% (14/17) of patients with baseline nodal involvement, corresponding to an overall ypN0 rate of 85.0%. Grade 3–4 treatment-related adverse events occurred in 15.0% (3/20), with no grade $\geq$2 radiation pneumonitis. scRNA-seq revealed enhanced cytotoxic T-cell activation, reduced immunosuppressive myeloid populations, and coordinated immune remodeling following neoadjuvant treatment. **Conclusions:** Neoadjuvant SF-SBRT combined with toripalimab-based immunochemotherapy was feasible, safe, and achieved high pathological response rates in resectable stage II–III NSCLC. These findings suggest that SF-SBRT may function as an immune-reprogramming strategy that amplifies neoadjuvant immunotherapy efficacy and warrants further validation in randomized clinical trials. Clinical trial information: NCT06293690. Research Sponsor: None.

Characteristics	No. of Patients (%)

Real-world outcomes and prognostic risk stratification of neoadjuvant immunotherapy for stage III lung squamous cell carcinoma. First Author: Wang Yishuo, Beijing Chest Hospital, Capital Medical University and Beijing Tuberculosis and Thoracic Tumor Research Institute, Beijing, China

Background: While neoadjuvant immunotherapy (nIO) is the standard of care for resectable NSCLC, its efficacy in "potentially resectable" (PR) stage III lung squamous cell carcinoma (LUSC)—specifically patients with T4 invasion or multi-station N2 disease—remains underrepresented in clinical trials. We evaluated whether nIO could facilitate surgical conversion in PR patients comparable to initially resectable (IR) candidates and constructed a multidimensional risk stratification system to optimize decision-making. **Methods:** We retrospectively analyzed patients with stage III LUSC treated with neoadjuvant PD-1/PD-L1 inhibitors plus chemotherapy (January 2019–December 2024). The cohort was stratified into IR and PR groups, with PR defined by complex anatomy (T4 invasion or multi-station N2). Endpoints included surgical conversion, major pathological response (MPR), disease-free survival (DFS), and overall survival (OS). Baseline predictors were identified via logistic regression. A pathological risk score (pRS) was developed using Cox regression based on independent risk factors for DFS in the R0 resection cohort. **Results:** Of 210 evaluable patients, 170 (81.0%) underwent surgery with a 96.5% R0 resection rate. The PR cohort (n = 128) achieved surgical conversion rates comparable to the IR cohort (n = 82) (82.9% vs. 90.7%; P = .19). Notably, PR patients demonstrated superior nodal downstaging (74.5% vs. 58.8%; P = .047) compared with IR patients. Long-term survival outcomes showed no statistically significant difference between PR and IR groups (DFS: HR, 1.25; 95% CI, 0.77-2.04; OS: HR, 1.41; 95% CI, 0.76-2.62). Multivariable analysis identified baseline NLR $\geq$ 2.75 and CYFRA 21-1 $\geq$ 6.0 ng/mL as independent predictors of poor therapeutic benefit. The constructed pRS system (integrating non-MPR status, vascular, and pleural invasion) effectively stratified postoperative recurrence risk (P $<$ .0001; 1-year AUC, 0.73). Analysis of treatment failure (n = 40) revealed that baseline fibrinogen $>$ 3.5 g/L was associated with disease progression, while grade 3–5 pneumonitis was a primary cause of surgical dropout in patients with high PD-L1 expression. **Conclusions:** In this real-world cohort, nIO facilitated high R0 resection rates in complex stage III LUSC, allowing potentially resectable patients to achieve survival outcomes equivalent to initially resectable candidates. Nodal clearance appears to be a key driver of benefit in the PR subgroup. The novel pRS system and biomarkers (NLR, CYFRA 21-1, fibrinogen) provide a robust framework for patient selection and postoperative management. Research Sponsor: None.

Post-progression treatment strategies and immunotherapy rechallenge sensitivity following chemoradiation and consolidation durvalumab in unresectable stage III NSCLC: The POST-PACIFIC study. First Author: Valentina Santo, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Durvalumab consolidation after platinum-based chemoradiotherapy (CRT) is the standard of care for unresectable stage III non-small cell lung cancer (NSCLC). However, optimal treatment strategies after progression remain undefined, and data guiding post-durvalumab strategies, including immunotherapy rechallenge, are limited. **Methods:** This global retrospective multicenter study included patients with unresectable stage III NSCLC treated with concurrent or sequential CRT who progressed after ≥1 dose of durvalumab consolidation. Survival outcomes were assessed using Kaplan-Meier and Cox methods. Immunotherapy sensitivity was defined by time from durvalumab initiation to progression: refractory (< 12 months) or sensitive (≥12 months) and correlated with outcomes after immunotherapy rechallenge. **Results:** Among 319 patients, median age was 66.5 years; 54.2% were male, and 96.7% had ECOG PS 0-1. Concurrent CRT was delivered in 96.5% (median RT dose 60 Gy). Median follow-up was 62.2 months. Progression pattern included locoregional recurrence in 34.8% and distant relapse in 65.2%. Of 293 patients receiving a first subsequent therapy (FST), chemotherapy (CT) ± VEGF inhibition was most common (31.7%), followed by local ablative therapy (LAT, 30.7%), immunotherapy ± CT (18.4%), targeted therapy (TT, 10.9%), and durvalumab beyond progression (BP) ± LAT (6.5%). When comparing FST, immunotherapy rechallenge demonstrated superiority over CT. Compared with CT ± VEGF inhibition, immunotherapy ± CT was associated with a higher objective response rate (ORR: 40.7% vs. 16.9%, $p < 0.01$) and significantly improved progression-free survival (mPFS2: 8.48 vs. 4.14 months; HR 0.41, $p < 0.01$) and overall survival (mOS2: 23.7 vs. 12.2 months; HR 0.41, $p < 0.01$), findings confirmed in multivariable analyses. Patients with actionable oncogenic drivers or indolent, focal relapses achieved the most favorable outcomes with TT or durvalumab BP ± LAT, respectively, reflecting a disease biology amenable to highly effective systemic or localized interventions. Among patients who received immunotherapy rechallenge, those relapsing ≥12 months after durvalumab initiation experienced higher ORR and numerically longer PFS and OS. Additionally, upfront rechallenge was independently associated with superior survival in multivariable models (PFS aHR: 0.51, $p < 0.01$; OS aHR: 0.46, $p < 0.01$) and with higher ORR (41.5% vs. 17.6%, p = 0.04), compared with later-line rechallenge. **Conclusions:** Post-PACIFIC treatment approaches are heterogeneous, but immunotherapy-based strategies provide superior efficacy over CT alone. Patients with prolonged benefit from durvalumab (≥12 months) retain immune sensitivity and derive the greatest benefit from immunotherapy rechallenge, particularly as FST. Research Sponsor: None.

Nodulomics: Histopathologic and genomic heterogeneity among multiple malignant pulmonary nodules sampled by robotic-assisted bronchoscopy. First Author: Jamie Rowell, Northwestern University, Chicago, IL

Background: Multiple pulmonary nodules (MPN) pose significant challenges for accurate staging of non-small cell lung cancer (NSCLC). As next generation sequencing (NGS) technologies have become more widely available on smaller amounts of tissue, the prevalence and clinical implications of heterogeneity between MPNs are poorly understood. This study retrospectively evaluates the histopathological and NGS findings after MPN biopsy in a single robotic-assisted bronchoscopy (RaB) procedure. **Methods:** 191 patients were retrospectively enrolled at 6 geographically diverse centers in the US. All patients had 2+ pulmonary nodules biopsied and staging EBUS in the same procedure. An expert molecular pathologist reviewed NGS data between nodule pairs to determine if they were discordant, concordant, or indeterminate. **Results:** Of 191 patients, 85 patients had 2 malignant nodules with 15 of those demonstrating histopathologic heterogeneity (e.g., one adenocarcinoma, one squamous cell carcinoma). 26 patients with 2 malignant nodules of similar histopathology demonstrated molecular heterogeneity between nodules. These cases were reviewed by an expert molecular pathologist who determined the following breakdown: -15 discordant pairs (57.7%) -3 concordant pairs (11.5) -8 indeterminate pairs (30.8%) Breakdown by nodule density: -Discordant: 7 same density, 8 different density -Concordant: 3 same density -Indeterminate: 5 same density, 3 different density Breakdown by nodule laterality: -Discordant: 7 ipsilateral, 8 contralateral -Concordant: 2 ipsilateral, 1 contralateral -Indeterminate: 4 ipsilateral, 4 contralateral Staging EBUS was performed in all 26 cases with malignancy identified in 2 cases. NGS sufficiency for NSCLC from three sites with standardized NGS reporting was as follows: 1st nodule biopsied: 42/54 (77.8%), 2nd nodule biopsied: 37/51 (72.5%), 3rd nodule biopsied: 2/4 (50%). In total, 90/109 (82.6%) NSCLC samples had adequate tissue for NGS. In 85 cases with 2 malignant nodules, 35 (41.2%) had all nodules Stage IIB or lower. Notably, 25 (29.4%) of the cases did not have NGS available on one or more of the nodules, thus precluding staging. **Conclusions:** This study highlights the frequency and clinical relevance of histopathologic and molecular heterogeneity among synchronous MPNs. Importantly, heterogeneity was not limited to contralateral or anatomically distant lesions, challenging the assumption that spatial proximity implies clonal relatedness. Further, this study shows that relying solely on density or radiographic features of a nodule is an incomplete discriminator between separate primary lung cancers and intrapulmonary metastasis. Our findings support the need for an integrated diagnostic paradigm in which sampling of multiple lesions is used to inform clonality, refine staging, and guide precision therapy. Sintilimab plus anlotinib and chemotherapy as first-line treatment for advanced malignant pleural mesothelioma (SACH-MPM): A prospective, single-arm, phase II trial. First Author: Yiyi Huang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Standard first-line treatments for advanced malignant pleural mesothelioma (MPM) include platinum-pemetrexed with bevacizumab or nivolumab plus ipilimumab. While the addition of atezolizumab to chemotherapy and bevacizumab improved PFS in the BEAT-meso trial (9.2 vs. 7.6 m, HR 0.72), it failed to show an OS benefit. Anlotinib is a multi-target TKI targeting VEGFR, FGFR, and PDGFR. We investigated the efficacy and safety of sintilimab (anti-PD-1) combined with anlotinib and chemotherapy as first-line treatment for advanced MPM. **Methods:** This open-label, dual-center, single-arm Phase II study (NCT05188859) enrolled systemic treatment-naive pts with unresectable locally advanced or metastatic MPM. Pts received sintilimab (200 mg D1) and anlotinib (12 mg D1-14) plus chemotherapy (pemetrexed 500 mg/m² with cisplatin 75 mg/m² or carboplatin AUC 5, D1) Q3W for 4-6 cycles, followed by maintenance sintilimab, anlotinib, and pemetrexed until disease progression, intolerable toxicity, or up to 24 months. Primary endpoint was ORR per modified RECIST (mRECIST) 1.1 for mesothelioma. A Simon's two-stage design (H0 = 41.3%, H1 = 60%, $\alpha = 0.1$) planned for 23 evaluable pts, requiring ≥12 responses. **Results:** From Sep 2024 to Jan 2026, 30 pts were enrolled (median age 58.5 y; 76.7% epithelioid, 80% stage IIIB). At data cutoff, 29 pts were evaluable. Median follow-up was 7.4 months (m). The primary endpoint was met, with a confirmed ORR of 65.5% (95% CI: 45.7-82.1). DCR was 100%. Median time to response was 1.4 m; median DoR was not reached (0.7+-8.4+ m). PFS and OS were not mature. The 6- and 12-m PFS rates were 100% and 67.5%, respectively. OS rate was 100% at cutoff. Grade ≥3 TRAEs (36.7%) included neutrophil count decreased (13.3%), platelet count decreased (10.0%), pulmonary embolism (6.7%), diarrhea (6.7%), and hypertension (3.3%; any grade 10.0%). Bleeding events were Grade 1-2 (epistaxis 13.3%). TRAEs led to anlotinib dose reduction or discontinuation in 20.0%. No Grade 5 events occurred. **Conclusions:** Sintilimab plus anlotinib and chemotherapy demonstrated superior ORR compared to historical controls with a manageable safety profile. The study met its primary endpoint, and the high 12-month PFS rate suggests a potential survival benefit. These findings support integrating a multi-target TKI with PD-1 blockade and chemotherapy as a potent first-line strategy for advanced MPM. Clinical trial information: NCT05188859. Machine learning–integrated transcriptomic clustering for prognostic stratification in epithelioid pleural mesothelioma. First Author: Mario Occhipinti, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy

Background: Survival outcomes in pleural mesothelioma (PM), particularly within epithelioid PM (ePM), are heterogeneous and inadequately captured by histological classification. We applied machine learning (ML) methods integrating transcriptomic and clinical features to improve prognostic stratification in ePM. **Methods:** RNA sequencing was performed on FFPE tumor samples from 125 ePM patients treated at two Italian centers (2006-2021). Overall survival (OS) was categorized as long (> 36 months), intermediate (12-36 months), or short (≤12 months). Unsupervised clustering of highly variable genes identified transcriptomic subgroups, and GSEA was performed. A previously published 20-gene sarcomatoid-like transcriptional score (S-score), derived from single-cell data was calculated. ML models were developed using age, sex, S-score, and a cluster-derived score related to cell proliferation as input features. Logistic Regression (LR) and Random Forest (RF) classifiers were trained to predict long and short survival, using class-balanced weighting and 5-fold stratified cross-validation. Model performance was assessed using AUC-ROC and balanced accuracy. Model interpretability was evaluated with SHapley Additive exPlanations (SHAP). External evaluation was performed in the TCGA PM cohort with cohort-specific standardization. **Results:** Unsupervised transcriptomic analysis identified three clusters with distinct survival patterns. Cluster 1 was enriched for immune-related pathways and associated with longer survival; Cluster 2 exhibited proliferative and cell-cycle-related programs and was enriched in short-survival patients. Cluster 3 showed immune-related transcripts, with variable expression patterns across histology and survival groups. Given the convergent GSEA results, Cluster 2 was selected as a ML feature. Both the S-score and Cluster 2 score were associated with OS, with stronger survival discrimination for Cluster 2. ML models showed good discriminative performance for long survival prediction (cross-validation AUC-ROC: LR 0.83 ± 0.10; RF 0.83 ± 0.04), with similar results in the TCGA cohort (LR AUC-ROC = 0.84; RF = 0.77). Predictive performance for short survival was moderate. SHAP analysis identified Cluster 2 score as the main contributor to ML predictions, with higher values associated with increased risk of short survival. **Conclusions:** Machine learning models integrating transcriptomic clustering with clinical variables improve prognostic stratification in ePM. ML-based risk prediction builds upon transcriptomic features, capturing survival-relevant heterogeneity beyond histology. These findings support the use of ML as a complementary tool to transcriptomic profiling for prognostic assessment in ePM. Research Sponsor: None.

Tumor methylation subtypes as a predictor of clinical outcome to immunotherapy in pleural mesothelioma patients from the NIBIT-EPI-MESO study. First Author: Luana Calabrò, University of Ferrara, Ferrara, Italy

Background: Pleural mesothelioma (PM) is an aggressive malignancy with a poor prognosis. The clinicalefficacy of standard therapy with immune checkpoint inhibitors (ICI) is limited and heterogeneous acrossPM subtypes. Tumor-intrinsic characteristics (i.e., inflammatory phenotype, molecular features, DNAmethylation) may influence immune responsiveness, but predictive biomarkers of ICI therapy efficacy inPM are still lacking. **Methods:** NIBIT-EPI-MESO is a retrospective, multicenter study, sponsored by theNIBIT Foundation, evaluating biological correlates of clinical outcomes in PM patients (pts) treated withICI (i.e., anti-CTLA-4 plus anti-PD-1, anti-CTLA-4 plus anti-PD-L1, or anti-CTLA-4 monotherapy). Pre-ICI therapy FFPE tumor samples were analyzed by RRBS methylation (n = 83 pts) and RNA-seq (n = 82pts), with methylation subtypes defined by consensus clustering of the top 1% most variable CpGs.Tumor microenvironment (TME) was characterized by multiplex immunofluorescence analysis of CD4,CD8, CD20, CD68, CD163 (n = 35 pts). Integrated multi-omics analyses were used to associate tumorbiology with clinical outcome of PM pts. **Results:** Unsupervised methylation profiling identified four PMsubsets with increasingly global DNA methylation levels: demethylated (DEM), LOW, intermediate (INT),and CpG island methylator phenotype (CIMP). Methylation subtypes were significantly associated withresponse to ICI, with LOW/DEM enriched among responder (R) pts and INT/CIMP in non-R pts (p =0.002); no association of response to ICI was found with PM histotype (p = 0.33). The LOW subsetexhibited the longest median overall survival (mOS) and the highest 3-year OS rate, expressed genesinvolved in pathways associated with innate and adaptive immune responses, and showed an "inflamed"TME (i.e., CD8+ T cells, CD20+ B cells). Conversely, the CIMP subtype had the shortest mOS and OSrate, was characterized by genes enriched in developmental, morphogenetic and cell cycle-relatedprocesses, along with a "desert" TME. Functional characterization of the identified methylation classes ofPM was validated in the MESOMICS dataset. Accordingly, a PM methylation subtype classifier wasdeveloped to predict response to ICI therapy. **Conclusions:** Tumor DNA methylation defines biologicallyand clinically distinct immune phenotypes in PM and robustly predicts clinical response and long-termsurvival in ICI-treated PM patients, regardless of tumor histology. The role of sarcopenia and adiposity in prognosis of pleural mesothelioma: A CT-based analysis. First Author: Senar Ebinc, Van Yuzuncu Yil University, Van, Turkey

Background: Pleural mesothelioma (PM) is a rare malignancy associated with asbestos exposure and characterized by an aggressive clinical course and poor prognosis. Identifying clinical and biological prognostic markers is of significant clinical importance. Recently, computed tomography (CT) based body composition parameters have been investigated for their association with survival outcomes in cancer patients; however, their prognostic value in PM remains unclear. This study aimed to evaluate the impact of clinical characteristics and CT-derived body composition parameters on survival in patients with PM. **Methods:** This retrospective study included 73 patients diagnosed with pleural mesothelioma. CT images were used to calculate the subcutaneous adipose tissue index (SATI), visceral adipose tissue index (VATI), total abdominal adipose tissue index (TATI), skeletal muscle index (SMI), and psoas muscle index (PMI). Patients were classified as sarcopenic or non-sarcopenic based on SMI. **Results:** The median age was 60 years, and 57.5% of patients were male. Most patients had good performance status (ECOG 0–1), and the epithelioid subtype was the most common histology. Approximately one-third of patients had a history of smoking or prior surgery. In univariate analysis, age ≥60 years was significantly associated with increased mortality. In multivariate analysis, age ≥60 years (HR 2.45) and male sex (HR 2.13) were identified as independent poor prognostic factors. Non-sarcopenic patients had a significantly lower risk of mortality compared with sarcopenic patients (HR 0.37). Additionally, higher TATI values were associated with increased mortality risk (HR 2.26). Kaplan–Meier analysis demonstrated significantly shorter OS in patients aged ≥60 years (Table). **Conclusions:** In patients with pleural mesothelioma, advanced age and male sex are associated with poorer survival, whereas preserved skeletal muscle mass is associated with improved outcomes. Increased abdominal adiposity is linked to higher mortality risk. CT-based body composition parameters may provide useful prognostic information in patients with PM. Research Sponsor: None.

Response to neoadjuvant chemoimmunotherapy in EGFR- or ALK-mutated non-small cell lung cancer. First Author: Giorgio Caturegli, Yale School of Medicine, New Haven, CT

Background: The role of immunotherapy in non-metastatic EGFR-and ALK-mutated lung cancer is limited, in part because of a lack of efficacy, and partly because of the high response rates to mutation-targeting therapies. However, a subset of immunotherapy-responsive lung cancers may be cured, but only if immunotherapy is included in the treatment strategy. Therefore, a blanket exclusion of all EGFR-and ALK-mutated patients from immunotherapy may restrict a small subset of patients from a potentially curative option. Our objective was to determine the rate of highly immunotherapy-responsive tumors harboring EGFR and ALK mutations. **Methods:** Adult patients in the NCDB with clinical stage I-III NSCLC diagnosed between 2021 and 2023 and treated with neoadjuvant chemoimmunotherapy followed by definitive surgery (wedge resection, segmentectomy, lobectomy, or pneumonectomy) were included. Outcomes were pathologic complete response (pCR, defined as pathologic T0N0 after definitive resection) and nodal downstaging (pathologic N lower than clinical N stage). Covariates of interest for univariate analyses and multivariable logistic regression were year of diagnosis, region, age, sex, race/ethnicity, insurance, Charlson-Deyo score, clinical stage, and receipt of neoadjuvant immunotherapy. **Results:** Of 3,107 eligible patients, 1,133 (36.4%) were tested for EGFR and/or ALK mutations. Overall, 132 (11.7%) patients were found to have mutation(s) in EFGR (99 patients), ALK (27 patients) or both (6 patients). Among those with cN1-3 tumors, nodal downstaging was observed in 57.4% of patients with EGFR/ALK mutations and 74.2% of wild-type patients ($p<0.001$). The rate of pCR was 16.7% in EGFR-/ALK-mutated patients, and 30.9% in wild-type patients ($p<0.001$). Higher tumor grade was associated with significantly higher odds of pCR in EGFR/ALK wild-type patients (OR 2.448, 95% CI 1.58-3.89, $p<0.001$), but not in EGFR-/ALK-mutated patients (OR 2.63, 95% CI 0.37-18.74, p=0.33). **Conclusions:** While a less common practice, neoadjuvant chemoimmunotherapy in patients with EGFR-/ALK-mutated NSCLC demonstrated a pCR rate of 17% in this large real-world NCDB cohort. Further study on the role of neoadjuvant chemoimmunotherapy for this population is indicated given the potential for curative response, particularly in patients with mutations lacking effective targeted therapy. Pathologic complete response with neoadjuvant chemoimmunotherapy in clinical stage II–III NSCLC: A large real-world analysis including older adults. First Author: Jorge Raul Vazquez Urrutia, Penn State Health Milton S. Hershey Medical Center, Hershey, PA

Background: Neoadjuvant chemoimmunotherapy is now the standard for clinical stage II-III non-small cell lung cancer (NSCLC) following CheckMate 816. However, older adults and socioeconomic factors have been underrepresented in clinical trials. This study aims to evaluate the impact of age and basic socioeconomic factors on pathological complete response (pCR) after neoadjuvant chemoimmunotherapy. **Methods:** Data from the National Cancer Database (NCDB) were obtained for patients diagnosed with clinical stage II-III NSCLC between 2019 and 2023 who underwent neoadjuvant chemotherapy (CT; 2019-2021) or chemoimmunotherapy (CTIO; 2022-2023) with complete T, N, and M staging data, as well as post-pathologic status (ypT, ypN). Those receiving neoadjuvant radiotherapy and with clinical or pathologic metastatic disease were excluded. Groups were stratified based on age (<75 vs ≥ 75 years). Group comparisons were performed using chi-square testing. The primary outcome was pCR, analyzed using univariate and multivariable Cox regression models. A p-value of <0.05 was considered statistically significant. **Results:** A total of 993 patients received CT alone, while 2,819 received CTIO. Among patients ≥ 75 years, pCR rates were significantly higher in the CTIO group compared with CT alone (25% vs 5%, $p<0.001$). This pattern was similar in patients <75 years (29% vs 8%, $p<0.001$). Among CTIO receivers, pCR rates did not differ significantly by age (25% ≥75 vs 29% <75; p=0.051) (Table 1). Patients with ≥10 lymph nodes examined had lower pCR rates compared with those with fewer nodes examined (26% vs 37%; $p<0.001$). On multivariate analysis, higher nodal stage (N1–N3; OR 1.23, 1.02-1.49, p=0.035) and non-adenocarcinoma histologies (OR 1.26, 1.07-1.49, p=0.006) were independently associated with higher odds of pCR. Notably, age, sex, race, and rural/urban residence were not independently associated with pCR, and no significant differences in race or rural/urban status were observed between groups. **Conclusions:** To our knowledge, this is the largest real-world analysis of neoadjuvant chemoimmunotherapy outcomes in older adults with clinical stage II-III non–small cell lung cancer. We found comparable pCR rates across age groups, supporting the use of this approach in older individuals. While racial disparities have been described in access to neoadjuvant therapy, our study suggests similar response rates across racial groups who underwent treatment. Higher nodal status was independently associated with pCR, which may be explained by greater tumor immunogenicity. These findings are hypothesis-generating and warrant validation in further prospective studies. Research Sponsor: None.

Pathologic complete response rate by age status.

Prediction of survival outcome in clinical stage II-III non-small cell lung cancer undergoing neoadjuvant chemoimmunotherapy: Role of ypN status vs PCR. First Author: Hannah Hoang, Department of Internal Medicine, Penn State College of Medicine, Hershey, Pennsylvania, Hershey, PA

Background: After FDA approval in 2022, neoadjuvant chemoimmunotherapy has become the standard of care for patients with non-small cell lung cancer (NSCLC) due to improved survival outcomes. Pathologic complete response (pCR) is often used as a predictor of patient survival following treatment. However, the role of posttreatment pathological nodal status (ypN) as a treatment predictor remains undefined. This study evaluates the predictive significance of ypN in comparison to established treatment predictors, such as pCR. **Methods:** Patients with clinical stage II-III NSCLC diagnosed in 2022 (n=29,017) who underwent neoadjuvant chemoimmunotherapy and resection (n=1,175) were identified using the National Cancer Database. Those with missing pCR data (n=16), pCR in tumor only (n=18), and those who died within one month of diagnosis were excluded. Chi-square tests were used for comparisons between groups. Survival analysis was performed using the Kaplan-Meier method, along with univariate and multivariable Cox proportional models. All tests were two-sided, and the statistical significance level used was 0.05. **Results:** The final cohort consisted of 720 patients divided into three groups: pCR-both (pCRb; ypT0N0; n=217; 30.1%), pCR-node (pCRn; ypN0; n=265; 36.8%), and residual viable in both (RVb; n=238; 33.1%). The pCRb group had a higher proportion of squamous cell carcinoma compared to the pCRn group (47% vs 34%, $p<0.001$). pCRn patients demonstrated a slightly higher rate of positive surgical margins (3% vs 1%, p=0.03) and subsequent use of adjuvant radiotherapy compared with pCRb (3% vs 1%, p=0.03). Kaplan-Meier analyses and Cox proportional hazards models showed similar overall survival (OS) between pCRb and pCRn groups (HR=1.37; p=0.363), while both had significantly higher OS compared with RVb (HRs 0.26 and 0.36; $p<0.0001$ for both). Subgroup analysis by number of examined lymph nodes showed comparable OS between pCRb and pCRn in patients with $\geq$10 lymph nodes examined (LN$\geq$10; HR=1.36; p=0.47) and in those with $<$10 nodes examined (LN$<$10; HR=1.50; p=0.40). **Conclusions:** In clinical stage II-III NSCLC treated with neoadjuvant chemoimmunotherapy followed by resection, pCRb and pCRn demonstrated similar rates of OS, highlighting the significance of post-treatment pathological nodal status (ypN) as a potential predictor of OS in this population. Since pCRb requires invasive tissue sampling, using ypN as a predictor of OS would allow for more efficient risk stratification with overall less invasive testing. Research Sponsor: None.

Differences in central versus local lab PD-L1 classification in the ALCHEMIST Alliance A151216 non–small cell lung cancer (NSCLC) study. First Author: David E. Kozono, Mass General Brigham Cancer Institute, Boston, MA

Background: The NCI Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trials (ALCHEMIST) study tested resected stage II-IIIB(N2) NSCLC for targetable EGFR and ALK alterations and PD-L1 expression to screen patients for biomarker-driven adjuvant therapy trials (NCT02194738). Local lab results were requested when available for comparison to central lab results. **Methods:** We identified patients with both central and local PD-L1 results in the ALCHEMIST adjuvant immunotherapy study screening population. Discrepancies in tumor proportion score (TPS) between central and local PD-L1 were defined using prespecified cut-points (granular: $<$1%, 1-$<$5%, 5-$<$10%, 10-$<$20%, 20-$<$30%, 30-$<$40%, 40-$<$50%, 50-60%, 60-$<$70%, 70-$<$80%, 80-$<$90%, 90-$<$100%; clinical: $<$1%, 1-$<$50%, 50-100%). Large discrepancies were defined as $\geq$ 50 percentage point differences; for these cases, local PD-L1 and hematoxylin & eosin-stained slides were requested. These and all central slides were digitally scanned at 40X. Three expert pathologists reviewed the scanned slides in a blinded fashion. Differences between patient or tumor characteristics were assessed by Chi-square and Wilcoxon rank sum tests. Percent agreement was computed within and between the reviewers. **Results:** Central and local PD-L1 results were available for 497 patients. 177 cases (36%) had discrepancies that placed patients in different clinical TPS categories ($<$1%, 1-$<$50%, 50-100%). Among these, 43 cases had large TPS discrepancies; 14 had available local testing slides. 46 of the 320 cases without discrepancy were randomly selected as controls. No patient or tumor characteristics were associated with discrepancy, including tumor location, histology, grade or cancer stage ($p > 0.05$). Pairwise comparisons of TPS according to three pathologists re-reading the same scanned PD-L1 slides showed similar levels of disagreement in clinical TPS category whether there was initial discrepancy between central and local results (24%, 34%, and 23%; mean 27%) or not (33%, 30%, and 20%; mean 28%). Among the 14 cases with large initial discrepancies and local slides available, there was agreement in clinical TPS category when the anonymized central and local scanned slides were re-read by the pathologists in 54%, 38%, and 43% of cases, despite 100% non-agreement in initial reads. There were higher rates of agreement when the tested slides both originated from the same (100%) versus different (35%) blocks, when the same (48%) versus different (40%) PD-L1 antibodies were used, and when the cases were of non-squamous (52%) versus squamous (14%) cell carcinoma. **Conclusions:** There are substantial differences in PD-L1 TPS read by pathologists that can result in placement of patients in different categories commonly used for clinical management. These differences have clear implications in clinical trials and routine patient care. Firmonertinib combined with cisplatin/carboplatin plus pemetrexed as neoadjuvant therapy in resectable stage II-IIIb *EGFR*-mutated non–small cell lung cancer: A single-arm, single-center, open-label phase II study. First Author: Jie Xu, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: For patients with resectable, locally advanced EGFR-mutated NSCLC, traditional neoadjuvant chemotherapy yields suboptimal efficacy. While EGFR-TKIs are standard in the adjuvant therapy, their role in neoadjuvant therapy is under active investigation. **Methods:** This single-arm, phase II study evaluated neoadjuvant firmonertinib plus platinum-based chemotherapy in patients with stage II-IIIB EGFR-mutated NSCLC. The primary endpoint was major pathological response (MPR), the major second endpoint were pathological complete response (pCR), objective response rate (ORR), R0 resection rate and rate of downstaging. **Results:** Among the 13 patients currently enrolled, 11 completed 4 cycles of neoadjuvant therapy, and 9 underwent radical surgery. The MPR rate and the pCR rate are both currently at 0. The ORR is 77.8%, and the radical resection rate reaches 100%. The TNM tumor stage reduction rate is 66.7%. The incidence of grade 3/4 adverse events is 11.1%, and there are no 5-grade adverse events. **Conclusions:** Firmonertinib with chemotherapy as neoadjuvant in II-IIIB EGFR-mutated NSCLC demonstrated a promising surgical conversion rate and a manageable safety profile, supporting its feasibility for further study. Clinical trial information: NCT06890182. Research Sponsor: None.

RATIONALE-315: Post hoc analysis of event-free survival by surgically relevant subgroups treated with perioperative tislelizumab and neoadjuvant chemotherapy vs neoadjuvant chemotherapy. First Author: Gustavo Schvartsman, Hospital Israelita Albert Einstein, Sao Paulo, Brazil

Background: RATIONALE-315 (NCT04379635) compared the efficacy and safety of perioperative tislelizumab (TIS) or placebo (PBO) + neoadjuvant chemotherapy (CT) in patients (pts) with resectable NSCLC. This post hoc analysis reports correlation of event-free survival (EFS) to key surgical outcomes. **Methods:** Pts with resectable stage II-IIIA NSCLC (N=453) were randomized 1:1 to 3-4 cycles of TIS 200 mg or PBO Q3W with neoadjuvant CT, followed by surgery and $\leq$8 cycles of adjuvant TIS 400 mg or PBO Q6W. Primary and key secondary endpoints were reported previously. Exploratory endpoints of surgical outcomes are presented here. **Results:** As of March 7, 2025, 190/226 pts in the TIS arm and 173/227 pts in the PBO arm underwent definitive surgery. EFS benefit with TIS vs PBO was observed in all surgically relevant subgroups (HR: 0.62; 95% CI: 0.44-0.88). Although R0 resection rates were similar between treatment arms, TIS showed greater EFS benefit vs PBO (HR: 0.62; 95% CI: 0.43-0.90). A similar trend was observed in R1/R2 pts (HR: 0.75; 95% CI: 0.19-3.05); however, data should be interpreted with caution due to small pt numbers. Pts in the TIS arm who underwent open and minimally invasive surgery (n=179) achieved improved EFS benefit compared with those in the PBO arm (n=157), regardless of disease stage and surgery type (Table). In pts who underwent minimally invasive and open surgery, respectively, grade $\geq$3 treatment-emergent adverse events occurred in 77.2% and 78.8% of pts in the TIS arm and 71.3% and 81.7% in the PBO arm. In pts who underwent minimally invasive surgery in the TIS arm, grade $\geq$3 immune mediated adverse events were reported in 11.4% of all pts (13/114), 10.4% of pts in stage II (5/48), and 12.3% in stage IIIa (8/65). **Conclusions:** Perioperative TIS + neoadjuvant CT improved EFS in pts with resectable NSCLC across all surgically relevant subgroups regardless of disease stage or surgery type. These results further support TIS + CT as an efficacious and safe treatment option that may reduce the burden of invasive surgical intervention. Clinical trial information: NCT04379635. Survival outcomes between neoadjuvant and adjuvant chemo-immunotherapy in patients with stage II–III NSCLC undergoing surgical resection. First Author: Joseph Zouein, Department of Medicine, Cooper University Health Care, Camden, NJ

Background: In patients with stage II–III NSCLC, perioperative systemic therapy is recommended; however, the optimal timing of chemo-immunotherapy relative to surgery remains an area of active investigation. The aim of this study was to compare overall survival outcomes between neoadjuvant and adjuvant chemo-immunotherapy in patients with stage II–III NSCLC undergoing surgical resection. **Methods:** We utilized the National Cancer Database (NCDB) and included patients with complete follow-up data, diagnosed between 2018 and 2023 with clinically staged IIA–IIIB NSCLC (cT1–cT4, cN0–cN2, cM0), who underwent definitive surgical resection, and received either neoadjuvant or adjuvant chemo-immunotherapy. Kaplan–Meier analysis and propensity score–adjusted Cox proportional hazards models were used to assess survival outcomes. **Results:** A total of 2,815 patients met the inclusion criteria, including 1,521 (54%) males, with a median age of 66 years. Of these, 1,186 (42%) patients received neoadjuvant therapy and 1,629 (58%) received adjuvant therapy. Median overall survival (OS) was not reached in the neoadjuvant group, compared with 79.4 months (95% CI, 68.1–90.7, $p < 0.001$) in the adjuvant group (Table 1). On propensity score–adjusted Cox regression, neoadjuvant therapy was associated with a significant OS advantage compared with adjuvant therapy (HR 0.71; 95% CI, 0.58–0.87; $p < 0.001$). Neoadjuvant therapy was associated with improved OS among patients with baseline cN2 disease (HR 0.64; 95% CI, 0.45–0.91; p = 0.012). No statistically significant difference in OS was observed among patients with cT3 or cT4 disease (HR 0.95; 95% CI, 0.66–1.36; p = 0.759) and HR 0.67; (95% CI, 0.45–1.01; p = 0.053), respectively. **Conclusions:** In patients with stage II–III NSCLC undergoing surgical resection, neoadjuvant chemo-immunotherapy was associated with improved overall survival compared with adjuvant therapy, particularly among those with a higher nodal or regional tumor burden at presentation. Research Sponsor: None.

Median overall survival and hazard ratios for neoadjuvant versus adjuvant chemo-immunotherapy in stage II–III NSCLC.

	Neoadjuvant Median OS (months)	Adjuvant Median OS (months)	Hazard Ratio (HR)	95% CI	p-value

Characteristics of patients with resectable early-stage non–small cell lung cancer treated with neoadjuvant chemoimmunotherapy or surgery ± adjuvant therapy. First Author: Pragya Rai, Merck & Co., Inc., Rahway, NJ

Background: The integration of immune checkpoint inhibitors (ICIs) into neoadjuvant, perioperative, and adjuvant treatment strategies for early-stage NSCLC (eNSCLC) has been associated with improved patient outcomes; however, despite these advances, uptake of ICIs in the neoadjuvant/perioperative setting remains limited. This study aimed to characterize differences in patient characteristics between those receiving neoadjuvant chemoimmunotherapy (neoadjuvant ICI+CTx) and those receiving upfront surgery ± adjuvant therapy. **Methods:** Adult patients with stage II-IIIB(N2) NSCLC (AJCC 8th edition) diagnosed between March 2022 and six months before data cut-off (November 2025) were identified in the Flatiron Health database. Patients who received ICI+CTx prior to surgery were assigned to the neoadjuvant ICI+CTx group, and patients that underwent upfront resection following an NSCLC diagnosis with no previous treatment, with or without adjuvant therapy, were assigned to the surgery± adjuvant therapy group. The Pearson chi-square or fisher exact tests were conducted to evaluate differences in baseline characteristics. All statistical analyses were two-sided. **Results:** A total of 1,807 patients were identified with resectable stage II-IIIB(N2) NSCLC, of which 204 (11%) initiated neoadjuvant ICI+CTx and 1,603 (89%) received surgery± adjuvant therapy (583 (36%) with adjuvant therapy; 1,020 (64%) without adjuvant therapy). Of the 204 patients, 144 (71%) underwent surgery and 76 (53% of those undergoing surgery) subsequently received adjuvant therapy. Significant differences were observed in the baseline characteristics between the two groups. Patients who received neoadjuvant ICI+CTx had higher proportion of stage III disease, cN2 status, evenly split histology, higher biomarker (PD-L1, EGFR) testing, PD-L1 positive expression levels, and fewer EGFR mutations while patients who received surgery± adjuvant therapy had higher proportion of stage II disease, cN0 status, non-squamous histology, lower biomarker testing, negative or low PD-L1 expression levels, and higher EGFR mutations (all $p < 0.001$). **Conclusions:** Despite the clear benefit across clinical trials of neoadjuvant and perioperative ICI strategies to treat resectable eNSCLC, their utilization in clinical practice remains limited. This study further demonstrates significant differences in baseline characteristics that might contribute to patient selection for neoadjuvant ICI+CTx versus upfront surgery ± adjuvant therapy as a primary therapeutic approach. Tailored interventions to further educate the medical community on recent clinical trial evidence may facilitate wider implementation of neoadjuvant and perioperative ICI strategies and broaden appropriate patient selection in resectable eNSCLC. Impact of adjuvant immunotherapy after pathologic complete response to neoadjuvant chemo-immunotherapy in resected stage II–III non–small cell lung cancer. First Author: Joseph Zouein, Department of Medicine, Cooper University Health Care, Camden, NJ

Background: Perioperative chemo-immunotherapy has recently emerged as a new standard of care for patients with resectable non–small cell lung cancer (NSCLC) following positive results from the CheckMate-77T (NCT04025879) and KEYNOTE-671 (NCT03425643) trials. However, whether patients who achieve a complete pathologic response (pCR) after neoadjuvant chemo-immunotherapy derive additional benefit from subsequent adjuvant immunotherapy remains uncertain due to limited available data (only 58 patients achieved pCR in CheckMate-77T and 72 patients in KEYNOTE-671). The INSIGHT clinical trial (NCT06498635) is an ongoing phase III study designed to address this question; however, the trial is expected to be completed in 2039. Therefore, generating additional data in this area is critically important. We performed a retrospective analysis to assess whether the addition of adjuvant immunotherapy improves overall survival (OS) among patients with stage II–III NSCLC who achieve pCR following neoadjuvant chemo-immunotherapy. **Methods:** We conducted a retrospective cohort study using the National Cancer Database (NCDB) and included patients with complete follow-up data who were diagnosed between 2018 and 2023 with clinically staged IIA–IIIB NSCLC (cT1–cT4, cN0–cN2, cM0), underwent definitive surgical resection with pCR (ypT0N0M0), and received either neoadjuvant chemo-immunotherapy alone or neoadjuvant chemo-immunotherapy followed by adjuvant immunotherapy (perioperative chemo-immunotherapy). Survival outcomes were analyzed using Kaplan–Meier methods. **Results:** A total of 1,816 patients were included, of whom 967 (53.2%) were male, with a median age of 65 years (IQR, 60–71). Among these patients, 1,186 (65.3%) received neoadjuvant chemo-immunotherapy alone, and 630 (34.7%) received perioperative therapy. No significant difference in overall survival was observed between the two treatment groups. Median OS was not reached in either group, with a hazard ratio of 1.235 (95% CI, 0.602–2.533; p = 0.565). **Conclusions:** Among patients with stage II–III NSCLC who achieve pCR following neoadjuvant chemo-immunotherapy and undergo surgical resection, we observed no significant difference in overall survival between those treated with neoadjuvant therapy alone versus perioperative chemo-immunotherapy. These findings suggest that neoadjuvant chemo-immunotherapy alone may be sufficient for patients who achieve pCR, and that adjuvant immunotherapy in this setting may not provide additional survival benefit. Postoperative re-profiling for identification of missed drivers and a high-risk fusion subgroup in non-pCR lung adenocarcinoma after neoadjuvant immunotherapy: A multicenter retrospective study. First Author: Xin Liu, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: For stage II-III driver-negative non–small cell lung cancer (NSCLC), neoadjuvant chemoimmunotherapy followed by surgery is standard. However, patients without pathological complete response (non-pCR) have suboptimal outcomes and heterogeneous benefit from adjuvant immunotherapy. Baseline driver-negative status may be confounded by false-negative PCR- or DNA-only testing and detecting missed drivers postoperatively could alter adjuvant strategies. This study characterized post-treatment driver alterations and its prognostic value in non-pCR NSCLC after neoadjuvant immunotherapy. **Methods:** The retrospective multicenter study enrolled 247 stage II-III lung adenocarcinoma (LUAD) patients initially tested as EGFR L858R/19del- and ALK-negative and treated with neoadjuvant immunotherapy (2018-2025). 76 lung squamous cell carcinoma (LUSC) cases were included for exploratory analysis. Postoperative samples underwent 35-gene synchronous DNA/RNA next-generation sequencing (DR-NGS) to identify SNV/indel and fusion events and assess prognostic associations. **Results:** Of 247 LUAD cases, 179 passed NGS quality control (QC). Driver alterations were identified in 104 (58.1%) patients, including 26 fusions: RETn = 9), MET ex14 skipping (n = 6), ALK(n = 4), ROS1(n = 3), NRG1(n = 2), MET fusion(n = 1), NTRK(n = 1) and 80 SNVs/indels :EGFR (n = 30), KRAS G12C/D (n = 16), HER2/3 (n = 16), BRAF (n = 2), KRAS non-G12C/D (n = 16). Notably, 10 classic EGFR mutations (19del/L858R) 、 9 rare EGFR mutations and 4 ALK fusions were newly identified, indicating baseline omissions. Driver-positive tumors had significantly higher residual tumor burden(median: 51.8% vs. 35.8%, p = 0.003) and a higher proportion of females (43.3% vs 20.0%, p = 0.001). Median recurrence-free survival (mRFS) differed significantly among fusion-positive, mutation-positive, and driver-negative groups (20.9 vs 41.5 vs 60.3 months; p = 0.024). In patients receiving adjuvant immunotherapy, mRFS was 34.6 months in driver-positive and not reached in driver-negative patients. Driver detection was rare (< 3%) in QC-failed samples (n = 68), which exhibited a higher major pathological response than QC-passed samples (58.1% vs 14.5%), indicating tumor cellularity as critical for detection. Exploratory analysis in 55 QC-passed LUSC samples showed a low driver detection rate (7.3%), suggesting limited utility in this cohort. **Conclusions:** DR-NGS reveals a high prevalence of drivers in non-pCR LUAD after neoadjuvant immunotherapy, with positivity associated with higher residual tumor burden. Fusion-positive patients have the poorest prognosis, identifying a subgroup that may benefit from tailored adjuvant strategies. These findings support routine postoperative molecular re-profiling in non-pCR patients to guide individualized treatment. CT-derived visceral fat phenotypes to reveal a metabolically defined TOFI subgroup in a lung cancer screening cohort: An imaging-based framework for evaluating the BMI paradox. First Author: Taofik Ahmed Suleiman, Wallace H. Coulter Department of Biomedical Engineering, Georgia Institute of Technology and Emory University, Atlanta, GA

Background: Body mass index (BMI) imperfectly reflects metabolic health and cannot distinguish subcutaneous from visceral fat, contributing to the long-standing "BMI paradox" in cancer, whereby higher BMI is sometimes associated with better survival. Visceral fat is metabolically active and promotes cancer progression. Individuals with normal BMI but high visceral fat, termed "Thin Outside, Fat Inside" (TOFI) are understudied in cancer populations. These TOFI patients may represent an unrecognized high-risk metabolic phenotype in cancer. We investigated whether CT-derived lower-thoracic visceral fat identifies TOFI as a high-risk subgroup for cancer mortality. **Methods:** Baseline CT scans from participants in the National Lung Screening Trial (NLST; n = 19,140), a lung cancer screening cohort designed to detect NSCLC, were segmented to extract subcutaneous fat, visceral fat, and vertebral levels. Because T9–T12 best captures abdominal visceral adiposity, the percentage volume of visceral fat relative to subcutaneous fat from this region was used for phenotyping. Low ($<$20%) and high ($>$40%) visceral fat groups were defined, yielding 9,887 participants. Visceral fat was combined with BMI ($<$25 vs $\geq$25) to define four phenotypes: P1 (LowBMI_LowVIS), P2 (HighBMI_LowVIS), P3 (HighBMI_HighVIS), and P_TOFI (LowBMI_HighVIS). Cancer-specific mortality was the primary endpoint, and Cox proportional hazards models were used to compare these phenotypes. **Results:** Distinct phenotypes demonstrated markedly different mortality risks (Table). The TOFI group exhibited the worst survival despite normal BMI, with nearly double the cancer mortality risk compared with the metabolically favorable reference group, P1 (HR 1.95; 95% CI, 1.31-2.91; p = 8.4e-04). In contrast, high-BMI groups showed only modest or no excess risk, supporting the limitation of BMI alone. **Conclusions:** CT-derived visceral fat phenotyping reveals a clinically relevant high-risk group TOFI, individuals who have normal BMI but significantly elevated cancer and all-cause mortality risk compared to even high-BMI patients. This finding directly exposes the BMI paradox, showing that normal BMI does not confer protection when visceral adiposity is high. Because this TOFI phenotype is undetectable by BMI, incorporating visceral fat assessment into lung cancer screening and survivorship models could enable earlier identification of high-risk TOFI patients and guide targeted prevention. Research Sponsor: None.

Stage-dependent divergence of immune prognostic signatures in non–small cell lung cancer. First Author: Praveen Thapa, Chirayu National Hospital, Kathmandu, Nepal

Background: Tumor mutational burden (TMB) and immune activation are widely studied biomarkers in non–small cell lung cancer (NSCLC), yet their prognostic relevance outside the context of immunotherapy remains unclear. We investigated how age, histology, and disease stage modify the relationships between tumor genomics, immune contexture, and overall survival in NSCLC. **Methods:** We analyzed The Cancer Genome Atlas NSCLC cohort from the "Pan-cancer atlas" (2018) with a total of 1053 patients evaluating TMB, CD8A expression, cytolytic activity score (CYT), age at diagnosis, histology, and overall survival. Associations among continuous variables were assessed using Spearman correlation. Multivariable Cox proportional hazards models adjusted for age, sex, and tumor mutational burden were performed and stratified by stage (I–II vs III–IV). **Results:** Age demonstrated an inverse correlation with tumor mutational burden ($\rho = -0.12$, $P < 0.001$) but was not associated with CD8A expression and showed a weak positive association with CYT, driven by non-squamous tumors. Tumor mutational burden was not associated with overall survival in either early- or late-stage disease. In contrast, immune biomarkers demonstrated marked association with stage of disease. Higher CD8A expression was associated with improved survival in early stage (HR 0.77 per SD, P = 0.021) but not in advanced disease. CYT exhibited a significant interaction with stage with higher CYT showing association with improved survival in early-stage NSCLC (HR 0.79 per SD, P = 0.026) but with worse survival in late-stage disease (derived HR $\approx$ 1.14). Tumor stage remained the dominant prognostic factor across all models. **Conclusions:** In untreated NSCLC, immune prognostic signatures are strongly stage dependent. Immune infiltration and cytolytic activity confer survival benefits in early-stage disease but not in advanced disease, where cytolytic activity may reflect aggressive tumor-associated inflammation. Tumor mutational burden does not provide prognostic value across disease stages. These findings highlight the importance of disease context when interpreting immune biomarkers and provide critical baseline insight for immunotherapy-era studies. Research Sponsor: None.

Survival outcomes of young patients with non-small cell lung cancer in Latin America: A real-world cohort study. First Author: Cristina Torres-Mallma, AUNA, Lima, Lima, Peru

Background: Young patients with non-small cell lung cancer (NSCLC) represent a distinct biological subgroup, frequently enriched with actionable oncogenic drivers. However, real-world survival data from Latin America are limited. We evaluated survival outcomes and prognostic factors in young versus older patients with NSCLC treated in Peru. **Methods:** We conducted a retrospective cohort study including patients with histologically confirmed NSCLC treated between 2018and 2024 at a national reference cancer center. Patients were stratified by age at diagnosis ($<$45 vs $\geq$45 years). Overallsurvival (OS) was estimated using the Kaplan–Meier method. Multivariable Cox regression was performed adjusting for sex,ECOG performance status, smoking history, clinical stage, histology, molecular alterations and first-line treatment. **Results:** A total of 317 patients were included; 19.9% were younger than 45 years. The cohort was predominantly female (59.3%),never-smokers (85.5%) and had adenocarcinoma histology (95.6%). Advanced disease (stage III–IV) was present in 94.0% ofcases. Actionable molecular alterations were identified in 69.4% of patients, most commonly EGFR mutations (48.3%).Younger patients showed a higher frequency of actionable mutations compared with older patients (70% vs 56%, p=0.038).After a median follow-up of 40.9 months, 92 deaths (29.0%) were recorded. In adjusted analysis, young age was notassociated with worse OS (adjusted HR 1.32; 95% CI 0.79–2.21; p=0.29). Former smoking history was the only independentpredictor of inferior OS (adjusted HR 2.38; 95% CI 1.16–4.91; p=0.018). **Conclusions:** Young age at NSCLC diagnosis was not associated with inferior survival. Despite advanced-stage presentation, youngerpatients exhibited a high prevalence of actionable oncogenic drivers, supporting routine comprehensive molecularprofiling. These results provide robust regional evidence and reinforce the importance of precision oncology inunderrepresented populations. Research Sponsor: None.

Immune aging within the tumor microenvironment as a predictor of survival in non–small cell lung cancer. First Author: Taeyun Kim, Kosin University College of Medicine, Busan, South Korea

Background: Immune aging has been associated with survival outcomes in patients with lung adenocarcinoma (LUAD), but its relevance within the tumor microenvironment (TME) remains unclear. **Methods:** Clinical and RNA-sequencing data from the TCGA LUAD cohort were analyzed. Immune aging within tumor tissue was quantified using a predefined 121-gene immune aging–related signature (IAS-121). For primary analyses, patients were dichotomized into high versus low IAS-121 groups based on the median value. Immune cell composition within the TME was inferred using xCell analysis and compared according to IAS-121 status. Overall survival (OS) was assessed using Kaplan–Meier analysis and Cox proportional hazards models adjusted for age, sex, tumor stage, smoking status, and EGFR mutation status. Sensitivity analyses were performed using quartile-based categorization of IAS-121 (lowest vs highest quartile), and external validation was conducted in two independent LUAD cohorts (GSE68465 and GSE50081). **Results:** A total of 518 patients with LUAD from the TCGA cohort were included. Patients with high IAS-121 had significantly poorer OS compared with those with low IAS-121 (p=0.026). In multivariable analysis using the median cut-off, high IAS-121 showed a non-significant trend toward increased mortality (adjusted hazard ratio [aHR] 1.33; 95% confidence interval [CI], 0.96–1.84). In sensitivity analyses comparing the lowest and highest quartiles of IAS-121, a significant association with OS was observed (aHR 1.87; 95% CI, 1.20–2.92). This association was further confirmed in a pooled analysis of the external LUAD cohorts (GSE68465 and GSE50081), in which higher IAS-121 was independently associated with worse OS (aHR 1.57; 95% CI, 1.02–2.43). Subgroup analyses showed generally consistent associations across age, sex, tumor stage, smoking status, and EGFR mutation status. Tumors with high IAS-121 exhibited reduced enrichment of $CD8^+$ T cells and $CD4^+$ naïve T cells, along with increased neutrophil enrichment. **Conclusions:** Immune aging within TME is associated with poorer survival in LUAD. As this study is hypothesis-generating, further investigations integrating tissue- and blood-based measures of immune aging are warranted to clarify its clinical and biological implications. Research Sponsor: None.

Cox proportional hazards models comparing the lowest versus highest quartile of immune aging score-121 and overall survival in lung adenocarcinoma.

	TCGA		GSE68465 plus GSE50081	
	HR (95% CI)	p	HR (95% CI)	p
Crude	1.648 (1.114 – 2.238)	0.012	2.093 (1.396 – 3.141)	$<$0.001
Adjusted	1.873 (1.200 – 2.924)	0.006	1.571 (1.016 – 2.429)	0.007

Models adjusted age, sex, tumor stage, smoking status, and EGFR mutation status for TCGA dataset and age, sex, tumor stage for GSE68465 plus GSE50081 cohorts.
LUAD = lung adenocarcinoma; HR = hazard ratio; CI = confidence level.

Age-based differences in outcomes among small cell lung cancer patients treated with tarlatamab. First Author: Raymart Macasaet, Monmouth Medical Center, Long Branch, NJ

Background: Tarlatamab has durable antitumor activity in patients with previously treated Small Cell Lung Cancer (SCLC). A rising fraction of SCLC diagnoses is now observed in older patient groups. To assess real-world outcomes, we analyzed a large, multi-institutional database evaluating age-related differences in survival, treatment patterns, and immune toxicities, including Cytokine Release Syndrome (CRS) and Immune Effector Cell-associated Neurotoxicity Syndrome (ICANS), to clarify factors affecting response and tolerability. **Methods:** A retrospective cohort study was conducted using de-identified data from the TriNetX Research Network. At the time of data analysis, it included 154,537,377 patients across 113 healthcare organizations. We identified adults aged 18 years or older with lung cancer treated with Tarlatamab. Kaplan-Meier analysis assessed overall survival. Statistical comparisons of survival rates between groups were performed using the log-rank test. Propensity matching was used to adjust for age, comorbidities, and lines of treatment. **Results:** A total of 616 patients were identified in the TriNetX cohort, with a mean age of 65.8 $\pm$ 9.89 years, and 51.9% were female. Age distribution was as follows: 124 patients (20.13%) were younger than 60 years, 271 (43.99%) were 60–70 years, and 221 (35.88%) were older than 70 years. Brain metastases were present in 53 patients (8.60%) in the $<$60 group, 116 (18.83%) in the 60–70 group, and 90 (14.61%) in the $>$70 group. Median overall survival of the entire cohort was 13.32 months; it was not reached in the $<$60 group, 13.32 months in the 60–70 group, and 12.72 months in the $>$70 group, with no significant differences across age groups or brain metastasis status. In the propensity score–matched cohorts, survival did not differ significantly between $<$60 and $>$70 age groups (HR 0.80 (95% CI 0.34–1.22; p=0.39)), and a similar lack of difference was observed between 60–70 and $>$70 age groups (HR 0.72 (95% CI 0.48–1.07; p=0.10)). In the overall population, 57 patients (9.25%) experienced ICANS and 67 (10.88%) developed CRS. By age group, ICANS and CRS occurred in 16 (2.60%) and 17 (2.76%) patients $<$60, 23 (3.73%) and 29 (4.71%) patients 60–70, and 18 (2.92%) and 21 (3.40%) patients $>$70, respectively. Overall, 91 patients (14.77%) required tocilizumab and 23 (3.73%) required vasopressors, with no significant differences across the three age groups. **Conclusions:** This study offers an extensive evaluation of age-related outcomes with Tarlatamab. Neither age nor brain metastases significantly influenced overall survival, indicating preserved efficacy in older adults. ICANS and CRS were infrequent and evenly distributed across age groups. Tocilizumab and vasopressor use were similar across groups, indicating comparable severity. These results support Tarlatamab's favorable safety, tolerability, and effectiveness across diverse real-world populations. Research Sponsor: None.

SPARK-Lung: A study of patterns and outcomes in young-onset lung cancer. First Author: Teja Voruganti, Penn Medicine Abramson Cancer Center, Philadelphia, PA

Background: Young onset lung cancer patients diagnosed before age 50 appear to have distinct features compared to their older counterparts, including a higher proportion of never-smokers and increased frequency of targetable driver mutations. Yet, the molecular characteristics and survival outcomes of young-onset non-small cell lung cancer (NSCLC) remain poorly defined in U.S. populations. Improved understanding of the demographic and molecular profile of this distinct disease is needed to guide diagnostic testing strategies and personalize treatment. **Methods:** We conducted a retrospective cohort study using the US-based, electronic health record-derived deidentified Flatiron Health Research Database, which included adults diagnosed with NSCLC between 2013 and 2025 who underwent next-generation sequencing. Young-onset NSCLC was defined as age $<$ 50 years and older-onset as $\geq$50 years. Demographics, stage at diagnosis, and prevalence of driver mutations and fusions were compared between age groups. Differences are reported using standardized mean differences (SMD) with SMD $\geq$0.2 indicating significant difference. Treatment patterns and overall survival (OS) were evaluated in metastatic patients adjusting for sex, histology, smoking status, performance status, insurance, and TP53 status. **Results:** Among 3792 young-onset and 120,161 older-onset patients with NSCLC across all stages, young-onset patients were more often female (54.2% vs 51.2%), Asian (5.3% vs 2.4%), Black (12.4% vs 8.1%), or Hispanic/Latino (8.5% vs 3.6%) (SMD 0.38). They were more often treated in academic settings (24.8% vs 16.0%; SMD 0.26) and more likely to have no tobacco history (36.6% vs 13.8%; SMD 0.65). Non-squamous histology predominated in younger patients (85.1% vs 73.1%; SMD 0.29) and actionable driver alterations were more common (47.8% vs 40.5%), particularly ALK (9.3% vs 1.2%; SMD 0.66) and EGFR (17.6% vs 11.0%; SMD 0.21). Young-onset patients were more likely to present with metastatic disease (69.8% vs 49.2%; SMD 0.43). After adjustment, treated young-onset patients received more lines of therapy than older patients (median no. 2 vs 1; incident rate ratio 1.16; 95% CI 1.12–1.20; $p < 0.0001$) and had longer median treatment duration (23.7 vs 14.3 mos, $p < 0.0001$). Among patients with metastatic disease at diagnosis, unadjusted median OS was longer in young-onset versus older-onset patients (2.0 vs 1.1 years), with higher 1-year (72.6% vs 57.2%) and 2-year (56.7% vs 41.8%) OS rates. **Conclusions:** Young-onset NSCLC represents a clinically distinct population in the United States, characterized by higher rates of advanced stage at diagnosis, a higher percentage of actionable molecular alterations and improved survival in the metastatic setting. Recognition of these differences may inform screening, testing, treatment, and survivorship strategies for younger adults with NSCLC. Research Sponsor: None.

Real-world impact of first immunotherapy infusion timing on outcomes in locally advanced non-small cell lung cancer. First Author: Mumtu Lalla, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: Emerging evidence suggests that earlier time-of-day (ToD) infusion of immune checkpoint inhibitors (ICIs) is associated with improved progression-free survival (PFS) and overall survival (OS) in patients with advanced non-small cell lung cancer (NSCLC). Although the timing of the initial infusion may be particularly influential, its impact on outcomes in earlier stages of NSCLC remains unclear. We investigated the association between first ICI infusion ToD and clinical outcomes in a racially and ethnically diverse population with locally advanced NSCLC. **Methods:** We conducted a retrospective cohort study of patients with locally advanced NSCLC treated with definitive chemoradiation followed by consolidation durvalumab between 2018-2025. Patient demographics, smoking status, ECOG performance status, PD-L1 tumor proportion score (TPS), lung cancer stage and histology, disease volume (DV), mean heart dose, and clinical outcomes were all obtained using chart review. Neighborhood distress was classified using patient zip codes and the Distress Communities Index. ICI administration timing was categorized into quartiles: $\leq$11:20 AM, 11:20 AM-12:32 PM, 12:32 PM-13:48 PM, $>$13:48 PM. Kaplan Meier methods and cox proportional hazards models, adjusted for major patient factors, were used to evaluate OS and PFS. **Results:** Among 109 eligible patients (median age 69.5 years), 55% were male, 42% were Non-Hispanic Black, 30% were Hispanic, 64% resided in distressed ZIP codes. Patients receiving ICIs in the latest ToD quartile ($>$13:48) had a significantly shorter PFS compared to those treated in the earliest quartile ($\leq$11:20) in both univariate (HR 2.10, p=0.024) and multivariate analysis (HR 3.32, p=.0.0057). A non-significant trend towards inferior OS was also observed with later ToD administration. Higher DV (HR 1.09 per 10 mL, p=0.029) and mean heart dose (HR 1.86, p=0.03) were independently associated with worse OS. **Conclusions:** In this real-world study of a diverse population with locally advanced NSCLC, later ToD ICI administration ($>$13:48) was associated with a significantly shorter PFS and a trend towards worsened OS. These findings suggest that the timing of ICI delivery may influence outcomes in locally advanced NSCLC, consistent with prior observations in metastatic disease, and highlight the need for prospective trials to validate the impact of infusion timing on survival and clarify the underlying circadian mechanisms contributing to these differences. Research Sponsor: None.

Trends in income-related lung cancer disparities since the introduction of USPSTF screening guidelines. First Author: Tyler Munchmeyer Healy, NYU Grossman School of Medicine, New York, NY

Background: In 2013, the USPSTF introduced guidelines for lung cancer screening to promote earlier detection. Prior screening programs have unintentionally widened disparities due to limited access in vulnerable populations. We examined national US administrative data to explore the effect of lung cancer screening according to area levels of income. **Methods:** We studied adults with lung cancer in the SEER 21 Registries Database diagnosed between 2005-2022 over two time periods (pre-screening: 2005-2013; screening: 2014-2022). We evaluated outcomes of survival and stage distribution over varied levels of county median household income (MHI). We calculated descriptive statistics for our sample and used a Cox PH model to evaluate the interaction of time period and MHI while adjusting for other covariates. **Results:** We identified 485,763 cases in the pre-screening era and 487,001 cases in the screening era, with the median age for each group in the 60-69 years range. Sex, race, rurality, MHI and stage are reflective of US lung cancer demographics. Compared to the pre-screening era, cases in the screening era were more likely to be diagnosed at a localized stage in all MHI groups. The lowest MHI group saw a 24.6% increase in proportion of cases detected at a localized stage, while the highest MHI group saw a 37.5% increase. Median survival increased for all MHI groups with a positive association between MHI and survival gains. In a multivariable Cox PH model, a time period and MHI interaction term indicated that the income-related survival disparity between the highest and lowest MHI groups is 12.2% larger in 2014-2022 than in 2005-2013 (HR = 1.122, $p < 0.001$). **Conclusions:** Since the introduction of USPSTF lung cancer screening guidelines in 2013, lung cancers are detected at earlier stages and survival has improved. These changes have been experienced across all income groups, but the income-related disparities in survival have widened. These results indicate a need for additional efforts to ensure that the benefits of lung cancer screening are distributed across all populations regardless of wealth. Research Sponsor: None.

A large prospective patient-advocacy assessment of fears, concerns, and challenges in patients diagnosed with lung cancer in the United States. First Author: Lisa Spain, Rexanna's Foundation, Prosper, TX

Background: Studies have been conducted assessing patient (pt) experiences with lung cancer, but minimal data is available on how fears and challenges differ by age, region, and disease stage. Through a pt advocacy organization, we performed a prospective analysis to capture pt and caregiver perceptions. **Methods:** 2055 surveys were sent out by non-profit organizations to US pts diagnosed with lung cancer and caregivers. 46% of the surveys (n = 956) were returned. Respondents included 63% (N = 603) pts (included in this abstract), 35.5% caregivers, and 1.5% medical professionals. Demographics included: ethnicity, time from diagnosis, gender, stage, region of country, age, role, and current disease status. Of 36 survey questions, 27 were multiple choice, 9 were open-ended and analyzed for recurring themes. Results were analyzed by region, stage, and age to determine if these influenced perspectives about living with lung cancer, and challenges with medical care or treatment. Chi-square test was used to assess differences in responses to survey questions across participant groups. Additional analysis was conducted using Fisher's exact test. Responses to each survey question were categorized, and the proportions of the topics were compared between participant groups. **Results:** Overall challenges reported by pts varied significantly by disease stage—both at the time of diagnosis ($p < 0.001$) and during treatment ($p < 0.001$). The fear cited most was disease progression or recurrence, in stage I (25.8%) or stage IV (27%) disease. Significant differences were observed across age groups relating to challenges with medical care or treatment ($p < 0.001$), and fears of living with lung cancer. ($p < 0.001$). Pts older than 45 were more concerned with side effects at diagnosis than younger than 45 (55.1% vs 33%, $p < 0.0001$) and were less concerned with financial issues (25.7% vs 44.7%, $p < 0.0001$) at treatment. Care costs and transportation challenges varied regionally, peaking in the Midwest (60.4%) and Southwest (56.5%). **Conclusions:** Fears, concerns and challenges faced by pts with lung cancer vary significantly by age, disease stage at diagnosis, and during treatment. The findings reveal an opportunity to deliver better support to pts throughout their journey and to allocate resources to address specific concerns. Research Sponsor: None.

Regional and gender disparities in lung cancer mortality in Guatemala. First Author: Natalia Pineda Grajeda, Independent Researcher, Miami, FL

Background: Lung cancer is the leading cause of cancer-related deaths worldwide and a major contributor in Latin America, where rates are generally lower. To date, there are no published population analyses describing lung cancer trends in Guatemala. **Methods:** Secondary analysis of publicly available national mortality data (Guatemala's National Institute of Statistics), extracting lung cancer deaths from 2012 to 2022. Deaths were summarized by region, department, year, and sex. Annual crude mortality rates (deaths per 100,000 inhabitants) using corresponding population denominators. **Results:** Between 2012 and 2022 Guatemala recorded 4273 lung cancer deaths (mean age 66,SD:16.17), concentrated in three regions (66.58%,n=2845): Metropolitan, Southwest and Central with the highest department-level counts in Guatemala (37.66%,n=1609), Quetzaltenango (6.53%,n=279), Huehuetenango (5.41%,n=231), San Marcos (5.24%,n=224) and Escuintla (5.29%,n=226). Crude lung cancer mortality ranged from 2.24 to 2.66 deaths per 100,000 inhabitants—highest in 2019 and 2020. Deaths were more frequent among men (54%,n=2,317), but deaths among women increased throughout the study period, resulting in a male-to-female ratio decline from 1.53 in 2012 to 1.07 in 2022. **Conclusions:** Guatemala's lung cancer mortality rates were lower compared to global estimates with nearly two-thirds of deaths concentrated in three regions —especially in Guatemala department— reflecting the concentration of health services in this region. Globally, lung cancer deaths show a marked sex disparity, with men accounting for about 68%. In contrast, Guatemala demonstrated a narrowing sex gap, with male-to-female mortality of nearly 1:1 by 2022, with rising mortality among women. These differences may reflect variations in smoking prevalence, access to early diagnosis, and health system capacity, with post-2020 shifts possibly influenced by COVID-19-related disruptions in diagnosis, treatment, referral pathways, or cause of death-of-death reporting. Research Sponsor: None.

Surgical resection versus stereotactic body radiation therapy in stage IV non–small cell lung cancer: A large, real-world, propensity-matched survival study. First Author: Harshitha Bandaru, Dr NTR Univeristy of Health Sciences, Tirupathi, India

Background: The role of definitive local thoracic therapy in metastatic non–small cell lung cancer (NSCLC) remains controversial. While stereotactic body radiation therapy (SBRT) is increasingly utilized, comparative survival outcomes with surgical resection in real-world populations remain limited. We evaluated survival and pulmonary outcomes associated with surgery versus SBRT in patients with stage IV NSCLC. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network including adults (≥18 years) with stage IV NSCLC treated between January 2013 and December 2023 who underwent definitive local thoracic therapy with either surgical resection or SBRT. Patients with small cell lung cancer, prior lung cancer diagnoses, prior thoracic radiation, or incomplete survival data were excluded. Propensity score matching (1:1) was performed to balance demographics, comorbidities, smoking history, and exposure to systemic therapy including chemotherapy and immunotherapy within 6 months of index treatment. Primary outcomes included landmark 1-year all-cause mortality and overall survival. Secondary outcomes included pneumonia and respiratory failure. Kaplan–Meier analysis and Cox proportional hazards regression were performed. **Results:** After matching, 1,934 patients were included (967 per cohort). At 1 year, surgical resection was associated with significantly lower mortality compared with SBRT (17.5% vs 31.4%; RR 0.56, 95% CI 0.47–0.66; $p < 0.001$), corresponding to an absolute risk reduction of 13.9% and an estimated number needed to treat of approximately 7. Kaplan–Meier analysis demonstrated superior survival in the surgical cohort (log-rank $p < 0.001$). Surgical resection remained associated with significantly improved long-term survival, with a 64% lower hazard of death (HR 0.36, 95% CI 0.30–0.44; $p < 0.001$) and prolonged median survival (3,942 vs 1,182 days). Pulmonary outcomes favored surgery. Pneumonia incidence was significantly lower in the surgical cohort at both 1 year (12.9% vs 29.3%; RR 0.44; $p < 0.001$) and 3 years (5.9% vs 14.2%; RR 0.42; $p < 0.001$). Rates of respiratory failure did not differ significantly between treatment groups. **Conclusions:** In this large real-world propensity-matched study, surgical resection was associated with significantly improved survival compared with SBRT in carefully selected patients with stage IV NSCLC. Surgery was additionally associated with lower long-term pulmonary infectious complications without increased respiratory failure risk. These findings suggest a potential role for aggressive local therapy in selected metastatic patients and support prospective trials to refine patient selection strategies. Research Sponsor: None.

Association of carbon tetrachloride with lung cancer incidence and mortality, including effects in low-smoking regions. First Author: Ashish Samaddar, Donald and Barbara Zucker School of Medicine at Hofstra University, Manhasset, NY

Background: Although cigarette smoking is the main risk factor for lung cancer, 10–20 percent of cases occur in non-smokers, with women disproportionately affected. This pattern suggests that community-level environmental exposures may contribute to lung cancer risk beyond smoking. **Methods:** In this ecologic, county-level study, average age-adjusted lung cancer incidence from 2017–2021 and sex-specific smoking prevalence were obtained from the NCI State Cancer Profiles. County-level exposure data were derived from the EPA National Air Toxics Assessment, with 73 air toxics screened to identify the most strongly associated pollutant. The leading exposure was evaluated in sex-stratified multivariable spatial error regression models adjusting for smoking prevalence and key county-level covariates, including radon, $PM_{2.5}$, Social Vulnerability Index (SVI). Analyses included 2,042–2,238 U.S. counties. Additional models were fit separately within strata of smoking prevalence to compare associations across lower and higher-smoking counties. **Results:** Among 73 EPA-tracked air toxins, carbon tetrachloride (CCl_4) showed the strongest association with lung cancer incidence (population-weighted $r = 0.34$, $p < 0.001$). In fully adjusted spatial models, each standard deviation increase in carbon tetrachloride was associated with a 10.6% increase in lung cancer incidence in women and 10.4% in men, and with a 6.5% and 7.6% increase in lung cancer mortality, respectively. In stratified analyses, associations between CCl_4 and lung cancer incidence were larger in lower-smoking counties (10–12% per SD) than in higher-smoking counties (5–6% per SD), with similar patterns by sex. **Conclusions:** CCl_4, a legacy industrial solvent with ongoing emissions, was the most predictive air toxin associated with population-level lung cancer incidence, showing larger adjusted associations than $PM_{2.5}$ or radon. Although effects were not sex-specific, incidence increases were greatest in lower-smoking communities, suggesting a greater relative contribution of environmental exposures. Research Sponsor: None.

Percent change in lung cancer incidence and mortality per 1 standard deviation increase in covariates.

Variable	Women – Incidence (% per 1-SD)	Men – Incidence (% per 1-SD)	Women – Mortality (% per 1-SD)	Men – Mortality (% per 1-SD)

Are lobectomy and neoadjuvant therapy the missing link in improving early-stage small cell lung cancer survival? First Author: Yahya Alwatari, Division of General Thoracic Surgery, Mayo Clinic Rochester, Rochester, MN

Background: Small cell lung cancer (SCLC) is an aggressive malignancy with poor prognosis. This study evaluates national trends in surgical management of early-stage SCLC using the National Cancer Database (NCDB), aiming to identify factors associated with improved outcomes and assess the survival benefit of surgical resection. **Methods:** Patients diagnosed with clinical stage T1–T3 N0 M0 SCLC between 2004 and 2022 were identified from the NCDB. Exclusions included non-SCLC histologies, advanced or missing staging, non-lobectomy surgeries, and incomplete survival data. Propensity score matching (1:1) was used to balance surgical and non-surgical cohorts based on demographic, clinical, and socioeconomic variables. Kaplan-Meier and Cox regression analyses were used to evaluate overall survival, stratified by T stage. **Results:** Among 17,762 patients with early-stage SCLC, 3,234 (18.2%) underwent lobectomy with mediastinal lymph node dissection. Surgical rates increased from 5% in 2004, 17% in 2013 to 24% in 2021. Surgery was more common in T1 (26.5%) than T2 (11.4%) or T3 (4.6%) disease. After matching, surgery was associated with improved survival across all T stages, with no significant interaction between T stage and surgical benefit (p=0.43). Older age, male sex, and higher comorbidity scores predicted worse outcomes. Among surgical patients, 2.3% received neoadjuvant therapy and 71.6% received adjuvant treatment. Systemic therapy-both neoadjuvant (HR 0.63) and adjuvant (HR 0.69)-was significantly associated with improved survival. **Conclusions:** Lobectomy remains underutilized in early-stage SCLC but is linked to significantly improved survival. Albeit small patient's number, neoadjuvant systemic therapy further enhanced survival, supporting broader use of surgery and multimodal treatment in appropriately selected patients Research Sponsor: None.

Chemoimmunotherapy for large cell neuroendocrine carcinoma (LCNEC) of the lung: A multi-institutional prospective study (NEJ044). First Author: Suguru Matsuda, Department of Pulmonary Medicine, Sendai Kosei Hospital, Sendai, Japan

Background: Large cell neuroendocrine carcinoma (LCNEC) is a rare pulmonary malignancy, comprising 1-3% of all lung cancers. It is a high-grade tumor exhibiting heterogeneous characteristics that overlap with both small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC). While chemoimmunotherapy (chemo-IO) has become the standard of care for SCLC and NSCLC, prospective data regarding its efficacy and safety in LCNEC are limited, and the optimal chemotherapy backbone remains unclear. We conducted the NEJ044 study to prospectively evaluate chemo-IO in patients (pts) with advanced LCNEC. **Methods:** This multi-institutional, prospective, observational study enrolled pts with advanced or recurrent LCNEC. Treatment consisted of atezolizumab and carboplatin combined with either etoposide (IMpower133), paclitaxel and bevacizumab (IMpower150), or nab-paclitaxel (IMpower130). The primary endpoint was the 1-year overall survival (OS) rate. Secondary endpoints included OS, progression-free survival (PFS), objective response rate, disease control rate, and safety. **Results:** Between July 2020 and June 2024, 77 pts were enrolled across 31 institutions within the North East Japan Study Group, of whom 76 received treatment. The median follow-up was 29.0 months (mos) (95% CI: 15.2–35.7). Baseline characteristics included: median age 71 years (range 51–83); male, 68 (89%); ECOG PS 0-1, 69 (91%); and postoperative recurrence, 29 (38%). Histology was confirmed as LCNEC in 61 pts (80%) and combined LCNEC in 15 pts (20%). Treatment distribution included the IMpower133 regimen in 56 pts (74%) and IMpower150/130 regimens in 20 pts (26%). The study met its primary endpoint with a 1-year OS rate of 70.1% (95% CI: 58.2–79.2). In the overall population, median OS (mOS) and PFS (mPFS) were 18.5 mos (95% CI: 14.3–22.6), and 6.2 mos (95% CI: 4.8–7.6). Exploratory analysis showed no significant differences in survival by chemotherapy backbone. The IMpower133 cohort demonstrated a 1-year OS of 70.3% (95% CI: 56.1–80.6), mOS of 18.4 mos (95% CI: 13.2-22.3), and mPFS of 5.2 mos (95% CI: 3.9-7.6), compared to a 1-year OS of 69.6% (95% CI: 44.5–85.1), mOS of 19.9 mos (95% CI: 7.3-not evaluable), and mPFS of 7.2 mos (95% CI: 4.3-19.9) in the IMpower150/130 cohort. Grade ≥3 non-hematological adverse events occurred in 23 pts (30%), and febrile neutropenia was observed in 9 pts (11%). Biomarker analysis identified oncogenic drivers in 5 pts (including 3 KRAS mutations). PD-L1 expression was ≥50% in 12%, 1–49% in 34%, and < 1% in 51%; PD-L1 TPS ≥1% was marginally associated with improved OS. **Conclusions:** The NEJ044 study met its primary endpoint, demonstrating that chemoimmunotherapy provides a favorable 1-year OS of approx. 70% with a manageable safety profile in LCNEC. These prospective results support chemoimmunotherapy as a viable standard treatment strategy for this population. Clinical trial information: UMIN000040876. Research Sponsor: Chugai Pharmaceutical.

Real-world (RW) effectiveness and safety of lurbinectedin (lurbi) for previously treated extensive-stage small cell lung cancer (ES-SCLC): Final primary and subgroup analysis results of Jazz EMERGE 402. First Author: Firas Benyamine Badin, Baptist Health Medical Group, Lexington, KY

Background: Lurbi received accelerated approval in 2020 for ES-SCLC that progressed on or after platinum-based treatment (Tx) based on a phase 2 basket trial and full approval in 2025 combined with atezolizumab as 1st-line maintenance Tx for ES-SCLC based on the phase 3 IMforte trial. **Methods:** The phase 4, prospective, observational Jazz EMERGE 402 trial (NCT04894591) evaluated lurbi for previously treated ES-SCLC in RW practice in North America (final data cut: July 17, 2025). The primary endpoint was overall response rate (ORR). Key secondary endpoints were progression-free survival (PFS), overall survival (OS), and safety. Effectiveness was assessed in all patients (pts) and in prespecified subgroups. **Results:** At the final data cut, 267 pts had received ≥1 cycle of lurbi. At baseline (BL), median (min–max) age was 67 (29–89) years, 52 (19%) pts had an ECOG PS ≥2, 67 (25%) had brain metastases, 84 (31%) had liver metastases, 88 (33%) had a chemotherapy-free interval (CTFI) <90 days, and 196 (73%) had ES-SCLC as the initial diagnosis. Pts received lurbi as 2nd-line (169 [63%]), 3rd-line (78 [29%]), or later (20 [7%]) Tx. Median (Q1–Q3) number of lurbi Tx cycles and Tx duration were 4 (2–7) and 91 (56–170) days. Granulocyte colony-stimulating factor was used in 99 (37%) pts (71 [27%] as primary prophylaxis). Six (2%) pts were receiving Tx at study completion; 261 (98%) discontinued Tx, with disease progression (183 [70%]) the primary reason. While lurbi was effective among all pts and poor-prognosis subgroups, better outcomes tended to occur in pts with CTFI ≥90 days and ECOG PS <2 (Table). Eighty-eight (33%) pts had Tx-related adverse events (TRAE); anemia (21 [8%]) and neutropenia (19 [7%]) were most common. Rates of serious neutropenic infection (5 [2%]), anemia (4 [1%]), and neutropenia (3 [1%]) were low. **Conclusions:** Lurbi was associated with clinically meaningful effectiveness and predictable/manageable safety in previously treated ES-SCLC in a RW population that included poor-prognosis subgroups. Clinical trial information: NCT04894591. Research Sponsor: Jazz Pharmaceuticals.

A retrospective real-world study on the efficacy and safety of anlotinib in combination with immunotherapy as maintenance therapy after standard immunochemotherapy for extensive-stage small cell lung cancer (ALTER-L059). First Author: Yong Fang, Sir Run Run Shaw Hospital, affiliated with Zhejiang University School of Medicine, Hangzhou, Zhejiang, China

Background: Although immune checkpoint inhibitors (ICIs) combined with chemotherapy have become the standard first-line treatment for extensive-stage small cell lung cancer (ES-SCLC), the use of immunotherapy as a maintenance strategy remains challenging. This study aims to evaluate the efficacy and safety of anlotinib combined with ICIs as first-line maintenance treatment for ES-SCLC. **Methods:** ALTER-L059 was a retrospective, multicenter study conducted at 9 hospitals in China. Eligible patients were 18 years or older with histologically or cytologically confirmed ES-SCLC and had completed 4–6 cycles of first-line immunochemotherapy as induction therapy without disease progression. They subsequently received maintenance therapy with immunotherapy combined with anlotinib. The primary endpoint was progression-free survival from the start of maintenance therapy (PFS2). Secondary endpoints included progression-free survival from the start of induction therapy (PFS), overall survival from the start of maintenance therapy (OS2), overall survival from the start of induction therapy (OS) and safety. **Results:** Between January 2022 and December 2024, a total of 100 patients were enrolled. By the data cutoff date on November 11, 2025, the median follow-up duration was 16.92 months (95% CI: 15.81-18.03). The median PFS2 was 6.05 months (95% CI: 4.83-7.59), and the median PFS was 9.53 months (95% CI: 8.31-11.93). The median OS2 was 17.74 months (95% CI: 15.24-19.71), and the median OS was 21.26 months (95% CI: 18.60-22.60). The incidence of grade 3 or higher treatment-related adverse events (TRAEs) was 30.0%. The most common TRAEs (incidence ≥20%) were hypertension (33.0%), hand-foot syndrome (23.0%), proteinuria (21.0%), and hypertriglyceridemia (20.0%). **Conclusions:** Patients who had been diagnosed with ES-SCLC and had completed 4–6 cycles of immunochemotherapy as induction therapy without disease progression subsequently received maintenance therapy with immunotherapy combined with anlotinib, demonstrating favorable survival outcomes and manageable toxicity. Clinical trial information: NCT06982287. Research Sponsor: None.

A validation study of a novel biomarker-based scoring system (EAST score) for limited-stage small-cell lung cancer: A secondary analysis of JCOG0202 and JCOG1011. First Author: Yu Ito, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Concurrent chemoradiotherapy (CCRT) followed by prophylactic cranial irradiation (PCI) is potentially curative for limited-stage small-cell lung cancer (LS-SCLC), yet reliable markers for identifying long-term survivors remain undefined. The Enhanced Assessment for SCLC Treatment (EAST) score was originally derived from a retrospective, single-center training cohort for prognostic stratification of LS-SCLC patients receiving CCRT. This score integrates N3 status, serum lactate dehydrogenase (LDH), pro-gastrin-releasing peptide (ProGRP), and cytokeratin 19 fragment (CYFRA 21-1) levels measured at diagnosis. This study (JCOG2401A) validated its prognostic utility using data from two randomized controlled trials (RCTs) of LS-SCLC. **Methods:** The validation cohort comprised patients enrolled in JCOG0202 and JCOG1011: randomized phase 3 and 2 studies, respectively, that compared multiple consolidation chemotherapy regimens following CCRT. External validation of the dichotomized EAST score (low: score 0–1, high: 2–5) was performed by assessing discrimination and calibration for progression-free survival (PFS) and overall survival (OS). Exploratory subgroup analyses were conducted in an integrated cohort of the training cohort (N = 224; median follow-up, 64.5 months) and the validation cohort. Hazard ratios (HRs) for PCI were estimated using propensity score-weighted Cox models. **Results:** Out of 309 patients in these trials, 205 with complete data for EAST score components were included in the validation cohort. Median age was 62 years. Low- vs. high-risk groups showed stage (I-II/III) distributions of 28/72% vs. 11/89%, and tumor response (CR-PR/SD) distributions of 89/3% vs. 91/2%, respectively. The low-risk group (N = 114) showed better outcomes than the high-risk group (N = 91) for both PFS and OS (Table). Integrated cohort analysis revealed a numerical survival benefit from PCI in low-risk patients (N = 214), whereas the benefit was highly limited in the high-risk group (N = 202) (Table). **Conclusions:** The prognostic value of the EAST score was validated even in external RCT datasets. High-risk patients, characterized by early recurrence and inferior OS, derive minimal benefit from PCI. These findings provide a rationale for a planned risk-adapted RCT utilizing the EAST score. Research Sponsor: None.

Prophylactic tocilizumab to mitigate cytokine release syndrome in patients receiving tarlatamab: A single-center exploratory experience informed by bispecific antibody safety data. First Author: Feras Al Moussally, University of Pittsburgh Medical Center (UPMC), Harrisburg, PA

Background: Tarlatamab, a bispecific T-cell engager (BiTE) targeting CD3 on T cells and DLL3 on small cell lung cancer (SCLC) cells, represents a major advance in treating relapsed or refractory SCLC. By activating T cells to release cytotoxic cytokines, it induces tumor cell death but carries risks such as cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS). In the phase 2 DeLLphi-301 trial, CRS occurred in up to 53% of patients treated with Tarlatamab. Current inpatient step-up dosing protocols aim to mitigate toxicity but add cost and complexity, particularly for immunocompromised patients. Tocilizumab, an interleukin-6 (IL-6) receptor inhibitor used for CRS, has demonstrated prophylactic benefit in mitigating cytokine-related adverse events with other BiTEs such as teclistamab. We hypothesized that prophylactic tocilizumab could similarly reduce Tarlatamab-related CRS in SCLC without compromising efficacy. **Methods:** We retrospectively analyzed 32 consecutive SCLC patients treated with Tarlatamab at our center. Tocilizumab (8 mg/kg) was administered 1 hour prior to the first Tarlatamab dose when approved by insurance. CRS incidence, grade, rescue interventions, treatment discontinuations, and cost implications were evaluated. CRS grading followed standard consensus guidelines. **Results:** Among 32 treated patients, 29 (90.6%) received prophylactic tocilizumab, and 3 did not. CRS developed in 3 of 29 patients (10.3%) who received pre-treatment—two grade 1 and one grade 2. In contrast, all 3 patients (100%) who did not receive pre-treatment developed CRS—two grade 1 and one grade 2. Overall, CRS occurred in 6 patients (18.8%). All cases resolved after tocilizumab rescue therapy, and no treatment discontinuations occurred. **Conclusions:** Prophylactic tocilizumab substantially reduced CRS incidence among SCLC patients receiving Tarlatamab, suggesting a feasible and safe mitigation strategy. Compared with historical data from DeLLphi-301 (53% CRS incidence), this cohort exhibited markedly lower toxicity rates with prophylactic IL-6 blockade. To our knowledge, this represents the first clinical evidence supporting IL-6 blockade before Tarlatamab administration. Despite the upfront drug cost ($2,800–$5,100 per dose), prevention of CRS-related hospitalizations offers significant economic benefit (estimated $11,000–$200,000 per event based on grade). Limitations include small sample size, lack of randomization, and single-center design. Nonetheless, these findings underscore the potential of integrating tocilizumab prophylaxis into standard Tarlatamab protocols and warrant larger prospective studies to confirm safety, efficacy, and cost-effectiveness. Research Sponsor: None.

Real-world second-line treatment patterns and outcomes by platinum sensitivity in extensive-stage small cell lung cancer in the post-immunotherapy era. First Author: Catherine Rinaldi, Flatiron Health, New York, NY

Background: Platinum-based chemotherapy (PBC) with checkpoint inhibitor (CPI) is standard first-line (1L) treatment for extensive-stage small cell lung cancer (ES-SCLC), though relapse is common. Second-line (2L) treatment selection is determined by platinum sensitivity status, with guidelines based on pre-CPI data, and the benefit of any CPI continuation is unknown. This study examined treatment patterns and real-world (rw) outcomes for patients following 1L PBC +/- CPI among platinum-sensitive (PS) patients, including the impact of continuing a CPI with platinum rechallenge. **Methods:** This retrospective study used EHR-derived US Flatiron Health Research Database. Eligible patients were diagnosed with ES-SCLC between January 1, 2018, and September 9, 2025, received 2L treatment following 1L PBC with a calculable platinum sensitivity and had a minimum potential follow up of 120 days. Platinum sensitivity was defined by a chemotherapy-free interval of $\geq$ 180 days, based on the last order or administration of 1L PBC to first real-world progression event prior to 2L initiation. Real-world response rate (rwRR), progression free survival (rwPFS) and overall survival (rwOS) were described based on 2L regimen class for patients with PS disease, and were compared via HR for platinum rechallenge with CPI continuation versus without. Time-to-event outcomes were analyzed using Kaplan-Meier methods, with medians and 95% CI reported for the overall cohort and subgroups of interest. **Results:** Among 5,126 eligible patients, 884 (17%) had PS and 4,242 (83%) had platinum refractory (PR) disease. Most patients (73%) received CPI with PBC in 1L. Patients with PR had worse outcomes than PS (rwPFS, 2.7 [95% CI, 2.6-2.8] vs 5.5 [95% CI, 5.3-5.7] mo; rwOS, 4.7 [95% CI, 4.5-4.9] vs 11.2 [95% CI, 10.6-12.4] mo). Among PS patients with 1L CPI exposure (n=666), 48% received 2L PBC, and 41% of 2L PBC continued a CPI. Clinical characteristics in PS disease were similar across classes of 2L regimen. Of patients with PS disease who had 1L CPI exposure, 81% had at least 1 response assessment during the study period. Of PBC patients, rwRR was 52% among CPI treated and 58% without CPI. 2L rwPFS and rwOS were similar regardless of CPI continuation (Table). **Conclusions:** In this large real-world study, nearly half of patients with PS disease were rechallenged with PBC in 2L, and CPI continuation was common despite limited evidence. CPI continuation did not improve response, progression, or survival, suggesting no additional benefit and highlighting the need for prospective data to guide post-CPI treatment in PS ES-SCLC. Research Sponsor: Flatiron Health, Inc.

Antigen presentation suppression as a hallmark of immune evasion and poor outcomes in small cell lung cancer. First Author: Triparna Sen, The Ohio State University, Columbus, OH

Background: Antigen-presenting machinery (APM) is critical for tumor immune recognition. The loss of APM promotes immune evasion and immunotherapy resistance in cancers, including small-cell lung cancer (SCLC). SCLC has a high tumor mutational burden (TMB), and it displays profound APM suppression, explaining its weak response to immune checkpoint inhibitors. We aimed to capture APM gene expression in a large real-world cohort (RWC) and prospective clinical trial datasets to address the clinical implications of APM suppression for current treatment strategies. **Methods:** We calculated a classical antigen-presenting MHCs (CAMs) score using a gene signature comprised of 18 genes closely associated with MHC-I expression and antigen presentation. We evaluated this score in 6,000 real-world lung cancer samples and in the transcriptomic dataset of a Phase III clinical trial evaluating the effect of chemo-immunotherapy as a first-line treatment in extensive-stage SCLC (IMpower133). Transcriptomic, genomic, and proteomic data were collected for analysis. **Results:** Patients with SCLC were stratified into 3 groups according to hierarchical clustering of CAM gene expression for functional enrichment, differential gene expression, response to drug, and survival analyses. CAM expression was markedly suppressed in SCLC compared to other lung cancer histologies. In SCLC, CAM-low accounted for 53% of patients, followed by CAM-intermediate (40%) and -high (7%). We found no statistical difference in TMB-high (^{3}10 mutations/Mb) proportion across CAM groups. CAM-intermediate- and high groups had lower *TP53, RB1,* and *PTEN* mutation rates and a higher *PI3K* mutation rate compared to CAM-low. CAM-low tumors displayed the highest DNA damage response and neuroendocrine signature scores and the lowest *RB1* expression. CAM-low tumors showed the lowest expression of cytokine and cytokine receptors involved in lymphocyte trafficking, as well as the lowest $CD8^+$/Treg and M1/M2 ratios, consistent with a highly immunosuppressive context. CAM-low and intermediate groups had the lower PD-L1 expression and worse overall survival from the start of chemoimmunotherapy in the RWC. Most targetable markers, such as *DLL3,* were downregulated in CAM-low tumors. We also identified high expression of novel immune targets in the CAM-low population that may inform future drug design. **Conclusions:** We demonstrate that in RWC and clinical trial samples, most patients with SCLC are CAM-low, exhibit immune evasion features, and have poor outcomes, as well as reduced expression of most druggable targets. Our data suggests that SCLC's immunosuppressive microenvironment may lessen the efficacy of new-generation compounds. We highlight potential novel treatment strategies targeting defective APM tumors that may activate the immune microenvironment and augment the effect of existing immunotherapy agents. Multiomic spatial analysis of tumor microenvironment during neuroendocrine (NE) transformation in *EGFR*-mutant LUAD. First Author: Elisa Gobbini, The Ohio State University, Columbus, OH

Background: Histological transformation of *EGFR* mutant lung cancer adenocarcinoma (LUAD) to small-cell lung cancer (SCLC) is a well-known resistance mechanism and has been found in about 14% resistant cases. This phenomenon is associated with extremely poor prognosis and limited therapeutic options. This underscores the need to identify the biological mechanisms triggering lineage plasticity in *EGFR+* LUADs. We and others have shown that several genomic and epigenetic alterations play a central role in the activation of small cell like neuroendocrine (NE) states. However, the impact of these changes on the immune microenvironment and vice versa is not understood, limiting the identification of novel immunotherapy approaches in this setting. **Methods:** We describe the evolution of the tumor microenvironment (TME) during SCLC transformation by comparing tissues from de novo LUAD (*n* = 10), de novo SCLC (*n* = 15), and transformed SCLC (n =12) including 11 cases with *EGFR*-mutant LUAD/SCLC mixed histology and 1 pre-transformed LUAD. Additionally, we used de novo lung squamous cancer (LUSC, *n* = 11), and transformed LUSC (n = 11) including 8 mixed LUSC/LUAD histology and 3 post-transformed samples to inform the LUSC transformation program as a comparator. All samples were analyzed by RNA sequencing, DNA methylation, and whole-exome sequencing. Spatial proteomics (ORION, *n* = 4) and transcriptomics (XENIUM, *n* = 6) were performed on pre- and post-transformed paired samples from *EGFR+* patients. **Results:** Differential gene expression and pathway analysis highlight the upregulation of G2M, E2F, and *MYC* targets during both SCLC and LUSC transformation, occurring at an earlier stage for SCLC compared to LUSC. Conversely, a more pronounced and broader and earlier downregulation of immune pathways was detected during SCLC, compared to LUSC, transformation. Analysis of the epigenetic regulators potentially driving these signaling changes pointed to *EZH2* as master regulators of SCLC transformation, while the LUSC program was mainly driven by the *TP63* and *FOXA1* transcription factors. Spatial proteomics and transcriptomics highlighted a decrease in immune-related programs with an increased proportion of immune suppressive subsets and NE features in SCLC-transformed samples compared to baseline specimens. Subclustering analysis showed a higher percentage of pro-tumoral macrophages and exhausted T-cells in transformed samples. **Conclusions:** Our results suggest that a broader transcriptional reprogramming is associated with the transition from LUAD to SCLC than from LUAD to LUSC. The TF profile associated with SCLC histological transformation negatively regulates immune pathways leading to profound remodeling of the immune compartment and a cold TME that supports the aggressive phenotype of transformed tumors. IMforte: Quality-adjusted time without symptoms or toxicity (Q-TWiST) analysis of first-line maintenance (1Lm) treatment (Tx) with lurbinectedin (lurbi) + atezolizumab (atezo) vs atezo in extensive-stage small cell lung cancer (ES-SCLC). First Author: Hossein Borghaei, Department of Hematology and Oncology, Fox Chase Cancer Center, Philadelphia, PA

Background: IMforte (NCT05091567) is the first positive phase 3 study of 1Lm in ES-SCLC to demonstrate statistically significant and clinically meaningful progression-free survival (PFS) and overall survival (OS) benefits (stratified hazard ratios, 0.54 and 0.73) with lurbi + atezo vs atezo. The combination was generally well tolerated based on safety findings and patient-reported outcomes. These data led to the approval of lurbi + atezo as 1Lm Tx for adults with ES-SCLC in the US and Switzerland in 2025. Here, we describe a post hoc Q-TWiST analysis using IMforte data to further elucidate the benefit-risk profile of lurbi + atezo. **Methods:** Eligible pts with ES-SCLC who were progression free after induction with atezo, carboplatin, and etoposide were randomized 1:1 to receive lurbi + atezo or atezo alone every 3 weeks. Survival time was partitioned into 3 health states: toxicity (TOX; time with grade ≥3 adverse events before disease progression), TWiST (time without TOX before disease progression), and relapse (REL; time from disease progression to death). The mean time spent in each health state was estimated using restricted mean survival times, calculated as area under the Kaplan-Meier curve. Q-TWiST was the sum of the mean time in each health state adjusted by respective utility weights, derived from EQ-5D-5L data. **Results:** Analyses were performed on all randomized pts from IMforte (lurbi + atezo, n = 242; atezo, n = 241) as of July 29, 2024, with a median follow-up of 15 months (mo). Utility weights in lurbi + atezo and atezo arms were 0.84 and 0.83 in TWiST, 0.83 and 0.83 in TOX, and 0.78 and 0.76 in REL health states. Pts in the lurbi + atezo arm spent most of their survival time in the TWiST state (66% vs 50% for atezo), and their mean duration of TWiST was substantially longer vs the atezo arm (9.8 vs 6.4 mo; Table). Lurbi + atezo arm pts spent more time in the TOX state vs atezo (0.7 vs 0.3 mo) but less time in the REL state (4.4 vs 6.1 mo). The lurbi + atezo arm had longer mean Q-TWiST vs atezo (12.2 vs 10.2 mo), representing a clinically important 14.9% gain in utility at the maximum follow-up of 26 mo. **Conclusions:** Lurbi + atezo pts had more time without toxicity before disease progression vs atezo and showed a clinically important improvement in quality-adjusted survival, further supporting a favorable benefit-risk profile of lurbi + atezo as 1Lm Tx for ES-SCLC. Clinical trial information: NCT05091567. Research Sponsor: F. Hoffmann-La Roche Ltd and Jazz Pharmaceuticals.

Mean duration of each health state, Q-TWiST, PFS, and OS.

Mo, Mean (95% CI)	Lurbi + Atezo n = 242	Atezo n = 241	Difference	Relative Gain
Q-TWiST	12.2 (11.1, 13.2)	10.2 (9.2, 11.3)	1.9 (0.5, 3.4)	14.9%
TWiST	9.8 (8.4, 11.2)	6.4 (5.2, 7.7)	3.4 (1.5, 5.2)	
TOX	0.7 (0.5, 0.9)	0.3 (0.1, 0.5)	0.4 (0.1, 0.6)

Impact of DLL3 expression and tumor subtype on response to tarlatamab. First Author: Jessica Ross, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Tarlatamab is a DLL3-targeted bispecific T-cell engager used to treat small cell lung cancer (SCLC). SCLC subtypes can be defined by relative expression of master transcription factors (TFs). Whether subtype and DLL3 expression are associated with outcomes on tarlatamab is unknown. **Methods:** We analyzed all patients (pts) with SCLC, including SCLC transformed from lung adenocarcinoma, treated with tarlatamab at Memorial Sloan Kettering prior to October 2025. DLL3 expression and subtyping were determined by IHC by dedicated thoracic pathologists. Expression of subtype TFs ASCL1, NEUROD1, POU2F3, and YAP1 was assessed. "Neuroendocrine (NE)-high" was defined as any ASCL1 or NEUROD1 expression. Pts with any "neuroendocrine (NE)-low" subtype expression—POU2F3 or YAP1—were grouped for analysis. DLL3 fractional expression was dichotomized as "high" (≥50%) or "low" (0-49%). Progression-free and overall survival (PFS, OS) were analyzed with Kaplan-Meier curves and compared with the Cox proportional hazards model. **Results:** We identified 39 pts with SCLC treated with tarlatamab with DLL3 and/or subtyping data available. Median age was 65, 49% were women, and median prior lines of therapy was 1. DLL3 expression was available in 34 pts. Median fractional DLL3 expression was 80% and ranged from 0 to 100%. 7 pts had low expression and 27 had high expression. There were more pts with transformed SCLC in the DLL3-low group (3/7 [43%] vs 1/27 [4%], p=0.02). Among pts with response data available, response was inferior in the DLL3-low group: complete or partial response (CR or PR) in 0/7 (0%; [95% CI, 0 to 35]) vs 12/25 (48%; [95% CI, 30 to 67]); stable disease (SD) in 2/7 (29%) vs 5/25 (20%); progressive disease (PD) in 5/7 (71%) vs 8/25 (32%); p=0.049. Median PFS was 1.4 mos in DLL3-low vs 4.5 mos in DLL3-high disease (p<0.001); median OS was 4.7 mos vs not reached (p=0.001). Incidence of CRS and ICANS did not differ (5/7 [71%] in DLL3-low vs 11/29 [38%] in DLL3-high with CRS, p=0.2; 0/9 vs 3/29 [10%] with ICANS, p>0.9). 30/39 pts had subtyping data available. 28/30 pts had NE-high tumors (15/28 ASCL1+/NEUROD1+; 11/28 ASCL1+/NEUROD1-; 2/28 ASCL1-/NEUROD1+). 5/30 had subtype biomarkers of NE-low status: 4 YAP1+ and 1 POU2F3+; the 4 YAP1+ tumors also expressed ASCL1. Response rates were similar between pts with and without NE-low expression: 1/5 (20%; [95% CI, 1 to 62]) vs 11/25 (44%; [95% CI, 27 to 63]), p=0.6. PFS was also similar (mPFS 1.1 vs 2.7 mos, p=0.3). **Conclusions:** Low DLL3 expression was potentially associated with inferior response to tarlatamab. A contributing factor may be enrichment of transformed SCLC, which is associated with poor outcomes. We did not detect an impact of POU2F3/YAP1 expression. The majority of pts in this cohort had DLL3-high, NE-high SCLC—in line with prior studies—and they had a response rate of 48%. These data emphasize the need for more discerning predictive biomarkers for tarlatamab in an evolving landscape of treatment options. Research Sponsor: None.

Analysis of corticosteroid exposure on efficacy of tarlatamab in small cell lung cancer: A multicenter retrospective study. First Author: Ty Michael Moore, The University of Kansas Cancer Center, Westwood, KS

Background: Tarlatamab, a delta-like ligand 3 (DLL3)-targeted bispecific T-cell engager, has shown meaningful activity in small cell lung cancer (SCLC). Immune-mediated toxicities such as cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) are common with T-cell–redirecting therapies and frequently require corticosteroids or cytokine-directed agents like tocilizumab. The impact of lymphodepleting corticosteroid exposure on tarlatamab efficacy remains unclear. **Methods:** We performed a retrospective analysis of patients with SCLC treated with tarlatamab from 2018–2025 across the University of Kansas and nine cancer centers included in the DLL3 PanTUMOR database. The primary endpoint was progression-free survival (PFS) stratified by cumulative dexamethasone dose. Other endpoints included overall response rate (ORR), characterization of CRS and ICANS, and overall survival (OS). A cost analysis of dexamethasone versus tocilizumab was also conducted. **Results:** Among 143 tarlatamab-treated patients, dexamethasone use for CRS or ICANS did not reduce PFS or ORR compared with patients not receiving corticosteroids. Tocilizumab did not reduce steroid needs. Median dexamethasone dose was higher in patients treated with tocilizumab. Severe CRS/ICANS was associated with significantly shorter OS. Cost analysis demonstrates the significant cost savings using dexamethasone compared to tocilizumab for treatment of immune-mediated toxicities. **Conclusions:** Corticosteroid exposure did not compromise tarlatamab efficacy, supporting optimized toxicity management without diminishing antitumor activity of DLL3-targeted T-cell–redirecting therapies. Research Sponsor: None.

Endpoints	Total Number of Evaluable Patients	Outcomes
Median PFS of tarlatamab with cumulative steroid dose **Arm 1: No dex** **Arm 2: 1-40 mg of dex** **Arm 3: 41+ mg of dex**	Arm 1: 66 Arm 2: 42 Arm 3: 16	Arm 1: 2.53 mo Arm 2: 4.70 mo Arm 3: 3.68 mo HR=1.02 95% CI: 0.73-1.42 p=0.31
ORR of tarlatamab with cumulative steroid dose **Arm 1: No dex** **Arm 2: 1-40 mg of dex** **Arm 3: 41+ mg of dex**	Arm 1: 55 Arm 2: 34 Arm 3: 11	Arm 1: 29.1% Arm 2: 47.1% Arm 3: 36.4%
Comparison of ORR with CRS (any grade) versus without CRS	CRS: 58 No CRS: 60	CRS: 34.5% No CRS: 33.3%
Comparison of ORR with ICANS (any grade) versus without ICANS	ICANS: 33 No ICANS: 85	ICANS: 36.4% No ICANS: 32.9%
Did the use of tocilizumab result in lower cumulative steroid use	No tocilizumab: 42 Tocilizumab: 28	Median dex dose without tocilizumab: 10 mg Median dex dose with tocilizumab: 35 mg
Median OS with grade 3+ CRS or ICANS versus with grade 0-2 CRS/ICANS	Grade 0-2: 133 Grade 3+: 10	Grade 0-2: 11.37 mo Grade 3+: 4.19 mo HR=0.34 95% CI: 0.15-0.76 p=0.006
Cost analysis for dex versus tocilizumab **Average wholesale price: tocilizumab $165,724, $3.13 dex10 mg**	CRS: 72 37 doses of tocilizumab	37 doses of tocilizumab substituted with 37 dex 10 mg doses would have saved $173,962

DAREON-8: Updated efficacy and safety from a phase I dose-escalation/expansion trial of first-line (1L) obrixtamig plus chemotherapy and atezolizumab in extensive-stage small cell lung carcinoma (ES-SCLC). First Author: Solange Peters, Oncology Department, Centre Hospitalier Universitaire Vaudois, Lausanne University, Lausanne, Switzerland

Background: Obrixtamig (BI 764532) is a DLL3/CD3 IgG-like T-cell engager that has shown promising efficacy in ES-SCLC, as monotherapy and in combination with other agents. Due to the aggressiveness of ES-SCLC, early initiation of optimal 1L induction therapy is critical, as many patients (pts) may not reach treatment maintenance. We report updated efficacy and safety data from the ongoing Phase I DAREON-8 (NCT06077500) dose-escalation/expansion trial investigating 1L obrixtamig + induction SoC (carboplatin + etoposide + atezolizumab) and maintenance obrixtamig + atezolizumab in pts with ES-SCLC. **Methods:** Obrixtamig was given IV as step-up dosing followed by target dose (Part A: 3 dose levels [10, 30, 60 mg] guided by a BLRM with overdose control; Part B: selected target dose) + SoC (given per label). After 4 cycles of obrixtamig + SoC, obrixtamig + atezolizumab was continued until disease progression or another reason requiring discontinuation. Primary endpoint: DLTs; secondary endpoints included PFS, DoR, and ORR (RECIST v1.1; investigator assessed). **Results:** As of Dec 17, 2025, 46 pts were treated (Part A/B: n=28/18); 44 pts received ≥1 dose of obrixtamig. Median cycles of obrixtamig: 10 (range: 1–21); median age: 69 yrs (range: 34–76); ECOG PS 0/1: 27%/73%; brain metastasis: 16%. MTD was not reached in Part A; the study continued in Part B with the highest dose level (60 mg). Key efficacy data are in the table. Confirmed ORR: 73% (95% CI: 58–84); DCR: 91% (95% CI: 79–96). mDoR: NC; mPFS: NC; 6- and 9-month PFS rates (95% CI): 76% (62–90), and 61% (44–79), respectively. In the 60 mg cohort, confirmed ORR: 76% (95% CI: 58–88); mDoR and mPFS: NC. Most common G≥3 AEs were cytopenias and were almost wholly related to chemotherapy. Most common obrixtamig-related AE: cytokine release syndrome (52%). SoC discontinuations due to TRAEs: n=2 (G2 asthenia, G2 decreased platelets, G3 anemia). Obrixtamig discontinuations due to TRAEs: n=1 (G2 asthenia). **Conclusions:** Obrixtamig + SoC demonstrated encouraging efficacy, supporting obrixtamig as a combination partner for 1L SoC. The combination showed a safety profile consistent with individual agents, supporting the favorable tolerability of obrixtamig in combination regimens. Updated safety data are consistent with previous findings (Peters S et al, *Ann Oncol* 2025;36: S1466–7), and results warrant further development in Phase III trials. Clinical trial information: NCT06077500. Research Sponsor: Boehringer Ingelheim.

Clinical outcomes of local treatments for oligoprogressive or oligorecurrent small cell lung cancer. First Author: Adrien Mathieu, Université de Lille, CHU Lille, Thoracic Oncology Department, Lille, France

Background: The role of local treatments in patients with oligoprogressive or oligorecurrent small cell lung cancer (SCLC) remains unclear. Our study aimed to describe the prognosis of patients with SCLC receiving a local treatment for oligoprogression or oligorecurrence in a real-life setting. **Methods:** The present study included all consecutive patients treated for SCLC at Lille University Hospital or Strasbourg University Hospital between January 2013 and March 2024, for whom local treatment was decided in a Multidisciplinary Tumor Board to control oligoprogression or oligorecurrence. Clinical data and characteristics of the local treatment were collected from medical records. **Results:** Of the 850 patients treated for a SCLC in both centers during the study period, 97 patients were eligible for inclusion. Of those, 84 received local treatment for oligoprogression (n = 47) or oligorecurrence (n = 37). At the time of oligoprogression or oligorecurrence, 82.1% of patients were being treated for extensive-stage disease. The brain was the predominant site of oligoprogression or oligorecurrence (71%) and the most commonly used local treatment was conformal radiotherapy (66.7%), followed by stereotactic radiotherapy (31%) and surgery (2.4%). Grade ≥3 adverse events were observed in only 2.4% of treated patients. After a median follow-up period of 11.9 months, the median overall survival (OS) and median progression-free survival (PFS), measured from the date of initiation of local treatment, were 12.4 months (95% CI: 10.7-18.9), and 3.4 months (95 %CI: 2.4-4.5), respectively. A good performance status (PS 0–1) was associated with better OS (HR 0.50; (95% CI: 0.26–0.97); p = 0.018). PFS was significantly longer in patients with limited-stage SCLC (HR 0.52; (95% CI: 0.31–0.89); p = 0.016) or with five or fewer metastases at the time of local treatment (HR 0.59; (95% CI: 0.37–0.94); p = 0.038). Most progressions observed after local treatment occurred distant from the treated sites (68.8%). **Conclusions:** This study demonstrates that the use of local treatments to control oligoprogression or oligorecurrence in SCLC is not uncommon in routine clinical practice. While this strategy is generally well tolerated, its efficacy remains limited. Further studies are needed to clarify its role in the era of tarlatamab development. Research Sponsor: None.

Paclitaxel, carboplatin, and durvalumab in extensive stage small-cell lung cancer (ES-SCLC; IFCT-2203 TAXIO phase II trial): Can we improve the chemotherapy (CT) immunotherapy combination in SCLC? First Author: Denis Lucien Moro Sibilot, Thoracic Oncology Unit, CHU-Grenoble-Alpes, Grenoble, France

Background: Etoposide+platinum-based CT and anti-PD-L1 is the backbone of ES-SCLC treatment. We hypothesize a deleterious action of etoposide on lymphocyte activation. A "proof-of-concept", multicenter and single arm phase II trial was designed to assess the efficacy and safety of an etoposide-free chemotherapy combining durvalumab (Durva) to paclitaxel and carboplatin (Pac-Carbo) CT in ES-SCLC. **Methods:** Patients (pts) with ES-SCLC, PS 0-1 were enrolled and received 4 induction cycles of Durva 1500 mg + paclitaxel 200 mg/m² + carboplatin AUC6 (PCD), every 3 weeks followed by single-agent Durva every 4 weeks until progression or unacceptable toxicity. The primary endpoint was overall survival at 12 months (OS@12m), secondary endpoints were overall response rate (ORR), overall survival (OS), OS at 24 and 36 months, progression-free survival (PFS), duration of response, safety (CTC v5.0) and quality of life (EORTC QLQ-C30 LC13). PFS and ORR were also assessed by independent reviewer committee. To reject the null hypothesis and achieve a 12-month survival rate of at least 34 patients (55.7%), 61 patients were required. Safety was assessed in all patients who received at least one dose of their study treatment. **Results:** 68 pts were enrolled between Nov 2023 and Feb 2025. Pts characteristics at baseline were: median age 66.6 years; 51.5% female, 67.6% PS1, 19.1% brain metastasis and 51.5% liver metastasis. The median number of cycles was 4 for chemotherapy and 6 for Durva injections. With a median follow-up of 17.1 months, the primary objective was reached. The OS@12m of the first 61 enrolled pts was 57.4% [IC95%: 44.1-70.0]. Median OS was 14.5 months [IC95%: 9.9-17.6]. ORR was 82.4% [IC95%: 73.3-91.4]. Median PFS was 4.6 months [IC95%: 4.4-4.7]. Treatment-related adverse events (TRAE) of grade 3-5 occurred in 48.5% of pts. TRAE leading to death occurred in 2 pts (sepsis). **Conclusions:** In the IFCT-2203 TAXIO phase 2 trial, the PCD regimen showed a signal of improved OS@12m and reached its statistical objective. Safety findings were consistent with the known safety profiles of all drugs received with no new safety signal for this population. PCD regimen is an active, easy to administer one-day regimen in ES-SCLC and should be integrated in future trials of new IO agents. Pac-Carbo is an alternative to etoposide platinum with potentially better synergy with durvalumab. Clinical trial information: 2023-504670-38-00. Research Sponsor: None.

Sex-specific trends and outcomes in small cell lung cancer (SCLC) in Spain: Insights from the CLARISSE study (2019–2024). First Author: Pilar Garrido, Ramón y Cajal University Hospital, Madrid, Spain

Background: SCLC is an aggressive malignancy with poor prognosis. Although overall incidence is declining, cases among women are increasing. European projections show decreasing mortality in men but stable rates in women—except in Spain, where a +2.4% rise is expected—highlighting the need to examine sex-specific trends. **Methods:** CLARISSE is a multicenter, retrospective, observational real-world study conducted in Spain. Data were collected from 29 oncology departments across the country and included adult patients (≥18 years) with histologically confirmed SCLC diagnosed between January 2019 and December 2024. Baseline characteristics, treatment patterns, and survival outcomes were analyzed by sex. **Results:** Among 3,488 SCLC patients, 1,177 (33.8%) were women. The annual distribution of included SCLC cases remained stable over time (15.1%–17.7%), while the proportion of women increased from 29.3% to 39.2% over 6 years. Women were diagnosed at a younger age (mean 64.5 *vs.* 67.8 years). Active smoking was more frequent in women (68.0% *vs.* 54.7%, p<0.001), whereas men showed longer smoking and greater cumulative exposure, with median durations of 45 *vs.*43 years (p=0.02) and median pack-years of 50 *vs.*44 (p<0.001), respectively At diagnosis, 27% had limited-stage (LS) disease, more often in women (29.6% *vs.* 25.7%, p=0.015). Most LS patients received platinum–etoposide plus thoracic radiotherapy. In this population, 1-year overall survival (OS) was 67.9% (95%CI, 64.8-71.0%), with a median OS of 22 months (95%CI, 19.3-24.6 months); women had longer survival than men (Table 1). Systemic first-line (1L) treatment for extensive-stage (ES) consisted predominantly of platinum-based chemotherapy (95.6%; carboplatin 83.0% and cisplatin 12.6%) combined with etoposide (92.1%). Since its approval in September 2021, immunotherapy has been given to 66.3% of patients, more often to women (70.6% *vs.* 63.9%, p=0.013). In the population receiving 1L therapy, 1-year OS was 34.0% (95%CI, 32.1–35.9%), and median OS was 8.5 months (95%CI, 8.1–8.8). Women had longer survival (Table 1). Patients who received 1L immunotherapy had longer OS than those who did not: 10.1 months (95%CI, 9.4–10.7 months) *vs.* 7.2 months (95%CI, 6.6–7.7 months). **Conclusions:** This large multicenter SCLC cohort shows marked sex-related differences in epidemiology, stage distribution, treatment patterns and survival in Spain. Women were increasingly represented over time, diagnosed younger, and experienced longer survival in both LS and ES disease. These results support the importance of integrating sex-specific perspectives in SCLC management and research. Research Sponsor: PharmaMar.

Comparison of real-world overall survival between atezolizumab- and durvalumab-containing first-line induction and maintenance regimens in extensive-stage small cell lung cancer. First Author: Apar Kishor Ganti, Division of Oncology-Hematology, VA Nebraska Western Iowa Health Care System/University of Nebraska Medical Center, Omaha, NE

Background: Both atezolizumab (atezo) and durvalumab (durva) are preferred first-line (1L) systemic treatment options for extensive-stage small cell lung cancer (ES-SCLC) with similar efficacy in the IMpower133 and CASPIAN phase 3 trials. There is limited evidence comparing their survival outcomes in the real-world (rw) setting. This study described rw overall survival (rwOS) in patients (pts) with ES-SCLC treated in 1L and 1L maintenance (1Lm) settings and also compared rwOS stratified by cohort and treatment with 1L atezo vs durva in combination with platinum-based chemotherapy (chemo) followed by atezo vs durva as 1Lm immunotherapy (IO). **Methods:** Using the US Flatiron Health Research Database, this retrospective noninferiority study included adults with ES-SCLC across 2 cohorts. The 1L cohort included pts treated with atezo or durva + chemo between Apr 1, 2020, and Sept 30, 2025. The 1Lm cohort included a subset of pts from the 1L cohort who were subsequently treated with atezo or durva monotherapy. The index date was the initiation of atezo or durva in the 1L or 1Lm setting in each cohort. rwOS hazard ratios (HRs) and 95% CIs comparing durva with atezo as reference in the 1L and 1Lm settings were calculated using Cox proportional hazard models, adjusting for prognostic covariates. Based on prior literature, the noninferiority margin was set at HR = 1.25. **Results:** A total of 2063 and 1122 pts were included in the overall 1L and 1Lm cohorts, respectively. In both cohorts, median age was 68 years, ≥20% of pts had an ECOG PS ≥2, and ≥19% had brain metastases at baseline. The 1L cohort had 1614 (78%) pts on atezo + chemo and 449 (22%) on durva + chemo. The 1Lm cohort had 865 (77%) pts on atezo and 257 (23%) on durva. Pt characteristics were generally similar between those treated with atezo vs durva in 1L or 1Lm settings. In the 1L cohort, median OS (95% CI) from the index date was 8.7 (8.2, 9.3) months for atezo and 8.5 (7.9, 9.5) months for durva. In the 1Lm cohort, median OS (95% CI) from index date (start of maintenance) was 9.3 (8.2, 10.2) and 9.2 (7.5, 10.8) months for atezo and durva. In the 1L cohort, the adjusted HR for OS for durva vs atezo was 0.98 (95% CI: 0.86, 1.10; P = 0.7), indicating no statistically significant difference between the 2 treatments. In the 1Lm cohort, the adjusted HR for OS for durva vs atezo was 1.04 (95% CI: 0.88, 1.22; P = 0.7). In both cohorts, the upper 95% CI was < 1.25, supporting the noninferiority of durva vs atezo. **Conclusions:** In this rw population, atezo and durva offered comparable rwOS, which was shorter than those reported in phase 3 clinical trials, for pts with ES-SCLC when used with chemo in 1L or as monotherapy in 1Lm. Research Sponsor: Jazz Pharmaceuticals.

MC1923: Phase II durvalumab plus lurbinectedin in platinum-resistant relapsed extensive-stage small cell lung cancer after prior chemoimmunotherapy (cohort B). First Author: Konstantinos Leventakos, Mayo Clinic Rochester, Rochester, MN

Background: Patients with extensive-stage small cell lung cancer (ES-SCLC) who progress after platinum-based chemotherapy plus immunotherapy have limited options. Whether adding lurbinectedin while continuing immune checkpoint blockade at relapse improves outcomes is unknown. We report results for the platinum-resistant cohort (progression ≤3 months from last chemotherapy) of MC1923. **Methods:** MC1923 is a phase II trial using a Simon optimal two-stage design. Patients were assigned to a starting dose of durvalumab 1500 mg IV plus lurbinectedin 3.2 mg/m^2 IV on Day 1 of 21-day cycle. The primary endpoint was the 6-month progression-free survival rate (PFS6). Accrual continued to 22 eligible patients if ≥2/9 achieved PFS6; the regimen would be considered promising if ≥7/22 (32%) were alive and progression-free at 6 months. Secondary endpoints included adverse events (AEs), objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Results:** Twenty-two patients enrolled (02/04/2022–05/21/2025); all were eligible and treated. Median age was 66 years; 32% were male; ECOG performance status was 0 in 9% and 1 in 91%; 96% had prior atezolizumab. Median cycles delivered were 4 (range 1–13). PFS6 was 4/22 (18.2%; 95% CI, 7.5–44.1%), below the prespecified threshold. Median PFS was 3.1 months (95% CI, 1.6–5.3). ORR was 13.6% (3/22; all partial responses; 95% CI, 2.9–34.9%). At data cutoff (12/18/2025), 4 patients were alive; median follow-up was 16.8 months (range 5.5–39.6). Median OS was 7.4 months (95% CI, 4.3–18.6) and 1-year OS was 33.1% (95% CI, 17.6–61.9%). One (1) patient discontinued treatment with durvalumab due to AE. No treatment-related Grade 5 AEs occurred; Grade 3–4 AEs at least possibly related to treatment occurred in 32% (7/22); Grade 4 AEs occurred in 5% (1/22), all hematologic. Most common Grade 3 AEs were decreased neutrophils and white blood cells (each 9%). **Conclusions:** Durvalumab plus lurbinectedin demonstrated manageable toxicity in platinum-resistant ES-SCLC after chemoimmunotherapy but did not meet the prespecified PFS6 efficacy threshold, supporting the need for alternative strategies in this high-risk population. Clinical trial information: NCT04607954. Research Sponsor: AstraZeneca.

BL0020, a novel tumor microenvironment (TME)-targeting nano-mediated polypeptide-drug conjugate (NMPDC), in patients with advanced solid tumors: Updated results from the small cell lung cancer (SCLC) subset of a phase 1 study. First Author: Shuhang Wang, Department of Clinical Trial Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: BL0020 is a novel polypeptide-drug nanoconjugate (~10 nm in size) composed of PEG-modified poly(amino acid), enzyme-responsive peptide linkers, and topoisomerase I inhibitor (Topo1i) payloads. It accumulates in the tumor microenvironment (TME), where payloads are continuously released by specific enzymes, penetrate tumor cells, and effectively induce cell death. BL0020 has shown promising efficacy in advanced SCLC. Here, we present updated results from the SCLC subset of an international Phase 1 study of BL0020 (NCT05886868). **Methods:** Patients with locally advanced/unresectable or metastatic SCLC received BL0020 injection (20 mg/m² or 25 mg/m² IV every three weeks) until disease progression, unacceptable toxicity, or withdrawal of consent. **Results:** As of November 30, 2025, 49 patients were enrolled. Treatment-related adverse events (TRAEs) were consistent with expected payload-related effects, primarily manageable hematological and gastrointestinal toxicities, with no new safety signals identified. Grade 3/4 TRAEs occurring in ≥10% of patients included neutropenia, decreased white blood cell count, and anemia. All SCLC patients had progressed after at least one prior platinum-based chemotherapy regimen, and 61% had received prior anti-PD-(L)1 therapy. The median number of prior lines of therapy was 2 (range: 1–6). Among 13 efficacy-evaluable SCLC patients, the disease control rate (DCR) was 100% and the objective response rate (ORR) was 84.6%, with a confirmed ORR of 76.9%. In addition, eight patients achieved >50% tumor shrinkage. Among SCLC patients with baseline brain metastases, both ORR and DCR were 100%, with brain lesions showing >50% shrinkage or complete disappearance. At a median follow-up of 12.58 months, median progression-free survival (mPFS) was 10.15 months (95% CI: 4.93, not reached), median duration of response (mDOR) was 8.18 months (95% CI: 3.54, not reached), and median overall survival (mOS) was 15.31 months (95% CI: 7.46, not reached). **Conclusions:** BL0020 monotherapy demonstrated a manageable safety profile and promising antitumor activity in patients with advanced SCLC who progressed after at least one prior platinum-based chemotherapy. The therapy showed a high response rate and potential for prolonged PFS compared with standard chemotherapy. Clinical trial information: NCT05886868. Research Sponsor: None.

Updated results of the phase 1 dose escalation and expansion study of alveltamig (ZG006), a trispecific T cell engager targeting DLL3/DLL3/CD3, as monotherapy in patients with refractory small cell lung cancer or neuroendocrine carcinoma. First Author: Qiming Wang, Henan Cancer Hospital Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China

Background: Alveltamig (ZG006) is a uniquely designed T cell engager, targeting two distinct delta-like ligand 3 (DLL3) epitopes and CD3 and, thereby bridging tumor cells and T cells together and mediating T cell-specific killing of DLL3-expressing tumor cells such as small cell lung cancer (SCLC) or neuroendocrine carcinoma (NEC). **Methods:** This is a multi-center, open-label, phase 1 clinical study of ZG006 as monotherapy in patients with SCLC or NEC who failed or were intolerant to the standard therapies. A standard "3+3" design, with an accelerated titration approach for the first two lower dose levels was used during the dose escalation stage. Here we report the updated results of the efficacy and safety data from the phase I study. **Results:** In this phase I study, patients received ZG006 at 0.1 mg Q2W and escalated at 8 dose levels up to 100 mg Q2W (Wang Q et al, ASCO 2025). A step dose of 1 mg was implemented for higher dose groups starting from 10 mg Q2W. Dose expansion was conducted at dose levels of 10, 30, and 60 mg. A total of 31 patients with SCLC, including 4, 15, and 12 patients from the 10 mg, 30 mg, and 60 mg dose groups respectively, were included in the current efficacy analysis. The overall median follow-up time was approximately 16 months. The median age was 59 years (range, 45.0-72.0), the median number of prior treatment lines was 3 (range,1-4), 80.6% of the patients had received prior immunotherapy, and 90.3% had a baseline ECOG performance status score of 1. The confirmed objective response rate (ORR) assessed by an independent review committee (IRC) was 74.2%. The median duration of response (DoR) was 12.6 months, with 12-month DoR rate at 65.3 %. The estimated 12-month PFS rate was 50.5%. The median overall survival (OS) was not reached yet, however,the 12-month and 18-month OS rates approached 74.2% and 58.6% respectively. Consistent with prior report, the most common adverse events with longer follow-up included CRS, anemia and other conditions, with most being Grade 1 or 2 and occurring during the first two cycles. Overall, ZG006 was well-tolerated and the treatment related adverse events including CRS were manageable. **Conclusions:** With longer follow up from phase I study, ZG006 continued to demonstrate robust antitumor activity in the dose expansion cohorts including high ORR, longer DoR/PFS, and clinically meaningful survival benefits in patients with refractory SCLC. No new safety signal was encountered. These data support ongoing development of ZG006 as monotherapy and in combination with other modalities in SCLC. Clinical trial information: NCT05978284. Research Sponsor: None.

Predictive markers of response and toxicity to tarlatamab in patients with extensive stage small cell lung cancer (ES-SCLC): A multi-institutional real-world analysis. First Author: Graeme Fenton, University of Maryland Medical Center, Baltimore, MD

Background: Tarlatamab (tarla) is a novel immunotherapeutic agent for the treatment of relapsed ES-SCLC associated with favorable response and survival outcomes. While tarla's unique side effect profile of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) is well described, factors influencing response or toxicity have yet to be fully established. **Methods:** We performed a retrospective, multivariate analysis of patients with ES-SCLC receiving tarla at three NCI-designated comprehensive cancer centers from 7/2024-10/2025. CRS and ICANS were reported using ASTCT consensus guidelines. Dysgeusia was graded using CTCAE v5.0. Overall response rate (ORR) was determined using clinical interpretation of radiographic assessments from patients with available post-treatment imaging. Time to event analyses were performed. Cox Proportional Hazards regression analyses assessed the association between patient characteristics and PFS and OS outcomes. Logistic and ordinal regression analyses evaluated the predictive value of variables contributing to the presence and severity, respectively, of CRS and ICANS. **Results:** 115 patients received at least 1 dose of tarla, with median age of 67 years, 55% female and ECOG PS ranging from 0-3 (median of 1). Rates of observed CRS, ICANS, and dysgeusia were 46%, 28%, and 47%, respectively. ORR was 44% and 6-month PFS/OS rates were 30.4% (95% CI: 22.5-41.1%)/54.9% (95% CI: 45.4-66.4%). Excluding patients on tarla $<$30 days, presence of dysgeusia was associated with a lower rate of progression (HR 0.44, p = 0.00691) and death (HR 0.34, p = 0.0145). Neither CRS nor ICANS were associated with treatment response. Both sum of liver metastasis diameter $>$10 cm (OR 4.4, p = 0.02) and elevated baseline LDH (p = 0.01) were significantly associated with increased likelihood of CRS, while female sex was a protective factor (OR 0.33, p = 0.01). Increased ECOG PS (OR 2.3, p = 0.02), sum of brain metastasis diameter $>$2 cm (OR 3.6, p = 0.02), development of CRS (OR 2.8, p = 0.04), elevated baseline LDH (p = 0.04) and elevated baseline ferritin (p =0.004) were all associated with increased risk of developing ICANS. **Conclusions:** In our multicenter cohort of patients with ES-SCLC, tarlatamab continued to demonstrate anticancer activity with similar ORR and 6 month PFS compared to existing DeLLphi-304 data. Importantly, the presence of dysgeusia was found to be a marker of treatment response associated with improved PFS and OS. CRS and ICANS incidence was associated with several baseline patient and disease characteristics. Collectively, these preliminary results identify several predictive biomarkers of toxicity that can be utilized in clinical practice, though validated models are needed to better stratify low and high-risk populations. Research Sponsor: None.

Monalizumab plus durvalumab plus platinum-based chemotherapy for first-line treatment of extensive stage small-cell lung cancer: Early efficacy results from MOZART trial. First Author: Hirva Mamdani, Department of Hematology and Oncology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI

Background: Extensive stage small cell lung cancer (ES-SCLC) is an area of unmet need where novel treatment strategies are urgently needed. Preclinical data in SCLC demonstrate higher expression of NKG2A, an immune checkpoint expressed on natural killer (NK) cells and CD8+ T cells, with consequent reduced NK cell mediated anti-tumor activity, substantially enhanced metastatic dissemination of tumor cells, and amelioration of metastasis with hyperactivation of NK cells. We hypothesized that NKG2A inhibitor monalizumab (M) may enhance the efficacy of first-line therapy in ES-SCLC by promoting both NK and CD8+ T cell functions. **Methods:** We conducted a single arm, multicenter, investigator-initiated phase II study with a safety lead-in cohort, evaluating M in combination with platinum (P), etoposide (E), and durvalumab (D) in patients (pts) with previously untreated ES-SCLC. One prior cycle of EP $\pm$ D was allowed. Pts received EP + D + M every 3 weeks for 4 cycles followed by D + M every 4 weeks until disease progression or unacceptable toxicity. Primary endpoints were 1-year (yr) progression-free survival (PFS) and safety. Secondary endpoints were objective response rate (ORR), 1-year overall survival (OS) and intracranial PFS (iPFS). We hypothesize that the combination will lead to improvement in 1-yr PFS to 33% compared to historical control of 18% (1-sided alpha:10%, power: 80%). **Results:** 30 pts were enrolled (median age:62.5yrs (range, 53-79)). 10pts (33.3%) were female and 6 (20%) were Black. 14pts (46.7%) received one cycle of EP $\pm$ D prior to study entry. ORR was 73.3% (complete response = 3, partial response = 19). At median follow-up of 14.2months (mo) (range, 6.4-not estimable (NE)): estimated 1-yr PFS: 20.6%, 18-mo PFS: 15.5%, median (m) PFS: 4.8mo (4.5-5.3), 1-yr OS: 67.4%, mOS: NE (10.2-NE). Most common site of progression was brain with miPFS of 5.3mo (4.8-10.8); 1-yr iPFS: 21.7%, 18-mo iPFS: 16.3%. 4pts had PFS longer than 1yr, 3 of whom had brain metastasis at baseline. No dose limiting toxicities were identified in the safety lead-in cohort. Treatment related AEs (TRAEs) at least possibly related to D and/or M occurring in $\geq$10% of pts were fatigue (23%), decreased lymphocyte count (13%), hypothyroidism (10%), decreased neutrophil count (10%), and increased lipase (10%). 5 pts (17%) had grade (G) 3/4 TRAEs: decreased neutrophil count (n = 3), encephalitis (n = 1), acute kidney injury (n = 1). Toxicities solely attributed to M were all G 1: increased lipase (n = 2), headache (n = 1), and increased amylase (n = 1). **Conclusions:** Addition of M to first-line EP + D led to no new severe AEs in patients with ES-SCLC. Estimated 1-yr PFS was not statistically superior to historical control with EP +D, yet a subset of patients including those with baseline brain metastasis derived durable benefit. Long term follow-up and biomarker analysis are ongoing. Clinical trial information: NCT05903092. Research Sponsor: AstraZeneca.

8099 **Poster Session**

Multicenter phase II trial of atezolizumab plus carboplatin and etoposide for extensive-stage small cell lung cancer older patients who underwent geriatric assessment (OLCSG2002 EPAS Trial). First Author: Yuka Kato, Department of Thoracic oncology and Medicine, National Hospital Organization Shikoku Cancer Center, Matsuyama-City, Ehime, Japan

Background: Combination therapy with anti-PD-L1 monoclonal antibodies and chemotherapy (ICI-chemotherapy) is the current standard treatment for patients(pts) with extensive-stage small cell lung cancer (ES-SCLC). However, its safety and efficacy in older pts ($\geq$ 71 years) remain limited. Given the pivotal role of geriatric assessment (GA) in the older care, prospective data remain scarce. This study aimed to clarify the efficacy and safety of ICI-chemotherapy in older pts and to evaluate the association between GA and survival. **Methods:** This multicenter prospective study enrolled pts $\geq$ 71 years with ES-SCLC who received atezolizumab plus carboplatin and etoposide as first-line therapy. The primary endpoint was 1-year survival rate (SR). Based on existing results, the expected value was 60%, the threshold was 40% (α-error = 0.1 [two-sided], power = 0.75). The calculated sample size was 32 pts. A pre-treatment G8 assessment was mandatory for all pts. Secondary endpoints included safety, objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Results:** Between August 2022 and March 2024, a total of 32 pts were enrolled: median age 77 years (range 71–83); male/female = 27/5; PS 0/1 = 8/24, G8 scores $\geq$12 / $<$ 12 /not collected were 19/12/1. The 1-year SR was 62.5% (95% confidence interval [CI]: 43.5–76.7). Median OS was 14.6 months (95% CI: 8.2–23.3), median PFS was 5.0 months (95% CI; 4.2–5.9), and ORR was 84.4% (95% CI; 66.3–93.7). Median OS by G8 (score $\geq$12 vs $<$ 12) was 15.4 vs 12.3 months. Cox regression analysis including clinically important factors for survival (age, PS, G8, bone and brain metastasis at diagnosis) identified brain (HR; 3.1, 95% CI: 1.06 to 8.87; p = 0.039) and bone metastases (HR 3.5, 95% CI: 1.20 to 10.1; p = 0.022) as an independent factor. grade $\geq$ 3 adverse events (AEs) occurred in 87.5% of pts, and dose reduction was required in 45.1%. The most frequent AE was neutropenia (93.8%); one treatment-related death (stroke) was reported. **Conclusions:** ICI-combined chemotherapy demonstrated efficacy comparable to that in existing studies, but greater caution was required regarding safety in older pts. While G8 status did not affect survival in SCLC pts, the presence of bone or brain metastasis at diagnosis was identified as an independent prognostic factor. Clinical trial information: jRCT1061200024. Research Sponsor: None.

Comparative real-world outcomes of tarlatamab and lurbinectedin in relapsed extensive-stage small cell lung cancer. First Author: Daniyal Aziz Khan, Charleston Area Medical Center, Charleston, WV

Background: Extensive stage small cell lung cancer is an aggressive malignancy with rapid progression and poor survival after relapse following platinum-based chemotherapy. Tarlatamab, a DLL3 directed bispecific T cell engager, demonstrated a significant overall survival benefit compared with physician's choice of chemotherapy, including lurbinectedin, in the phase 3 DeLLphi 304 trial. However, access to tarlatamab remains limited in routine clinical practice, and lurbinectedin continues to be commonly used in the post platinum setting. As a result, real world data comparing the effectiveness and toxicity of these agents are needed to better inform treatment decisions for patients with relapsed small cell lung cancer. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, a federated, de-identified electronic health record database. Adults with lung cancer who received platinum-based chemotherapy or immunotherapy as first-line treatment and subsequently initiated tarlatamab or lurbinectedin as second-line therapy between January 1, 2020 and November 1, 2025 were included. Propensity score matching was then performed and overall survival was evaluated using Kaplan–Meier methods. Secondary outcomes included immune- and treatment-related adverse events, including cytokine release syndrome (CRS), immune effector cell–associated neurotoxicity syndrome (ICANS/ICE), and corticosteroid use. **Results:** After 1:1 propensity score matching, both groups had 133 patients each with good balance across demographics, comorbidities, metastatic burden, prior therapies, and baseline laboratory. At 1 year, mortality was 33.1% with tarlatamab versus 72.2% with lurbinectedin (absolute risk reduction 39.1%, 95% CI 28.1–50.1; $p<$ 0.0001), with improved 1-year survival probability (59.2% vs 17.1%) and superior overall survival (HR 0.46, 95% CI 0.32–0.66; log-rank $p<$ 0.0001). The survival benefit persisted at 2 years, with median survival of 417 days versus 149 days and survival probabilities of 47.4% versus 15.9%, respectively (HR 0.48, 95% CI 0.34–0.68; p= 0.0015). Tarlatamab was associated with higher corticosteroid use (56.4% vs 33.8%, p= 0.0002) and immune-mediated toxicities, including cytokine release syndrome in 45.1% (grade 1: 23.3%, grade 2: 13.5%) and ICANS/ICE in 17.3%, with no grade 4–5 events. **Conclusions:** In this propensity score–matched analysis, tarlatamab demonstrated a significant and durable overall survival advantage over lurbinectedin, with an approximately 50% relative reduction in the risk of death at both 1 and 2 years based on hazard ratios. While tarlatamab was associated with higher rates of expected immune-mediated toxicities, including CRS and ICANS, events were predominantly low-grade, supporting a favorable benefit–risk profile in this heavily pretreated metastatic population. Research Sponsor: None.

8102 Poster Session

Impact of lung cancer screening in patients diagnosed with small cell lung cancer. First Author: Paresh Kumar, Indiana University School of Medicine, Indianapolis, IN

Background: The advent of immunotherapy significantly improved overall survival (OS) for limited-stage SCLC (LS-SCLC), highlighting how early detection may drive maximal therapeutic benefit. Lung cancer screening (LCS) with low-dose CT scans (LDCT) in high-risk individuals reduced the risk of lung cancer mortality and identified more Stage I lung cancer (National Lung Screening Trial (NLST), NELSON). Within the NLST, SCLC distribution by stage (I-IV) was similar between LDCT or chest x-ray, thereby limiting the perceived absolute impact of LCS for SCLC detection. Here, we report on the utility of LCS in SCLC in the era of immunotherapy. **Methods:** We retrospectively reviewed the charts of patients diagnosed with SCLC in the Indiana University (IU) Health System from 2018 to 2024. Patients were stratified by whether SCLC was identified from LDCT or non-screen detected. Kaplan-Meier, Wilcoxon rank sum, Pearson's Chi-squared, and Fisher's exact test were applied. **Results:** Among the 301 LCS-eligible individuals with SCLC, 67 patients (22.3%) received LDCT preceding their diagnosis. With LDCT, a significant shift in stage was observed (P <0.001). In the non-LDCT cohort, 28% were diagnosed with LS-SCLC and 72% with ES-SCLC. In the LDCT cohort, 60% were diagnosed with LS-SCLC and 40% with ES-SCLC. After robust adjustment for confounders in a multivariable logistic regression model, LCS was independently associated with higher odds of LS-SCLC at diagnosis (odds ratio 4.22; 95% CI, 2.20-8.28, P <0.001). Significant delays post-LDCT were noted including time from scan to biopsy (52 vs 10 days, P <0.001) and biopsy to treatment (20 vs 13 days, P <0.001). LCS did not improve response rates, treatment completion rates, or progression-free survival, regardless of stage. At diagnosis, patients with ES-SCLC in the LDCT cohort tended to have less CNS involvement (11% vs 30%, P = 0.06) but had more bone metastases (74% vs 45%, P = 0.006), compared to non-LDCT. Survival between LDCT and non-LDCT was similar for LS-SCLC (22.9 vs 40.4 months, P = 0.15) and ES-SCLC (12.2 vs 10.8 months, P = 0.89). To account for stage migration and unequal follow-up between groups (41.4 vs 25.3 months), a pre-specified, stage-agnostic 1-year OS was compared. The LDCT group had a higher 1-year OS compared to the non-LDCT group (69.2% vs 54.6%, P = 0.03). **Conclusions:** Use of LCS in eligible patients resulted in a significant "stage-shift" to LS-SCLC for individuals diagnosed with SCLC. At a pre-specified cut-off, LCS significantly improved OS for patients diagnosed with SCLC. Research Sponsor: Indiana University Simon Comprehensive Cancer Center; Tom and Julie Wood Center for Lung Cancer Research.

Comparison by immunotherapy agent of real-world outcomes with chemo-immunotherapy in first-line extensive-stage small cell lung cancer. First Author: Anthony Alfonso, Indiana University School of Medicine, Indianapolis, IN

Background: Chemoimmunotherapy became the standard of care for extensive-stage small cell lung cancer (ES-SCLC) after two Phase III trials (IMpower133, CASPIAN) demonstrated significant improvement in overall survival (OS) over platinum-based chemotherapy. While both anti-PD-L1 agents provide durable responses in a subset (~10%), the magnitude of benefit with immunotherapy (IO) is similar, suggestive of therapeutic interchangeability. Real-world data (RWD) suggests durvalumab confers superior outcomes in ES-SCLC, compared to atezolizumab. Recently, durvalumab received regulatory approval for limited-stage SCLC, whereas atezolizumab failed to demonstrate benefit after chemoradiation. Here, we investigate whether IO choice impacts outcomes for first-line ES-SCLC. **Methods:** We retrospectively reviewed the charts of patients diagnosed with ES-SCLC in the Indiana University (IU) Health System from 2018 to 2024. Patients were stratified by receipt of either atezolizumab or durvalumab for first-line chemoIO for comparison of demographics and outcomes. Kaplan-Meier, univariate Cox regression, and Fishers exact test was applied. **Results:** We identified 158 patients diagnosed with ES-SCLC who received chemoIO (Table 1). Platinum-sensitivity and objective response rates were similar between groups (P = 0.14 and P >0.9, respectively). The median number of IO cycles received (induction and maintenance) was significant higher with atezolizumab (9), compared to durvalumab (7, P <0.001). Similarly, median progression-free survival (PFS) trended in favor of atezolizumab over durvalumab (6.3 vs 5.2 months, P = 0.08). Subsequent therapy post-progression was comparable between groups, including lurbinectedin (31% vs 23%, P = 0.5) and tarlatamab (17% vs 23%, P = 0.4). The unadjusted median OS for atezolizumab was 16.5 months (95% CI, 13.2-19.5), compared to durvalumab 12.4 months (95% CI, 9.9-17.3) (P = 0.11). To account for group imbalances, overlap-weighted multivariable Cox regression was performed, in which ECOG performance status (PS) of 0-1 (HR 0.53, 95% CI, 0.30-0.92, P = 0.03) and receipt of atezolizumab (HR 0.56, 95% CI, 0.34-0.93, P = 0.02) were independently associated with improved OS. **Conclusions:** In our study, atezolizumab demonstrated improved OS and trended to improve PFS in first-line ES-SCLC, compared to durvalumab. Potential confounders when evaluating the impact of IO agents across RWD studies include ECOG PS, variable use of thoracic radiotherapy, geographical differences, and ethnic distributions. Research Sponsor: Indiana University Simon Comprehensive Cancer Center; Tom and Julie Wood Center for Lung Cancer Research.

Demographics and outcomes of individuals with young-onset small cell lung cancer. First Author: Paresh Kumar, Indiana University School of Medicine, Indianapolis, IN

Background: A diagnosis of lung cancer before the age of 50 is commonly driven by oncogenic alterations and observed in patients without a history of tobacco use. Little is known about the characteristics and outcomes of individuals with young-onset small cell lung cancer (YO-SCLC). **Methods:** We retrospectively reviewed the charts of patients diagnosed with SCLC treated in the Indiana University (IU) Health System from 2018 to 2024. Patients were stratified by age <50 or >50 years at diagnosis of SCLC for statistical comparison of key variables and outcomes. Fisher's exact and Wilcoxon rank sum tests were applied to categorical and continuous variables, respectively. **Results:** Among 416 individuals with SCLC, we identified 23 patients with YO-SCLC. The incidence of YO-SCLC was 5.5 cases per 100 cases of SCLC (95% CI, 3.7-8.2) with a median age of 47 (40-49). None of the YO-SCLC were detected by lung cancer screening (LCS), compared to 17% in the >50 cohort (Table 1). Patients with YO-SCLC are more likely to have active tobacco use but significantly less pack years, compared to >50. Majority of YO-SCLC (74%) were diagnosed with extensive-stage SCLC, analogous to >50. Extensive-stage YO-SCLC patients had similar platinum-sensitivity and PFS with platinum-based therapy with or without immunotherapy but trended to have improved median OS (24.7 vs 11.1 months, HR 1.67, 95% CI 0.88-3.15, P = 0.12). Limited-stage YO-SCLC patients were more likely to receive prophylactic cranial irradiation (PCI, 67% vs 25%, P = 0.04) but demonstrated no significant difference in PFS or OS with guideline-directed therapy, compared to >50. **Conclusions:** YO-SCLC represents a unique under-recognized population with trends toward improved OS, despite comparable platinum-sensitivity and PFS with chemoimmunotherapy for ES-SCLC. Such patients are currently excluded from LCS due to age. These results suggest eligibility criteria for LCS could be expanded to include individuals <50 with active tobacco use (>20 PY) and a family history of lung cancer to increase detection of YO-SCLC. The molecular underpinnings of YO-SCLC remain to be elucidated. Investigation into the genomic and neuroendocrine subtype composition of YO-SCLC is underway. Research Sponsor: Indiana University Simon Comprehensive Cancer Center; Tom and Julie Wood Center for Lung Cancer Research.

A multi-institutional, single-arm, phase 2 study of durvalumab plus amrubicin in patients with relapsed extensive-stage small cell lung cancer (Aphrodite trial). First Author: Yuka Kato, Department of Thoracic oncology and Medicine, National Hospital Organization Shikoku Cancer Center, Matsuyama-City, Ehime, Japan

Background: In patients (pts) with sensitive relapsed (SR) and refractory relapsed (RR) small cell lung cancer (SCLC), amrubicin (AMR) is one of the current standard treatments in Japan. However, the overall survival (OS) in RR is particularly poor, with approximately 6-9 months and a 1-year overall survival rate (1yr-OS rate) of 34%, which is not satisfactory. We conducted the phase 2 exploratory proof-of-concept trial based on preclinical results, which showed that the combination of an anti-PD-1 antibody and a topoisomerase II inhibitor had a synergistic effect on cancer cells. This trial was funded by AstraZeneca K.K. **Methods:** This trial enrolled pts with SR or RR SCLC that recurred after first-line chemo-immunotherapy. They were treated with durvalumab (1,500 mg on day1) and AMR (40 mg/m^2 on days1-3), every three weeks until progression. After assessing the safety of the combination therapy in the lead-in cohort, we initiated the phase 2 part of the trial. The primary endpoint was the 1yr-OS rate calculated based on a year consisting of 48 weeks. The secondary endpoints consisted of OS, progression-free survival (PFS), overall response rate (ORR) etc. The expected 1yr-OS rate for SR and RR were 61.1% and 44.4%, respectively, which were 10% higher than the systematic review result for AMR alone in Japanese pts. Based on this review result and considering feasibility, the sample size was planned as 18 pts for each SR and RR. **Results:** Between July 2022 and August 2024, a total of 23 (SR: 5; RR: 18) pts were enrolled. All pts had previously received treatment with platinum-containing drugs and immune checkpoint inhibitors (ICI). The SR group could not be enrolled till sufficient sample size for statistical analysis. The 1yr-OS rate was 80.0% for SR group, which included a complete responder. The efficacy results for the RR group were: The 1yr-OS rate was 44.4% (95% confidence interval (CI): 21.6-65.1). The median PFS and OS were 15.1 weeks (95% CI: 11.0-23.3) and 43.1 weeks (95% CI: 24.6-64.3), respectively. The ORR was 38.9% (95% CI: 17.3-64.3). Grade 3 or higher adverse events were observed in 65.2% of all 23 pts, but no new events beyond those previously reported were identified. The most frequent Grade 3 or higher adverse event was neutropenia (43.5%), with febrile neutropenia occurring in 13.0%. Grade 3 or higher pneumonia was observed in 4.3%, and no treatment-related deaths were reported. **Conclusions:** The combination therapy of durvalumab and AMR suggests favorable efficacy and tolerable safety, particularly in pts with RR, even in those who had already received ICI treatment. Clinical trial information: jRCT2061220036. Research Sponsor: AstraZeneca.

Safety, pharmacokinetic, and preliminary efficacy of SNC115 in patients with relapsed/refractory small cell lung cancer (SCLC) and large cell neuroendocrine carcinoma (LCNEC): A phase 1 study. First Author: Tianqing Chu, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: SCLC and LCNEC are characterized by aggressive clinical courses and limited therapeutic options following progression on platinum-based chemotherapy. DLL3(Delta-like ligand 3) is highly expressed and selectively on the surface of these high-grade neuroendocrine tumors, making it an ideal therapeutic target. SNC115 is a novel CAR-T cell armored with CD70 to target DLL3-expressing cells. **Methods:** This phase 1, open-label study utilized an accelerated titration design followed by a standard 3+3 escalation to evaluate the safety, tolerability, and pharmacokinetics of SNC115 in patients (pts) with R/R SCLC or LCNEC who progressed after ≥1 line of standard therapy. Following leukapheresis and a 3-day lymphodepletion regimen (fludarabine/cyclophosphamide), pts received a single infusion of SNC115 at one of five planned dose levels (DL): 1.0×10^5 (DL1), 3.0×10^5 (DL2), 1.0×10^6 (DL3), 3.0×10^6 (DL4), and 6.0×10^6 (DL5) CAR^+ T cells/kg. The primary endpoints were the determination of the maximum tolerated dose (MTD) and the recommended dose (RD). **Results:** As of 23 January 2026, 8 pts with R/R SCLC were treated across four DLs: DL1 (n = 1), DL2 (n = 3), DL3 (n = 2) and DL4 (n = 2). Median age was 53.5 (range 40-69) years, with a median of three prior therapy lines (range 2-6). 6 pts received bridging therapy. SNC115 demonstrated a manageable safety profile. CRS occurred in 3 pts (DL1: 1pt, DL4: 2pts), all Grade 1 or 2 and resolved with tocilizumab/corticosteroids. Grade ≥3 hematologic TEAEs included lymphocyte count decreased (8/8), white blood cell count decreased (2/8) and anaemia (1/8), all attributed to LD. Only one patient (DL4) experienced Grade ≥3 non-hematologic TEAEs related to SNC115, including alanine aminotransferase increased (G3), Gamma-glutamyltransferase increased (G3) and diarrhea (G3), which resolved with symptomatic care. No DLTs, SAEs or ICANS were reported. Among evaluable pts (n = 8), the ORR and DCR were 37.5% and 75%, respectively. All patients (n = 2) in the higher-dose level (DL4) achieved PR. CAR-T cells expansion peaked at a median of 7 days post-infusion, with Cmax ranging from 68.77 to 4359.89 copies/μg DNA. **Conclusions:** SNC115 demonstrated a manageable safety profile and encouraging preliminary antitumor activity in heavily pretreated pts with SCLC. The absence of DLTs and ICANS, combined with low-grade transient CRS, supports continued dose escalation. These early efficacy signals suggest that SNC115 may provide a novel therapeutic avenue for R/R SCLC. Clinical trial information: NCT06384482. Research Sponsor: Shanghai Simnova Biotechnology Co.,Ltd.

Prognostic factors and impact of concomitant medication in extensive-stage small cell lung cancer (ES-SCLC) treated with first-line chemotherapy plus anti-PD-L1: A Spanish multicenter real-world study. First Author: Mikel Portu, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Platinum - etoposide with PD-L1 inhibitors is the standard first-line treatment for ES-SCLC. However, real-world outcome data remain limited, particularly regarding the prognostic impact of frequently used concomitant medications. **Methods:** Retrospective multicenter cohort (9 Spanish centers; Oct 2019 - Apr 2025) of ES-SCLC treated with first-line platinum - etoposide plus anti-PD-L1. Overall survival (OS) and progression-free survival (PFS) were estimated by Kaplan - Meier. Proton pump inhibitor (PPI), corticosteroid*, and antibiotic use within 30 days before treatment initiation were recorded. Multivariable Cox models were adjusted for Eastern Cooperative Oncology Group performance status (ECOG PS), liver/bone/central nervous system (CNS) metastases (mets), and medications. The immune-related adverse event (irAE) - OS association was explored using time-fixed and 12-week landmark analyses. **Results:** A total of 442 patients were included (median age 66, 67% male, 90% ECOG PS 0–1); PD-L1 inhibitor: atezolizumab 97%, durvalumab 3%, pembrolizumab <1%. Liver, bone, and CNS mets were present in 40%, 34%, and 27%. PPIs, corticosteroids, and antibiotics were used in 51%, 33%, and 26%. Most (77%) completed induction (4 cycles); 79% initiated maintenance (6% after <4 cycles). ORR was 80% and DCR 90% (n=404 evaluable; routine assessment). With median follow-up of 27.2 months (reverse Kaplan - Meier), median PFS was 5.6 months (95% CI 5.3 - 6.1) and median OS 10.2 months (95% CI 8.4 - 11.3); 12-month OS 43%. On multivariable analysis (complete-case n=415; Table), ECOG PS ≥2 and liver/bone/CNS mets were associated with worse OS, while PPIs, corticosteroids, and antibiotics were not. irAEs occurred in 24%; time-fixed analysis suggested improved OS (adjusted HR 0.61; 95% CI 0.45 - 0.81; p<0.001), but this was not confirmed in 12-week landmark analysis (HR 0.84; 95% CI 0.55 - 1.29; p=0.43). **Conclusions:** In this large real-world ES-SCLC cohort treated with first-line chemoimmunotherapy, ECOG PS and metastatic burden remained key prognostic factors. Concomitant PPIs, corticosteroids, and antibiotics were not independently associated with OS, although residual confounding by indication cannot be excluded. The irAE - OS association was not confirmed by landmark analysis, highlighting the importance of time-dependent methods. Research Sponsor: None.

Multivariable Cox regression for OS (n=415).

Variable	HR (95% CI)	p-value
ECOG PS ≥2 vs 0-1	1.47 (1.02–2.12)	0.039
Liver mets	1.53 (1.22–1.94)	<0.001
Bone mets	1.52 (1.19–1.93)	<0.001
CNS mets	1.41 (1.10–1.81)	0.006
PPI (≤30d)	1.13 (0.89–1.44)	0.311
Corticosteroids (≤30d)*	1.03 (0.79–1.33)	0.842
Antibiotics (≤30d)	1.18 (0.89–1.55)	0.245

*Non-prophylactic systemic corticosteroids (≥10 mg/day prednisone-equivalent).

Tarlatamab in small cell lung cancer with brain metastases: A real-world experience. First Author: Santiago Sucre, Jackson Memorial Hospital, University of Miami, Miami, FL

Background: Tarlatamab, a DLL3-directed bispecific T-cell engager, has demonstrated survival benefit in previously treated small cell lung cancer (SCLC) in pivotal clinical trials. However, real-world evidence remains limited, particularly in ethnically diverse populations and in patients with a high burden of central nervous system (CNS) disease who are often underrepresented in clinical trials. We evaluated the safety, radiographic response, and treatment durability of tarlatamab in a real-world cohort treated at a single academic center. **Methods:** We retrospectively reviewed patients with extensive-stage SCLC treated with tarlatamab at Sylvester Comprehensive Cancer Center between January 2024 and October 31, 2025. Demographic, clinical, radiographic, and toxicity data were abstracted from medical records. Radiographic response was assessed per RECIST criteria, with best overall and 6-month responses recorded. Objective Response Rate (ORR) and Disease Control Rate (DCR) were calculated. Progression-free survival (PFS) and Overall Survival (OS) were estimated using Kaplan–Meier methods with multivariable analyses performed using Cox regression. **Results:** Among 23 patients (median age 72 years), male sex, Hispanic ethnicity, and brain metastases were each present in 61% of the cohort at tarlatamab initiation. 43% had received ≥2 prior lines of therapy. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANs) occurred predominantly during cycle 1 and were limited to grade 1 or 2 events, with no grade ≥ 3 toxicities observed. Median time on treatment was 92 days, with a median of 4 cycles. Three patients required treatment discontinuation due to toxicities. Radiographic response was evaluable in 18 patients; five were not evaluable due to early death after cycle 1 day 1 (n=2), loss to follow-up (n=2), and transition to hospice after first cycle (n=1). In those 18 patients, best overall response included partial response in 5 patients (27.7%) and stable disease in 3 patients (16.7%), yielding an ORR of 27.7 % and a DCR of 44.4%. Median PFS was 139 days, and median OS was 323 days (95 % CI, 31 to 614). No variables were independently associated with outcomes on multivariable Cox proportional regression analysis. **Conclusions:** In a predominantly Hispanic, heavily pretreated real-world SCLC population with a high prevalence of brain metastases, tarlatamab demonstrated feasible administration, manageable immune-mediated toxicity, and clinically meaningful antitumor activity. These findings support the effectiveness of tarlatamab beyond clinical trial populations and highlight the importance of real-world evidence in informing care for underrepresented patients. Research Sponsor: None.

Best Overall Response	N (%)
Complete Response	0 (0)
Partial Response	5 (27.7)
Stable Disease	3 (16.7)
Progression of Disease	10 (55.5)
ORR	5 (27.7)
DCR	8 (44.4)

8109 **Poster Session**

Updated results of the randomized phase 2 dose optimization study of alveltamig (ZG006), a trispecific T cell engager targeting DLL3/DLL3/CD3, as monotherapy in patients with advanced small cell lung cancer. First Author: Xinghao Ai, Shanghai Chest Hospital, Shanghai, China

Background: Alveltamig (ZG006) is a trispecific T cell engager (Tri-TE) targeting Delta-like ligand 3 (DLL3) and CD3, designed to bridge tumor cells and T cells by binding to two distinct DLL3 epitopes on tumor cells and CD3 on T cells, thereby mediating T cell-specific killing of DLL3-expressing tumor cells such as small cell lung cancer (SCLC). **Methods:** This is a multicenter, randomized, open-label, phase 2 dose-optimization study. Patients with SCLC who have failed at least two prior lines of standard therapy are randomized 1:1 to receive ZG006 at either 10 mg or 30 mg Q2W (both with a 1 mg priming dose). Based on the prior data from dose optimization in this study with an objective response rate (ORR) at 53.3% and median progression-free survival (PFS) at 7.03 months in the 10 mg group, 10 mg Q2W was selected as the recommended dose schedule for ongoing pivotal studies in advanced SCLC. Here we present the updated efficacy data with longer follow up and key subgroup analyses from this study. **Results:** This analysis included 60 treated patients (30 each from 10 and 30 mg group). With a median follow-up of about 13.5 months, the median duration of response (DoR) was not mature with 9-month DoR rates reaching 61.6% and 58.4% for 10 mg and 30 mg respectively. Likewise, the median OS for both groups was not reached, however, 12-month OS rates for two groups have approached 65.9% and 59.2% respectively. Based on the IRC data as of Sept 30, 2025, for the 10 mg and 30 mg groups, patients with previously treated and stable brain metastases at baseline achieved a confirmed ORR of 50.0% (4/8) and 44.4% (4/9), respectively, while patients without baseline brain metastases had an ORR of 54.5% (12/22) and 61.9% (13/21). Patients presented with baseline liver metastases achieved an ORR of 58.3% (7/12) and 46.2% (6/13), compared with 50.0% (9/18) and 64.7% (11/17) in patients without liver metastases. While 27 patients in 10 mg and 24 patients in 30 mg had previously received immune checkpoint inhibitors, a notable ORR of 55.6% (15/27) and 58.3% (14/24) was observed. Among patients with exactly two prior lines of systemic therapy, the ORRs were 50.0% (8/16) and 64.7% (11/17), whereas those who had received three or more prior lines demonstrated an ORR of 57.1% (8/14) and 46.2% (6/13) in 10 and 30 mg groups. **Conclusions:** With longer follow up, both ZG006 10 mg Q2W and 30 mg Q2W continued to demonstrate robust antitumor activity with a trend of longer DoR and OS in patients with relapsed or refractory SCLC. Subgroup analyses demonstrated consistent antitumor activity across key prognostic subgroups including those with baseline treated brain metastases, those with baseline liver metastases, and those who received multiple lines of prior systemic treatment. These results also support further development of ZG006 in SCLC with ongoing pivotal studies. Clinical trial information: NCT06283719. Research Sponsor: None.

Evaluation of survival after chemo-immunotherapy in veterans with extensive-stage small cell lung cancer and brain metastases. First Author: Jason Cham, Division of Hematology Oncology, Department of Medicine, Columbia University Irving Medical Center, New York, NY

Background: Extensive-stage small cell lung cancer (ES-SCLC) is an aggressive malignancy with rapid progression and poor long-term survival. For decades, platinum–etoposide chemotherapy has produced high initial response rates, but relapse is nearly universal. The addition of atezolizumab or durvalumab to first-line chemotherapy is now standard of care based on improved survival in the IMpower133 and CASPIAN trials, with reported OS 12.3 and 13 months, respectively. However, these pivotal trials enrolled highly selected populations and largely excluded patients with active brain metastases, limiting generalizability. Veterans are particularly underrepresented in clinical trials due to comorbidities and performance status, leaving the real-world effectiveness of chemo-immunotherapy and immune biomarkers in this population poorly defined. **Methods:** We conducted a retrospective cohort study of Veterans with ES-SCLC treated with first-line chemotherapy alone or chemo-immunotherapy within the Veterans Affairs (VA) health system. Overall survival (OS) was assessed using Kaplan–Meier methods and Cox proportional hazards models in propensity-matched cohorts. Prespecified subgroup analyses evaluated whether treatment effects differed by brain metastasis status. Exploratory analyses also assessed the prognostic association between baseline absolute neutrophil-to-lymphocyte ratio (ANC/ALC) and survival. **Results:** In the matched overall cohort (n = 1,250), chemo-immunotherapy significantly improved OS compared with chemotherapy alone (median OS 8.88 vs 7.44 months; HR 0.75, $p < 0.0001$). Among patients who received chemo-immunotherapy (n = 625), 87.0% were treated with atezolizumab and 9.6% with durvalumab. For patients with brain metastases at diagnosis (n = 312), chemo-immunotherapy significantly improved survival (median OS 8.76 vs 5.52 months; HR 0.57, $p < 0.0001$). An elevated pre-treatment absolute neutrophil count (ANC) to absolute lymphocyte count (ALC) ratio > 2.5 was independently associated with worse survival in both chemo-immunotherapy (HR 1.35, p = 0.013) and chemotherapy-only (HR 1.47, p = 0.0004) groups. **Conclusions:** This study represents the largest real-world cohort of Veterans with ES-SCLC and demonstrates a significant overall survival benefit with chemo-immunotherapy. The benefit was particularly pronounced among patients with brain metastases, a group historically underrepresented in clinical trials. Elevated ANC/ALC was identified as a potential prognostic biomarker associated with poor outcomes regardless of treatment. Notably, overall survival in our Veteran cohort remained substantially lower than in registrational trials, highlighting the urgent need for future studies with broader eligibility criteria that better reflect real-world populations. Research Sponsor: None.

An innovative team approach to improve SCLC care across an integrated health system. First Author: Melinda Laine Hsu, University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland, OH

Background: Small cell lung cancer (SCLC) is a highly aggressive cancer, with improved overall survival due to recent advancements in therapy. However, as many as 40% of patients (pts) may not receive guideline-concordant care for SCLC due to barriers including delays in diagnosis and referrals to oncology. We developed and implemented an electronic medical record (EMR) alert system based on ICD codes for early identification of pts with suspected SCLC and early intervention by thoracic medical oncology at University Hospitals Seidman Cancer Center. We hypothesized our intervention would increase rates of guideline concordant care and ultimately improve pt outcomes, compared to historical control. **Methods:** An informatics approach was used to identify pts with possible SCLC from 5/5/2024-5/17/2025 by incorporating Structure Query Language, Server Reporting Services, and text search of the EMR and pathology systems. Daily reports were reviewed by the thoracic medical oncology team, who intervened when needed to ensure appropriate staging and referrals. Clinicodemographic data was collected of pts with confirmed SCLC compared to a historical control of patients diagnosed between 2/5/2019-11/29/2021. Chi-square tests assessed statistical differences between the groups, and Kaplan-Meier (KM) survival analysis estimated overall survival (OS) and progression free survival (PFS). **Results:** 101 pts with SCLC were identified in the current group (C), and 130 pts in the historical group (H). Age, sex, smoking history, and baseline ECOG status, were similar between groups. A numerically higher percentage of pts in C were diagnosed with limited-stage SCLC (38.6%) compared to H (27.7%), p = 0.106). A numerically higher number of pts in C received guideline-concordant baseline imaging (93.1%) compared to H (83.8%, p = 0.05). Among pts who received treatment (tx), median time to tx was longer in C (19 days, interquartile range [IQR] 9-31) than H (13 days, IQR 5-22, p = 0.001). Pts in C were significantly more likely to receive 1st-line guideline-concordant tx than H (94.0% vs 83.3%, p = 0.02), although similar likelihood of enrolling in hospice before any therapy (12.9% vs. 11.5%, p = 0.917). Pts in C with progression were numerically more likely to receive 2nd-line and 3rd-line tx than H (61.3% vs. 57.1%; 78% vs. 53.1%, respectively). Pts in C had statistically significantly improved PFS compared to H (p = 0.008). **Conclusions:** Successful creation of an EMR alert system to identify SCLC significantly increased rates of guideline-concordant tx of SCLC. Although not statistically significant, pts were also more likely to receive guideline-concordant imaging and treatment in the 2nd and 3rd line settings compared to historical control. Predictive role of immune cell subsets and intestinal flora in immune-related adverse event of small cell lung cancer. First Author: Mei-xi Lin, The Second Hospital of Dalian Medical University, Dalian, Liaoning, China

Background: While immune checkpoint inhibitors (ICIs) have reshaped the therapeutic landscape for extensive-stage small-cell lung cancer (ES-SCLC), they are frequently associated with immune-related adverse events (irAEs) that may lead to treatment disruption. Early prediction of irAEs remains challenging due to their atypical clinical manifestations. This study aimed to identify risk factors and predictive biomarkers for irAEs in ES-SCLC patients undergoing ICIs therapy. **Methods:** 88 patients with ES-SCLC who received ICIs treatment between May 2021 and September 2023 were enrolled. Fecal samples were collected at baseline and before each treatment cycle until therapy discontinuation. The metagenomic and untargeted metabolomic analyses were performed on the fecal samples. Peripheral blood samples were collected from patients for flow cytometry analysis. Tumor response was assessed in accordance with RECIST 1.1 criteria, and irAEs were graded based on the Common Terminology Criteria for Adverse Events (CTCAE) v5.0. **Results:** Among 88 patients, 41 developed irAEs (median onset: 118 days), with the most common manifestations being pneumonia (41.5%) and hepatitis (22.0%). Patients who developed irAEs exhibited distinct peripheral immune profiles. Compared to their own baseline levels, these patients exhibited decreased peripheral B-cell counts alongside elevated percentages of activated $CD4^+$ and $CD8^+$ T cells, including early-activated $CD8^+$ T cells ($CD3^+CD8^+CD69^+$ T cells), late-activated helper T cells ($CD3^+CD4^+CD38^+$ T cells), and Th2 cells. Furthermore, at baseline, the irAE group demonstrated a significantly higher percentage of PD-1 in $CD8^+$ T cells compared to the non-irAE group. Metabolomic analyses revealed distinct baseline metabolic profiles between the two groups, *Micrococcus* was significantly enriched at baseline in the irAE group, whereas *Phocaeicola coprocola* and *Oscillibacter* were more abundant in patients without irAEs, and calcitriol was identified as a potential predictive biomarker for irAEs. Following irAE onset, significant enrichment of *Selenomonadaceae*, *Ruminococcus*, *Actinobacteria*, and *Erysipelatoclostridium* was observed, along with significant shifts in metabolites and related metabolic pathways. **Conclusions:** In ES-SCLC patients treated with ICIs, the development of irAEs is associated with distinct alterations in peripheral immune cell subsets, as well as gut microbial and metabolic profiles at baseline. Monitoring these features, particularly PD-1 expression on CD8+ T cells and calcitriol levels, may help predict the risk of irAEs. Dynamic changes in the gut microbiome and metabolome after ICIs initiation further aid in the early recognition of irAEs. Research Sponsor: National Natural Science Foundation of China; 82203056.

Real-world challenges in the adoption of emerging therapies for extensive-stage small cell lung cancer in community settings. First Author: Jacob Sands, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Despite advances in the treatment of extensive-stage small cell lung cancer (ES-SCLC), outcomes remain poor, and uptake of novel therapies in community oncology settings is inconsistent. As the ES-SCLC treatment landscape rapidly evolves, understanding real-world knowledge gaps, operational barriers, and challenges in patient-centered care is critical to improving evidence-based practice. This study evaluated community oncologists' confidence, practice patterns, and perceived barriers to integrating novel and emerging ES-SCLC therapies. **Methods:** From September–October 2025, 100 US community oncologists completed surveys assessing treatment selection, shared decision-making, adverse event (AE) management, clinical trial referral practices, and system-level barriers to care delivery for patients with SCLC. **Results:** Knowledge and training gaps were the most frequently cited challenges to incorporating novel therapies (55%), followed by electronic medical record workflow limitations (41%) and patient selection complexity (33%). While most oncologists reported a basic understanding of novel antibody-drug conjugates (72%), few actively followed emerging clinical data (19%). Delays in initiating first-line therapy were commonly attributed to unfamiliarity with available treatments or need for academic referral (56%), prolonged staging evaluations (53%), and limited infusion center capacity (39%). AE management represented a major unmet need: 90% reported difficulty educating patients and caregivers on early AE recognition, and 62% reported challenges distinguishing disease progression from treatment-related toxicity. These gaps directly affected patient-centered care, with barriers to shared decision-making including limited clinician knowledge of treatment options (80%) and difficulty tailoring communication to patient preferences (66%). Accordingly, improved AE management was identified as the single greatest opportunity to enhance quality of care (51%). Although most oncologists reported referring patients for clinical trial evaluation after progression most or all of the time (85%; 4-5 on 5-point Likert scale), enrollment was hindered by patient preferences (63%), limited infrastructure to identify and enroll eligible patients (51%), and poor performance status (40%). **Conclusions:** Community oncologists face significant knowledge and operational barriers to integrating novel therapies for ES-SCLC, particularly related to emerging mechanisms of action, AE recognition and management, patient communication, and clinical trial enrollment. Targeted educational and practice-based interventions are needed to support timely, patient-centered, and evidence-based care in the community setting. Phenotypic heterogeneity in primary tumors and brain metastases of small cell lung cancer: Insights into tumor microenvironment and metastatic behavior. First Author: Alan Amaral Oliveira, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, São Paulo, Brazil

Background: Small cell lung cancer (SCLC) is an aggressive malignancy with frequent brain metastases and pronounced phenotypic plasticity. How the tumor microenvironment and phenotypic heterogeneity relate to brain metastases remains poorly understood. **Methods:** We conducted a retrospective study of 124 patients with pathologically confirmed SCLC treated at a tertiary cancer center. In primary tumors, pathological features—including tumor-infiltrating lymphocytes (TILs), morphological patterns (necrosis, hyalinization, desmoplasia), and immunohistochemical characterization of lineage-associated SCLC markers—were assessed on H&E-stained sections. Immune-desert tumors were defined as having no detectable lymphocytic infiltration. Associations between these pathological features and baseline brain metastases were evaluated using appropriate statistical tests for categorical and continuous variables, with available brain metastasis samples also analyzed histopathologically and immunohistochemically to assess spatial heterogeneity and microenvironmental plasticity. **Results:** Among 124 patients, TIL levels were lower in those with baseline brain metastases than without (1.46% $\pm$ 4.54 vs 3.04% $\pm$ 5.29; p = 0.049), and the immune-desert phenotype was more frequent (88% vs 65%; p = 0.041), indicating a cold tumor microenvironment in patients with brain metastases. Immunohistochemical and morphological patterns were similar regardless of baseline brain metastases. Histopathological evaluation of the two available brain metastases showed marked intralesional heterogeneity. Regions had inflammatory infiltrates, coagulative necrosis, or stromal hyalinization. Tumor cells showed a spiculated growth pattern along the GFAP-positive astrocytic network, suggesting interaction with astrocytes. Synaptophysin expression was higher adjacent to lymphocytes, NEUROD1 predominant near necrotic zones, and POU2F3 higher in hyalinized regions. These findings indicate regional activation of different SCLC transcriptional programs, reflecting microenvironmental plasticity. **Conclusions:** An immune-desert phenotype in primary SCLC tumors is associated with baseline brain metastases, which exhibit pronounced spatial heterogeneity and region-specific tumor programs. These findings suggest that the immune context of the primary tumor may influence microenvironmental plasticity and contribute to brain metastasis development, warranting validation in larger cohorts. Does treatment delay matter?: Impact of time to immunotherapy on survival in extensive-stage small cell lung cancer. First Author: Anand Shah, Rutgers New Jersey Medical School, Newark, NJ

Background: Immune checkpoint inhibitors (ICI) combined with platinum-etoposide chemotherapy are the standard first-line treatment for extensive-stage small cell lung cancer (ES-SCLC) based on the CASPIAN and IMpower133 trials. Given the aggressive nature of ES-SCLC, timely initiation of systemic therapy is critical; however, delays in treatment initiation are common in real-world practice. The impact of time to immunotherapy initiation (TTI) on survival has not been well characterized. **Methods:** Adult patients diagnosed with EO-SCLC (2019-2021) who received immunotherapy as part of first-line systemic therapy were identified from NCDB. TTI was defined as the time from diagnosis to first immunotherapy and categorized as $\leq$30, 31–60, or $>$ 60 days. Association between TTI and OS was analysed using multivariable Cox proportional hazards models adjusting for patient and facility-level factors. A 90-day landmark analysis were performed to mitigate immortal time bias. Multivariable logistic regression was used to identify predictors of delayed initiation ($>$ 30 days). **Results:** A total of 18,630 patients were identified. 2,652 (14.24%) died during follow-up. Median TTI was 29 days (IQR 18–45), with median follow-up of 9.36 months. In multivariable Cox models, TTI was not independently associated with OS (31–60 vs $\leq$30 days: HR 0.92 [0.84–1.00]; $>$ 60 vs $\leq$30 days: HR 1.00 [0.89–1.11]). Results were consistent in a 90-day landmark analysis. Increasing age was associated with higher mortality (HR 1.01 per year, p = 0.003). Treatment at academic/research programs was associated with better OS (HR 0.71 [0.61–0.82]), while Medicaid insurance was associated with worse OS (HR 1.31 [1.15–1.49]). Black patients were more likely to receive delayed treatment (OR 1.31 [1.16–1.48]) while Asian patients were less likely (OR 0.74 [0.55–0.98]), when compared with Non-Hispanic White patients. Medicaid (OR 1.36 [1.20–1.53]) and Medicare insurance (OR 1.10 [1.01–1.21]) were associated with increased odds of delay versus private insurance. Higher comorbidity burden (Charlson–Deyo score $\geq$2 vs 0: OR 1.10 [1.02–1.19]) and treatment at academic centers (OR 1.33 [1.17–1.51]) were also associated with delay. Higher neighborhood income was protective (highest vs lowest quartile: OR 0.86 [0.77–0.95]). **Conclusions:** In a large national cohort of ES-SCLC patients receiving immunotherapy, modest delays in treatment initiation were not associated with OS. However, significant disparities exist in timely access, highlighting opportunities for system-level interventions to improve equity in cancer care delivery. Research Sponsor: None.

Efficacy and safety of second or further line KC1036 in patients with thymoma and thymic carcinoma: A multicenter, single-arm phase II trial. First Author: Wentao Fang, Shanghai East Hospital, Tongji University, Shanghai, China

Background: Patients with advanced or recurrent thymoma or thymic carcinoma (T/TC) progressing after platinum-based chemotherapy have an unmet therapeutic need. This report assessed the clinical efficacy and safety of KC1036, a novel multi-kinase inhibitor of AXL, VEGFR2, and FLT3, in the treatment of T/TC. **Methods:** This open-label, multicenter, single-arm, phase II study enrolled patients with advanced or recurrent T/TC who had progressed on at least one prior line of chemotherapy. Eligible participants were required to have measurable disease according to RECIST v1.1 and an ECOG performance status of 0 or 1. KC1036 was administered orally at 60 mg QD, every 21 days as a cycle, until disease progression, death or intolerable toxicities. The primary endpoint was investigator-assessed objective response rate (ORR). **Results:** Between February 23, 2023 and January 4, 2024, 6 thymoma (T) and 25 thymic carcinoma (TC) patients were enrolled; all had distant metastases. Median age was 47.5 years (range, 34-71) for T and 57.0 years (37-73) for TC. Most patients had an ECOG PS of 1 (T: 100%; TC: 88.0%). While all T patients received one prior line of therapy, 48.0% of TC patients had received $\geq$2 prior lines. At the data cutoff of June 9, 2025, with a median follow-up of 19.3 months (95% CI, 13.4-NR), the T cohort achieved 100% SD with a median PFS of 13.6 months (95% CI, 4.1-NR). The TC cohort showed an ORR of 20.0% (n=5, PR) and a DCR of 80.0% (n=15, SD), with a median PFS of 8.2 months (95% CI: 4.1-15.1) and a median DOR of 15.3 months (95% CI: 1.5-NR). Median OS was not reached in either cohort; and the 18-month OS rates were 100% and 75.5% in the T and TC cohorts, respectively. The median duration of treatment exposure was 7.1 months. Treatment-related adverse events (TRAEs) were predominantly Grade 1 or 2. Grade 3 TRAEs occurring in $\geq$5% of subjects were hypertension (4 [12.9%]) and diarrhea (3 [9.7%]). No Grade 4 or 5 TRAEs were reported. TRAEs leading to dose reduction and treatment discontinuation occurred in 41.9% and 3.2% of patients, respectively. **Conclusions:** KC1036 demonstrated promising antitumor efficacy in patients with advanced or recurrent T/TC. Additionally, KC1036 exhibited a favorable safety profile and tolerability. These encouraging outcomes support further evaluation of KC1036 in a forthcoming phase III trial. Clinical trial information: NCT05683886. Research Sponsor: Beijing Konruns Pharmaceutical Co., Ltd.

Platinum rechallenge versus non-platinum regimens as second-line treatment for advanced thymoma: Analysis of the largest retrospective cohort to date. First Author: Go Saito, Department of Respirology, Graduate School of Medicine, Chiba University, Chiba, Japan

Background: Although guidelines list platinum-based combination chemotherapy (Pt-rechallenge) as a second-line strategy for patients with thymoma ineligible for curative-intent therapy, evidence is limited to small case series. We investigated the efficacy of Pt-rechallenge versus non-platinum regimens in the largest retrospective cohort of second-line thymoma treatment reported to date. **Methods:** This multicenter study analyzed patients treated at 39 Japanese institutions. Of 157 patients ineligible for curative-intent therapy who initiated palliative platinum-based chemotherapy (2000–2020), 91 patients receiving second-line systemic cytotoxic chemotherapy were evaluated. Efficacy outcomes, including objective response rate (ORR), progression-free survival (PFS), and overall survival (OS), were compared between second-line Pt-containing (Pt-rechallenge) and non-platinum (non-Pt) regimens. **Results:** Among the 91 patients (median age 59; 91% ECOG PS 0-1) with a median follow-up of 1056 days, 64 (70%) received Pt-rechallenge and 27 received non-Pt regimens (S-1 [tegafur/gimeracil/oteracil], n=15; pemetrexed, n=6; amrubicin, n=5; paclitaxel, n=1). First-line ORR was 51%, and the median chemotherapy-free interval from first-line chemotherapy was 394 days. Pt-rechallenge achieved a significantly higher ORR than non-Pt chemotherapy (40% vs 5%; p=0.0012). Regarding survival outcomes, median PFS was 8.8 months (95% CI, 5.9–11.9) in the Pt-rechallenge group vs 8.0 months (95% CI, 4.8–30.4) in the non-Pt group (HR, 1.29; 95% CI, 0.77–2.18; p=0.325). Median OS was 70.6 months (95% CI, 53.5–82.4) vs 64.4 months (95% CI, 38.7–not estimable) (HR, 1.12; 95% CI, 0.53–2.37; p=0.759); differences in PFS and OS were not statistically significant. In the Pt-rechallenge cohort, outcomes were stratified by anthracycline (A) use in 1st/2nd-line (A→A, n=17; A→non-A, n=28; non-A→A, n=12; non-A→non-A, n=7): ORRs were 50%, 35%, 27%, and 29%; median PFS were 9.3 (95% CI, 4.5–12.2), 6.4 (95% CI, 4.6–10.6), 21.0 (95% CI, 8.7–41.9), and 4.1 (95% CI, 1.8–9.3) months, respectively. Stratified by platinum-free interval (PFI) ($<$6 months, n=15; 6–12, n=10; 12–36, n=27; $\geq$36, n=12), ORR were 14%, 63%, 46%, and 20%; median PFS were 5.8 (95% CI, 1.8–19.8), 7.3 (95% CI, 2.1–14.5), 10.3 (95% CI, 5.5–23.5), and 9.0 (95% CI, 3.1–16.9) months. **Conclusions:** In this largest comparative study to date, platinum rechallenge demonstrated superior response rates compared to non-platinum regimens, particularly in patients with favorable PFI. Study registration: UMIN000048181. Research Sponsor: None.

8118 **Poster Session**

Cell-free DNA fragmentomics and methylomics for thymic epithelial tumors. First Author: Michael Daniels, National Institutes of Health, Rockville, MD

Background: Development of circulating cell-free (cf) DNA assays for cancer detection and monitoring is an area of active research. Limited data are available on the utility of cfDNA for thymic epithelial tumors (TETs). Evaluation of cfDNA fragmentation patterns (fragmentomics) offers advantages over conventional cfDNA analysis. Studies have shown that concurrent generation of fragmentomics and methylomics features via enzymatic methyl-sequencing (EM-Seq) are highly predictive at classifying cancer vs. non-cancer and capture key cancer-related biological features. We conducted a study to determine the feasibility of fragmentomics and methylomics for evaluation of TETs. **Methods:** cfDNA was extracted from 1-2 mL of plasma EDTA derived from patients with advanced TETs using the QIAamp Circulating Nucleic Acid Kit, underwent enzymatic conversion via the NEBNext Enzymatic Methyl-Seq v2 Kit, and sequenced on a NovaSeq X 10B flowcell. Estimated tumor fractions were generated using *ichorCNA* with low tumor settings and via *fragle*. Recurrent copy number alterations (CNAs) were plotted and compared against external TET copy number datasets. Short fragment percentage (90-150 bps) was calculated and average DELFI scores (DNA evaluation of fragments for early interception) were generated via *FinaleToolkit*. **Results:** Plasma samples from 47 of 50 participants (thymic carcinoma: 26, thymoma: 24; median age: 55 years (range 23-77); females 22; stage distributions: I/II/III/IV = 1/0/1/48) yielded high-quality cfDNA which was sufficient for sequencing. Individuals with thymic carcinoma displayed higher estimated tumor fractions via ichorCNA ($P<0.05$) and Fragle (P=0.05). Moreover, although not statistically significant, individuals with thymic carcinoma exhibited a general trend of higher short fragment percentage and higher average DELFI scores. When evaluating recurrent CNAs, individuals with thymic carcinoma displayed greater enrichments in CNAs in general with noted amplifications/gains at chr 1, 5, 12, and 17 and deletions at chr 16, whereas individuals with thymoma showed deletions at chr 3. When grouped and compared to external thymoma tissue CNAs, recurrent CNAs detected in plasma showed partial concordance. Large alterations in fragmentation profiles were also identified across both groups, which showed increased variability near recurrent CNA regions. **Conclusions:** This proof-of-concept study demonstrates that plasma cfDNA is detectable and fragmentomics is feasible among individuals with TETs, thus providing a non-invasive means of capturing cancer-related aberrant signals. Validation of this result in larger studies would establish cfDNA fragmentomics as a novel non-invasive means for disease monitoring and biomarker identification in patients with TETs. Research Sponsor: None.

8119 **Poster Session**

Surufatinib for advanced or metastatic chemotherapy-refractory thymic epithelial tumor: A single-arm, single-center, phase II study. First Author: Bei Xu, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Thymic epithelial tumors (TETs), though relatively rare, represent the most common anterior mediastinal malignancy in adults. Platinum-based regimens are the standard first-line therapy; however, treatment options for subsequent lines remain poorly defined. Surufatinib, an oral tyrosine kinase inhibitor targeting VEGFR1/2/3, FGFR1, and CSF-1R, exerts both anti-angiogenic and immune-modulating effects. This study aimed to evaluate the efficacy and safety of surufatinib in patients (pts) with type B2/B3 thymoma (TM) or thymic carcinoma (TC), providing a potential new therapeutic strategy for TETs following anthracycline/taxane-based therapy. Here, we report the initial results. **Methods:** This was a single-arm, prospective phase II study. Eligible pts had histologically or cytologically confirmed, unresectable or radiotherapy-ineligible, advanced recurrent or metastatic B2/B3 TM or TC, with progression following at least one prior platinum-based chemotherapy regimen. Pts were aged $>$18 years and had at least one measurable lesion per RECIST 1.1 criteria. Treatment consisted of surufatinib 300 mg orally once daily in a 4-week cycle. Tumor assessments were conducted every 8 weeks. The primary endpoint was the objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), disease control rate (DCR), and overall survival (OS). **Results:** As of December 25, 2025, 20 pts were enrolled and evaluated. The median age was 55.5 years (range: 35–69), with 55% being male. Pathological subtypes included B2 TM (30%), B3 TM (15%), and thymic squamous cell carcinoma (TSCC, 55%). Eighteen pts (90%) presented with $>$5 metastatic sites. Ten pts (50%) achieved a partial response, and ten pts (50%) achieved stable disease. The ORR was 50%, and the DCR was 100%. With a median follow-up of 9.50 months, the median PFS was 11.9 months, and the 9-month PFS rate was 73.5%. Median OS was not reached, with an 18-month OS rate of 91.7%. The most common treatment-related adverse events (TRAEs) of any grade were hypertension (70%), diarrhea (40%), elevated bilirubin (40%), and elevated transaminases (25%). Grade 3 TRAEs included hypertension (15%), diarrhea (5%), and elevated transaminases (5%). No treatment-related deaths were reported. **Conclusions:** Surufatinib monotherapy demonstrated promising antitumor activity and a manageable safety profile in patients with previously treated, advanced recurrent or metastatic TETs, supporting further investigation in this population. Clinical trial information: ChiCTR2600116776. Research Sponsor: None.

Penpulimab (PD-1 inhibitor) combined with platinum-based chemotherapy as induction therapy for newly diagnosed thymic carcinoma: A multicenter, single-arm, phase II trial. First Author: Weixiong Yang, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Our retrospective study showed that immune checkpoint inhibitors plus chemotherapy had encouraging anti-tumor activity and durable response for unresectable thymic carcinoma (TC). This prospective clinical trial aimed to evaluate the efficacy and safety of penpulimab—a humanized anti-PD-1 monoclonal antibody—in combination with platinum-based chemotherapy as induction therapy for patients with newly diagnosed TC. **Methods:** Patients with histologically confirmed TC at Masaoka stage II–IV, an ECOG performance status of 0 or 1, and no history of prior systemic anticancer therapy were enrolled. Following 4 cycles of induction therapy with penpulimab penpulimab (200 mg), carboplatin (AUC 5 mg/mL per min), and nab-paclitaxel (260 mg/m²) administered intravenously every 3 weeks, patients were re-evaluated by a multidisciplinary team (MDT). Subsequent treatment was stratified based on resectability: operable patients proceeded to surgery, whereas inoperable patients received standard radiotherapy or chemotherapy. Based on a Fleming two-stage design, the treatment would be promising if at least 10 of the first 18 evaluable patients in stage I or at least 14 of the 36 evaluable patients at the end of stage II have a confirmed response. The primary endpoint was objective response rate (ORR) evaluated by independent central review. **Results:** Between June 2023 and July 2025, 18 eligible patients were enrolled. Fourteen patients (77.8%) had WHO stage IV disease. Ten patients achieved a partial response (PR), meeting the predefined efficacy threshold for early termination according to the Fleming design. The ORR and disease control rate (DCR) were 55.6% and 94.5% respectively in the overall population, with corresponding rates of 57.1% and 92.8% in the subgroup with stage IV disease. Nine patients underwent surgical resection, including 6 with stage IV disease, and an R0 resection was achieved in 7 cases. Among the 9 patients who underwent surgery, one patient (11.1%) with stage III disease achieved a pathological complete response (pCR), and another patient (11.1%) with stage IV disease achieved a major pathological response (MPR). At a median follow-up of 20.15 months, the 1-year relapse-free survival (RFS) and overall survival (OS) rates were 72.2% and 88.9% for the entire population, and 64.3% and 78.6% for patients with stage IV disease, respectively. The most common adverse events of grade 3 or worse were neutropenia (44.4%), anemia (16.7%), and hepatotoxicity (11.2%). One patient died from immune-mediated myocarditis with concurrent hepatitis and myasthenia gravis. **Conclusions:** Penpulimab combined with platinum-based chemotherapy showed promising antitumour activity in previously untreated TC, with vigilance required for immune-mediated myocarditis. Clinical trial information: ChiCTR2300076314. Combining SBRT with GM-CSF and Peg-IFNα to induce abscopal effects in previously treated patients with metastatic thymic tumors: A single-institution, phase II trial. First Author: Min Fan, Fudan University Shanghai Cancer Center, Shanghai, China

Background: After the failure of multi-line treatment, patients with metastatic thymic tumors have a poor prognosis and few therapeutic options. Combining stereotactic body radiotherapy (SBRT) with granulocyte-macrophage colony-stimulating factor (GM-CSF) and Pegylated interferon-α (Peg-IFNα) may induce abscopal effects and improve prognosis. **Methods:** We conducted this open-label, single-arm, phase II trial to evaluate SBRT plus GM-CSF and Peg-IFNα in previously treated patients with metastatic thymic tumors. A 21-day treatment cycle consisted of SBRT delivered to one metastatic lesion with 30 Gy in 5 fractions from day 1, synchronous subcutaneous injection of GM-CSF 125 μg/ m^2 once daily for 14 days, and subcutaneous injection of Peg-IFNα 90 μg on day 8. If the patient has more than two metastatic lesions, another treatment cycle was repeated. After the completion of 1 or 2 treatment cycles, Peg-IFNα therapy was maintained for at least half a year with a subcutaneous injection of 90 μg once a month. The two primary endpoints were the proportion of patients with abscopal effects and the objective response rate (ORR). The secondary endpoints included overall survival (OS), progression-free survival (PFS), and therapeutic safety. **Results:** A total of 32 patients from March 2021 to December 2025, were enrolled in this trial, with 2 (6.25%) type A thymoma, 4 (12.50%) type B1 thymoma, 6 (18.75%) type B2 thymoma, 2 (6.25%) type B3 thymoma, 16 (50.00%) thymic squamous cell carcinoma and 2 (6.25%) thymic neuroendocrine tumor. One patient with type B3 thymoma died of cardiac arrest amid the COVID-19 pandemic, rendering tumor evaluation unfeasible. Out of the remaining 31 patients, 9 (29.03%) had abscopal effects, and the ORR was 38.71%. At a median follow-up of 17.20 months, the median OS had not been attained yet. The median PFS was 6.37 months for the whole group. We observed that patients with abscopal effects tended to have longer PFS than those without abscopal effects (13.03 vs. 4.40 months ; p = 0.003). 5 patients (16.13%) experienced Grade 3 treatment-related adverse events (CTCAE version 5.0), among which cardiac insufficiency compelled 1 patient (3.23%) to drop out of treatment. **Conclusions:** Combining SBRT with GM-CSF and Peg-IFNα was well tolerated with acceptable toxicity and may represent a promising salvage therapy for previously treated patients with metastatic thymic tumors. The occurrence of abscopal effects is likely to improve patient outcomes. Clinical trial information: NCT04517539. Research Sponsor: None.

Development and validation of a preoperative pathological risk prediction model for thymic tumors: A retrospective multicenter diagnostic study. First Author: LuYu Huang, Department of Thoracic Surgery, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: The preoperative diagnosis of thymic tumors currently relies on preoperative CT data and the experience of the surgeon, and there is still a lack of highly effective noninvasive radiomic prediction model to assist in clinical decision making. To develop and validate a preoperative CT-based radiomic model to accurately predict the pathological risk staging of thymic tumors. **Methods:** This is a retrospective diagnostic study that included patients from two independent centers Charité Universitätsmedizin Berlin (N = 74) as well as the First Hospital of Zhengzhou University (N = 143) between September 2003 and July 2024. WHO pathological type A, AB, and B1 of the postoperative thymic tumor were divided into low-risk groups (N = 110), and type B2, B3, and C (N = 107) were classified as high-risk groups. The patients were randomly divided into a training group (N = 130) and a validation group (N = 87) in a ratio of 6:4. Preoperative CT imaging of thymic tumor was used to define the tumor area and the peritumoral area (5 mm) and to extract the radiomic features using 3Dslicer software and the in-house pyradiomic software package. Feature selection and model development were conducted using the least absolute shrinkage and selection operator (LASSO) algorithm and logistic regression analysis. **Results:** A total of 217 patients undergoing thymectomy were included in this study. After univariate analysis, patients' age, smoking history, and the presence of combined myasthenia gravis (MG) were included in the clinical model, and the clinical model achieved AUC = 0.75 and 0.65 in the training and validation groups, respectively. The combined radiomic model has better performance than the two radiomic models alone, with AUC values of 0.86, 0.73, respectively. The nomogram model conducted by combined radiomic model with the clinical model achieved the best results in training (AUC = 0.89) and validation cohort (AUC = 0.84). Calibration curve and decision curve analysis (DCA) illustrated the clinical usability and reliability of the model. **Conclusions:** By combining the clinical model with a combined radiomic model, the nomogram model can effectively differentiate pathological risk staging of thymic tumors, providing surgeons with a potential preoperative decision support. Research Sponsor: None.

TPS8123 **Poster Session**

A multi-institutional, randomized, phase III trial comparing anatomical segmentectomy and lobectomy for clinical stage IA3 pure-solid non–small-cell lung cancer: West Japan Oncology Group study WJOG16923L (STEP UP trial). First Author: Atsushi Kamigaichi, Hiroshima University, Hiroshima, Japan

Background: Recent pivotal clinical trials, conducted by the Japan Clinical Oncology Group and West Japan Oncology Group (JCOG0802/WJOG4607L) or Cancer and Leukemia Group B (CALGB140503), have demonstrated the efficacy of anatomical segmentectomy for small-sized early-stage NSCLC measuring $\leq$ 2 cm. Segmentectomy is gaining attention as an alternative procedure to lobectomy for early-stage NSCLC. However, for tumors larger than 2 cm, particularly those with a pure-solid appearance which indicates higher malignant potential, the efficacy of segmentectomy remains controversial. Therefore, we initiated this randomized phase III trial (WJOG16923L: STEP UP) to confirm the non-inferiority of anatomical segmentectomy to lobectomy for patients with pure-solid NSCLC measuring $>$ 2 cm and $\leq$ 3 cm. **Methods:** This multi-institutional, open-label, randomized phase III study is designed to confirm the non-inferiority of anatomical segmentectomy to lobectomy in terms of overall survival (OS) in patients with clinical stage IA3 pure-solid peripheral NSCLC (tumor's center located in the outer third of the lung field, tumor measuring $>$ 2 cm and $\leq$ 3 cm, and consolidation-to-tumor ratio = 1). Patients are randomized 1:1 to undergo either lobectomy or anatomical segmentectomy using a minimization method by balancing the arms with the institution, age ($\geq$ 70 or $<$ 70), sex (male or female), location (right upper, right lower, left upper, or left lower lobes), and histological type (adenocarcinoma or non-adenocarcinoma). The primary endpoint is OS in all randomized patients. Secondary endpoints include relapse-free survival, postoperative respiratory function (at 6 months and 1 year after surgery), proportions of patients with respiratory failure and cerebrovascular disease, cumulative incidence of death from other diseases, cumulative incidence of local recurrence, proportion of patients who undergo segmentectomy, number of resected segments, operative time, blood loss, and adverse events. We plan to enroll 520 patients from 64 institutions over a period of 5 years. Enrollment began in January 2024. As of November 2025, 319 patients have been enrolled. This trial is registered with the UMIN Clinical Trials Registry (UMIN000052064). Clinical trial information: UMIN000052064. Research Sponsor: None.

TPS8124 **Poster Session**

CCTG BR.38: Consolidative use of radiotherapy to block (CURB2) oligoprogression in patients with metastatic non–small-cell lung cancer—A randomized phase III trial. First Author: Chiaojung Jillian Tsai, Princess Margaret Hospital, University Health Network, Toronto, ON, Canada

Background: Immune checkpoint inhibitor (ICI)–based regimens are standard first-line therapy for metastatic non–small-cell lung cancer (NSCLC) without actionable driver mutations; however, most patients experience disease progression within 12 months. A subset develop oligoprogression, defined by progression at a limited number of metastatic sites with otherwise controlled disease. Oligoprogression represents a therapeutic window in which local ablative therapy could be used to prolong disease control. In the prior phase II CURB trial, SBRT was shown to significantly prolong progression-free survival (PFS) in patients with oligoprogressive NSCLC. **Methods:** CCTG-BR38 is an international, multicenter, open-label, randomized phase III trial conducted through the NCI National Clinical Trials Network. Adults with stage IV NSCLC receiving first-line ICI $\pm$ chemotherapy who develop $\leq$5 extracranial oligoprogressive lesions are randomized 1:1 to: (1) switch to second-line standard systemic therapy or (2) SBRT (30 Gy in 3 fractions) to all oligoprogressive sites followed by continuation of the same first-line systemic therapy. Randomization is stratified by type of first-line systemic therapy (ICI alone vs ICI + chemotherapy), number of oligoprogressive lesions (1–2 vs 3–5), and ECOG performance status (0-1 vs 2). Patients with treated, stable brain metastases are eligible. Primary Endpoints: Dual primary endpoints are PFS and overall survival (OS). Secondary endpoints include safety (CTCAE v5.0), patient-reported adverse events (PRO-CTCAE), quality of life (EORTC QLQ-C30/LC13), and cost-effectiveness (EQ-5D-5L; Canadian sites). Optional blood and tissue collection for exploratory biomarker analyses are planned. Statistical Considerations: A total of 320 patients (160 per arm) will be enrolled. The sample size is based on detecting a HR of 0.7 for OS (an improvement in median OS from 10 to 14.3 months) with 80% power using a 1-sided 2% level test (the overall 1-sided 2.5% type I error will be assigned 2% to OS and 0.5% to PFS). Interim analyses for futility and efficacy are planned. Current Status: The trial was centrally activated on April 3, 2025. Accrual is ongoing across Canadian and US NCTN sites. Clinical trial information: NCT06686771. Research Sponsor: National Clinical Trials Network; CA180863; Canadian Cancer Society Research Institute; 707213; University Health Network.

TPS8125 **Poster Session**

InDuRanS: A randomized phase II trial on induction immunochemotherapy followed by surgery or chemoradiotherapy and consolidation durvalumab in stage III NSCLC. First Author: Eleni Gkika, Department of Radiation Oncology, Bonn, Germany

Background: The optimal local treatment strategy for patients with resectable or borderline resectable stage IIIA/B (N2) non-small-cell lung cancer (NSCLC) remains controversial. Earlier randomized trials comparing surgery with definitive chemoradiotherapy (CRT) failed to demonstrate a survival advantage for either modality; however, these studies predated routine PET staging, modern radiotherapy techniques, and standard-of-care immunotherapy. Consolidation durvalumab after definitive CRT has significantly improved survival in unresectable stage III NSCLC, while neoadjuvant immunochemotherapy has shown promising pathologic and survival outcomes in resectable disease. Whether surgery or definitive CRT provides superior outcomes following induction immunochemotherapy in stage III NSCLC is unknown. The InDuRanS trial aims to address this question in a randomized setting. **Methods:** InDuRanS (ARO-2024-12; NCT06810609) is a prospective, multicenter, open-label, randomized phase II trial conducted across approximately 10 centers in Germany. Eligible patients have (borderline) resectable stage IIIA/B (N2) NSCLC without targetable EGFR or ALK alterations. All patients receive three cycles of induction immunochemotherapy consisting of durvalumab (1,500 mg every 3 weeks) combined with platinum-paclitaxel. Following PET-based restaging, patients with persistent resectable disease are randomized 1:1 to surgery (Arm A) or definitive CRT (Arm B). CRT consists of 60–70 Gy in conventional fractionation with two cycles of concurrent platinum-vinorelbine. Both treatment arms subsequently receive consolidation durvalumab (1,500 mg every 4 weeks) for up to 13 cycles. The primary endpoint is 2-year event-free survival (EFS). Secondary endpoints include overall survival, progression-free survival, treatment-related toxicity, surgical outcomes, and quality of life. Exploratory analyses include radiomics, plasma proteomics, circulating tumor DNA, and immune profiling. A total of 176 patients will be enrolled, with 158 evaluable patients planned for randomization. Interim safety analyses are scheduled after treatment completion in the first 10 randomized patients. The trial is currently open and recruiting. Research Sponsor: AstraZeneca.

TPS8126 **Poster Session**

Volrustomig, a novel bispecific PD-1/CTLA-4 monoclonal antibody, as single-agent first-line therapy for unresectable pleural mesothelioma: Substudy 5 of the eVOLVE-02 phase 2 study. First Author: Michael Offin, Mesothelioma Program, Department of Medicine, Memorial Sloan Kettering Cancer Center, and Weill Cornell Medical College, New York, NY

Background: Standard first-line treatment for unresectable pleural mesothelioma has evolved recently to include anti-PD-1 ± anti-CTLA-4 immunotherapy-based options. Nivolumab + ipilimumab and pembrolizumab + pemetrexed + platinum chemotherapy showed improved survival vs chemotherapy alone, with greater benefit in non-epithelioid compared to epithelioid pleural mesothelioma. However, there is still significant unmet need given the ongoing poor prognosis; further study is needed to optimize dual checkpoint approaches across histologic subtypes and refine regimen selection. Volrustomig is a monovalent, bispecific, humanized IgG1 monoclonal antibody engineered to specifically inhibit PD-1 and CTLA-4, with increased CTLA-4 blockade on PD-1-positive activated T cells compared to PD-1-negative resting peripheral T cells. Volrustomig + chemotherapy is being evaluated as first-line treatment in unresectable pleural mesothelioma in the phase 3 eVOLVE-Meso trial. Volrustomig monotherapy has shown encouraging results in a Phase 1 study of patients with solid tumors; this new eVOLVE-02 (NCT06535607) substudy will evaluate its efficacy and safety as monotherapy in unresectable pleural mesothelioma. **Methods:** ~75 patients with unresectable pleural mesothelioma (epithelioid or non-epithelioid histology) will receive intravenous volrustomig until disease progression, unacceptable toxicity, consent withdrawal, or maximum treatment duration is reached. Eligibility criteria include age ≥18 years, Eastern Cooperative Oncology Group performance status 0/1, histologically confirmed pleural mesothelioma with known histology, advanced unresectable disease, measurable disease per mRECIST (modified Response Evaluation Criteria in Solid Tumors) v1.1 (pleural lesions) and/or RECIST v1.1 (metastatic non-pleural lesions), no prior systemic therapy for pleural mesothelioma, and no prior exposure to immune-mediated therapy. The primary endpoint is objective response rate. Secondary endpoints include disease control rate, time to response, duration of response, progression-free survival, and overall survival. eVOLVE-02 is recruiting patients; 3 substudies are ongoing in cervical cancer and head and neck squamous cell carcinoma. Substudy 5 enrollment is planned at sites in 8 countries/regions: Australia, Canada, China, Germany, Italy, Taiwan, UK, and USA. Clinical trial information: NCT06535607. Research Sponsor: AstraZeneca.

TPS8127 **Poster Session**

Neoadjuvant chemo-immunotherapy and surgical resection in locally advanced non-small cell lung cancer with N3 lymph node involvement (NEOSURG). First Author: Joshua E. Reuss, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC

Background: The emergence of neoadjuvant and peri-operative chemoimmunotherapy in locally-advanced non-small cell lung cancer (NSCLC) has revolutionized the treatment of resectable NSCLC. Importantly, in multiple phase III trials, patients with multi-station N2 disease derive profound benefit from neoadjuvant chemoimmunotherapy. NSCLC with N3 involvement has been excluded from neoadjuvant/perioperative studies, as these cancers have historically been considered unresectable and treated with definitive chemoradiotherapy (CRT) followed by durvalumab. However, CRT is associated with high rates of treatment-related adverse events and most patients experience disease relapse within 2 years. Whether patients with select N3 lymph node-positive NSCLC may benefit from neoadjuvant chemo-immunotherapy followed by surgery is an important unaddressed question. This phase II trial seeks to evaluate the feasibility and clinical utility of neoadjuvant chemoimmunotherapy followed by surgery in patients with locally-advanced stage III B/C NSCLC with select N3 involvement. **Methods:** This phase II, multi-center, single-arm study is evaluating neoadjuvant chemoimmunotherapy in patients with stage III B/C NSCLC with contralateral mediastinal or ipsilateral supraclavicular (N3) lymph node involvement. Select eligibility criteria include: ECOG performance status 0-1, pathologically-confirmed contralateral mediastinal or ipsilateral supraclavicular N3 disease, ≤2 involved lymph node stations, primary tumor appropriate for resection per multi-disciplinary review (any T stage), physical fitness for resection, wild-type *EGFR/ALK*. Patients will receive neoadjuvant cemiplimab 350mg IV plus histology-specific chemotherapy every 3 weeks for 4 cycles prior to planned surgical resection followed by adjuvant radiotherapy (optional) and 1 year of adjuvant cemiplimab. The primary endpoint is pCR rate defined by IASLC consensus guidelines. Secondary endpoints include objective response rate (per RECIST v1.1), R0 resection rate, major pathologic response (≤10% viable tumor) rate, disease-free survival and overall survival. A total of 21 patients will be enrolled. A Simon-2 stage design will be used such that 12 patients will be enrolled initially and, if at least one pCR is observed, the trial will proceed to the second stage with enrollment of an additional 9 patients. This design yields a type I error rate of 5% and power of 80% when the true pCR rate is 20%. In addition, a Pocock stopping rule at 5% type I error will be deployed to assess feasibility of surgical resection. The study will be halted for futility if 8 of the first 12 patients do not proceed with surgical resection. The study is open for accrual at Georgetown University, University of Virginia, and Washington University. Clinical trial information: NCT06449313. Research Sponsor: Regeneron.

TPS8128 **Poster Session**

IFCT-2401 SPORADIC trial: Integrating cemiplimab to sequential hypofractionated chemoradiotherapy for unfit or elderly patients with unresectable stage III non–small cell lung cancer. First Author: Sébastien Thureau, Radiotherapy Department, QuantiF AIMS, Centre Henri Becquerel, Rouen, France

Background: Patients with unresectable stage III non-small cell lung cancer (NSCLC) who are elderly or have significant comorbidities are frequently ineligible for concurrent chemoradiotherapy (CCRT). Sequential chemoradiotherapy (seq-CRT) remains the preferred approach in this population. While consolidation immunotherapy after CCRT improves survival, evidence supporting its optimal integration with seq-CRT is limited. Preclinical and clinical data suggest that combining chemotherapy and immunotherapy enhances tumor immunogenicity through increased antigen release, immune priming, and modulation of the tumor microenvironment. Hypofractionated radiotherapy may further potentiate immune-mediated effects while shortening overall treatment duration, which is particularly relevant for frail patients. The IFCT-2401 SPORADIC trial evaluates in unfit or elderly patients a sequential strategy integrating neoadjuvant chemo-immunotherapy prior to hypofractionated radiotherapy, followed by maintenance immunotherapy, in patients with unresectable stage III NSCLC not eligible for CCRT. Exploratory correlative studies include circulating biomarkers, immune profiling, lymphopenia, and metabolic response assessment. **Methods:** IFCT-2401 SPORADIC is a multicenter, randomized, open-label phase II trial (EU-CT 2024-517316-29-00). Patients are randomized in a 2:1 ratio to receive neoadjuvant chemotherapy alone (arm A) or neoadjuvant chemo-immunotherapy (arm B). Neoadjuvant treatment consists of three 28-day cycles of carboplatin (AUC 5, day 1) and paclitaxel (80 mg/m², days 1, 8 and 15). Cemiplimab (350 mg, every 3 weeks) is added in arm B. All patients subsequently receive curative hypofractionated thoracic radiotherapy (55 Gy in 20 fractions), followed by maintenance cemiplimab every 3 weeks for up to 12 months. Eligible patients have unresectable stage IIIA–C NSCLC. Three categories of patients are considered unfit for CCRT: age ≥70 years with ECOG performance status (PS) 0 to 1, age < 70 years with ECOG PS 0 to 1 and significant comorbidities or age < 70 years with ECOG PS 2. Key exclusion criteria include actionable oncogenic drivers, prior systemic therapy for NSCLC and active autoimmune disease. The primary endpoint is progression-free survival. A total of 152 patients are planned for enrollment across 25 centers. First patient was enrolled on November 17, 2025. Clinical trial information: EU-CT 2024-517316-29-00. Research Sponsor: None.

TPS8129 **Poster Session**

Beamion LUNG-3: Zongertinib in resectable *HER2*-mutant NSCLC. First Author: Amy Lauren Cummings, University of California, Los Angeles (UCLA), Los Angeles, CA

Background: Zongertinib is an irreversible tyrosine kinase inhibitor that selectively inhibits HER2 while sparing wild-type EGFR, thereby minimizing associated toxicities. Based on recent data from the Phase Ib Beamion LUNG-1 trial (NCT04886804), zongertinib was approved in the USA (accelerated), China (conditional), and Japan for previously treated patients with advanced/metastatic *HER2*-mutant NSCLC. Clinically meaningful efficacy has also been seen with zongertinib as first-line therapy in treatment-naïve patients with advanced *HER2*-mutant NSCLC. Beamion LUNG-3 (NCT07195695) is an ongoing, global Phase III trial investigating zongertinib as adjuvant monotherapy compared with SoC (immunotherapy [IO] or observation) in patients with early-stage, resectable *HER2*-mutant NSCLC. **Methods:** Patients with histologically confirmed, resectable, Stage II–IIIB (post-operative, AJCC 9th edition) *HER2*-mutant NSCLC will be enrolled. Patients must be aged ≥18 years, have an ECOG PS of 0 or 1, have tumors that harbor a *HER2* mutation within the tyrosine kinase domain, and have completed 3–4 cycles of neoadjuvant platinum-based chemotherapy + IO or 4 cycles of adjuvant platinum-based chemotherapy (≥2 cycles permitted if discontinued due to toxicity), followed by complete surgical resection. Patients must have a full recovery from surgical procedures and the ability to be randomized within 2–8 weeks of the last treatment for patients who underwent adjuvant chemotherapy, or within 4–10 weeks of surgery for patients who underwent neoadjuvant therapy. Approximately 400 patients will be randomized 1:1 to receive zongertinib 120 mg once daily or physician's choice SoC (observation or IO with nivolumab, pembrolizumab, atezolizumab, or durvalumab). Stratification will be based on tumor stage (II, IIIA, IIIB), pretreatment (neoadjuvant/adjuvant), and physician's choice of SoC (IO/observation). Patients will remain on treatment for up to 3 years (if receiving zongertinib) or up to 1 year (if receiving SoC), or until tumor recurrence, undue toxicity, or any other protocol-defined stopping criterion. The primary endpoint is disease-free survival (DFS) by investigator assessment, defined as the time from randomization until tumor recurrence or death from any cause. Secondary endpoints include overall survival (OS, defined as the time from randomization until death from any cause) and occurrence of grade ≥3 adverse events from first treatment administration (or from randomization for patients in the observation arm) until the earliest of tumor recurrence or 3 years since treatment started. The trial will be conducted at ~200 sites in 32 countries; enrollment is ongoing. Results will inform whether HER2-targeted adjuvant therapy improves DFS and OS in patients with early-stage *HER2*-mutant NSCLC. Clinical trial information: NCT07195695. Research Sponsor: Boehringer Ingelheim.

TPS8130 **Poster Session**

Randomized, double-blind, phase 3 TRUST-IV study of adjuvant taletrectinib vs placebo in patients with stage IB–IIIA ROS1+ non-small cell lung cancer (NSCLC). First Author: Alexander I. Spira, Virginia Cancer Specialists and US Oncology, Fairfax, VA

Background: Taletrectinib is a next-generation, CNS-active, selective ROS1 tyrosine kinase inhibitor (TKI) approved by the US FDA for the treatment of locally advanced or metastatic ROS1+ NSCLC. In stage IB–IIIA NSCLC, which represents about 30% of NSCLC cases, the standard of care is surgical resection with perioperative systemic therapy (neoadjuvant or adjuvant). Results from Phase 3 trials have shown significantly improved outcomes for EGFR and ALK TKIs as adjuvant therapy compared with placebo or chemotherapy in early-stage NSCLC with EGFR mutations or ALK fusions, respectively. However, there remains an unmet need for patients with stage IB–IIIA ROS1+ NSCLC. Given the efficacy and tolerability of taletrectinib in advanced ROS1+ NSCLC, there is a rationale for investigating taletrectinib in patients with earlier-stage NSCLC who have undergone complete tumor resection. **Methods:** TRUST-IV (NCT07154706) is a randomized, double-blind, multicenter, Phase 3 study evaluating the efficacy and safety of taletrectinib compared with placebo in patients with stage IB, II, or IIIA ROS1+ NSCLC following curative surgery (negative surgical margins). ROS1 fusions may be detected using validated local tissue or liquid assays but must be confirmed by central tissue testing. Patients may have received prior adjuvant platinum-based chemotherapy ($\leq$4 cycles) if clinically indicated, which must be completed $\geq$7 days prior to randomization. Surgical resection must have occurred 4–16 weeks prior to randomization if no adjuvant chemotherapy was given or 4–30 weeks if adjuvant chemotherapy was given. The estimated enrollment is 180 patients, randomized 2:1 to receive either taletrectinib 400 mg once daily or a matched placebo, stratified by prior adjuvant chemotherapy (yes vs no) and pathological stage (IB vs II vs IIIA). Patients will receive blinded study drug in continuous 28-day cycles until disease recurrence or consent withdrawal, or up to a maximum of 3 years. Contrast computed tomography or magnetic resonance imaging (MRI) of the chest/abdomen/pelvis will be performed at screening, Cycle 4 Day 1 (C4D1), and C7D1, while brain MRI will be performed at screening and C7D1; thereafter, all imaging will be performed every 24 weeks until 5 years and then annually until disease recurrence or end of study. The primary endpoint is disease-free survival (DFS) by investigator assessment. Select secondary endpoints include: DFS rates at 2, 3, 4, and 5 years; DFS by blinded independent central review; overall survival; CNS-DFS; and safety. Exploratory endpoints include patient-reported outcomes for health-related quality-of-life measures and progression-free survival 2. The trial is currently recruiting. Clinical trial information: NCT07154706. Research Sponsor: This study was sponsored by Nuvation Bio Inc. Medical writing support was provided by Caroline Creasey, MSc, and Flaminia Fenoaltea, MSc, of Ashfield MedComms, an Inizio company, and was funded by Nuvation Bio Inc.

TPS8131 **Poster Session**

SWOG S2414 (INSIGHT): A randomized phase III trial incorporating pathologic complete response in participants with early-stage non-small cell lung cancer to optimize immunotherapy in the adjuvant setting. First Author: Jeremy Paul Cetnar, Oregon Health and Science University Knight Cancer Institute, Beaverton, OR

Background: Neoadjuvant chemo-immunotherapy (chemo-IO) followed by surgery is a standard of care for resectable clinical stage II-IIIB non-small cell lung cancer (NSCLC). Pathologic complete response (pCR), achieved in roughly 20% of patients, is associated with a favorable overall survival rate, but the benefit of additional adjuvant immunotherapy (IO) after pCR has not been independently studied and remains uncertain. The potential for overtreatment and unnecessary toxicity is a critical question in these patients. SWOG S2414 (INSIGHT) is designed to determine the optimal adjuvant therapy strategy for patients with pCR after neoadjuvant chemo-IO. **Methods:** INSIGHT (NCT06498635) is an open-label, randomized phase III trial, in which patients with clinical stage II-IIIB NSCLC who achieved pCR after standard of care neoadjuvant chemo-IO are randomized to adjuvant durvalumab IV every 28 days for up to 12 cycles (durvalumab, arm A) versus no further treatment (active surveillance, arm B). The primary objective is to compare disease free survival (DFS) between participants in the two arms. Key secondary endpoints include overall survival, event-free survival, and patient-reported quality of life (using the FACT-L and FACT-BRM) and symptoms (using PRO-CTCAE). The total enrollment goal is 306 participants. The design includes 2 interim analyses. Participants must have NSCLC with no known EGFR mutations or ALK fusions, and must have received at least two cycles of an FDA-approved neoadjuvant platinum-based chemo-IO regimen with an anti-PD-1/PD-L1 agent. Pathologic complete response will be confirmed by local pathology. Current Status: S2414 was activated on 3/14/2025, the first patient was registered on 4/1/2025. Enrollment is open and ongoing. Clinical Significance: INSIGHT is a pivotal trial addressing the therapeutic dilemma of adjuvant treatment for early-stage NSCLC patients with pCR after neoadjuvant chemo-IO. The results will help determine whether adjuvant IO provides a significant DFS benefit over surveillance in patients with a pCR, potentially leading to de-escalation of therapy and reduced toxicity. Funding: NIH/NCI grants U10CA180888, U10CA180819; additional support by AstraZeneca. Clinical trial information: NCI-2024-05588. Research Sponsor: NIH/NCI grants U10CA180888, U10CA180819; additional support by AstraZeneca.

TPS8132 **Poster Session**

Randomized multicenter phase II trial of radioimmunotherapy versus chemoimmunotherapy followed by surgery for c-stage IB-III NSCLC (RICHIS trial). First Author: Jonathan Villena-Vargas, Weill Cornell Medicine, New York, NY

Background: Chemotherapy combined with PD-1 or PD-L1 blockade (chemoimmunotherapy, ChemoIO), administered in the neoadjuvant, adjuvant, or perioperative setting, has become standard of care for surgically resectable non-small cell lung cancer (NSCLC). However, ChemoIO may be associated with significant toxicity that may limit treatment delivery and compromise surgical fitness. Preclinical data demonstrate that non-ablative stereotactic body radiotherapy (SBRT) can synergize with immunotherapy by enhancing tumor antigen release, interferon signaling, T-cell priming, and systemic antitumor immunity. We previously completed a phase II trial comparing neoadjuvant non-ablative SBRT (24 Gy) plus immunotherapy (SBRT-IO) versus immunotherapy alone, demonstrating favorable tolerability and higher rates of major and complete pathological response (MPR, pCR) in the SBRT-IO arm. SBRT-IO may therefore represent a neoadjuvant alternative for selected patients, with the potential to reduce treatment-related toxicity. **Methods:** RICHIS (NCT06623656) is an open-label, multicenter, randomized phase II trial enrolling approximately 112 patients with histologically confirmed, surgically resectable clinical stage IB-III (N2) NSCLC. Eligible patients are $\geq$18 years old, have ECOG performance status 0-1, and lack EGFR mutations or ALK fusions. Participants are randomized 1:1 to receive neoadjuvant SBRT-IO (SBRT 8 Gy $\times$ 3 fractions plus up to three cycles of cemiplimab) or standard ChemoIO (platinum-based doublet chemotherapy plus up to three cycles of cemiplimab). Randomization is stratified by tumor PD-L1 expression ($<$ 1% vs. $\geq$1%) and clinical stage (IB/II vs. III). Following neoadjuvant therapy, all patients undergo surgical resection and receive adjuvant cemiplimab for up to 12 months; patients in the SBRT-IO arm may additionally receive adjuvant chemotherapy. The primary endpoint is pCR. Key secondary endpoints include grade 3-5 adverse events (neoadjuvant and postoperative), event-free survival, MPR, and postoperative length of stay. Correlative immune and molecular biomarker studies are planned. Trial enrollment began on 2/4/2025 and is currently enrolling across 2 sites, with planned enrollment at 5 US sites. 19 of 112 patients are currently accrued. Clinical trial information: 24-02027124. Research Sponsor: Regeneron Pharmaceuticals.

TPS8133 **Poster Session**

A double-blind, double-dummy, randomized, controlled phase 3 trial of iparomlimab and tuvonralimab (QL1706) vs QL1604 as consolidation therapy following concurrent or sequential chemoradiotherapy (cCRT/sCRT) in patients (pts) with limited-stage small-cell lung cancer (LS-SCLC). First Author: Linlin Wang, Cancer Hospital of Shandong First Medical University (Shandong Cancer Institute, Shandong Cancer Hospital), Jinan, China

Background: LS-SCLC is a highly aggressive malignancy with poor prognosis. Positioning effective consolidation strategies is a key focus to improve long-term patient outcomes. Prominently, immune checkpoint inhibitors (ICIs) have emerged as consolidation therapy after cCRT or sCRT for LS-SCLC. QL1706 is a bifunctional antibody against both programmed cell death protein 1 (PD-1) and cytotoxic T-lymphocyte antigen 4, and iparomlimab (QL1604) is an anti-PD-1 agent. In previous studies, both QL1706 and QL1604 demonstrated manageable safety profiles. Notably, QL1706 also showed encouraging preliminary anti-tumor signals in SCLC, which indicated the potential as consolidation therapy (Zhao et al. 2023; Huang et al. 2023). This trial aims to compare the efficacy and safety of QL1706 and QL1604 as consolidation therapy in pts with LS-SCLC without progression after cCRT or sCRT. **Methods:** In this multicenter double-blind double-dummy randomized controlled phase 3 trial (NCT06789796), pts with pathologically-confirmed LS-SCLC per AJCC 8th edition are recruited. Pts are eligible if aged $\geq$18 years, with adequate organ function, ECOG PS scored 0 or 1, and do not have disease progression after completion of the requested cCRT or sCRT. Prophylactic cranial irradiation (PCI) is permitted before randomization. Approximately 636 pts are planned to be randomized 1:1 to receive either QL1706 (at 5 mg/kg) plus QL1604 placebo or QL1604 (at a fixed dose of 200 mg or at 3 mg/kg for pts weighing $<$40 kg) plus QL1706 placebo via intravenous infusion on day 1 in a 21-day cycle. Treatment will be continued until disease progression, intolerable toxicity, initiation of new anti-tumor treatment, withdrawal of informed consent, loss to follow-up, trial termination, or up to 24 months, whichever occurs first. Randomization is stratified by disease stage (I/II vs. III), receipt of PCI (yes vs. no), and the type of CRT (cCRT vs. sCRT). The co-primary endpoints are progression-free survival (PFS) per RECIST v1.1 assessed by blinded independent central review (BICR), and overall survival (OS). Secondary endpoints are investigator-assessed PFS, 1-year and 2-year PFS rates assessed by BICR and investigator, objective response rate, disease control rate, duration of response, 1-year and 2-year OS rates, safety, pharmacokinetics, and immunogenicity. Exploratory endpoints are biomarker assessments and their relationship to efficacy and prognosis, as well as patient-reported outcomes. Overall two-sided Type I error (α=0.05) controlled by fixed-sequence testing: BICR assessed PFS will be tested first, followed by OS if significant. An interim analysis is planned. The study will be conducted across around 79 sites in China, and enrollment is ongoing. Clinical trial information: NCT06789796. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

TPS8134 **Poster Session**

TIGOS-LS, an open-label, randomized study of BMS-986489 (atigotatug + nivolumab fixed-dose combination) vs durvalumab as consolidation therapy following chemoradiotherapy in limited-stage small-cell lung cancer. First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN

Background: Durvalumab consolidation was added to concurrent chemoradiotherapy for standard-of-care treatment of limited-stage small-cell lung cancer (LS-SCLC) in 2024. Although durvalumab improves overall survival (OS) and progression-free survival (PFS; Cheng et al. 2024), other agents may provide further improvement. BMS-986489 is a first-in-class fixed-dose combination of atigotatug and nivolumab. Atigotatug binds to fucosyl-monosialoganglioside-1 (fuc-GM1), which is highly expressed on SCLC cells and often absent in normal tissues. This binding causes tumor cell death via antibody-dependent cellular cytotoxicity, antibody-dependent cellular phagocytosis, or complement-dependent cytotoxicity. These processes trigger T cells, whose activation is also potentiated by nivolumab, which is hypothesized to improve outcomes after chemoradiotherapy. In a randomized Phase II study in extensive-stage SCLC, adding atigotatug to carboplatin, etoposide, and nivolumab (CE/NIVO) improved median OS vs CE/NIVO alone (15.6 months vs 11.4 months; Kalinka et al. 2024). **Methods:** TIGOS-LS is an open-label, randomized study evaluating the safety and efficacy of BMS-986489 vs durvalumab consolidation after chemoradiotherapy in LS-SCLC. Approximately 250 participants will be enrolled at 70 sites within the US. Eligible participants are adults with an Eastern Cooperative Oncology Group performance status of 0 or 1, histologically or cytologically confirmed SCLC evaluable by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 before standard treatment was initiated, LS disease determined by PET scan at the time of initial diagnosis or justified by the participant history, and inoperable disease, if Stage I/II. All participants must have completed concurrent chemoradiotherapy without progression. Prophylactic cranial irradiation (PCI) is permitted before study treatment. Expression of fuc-GM1 is not required; participants can enroll regardless of tissue availability for the trial. Participants requiring chronic systemic corticosteroids equivalent to $>$10 mg of prednisone at the time of enrollment are excluded. Stratification factors include disease stage (I/II vs III) and receipt of PCI. Randomization is 1:1 to BMS-986489 or durvalumab. BMS-986489 or durvalumab is administered intravenously at a fixed dose once every 4 weeks for up to 2 years or until discontinuation criteria are met. Response is evaluated by RECIST v1.1. Survival follow-up occurs every 12 weeks for up to 3 years. The primary endpoint is OS. Secondary endpoints include PFS, objective response rate, clinical benefit rate, disease control rate, duration of response, and safety parameters. TIGOS-LS (NCT06773910) opened to enrollment in March 2025; 232 enrollment slots remain. Clinical trial information: NCT06773910. Research Sponsor: Bristol Myers Squibb.

TPS8135 **Poster Session**

SEZanne: A phase 2 randomized, open-label, multicenter study to evaluate the optimal dose, safety, and efficacy of ABBV-706 in combination with atezolizumab (atezo) versus standard of care (SOC) in patients (pts) with previously untreated extensive-stage (ES) small cell lung cancer (SCLC). First Author: Kristof Cuppens, Jessa Hospital, Hasselt, Belgium and Faculty of Medicine and Life Sciences LCRC, UHasselt, Diepenbeek, Belgium

Background: SCLC is a neuroendocrine tumor accounting for ~15% of lung cancers, with a 5-year survival rate of ~7%. Platinum-based chemotherapy (PCT) remains the 1L SOC, achieving response rates of 60–70% in pts with ES-SCLC, though durable responses are rare. Adding a PD-L1 inhibitor (atezo or durvalumab) to PCT only modestly improves survival, and novel therapies are needed. Seizure-related homolog 6 (SEZ6), a neuroendocrine lineage marker highly expressed in SCLC, represents a promising target. ABBV-706, a SEZ6-directed antibody-drug conjugate with a topoisomerase 1 inhibitor payload, has shown promise as monotherapy in pts with relapsed SCLC, with an ORR of 57.3% (Byers et al. *J Thorac Oncol.* 2025;10:S23). The phase 2 SEZanne study (NCT07155174) evaluates the dose optimization, safety, and efficacy of ABBV-706 + atezo as a 1L regimen vs SOC. **Methods:** This global, open-label, randomized phase 2 study (~75 sites; up to 180 pts) compares ABBV-706 + atezo vs SOC. Eligible pts ($\geq$18 years) have ES-SCLC requiring 1L therapy, ECOG 0–1, measurable disease per RECIST v1.1, and are candidates for PCT. Primary objectives are to evaluate safety/tolerability, identify the recommended phase 3 dose, and assess PFS of ABBV-706 in combination with atezo. Secondary objectives are to further evaluate efficacy (ORR, DOR, DCR, OS) and characterize the PK/immunogenicity of the combination. The study consists of 2 parts: a safety lead-in (~30 pts) and a dose optimization (~150 pts) stage. During safety lead-in, pts are randomized 1:1:1 to 2 doses of ABBV-706 Q3W + atezo or SOC. SOC includes 4 cycles of PCT (carboplatin) + etoposide + atezo followed by atezo maintenance; lurbinectedin may also be used in maintenance where locally approved. After the safety lead-in, additional pts will be randomized to the ABBV-706 + atezo arms that were deemed safe, or the SOC arm. Treatment continues until progression, intolerable toxicity, or other discontinuation criteria are met. The study is enrolling. Clinical trial information: NCT07155174. Research Sponsor: AbbVie Inc.

TPS8136 **Poster Session**

A randomized, open-label, phase 3 study of ZL-1310, a DLL3 antibody-drug conjugate (ADC), compared to investigator's choice therapy in participants with relapsed small cell lung cancer (DLLEVATE). First Author: Afshin Dowlati, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH

Background: Small Cell Lung Cancer (SCLC) is a neuroendocrine tumor with high proliferation rate, early metastasis and poor prognosis. DLL3 is a validated target for neuroendocrine tumor and is highly expressed in SCLC. ZL-1310 is a novel antibody-drug conjugate (ADC) that employs the TMALIN (Tumor Microenvironment Activable LINker-payload) platform, an anti-DLL3 monoclonal antibody linked to a topoisomerase I inhibitor payload via a protease-cleavable linker. ZL-1310 has demonstrated encouraging systemic efficacy in heavily pre-treated ES-SCLC and showed intracranial activities. **Methods:** DLLEVATE is a randomized, open-label phase III study to further evaluate the efficacy and safety of ZL-1310 compared to investigator's choice of locally approved and available single agent therapy (ICT). This multi-country Phase III study (NCT07218146) enrolls adults with Extensive Stage (ES)-SCLC patients (pts) who have progressed after platinum-based first-line (1L) therapy or after tarlatamab as second-line (2L) therapy. Those with stable or asymptomatic BM are eligible (including those with no prior brain radiotherapy). The eligible pts are randomized at 1:1 according to presence/absence of brain metastasis, sensitivity to prior chemotherapy and with/without prior tarlatamab. ZL-1310 is given intravenously every 3 weeks until disease progression or unacceptable toxicity. Systemic efficacy is assessed by investigators using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Intracranial efficacy is assessed by blind independent radiologists using Modified Criteria for Radiographic Response Assessment in Neuro-Oncology (mRANO). The study has one interim analysis based on Objective Response Rate (ORR) assessed by Blind Independent Review Committee (BIRC) and the primary analysis based on Overall Survival (OS). Enrollment is underway, and is planned at ~250 sites across several continents. Clinical trial information: NCT07218146. Research Sponsor: Zai Lab (Shanghai) Co., Ltd.

TPS8137 **Poster Session**

A phase 3 study of sacituzumab govitecan in patients with previously treated extensive-stage small cell lung cancer. First Author: Afshin Dowlati, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH

Background: Treatment options for extensive-stage small cell lung cancer (ES-SCLC) that has progressed after platinum-containing therapy with or without anti–programmed cell death protein (ligand) 1 (anti–PD-[L]1) therapy are limited. Despite the evolving treatment landscape for ES-SCLC, toxicities and poor clinical outcomes with the current globally approved standard of care (SOC), topotecan, highlight the unmet need for novel agents. Sacituzumab govitecan (SG), a Trop-2–directed antibody-drug conjugate, demonstrated encouraging antitumor activity and manageable safety as a second-line treatment for ES-SCLC in the phase 2, open-label TROPiCS-03 study. At a median study follow-up of 12.3 months in TROPiCS-03, the investigator-assessed objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors, version 1.1 (RECIST v1.1) was 42% and median overall survival (OS) was 13.6 months. Neutropenia (44%) and diarrhea (9%) were the most common grade $\geq$3 treatment-emergent adverse events (TEAEs), and no TEAEs led to discontinuation of SG; 1 treatment-related TEAE caused death. EVOKE-SCLC-04 (NCT06801834) is a randomized, phase 3, open-label, multicenter study evaluating the efficacy and safety of SG versus SOC (topotecan, lurbinectedin [in countries/regions where approved], or amrubicin [Japan only]) in patients with previously treated ES-SCLC. **Methods:** Key eligibility criteria for EVOKE-SCLC-04 include age $\geq$18 years, confirmed SCLC diagnosis, Eastern Cooperative Oncology Group performance status score of 0–1, measurable disease per RECIST v1.1, and disease progression after 1 prior line of platinum-containing therapy with or without anti–PD-(L)1 therapy. Prior tarlatamab treatment is allowed. Patients with untreated central nervous system (CNS) metastases and/or carcinomatous meningitis are excluded unless these are asymptomatic and immediate CNS-specific treatment is not required. Patients will be randomized 1:1 to either SG (10 mg/kg on Days 1 and 8) or SOC: topotecan (1.5 mg/m^2 daily on Days 1–5), lurbinectedin (3.2 mg/m^2 on Day 1), or amrubicin (40 mg/m^2 daily on Days 1–3) administered as intravenous infusion in 21-day cycles, until progressive disease (assessed by investigator review per RECIST v1.1), unacceptable toxicity, or death. Randomization will be stratified by chemotherapy-free interval ($\geq$90 vs $<$90 days), CNS involvement (yes vs no), geographic region (East Asia vs non-East Asia), and prior anti–PD-(L)1 therapy (yes vs no). The primary endpoint is OS; secondary endpoints include progression-free survival, ORR, duration of response, patient-reported outcomes (time to first deterioration in shortness of breath and physical functioning), and safety/tolerability. This study is open and actively recruiting as of February 2025 and plans to enroll 695 patients from approximately 275 sites globally. Clinical trial information: NCT06801834. Research Sponsor: Gilead Sciences, Inc.

TPS8139 **Poster Session**

Durvalumab plus chemotherapy prior to chemoradiotherapy and followed by durvalumab as consolidation for patients with limited-stage small cell lung cancer (CONCUR study). First Author: Qian Chu, Department of Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: The ADRIATIC study demonstrated that durvalumab consolidation therapy following concurrent chemoradiotherapy (CRT) significantly improved both progression free survival (PFS) and overall survival (OS) in patients with inoperable limited-stage small-cell lung cancer (LS-SCLC), establishing the standard of care for this population. Building on emerging immune checkpoint inhibitor (ICI) strategies (pre-CRT induction, post-CRT consolidation or concurrent ICI-CRT), CONCUR study innovatively introduces durvalumab plus chemotherapy as induction to synergize early immune priming with cytotoxic effects, aiming to enhance responses during subsequent CRT while preserving safety, with potential to reshape the treatment landscape for LS-SCLC. **Methods:** Approximately 100 eligible patients (aged $\geq$ 18 years) with histologically or cytologically confirmed LS-SCLC, ECOG 0-1, at least one measurable lesion (RECIST 1.1), having received no prior thoracic radiotherapy or chemotherapy will be enrolled in this multi-center, phase II study. Patients will receive durvalumab (1500mg day[D] 1) combined with cisplatin (75 mg/m² D1 or 25 mg/m² D1-3) or carboplatin (AUC 5-6 D1 or AUC 2.5-3 D1 and D8) and etoposide (100 mg/m² D1-3) every 3 weeks for 2 cycles as induction therapy, followed by concurrent or sequential CRT. Thoracic radiotherapy will be delivered as 60 $\pm$ 6 Gy (1.8-2 Gy/day) or 45 $\pm$ 1.5 Gy (1.5Gy twice daily), with optional prophylactic cranial irradiation per clinical indication and local clinical practice. Patients showing at least stable disease after the definitive CRT will continue durvalumab (1500 mg every 4 weeks) until disease progression, unacceptable toxicities, or for up to 24 months (whichever occurs first). The primary endpoint is PFS by investigator per RECIST 1.1. Secondary endpoints include OS, objective response rate, duration of response, and safety. The primary analysis on PFS will be performed at approximately 60% data maturity. Assuming the median PFS is 16 months (defined from first dose of treatment), with an enrollment period of 12 months and drop-out rate of 7%, 100 patients and 60% PFS maturity will provide a precision of $\pm$ 4.8 months with 95% CI (11.6m, 21.1m) estimated by Kaplan-Meier method using Brookmeyer and Crowley method. Enrollment is ongoing. Clinical trial information: NCT07055581. Research Sponsor: None.

TPS8140 **Poster Session**

A phase II trial of ivonescimab for previously treated thymic carcinoma: UCLA L-11. First Author: Jonathan Boiarsky, University of California, Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Thymic carcinoma (TC) is a rare and aggressive thymic epithelial tumor (TET), accounting for approximately 20% of thymic neoplasms. TC is often more invasive and less responsive to standard therapy than other TETs, with a 5-year survival rate of 30-50% in the advanced/metastatic setting. Effective treatment remains limited following progression with platinum-based chemotherapy. Programmed Death-(Ligand) 1 (PD-(L)1) inhibition demonstrates modest activity in recurrent TC, with an objective response rate (ORR) of 19.5-22.5% with manageable toxicities [Cho, *Clin Oncol*. 2019; Giaccone, *J Thorac Oncol*. 2021]. Moreover, vascular epithelial growth factor (VEGF) inhibition with sunitinib or lenvatinib achieved ORRs of 26-38% in second line therapy and beyond (Thomas, *Lancet Oncol*. 2015; Sato, *Lancet Oncol*. 2020). Combination of lenvatinib and pembrolizumab as second line therapy and beyond has shown an ORR of 22.5%, with a median duration of response of 8.2 months (Remon, *Lancet Oncol. 2025*). Ivonescimab is a humanized bispecific monoclonal antibody targeting both PD-1 and VEGF and shows favorable safety and efficacy in non-small cell lung cancer. In light of the known benefit of VEGF and PD-(L)1 blockade in TC, this study aims to evaluate the safety and efficacy of ivonescimab in patients with previously treated TC. **Methods:** This study is a multi-center, open-label, single-arm Phase II trial enrolling adults with histologically or cytologically confirmed unresectable/metastatic TC whose disease has progressed following systemic therapy. Key inclusion criteria include one-prior line of treatment, ECOG performance status $\leq$1, and adequate organ function. Exclusion criteria include prior treatment with PD-(L)1 inhibitors, positive paraneoplastic serologies, or autoimmune disease requiring active systemic therapy. Ivonescimab is administered intravenously on D1 of a 21-day cycle until disease progression, unacceptable toxicity, withdrawal, or loss of follow up. The primary endpoints are investigator confirmed ORR via RECIST 1.1 and safety/tolerability of ivonescimab. Secondary endpoints include progression-free survival, duration of response, time to response, and overall survival. Exploratory analyses will evaluate correlation of antitumor activity with tissue and blood-based biomarkers, such as PD-L1 expression and circulating tumor DNA (ctDNA). The study uses a Simon's two stage design: in stage 1, 15 patients will be enrolled. The study will be stopped if $\geq$ 5 treatment-related serious adverse events or if $\leq$1 patient achieves an objective response within the first three months of treatment. Otherwise, an additional 10 patients will be enrolled in stage 2. The design has 80% power with a 5% Type I error to detect an ORR of 30% over the null hypothesis of 10%. The study is currently enrolling patients. Copyright © 2026 AACR. Originally presented at AACR 2026. Reprinted with permission. Clinical trial information: NCT06980077. Research Sponsor: Jonsson Comprehensive Cancer Center.

Sunvozertinib monotherapy versus platinum-based chemotherapy as first-line treatment for advanced NSCLC with EGFR exon20ins: Primary analysis of a multinational phase 3 randomized study (WU-KONG28). First Author: John V. Heymach, Department of Thoracic/Head and Neck Medical Oncology, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

8501 **Oral Abstract Session**

Overall survival of first-line amivantamab plus lazertinib in atypical *EGFR*-mutated advanced non-small cell lung cancer (NSCLC): Updated results from the CHRYSALIS-2 study. First Author: Joel W. Neal, Stanford Cancer Institute, Stanford University, Stanford, CA

Background: Patients with atypical *EGFR*-mutated advanced NSCLC have worse long-term outcomes with EGFR-targeted therapies than classical exon 19 deletion/L858R mutations (c*EGFR*). Afatinib, approved for atypical *EGFR*-mutated NSCLC, showed a median overall survival (OS) of 19.4 months among 38 participants (pts) with atypical *EGFR*-mutations globally (Yang *Lancet Oncol* 2015). Amivantamab (ami)-based regimens are approved across multiple lines of therapy in different settings for c*EGFR* and exon 20 insertion (Ex20ins)-mutated advanced NSCLC. In MARIPOSA, first-line (1L) ami plus lazertinib (ami-laz) significantly prolonged OS vs osimertinib (HR, 0.75; *P*=0.005) in c*EGFR*-mutated NSCLC. In an earlier report of 49 pts with atypical *EGFR*-mutated advanced NSCLC who received 1L ami-laz, objective response rate (ORR) was 57%, median response duration was 20.7 months, median progression-free survival (PFS) was 19.5 months, and OS was still immature (Tomasini *JCO* 2025). Here we report OS data with longer follow-up for pts with atypical *EGFR*-mutated NSCLC who received 1L ami-laz. **Methods:** Cohort C of the global, phase I/Ib CHRYSALIS-2 study (NCT04077463) enrolled pts with atypical *EGFR* mutations, excluding Ex20ins and co-mutations with c*EGFR*, who were previously untreated or had ≤2 prior lines of therapy, which may have included a 1st/2nd-generation EGFR TKI. All enrolled pts received intravenous ami-laz. The primary endpoint was ORR by investigator per RECIST v1.1, which has been previously reported. Here we report OS, a key secondary endpoint, in the treatment-naïve population (n=49). **Results:** As of Oct 31, 2025, the median follow-up was 31.3 months (range, 0.1–53.2). The median OS was 41.0 months (95% CI, 27.7–not estimable), with 55% alive at 3 years and 46% alive at 4 years. As of data cutoff, 20% (10/49; 6 were confirmed responders and 4 had stable disease) of pts were still ongoing 1L treatment (range, 2.5–4.4 years), with 7 pts receiving ami treatment for >3 years. Safety profile was consistent with prior reports; no additional safety signals were identified with longer-term follow-up. Among pts whose disease had progressed and discontinued 1L treatment, 71% (20/28) received subsequent therapy. The most common subsequent regimens included platinum-based chemotherapy agents (55%). **Conclusions:** 1L treatment of atypical *EGFR*-mutated advanced NSCLC with ami-laz resulted in a clinically meaningful median OS of nearly 3.5 years. Many pts were able to stay on 1L treatment long term, with 20% still ongoing. Ami-laz has now shown substantial survival benefit in both 1L c*EGFR*- and atypical *EGFR*-mutated disease. The recently FDA-approved subcutaneous formulation of ami may further simplify the overall treatment experience for this regimen. Clinical trial information: NCT04077463. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

8502 **Oral Abstract Session**

Lorlatinib vs crizotinib as first-line treatment for advanced *ALK*+ non-small cell lung cancer: 7-year update from the phase 3 CROWN study. First Author: Tony S.K. Mok, State Key Laboratory of Translational Oncology, Chinese University of Hong Kong, Hong Kong, China

Background: Median progression-free survival (PFS) was not reached (NR) with lorlatinib in the phase 3 CROWN study after 5 yrs of f/u, representing the longest PFS reported in advanced non-small cell lung cancer (NSCLC). Due to the unprecedented PFS benefit with lorlatinib after 5 yrs of f/u and the decreased event rate after the first 24 mos in the study, we aimed to quantify long-term outcomes at 7 yrs. **Methods:** 296 treatment-naive patients (pts) with advanced *ALK*+ NSCLC were randomized 1:1 to receive lorlatinib 100 mg once daily (n=149) or crizotinib 250 mg twice daily (n=147). This post hoc analysis presents investigator-assessed efficacy outcomes, safety, and biomarker analyses. Formal statistical testing between arms was not performed. **Results:** As of October 31, 2025, 66 of 149 pts (44%) vs 4 of 142 (3%) were receiving lorlatinib vs crizotinib. With a median f/u for PFS (95% CI) of 83.0 (81.2-86.3) and 77.2 mos (36.8-not evaluable), respectively, median PFS (95% CI) was NR (68.5-NR) with lorlatinib and 9.1 mos (7.4-10.9) with crizotinib (HR, 0.19; 95% CI, 0.13-0.26); the 7-yr PFS (95% CI) was 55% (46-63) and 3% (1-8). In the lorlatinib arm, pts without a PFS event at the end of 24 mos had a 79% probability of survival without progression at yr 7. PFS benefit was consistent across all prespecified subgroups. No new intracranial (IC) progression events occurred after the first 30 mos on lorlatinib. Median time to IC progression (95% CI) was NR (NR-NR) with lorlatinib and 16.4 mos (12.7-21.9) with crizotinib (HR, 0.06; 95% CI, 0.03-0.12). The number of overall survival (OS) events for a protocol-specified analysis has not been met; OS f/u is still ongoing. The safety profile was consistent with the 5-yr results, with all-cause grade 3/4 adverse events (AEs) in 77% of pts with lorlatinib and 57% with crizotinib. Treatment-related AEs (TRAEs) led to permanent treatment discontinuation in 5% of pts with lorlatinib and 6% with crizotinib. No new permanent discontinuations due to TRAEs occurred after the first 26 mos with lorlatinib. Dose reductions were reported in 34% of pts in the lorlatinib arm (17% had 1 dose reduction and 17% had 2 reductions). Long-term efficacy was similar between pts with and without dose reduction. Exploratory translational analyses of outcomes in pts with different molecular subtypes and resistance mechanisms at the end of treatment are ongoing. **Conclusions:** With median PFS yet to be reached after 7 yrs of f/u in CROWN, lorlatinib continues to show unprecedented and highly durable benefit in treatment-naïve pts with advanced *ALK*+ NSCLC. In pts without a PFS event at 24 mos, the probability of survival without progressive disease at 7 yrs was 79%. Longer f/u showed very few additional PFS events, no new IC progression, and no new treatment-related discontinuation, suggesting long-term substantial benefit with lorlatinib for the majority of pts with advanced *ALK*+ NSCLC. Clinical trial information: NCT03052608. Research Sponsor: Pfizer.

8503 **Oral Abstract Session**

ALKOVE-1: Efficacy and safety of neladalkib in patients with advanced *ALK*+ NSCLC. First Author: Jessica Jiyeong Lin, Mass General Brigham Cancer Institute, Boston, MA

Background: Neladalkib is an investigational ALK TKI designed for inhibition of ALK single and compound resistance mutations, brain penetrance, and sparing TRK. We report the first analyses of phase 2 TKI pre-treated patients (pts) and preliminary data in TKI-naïve pts with *ALK*+ NSCLC. **Methods:** The global, single arm phase 1/2 ALKOVE-1 trial (NCT05384626) enrolled pts with advanced/metastatic *ALK*+ NSCLC. Key study endpoints are objective response rate (ORR, RECIST v1.1 by BICR), duration of response (DOR), intracranial ORR (IC-ORR) and safety. Efficacy analyses included TKI pre-treated pts who initiated neladalkib 150 mg QD by 30 Sep 2024 or all treated TKI-naïve pts. Data cut: 29 Aug 2025. **Results:** 656 pts with *ALK*+ NSCLC received neladalkib. Efficacy-evaluable TKI pre-treated pts (n=253) had received a median of 3 prior anticancer therapies (range 1-11, 51% prior chemo). 78% of pts received ≥2 (range 2-5) prior ALK TKIs, of whom 91% had prior lorlatinib. 19% had single or compound ALK G1202R resistance mutations. 40% had CNS disease by BICR. ALK TKI pre-treated results are reported in the Table. In a preliminary analysis of TKI-naïve pts, ORR was 86% (38/44, 2 uPRs); 12-month DOR rate was 91%. IC-ORR was 78% (7/9) with no CNS progression events as of data cutoff. **Conclusions:** In this ALK TKI pre-treated data set, neladalkib demonstrated clinically meaningful activity, including in pts with CNS disease, ALK G1202R single or compound mutations, and prior lorlatinib. Encouraging preliminary activity was also observed in TKI-naïve pts. Neladalkib's safety profile was consistent with its ALK-selective, TRK-sparing design. Clinical trial information: NCT05384626. Research Sponsor: Nuvalent, Inc.

Efficacy Parameter (RECIST v1.1, BICR)	All ALK TKI Pre-treated ± chemo	ALK TKI Pre-treated, Lorlatinib-naïve ± chemo
ORR % (n/N)	31 (79/253)[a, b]	46 (29/63)[c]

8504 Oral Abstract Session

Efficacy and safety of pralsetinib as first-line treatment of *RET* fusion–positive advanced or metastatic non–small cell lung cancer (NSCLC): The phase 3 AcceleRET-Lung study. First Author: Sanjay Popat, Royal Marsden Hospital & Institute of Cancer Research, London, United Kingdom

Background: Pralsetinib, an oral tyrosine kinase inhibitor, selectively and potently targets oncogenic *RET* fusion and mutation proteins. Pralsetinib is FDA approved to treat adults with metastatic *RET*-altered NSCLC. We present efficacy and safety of pralsetinib vs standard of care (SOC) in first-line *RET* fusion-positive NSCLC from a randomized phase 3, open-label study, AcceleRET-Lung (NCT04222972). **Methods:** AcceleRET-Lung was conducted at 74 sites in 22 countries. Adults with *RET* fusion-positive advanced or metastatic NSCLC received pralsetinib 400 mg/d or platinum-based SOC therapy. Crossover to pralsetinib was optional upon progression. The primary end point was progression-free survival (PFS) per RECIST v1.1. Secondary end points included overall response rate (ORR), overall survival (OS), duration of response (DOR), and safety. Efficacy was evaluated in randomized patients (intent-to-treat population [ITT]). Safety was assessed in patients receiving ≥1 dose of study drug. **Results:** 223 ITT patients were randomized to pralsetinib (n=110) or SOC (n=113). Pralsetinib and SOC groups had similar baseline characteristics (median age: 62 and 63 y, respectively; female: 48% and 57%; median lesions: both 4; brain metastases: 15% and 16%). The study was terminated early per sponsor decision on January 27, 2025. ITT patients in the pralsetinib group had significantly greater median PFS vs SOC (18.7 vs 9.0 mo; P=0.003), ORR (65.5% vs 41.6%; $P<0.001$), and median DOR (20.6 vs 9.7 mo; P=0.004; Table). Safety was generally consistent with the known pralsetinib profile except for a higher rate of infection in the pralsetinib group vs SOC (71.3% vs 51.9%), including pneumonia (19.4% vs 5.8%), urinary tract infections (17.6% vs 7.7%), and opportunistic infections (9.3% vs 1.0%). There were 32 (30.0%) and 26 (25.0%) deaths in the pralsetinib and SOC groups, respectively, with 8 (7.4%) and 0 due to infection. Common grade ≥3 TRAEs in the pralsetinib vs SOC groups were hypertension (11.1% vs 0), neutropenia (10.2% vs 8.7%), anemia (8.3% vs 10.6%), and decreased neutrophil count (7.4% vs 4.8%). **Conclusions:** In a Phase 3 study, pralsetinib met the primary PFS end point and had a significantly greater and more durable ORR vs SOC, confirming the clinical utility of pralsetinib in *RET* fusion-positive NSCLC. Monitoring for infections with pralsetinib is warranted. Clinical trial information: (1) NCT04222972; (2) 2023-505035-12-00; (3) 2019-002463-10. Research Sponsor: Rigel Pharmaceuticals, Inc.

8505 Oral Abstract Session

Efficacy and safety of lunbotinib (A400/EP0031), a next-generation selective RET inhibitor (SRI), from a pivotal phase II study in patients with advanced *RET* fusion–positive non–small cell lung cancer (NSCLC). First Author: Qing Zhou, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: RET-fusion positive NSCLC accounts for 1-2% of all lung cancers. Lunbotinib is a next gen brain-penetrant SRI with high potency against RET fusion and mutant proteins (*Zhou et al., 2023; Alonso et al., 2025*). We report findings from a pivotal phase II study in advanced RET-fusion positive NSCLC in China (NCT05265091). An ongoing study is assessing lunbotinib alone or in combination with chemotherapy in Western patients (pts) (NCT05443126). **Methods:** The phase II part enrolled two single-arm cohorts: cohort 1 included pts with prior platinum-based chemotherapy and immunotherapy (pre-treated), and cohort 2 included treatment-naïve pts. All pts received oral lunbotinib 90 mg once daily in 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint was ORR assessed by an independent review committee (IRC) per RECIST v1.1. **Results:** As of Oct 29, 2025, 71 pre-treated pts and 92 treatment-naïve pts were enrolled, with median follow-up of 22.6 and 20.7 mos, respectively. Among pre-treated and treatment-naïve pts in full analysis set (FAS), ECOG PS 1 rates were 90% and 80.2%, and metastases involving ≥3 organ sites were observed in 75.7% and 57.1%. IRC-assessed confirmed ORR was 87.1% (95% CI: 77.0-93.9) in pre-treated pts and 81.3% (95% CI: 71.8-88.7) in treatment-naïve pts. mPFS was 27.5 mos and NR, respectively. Among pts with baseline CNS metastases (23 pre-treated, 16 treatment-naïve), ORR was 82.6% and 75.0%, respectively, and 6 pts in each cohort had complete intracranial response. Full efficacy data are in Table. Treatment-related AEs (TRAEs) occurred in 98.8% of pts, the most common were AST (72.4%), ALT (68.1%), anemia (63.2%), urinary retention (45.4%), dry eye (43.6%), and increased blood creatinine (42.9%). Grade ≥ 3 TRAEs observed in 40.5%. Two pts (1.2%) discontinued due to TRAEs. No fatal TRAEs occurred. **Conclusions:** Lunbotinib demonstrated robust efficacy in pts with advanced RET-fusion positive NSCLC, with high ORR and prolonged PFS in both pre-treated and treatment-naïve populations, and notable intracranial activity. Safety profile was manageable, with no new signals identified. These data support the potential of lunbotinib as a valuable therapeutic option for this population. Clinical trial information: NCT05265091. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

8506 Oral Abstract Session

Sacituzumab tirumotecan (sac-TMT) plus pembrolizumab (P) versus pembrolizumab (P) as first-line treatment for PD-L1–positive advanced non-small cell lung cancer (NSCLC): Results from the randomized phase 3 OptiTROP-Lung05 study. First Author: Caicun Zhou, Department of Oncology, Shanghai East Hospital, Tongji University, Shanghai, China

Background: Pembrolizumab has been the standard first-line treatment for PD-L1 positive advanced NSCLC. Sac-TMT, a TROP2-directed antibody-drug conjugate with a unique bifunctional linker, and PD-1/L1 inhibitors demonstrate complementary mechanisms that enhance antitumor activity in the first-line treatment of NSCLC (*Hong et al., Nat Med, 2025*). Here, we report the results from the planned interim analysis for PFS in this phase 3 OptiTROP-Lung05 study (NCT06448312). **Methods:** Eligible patients (pts) had treatment-naïve, locally advanced or metastatic NSCLC without *EGFR/ALK* alterations and positive PD-L1 expression (defined as TPS ≥1%, 22C3 assay). Pts were stratified by PD-L1 (TPS 1-49% vs ≥ 50%), histology (squamous vs non-squamous) and ECOG (0 vs 1) and then randomized (1:1) to receive sac-TMT 4 mg/kg Q2W plus P 400 mg Q6W or P 400 mg Q6W. The primary endpoint was PFS per RECIST 1.1 assessed by blinded independent central review (BICR), and the key secondary endpoint was OS. **Results:** A total of 413 pts (median age 65 yrs; 84.5% ECOG 1; 40.0% squamous; 40.0% PD-L1 TPS ≥ 50%) were randomized to receive sac-TMT + P (n = 208) or P (n = 205). As of Sep 29, 2025, the median follow-up was 10.5 months. PFS by BICR was significantly longer in the sac-TMT + P group than the P group (median, not reached vs 5.7 months; HR, 0.35; 95% CI, 0.26-0.47; $p< 0.0001$). The data for OS were not mature, and a favorable trend was observed in the sac-TMT + P group (HR, 0.55; 95% CI, 0.36-0.85). The BICR-assessed ORR was 70.2% in the sac-TMT + P group versus 42.0% in the P group. In the pre-specified PD-L1 subgroups, the HRs for PFS in pts with TPS 1-49% and TPS ≥ 50% were 0.28 (95% CI, 0.19-0.41) and 0.47 (95% CI, 0.29-0.77). In the pre-specified histology subgroups, the HRs for PFS in pts with non-squamous and squamous were 0.28 (95% CI, 0.18-0.43) and 0.44 (95% CI, 0.29-0.66). Grade ≥ 3 TEAEs were 55.3% in the sac-TMT + P group and 31.4% in the P group. Most common grade ≥3 TEAEs of special interest for sac-TMT were neutrophil count decreased (17.3%), anemia (9.1%), and stomatitis (5.3%). TEAEs led to discontinuation of sac-TMT/ pembrolizumab in 3.8%/5.3% of pts in the sac-TMT + P group while discontinuation of pembrolizumab occurred in 4.9% of pts in the P group. **Conclusions:** To our knowledge, this is the first phase 3 study to demonstrate the significant PFS benefit of an antibody-drug conjugate plus pembrolizumab in the first-line treatment of PD-L1 positive advanced NSCLC compared to pembrolizumab. The safety profile of sac-TMT + P was generally manageable and consistent with the safety profile of the components. No new safety signals were seen. These results from phase 3 OptiTROP-Lung05 study support sac-TMT + P as a potential new treatment option for this population. Clinical trial information: NCT06448312. A randomized, open-label, parallel-controlled phase 3 trial of benmelstobart plus chemotherapy and anlotinib for first-line treatment of advanced non-squamous non–small cell lung cancer. First Author: Yuankai Shi, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College., Beijing, China

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

8509 Clinical Science Symposium

Neoadjuvant almonertinib followed by chemo-immunotherapy in II-IIIb EGFR-mutant NSCLC: A single arm, phase II study (NEOVADE). First Author: Jun-Tao Lin, Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: Neoadjuvant target therapy has improved objective response rate (ORR) or major pathological response (MPR) of stage IIA-IIIB non-small cell lung cancer (NSCLC) with EGFR mutation. EGFR-TKI-induced evolution indicated a hot-tumor status in residual disease. However, the role of immunotherapy in this phrase remained unclear. Here, we present the results of a phase II, open-label study investigating the efficacy and safety of sequential almonertinib and chemo-immunotherapy (IO) in potentially resectable stage IIA-IIIB EGFR-mutant NSCLC patients. (NCT06300424). **Methods:** Untreated patients with II-IIIB NSCLC were enrolled in this study. Patients received almonertinib for 6 weeks, followed by 3 cycles of adebrelimab and chemotherapy before surgery. Primary end point was MPR, Secondary end points included pathological complete response (PCR), ORR, event-free survival (EFS), overall survival (OS) and safety. **Results:** A total of 32 patients were enrolled from Apr 2024 to Aug 2025. EGFR mutation subtype was 19del in 16 (50.0%) patients, L858R in 11 (34.4%) patients, others in 5 (15.6%) patients. All the patients completed neoadjuvant almonertinib, 30 (93.8%) patients completed 3 circles of chemo-IO and underwent surgery, R0 was achieved in 29 (96.7%) patients. ORR was 46.9% (15/32) and 59.4% (19/32) after target therapy and chemo-IO, respectively. MPR was documented in 13 (40.6%) patients, including PCR in 5 (15.6%) patients. In patients underwent resection, MRP and PCR rate were 66.7% and 33.3% in patients with PD-L1≥1%, compared with 21.4% and 0% in PD-L1 < 1% subgroup, respectively, N downstage was confirmed in 44.8% (13/29) patients. After a median follow-up of 13.5 months (interquartile range [IQR], 7.5–16.1 months), 31 (96.9%) patients were alive. Median EFS and OS were not reached. One-year EFS and OS rate was 89.5% and 95.2%, respectively. Grade ≥ 3 AEs occurred in 28 (87.5%) patients during neoadjuvant therapy. **Conclusions:** This study met its primary endpoint, indicating almonertinib followed by chemo-IO was a feasible neoadjuvant treatment in patients with resectable stage IIA-IIIB EGFR-mutant NSCLC, especially in patients with PD-L1 expression. The study was partially supported by Jiangsu Hengrui Pharmaceuticals and Hansoh Pharmaceutical Group Co. Ltd. Clinical trial information: NCT06300424. Research Sponsor: None.

Primary and secondary outcomes.

Outcomes	ITT (N=32)	Resection (N=29)
Major pathological response rate	40.6% (13/32)	44.8% (13/29)
PD-L1 < 1%	18.8% (3/16)	21.4% (3/14)
PD-L1≥1%	62.5% (10/16)	66.7% (10/15)
Complete pathological response rate	15.6% (5/32)	17.2% (5/29)
PD-L1 < 1%	0.0% (0/16)	0.0% (0/14)
PD-L1≥1%	31.3% (5/16)	33.3% (5/15)
After receiving neoadjuvant TKI		
ORR	46.9% (15/32)	44.8% (13/29)
DCR	93.8% (30/32)	96.6% (28/29)
After receiving neoadjuvant TKI+IO		
ORR	59.4% (19/32)	58.6% (17/29)
DCR	100.0% (32/32)	100.0% (29/29)

TKI: Tyrosine kinase inhibitor; IO: Immunotherapy.

8510 Clinical Science Symposium

First-line (1L) divarasib plus pembrolizumab (pembro) in advanced or metastatic *KRAS* G12C+ non–small cell lung cancer (NSCLC): Results from the Krascendo-170 study. First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Krascendo 170 (NCT05789082) is an open-label, phase Ib/II, dose-finding and -expansion study of divarasib, an oral next-generation KRAS G12C inhibitor, with/without other anti-cancer therapies in 1L *KRAS G12C*+ NSCLC. We report the primary analysis for pts receiving divarasib plus pembro in the programmed death-ligand 1 (PD-L1)-positive cohort (tumor cell [TC] ≥1%; cohort A1) and key preliminary data for the PD-L1-negative cohort (TC <1%; cohort A2). **Methods:** Eligible pts were aged ≥18 years with untreated advanced or metastatic *KRAS G12C*+ NSCLC and ECOG PS ≤1. All pts received oral divarasib once daily plus intravenous pembro 200 mg once every 3 weeks until loss of clinical benefit, disease progression, study withdrawal or unacceptable toxicity. In cohort A1, pts were randomized 1:1 to receive divarasib 200 or 400 mg. In cohort A2, all pts received divarasib 400 mg. We present data only from pts receiving divarasib 400 mg. Primary endpoints were safety and tolerability. Secondary endpoints included objective response rate (ORR), progression-free survival (PFS) and duration of response (DOR; all investigator-assessed per RECIST v1.1). **Results:** At data cutoff (Oct 29, 2025), 59 pts were enrolled to receive divarasib 400 mg in cohort A1 and 23 pts in cohort A2. In cohort A1 (median duration of divarasib treatment 10.6 months [range 0.3–24.3]), treatment-related AEs (TRAEs; divarasib- or pembro-related) were reported in 98% of pts; 65% of pts had grade (gr) 3/4 TRAEs and 0% had gr 5 TRAEs (Table). The most common TRAEs were diarrhea (75%; gr 3/4 16%), nausea (64%; gr 3/4 2%), vomiting (49%; gr 3/4 2%), ALT increase (49%; gr 3/4 20%) and AST increase (47%; gr 3/4 18%). In cohort A1, confirmed ORR was 73%, no patients had progressive disease as their best response, median DOR was not reached and median PFS was 19.3 months (95% CI 12.4–not estimable [NE]). In cohort A2 (median duration of divarasib treatment 2.8 months [range 0.5–8.8]), TRAEs were reported in 100% of pts (65% gr 3/4; 0% gr 5) and unconfirmed ORR was 70%. **Conclusions:** In Krascendo 170, divarasib 400 mg once daily plus pembro had a manageable safety profile. Promising efficacy was shown in pts with advanced *KRAS G12C*+ NSCLC in both PD-L1- positive and -negative cohorts. A global, phase III trial investigating divarasib 400 mg in 1L advanced *KRAS G12C*+ NSCLC (Krascendo 2; NCT06793215) is currently enrolling. Clinical trial information: NCT05789082. Research Sponsor: This study is sponsored by F. Hoffmann-La Roche Ltd.; Third-party medical writing assistance, under the direction of the authors, was provided by Tahmina S. Alam, MA, and Rebecca Benatan, BSc, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

8511 Clinical Science Symposium

Elisrasib (D3S-001), a next-generation GDP-bound KRAS G12C inhibitor, as first-line therapy for *KRAS* G12C mutation–positive non–small cell lung cancer (NSCLC). First Author: Shun Lu, Shanghai Chest Hospital, Shanghai, Jiao Tong University, School of Medicine, Shanghai, China

Background: Elisrasib (D3S-001) is a next-generation KRAS G12C inhibitor (G12Ci) designed to improve target engagement (TE) efficiency and overcome growth factor-induced nucleotide exchange. This unique MoA distinguishes elisrasib from prior G12Ci and has demonstrated robust and durable anti-tumor activity in PDX models, and in combination with immunotherapy (IO) in immunocompetent models. Current ongoing phase 1/2 trial (NCT05410145) evaluates elisrasib as monotherapy (mono) or combination (combo) with pembrolizumab as first line (1L) therapy for advanced NSCLC harboring G12C mutation. **Methods:** Treatment naïve patients (pts) with G12C mutant advanced stage NSCLC were eligible. Elisrasib is administered 600mg QD orally in a 21-day cycle as mono or combo with pembrolizumab i.v. 200mg Q3W. The key objectives included safety and efficacy. ctDNA dynamic was analyzed by Guardant360 CDx or OncoCompass Target panels. **Results:** As of 06 Jan 2026, 43 pts and 52 pts received mono and combo. Median study follow up was 8.5m and 5.7m in mono and combo, respectively. In mono, 41 (PD-L1 TPS [22C3]: 21 <1% and 20 ≥1%) out of 43 pts were efficacy evaluable. Overall ORR was 78.0% (32/41). Subgroup ORRs in TPS <1% and ≥1% were 76.2% and 80.0%, respectively. Median PFS and DOR were immature. 6m PFS rate was 68.9% and 6m DOR rate was 77.2%. Above results provide first time evidence of G12Ci monotherapy in 1L NSCLC. In combo, 48 (PD-L1 TPS [22C3]: 17 <1%, 11 1-49%, and 20 ≥50%) out of 52 pts were efficacy evaluable. Overall ORR was 81.2% (39/48). Subgroup ORRs in TPS <1%, 1-49%, and ≥50% were 70.6%, 72.7% and 95.0%, respectively. Median PFS and DOR in the overall combo population were immature. 6m PFS rate was 74.6% and 6m DOR rate was 80.5%. Toxicity profile is summarized in Table. Baseline ctDNA G12C+ was detected in 90% (37/41) of mono and 80% (37/46) of combo. 35 mono and 25 combo pts completed on-treatment ctDNA analysis, with 83% and 100% achieved molecular response (≥90% G12C MAF reduction), respectively. PK at 600mg QD achieved C_{trough} exposure of ~5nM and ~3nM with mono and combo, respectively, with overlapping variabilities at steady state, both well above the required exposure (1nM) for complete TE. **Conclusions:** Both elisrasib monotherapy and in combination with pembrolizumab show strong efficacy and good tolerability as 1L treatments for G12C-mutant NSCLC, warrant for randomized study to evaluate elisrasib as a potential new standard of care. Clinical trial information: NCT05410145. Research Sponsor: D3 Bio.

8512 Rapid Oral Abstract Session

Efficacy and safety of HLX43 (anti–PD-L1 ADC) in patients with advanced non–small cell lung cancer. First Author: Jie Wang, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: HLX43 (a PD-L1 ADC) has demonstrated encouraging efficacy with a manageable safety in a phase 1 study. Here, we present the pooled findings from patients with NSCLC in a phase 1 study (HLX43-FIH101) as well as a global phase 2 study investigating HLX43 in NSCLC (HLX43-NSCLC201). **Methods:** The phase 1 study included a dose-escalation phase in patients with advanced solid tumors (0.5–4.0 mg/kg Q3W), followed by a dose-expansion phase in patients with advanced or metastatic NSCLC at doses of 2.0, 2.5, and 3.0 mg/kg Q3W. The phase 2 study was conducted in NSCLC and comprised two parts: Part A was dose-exploration for patients who had failed prior first-line therapy and had no actionable genomic alterations, to receive HLX43 at 2.0 or 2.5 mg/kg Q3W; Part B was dose-expansion in which patients received HLX43 at the recommended dose determined from Part A. This analysis integrated data from heavily pretreated NSCLC patients enrolled across both studies. Efficacy and safety outcomes were evaluated in the pooled population. **Results:** As of December 31, 2025, 205 patients were enrolled and received HLX43 at 1 mg/kg (n = 3), 2 mg/kg (n = 89), 2.5 mg/kg (n = 85), 3 mg/kg (n = 23), and 4 mg/kg (n = 5). Patients received a median of 2 lines of prior antitumor therapy (range, 1–9). Among the 161 response-evaluable patients (2, 69, 64, 21, and 5 in the 1, 2, 2.5, 3, and 4 mg/kg groups, respectively), the investigator-assessed ORR was 31.1%. In the 2.0 mg/kg group, investigator-assessed ORR was 36.4% for squamous NSCLC (n = 33); among these patients, ORR was 40.0% for those who previously failed docetaxel (n = 15). ORR was 47.4%, and 50.0% for patients with EGFR-wildtype (n = 19), and EGFR-mutant (n = 16) nonsquamous NSCLC receiving HLX43 at 2.5 mg/kg. Biomarker exploratory analyses showed that efficacy was not associated with PD-L1 expression, with ORRs of 30.1% and 32.1% in patients with PD-L1-positive (n = 83) and PD-L1-negative tumors (n = 78), respectively. Overall, 199 (97.1%) patients experienced treatment-related adverse events (TRAEs), of whom 88 (42.9%) had grade ≥3 in severity. Most common Grade ≥3 TRAEs (incidence ≥10%) included lymphocyte count decreased (n = 47, 22.9%), white blood cell count decreased (n = 27, 13.2%), anemia (n = 25, 12.2%), and neutrophil count decreased (n = 23, 11.2%). TRAEs led to treatment discontinuation in 17 (8.3%) patients. **Conclusions:** HLX43 exhibited promising efficacy in patients with heavily pretreated advanced NSCLC, regardless of histology subtypes, and PD-L1 expression, along with manageable tolerability. Further investigation is warranted. Clinical trial information: NCT06115642 (HLX43-FIH101-phase 1 study), NCT06907615 (HLX43-NSCLC201- phase 2 study). Research Sponsor: Shanghai Henlius Biotech, Inc.

Phase 2 data from ROSETTA Lung-02, a global randomized phase 2/3 trial of pumitamig (PD-L1 × VEGF-A bsAb) + chemotherapy in 1L NSCLC. First Author: Solange Peters, Oncology Department, Centre Hospitalier Universitaire Vaudois, Lausanne University, Lausanne, Switzerland

Background: Pumitamig (BNT327/BMS986545) is an investigational PD-L1 × VEGF-A bsAb designed to restore effector T-cell function by binding PD-L1 and localizing VEGF-A neutralization within the tumor microenvironment. We present the prespecified interim analysis of the Phase 2 dose-optimization part of the global Phase 2/3 ROSETTA Lung-02 trial (NCT06712316) evaluating the recommended Phase 3 dose of pumitamig + chemotherapy in 1L NSCLC. **Methods:** The Phase 2 part of ROSETTA Lung-02 enrolled pts with treatment-naïve advanced NSCLC, no actionable genomic alterations, regardless of PD-L1 status, ECOG PS ≤1, and ≥1 measurable lesion per RECIST v1.1 into two substudies based on histology (nonsquamous [NSQ] and squamous [SQ]). Pts were randomized 1:1 to 1400 mg (dose level [DL] 1) or 2000 mg (DL2) pumitamig + histology-specific chemotherapy Q3W (NSQ: carboplatin + pemetrexed; SQ: carboplatin + paclitaxel). Primary endpoints were safety, overall response rate (ORR), and best percentage change in tumor size from baseline. Key secondary endpoints include duration of response (DOR) and disease control rate (DCR). **Results:** The Phase 2 part enrolled 44 pts (NSQ n=23; SQ n=21; data cutoff Nov 21, 2025). Median age was 66 y (range: 41–87), and 27 (61.4%) pts had ECOG PS 1. Among 40 response-evaluable pts, best overall response was CR in 2 pts, PR in 26, and SD in 12, for an ORR of 70.0% (28/40; confirmed ORR was 52.5% [21/40], 5 pending confirmation) and DCR of 100%. DOR data were not mature at the time of data cutoff. Median best change in tumor volume was -38.2% (NSQ -36.6%; SQ -39.7%). In NSQ NSCLC, ORR was 66.7% (14/21) and, by pumitamig dose, it was 72.7% for DL1 (8/11) and 60.0% for DL2 (6/10). In SQ NSCLC, ORR was 73.7% (14/19), 81.8% for DL1 (9/11) and 62.5% for DL2 (5/8). Central PD-L1 levels were available for 35 pts (PD-L1 <1% [n=20], 1–49% [n=9], ≥50% [n=6]), with activity across PD-L1 levels. Circulating tumor DNA dynamics were assessed. Median treatment duration was 4.5 mo (range: 0.1–8.8) with 30 (69.8%) pts still on treatment. In the safety set (N=43), 40 (93.0%) pts had a treatment-related adverse event (TRAE). Grade ≥3 TRAEs were reported in 19 (44.2%) pts and were considered pumitamig-related in 8 (18.6%). Pumitamig-related TRAEs led to treatment discontinuation in 2 (4.7%) pts. Immune-related AEs (irAEs) occurred in 6 (14.0%) pts and grade ≥3 irAEs in 1 (2.3%). Bleeding events were reported in 7 (16.3%) pts, with only 1 event being grade 3. **Conclusions:** In these first global data for a PD-(L)1 × VEGF-A bsAb in 1L NSCLC regardless of PD-L1 status, pumitamig + chemotherapy showed encouraging efficacy with a manageable safety profile. Efficacy of the lower dose + chemotherapy was particularly encouraging (ORR 72.7% in NSQ, 81.8% in SQ) and is being evaluated vs pembrolizumab + chemotherapy in the ongoing Phase 3 part of the trial. Clinical trial information: NCT06712316. Research Sponsor: BioNTech.

8514 **Rapid Oral Abstract Session**

Updated results from a phase 2 trial of SSGJ-707 (PF-08634404), a PD-1/VEGF bispecific antibody, as monotherapy in patients with advanced non-small cell lung cancer (NSCLC). First Author: Lin Wu, Hunan Cancer Hospital, Changsha, Hunan, China

Background: SSGJ-707 is a fully human IgG4 bispecific antibody that simultaneously binds PD-1 and VEGF. In the phase 2 study (NCT06361927), SSGJ-707 monotherapy demonstrated promising efficacy and manageable safety in first-line NSCLC with PD-L1 tumor proportion score (TPS) ≥1%. We report updated results from this study with the FDA-aligned pivotal dose of 10 mg/kg Q3W. **Methods:** Patients (pts) with treatment-naive advanced NSCLC (without actionable genomic alterations and PD-L1 TPS ≥1%) were enrolled to receive SSGJ-707 at 5 mg/kg, 10 mg/kg, 20 mg/kg, or 30 mg/kg Q3W until disease progression or unacceptable toxicity. Primary endpoint is objective response rate (ORR) per RECIST 1.1. Secondary endpoints include safety, duration of response (DOR), progression-free survival (PFS), overall survival (OS), and correlation between circulating tumor DNA (ctDNA) and efficacy. **Results:** As of Nov 28, 2025, 83 pts received ≥1 dose of SSGJ-707, of which 27.7% remained on treatment. In pts treated with the FDA-aligned dose of 10 mg/kg Q3W (n = 34), 41.2% remained on treatment and median duration of follow-up was 15.2 mos (95% CI, 14.3-16.2). In the 10 mg/kg group, confirmed ORR was 67.6% (95% CI, 49.5-82.6%), median DOR was not reached (NR; 95% CI, 10.9-NR), median PFS was 12.4 mos (95% CI, 8.2-NR), and median OS was NR (95% CI, 14.8-NR). High efficacy was noted for the 10 mg/kg Q3W dose irrespective of histology and TPS (table). Among all treated pts (n = 83), treatment-related adverse events (TRAEs) occurred in 92.8%; grade ≥3 TRAEs occurred in 42.2%. The most common grade ≥3 TRAEs (≥5%) were pneumonia (8.4%), hypertension (7.2%), and hemoptysis (6.0%). VEGF-related AEs occurred in 62.7% (grade ≥3, 18.1%) of pts; immune-mediated AEs occurred in 37.3% (grade ≥3, 8.4%). In the 10 mg/kg group, TRAEs led to permanent discontinuation in 1 pt (2.9%) and none had grade 5 TRAE. In pts with detectable ctDNA at baseline (n = 65), median PFS was NR (95% CI, 12.4-NR) in pts with nondetectable ctDNA at C3D1 (n = 19) compared to 7.6 mos (95% CI, 5.6-9.4) in those with detectable ctDNA at C3D1 (n = 33). **Conclusions:** With longer follow-up, SSGJ-707 monotherapy continues to show promising efficacy with a manageable safety profile in pts with treatment-naive advanced NSCLC across histology and PD-L1 expression subgroups. These results supported initiation of the phase 3 study (Symbiotic-Lung-01) of SSGJ-707 with platinum-based chemotherapy in 1L squamous (SQ) and nonsquamous (NSQ) NSCLC irrespective of TPS (NCT07222566). Clinical trial information: NCT06361927. Research Sponsor: Pfizer.

8515 **Rapid Oral Abstract Session**

Tremelimumab (T) + durvalumab (D) + chemotherapy (CT) vs pembrolizumab (P) + CT in 1L non-squamous (NSQ) metastatic NSCLC (mNSCLC) with *STK11*, *KEAP1*, and/or *KRAS* mutations (mut): Interim analysis (IA) of the phase 2b TRITON study. First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Pts with *STK11*, *KEAP1* and/or *KRAS*-mutated mNSCLC may benefit from the addition of anti-CTLA-4 to anti-PD-(L)1-based chemo-immunotherapy. In the phase 3 POSEIDON study, 1L T+D+CT significantly improved OS vs CT in pts with mNSCLC. Exploratory analyses showed sustained OS improvement with T+D+CT vs CT in subgroups with *STK11*, *KEAP1* and/or *KRAS* mut; in each mut subgroup, magnitude of OS benefit with T+D+CT vs CT was numerically greater than with D+CT vs CT. The phase 2b, open-label, multicenter, US-based TRITON study is comparing 1L T+D+CT vs P+CT in pts with NSQ mNSCLC and *STK11, KEAP1* and/or *KRAS* mut. Here we report results of a planned IA (data cutoff [DCO] 15 mo after 1st pt randomized) of objective response rate (ORR), duration of response (DoR) and safety. **Methods:** Pts with treatment [tx]-naïve, *EGFR*/*ALK* wild-type, NSQ mNSCLC and *STK11*, *KEAP1* and/or *KRAS* mut (ECOG PS 0/1) were randomized 1:1 to T+D+CT or P+CT. T+D+CT arm: T 75 mg + D 1500 mg + pemetrexed-platinum Q3W for 4 cycles, then maintenance D + pemetrexed Q4W until disease progression (PD); additional doses of T given at week 16 and, optionally, at mo 24. P+CT arm: P 200 mg + pemetrexed-platinum Q3W for 4 cycles, then maintenance P + pemetrexed Q3W until PD, for up to 24 mo. Randomization was stratified by mut type and tumor PD-L1 expression (≥1% vs <1%). The primary endpoint is PFS (RECIST v1.1; investigator-assessed) with planned sample size ~100 pts. Key secondary endpoints include OS, ORR, DoR and safety. **Results:** At DCO (12 Nov 2025), 41 pts were randomized to T+D+CT and 43 to P+CT. Overall, 27.4%, 21.4% and 78.6% of pts had *STK11*, *KEAP1* and *KRAS* mut (not mutually exclusive); 39.3% had PD-L1 <1%. In the T+D+CT vs P+CT arms, median (range) age was 69 (47–82) vs 69 (51–86) y, 48.8% vs 62.8% pts were male, 70.7% vs 72.1% were White and 14.6% vs 20.9% Black or African American, 78.0% vs 62.8% had ECOG PS 1. Median (range) safety follow-up for D/P was 5.6 (0.0–14.0)/5.1 (0.0–17.5) mo; median no. of D/P doses was 8/7. ORR (95% CI) was 39.0% (24.1–54.0) in the T+D+CT arm vs 34.9% (20.6–49.1) in the P+CT arm [unconfirmed ORR 48.8% (33.5–64.1) vs 41.9% (27.1–56.6)]. Median DoR (95% CI) was not reached (6.3–NR) vs 6.4 (4.2–NR) mo; 100% vs 58.3% pts remained in response at 6 mo. In *KRAS* mut-only pts (n=52; exploratory), ORR was 48.0% (12/25) with T+D+CT vs 33.3% (9/27) with P+CT. The sponsor remains blinded to PFS at this IA. With T+D+CT vs P+CT, 41.5% vs 41.9% of pts had Grade 3/4 AEs possibly related to tx (TRAEs); 2.4% vs 4.7% had TRAEs leading to tx discontinuation and 0% vs 2.3% had TRAEs leading to death. **Conclusions:** At IA, ORR and DoR results from the prospective TRITON study support a role for the addition of anti-CTLA-4 (T) to 1L anti-PD-L1 (D) + CT in pts with *STK11*, *KEAP1* and/or *KRAS*-mutated mNSCLC. Safety was similar in the two arms and consistent with known safety profiles. Clinical trial information: NCT06008093. Research Sponsor: AstraZeneca.

8516 **Rapid Oral Abstract Session**

A phase 1/2 study of TSN1611, a highly selective oral KRAS G12D inhibitor, in solid tumors: Efficacy and safety in *KRAS* G12D–mutated NSCLC patients. First Author: Yongfeng Yu, Department of Medical Oncology, Shanghai Chest Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China

Background: There remains an unmet clinical need for effective therapies targeting KRAS G12D mutation in patients (pts) with advanced non-small cell lung cancer (NSCLC) refractory to prior treatments. TSN1611 is a novel oral small-molecule inhibitor designed to bind both the active GTP-bound (ON) and inactive GDP-bound (OFF) conformations of KRAS G12D, providing a differentiated mechanism of action and broad antitumor activity in preclinical models. **Methods:** This multi-regional Phase 1/2 study enrolled pts with advanced solid tumors harboring KRAS G12D mutation. Phase 1a dose-escalation part evaluated TSN1611 at 50–1200 mg twice daily (BID). A subsequent Phase 1b dose-optimization part evaluated 800 mg and 1200 mg BID. In Phase 2, efficacy is being further explored across multiple tumor types at the recommended Phase 2 dose of 1200 mg BID. **Results:** As of Jan 23, 2026, 117 pts received TSN1611 across all dose levels in Phase 1/2. Tumor types included NSCLC (n = 26), pancreatic adenocarcinoma (n = 50), colorectal cancer (n = 35), and others (n = 6). Median age was 62 yrs (range 22-81). The median prior lines of systemic therapy were 2 (range 0-7). The most common (≥10%) treatment-related adverse events (TRAEs) in all treated pts were diarrhea (53.0%), nausea (48.7%), vomiting (46.2%), anemia (17.9%), decreased white blood cell count (16.2%), decreased neutrophil count (13.7%), increased ALT (12.8%), decreased appetite (12.0%), decreased platelets (11.1%), fatigue and increased AST (10.3% each). Grade 3 TRAEs occurred in 9.4% of pts; these were all single events (0.9% each) except for anemia, diarrhea, and asymptomatic lipase elevation, which occurred in 1.7% of pts each. TRAEs led to dose interruption in 17.1% pts and dose reduction in 7.7% pts; no treatment discontinuations due to TRAEs occurred. Among 26 NSCLC pts, all had stage IV metastatic disease; 22 (84.6%) had received prior chemotherapy and/or PD-1/PD-L1 inhibitors, and 9 (34.6%) had received prior anti-angiogenic therapy. Among 20 response-evaluable NSCLC pts treated with TSN1611 at 600–1200 mg BID, 10 achieved partial response, 8 had stable disease, and 2 had progressive disease, yielding an objective response rate (ORR) of 50% (95% CI 27.2–72.8) and a disease control rate (DCR) of 90% (95% CI 68.8–98.3). Median time to response was 1.4 months (range 1.2–3.5). In addition to extracranial responses, rapid intracranial responses were observed. Median progression-free survival (PFS) was not mature yet (range 1.3+ to 12.9+ months), with a 9-month PFS rate of 54.5% (95% CI 24.4–77.0). Enrollment continues and updated data will be presented at the conference. **Conclusions:** TSN1611 demonstrated a favorable safety profile and clinically meaningful antitumor activity in pts with KRAS G12D mutated NSCLC. Further development of TSN1611 as monotherapy and in combination regimens is ongoing. Clinical trial information: NCT06385925. Research Sponsor: Tyligand Pharmaceuticals (Suzhou) Limited.

8517 **Rapid Oral Abstract Session**

Prophylactic peptide vaccine targeting resistance mutations in advanced ALK-positive lung cancer: Primary analysis from the ARCHER trial. First Author: Michael R. Conroy, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD

Background: Acquired resistance to targeted therapy remains a major challenge in ALK-positive NSCLC and is often mediated by mutations in the ALK kinase domain. Prophylactic immune targeting of common ALK resistance mutations represents a novel strategy to delay or prevent the emergence of ALK inhibitor resistance. **Methods:** We conducted a first-in-human phase 1b clinical trial of a prophylactic peptide vaccine (ALK-Vac) in advanced ALK-positive NSCLC patients without progression on standard-of-care tyrosine kinase inhibitor (TKI) therapy. Patients continued their ALK TKI and received ALK-Vac, consisting of synthetic long peptides targeting seven common ALK resistance mutations (I1171T, I1171N, I1171S, L1196M, G1202R, D1203N, E1210K) plus poly-ICLC adjuvant. ALK-Vac was administered subcutaneously on days 1, 4, 8, 15, and 22 (priming) and weeks 12 and 20 (boost). Primary objectives were safety and vaccine-specific T cell responses assessed by IFN-γ ELISpot. Exploratory objectives included molecular and immune-phenotype dynamics assessed by ultrasensitive cell-free DNA (cfDNA) duplex sequencing and CyTOF mass cytometry. **Results:** Fifteen patients were enrolled and all completed the planned ALK-Vac regimen. Most patients (13/15, 87%) were receiving first-line TKI therapy. Concomitant TKIs included alectinib (7/15, 47%), lorlatinib (5/15, 33%), and brigatinib (3/15, 20%). At enrollment, median TKI duration was 43.7 months (range 4.6-74.2) and 67% of patients had no measurable disease. Treatment-related adverse events (TRAEs) were primarily grade 1 (93% of patients); most commonly injection site reactions (93%), fatigue (60%), and flu-like symptoms (40%). No grade $\geq$ 3 TRAEs were observed. T cell responses ($\geq$2-fold increase in SFU) were detected in 71% (10/14) of evaluable patients, with a median 11.9-fold increase. Responses were observed to G1202R, L1196M, and D1203N (each 10/14, 71%), E1210K (9/14, 64%), and I1171N/S/T (each 7/14, 50%). With a median follow-up of 11.5 months, the disease control rate was 93% (14/15). One patient who achieved robust immune response against multiple resistance mutations developed oligoprogression on alectinib 8.5 months after starting ALK-Vac; molecular profiling of this lesion identified an emergent KRAS G12D mutation without detectable ALK resistance mutation. **Conclusions:** ALK-Vac was well-tolerated and induced vaccine-specific T cell responses in a minimal residual disease setting, demonstrating feasibility of prophylactic targeting of ALK resistance mutations as an adjunct to TKI therapy and supporting a broader immune-interception framework potentially applicable to other oncogene-driven NSCLC. Comprehensive cfDNA and immune-phenotyping analyses will be reported. Clinical trial information: NCT05950139. Research Sponsor: None.

LBA8518 **Rapid Oral Abstract Session**

Phase 3 clinical trial of the combination of erlotinib plus ramucirumab compared with osimertinib in untreated advanced or recurrent non-small cell lung cancer with EGFR L858R mutation: The REVOL858R trial (WJOG14420L). First Author: Naoki Haratake, Department of Thoracic Oncology, National Hospital Organization, Kyushu Cancer Center, Fukuoka, Japan

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

8519 **Rapid Oral Abstract Session**

Safety and efficacy results of the phase 2 study of silevertinib (BDTX-1535) in treatment-naïve patients with non-small cell lung cancer with non-classical EGFR mutations. First Author: Julia K. Rotow, Dana-Farber Cancer Institute, Boston, MA

Background: Non-classical mutations (NCM) of epidermal growth factor receptor (EGFR) represent a broad group of oncogenic mutations in non-small cell lung cancer (NSCLC), often associated with resistance to osimertinib (e.g., P-loop and αC-helix compressing [PACC] mutations). Patients (pts) with NCM have inferior clinical outcomes with a high incidence of CNS metastases (CNSm). Silevertinib (BDTX-1535) is a fourth-generation, covalent EGFR TKI with high CNS penetrance targeting both EGFR classical mutations and NCM. The antitumor activity and safety of silevertinib in pts with advanced NSCLC were evaluated in a Phase 2 trial (NCT05256290). **Methods:** Pts with advanced EGFR NCM NSCLC who received no prior systemic therapy were enrolled (Cohort 3) based on a local molecular test. Silevertinib 200 mg was administered orally once daily. The primary endpoint of objective response rate (ORR) was assessed using RECIST v1.1. CNS ORR was assessed using Response Assessment in Neuro-Oncology for Brain Metastases (RANO-BM) in pts with no prior CNS therapy. Secondary endpoints include progression-free survival (PFS), duration of response (DOR), disease control rate (DCR), and safety. **Results:** From February 2024 to July 2025, 43 pts with 35 unique NCMs (including 25 pts with PACC mutations) were enrolled in Cohort 3: median age 70.0 years, 72% female, 74% white, and 42% never smoked cigarettes. As of November 3, 2025, median follow-up was 7.2 months. ORR by RECIST v1.1 is shown in the table. Sixteen pts (37%) had CNSm, including 7 pts (16%) with measurable CNS disease. RANO-BM CNS response was 86% (n=6/7). Complete clearance of EGFR VAF ctDNA was observed in 21/26 (81%) evaluable pts. Serious treatment-related adverse events (TRAEs) were reported in 5 pts (12%), and 4 pts (9%) discontinued treatment due to TRAEs. The most common TRAEs included rash (19%, grade 3), diarrhea (19%, grade 3), stomatitis (9%, grade 3), and paronychia (5%, grade 3). While 77% of pts had a dose reduction, 19/22 (86%) patients with a radiographic response maintained or deepened their response after dose reduction, including all patients with CNS response. **Conclusions:** Silevertinib demonstrated robust antitumor activity in treatment-naïve pts with a broad spectrum of NCM EGFR driver mutations with high intracranial activity in pts with brain metastases. The safety profile was consistent with the known AEs of the EGFR TKI class. Clinical trial information: NCT05256290. Research Sponsor: Black Diamond Therapeutics.

Data as of November 3, 2025	N	ORR n (%) 95% CI	DCR n (%) 95% CI
ITT Population*	43	26 (60) (44.4, 75.0)	39 (91) (77.9, 97.4)
PACC mutations	25	14 (56) (34.9, 75.6)	22 (88) (68.8, 97.5)
Compound mutations†	16	11 (69) (41.3, 89.0)	15 (94) (69.8, 99.8)

*No pts with classical (E746_A750del or L858R) mutations were enrolled.
†Presence of $\geq$ 2 NCMs.
As of December 27, 2025, the 6-month PFS rate was 86% overall and 80% in pts with CNSm; available PFS and DOR data will be presented.

8520 **Rapid Oral Abstract Session**

DZD6008, a fourth-generation EGFR TKI, in pretreated NSCLC patients with *EGFR* C797X mutations: Results from phase 1/2 studies. First Author: Mengzhao Wang, Peking Union Medical College Hospital, Beijing, China

Background: Patients with EGFR-mutant NSCLC whose disease progresses on or after 3rd generation EGFR TKI treatment often acquire resistance mutations, among which EGFR C797X is one of the most frequently reported. DZD6008 is a 4th generation EGFR TKI, designed to target classical EGFR sensitizing mutations (L858R/19del), as well as resistant double (T790M and L858R/19del) and triple mutations (C797X, T790M and L858R/19del), with preclinical data showing high selectivity over wild-type EGFR and other kinases and full blood-brain-barrier (BBB) penetration. Here we report results in pretreated NSCLC patients with EGFR C797X mutations (C797X+) from phase 1/2 studies. **Methods:** TIAN-SHAN1 (NCT06905197) and TIAN-SHAN2 (NCT06813365; CTR20241790) are ongoing, multicenter phase 1/2 studies evaluating the safety, tolerability, and anti-tumor activity of DZD6008 in EGFR-mutant NSCLC patients, conducted in the US/Australia and China, respectively. The efficacy endpoints include objective response rate (ORR), duration of response (DoR) and progression-free survival (PFS) by investigator per RECIST v1.1, and safety endpoints include treatment-related adverse events (TRAEs) per CTCAE 5.0. **Results:** As of December 19, 2025, a total of 24 patients with confirmed C797X+ NSCLC were treated with once daily (QD) oral DZD6008 (20 mg, n=1; 40 mg, n=13; 60 mg, n=10), and had at least 1 post-baseline tumor assessment. The median age was 66.5 years, 58.3% were female, 91.7% were Asian, 58.3% had ECOG PS of 1. All patients had metastatic disease upon study entry and received median 2 (range 1 - 6) lines of prior therapies. Across all dose levels, tumor shrinkage was observed in 75% of patients, with an ORR of 41.7%. Intracranial anti-tumor activity was observed in patients with baseline brain metastasis. The doses of 40 mg and 60 mg QD were defined as the recommended phase 2 doses (RP2Ds). The ORRs were 23.1% and 60.0% at these two dose levels, respectively. The median DoR and median PFS were not reached for either dose. The 9-month PFS rates were 54.5% and 64.8%, respectively. DZD6008 was well tolerated at the doses evaluated, with no dose limiting toxicities observed. The majority of TRAEs were grade 1 or 2. The TRAEs with grade $\geq$3 included lymphocyte count decreased (8.3%), anemia, malaise, fatigue and amylase increased (all 4.2%). There were no Grade 5 TRAEs. **Conclusions:** DZD6008 demonstrated promising and durable anti-tumor activity in patients with EGFR C797X+ NSCLC with a manageable safety profile, supporting its potential use as a later line treatment option after 3rd generation EGFR TKI failure. The updated data will be presented at the meeting. Clinical trial information: NCT06905197, NCT06813365. Research Sponsor: None.

8521 Poster Session

Amivantamab in *EGFR*-mutated NSCLC with refractory brain or leptomeningeal metastases: A multi-center real-world study. First Author: Chang Lu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: The central nervous system (CNS), particularly after progression on third-generation EGFR TKIs, represents a common yet challenging scenario. While recent trials establish amivantamab-lazertinib for EGFR-mutant NSCLC, their real-world applicability is limited by patient complexity and access barriers, highlighting an urgent need for flexible, real-world solutions. **Methods:** To evaluate the intracranial efficacy of amivantamab, used as monotherapy or in combination, we conducted a multi-center, retrospective study of patients with EGFR-mutated NSCLC and brain parenchymal metastases (BM) and/or leptomeningeal metastases (LM) treated with amivantamab monotherapy or combination based on routine clinical practice. The cohort included two key populations: heavily pretreated patients with sensitizing exon19del/L858R mutations after progression on third-generation EGFR TKIs, and treatment-limited patients with atypical mutations. Efficacy endpoints included intracranial progression-free survival (PFS) and intracranial objective response rate (ORR) by RANO-BM and/or RANO-LM. Exploratory endpoints included symptom improvement, and longitudinal cerebrospinal fluid (CSF) biomarker dynamics. **Results:** Thirty-one patients from seven centers were included (BM, n=13; BM+LM, n=18). Most (25/31, 80.6%) harbored EGFR sensitizing mutations and had progressed on third-generation EGFR TKIs; six (19.4%) carried atypical EGFR mutations. Over half (17/31, 54.8%) had received ≥4 prior lines. Amivantamab monotherapy was received in 10/31 patients (32.3%). Median intracranial PFS was 10.3 months (95% CI, 4.5-16.1). Among 24 evaluable patients, intracranial ORR was 25.0% (n=6), and disease control rate was 91.7% (n=22). CNS-related symptoms improved in 26/31 (83.9%). CSF analyses showed decreased pressure and CEA, reduced EGFR amplification, and clearance of EGFR C797S. **Conclusions:** In real-world settings, amivantamab-based regimens demonstrate promising intracranial efficacy in EGFR-mutated NSCLC patients with refractory brain or leptomeningeal metastases. These findings support the use of amivantamab as a viable therapeutic strategy in this challenging population and suggest that CSF biomarkers can serve as a valuable tool for monitoring treatment response. 8522 Poster Session

Sigvotatug vedotin (SV), an investigational integrin beta-6 (IB6)—directed antibody-drug conjugate (ADC), plus pembrolizumab: Updated results from the phase 1 study (SGNB6A-001). First Author: Jesus Corral Jaime, Hospital Universitario de Jerez, Cádiz, Spain

Background: IB6 is overexpressed in many tumors, such as non-small cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC). SV, an IB6-directed ADC, demonstrated encouraging antitumor activity and manageable safety as monotherapy or in combination with pembrolizumab (SV+P) in advanced NSCLC (aNSCLC) in the ongoing phase 1 SGNB6A-001 study. We report updated results for SV+P. **Methods:** SGNB6A-001 (NCT04389632) is an open-label, multicenter, dose-escalation and -expansion study evaluating safety, pharmacokinetics, and antitumor activity of SV. SV+P is being evaluated in safety and expansion cohorts of treatment-naive locally advanced, unresectable, or metastatic NSCLC across PD-L1 scores and HNSCC CPS ≥1. Additional cohorts currently enrolling are not included in this analysis. We describe patients (pts) who received SV 1.8 mg/kg AiBW (adjusted ideal body weight) IV Q2W and P 400 mg IV Q6W. Primary endpoint is safety; secondary endpoints include efficacy, such as confirmed objective response rate (cORR) per RECIST v1.1 by investigator. **Results:** 71 pts across cohorts received ≥1 SV+P dose (37 aNSCLC, 33 HNSCC, 1 esophageal cancer). As of Sep 30, 2025, 34 pts were on treatment. Overall, any-grade (Gr) and Gr ≥3 treatment-emergent adverse events (TEAEs) occurred in 96% and 59% of pts, respectively; treatment-related any-Gr and Gr ≥3 TEAEs occurred in 85% and 44% of pts, respectively. Most common TEAEs (> 30%) were alopecia, decreased appetite, fatigue, and nausea. In the expansion cohort, 35 pts with aNSCLC were treated, with median follow-up of 10.6 mo (95% CI, 7.6-11.9). In the efficacy-evaluable pts, cORR was 50% in both the PD-L1 TPS < 1% (n = 10) and ≥1% (n = 18) subgroups, with 1 additional partial response (PR) pending confirmation in the PD-L1 TPS ≥1% subgroup (Table). In 5 pts with PD-L1 TPS ≥50%, cORR was 80%, with 1 additional PR pending confirmation. Regardless of TPS, cORR was numerically higher in pts with nonsquamous (n = 19 [53%]) vs squamous (n = 9 [44%]) histology. **Conclusions:** SV+P continued to show manageable safety and encouraging antitumor activity in treatment-naive NSCLC across PD-L1 TPS and histologies. This supports the ongoing phase 3 SigVie-003 study (NCT06758401) of SV+P vs P for treatment-naive aNSCLC with PD-L1 TPS ≥50% as well as further investigation in the enrolling phase 1 cohorts and future studies. Clinical trial information: NCT04389632. Research Sponsor: Pfizer.

Dose-escalation results from a phase I study of FZ-AD004, a TROP2-directed ADC, in patients with advanced solid tumors. First Author: Ziming Li, Shanghai Chest Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: FZ-AD004 is an ADC (antibody-drug conjugate) targeting Trop-2 (trophoblast cell-surface antigen 2), an intracellular calcium signaling transducer overexpressed on many epithelial tumors. It delivers the topoisomerase inhibitor DXd. This first-in-human study evaluated the safety and efficacy in patients(pts) with advanced solid tumors, mainly in non–small-cell lung cancer (NSCLC). **Methods:** PTs with unresectable, treatment-refractory or relapsed solid tumors received FZ-AD004 intravenously on days 1 of 21-day cycles. The primary objectives were to determine maximum tolerated dose (MTD), safety, and tolerability; secondary objectives included efficacy, pharmacokinetics, and immunogenicity of FZ-AD004. Pts were eligible regardless of TROP2 level. **Results:** As of November 28, 2025, 22 pts were treated with ≥1 dose of FZ-AD004 (median age: 61.5 years [range from 45-75], male: 77.3%, EOCG PS 1: 100%, prior lines of anticancer treatment ≥ 2: 77.3%). Diagnoses included NSCLC (n=21) and SCLC (n=1). Doses evaluated were at 3.2 (n=3), 5.6 (n=3), 6.4 (n=3), 8.0 (n=4), 10.0 (n=3), and 12.0 mg/kg (n=6). No dose-limiting toxicity (DLT) was observed across all dose levels.19 pts (86.4%) discontinued (15 (68.2%) due to disease progression per RECIST v1.1). Treatment emergent adverse events (TEAEs) regardless of causality were reported in all of 22 pts (100%; 10 pts [45.5%] experienced ≥grade 3, 5 pts [22.7%] had serious adverse events). Treatment-related AEs (TRAEs) occurred in all pts (100%; grade ≥3 in 36.4%; serious TRAEs in 13.6%). Grade ≥3 TRAEs included stomatitis (13.6%), decreased lymphocyte count (9.1%), nausea (4.5%), hypokalemia (4.5%), and keratitis (4.5%).Among 12 efficacy-evaluable pts at doses ≥8.0 mg/kg, the objective response rate (ORR) was 50.0% and the disease control rate (DCR) was 83.3%. Responses were observed in pts harboring KRAS G12C (n=1), EGFR mutations (n=3), and without AGA mutations (n=2). The longest duration treatment was 11.4 months. **Conclusions:** FZ-AD004 demonstrated a manageable safety profile with no DLTs observed up to 12.0 mg/kg and promising antitumor activity in heavily pretreated NSCLC patients, particularly at doses of 8.0 and 10.0 mg/kg. These doses are being further explored in the expansion phase. Clinical trial information: NCT05914545. Research Sponsor: None.

Impact of *MET* amplification (amp) on telisotuzumab vedotin (Teliso-V) efficacy and safety in 2L+ non-squamous (NSQ) *EGFR* wild-type (WT) NSCLC with c-Met protein overexpression (OE). First Author: Jair Bar, Jusidman Cancer Center, Sheba Medical Center, Ramat Gan, Israel; The Gray Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel

Background: Teliso-V is a c-Met–directed antibody-drug conjugate comprising telisotuzumab and the microtubule polymerization inhibitor monomethyl auristatin E (MMAE) payload. In the Ph2 LUMINOSITY study (NCT03539536), Teliso-V showed durable responses and manageable safety (Camidge et al, JCO 2024;42:3000-11) resulting in its accelerated approval in locally advanced/metastatic NSQ NSCLC with high c-Met protein OE (3+, ≥50%), as determined by an FDA-approved test. *MET* amp is a negative prognostic risk factor in advanced NSCLC, frequently associated with recurrent disease. High levels of *MET* amp and c-Met OE are hallmarks of *MET*-addicted tumors. Here, we analyzed the effects of *MET* amp on clinical responses to Teliso-V in LUMINOSITY. **Methods:** *MET* amp was evaluated by FISH and ctDNA in baseline samples from 108 NSQ *EGFR* WT NSCLC pts with c-Met OE (3+, ≥25%). *MET* amp by FISH was defined as having focal *MET* amp (MET/CEP7 ≥2.0) with *MET* gene copy number (GCN) ≥4. *MET* amp *(focal)* by ctDNA was defined as having plasma *MET* GCN ≥4 with no co-amplification in *CDK6* and *EGFR*. c-Met OE by Immunohistochemistry (IHC; SP44) was defined as 3+ tissue staining intensity in ≥25% tumor cells (high c-Met OE: 3+, ≥50%; intermediate [int] c-Met OE: 3+, 25% to 49%). Exploratory analysis of tumor response was assessed in 76 efficacy evaluable pts with c-Met OE and *MET* amp assay results. **Results:** *MET* amp was detected in 34% (37/108) of pts with c-Met OE (3+, ≥25%) and was enriched by c-Met levels: 22% (11/50) in pts with Int c-Met OE (3+, 25% to 49%) and 45% (26/58) in pts with high c-Met OE (3+, ≥50%). The effects of *MET* amp on tumor response in LUMINOSITY are shown in Table 1. The majority of c-Met OE pts (79%) with PFS ≥10 mo (n=14) had GCN ≥10 and/or c-Met IHC 3+ ≥50%. No new safety signals were reported in pts with c-Met OE and *MET* amp. **Conclusions:** *MET* amp is more common in pts with high c-Met OE in this retrospective subgroup analysis. Tumor activity with Teliso-V was observed regardless of *MET* amp status. The impact of *MET* amp in pts with c-Met OE will be further evaluated in ongoing Phase 3 study (NCT04928846). Research Sponsor: None.

SHR-1826, a c-MET directed antibody-drug conjugate (ADC), in advanced solid tumors: Updates from a phase 1 study. First Author: Longhua Sun, The First Affiliated Hospital of Nanchang University, Nanchang, China

Background: SHR-1826 is a novel ADC comprising a humanized IgG2 monoclonal antibody targeting c-MET, conjugated via a cleavable peptide-based linker to a topoisomerase I inhibitor payload. We conducted a multi-center, first-in-human, phase 1 trial of SHR-1826 in patients with advanced solid tumors. Here we report updated results, with a focus on patients with *EGFR*-mutated (*EGFRmut*) lung adenocarcinoma (LUAD). **Methods:** The study consisted of dose-escalation (i3+3 design), dose-expansion and efficacy-expansion phases. Patients with advanced solid tumors harboring MET alterations, who had failed standard therapy or had no available standard treatment options, were enrolled and received SHR-1826 intravenously at 2.2–6.0 mg/kg Q3W. In patients with *EGFRmut* LUAD, 4.0 and 5.0 mg/kg Q3W were evaluated during dose and efficacy expansion. **Results:** As of Dec. 3, 2025, 195 patients with lung (n=126), colorectal (n=40), gastric (n=22), liver (n=5), or pancreatic (n=2) cancer were treated. Median age was 59.0 yrs; 89.7% had ECOG performance status 1. Among 36 patients with *EGFRmut* LUAD, median number of prior lines of therapy was 2 (range 1–9); 97.2% had previously received EGFR-TKI (3rd generation, 88.9%) and 75.0% received platinum-based chemotherapy. As of data cutoff, median follow-up was 14.4 months. Efficacy in *EGFRmut* LUAD across doses is shown in Table 1. Overall, the confirmed objective response rate (ORR) was 41.7% (95% CI 25.5–59.2) and median duration of response (DoR) was 14.1 months (95% CI 5.6–not reached [NR]). Median progression-free survival (PFS) was 9.8 mo (95% CI 5.8–15.4). Median overall survival (OS) was not reached; 12-month OS rate was 67.4% (95% CI 48.9–80.5). In all 195 patients, grade ≥3 treatment-related adverse events (TRAEs) were reported in 129 patients (66.2%), with all occurring in ≥5% being hematological toxicities. Interstitial lung disease occurred in 4 (3.1%; grade ≥3, n=2 [1.6%]) patients. TRAEs led to treatment discontinuation in 8 (4.1%) patients. No treatment-related deaths were reported. **Conclusions:** SHR-1826 demonstrated encouraging activity with manageable safety in heavily pretreated patients with MET-altered *EGFRmut* LUAD. Multiple trials are ongoing to assess SHR-1826 combined with other anti-tumor therapies in NSCLC. Clinical trial information: NCT06094556. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

SHR-A2102 in combination with adebrelimab as first-line treatment in patients with locally advanced or metastatic squamous or non-squamous non-small cell lung cancer (NSCLC): Results from a phase 1b/2 study. First Author: Yi Hu, Cancer Center, Chinese PLA General Hospital, Beijing, China

Background: SHR-A2102 is a novel antibody-drug conjugate composed of a monoclonal antibody targeting nectin-4, a cleavable linker, and a topoisomerase I inhibitor payload. Here, we report the preliminary efficacy and safety of SHR-A2102 plus adebrelimab (an anti-PD-L1 antibody) as first-line therapy in patients with locally advanced or metastatic squamous or non-squamous NSCLC. **Methods:** This is a multicenter, open-label phase 1b/2 study (NCT06512051). In the phase 2 part, patients aged 18-70 years with ECOG PS 0-1 and histologically/cytologically confirmed stage IIIB-IV squamous (cohort A) or non-squamous (cohort B) NSCLC who had received no prior systemic therapy were enrolled. All patients received intravenous SHR-A2102 (8 mg/kg, day 1 Q3W) plus adebrelimab (1200 mg, day 1 Q3W) until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR). **Results:** Between Dec 13, 2024 and Nov 19, 2025, 67 patients were enrolled and received treatment (27 with squamous NSCLC and 40 with non-squamous NSCLC). In cohort A, 92.6% were male, the median age was 64 years (range 42-70), 14 patients had PD-L1 TPS 1-49%, and 13 patients had PD-L1 TPS ≥50%. In cohort B, 60.0% were male, the median age was 62 years (range 42-70), 7 patients had PD-L1 TPS <1%, 20 patients had PD-L1 TPS 1-49%, and 13 patients had PD-L1 TPS ≥50%. Efficacy was evaluated in 26 and 33 patients from cohorts A and B, respectively, while all patients were included in the safety analysis. As of Nov 30, 2025, the median follow-up was 9.1 months (range 2.0-11.1), with 9.9 months (range 3.0-11.0) with squamous NSCLC and 9.0 months (range 2.0-11.1) with non-squamous NSCLC. Antitumor activities are shown in Table 1. In patients with PD-L1 TPS ≥1%, ORR was 80.8% (95% CI 60.6%-93.4%) for squamous NSCLC and 69.2% (95% CI 48.2%-85.7%) for non-squamous NSCLC. Grade ≥3 treatment-related adverse events (TRAEs) were reported in 53.7% (36/67) of patients. The most common Grade ≥3 TRAEs were decreased neutrophil count (32.8%), decreased white blood cell count (14.9%), and anemia (9.0%). **Conclusions:** These results suggested the combination of SHR-A2102 and adebrelimab as the first-line therapy is a promising treatment strategy in patients with squamous or non-squamous NSCLC, supporting further investigation. Clinical trial information: NCT06512051. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Necitumumab plus pembrolizumab and chemotherapy for untreated advanced squamous NSCLC: Phase I/II NEJ048A/NEXUS. First Author: Tomoiki Aiba, Department of Pulmonary Medicine, Sendai Kousei Hospital, Sendai, Japan

Background: EGFR blockade enhances tumor antigen presentation and may potentiate PD-1 inhibition. This phase I/II study evaluated the safety and efficacy of adding necitumumab to pembrolizumab plus platinum-based chemotherapy in patients with previously untreated advanced squamous non–small cell lung cancer (NSCLC), a population with limited biomarker-driven treatment options. **Methods:** Patients received necitumumab (400–800 mg on days 1 and 8), pembrolizumab (200 mg on day 1), nab-paclitaxel (100 mg/m² on days 1, 8, and 15), and carboplatin (AUC 5 on day 1) every 3 weeks for four cycles, followed by necitumumab plus pembrolizumab maintenance. Phase I used a standard 3+3 dose-escalation design. Per protocol amendment, patients treated at the recommended dose (RD) in phase I (n = 6) and all phase II patients (n = 6) were pooled for efficacy analyses (n = 12). Tumor assessments were performed every 6 weeks per RECIST v1.1. Primary endpoints were safety and objective response rate (ORR). Data cutoff was September 14, 2025. **Results:** Twenty-one patients were enrolled, including 15 in phase I (400 mg, n = 6; 600 mg, n = 3; 800 mg, n = 6). One dose-limiting toxicity (DLT) occurred in the 800 mg cohort, which was determined as the RD and maximum tolerated dose (MTD). Among the 12 patients treated at the RD, the ORR was 75.0% (9/12; 95% CI, 42.8–94.5), with partial response in 9 patients, stable disease in 1 patient, and progressive disease in 2 patients. The disease control rate was 83.3%. The 24-week survival rate was 95.2%. Median progression-free survival and overall survival were not reached at the time of analysis. The most frequent adverse events (AEs) in 21 patients were hypomagnesemia (66.7%), acneiform dermatitis (66.7%), neutropenia (61.9%), decreased appetite (52.4%), anemia (52.4%), constipation (47.6%), stomatitis (42.9%), and leukopenia (42.9%). Grade 3 and 4 AEs occurred in 66.7% and 28.6% of patients, respectively, with no grade 5 events. **Conclusions:** The addition of necitumumab to pembrolizumab and platinum-based chemotherapy demonstrated manageable toxicity and resulted in a high ORR in patients with untreated squamous NSCLC. These findings support the potential activity of EGFR blockade–based immunochemotherapy and warrant further clinical investigation. Clinical trial information: 2031210387. Research Sponsor: Nippon Kayaku Co., Ltd.

8530 Poster Session

First-in-human study of DM005, an anti-EGFR/c-MET bispecific antibody-drug conjugate, in patients with advanced solid tumors. First Author: Jin-Ji Yang, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: DM005 is a bispecific ADC (BsADC) conjugated to BLD1102, a linker/payload system composed of a linker and a DNA topoisomerase I inhibitor (BCPT02), targeting EGFR and c-MET with an average DAR value of 4. EGFR and c-MET are highly co-expressed in NSCLC, SCLC, HNSCC, breast cancer, gastric cancer, colorectal cancer, and some other solid tumors, for which DM005 has demonstrated robust anti-tumor activity in PDX/CDX models. **Methods:** This is a First-in-human dose-escalation study (NCT 06515990). Patients (pts) with advanced solid tumors received DM005 by IV administration from 0.5 to 6.5 mg/kg Q3W. The classical "3+3" design was utilized to evaluate safety, tolerability and preliminary efficacy. Tumor response was evaluated by the Investigators based on RECIST v1.1. A Safety Monitoring Committee (SMC) was established to determine the dose levels, dose regimen, and the maximum tolerated dose (MTD)/ recommended dose for expansion (RDE). **Results:** As of 2 Jan 2026, a total of 45 pts from China, United states of America and Australia were enrolled and received ≥1 dose of DM005 across 8 dose cohorts. Median age was 59 years (range 40-76). Baseline ECOG scores were 0 (n = 7), 1 (n = 38) with all pts progressed after an average of 3 (range 1-7) prior lines of available standard therapy. There were no dose limiting toxicities (DLT) observed up to 6.5 mg/kg. The MTD was not reached. Thirty-six pts (80%) experienced treatment-related adverse events (TRAEs), the most common TRAEs (≥10%) including: nausea (28.9%), anemia (28.9%), fatigue (26.7%), decreased appetite (26.7%), leukopenia (20%), aspartate aminotransferase increased (15.6%), lymphopenia (13.3%), constipation (11.1%). Most TRAEs were Grade 1-2 and Grade ≥3 TRAEs reported in 10 pts (2 lymphopenia, 1 neutropenia, anemia, leukopenia, nausea, stomatitis, vomiting, fatigue, pain, urinary tract infection, hypoxia, hypotension). No ILD or Infusion reaction were observed. Among 32 patients evaluable, there were 8 PRs, including 1pt with NSCLC EGFR-mutant (NSCLCm) at 3.3 mg/kg, 4 pts with NSCLCm and 1pt with SCLC at 4.2 mg/kg, and 1pt with NSCLCm and 1pt with NSCLC EGFR wildtype (NSCLCw) at 5.2mg/kg, and 14 pts with stable disease (SD). In the 3.3/4.2/5.2 mg/kg dose groups, a total of 13 NSCLCm pts underwent imaging tumor assessment, with 6 subjects achieving PR, and 5 subjects achieving SD. The unconfirmed objective response rate (ORR) is 46.2%, and the disease control rate (DCR) is 84.6%. **Conclusions:** DM005 is safe and tolerable up to 6.5 mg/kg dose level. In both NSCLCm and NSCLCw pts, and SCLC pts, DM005 has demonstrated an encouraging efficacy with a manageable safety profile. The putative RDE ranges from 4.2 to 6.5 mg/kg which will be further evaluated in phase II trials. Clinical trial information: NCT06515990. Research Sponsor: None.

The efficacy of trastuzumab deruxtecan after HER2-TKI exposure in HER2 exon 20 insertion–positive non–small cell lung cancer: Results from a large-scale nationwide genomic screening (LC-SCRUM-Asia). First Author: Yu Tanaka, Department of Thoracic Oncology, National Cancer Center Hospital East, Chiba, Japan

Background: Although reduced efficacy of HER2-TKIs after trastuzumab deruxtecan (T-DXd) has been reported in HER2 exon 20 insertion–positive non–small cell lung cancer (NSCLC), the efficacy of T-DXd following prior HER2-TKI exposure remains unclear. **Methods:** We identified patients with HER2 exon 20 insertion–positive NSCLC treated with T-DXd from two cohorts: the National Cancer Center Hospital East (N = 26,971) and the LC-SCRUM-Asia (N = 20,902). Clinical outcomes (ORR, DCR, and PFS) were evaluated across three groups based on prior HER2-TKI therapy: (1) HER2-TKI-naïve patients (naïve cohort), (2) those treated with selective HER2-TKIs (zongertinib or severtinib) (selective TKI cohort), and (3) those treated with non-selective pan-HER2-TKIs (such as poziotinib, afatinib, and others) (non-selective TKI cohort). **Results:** Of 77 patients (0.2%) included, 60 in the naïve cohort, 7 in the selective TKI cohort, and 10 in the non-selective TKI cohort. Overall, the median age was 60 years (range, 44–76), and 56% of patients were female. By NGS analysis, all tumors harbored ERBB2 exon 20 insertions within the tyrosine kinase domain; the YVMA subtype was the most common (57%). T-DXd was administered as a median fourth-line therapy (range, 2–8). Baseline clinical and genomic characteristics were generally comparable across the three groups. According to prior HER2-TKI exposure, the ORR was 60% (36/60) in the naïve cohort, 29% (2/7) in the selective TKI cohort, and 60% (6/10) in the non-selective TKI cohort. The DCRs were 83% (50/60), 71% (5/7), and 80% (8/10), respectively. Median PFS with T-DXd was 9.9 months in the naïve cohort, compared with 6.5 months in the selective TKI cohort and 5.3 months in the non-selective TKI cohort. The 6-month PFS rate was 72%, 71%, and 50%, respectively. Among 10 patients who did not achieve an objective response to prior HER2-TKIs (best response of stable or progressive disease), 6 achieved a partial response with subsequent T-DXd. **Conclusions:** Although prior HER2-TKI exposure, particularly selective HER2-TKIs, may attenuate the efficacy of T-DXd in HER2 exon 20 insertion–positive NSCLC compared with HER2-TKI–naïve patients, T-DXd retained clinically meaningful activity in a subset of patients, including those who did not achieve objective responses to prior HER2-TKIs. Integrating tumor growth models to improve late-stage lung cancer outcome prediction using early-stage clinical trial data. First Author: Janos Szalma, Clario, Budapest, Hungary

Background: Immunotherapy has substantially improved clinical outcomes but poses distinct challenges for response assessment due to heterogeneous and non-monotonic tumor kinetics. RECIST 1.1 rely on unidimensional lesion measurements that may incompletely capture spatial heterogeneity which can result in limited characterization of tumor growth. Tumor growth modeling provides a complementary, quantitative framework for capturing longitudinal tumor dynamics. Different frameworks have been proposed to model total disease progression and response to treatment from total tumor volume. However, model selection may be challenging with each model capturing distinct growth mechanisms. In this work, we present a framework integrating complementary tumor growth models using a neural network classifier to predict late-stage outcomes from early-stage timepoints. **Methods:** We retrospectively aggregated deidentified data from 417 anonymized subjects with metastatic non-small cell lung cancer (NSCLC) treated with immunotherapy. Serial CT datasets were acquired at five timepoints over a 30-week period and lesions were annotated by expert radiologists according to RECIST 1.1 criteria. Tumor burden was derived from radiologist annotations using a previously validated AI method that reconstructs 3D lesion volumes from bidimensional data. For each subject, Modified Gompertz (MG) and Stein-Claret (SC) models were implemented to estimate intrinsic tumor growth parameters. Both models were fitted using early on-treatment data up to 21 weeks and used to predict response to treatment at week 30. To evaluate complementarity and the ability of early tumor dynamics to predict radiological response, model parameters were combined and used to train a two-layer neural network for radiological outcome classification. Performance of the combined MG+SC was compared with single-model classifiers on response (CR/PR) vs non-response (SD/PD) and progression (PD) vs non-progression (CR/PR/SD) using accuracy and sensitivity metrics. **Results:** The cross-validated accuracy in classifying responders and non-responders at week 30 was 81.1% from the combined MG+SC model (sensitivity=79.2%; specificity=83.0%), higher than both individual models (accuracy = 77.8% and 68.0% for MG and SC respectively). The combined modeling framework confirmed higher accuracy (70.7%) when distinguishing progressive disease from the non-progressor group (sensitivity=64.5%, specificity=76.5%) when compared to both MG (69.1%) and SC (66.8%). **Conclusions:** This work showed that integrating early-stage dynamics from complementary mechanistic growth models improves week-30 radiographic outcome prediction over individual models in metastatic NSCLC immunotherapy trials. This framework can enable earlier identification of patient-level response that may support treatment adaptation. Research Sponsor: None.

GEMINI-NSCLC: Multiomics and single-cell spatial profiling to benchmark, back-translate, and build digital twins of IO response. First Author: Vincent Perez, Tempus AI, Chicago, IL

Background: Response to first-line standard-of-care (SoC) chemo-immunotherapy (IO) for patients with NSCLC without targetable mutations is heterogeneous, highlighting the need for predictive biomarkers. GEMINI (NCT05236114) integrates real-world outcomes, whole exome sequencing (WES), single-cell spatial transcriptomics (SpTx), and AI-pathology to establish a benchmarking resource and patient-level digital twins, enabling back-translation into testable hypotheses. With >4 million cells from 53 biopsies, GEMINI is one of the largest single-cell spatial datasets linked to IO outcomes. **Methods:** Patients with metastatic NSCLC were analyzed for outcome associations. Progression-free survival (PFS) was defined from IO start to progression, next regimen, last follow-up, or 2 years. Patients were classified as fast progressors (<3 months PFS) or slow progressors (>3 months PFS). Baseline biopsies (n=53) underwent WES and SpTx. Neural networks traced single-cell boundaries on H&E to quantify gene expression; cells were annotated via clustering and LLM-assisted labeling. AI-, manual-, and digital-pathology (DSP) defined tumor, immune, and stroma regions. Cohort-level benchmarking was integrated into patient-level digital twins to back-translate spatial-genomic features into individualized risk and mechanism hypotheses. **Results:** WES revealed expected mutation frequencies: *STK11* 15%, *TP53* 73%, *KEAP1* 21%, *KRAS* 46%, supporting cohort representativeness. Stroma-associated TIL counts were higher in slow versus fast progressors by AI-path (p=0.034) and manual-path (p=0.014). DSP showed immune aggregates in slow progressors were lymphocyte-diverse, whereas fast progressors were enriched for five macrophage subtypes consistent with immunosuppressive niches. Spatial proximity of lymphocytes and stroma to a tumor subcluster (C2) predicted progression (p<0.01). Immunoglobulin light-chain expression localized to the tumor core in slow progressors, suggesting tumor–B cell interactions with disease arrest. Differential expression identified 14 EMT/ECM genes overexpressed in fast-progressor stroma, implicating stromal barrier/ECM remodeling in IO resistance. Digital twins captured these spatial-omic signatures to forecast risk and generate patient-specific, testable hypotheses. **Conclusions:** GEMINI provides a large single-cell spatial transcriptomic benchmark linked to IO outcomes for patients with NSCLC and enables AI-driven digital twins for clinical decision support. Fast progressors show stromal EMT/ECM programs and immunosuppressive myeloid niches; slow progressors exhibit lymphocyte diversity and tumor–B cell interactions near subcluster C2. Findings support multimodal risk stratification and nominate stromal EMT/ECM targeting to overcome IO resistance, with prospective validation via digital-twin biomarkers. Clinical trial information: NCT05236114. Research Sponsor: AstraZeneca; Tempus AI.

AI-derived CD8⁺ cytotoxic T-cell immune signatures from baseline H&E images to predict immunotherapy benefit over chemotherapy in non–small cell lung cancer: Blinded validation in CheckMate-227 (CM227). First Author: Cristian Barrera, Emory University and Georgia Institute of Technology, Atlanta, GA

Background: Immunotherapy (IO) has transformed treatment for non–small cell lung cancer (NSCLC), but not all patients (pts) benefit, underscoring the need for predictive biomarkers to guide IO versus chemotherapy (Ch). CheckMate 227 (CM227; NCT02477826) showed a survival benefit of first-line nivolumab plus ipilimumab (nivo+ipi) over Ch in stage IV NSCLC. $CD8^+$ T cells are key mediators of antitumor immunity and are associated with IO benefit. We developed an artificial intelligence (AI)–based pipeline (VIGOR-CD8) that predicts spatial $CD8^+$ immune signatures from routine baseline H&E whole-slide images using histopathology foundation model embeddings (H-Optimus-0) and virtual gene expression modeling (HE2Gene), and evaluated its ability to identify pts who do and do not derive IO benefit over Ch in CM227. **Methods:** 1,598 pts with advanced NSCLC were analyzed, including multi-institutional retrospective cohorts (n = 487; 65 for patch-level $CD8^+$ prediction and overall survival (OS), 422 for patient-level OS) and a blinded CM227 validation subset (n = 1,111). For orthogonal validation, 86,470 H&E patches were co-registered with quantitative $CD8^+$ immunofluorescence. H-Optimus-0 and HE2Gene immune-related embeddings were used to train a random forest classifier to predict patch-level $CD8^+$ probability. Patch-level probabilities were aggregated into a patient-level $CD8^+$ signature and dichotomized into biomarker-positive (B^+) and biomarker-negative (B^-) groups by the training-set median. Cox models assessed the impact of VIGOR-CD8 on OS. In CM227, prognostic and predictive utility were evaluated using treatment-specific analyses; investigators were blinded to outcomes, and models were trained on independent, non-overlapping cohorts. **Results:** VIGOR-CD8 was associated with longer OS in the testing cohort (n = 422; HR 0.68, 95% CI 0.53–0.87, p = 0.00163) and CM227 (n = 1,111; HR 0.8, 95% CI 0.67–0.96, p = 0.016), irrespective of treatment type and PD-L1 expression. Among pts with evaluable PD-L1, B^+ pts treated with nivo+ipi had superior OS versus Ch (n = 617; HR 0.72, 95% CI 0.58–0.90, p = 0.003), while in B^- pts there was no significant OS difference between treatment arms (n = 130; HR 1.18, 95% CI 0.79–1.75, p = 0.436), supporting a predictive rather than purely prognostic role for VIGOR-CD8. **Conclusions:** An AI-derived $CD8^+$ immune signature from routine baseline H&E slides was associated with favorable OS in CM227 and predicted differential benefit from nivo+ipi versus Ch. VIGOR-CD8 may help identify advanced NSCLC pts most likely to benefit from first-line dual IO, but further validation in independent and prospective trials is warranted. Impact of NCCN-guided training on large language model performance in mNSCLC. First Author: Andrew Gould, University of Illinois Chicago, Chicago, IL

Background: Publicly available large language models (LLMs) such as ChatGPT may support clinical decision-making in precision oncology by rapidly synthesizing complex information. We previously evaluated ChatGPT's ability to generate NCCN-concordant first-line (1L) treatment recommendations for metastatic non-small cell lung cancer (mNSCLC) using a novel Generative AI Performance Score (G-PS). We evaluated whether NCCN-guideline–based training improves LLM treatment recommendations across multiple lines of therapy and targetable genotypes in metastatic NSCLC. **Methods:** NCCN Guidelines (v3.2025) were reviewed and eight driver alterations with FDA-approved therapies were selected: EGFR Ex19del, BRAF V600E, ALK fusion, KRAS G12C, NTRK1/2/3 fusion, ROS1 fusion, RET fusion, and MET exon 14 skipping. Standardized prompts requesting 1L, second-line (2L), and third-line (3L) recommendations were generated and run through ChatGPT-5.2. Prompts included information on patient demographics, disease stage, and prior therapy where appropriate. Each scenario was repeated five times per line of treatment (N = 15 per mutation). In trained sessions, the LLM was explicitly instructed to defer to an uploaded PDF copy of the NCCN guidelines prior to generating recommendations. Responses were scored using the G-PS, which quantifies guideline concordance on a continuous scale from -1 (all hallucinations) to 1 (all correct answers) based on alignment with NCCN-recommended therapies. Additionally, we calculated ratios for the mean trained G-PS and untrained G-PS across groups, to estimate the relative fold change effect of training on ChatGPT performance (called the "Training Ratio"). **Results:** A total of 240 prompts were analyzed (120 untrained, 120 trained). NCCN-guided training significantly improved overall LLM guideline concordance (mean G-PS 0.462 vs 0.313, p = 0.049) and reduced irrelevant recommendations (mean irrelevant rate of 23.7% vs 39.8%, $p < 0.001$) but did not significantly affect the rate of hallucinations (10.4% vs 8.1%, p = 0.297). 1L responses demonstrated significantly higher mean G-PS than 2L ($p < 0.001$) or 3L ($p < 0.001$) for both trained and untrained sessions. Training also significantly improved the mean G-PS of 1L responses compared to untrained responses (0.902 vs 0.647, $p < 0.001$) but not in 2L or 3L. The overall Training Ratio was 1.48, with the greatest Training Ratio seen in EGFR Ex19del and ALK fusion (> 4) and the poorest in NTRK fusions (0.53). **Conclusions:** While guideline-based training improves ChatGPT's overall performance and reduces irrelevant outputs, recommendation quality declines substantially beyond the first line of therapy and shows marked variability by mutation. These findings highlight important limitations of LLMs in complex oncology decision-making and reinforce that clinicians must independently verify recommendations against established guidelines. A triage-aware neuro-symbolic approach for clinical trial matching in oncology: Real-world validation in lung and genitourinary cancer. First Author: Vittoria Peppoloni, Fondazione IRCSS Istituto Nazionale dei Tumori di Milano, Milan, Italy

Background: Low clinical trial accrual remains a critical barrier in oncology, driven by fragmented electronic health records (EHRs), limited trial awareness, and the substantial time required for manual eligibility screening. While large language models (LLMs) can extract clinical information from unstructured data, their probabilistic nature limits direct use for eligibility decisions that require protocol-level determinism and auditability. We developed a neuro-symbolic clinical trial matching platform that combines LLM-based information extraction with explicit rule-based eligibility reasoning, augmented by an uncertainty-aware triage strategy to safely integrate automation into real-world workflows. **Methods:** Unstructured EHRs were processed using a large language model (Llama 3.1–70B) to extract key clinical variables, which were normalized to a domain ontology. Trial eligibility was evaluated using deterministic inclusion and exclusion criteria encoded directly from full trial protocols, producing per-criterion explanations and an overall classification (eligible, not eligible, or indeterminate). A triage module quantified evidentiary completeness and logical consistency, categorizing cases into low-uncertainty confidence results suitable for automated screening, moderate and high-uncertainty cases requiring clinician review. Performance was assessed against clinician-validated ground truth in a real-world cohort of 107 patients, including advanced lung cancer patients and an independent genitourinary cancer validation cohort. **Results:** Among matchable patients (n = 79), the system achieved perfect Top-1 accuracy and Recall@3 of 1.00, with all eligible patients correctly identified within the top three trial recommendations. Thirty-nine patients (49%) were triaged as low-uncertainty and suitable for automated screening, while the remainder were appropriately flagged for clinician review. Among non-matchable patients (n = 28), no false-positive eligibility assignments were observed (false-positive rate 0.0). Triage correctly identified high-uncertainty cases, minimizing unsafe automation. In indeterminate cases (ground truth unknown, n = 6), the system deferred to manual review in two-thirds of cases, with zero unsafe automated classifications. Median end-to-end processing time was under one minute per patient. **Conclusions:** This neuro-symbolic, triage-aware approach enables transparent and deterministic clinical trial matching in oncology. By combining automated eligibility assessment with uncertainty-based triage, the system reduces manual screening burden while preserving clinician oversight, supporting scalable and trustworthy trial enrollment in real-world practice. Discrepancy between plasma cell-free DNA and tissue-based analysis for detection of gene amplifications in non–small cell lung cancer. First Author: Haruka Nakatani, National Cancer Center Hospital East, Kashiwa, Japan

Background: Therapeutic strategies have been developed in patients with non-small cell lung cancer (NSCLC) harboring gene amplifications (amp) such as *MET* and *HER2*. Although both plasma cell-free DNA (cfDNA) and tissue-based next-generation sequencing (NGS) are available for the detection of gene amp, the concordance between plasma cfDNA and tissue-based analysis for the detection of gene amp remains unclear. **Methods:** We investigated plasma cfDNA and tissue-based NGS concordance for detection of gene amp in NSCLC using a large-scale screening cohort (LC-SCRUM-Liquid). Paired blood samples were prospectively collected within 4 weeks of corresponding tumor tissue sampling from patients with advanced NSCLC. Guardant360 panel or Oncomine Precision Assay panel was used for plasma cfDNA NGS. Oncomine Comprehensive Assay panel or Oncomine Precision Assay was used for tissue-based NGS. The concordance of *EGFR*, *MET* and *HER2* gene amp were evaluated. **Results:** A total of 1,133 pairs of blood and tissue samples were successfully analyzed between December 2017 and December 2024. The median age of the patients was 69 years (range 25-91), 60% were male, 68% were ever smokers, and 79% had a histopathological diagnosis of adenocarcinoma. The positive percent agreement (PPA) and positive predictive value (PPV) of plasma cfDNA analysis relative to tissue-based analysis are shown in the table. For detecting *MET* amp, the PPA of plasma cfDNA analysis relative to tissue-based analysis tended to be lower in the patients with metastases involving fewer than two organs compared to those with metastases involving two or more organs (25% vs. 63%, P = 0.07). Among the patients with *EGFR*, *MET*, or *HER2* amp detected by either tissue-based or plasma cfDNA analysis, the correlation of the copy number variants between tissue-based and plasma cfDNA analysis was very weak (r = 0.20). **Conclusions:** The concordance between plasma cfDNA and tissue-based analysis for detecting gene amp is markedly low, particularly in patients with a low tumor burden. Detection of gene amp using plasma cfDNA analysis may be insufficient for accurately evaluating the efficacy of targeted therapies for patients with lung cancer harboring gene amp. Smoking signature as used to define a genomically distinct subset of class I BRAF-mutant NSCLC. First Author: Shuai Wang, Vanderbilt University Medical Center, Nashville, TN

Background: Class I *BRAF* mutant (*BRAF* mut) non–small cell lung cancer (NSCLC) is biologically heterogeneous, occurring in both smokers and never-smokers with disparate benefits from immunotherapy (IO). Genomically defined tobacco-induced damage may better identify biologically and clinically distinct subsets than self-reported smoking history. We evaluated COSMIC mutational signature-SBS4 as a genomic surrogate of smoking exposure and examined its association with molecular features, tumor microenvironment (TME) and outcomes in *BRAF* mut NSCLC. **Methods:** Retrospective review of 33,217 NSCLC specimens that underwent whole exome and whole transcriptome sequencing at Caris Life Sciences. Mutation profiles of specimens were deconvolved using the COSMIC SBS4 signature to estimate tobacco-associated mutational exposure (filter: total mutation count>=200, Nfiltered=26448; *BRAF* mut = 276). TME was estimated using QuanTIseq method. Overall survival (OS) and survival on IO (IO-OS) were obtained from insurance claims and calculated from date of tumor biopsy (for OS) or initiation of IO (for IO-OS) to last contact using Kaplan-Meier estimates and Cox proportional hazards models. Statistical significance was determined by Fishers Exact, chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($P<0.05$). **Results:** Among 6,405 patients with smoking history and SBS4 data, SBS4+ (SBS4>0) was strongly associated with smoking (OR 11.2, $P<0.001$). SBS4+ tumors exhibited elevated TMB (mean:13 vs 9 mut/Mb, and TMB-High [>=10 mut/Mb], $P<0.05$, Table). SBS4+ *BRAF* mut tumors had a lower prevalence of mutations in *SETD2* (OR 0.33), *PIK3CA* (OR 0.26) and *SMAD4* (OR 0.25, all $P<0.05$). Regardless of SBS4 status, *BRAF* mut tumors were more often PD-L1+ (OR 3.2, TPS>=1), while mutations in *STK11*, *KEAP1*, and *SMARCA4* were less frequent (OR 0.07-0.37, all $P<0.05$). Evaluation of the TME revealed that SBS4+ *BRAF* mut were enriched for regulatory T cells (vs. SBS4-,1.44 fold, $P<0.05$). In metastatic disease, *BRAF* mut showed improved OS (HR 0.8[0.66-0.97], $P=0.03$) and IO-OS (HR 0.8[0.66-0.99], $P=0.04$) compared to WT. The OS benefit was preserved in the SBS4+ tumors (HR 0.64[0.43-0.95], $P=0.03$), but not in SBS4- tumors. No difference in IO-OS was observed in SBS4+ subgroups likely due to small size. **Conclusions:** SBS4 identifies biologically distinct subsets in class I BRAF mut NSCLC, with differences in mutational landscape, TMB, and TME. SBS4+ tumors show a survival benefit over WT disease, whereas SBS4- tumors do not. These findings support SBS4 as a genomic marker of smoking-related biology and a potential tool to refine therapeutic decision-making between targeted therapy and IO in NSCLC and potentially other smoking-associated cancers. Research Sponsor: None.

Smoking signature in BRAF mut NSCLC (% prevalence and OS).

Characteristics	SBS4 +	SBS4 -
SETD2	20	43
PIK3CA	6	19
SMAD4	3	12
TMB-high	41	18
OS (months)	29.9 vs. 11.9 ($P=0.03$)	16.0 vs. 10.9 ($P=0.47$)

A real-world analysis of ctDNA methylation-based histology prediction and associated clinical characteristics in non–small cell lung cancer (NSCLC). First Author: Jessica Zhang, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: The treatment of NSCLC differs by histologic subtype, though traditional histologic review faces several challenges including insufficient tissue and intratumoral heterogeneity. The circulating tumor DNA (ctDNA) assay Guardant360 Liquid (G360) now includes a molecular tumor type (TT) and lung subtype (ST) predictor based on DNA methylation patterns. This study aimed to evaluate the concordance between G360 TT/ST prediction and tissue-based histology in a real-world sample of patients (pts) with NSCLC. A comparative analysis was conducted to understand differences in clinical characteristics between pts with and without G360 TT/ST prediction. **Methods:** This retrospective study included pts with NSCLC who underwent G360 testing from May to October of 2025. G360 predicted TT and ST (proportion of adenocarcinoma (AD), squamous cell carcinoma (SQ), and small cell carcinoma (SC)). Dominant TT was defined as the top cancer of origin prediction. Dominant ST was defined as a proportion >80%. G360 TT/ST was compared to tissue histology to determine concordance using Cohen's kappa coefficient. Demographic and clinical characteristics were collected, and statistical differences ($p<0.05$) between pts with and without TT/ST prediction were evaluated. **Results:** Of 145 pts who underwent a combined 176 G360 assays, 47 (32%) had assays predicting TT/ST, including 9 pts with TT prediction only and 38 with both. Of these 38 pts, 32 had tissue-proven AD, 3 had SQ, and 3 had poorly differentiated NSCLC. The overall accuracy of G360 TT prediction was 100% (47/47). The accuracy of ST prediction, excluding the 3 pts with poorly differentiated NSCLC, was 94% (33/35, k=0.72), with 2 discordant cases. One case was a pt with AD whose G360 at diagnosis predicted AD, but 4 months later predicted a SC component (40%). Both pts with discordant subtyping died within 4 months of their G360 result. Pts with TT/ST prediction were statistically younger, had more advanced disease, higher extra-thoracic metastatic burden, and higher ctDNA tumor fraction (TF) than pts without TT/ST prediction (Table 1). **Conclusions:** In this real-world analysis, G360 TT/ST prediction demonstrated good concordance with tissue-based histology, though prediction was more likely in pts with more advanced disease and higher TF. In the future, ctDNA-based TT/ST prediction may be a useful noninvasive tool to confirm primary lung cancer, classify histologic subtype, and identify histologic transformation, particularly during periods of disease progression, leading to better therapeutic decisions. Research Sponsor: None.

Baseline pt characteristics.

	(+) G360 TT/ST prediction (n=47)	(-) G360 TT/ST prediction (n=98)	*P*-value
Median age (IQR)	68 (64-77)	71 (60-74)	0.03
Female (%)	27 (57.4)	60 (61.2)	0.66
Stage III/IV (%)	46 (97.9)	67 (68.4)	<0.0001

Longitudinal circulating tumor DNA surveillance as predictor of progression in advanced non-small-cell lung cancer with long-term benefit to immunotherapy. First Author: Fang Wu, Department of Oncology, The Second Xiangya Hospital, Central South University, Changsha, China

Background: Radiographic assessments often lag behind biological progression, and reliable biomarkers to stratify the post-treatment progression risk remain lacking in advanced non-small-cell lung cancer (NSCLC). The clinical utility of minimal residual disease in advanced solid tumors also requires further evaluation. We investigated ctDNA-based post-immunotherapy molecular residual disease (ctDNA-iMRD) in advanced NSCLC with long-term benefit from immunotherapy and assessed its predictive value for subsequent progression. **Methods:** This prospective, observational, multicenter CR1STAL study, is designed to evaluate whether longitudinal ctDNA-iMRD surveillance can can stratify progression risk in advanced NSCLC patients with long-term benefit from immunotherapy (defined as non-PD at 12 months after treatment initiation). The primary endpoint was progression-free survival (PFS), defined as the time from enrollment to radiographic progression or death. For ctDNA detection, tumor-informed and tumor-agnostic approaches were selected according to tumor tissue availability. ctDNA-iMRD positive was defined as detectable ctDNA at at any surveillance timepoint. **Results:** A total of 97 advanced NSCLC patients were included, comprising 46 in the tumor-informed cohort and 51 in the tumor-agnostic cohort. At median follow-up of 36.4 months and a median ctDNA-iMRD surveillance duration of 10.5 months, 49 patients (50.5%) were classified as ctDNA-iMRD positive during longitudinal monitoring. Patients who were ctDNA-iMRD positive had a significantly shorter median PFS than those who remained ctDNA-iMRD negative (10.1 months vs not reached; HR = 4.85; 95% CI, 2.66 to 8.82; $p < 0.001$). ctDNA-iMRD detectable preceded radiographic progression by a median of 5.9 months. The positive and negative predictive values of longitudinal ctDNA-iMRD surveillance were 85.1% and 72.7%, respectively. Between ctDNA detection approachs, ctDNA-iMRD positive was strongly associated with increased progression risk in both the tumor-informed (HR = 6.29; $p < 0.001$) and tumor-agnostic (HR = 3.67; $p < 0.001$) cohorts. In addition, longitudinal ctDNA-iMRD negative was associated with long-term overall survival (HR = 0.22, 95% CI, 0.09 to 0.55; $p < 0.001$), with 2-year and 3-year OS rates of 97.2% and 89.8%, respectively. Furthermore, ctDNA clonal status and high ctDNA growth rates were correlated with early progression. **Conclusions:** Both tumor-informed and tumor-agnostic ctDNA-iMRD approaches showed strong predictive performance. Longitudinal ctDNA-iMRD surveillance effectively stratified advanced NSCLC patients at high risk of progression after achieving long-term benefit from immunotherapy, supporting its potential role in enabling earlier, risk-adapted intervention in future prospective studies. ClinicalTrials.gov Identifier: NCT05198154. Research Sponsor: None.

Association of gut microbiota and peri-initiation proton pump inhibitor/antibiotic exposure with outcomes of atezolizumab-bevacizumab-carboplatin-paclitaxel regimen in patients with advanced non-squamous NSCLC: Prospective phase II study (K-TAIL-201). First Author: Hiroshi Wakui, Division of Respiratory Diseases, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan

Background: Concomitant medications that alter gut microbiome composition, such as proton pump inhibitors (PPIs) and antibiotics, have been suggested as possible modifiers of immune checkpoint inhibitor outcomes; however, there is a paucity of prospective data with pre-specified exposure windows during atezolizumab-bevacizumab-carboplatin-paclitaxel (ABCP) treatment. This study investigated the associations between peri-initiation PPI/antibiotic exposure and gut microbiota with clinical outcomes. **Methods:** K-TAIL-201 is a prospective, single-arm, phase II study (jRCT031200088) that enrolled Japanese patients with previously untreated advanced non-squamous non-small cell lung cancer (NSCLC) who received an induction ABCP regimen, followed by maintenance with atezolizumab plus bevacizumab. The primary endpoint was six-month progression-free survival (PFS) rate. PPI/antibiotic exposure was evaluated in two pre-specified windows: pre-treatment (up to 21 days before ABCP) and early on-treatment (the first 21 days of treatment). Longitudinal fecal samples were collected and analyzed using 16S rRNA gene sequencing. Exploratory analyses were conducted to investigate the relationships between exposure/microbiota features and outcomes. **Results:** Thirty-two patients were enrolled, with a median follow-up period of 20.6 months. The 6-month PFS rate was 59.4% (95% confidence interval (CI), 40.6–76.3), objective response rate was 50.0% (95% CI, 31.9–68.2), median PFS was 7.1 months (95% CI, 5.9–9.6), and the median overall survival (OS) was 24.3 months (95% CI, 18.7–not reached). Early on-treatment PPI exposure was associated with poorer outcomes, including shorter PFS (hazard ratio [HR] 7.07, $p < 0.001$) and OS (HR 5.66, p = 0.009), whereas pre-treatment PPI exposure was not associated with PFS of at least six months. Early on-treatment antibiotic exposure was associated with a lower 6-month PFS rate (21% versus 89%, $p < 0.001$), but showed no association with time-to-event PFS (HR 1.62, p = 0.41). Microbiota analyses revealed no significant differences in alpha or beta diversity by outcome or exposure group. However, *Bifidobacterium* was more frequently detected among responders. **Conclusions:** Early on-treatment (but not pre-treatment) PPI exposure is strongly associated with inferior PFS and OS in patients with advanced non-squamous NSCLC on ABCP regimen, supporting the clinical relevance of exposure timing. These findings suggest careful PPI use during the induction phase and warrant validation in larger prospective cohorts. Clinical trial information: 031200088. Research Sponsor: Chugai Pharmaceutical Co., Ltd.

USP10 activity as sensitizer of lung adenocarcinoma to immune checkpoint inhibitors: Upregulating PD-L1 via the ANT3-mediated activation of the cGAS-STING pathway. First Author: Aman Wang, The First Affiliated Hospital of Dalian Medical University, Dalian, China

Background: Although immune checkpoint inhibitors (ICIs) have reshaped the treatment landscape for advanced lung adenocarcinoma (LUAD), response heterogeneity remains substantial. The cGAS–STING pathway plays a pivotal role in activating antitumor immune responses, yet its upstream regulatory mechanisms remain poorly defined. This study investigated the role of the deubiquitinating enzyme USP10 in remodeling the LUAD immune microenvironment and its mechanistic link to PD-L1 expression via the cGAS-STING axis to establish its potential as a predictive biomarker for ICIs efficacy. **Methods:** Interactions between USP10 and the mitochondrial protein ANT3 were characterized using Co-IP, LC-MS/MS, and in vitro deubiquitination assays. Mitochondrial DNA (mtDNA) leakage and cGAS-STING activation were assessed via immunofluorescence and qPCR. The therapeutic impact of USP10 on PD-1 blockade was evaluated in an orthotopic murine LUAD model. Furthermore, Furthermore, a clinical cohort of 228 patients with advanced driver-gene negative LUAD receiving first-line ICIs treatment was analyzed to correlate USP10 expression with objective response rate (ORR), disease control rate (DCR), and progression-free survival (PFS). **Results:** Mechanistically, USP10 directly interacts with mitochondrial adenine nucleotide translocase 3 (ANT3) and stabilizes its protein level by removing K48-linked ubiquitin chains. USP10-mediated ANT3 accumulation triggers mitochondrial stress and promotes mtDNA release into the cytosol, thereby activating the cGAS-STING-TBK1-IRF3 signaling pathway and ultimately driving transcriptional upregulation of PD-L1. In orthotopic LUAD models, USP10-overexpressing tumors exhibited an "inflamed" phenotype characterized by a significant increase in CD8+ T cell infiltration. USP10 expression levels sensitized tumors to immunotherapy; USP10-high tumors demonstrated dramatic regression upon anti-PD-1 treatment compared to controls. In the cohort of 228 patients, high USP10 expression was identified as a robust predictor of superior clinical benefit to first-line ICIs treatment . Patients in the USP10-high group achieved significantly prolonged PFS (p = 0.028), higher ORR (p = 0.037), and improved DCR (p = 0.041) compared to the USP10-low group. **Conclusions:** Our study identifies a novel USP10-ANT3-cGAS-STING-PD-L1 regulatory axis that converts "cold" tumors into "hot" tumors. By inducing a pro-inflammatory TIME, USP10 enhances the sensitivity of LUAD to ICIs. These findings establish USP10 as a promising predictive biomarker and a potential therapeutic target to optimize immunotherapy strategies in lung adenocarcinoma. Research Sponsor: None.

Smoking–genomic discordance in metastatic non–small cell lung cancer. First Author: Ilit Turgeman, Lowe Center for Thoracic Oncology, Dana Farber Cancer Institute, Boston, MA

Background: Smoking is the dominant risk factor for lung cancer, yet clinical smoking history does not consistently align with the presence of tobacco-associated mutational patterns (C > A transversions). We hypothesized that smoking-genomic discordance identifies a biologically distinct subset of tumors arising through endogenous, aging-enriched mutational processes. **Methods:** We analyzed metastatic NSCLC patients with documented smoking history and tumor sequencing from a discovery cohort (n = 111) and an independent Dana-Farber validation cohort (n = 2,680). Tumors were stratified by presence or absence of C > A tobacco transversions. Endpoints included C > T transition burden as a surrogate for aging-related mutational processes, transition-to-transversion (Ti/Tv) ratio for endogenous mutational contribution, tumor mutational burden (TMB), oncogenic driver distribution, and first line treatment outcomes. Multivariable regression models adjusted for age, sex, smoking intensity, and driver genotype. **Results:** Among patients with smoking history, 30% of the discovery and 15.2% of the validation cohort lacked detectable C > A transversions, including 29% with > 30 pack-years. Smoking intensity correlated with C > A but not C > T burden, while C > T increased with age in binomial models, consistent with clock-like aging accumulation. C > A negative discordant tumors had higher C > T fractions and Ti/Tv ratios than both concordant smokers and never smokers ($p < 0.001$). After multivariable adjustment, discordance was independently associated with higher C > T fractions ($\beta = 0.21$, $p < 2\times10^{-16}$) and increased odds of aging-dominant profiles defined by C > T quartiles (OR = 9.2, $p < 2\times10^{-16}$). Associations varied by driver (interaction p = 0.007), with EGFR mutant and oncogene fusion driven tumors enriched for C > T high discordant profiles and weak coupling between smoking intensity and C > A burden. Discordance differed by age ($p = 7.6\times10^{-4}$): among patients < 50 years, discordant smokers paradoxically had highest C > T fractions, whereas never smokers showed greatest C > A transversions, suggesting bidirectional smoking-genomic mismatch. C > A negative discordant tumors had lower TMB and depletion of KRAS/STK11/KEAP1 alterations. PD-L1 and TMB predicted immunotherapy PFS only in C > A positive tumors, suggesting limitations of conventional biomarkers in discordant cases. Conversely, C > A presence correlated with shorter targeted therapy PFS across oncogenic drivers. **Conclusions:** Clinical smoking history alone does not capture the dominant mutational processes shaping NSCLC. Smoking–genomic discordance identifies a biologically coherent phenotype with endogenous aging-associated patterns, driver- and age- related heterogeneity, and distinct therapeutic vulnerabilities. These findings motivate research into germline susceptibility and environmental exposures that may underlie tobacco-independent mutagenesis. Research Sponsor: None.

STK11 and/or KEAP1 alterations in KRAS-mutant NSCLC treated with immune checkpoint inhibitors or chemotherapy: An episode-based Project GENIE analysis. First Author: Aayushi Pareek, St. Bernards Medical Center, Jonesboro, AR

Background: STK11 and KEAP1 alterations are linked to aggressive biology in KRAS-mutant NSCLC and have been proposed to confer immune resistance and inferior outcomes with immune checkpoint inhibitor (ICI) though data remains inconsistent. We evaluated whether STK11 and/or KEAP1 alterations are associated with inferior overall survival (OS) and whether outcomes differ by treatment class (ICI vs chemotherapy) in a real-world clinic-genomic cohort. **Methods:** Using GENIE BPC NSCLC v2.0-public data, we created an episode-based cohort of KRAS-mutant NSCLC treatment regimens categorized as ICI or chemotherapy. STK11 and/or KEAP1 alteration status (single or dual) was the primary exposure. OS was measured from regimen start and analyzed with multivariable Cox models using patient-level clustering, adjusting for available covariates (age, sex, histology, tumor mutational burden [TMB], and KRAS G12C). We tested effect modification with an interaction term (STK11/KEAP1 × ICI). Sensitivity analyses included 3-, 6-, and 12-months landmark models and inverse probability of treatment weighting (IPTW). PD-L1, ECOG PS and line of therapy were not available. **Results:** We identified 542 treatment episodes from 293 patients (ICI = 149; chemo = 393) including 181 episodes that were STK11/KEAP1-altered. In the main cluster-robust model, STK11/KEAP1 alterations were associated with worse OS (aHR 1.68, 95% CI 1.27 - 2.24; $p < 0.001$). ICI (vs chemo) was associated with higher hazard ratio (aHR 1.76, 95% CI 1.42 - 2.18; $p < 0.001$) likely reflecting later-line use of ICI. The STK11/KEAP1 × ICI interaction was not significant as aHR 1.13, 95% CI 0.76 - 1.67; p = 0.559). In the 3-month landmark analysis STK11/KEAP1 remained adverse (aHR 1.61, 95% CI 1.19 - 2.18; p = 0.002), and the interaction estimate shifted below 1.0 (aHR 0.86, 95% CI 0.55 - 1.35; p = 0.519) suggesting a possible trend toward relatively greater ICI benefit among altered patients who survive beyond early attrition. Results were directionally consistent across 6- and 12-month landmark and IPTW analyses. **Conclusions:** In this real-world KRAS-mutant NSCLC cohort, STK11 and/or KEAP1 alterations were consistently associated with worse OS across treatment classes, supporting a primarily prognostic role. We did not find evidence of ICI-specific resistance by STK11/KEAP1 status, although modest interaction effects may be underpowered. Unmeasured confounding (ECOG PS, PD-L1 and line of therapy) remains a key limitation highlighting the need for larger, highly annotated datasets. Research Sponsor: None.

AI-powered characterization of the tumor microenvironment landscape in HER2-overexpressing non–small cell lung cancer. First Author: Woochan Hwang, Lunit Inc., Seoul, South Korea

Background: Antibody-drug conjugate (ADC) targeting HER2 in NSCLC is an opportunity for biomarker-guided therapy independent of oncogenic driver status. As such, HER2 overexpressing (OE) tumors remain a clinically relevant yet under-characterized subgroup of NSCLC patients. Given the role of the tumor microenvironment (TME) in modulating response to ADCs, we applied AI-powered spatial analysis to comprehensively characterize the immunological landscape of NSCLC stratified by HER2 expression. **Methods:** We performed a retrospective analysis of a proprietary dataset comprising 2,054 H&E whole-slide images (WSIs) of NSCLC cases collected globally and enriched for HER2 OE tumors. HER2 OE was defined as IHC 3+ by pathologist reading based on ASCO/CAP guidelines and compared against IHC 0-2+. An AI-powered H&E analyzer (Lunit SCOPE IO) was used to quantify tumor-infiltrating lymphocytes (TILs) in the epithelial and stromal compartments. Immune phenotypes were classified as inflamed, excluded, or desert. For a subset of 1,099 cases with paired HER2 IHC WSIs, the proportion of tumor cells with 3+ intensity was quantified using an IHC analyzer (Lunit SCOPE HER2). Findings were further validated using 318 H&E WSIs and differential gene expression analysis of the TCGA Lung Adenocarcinoma (LUAD) cohort, stratified by ERBB2 protein expression (RPPA). **Results:** Of the 2,054 NSCLC cases, the primary analysis focused on adenocarcinoma cases (n = 1,641), which included 229 (14.0%) HER2 OE tumors. These tumors exhibited a significantly lower proportion of inflamed immune phenotype compared to the non-OE group (10.2% vs 22.1%, $P < 0.0001$). Intratumoral TIL and stromal TIL densities were reduced by 26.1% ($P < 0.0001$) and 14.7% ($P < 0.001$), respectively. Notably, even among HER2 OE tumors, a subset with high 3+ cell proportion (≥50% 3+ tumor cells) demonstrated a dose-dependent trend with an even lower inflamed proportion (3.7% vs 14.0%, P = 0.004) and reduced intratumoral TIL density (-36.7%, $P < 0.001$). The non-adenocarcinoma cohort (n = 413), where HER2 OE was present in 57 (13.8%) cases, showed a trend towards reduced intratumoral TIL density (-20.6%, P = 0.080). Analysis of H&E WSIs in TCGA LUAD validated that ERBB2-high tumors had significantly lower intratumoral TIL density (-16.1%, P = 0.027). Furthermore, gene expression analysis revealed that these tumors had down-regulation of immune effector (GZMB, PRF1) and exhaustion (LAG3) markers, while maintaining an epithelial phenotype (OCLN, CDH1) with decreased mesenchymal markers (CDH2). **Conclusions:** NSCLC with HER2 OE is characterized by a distinct, immune-cold phenotype that is more pronounced with higher HER2 expression. These findings highlight a unique TME landscape that warrants further investigation to understand its potential impact on therapeutic responses. Research Sponsor: None.

Comparing becotarug plus osimertinib with a real-world osimertinib therapy cohort in platinum-refractory, advanced non–small cell lung cancer with EGFR exon 20 insertion. First Author: Jian Fang, Second Department of Thoracic Medical Oncology, Beijing Cancer Hospital, Beijing, Beijing, China

Background: EGFR exon 20 insertion (20ins)-positive non-small-cell lung cancer (NSCLC) is a rare subtype with limited therapeutic options and poor prognosis. Becotarug plus osimertinib showed encouraging activity and acceptable safety in a phase 1 study (NCT04448379). To assess its efficacy in EGFR 20ins-positive NSCLC, a phase 2 single-arm trial (NCT05132777) was initiated. To provide a comparator, a multicenter retrospective real-world study (NCT05513664) was served as an external control arm. **Methods:** Eligible patients in the phase 2 study had unresectable stage IIIB–IV NSCLC with EGFR exon 20 insertion mutations and ≥1 prior platinum-based chemotherapy; those relapsing within six months after neoadjuvant or adjuvant chemotherapy were also eligible. The external control comprised a real-world cohort treated with osimertinib, matched 1:1 on age, sex, stage, ECOG PS, brain metastases, and number of prior systemic therapies. The primary endpoint was independent review committee (IRC)-assessed objective response rate (ORR) in the trial arm and real-world ORR in the control arm. Secondary endpoints included disease control rate (DCR), duration of response (DoR) and progression-free survival (PFS). Safety was evaluated by incidence and severity of adverse events. **Results:** Of the 126 and 96 patients enrolled in the trial and control arms, respectively, 112 and 91 patients met criteria for the pre-matching cohort. After 1:1 propensity-score matching, 158 patients (79 per arm) comprised the post-matching population. Baseline characteristics were well balanced between arms, with 62.0% and 60.8% of patients, respectively, having received ≤1 prior line of systemic therapy. The IRC-assessed ORR was 46.8% (95% CI, 36.24–57.73) in the trial arm versus 7.6% (95% CI, 3.53–15.60) in the control arm. Notably, the lower bound of the trial-arm 95% CI (36.24%) exceeded the control-arm point estimate (7.6%). The absolute ORR difference was 39.2% (95% CI, 25.96–50.87; $P < 0.0001$), corresponding to an odds ratio of 10.72 (95% CI, 4.18–27.51). Furthermore, in a propensity score–matched analysis restricted to patients receiving osimertinib monotherapy (64 per arm), the combination therapy produced a greater ORR (42.2% [95% CI, 27.5-54.8], $P < 0.0001$). Higher DCR were achieved in trial arm compared to control arm (77.2% [95% CI, 66.8-85.1] vs 64.6% [95% CI, 53.6-74.2], $P = 0.080$). The median PFS in trial arm was significantly longer than that in control arm (6.9 vs. 4.8 months, $P = 0.007$). Other efficacy endpoints showed consistent trends favoring the combination therapy. The most common adverse events were EGFR-related mucocutaneous toxicities in both arms. **Conclusions:** This study further supports the efficacy and tolerability of becotarug plus osimertinib in patients with platinum-refractory, EGFR 20ins-positive NSCLC. Clinical trial information: NCT05513664; NCT05132777. Research Sponsor: Shanghai JMT-BIO Technology Co., Ltd.

Genomic characterization of *SMARCA4*-mutant versus wild-type non–small cell lung cancer in a Chinese population: A large-scale next-generation sequencing study. First Author: Tongguo Si, Tianjin Cancer Hospital Airport Hospital, Tianjin, China

Background: SMARCA4 is a core component of the SWI/SNF chromatin remodeling complex and plays a critical role in transcriptional regulation and tumor suppression. SMARCA4 mutations define a biologically aggressive subset of lung cancer; however, their genomic landscape and clinical implications in Chinese patients with non–small cell lung cancer (NSCLC) remain incompletely characterized. This study aimed to comprehensively compare the genomic alteration profiles between SMARCA4-mutant and SMARCA4–wild-type NSCLC to better define distinct molecular subtypes and potential therapeutic implications. **Methods:** A total of 2,362 Chinese patients with NSCLC underwent comprehensive next-generation sequencing (NGS) using a 733-gene DNA panel. The prevalence and mutation spectrum of SMARCA4 were analyzed. Genomic alteration profiles, including co-occurring mutations, tumor mutational burden (TMB), and microsatellite instability (MSI) status, were systematically compared between SMARCA4-mutant and wild-type tumors. **Results:** SMARCA4 mutations were identified in 29 of 2,362 patients (1.23%). The mutation spectrum included frameshift (10.34%), nonframeshift (10.34%), nonsynonymous missense (51.72%), stop-gain (24.14%), and synonymous (3.45%) alterations. SMARCA4-mutant tumors exhibited a distinct genomic profile compared with wild-type tumors. Several genes were significantly enriched in the SMARCA4-mutant group, including STK11 (25.0% vs 5.8%, $P < 0.001$), FAM135B (25.0% vs 8.2%, P = 0.0068), CDH10 (17.9% vs 4.2%, P = 0.0063), and FUBP1 (7.1% vs 0.3%, P = 0.0036), suggesting increased genomic instability and aggressive tumor biology associated with chromatin remodeling dysfunction. In contrast, EGFR mutations were significantly enriched in the SMARCA4–wild-type group (49.1% vs 14.3%, $P < 0.001$), indicating a strong mutual exclusivity between SMARCA4 alterations and classical EGFR-driven oncogenesis. SMARCA4-mutant tumors also demonstrated a significantly higher tumor mutational burden compared with wild-type tumors (7.8 vs 3.1 muts/Mb, $P < 0.0001$), whereas no significant difference in MSI status was observed between the two groups. **Conclusions:** SMARCA4-mutant NSCLC represents a distinct molecular subtype characterized by enrichment of tumor suppressor gene alterations, chromatin remodeling dysfunction, and elevated TMB, while SMARCA4–wild-type tumors are predominantly driven by canonical tyrosine kinase oncogenes such as EGFR. These findings highlight fundamental differences in tumor biology and suggest divergent therapeutic strategies, with SMARCA4-mutant NSCLC potentially benefiting from immunotherapy-oriented approaches rather than traditional targeted therapies. Effect of gut microbiota–derived testosterone on distant metastasis in non–small cell lung cancer. First Author: Chen-Guang Liu, The Second Hospital of Dalian Medical University, Dalian, Liaoning, China

Background: Distant metastasis is the major cause of poor prognosis in non–small cell lung cancer (NSCLC). Emerging evidence suggests that gut microbiota and their metabolites influence tumor progression, but their role in NSCLC metastasis remains unclear. This study aimed to characterize gut microbiota and metabolic features associated with NSCLC metastasis and to elucidate the role and mechanism of the key metabolite testosterone. **Methods:** Fecal samples from 60 NSCLC patients (48 with distant metastasis, 12 without) were analyzed using metagenomic sequencing and untargeted metabolomics. Multi-omics integration with machine learning identified metastasis-associated metabolites. The effects of testosterone on NSCLC cell migration, invasion, and epithelial–mesenchymal transition (EMT) were evaluated in vitro (PC9, A549, H1299) and in vivo using a mouse metastasis model. Molecular mechanisms were investigated by Western blot, transcriptomics, Mendelian randomization analysis, and functional studies of FGF21. Finasteride was used as a pharmacologic antagonist. **Results:** Patients with metastatic NSCLC showed distinct gut microbiota profiles, with increased alpha diversity and altered community structure compared with non-metastatic patients. Opportunistic pathogens including Oscillospiraceae, Ruminococcus, and Actinobacteria were enriched in metastatic patients, while Fusobacteria was enriched in non-metastatic patients. Metabolomic analysis revealed significant enrichment of steroid-related metabolites in metastatic NSCLC, with markedly elevated testosterone levels. Testosterone demonstrated good predictive value for metastasis (AUC = 0.761). Testosterone significantly enhanced NSCLC cell migration and invasion and induced EMT, characterized by decreased E-cadherin and ZO-1 and increased N-cadherin and Snail expression. In vivo, testosterone promoted liver metastasis and EMT marker expression. Mechanistically, testosterone activated AKT/mTOR signaling, showed a causal association with AKT phosphorylation, and upregulated FGF21. Functional assays confirmed that FGF21 promoted EMT and metastasis via AKT/mTOR activation. Finasteride reversed testosterone-induced EMT, signaling activation, and metastasis by inhibiting the FGF21/AKT/mTOR axis. **Conclusions:** Metastatic NSCLC is associated with a distinct gut microbiota and metabolic profile. Gut microbiota–derived testosterone is a key metabolite that promotes NSCLC distant metastasis by activating the FGF21/AKT/mTOR pathway and inducing EMT. Finasteride effectively antagonizes this process, suggesting potential therapeutic value. The testosterone/FGF21/AKT/mTOR axis may serve as a biomarker and therapeutic target for metastatic NSCLC. Baseline CT-derived QVT score as predictor of bevacizumab benefit in advanced non-squamous NSCLC: A retrospective biomarker analysis of SWOG S0819. First Author: Kai Zhang, Picture Health Inc., Cleveland, OH

Background: Despite two decades of anti-angiogenic therapy in NSCLC, no predictive biomarker identifies which patients benefit. As VEGF-targeted combinations advance in clinical development, patient selection biomarkers remain a critical unmet need. QVT (Quantitative Vessel Tortuosity) Score is an automated imaging biomarker measuring chaotic tumor vasculature from baseline CT scans and has been shown to be associated with immune checkpoint inhibitor (ICI) outcomes. We hypothesized that QVT Score could identify patients with chaotic angiogenesis tumors and greater sensitivity to anti-angiogenic therapy. **Methods:** We analyzed a subset of 334 patients from the SWOG S0819 (NCT00946712) trial with treatment-naïve stage IV non-squamous NSCLC receiving carboplatin/paclitaxel with (56%) or without (44%) bevacizumab. QVT Scores were derived from baseline CTs based on radiologist-defined tumor annotations and radiomic features of tumor vasculature (e.g. vessel twisting, curvature, and branching). Overall survival (OS) was evaluated as the primary endpoint using Cox proportional hazards models with QVT $\times$ bevacizumab interaction terms. Bevacizumab was non-randomized in S0819 (physician/patient discretion): to address this, we employed doubly robust estimation combining inverse probability of treatment weighting (IPTW) with multivariable covariate adjustment for age, performance status, histology, smoking history, and stage. **Results:** The QVT Score $\times$ bevacizumab interaction was significant (p=0.007, doubly robust estimation) and stayed consistent across sensitivity analyses (p=0.017 multivariable; p=0.047 IPTW), suggesting differential treatment benefit based on pre-treatment vascular phenotype. QVT Score was strongly OS-associated without bevacizumab (HR=3.03, p=0.003) but not with bevacizumab (HR=1.71, p=0.079), consistent with mitigation of high-risk biology. Bevacizumab benefit increased across QVT quartiles (Table 1): patients in the highest quartile had a 60% reduction in mortality (HR=0.40, $p<0.001$), while patients in the lowest quartile showed no OS benefit (HR=0.89, p=0.64). **Conclusions:** Despite unfavorable prognosis on standard-of-care therapies (chemotherapy, ICIs), we found that patients with elevated baseline QVT Score may benefit from the addition of anti-angiogenic agents. As VEGF-targeted combinations including bispecific antibodies enter development, radiomic biomarkers may play a crucial role in enriching trial populations and enabling mechanistic longitudinal monitoring. These findings warrant prospective validation in independent randomized clinical trials. Research Sponsor: None.

Bevacizumab treatment effect by QVT score quartile.

QVT Score Quartile	N	Bevacizumab effect (Hazard Ratio)	P
Q1	84	0.89 (0.56 -1.42)	0.64
Q2	83	0.70 (0.44-1.12)	0.14
Q3	83	0.54 (0.34-0.85)	0.01
Q4	84	0.40 (0.24-0.65)	0.0003

Impact of *KRAS* co-mutations on the efficacy of durvalumab in patients with locally advanced non–small cell lung cancer (LA-NSCLC) treated with concurrent chemoradiotherapy (ChRT). First Author: Jaime Rubio Perez, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Durvalumab improves survival after platinum-based ChRT in LA-NSCLC. Although immunotherapy is effective in KRAS-mutant tumors across treatment lines, co-mutations are associated with poorer prognosis and treatment resistance. Data efficacy in this context remains limited. **Methods:** We conducted a retrospective, single-institution analysis of patients with locally advanced NSCLC to evaluate the impact of KRAS mutations on progression-free survival (PFS) and overall survival (OS) after concurrent chemoradiotherapy (ChRT) and durvalumab, accounting for key clinical factors and co-mutations (TP53, STK11, KEAP1). Patients with other actionable genomic alterations (EGFR, ALK, ROS1, BRAF, MET, HER2, RET, FGFR) were excluded. PFS was defined from the first durvalumab dose to progression or death and estimated using the Kaplan–Meier method with comparisons by log-rank test. **Results:** A total of 290 patients were included (113 KRAS-mutant, 177 non-KRAS [non-AGA]). Median age was similar (69.7 vs 68.5 years), and baseline characteristics were comparable, except that KRAS-mutant patients were more often female(65% vs 38%, $p < 0.001$) and enriched for adenocarcinoma histology (90% vs 42%; squamous 2.7% vs 49%; p = 0.009) and PD-L1 expression (negative: 34% vs 48%; 1–49%: 25% vs 28%; $\geq$50%: 41% vs 34%). No significant differences in PFS were observed between KRAS and non-KRAS patients (median PFS: 22.9 months [95% CI, 16.0–29.2] vs 19.6 months [95% CI, 13.4–35.2]; log-rank p = 0.087), nor in overall survival (OS) (median OS: 44.5 months [95% CI, 34.4–NR] vs 40.9 months [95% CI, 30.0–59.4]; log-rank p = 0.40). In contrast, PFS differed significantly across KRAS-mutant subgroups: isolated KRAS mutations (median PFS 23.9 months [95% CI, 17.4–30.0]), KRAS with STK11 or KEAP1 co-mutations (8.3 months [95% CI, 3.8–20.8]), and concurrent KRAS/STK11/KEAP1 mutations (3.0 months [95% CI, 2.7–NR]; log-rank $p < 0.0001$). OS showed a similar numerical trend without statistical significance (49.4 months [95% CI, 37.4–NR], 27.3 months [95% CI, 18.4–NR], and 10.0 months [95% CI, 6.7–NR], respectively; log-rank p = 0.08). **Conclusions:** While KRAS mutations alone were not associated with inferior outcomes with durvalumab, concurrent STK11 and KEAP1 co-mutations were associated with markedly worse clinical outcomes. Serial ctDNA genomic profiling integrated with a networked molecular tumor board in first-line advanced NSCLC: The COPE randomized phase II trial. First Author: Antoine Italiano, Institut Bergonié, Bordeaux Cedex, France

Background: Circulating tumor DNA (ctDNA) complements tissue profiling and may provide early response information in advanced NSCLC, but prospective evidence is limited. **Methods:** COPE is an open-label, multicenter, randomized (2:1), two-arm non-comparative phase II trial in stage IIIB/IV NSCLC (NCT04258137). Arm A included FoundationOneLiquidCDx ctDNA profiling at baseline, week 3, each radiologic assessment, and progression with centralized molecular tumor board (MTB) review; Arm B used baseline tissue profiling and standard imaging. ctDNA-guided treatment changes were discretionary. The primary endpoint was18-month (mo) overall survival (OS) rate in Arm A vs a prespecified historical benchmark; secondary/exploratory endpoints included profiling success, objective response rate (ORR), ctDNA dynamics, and genomic evolution. **Results:** From 2020–2023, 176 patients (pts) were enrolled (Arm A n = 117; Arm B n = 59). At median follow-up 24.0 mo, 18-mo OS was 53.8% (95% CI 44.3–62.5) in Arm A (median OS 22.4 mo) and 65.7% (95% CI 52.0–76.3) in Arm B. Baseline plasma profiling rescued genotyping in 32/35 pts with tissue insufficiency, increasing genotyping success from 69% (tissue alone) to 97% (tissue + plasma). In Arm A, 90/117 had evaluable paired baseline and week-3 plasma samples. Among pts receiving first-line (1L) chemo-immunotherapy (chemo + ICI), early molecular response (MR), defined as ctDNA no longer detected at day 21 was strongly associated with more favorable outcomes, including higher ORR (81.8% vs 50.0%), longer progression-free survival (median PFS 22.9 vs 5.9 mo), and OS (18-mo OS 81.8% vs 57.1%). Similar results were observed in the overall study population. MR50, defined as ≥50% reduction at day 21, showed similar associations with more favorable outcomes. In pts on chemo + ICI with further ctDNA testing, those with durable MR50 through mo 5-9 had longer mPFS (23 mo vs 11 mo), similar to pts with early ctDNA clearance. Importantly, excluding pts who progressed at/before week 3, the median lead time in detecting progression on chemo + ICI with ctDNA prior to radiographic progression was 3.5 mo (N = 19pts). Among 59 responders with paired baseline and any on treatment plasma, 35 were treated with 1L chemo + ICI and 13 with 1L targeted therapy. Tumor-associated emergent alterations were detected in 37 pts (63%), with treatment-specific resistance patterns observed across therapeutic classes. **Conclusions:** COPE is, to our knowledge, the first randomized prospective study of sequential ctDNA profiling in 1L advanced NSCLC. Serial ctDNA analysis within a networked MTB model was feasible, improved baseline molecular profiling, and provided a strong exploratory early molecular response signal, supporting future ctDNA-guided interventional trials. Clinical trial information: NCT04258137. Research Sponsor: Foundation Medicine.

Clinico-genomic landscape and prognostic impact of APC/CTNNB1 oncogenic alterations in non–small cell lung cancer. First Author: Leonardo Brunetti, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Genomic activation of the WNT/β-catenin pathway via APC loss-of-function or activating CTNNB1 mutations is well established across multiple cancer types, but its prevalence and genomic context in non–small cell lung cancer (NSCLC) remain poorly characterized. We systematically characterized the prevalence of APC and CTNNB1 alterations in NSCLC, and defined their mutational landscape and prognostic impact. **Methods:** We conducted a multicenter cohort study including patients with NSCLC whose tumors underwent targeted exon sequencing at Dana-Farber Cancer Institute (DFCI) and Memorial Sloan Kettering Cancer Center (MSKCC). Tumors were classified as APC-mutated, CTNNB1-mutated, or WNT-mutated (APC and/or CTNNB1 mutated). Pathogenic alterations were defined as oncogenic or likely oncogenic per OncoKB, or as missense variants with a REVEL score $>$ 0.5. Gene enrichment analyses used gene-wise logistic regression adjusted for tumor mutational burden (TMB), testing genes meeting a predefined prevalence threshold, with Bonferroni correction within each analysis. **Results:** In the DFCI cohort (N = 4,717), APC or CTNNB1 alterations were identified in 4.5% of NSCLC (212/4,717), including APC in 1.7% (79/4,717) and CTNNB1 in 2.8% (133/4,717), and were mutually exclusive. APC alterations were predominantly loss-of-function events (85.3% of qualifying APC variants) and splice-region/site variants (14.8%). CTNNB1 alterations were all missense mutations (100%), clustering in exon 3, consistent with β-catenin stabilization and gain-of-function. Relative to WNT–wild-type tumors, WNT-mutated NSCLC occurred more frequently in never-smokers (32% vs 24%, p = 0.03), patients of Asian race (11.8% vs 4.2%, $p < 0.001$), and non-squamous histology (99.5% vs 88.6%, $p < 0.001$). These tumors exhibited lower median PD-L1 expression ($p < 0.001$) and TMB (p = 0.03). Similarly, in the MSK cohort (N = 4710), the prevalence of APC and CTNNB1 alterations was 0.7% and 2.7%, respectively. Relative to WNT–wild-type tumors, WNT-altered NSCLC was significantly enriched for EGFR mutations (19.3% vs 10.5%; OR 2.18; $p < 0.01$) and SMAD4 mutations (7.1% vs 2.1%; OR 3.47; p = 0.0026), with relative depletion of KRAS alterations (20.8% vs 32.1%; OR 0.55; p = 0.027). External validation reproduced these findings, with WNT-altered tumors enriched for EGFR (42% vs 21.7%; OR 3.21: $p < 0.001$) alterations and depleted for KRAS (16.7% vs 29.4%; OR 0.47; p = 0.011). In the DFCI cohort, APC/CTNNB1 alterations were not associated with overall survival [HR 1.05 (0.88-1.25 95% CI; p = 0.57)]. **Conclusions:** Genomic activation of the WNT/β-catenin pathway is characterized by EGFR and SMAD4 co-alterations, relative KRAS depletion, and lower PD-L1 and TMB. These results suggest that WNT pathway alterations contribute to molecular heterogeneity in NSCLC with potential relevance for future biomarker and therapeutic studies. Research Sponsor: None.

Use of LIF and LIFR expression to characterize survival and tumor microenvironment composition in lung adenocarcinoma. First Author: Michael Borecky, Department of Internal Medicine, Loma Linda University, Loma Linda, CA

Background: In lung adenocarcinoma (LUAD), EGFR-directed therapy has transformed clinical practice, yet heterogeneity in treatment response persists. Novel biomarkers are needed to refine therapeutic selection and identify new treatment targets. Leukemia inhibitory factor (LIF) and its receptor (LIFR) have emerged as potential mediators of the tumor microenvironment (TME), but their clinical significance in LUAD remains poorly defined. This study sought to investigate LIF and LIFR expression in LUAD, especially *EGFR*-mutant (EGFRm), and their TME composition and impact on survival outcomes. **Methods:** 10,041 LUAD tumors underwent next-generation sequencing of DNA (592-gene panel or whole exome sequencing) and RNA (whole transcriptome) at Caris Life Sciences. Tumors were stratified by LIR and LIFR RNA expression quartiles (Q1, low; Q4, high). QuantiSEQ was used to profile TME. Statistical analyses were performed using chi-square and Mann–Whitney U tests. Overall survival (OS) was estimated from insurance claims data using Cox proportional hazards models to calculate hazard ratios and log-rank tests to determine p-values. **Results:** In LUAD, LIF Q4 tumors demonstrated lower abundance of $CD8^+$ T cells (fold change (FC) 0.75, $p < 0.001$), but higher abundance of NK cells, M1 macrophages, neutrophils, Tregs and B cells vs LIF Q1 tumors (FC 1.1-1.4, $p < 0.001$). LIFR Q4 tumors exhibited higher abundance of dendritic cells, NK cells and M2 macrophages vs Q1 tumors (FC: 1.2-1.5, $p < 0.001$). For LIF, Q4 tumors had higher median MAPK activation (1.73 vs -0.93, $p < 0.001$) and T-cell–inflamed scores (94 vs -2, $p < 0.001$). LIFR Q4 tumors demonstrated higher MAPK activation (1.51 vs -0.83, $p < 0.001$), and higher T-cell–inflamed scores (105 vs -29, $p < 0.001$). IFN-γ signaling was modestly lower in LIF Q4 and LIFR Q4 tumors. Longer OS was observed in LIF Q1 vs Q4 (HR 0.79, 95% CI: 0.75-0.84, 25.1 vs 18.1 m, $p < 0.001$) but shorter OS in LIFR Q1 vs Q4 (HR 1.59 , 95% CI: 1.5-1.7, 14.0 vs 27.9 m, $p < 0.001$). *EGFR* mutations were significantly more frequent in LIF Q1 vs Q4 (21.2% vs 12.8%, $p < 0.001$) and LIFR Q4 vs Q1 (27.2% vs 7.6%, $p < 0.001$). In *EGFR*m tumors treated with osimertinib, OS differences based on LIF expression were accentuated:(LIF Q1 vs Q4, HR 0.681, 95% CI: 0.58-0.80, 35.7 vs 24.7 m, $p < 0.00001$). **Conclusions:** Findings demonstrate distinct transcriptional immune activation profiles between LIF- and LIFR-driven states, with superior survival in low LIF and high LIFR expressors. Despite elevated T-cell–inflamed scores, differences in immune cell composition suggest qualitative differences in immune activation between LIF- and LIFR-driven states. These findings support their relevance as prognostic and biologically informative biomarkers, and identify the LIF–LIFR axis as a key stratifier of immune state and survival heterogeneity in LUAD, with additional survival differences observed in EGFRm LUAD treated with osimertinib. Research Sponsor: None.

A randomized phase III study of pembrolizumab versus pembrolizumab with carboplatin plus pemetrexed for locally advanced or metastatic nonsquamous non–small cell lung cancer with PD-L1 TPS ≥ 50%: LAPLACE-50. First Author: Yoshihito Kogure, Department of Respiratory Medicine, NHO Nagoya Medical Center, Nagoya, Japan

Background: For patients with advanced non-squamous non-small cell lung cancer (NSCLC) and high PD-L1 expression (TPS ≥50%), both pembrolizumab monotherapy and immune checkpoint inhibitor with platinum and pemetrexed combination chemotherapy are recognized as standard first-line therapies. However, direct head-to-head comparisons to determine the optimal strategy in this specific population are limited. We conducted a randomized phase III trial to compare these approaches. **Methods:** In this open-label, randomized phase III trial, previously untreated patients with advanced/metastatic non-squamous NSCLC and PD-L1 TPS ≥50% were randomized (1:1) to receive either pembrolizumab monotherapy (Arm A) or pembrolizumab plus carboplatin and pemetrexed (Arm B). The primary endpoint was progression-free survival (PFS) with a predefined non-inferiority margin of 1.25 for the hazard ratio (HR). Secondary endpoints included overall response rate (ORR), overall survival (OS), and safety. Due to slow accrual, the trial was terminated prematurely, and a final analysis was performed on the available cohort. **Results:** A total of 70 patients were randomized (Arm A, n=35; Arm B, n=35), and 69 patients were included in the full analysis set. Median PFS was 8.1 months in Arm A and 9.2 months in Arm B (HR 1.25; 90% CI, 0.77–2.04), and non-inferiority of pembrolizumab monotherapy was not demonstrated. ORR was 57.1% in Arm A and 73.5% in Arm B (odds ratio 0.49, 95% CI, 0.18–1.36; p=0.172). Median OS was 55.1 months in Arm A and 23.5 months in Arm B (HR 0.83, 95% CI, 0.42–1.63; p=0.663). Grade ≥3 hematologic toxicities were more frequent in Arm B. Serious adverse events occurred in 20.0% of patients in Arm A and 26.5% in Arm B. **Conclusions:** Although this trial was limited by early termination and did not statistically demonstrate the non-inferiority of pembrolizumab monotherapy in terms of PFS, the numerical OS favored the monotherapy group despite a lower ORR. These findings suggest that for patients with PD-L1 TPS ≥50%, pembrolizumab monotherapy remains a robust treatment option with a favorable safety profile, though the addition of chemotherapy may offer higher initial response rates. Clinical trial information: jRCTs031200078. Research Sponsor: NHO Multi-Center Clinical Research for Evidence-Based Medicine.

Combination of golidocitinib (a JAK1 inhibitor) with anti–PD-1 antibody to improve tumor response and patient quality of life: Preliminary results from an ongoing JACKPOT 33 study. First Author: Jie Wang, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Chemo-immunotherapy remains the standard first-line treatment for advanced non-small cell lung cancer (NSCLC) without driver mutations. Unfortunately, treatment resistance is inevitable. Janus kinase (JAK) inhibition may improve the efficacy of immunotherapy by pivoting T cell exhaustion dynamics, enhancing and extending patient response. Herein, we report the anti-tumor efficacy and safety data from an ongoing phase 2 study (NCT06198907, JACKPOT33) evaluating golidocitinib, a JAK1-specific inhibitor, combined with sintilimab, an anti-PD-1 antibody, as first-line treatment in patients with PD-L1 positive advanced NSCLC without driver mutations. **Methods:** Eligible patients with advanced NSCLC with PD-L1 TPS $\geq$ 1% were enrolled in the study. Patients received two cycles of chemo-immunotherapy only, followed by golidocitinib 150 mg orally once daily plus sintilimab 200 mg intravenous every 3 weeks until disease progression, intolerance, up to 2 years of treatment, or other discontinuation criteria were met. The primary objective was to evaluate the anti-tumor efficacy, and the secondary objectives included safety and tolerability. **Results:** As of December 23, 2025, a total of 47 patients were enrolled in the JACKPOT33 study. The median age of these patients was 63 years, with 87.2% males, 61.7% with non-squamous histology, 40.4% with PD-L1 high (TPS $\geq$50%) and 59.6% with PD-L1 low (TPS 1-49%) expression. Most (74.5%) of the patients had metastatic disease at baseline, with 8.5% having brain metastasis. Per investigator assessment, the overall response rate (ORR) after two cycles of chemo-immunotherapy was 42.6%. Following the addition of golidocitinib with sintilimab, deeper tumor shrinkage and additional responders were observed, resulting in an ORR of 63.8% (30/47). The improvement in ORR with golidocitinib was most profound in patients with high PD-L1 levels, with rates of 84.2% vs. 50% in the high and low expression cohorts, respectively. No difference in ORR was observed between patients with squamous or non-squamous carcinoma (61.1% vs 65.5%). As of the data cut-off date, 32 out of 47 patients remained on treatment and benefiting. The longest treatment duration reached 15.9 months. The combination of golidocitinib and sintilimab was well tolerated. The incidence of immune-related adverse effects was markedly decreased, and patients' self-reported quality of life significantly improved. No new safety signal was observed. **Conclusions:** In treatment-naïve patients with advanced NSCLC, golidocitinib plus sintilimab following chemo-immunotherapy demonstrated encouraging and durable anti-tumor efficacy, particularly in those with high PD-L1 expression. A profound decrease in immune-related adverse effects was observed. Updated data will be presented at the conference. Clinical trial information: NCT06198907. Research Sponsor: None.

A first-in-human (FIH), phase I/II open-label, dose-escalation and -expansion study of ILKN421H, an LNP mRNA encoding an IL2Rβγ selective IL-2v, as monotherapy and in combination with pembrolizumab, in patients with advanced solid tumors. First Author: Kai Wang, Department of Respiratory and Critical Care Medicine, Center for Oncology Medicine, the Fourth Affiliated Hospital of School of Medicine, and International School of Medicine, International Institutes of Medicine, Zhejiang University, Yiwu, China

Background: ILKN421H is an LNP mRNA encoding an IL2Rβγ selective IL-2v derivative fused with Human Serum Album. Preclinically, the novel LNP mRNA platform allowed expression and therefore extended plasma half-life of IL2v in animal models, which is not achieved with other protein-based IL-2 drugs. ILKN421H stimulated significant and sustained expansion of CD8 T cells for more than three weeks, with minimal expansion of regulatory T cells. Moreover, ILKN421H demonstrated superior efficacy than IL-2 based drugs in multiple cancer models and has an excellent safety profile in rodents and non-human primates. Therefore, the novel design of ILKN421H has the potential to fully unleash the antitumor effects of the IL-2 pathway while mitigating unwanted toxicity. **Methods:** This first-in-human, open label phase 1 study evaluates the safety, tolerability, and initial efficacy of ILKN421H with or without pembrolizumab in patients with advanced solid tumors. The design includes two portions of the study: Parts A, ILKN421H monotherapy in which patients receive intravenous ILKN421H once every 3 weeks (Q3W) and Part B in which patients receive ILKN421H in combination with pembrolizumab (200 mg on day 1), both intravenous Q3W. Both portions of the study consist of 3+3 escalation cohorts to define maximum tolerated dose (MTD). If response signal is observed in a given dose cohort, additional 10 patients will be enrolled in the expansion portion of the study to further evaluate the safety and efficacy. The trial is ongoing and data as of 5/7/2024 is presented in this abstract. **Results:** A total of 47 participants were enrolled so far. In Part A, 9 patients in three dose cohorts received ILKN421H. All patients demonstrated high and prolonged plasma level of IL-2, and remarkable elevation of CD8 T cells (up to 5 folds) and NK cells (up to 25 folds). No dose-limiting toxicities (DLT) were observed. In Part B, 38 patients in three dose cohorts were enrolled, 24 of which are 1L advanced NSCLC. All patients showed robustly increased CD8 T cells and NK cells, and well tolerated safety profile (TESAE=26%). At the cut-off date (Nov 25th, 2025), of the 22 efficacy evaluable 1L NSCLC patients regardless of the PDL1 expression levels, 17 were evaluated to be PR (ORR=77.2%), and 50% PFS was not reached and was projected to be more than 14 month. In PDL1 negative patients (TPS $<$1%), 3 out of 6 patients achieved PR (ORR=50%). **Conclusions:** ILKN421H was generally well tolerated at the current dose level, which already demonstrated high and prolonged plasma level of IL-2, and robust immune stimulatory activity in promoting CD8 T cells and NK cells proliferation. Initial signs of antitumor efficacy were seen in combination with pembrolizumab. Clinical trial information: NCT05978102. Research Sponsor: iLeukon Therapeutics.

Race-associated clinicogenomic predictors in non-small cell lung cancer treated with immune checkpoint inhibitors. First Author: Nirosha Perera King, Department of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: PD-L1 low and STK11 mutation associate with immune checkpoint inhibitor (ICI) resistance in non-small cell lung cancer (NSCLC), but appear differentially expressed among racial ethnic groups. This has not been validated in large, diverse studies. **Methods:** We retrospectively studied NSCLC patients 18 or older, without targetable EGFR or ALK alterations, treated with frontline ICI between January 2014 and February 2020 at MD Anderson Cancer Center and University of Illinois Chicago. We analyzed clinicogenomic and survival characteristics by race/ethnicity. Differences in clinicogenomic predictors were assessed through log-rank and chi-squared comparison of proportions tests. Survival differences were estimated via Kaplan-Meier method. **Results:** 1694 patients met inclusion criteria, 383 (22.6%) were minorities. Poor performance status (PS 2-3) was most frequent in African American (AA) (32.5%) and Native Alaskan/Hawaiian or American Indian (NAHAI) (27.3%) patients (p=0.005) (Table). Heavy smoking was more frequent in White (50.3%) patients. PD-L1 $<$1% was most prevalent among Asian (31.3%) and least prevalent among Hispanic/Latino (HL) (15.8%) patients (p=0.001). STK11 mutation rate was most prevalent in AA (14.7%) and least prevalent in HL (6.9%) and Asian (2.5%) patients (p=0.056). Median overall survival (OS) was lower (21.3, 23.5, and 24.3 months) for HL, NAHAI, and AA patients, and higher (25.4 and 30.6 months) for White and Asian patients, respectively ($p<0.01$). **Conclusions:** Our dual center study with 22% minority patient representation shows self-reported race can result in biological differences, because of ancestry and/or environmental differences. AA, HL, and NAHAI patients had lower rates of heavy smoking and different clinicogenomic patterns than White patients. AA tended towards higher prevalence of STK11 mutation—while not statistically significant, it was overall not highly represented in the sample. In line with these poor prognostic factors, AA had statistically significant lower median overall survival (OS) than their White and Asian counterparts. Asians had the lowest rates of heavy smoking and STK11 mutation, highest rates of PD-L1$<$1%, and highest median OS. HL had the lowest OS, with low prevalence of PD-L1$<$1% and STK11 mutation – future studies should evaluate other clinicogenomic factors to determine potential culprits. Research Sponsor: The University of Texas MD Anderson Lung Moon Shot Program and the MD Anderson Cancer Center Support Grant P30 CA016672.

Safety and efficacy of CS2009, a first-in-class PD-1/VEGF/CTLA-4 trispecific antibody, in patients with advanced non-small cell lung cancer: Results from a phase 1/2 study. First Author: Wei Li, Department of Medical Oncology, Shanghai East Hospital, Shanghai, China

Background: CS2009 is a novel PD-1/VEGF/CTLA-4 trispecific antibody. An ongoing phase 1/2 study is evaluating its safety, tolerability, PK, PD, and anti-tumor activity as a single agent and in combination with systemic treatment in patients (pts) with advanced solid tumors. This study comprises a phase 1 dose escalation and phase 2 dose expansion. Here, we report the initial efficacy and safety data from advanced non-small cell lung cancer (NSCLC) pts treated in first-line and later-line settings. **Methods:** The study enrolled both treatment-naïve (1L) and heavily pre-treated later-line ($\geq$2L) NSCLC pts. The $\geq$2L group included previously treated pts without known actionable oncogenic alterations (AGA) who had progressed on at least one prior line containing an anti-PD-1/L1 antibody and platinum-based chemotherapy; these pts received CS2009 at 10, 20, 30, or 45 mg/kg, i.v., Q3W, until disease progression or intolerance. The 1L cohort enrolled treatment-naïve pts with PD-L1 TPS $\geq$1% NSCLC without known AGA; these pts were randomized 1:1 to receive CS2009 at 20 or 30 mg/kg, i.v., Q3W, until disease progression or intolerance. Safety was assessed in all treated pts. Efficacy was assessed in pts who had at least one post-baseline tumor assessment per RECIST v1.1. **Results:** As of Jan. 4, 2026, 40 pts with $\geq$2L NSCLC were treated with CS2009 across four dose levels (10 mg/kg, n=3; 20 mg/kg, n=12; 30 mg/kg, n=20; 45 mg/kg, n=5). Median age was 67 (range 37-78) years; 72.5% were Asian, 27.5% were White; 77.5% were male; 77.5% had ECOG PS 1 at baseline. Among 30 efficacy-evaluable pts, ORR was 20.0% (6 PRs); in 16 pts treated at 30 mg/kg, ORR was 25.0% (4 PRs). Any-grade and grade $\geq$3 treatment-related adverse events (TRAEs) occurred in 27 (67.5%) and 8 (20.0%) pts, respectively. The most common TRAEs were proteinuria (12.5%), hypertension (12.5%), bilirubin conjugated increased (10.0%), and fatigue (10.0%), which were mostly grade 1 or 2, except for grade $\geq$3 hypertension in two pts. No treatment-related deaths were reported. TRAEs led to discontinuation in 3 (7.5%) pts. More mature $\geq$2L efficacy data with additional evaluable pts will be presented at the conference. As of Jan. 4, 2026, 19 pts with 1L NSCLC (PD-L1 TPS $\geq$1%) were randomized to receive CS2009 at 20 mg/kg (n=10) or 30 mg/kg (n=9). Median age was 69 (range 52-82) years; 84.2% were male; 89.5% had ECOG PS 1 at baseline. Preliminary encouraging efficacy and favorable safety signals were observed. Updated efficacy and safety data in approximately 50 1L pts will be disclosed at the conference. **Conclusions:** CS2009, as a first-in-class trispecific antibody targeting PD-1, VEGF, and CTLA-4, demonstrated a favorable safety profile and clinically meaningful anti-tumor activity in advanced NSCLC pts without known AGA. These findings warrant further investigation of CS2009 in this population. Clinical trial information: NCT06741644. Research Sponsor: CStone Pharmaceuticals.

A phase II study of ubenimex combined with pembrolizumab, nab-paclitaxel, and carboplatin for previously untreated advanced squamous non−small cell lung cancer: TORG2241(UBE-Q). First Author: Akane Narumi, Sendai Kousei Hospital, Sendai, Miyagi, Japan

Background: Pembrolizumab plus platinum-based chemotherapy is a standard first-line treatment for previously untreated advanced squamous non-small cell lung cancer (NSCLC) based on the KEYNOTE-407 trial. Ubenimex, an oral CD13/aminopeptidase inhibitor, has immunostimulatory and antitumor activity. We conducted a phase II trial to assess the safety and efficacy of ubenimex in combination with pembrolizumab, nab-paclitaxel, and carboplatin in patients with previously untreated advanced squamous NSCLC. **Methods:** This study was a prospective, multicenter, single-arm phase II trial. Eligible patients with previously untreated advanced squamous NSCLC received ubenimex orally plus 4 cycles of pembrolizumab, nab-paclitaxel, and carboplatin, followed by continuous administration of ubenimex and pembrolizumab for a maximum of 2 years. To confirm tolerability, the daily dose of ubenimex started at level 1 (30mg/day), which was increased to levels 2 (60 mg/day) and 3 (120 mg/day) according to the escalation criteria, with a standard 3 + 3 design for achieving the target dose-limiting toxicity (DLT) rate of 33%. The efficacy, safety, and tolerability of ubenimex at the determined dose level were analyzed. The primary efficacy endpoint was objective response rate (ORR) by independent central review, estimated descriptively with a 90% confidence interval; the ORR in the KEYNOTE-407 (62.6%) served as a reference value for study design. **Results:** No DLTs were observed across dose levels 1−3. Therefore, level 3 was selected as the recommended dose. From January 2024 to January 2025, 28 patients were enrolled from 18 institutions, and all patients were evaluable for efficacy and safety. Baseline characteristics were male/female 25/3; median age 72 (range, 40-86); ECOG PS 0/1 12/16. The ORR was 71.4% (90% CI, 54.3-84.9). With a median follow-up of 12.8 months, median progression-free survival (PFS) was 16.8 months (95% CI, 5.6-not reached); median overall survival (OS) was not reached. Grade 3/4 adverse events included pneumonitis (3.6%), anemia (46.4%), febrile neutropenia (10.7%). There was no treatment-related death. **Conclusions:** Ubenimex with 120 mg/day (60 mg twice daily) combined with pembrolizumab, nab-paclitaxel, and carboplatin was feasible and showed encouraging antitumor activity with manageable safety in previously untreated advanced squamous NSCLC, supporting further randomized evaluation. Clinical trial information: jRCT2031210707. Research Sponsor: Nippon Kayaku Co., Ltd.

FF-10832 liposomal gemcitabine monotherapy or combination with pembrolizumab in patients with advanced non−small cell lung cancer. First Author: Hamid Emamekhoo, University of Wisconsin-Madison, Madison, WI

Background: FF-10832, a stable liposomal formulation of gemcitabine with a prolonged half-life (mean $t_{1/2}$ of 26 hours compared to ~3 hours for gemcitabine HCl), has demonstrated single agent activity in patients (pts) with solid tumors. In pre-clinical models, FF-10832 has yielded superior anti-tumor activity compared to gemcitabine alone and in combination with PD-1 inhibitors. Following a safety run-in, we investigated the clinical activity of FF-10832 in an expansion study, administered alone or in combination with pembrolizumab (PEM), in pts with advanced/metastatic (m) NSCLC (NCT05318573). **Methods:** In the open-label single arm safety run-in, 40 mg/m^2 FF-10832 and 200 mg PEM every 3 weeks was established as safe and tolerable in 12 pts including 6 mNSCLC patients with unlimited prior therapies. The trial was expanded using this regimen. Pts were randomized to receive FF-10832 alone (mono) or FF-10832 +PEM (combo). Eligibility stipulated up to 3 prior therapies in the advanced/metastatic setting with prior disease progression (PD) on platinum and PD-(L)1-directed therapy. Pts receiving FF-10832 monotherapy could add PEM to FF-10832 upon PD determined by RECIST 1.1. To be evaluable for anti-tumor activity, pts must have had at least one RECIST assessment ≥6 weeks after baseline. All pts were evaluable for safety. **Results:** A total of 41 NSCLC pts were treated with FF-10832 (N=21) or FF-1032+PEM (N=20); median # of prior therapies was 2 for both arms. RECIST evaluability was achieved in 30 pts (14/16; mono/combo); 11 pts (7/4; mono/combo) came off study before evaluation for anti-tumor activity. No objective responses were observed. Stable disease (SD) was recorded in 9/14 pts in the mono arm and 13/16 in the combo arm; 4 pts (1 mono/3 combo) with >20% tumor shrinkage. Median time on study for the mono and combo arms was 9 (1 − 48.1) and 12.1 (1.1 − 44) weeks, respectively. Median (95% CI) PFS in months: mono arm, 2.7 (1.4 − 4.3); combo arm, 2.8 (1.9 − 5.5). Five mono pts began FF-10832+PEM treatment upon PD, two that remain on combination therapy with SD for 23 and 33 weeks after progressing on FF-10832 monotherapy. Related AEs were similar in mono vs combo arms; those in ≥15% of pts in each arm included nausea, vomiting, fatigue, rash, infusion-related reaction, and anemia. Related grade ≥3 AEs occurred in 33% (mono) and 45% (combo) of pts. The only attributable grade ≥3 events in >1 pt were in the combo arm (n): anemia (3), fatigue (2), dyspnea (2), and lymphopenia (2). FF-10832 PK showed a profile consistent with that previously reported (terminal $t_{1/2}$, ~30 hours). Overall survival data are pending. **Conclusions:** FF-10832 alone or in combination with PEM in platinum-CPI refractory pts proved tolerable with a safety profile matching previous experience. There were no objective responses, but the majority of evaluable pts had SD at 1st assessment, some with tumor shrinkage. Aggregate mPFS was 2.7 mos. Clinical trial information: NCT05318573. Disease kinetics and practice patterns in ≥ 4-year long-term beneficiaries of immune checkpoint inhibitors for advanced non−small cell lung cancer. First Author: Masahiro Torasawa, Department of Respiratory Medicine, Juntendo University Faculty of Medicine and Graduate School of Medicine, Tokyo, Japan

Background: Immune checkpoint inhibitors (ICIs) have transformed outcomes in advanced non-small cell lung cancer (NSCLC), enabling durable responses in a subset of patients (pts). However, detailed clinical trajectories and patterns of late disease progression among long-term survivors remain poorly characterized. **Methods:** This multicenter retrospective cohort study enrolled advanced NSCLC pts who initiated ICI-containing therapy between January 2015 and April 2020. Long-term beneficiaries (LTBs) were defined as pts achieving both overall survival (OS) and time to next cytotoxic chemotherapy (TTNC) ≥4 years (yrs). We performed 4-yr landmark analyses, characterized late progression (defined as the first radiographic progression ≥4 yrs from ICI initiation), and evaluated cause-specific mortality using competing risk analysis. **Results:** Of 3,144 pts, 537 (17%) survived ≥4 yrs; 295 (9.4%) were LTBs (median follow-up, 68.6 months; only 8.1% lost to follow-up). ICI was initiated as first-line therapy in 186 pts (63.1%) and as second-line or later in 109 pts (36.9%). The median age was 67 yrs, and PD-L1 Tumor Proportion Score ≥50% was observed in 57%. Among 235 LTBs without progression at 4 yrs, 156 (66%) had discontinued ICI. Among pts progression-free at 4 yrs, lung cancer-specific OS (LC-OS) rates from ICI initiation were 97.8% at 6 yrs and 88.0% at 8 yrs (Table). Late progression occurred in 26 of 235 progression-free LTBs (11.1%); all had progression involving ≤5 lesions. The median interval from the last non-progressive assessment to the first assessment meeting radiographic progression was 98 days (IQR, 56−189), with a median sum-of-diameters growth rate of 6.2 mm/month (IQR, 3.4−9.6). Local therapy was selected in 42% after progression. Among 22 deaths occurring ≥4 yrs after ICI initiation, only 7 (32%) were lung cancer−related, whereas 15 (68%) were due to other causes, including five secondary malignancies. Competing risk analysis showed that the cumulative incidence of other-cause death consistently exceeded that of lung cancer death throughout follow-up (lung cancer death: 0.5% at 5 yrs to 10.7% at 8 yrs; other-cause death: 2.3% to 14.8%). **Conclusions:** LTBs of ICIs achieved durable disease control, with LC-OS approaching 90% at 8 yrs. In these pts, late progression was uncommon, typically involving ≤5 lesions with modest growth kinetics, often treated with local therapy without requiring immediate systemic treatment. The predominance of non-lung cancer mortality suggests that survivorship care addressing second malignancies is increasingly important in this population. Research Sponsor: None.

Landmark survival analysis from 4 years after ICI initiation (n=235).

Timepoint	PFS	TTNC	OS	Other Cause OS	LC-OS
5-year	90.1%	96.4%	97.2%	97.7%	99.5%
6-year	82.4%	90.3%	91.8%	93.8%	97.8%
7-year	74.6%	81.3%	82.7%	87.3%	94.7%
8-year	69.9%	74.3%	74.5%	84.7%	88.0%

Impact of immunotherapy era on survival in stage IV non−small cell lung cancer. First Author: Tahreem Malik, Department of Internal Medicine, HCA Healthcare/USF Morsani College of Medicine GME: HCA Florida Citrus, Inverness, FL

Background: The introduction of immunotherapy (IO) has transformed treatment paradigms in Stage IV non-small cell lung cancer (NSCLC). However, large-scale population-based evidence quantifying its impact on survival remains limited. We evaluated overall survival trends before and after the IO era using SEER data. **Methods:** We identified patients diagnosed with Stage IV NSCLC from 2006 to 2020 in the SEER 17 database. Patients were grouped by era: pre-IO (2006−2014) and post-IO (2015−2020). Demographics, histology, and socioeconomic variables were included. Overall survival (OS) was assessed using Kaplan-Meier analysis. Multivariable Cox proportional hazards models estimated hazard ratios (HRs) with 95% confidence intervals (CIs) adjusting for age, sex, race, and histology. **Results:** A total of 101,243 Stage IV NSCLC patients were included. The post-IO era was associated with a 19% reduction in mortality compared to the pre-IO era (HR 0.81; 95% CI 0.79−0.82; p<0.001). Older age (≥75 years) conferred increased mortality risk (HR 1.32; 95% CI 1.30−1.34; p<0.001), while younger patients (<65 years) had better outcomes (HR 0.91; 95% CI 0.89−0.93; p<0.001). Male sex (HR 1.16; 95% CI 1.14−1.17; p<0.001), non-adenocarcinoma histology (HR 1.30; 95% CI 1.28−1.32; p<0.001), and Black race (reference group) were independently associated with worse survival. White (HR 0.83; 95% CI 0.81−0.85; p<0.001) and Other races (HR 0.75; 95% CI 0.73−0.77; p<0.001) demonstrated survival advantages. Kaplan-Meier curves confirmed significantly improved OS in the post-IO era (median OS 8 vs 10 months, log-rank p<0.001). **Conclusions:** This large population-based study confirms a significant survival benefit in Stage IV NSCLC patients diagnosed in the immunotherapy era, alongside expected demographic and histologic disparities. These findings support the real-world impact of immunotherapy and underscore the need for continued efforts to address survival inequities. Research Sponsor: None.

Ablation plus immunotherapy in advanced NSCLC patients who develop oligo-residual disease after anti–PD-1/L1 therapy: Updated results from the BOOSTER trial. First Author: Shuo Yang, Department of Medical Oncology, Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai, Shanghai, China

Background: Local consolidative therapy (LCT) has been demonstrated to augment the survival benefits of immunotherapy in non-small cell lung cancer (NSCLC) patients with oligo-residual disease (ORD) in the phase2 BOOSTER Trial (ChiCTR2000032479) as previously reported (2024 WCLC OA05.03; *Signal Transduction and Targeted Therapy* 2025). Here we report updated data with longer follow-up. **Methods:** This randomized, phase 2 trial enrolled patients with advanced NSCLC who developed oligo-residual disease after anti-PD-1/L1 therapy, defined as partial response or stable disease as the best response with residual tumors confined to a maximum of three organs and five lesions. Participants were randomly assigned (2:1) to receive ablation (thermal ablation or cryoablation) plus immunotherapy or immunotherapy maintenance alone. The primary endpoint was progression-free survival (PFS). The secondary endpoints were overall survival (OS), safety, patterns of disease progression and immunogenic changes after ablation. **Results:** Among 65 patients enrolled, the full analysis set finally included 42 patients in ablation plus immunotherapy group and 20 patients in immunotherapy maintenance group. In this updated data cutoff (December 2025) compared to the prior data cutoff (March 2024), median duration of follow-up has increased from 17.8 months to 28.9 months. Patients receiving ablation were associated with significantly longer PFS than those without ablation (median 28.1 vs. 12.8 months, $p < 0.001$, HR = 0.310, 95%CI 0.169–0.596). The median OS was not reached in either group. The 48-months OS rate were 79.0% (95% CI, 59.5–90.0) in ablation group and 67.6% (95% CI, 41.3–84.1) in the without ablation group. Updated subgroup analysis further suggested a trend of superior efficacy of cryoablation (n=13) compared with thermal ablation (n=29), with a median PFS of 37.6 versus 22.4 months, respectively (p=0.028). The safety profile of ablation combining with immunotherapy was similar to previously reported, and most of the adverse events were well managed. **Conclusions:** With extended follow up, the updated data suggested that the addition of local consolidative ablation confers durable clinical benefit in patients with advanced NSCLC who develop ORD after anti-PD-1/L1 therapy. Cryoablation was associated with potentially superior survival outcomes compared with thermal ablation. Clinical trial information: ChiCTR2000032479. Research Sponsor: None.

Inhaled delivery of KB707, a novel HSV-based immunotherapy, in combination with pembrolizumab in advanced non–small cell lung cancer: A phase 1/2 study. First Author: Wen Wee Ma, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH

Background: Though immune checkpoint inhibitors (ICIs) have significantly improved the treatment for lung cancers, resistance invariably develops and novel approaches are needed to overcome such resistance and enhance anti-tumor immunity. KB707 is a replication-defective herpes simplex virus type 1 (HSV-1)-based vector engineered to deliver human interleukin (IL)-12 and IL-2 to induce both innate and adaptive antitumor immunity. Inhaled KB707 monotherapy was previously shown to be well tolerated with encouraging efficacy in pts with advanced non-small cell lung cancer (aNSCLC): 4 of 11 pts achieved partial response (PR). Delivery of IL-12/IL-2 by inhaled KB707 may significantly increase the anti-tumor efficacy of ICI (pembro) in pts with aNSCLC who are relapsed or refractory to standard therapy. Extending from the monotherapy results, the safety and efficacy of adding inhaled KB707 to pembro in pts with aNSCLC is presented. **Methods:** KB707-02 is a Phase 1/2, open-label, multicenter study of inhaled KB707 (NCT06228326). Eligible pts with at least one measurable lung lesion at screening and histological confirmation of stage 3 or 4 NSCLC received nebulized KB707 (10^9 PFU) every 2 weeks and pembro (400 mg) every 6 weeks. Pts must have previously received one line of prior ICI, with or without platinum-based chemotherapy. The primary objective is to assess safety and tolerability per CTCAE v5.0, with a secondary objective to evaluate preliminary efficacy per RECIST 1.1. **Results:** As of 01 Jan 2026, a total of 21 pts (11 female) were enrolled and received at least one dose of inhaled KB707 plus pembro. The majority of treatment-related adverse events (TRAE) have been mild to moderate in severity and transient. Consistent with known adverse event profiles of IL-2 and IL-12, the most common TRAE were flu-like symptoms (fever, chills, vomiting, fatigue) and dyspnea. The efficacy population (n=16) received at least one treatment cycle and had at least one evaluation per RECIST 1.1. The 16 pts were of advanced age (median 72 [50-88] years old) and heavily treated (3 median lines of prior therapies). The ORR was 31.3% (5/16) and DCR was 75% (12/16) with 5 pts achieving confirmed PR and 7 with stable disease (SD). Median treatment duration was 24.1 weeks (6.1-71.9) with 5 out of 16 pts remaining on study. Median overall survival and progression free survival were not reached. **Conclusions:** Delivery of IL-12/IL-2 by inhaled KB707 in combination with pembro was well tolerated and encouraging antitumor effects were observed in heavily treated aNSCLC, as evidenced by 31.3% ORR and 75% DCR. The study is proceeding with enrollment of an additional cohort to further evaluate inhaled KB707 in combination with docetaxel in aNSCLC. Clinical trial information: NCT06228326. Research Sponsor: Krystal Biotech Inc.

Impact of *STK11/KEAP1/SMARCA4* co-mutations in RAS-activated *KRAS* wild-type metastatic NSCLC treated with immune checkpoint inhibitors. First Author: Cassio Murilo Hidalgo-Filho, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: RAS-activated *KRAS* wild-type (RASa/KRASwt) non-small cell lung cancer (NSCLC) shares key biological features with KRAS-mutant (KRASm) tumors, including MAPK pathway activation. In KRASm NSCLC, co-mutations in *STK11*, *KEAP1* and *SMARCA4* are associated with poor outcomes to immune checkpoint inhibitors (ICI). Whether these alterations similarly impact outcomes in RASa/KRASwt tumors is unknown. **Methods:** We analyzed patients with metastatic NSCLC treated with ICI at Dana-Farber Cancer Institute. RASa/KRASwt tumors were defined by pathogenic alterations in RAS–MAPK pathway genes (*NF1*, *NF2*, *BRAF*, *RAF1*, *MAP2K1/2*, *MAP3K1*, *MAPK1*, *PTPN11*, *SOS1*, *HRAS*, *NRAS*, *RIT1*, *RASA1*, *GNAS*). Co-mutations in *STK11*, *KEAP1* and *SMARCA4* were evaluated using targeted exome sequencing. Survival analyses were performed using log-rank test and survival risks estimated with Cox regression models. **Results:** Among 1,215 patients included, 492 (40%) had KRASm tumors and 264 (22%) were RASa/KRASwt. Compared with RASa/KRASwt tumors, KRASm tumors were more frequent in female patients (65% vs 50%, $p<0.001$), ever-smokers (93% vs 86%, p=0.004) and non-squamous histology (98% vs 88%, $p<0.001$). The frequency of *KEAP1* (21% vs 22%), *STK11* (26% vs 20%) and *SMARCA4* (10% vs 12%) mutations was similar between the groups. High tumor mutation burden (≥10 mut/Mb) was more frequent in RASa/KRASwt tumors (60% vs 46%, $p<0.001$), while PD-L1 expression, age and performance status were comparable. Within the RASa/KRASwt cohort, 103 patients (39%) had co-mutations in *STK11*/KEAP1/*SMARCA4* and were more frequently ever-smokers compared with non co-mutated RASa/KRASwt (95% vs 80%, $p<0.001$), with otherwise similar clinical characteristics. As expected, co-mutations were associated with shorter median progression free survival (mPFS) and median overall survival (OS) in KRASm group (mPFS: 4.4 vs 6.2 mo., HR:1.33 (1.1-1.62), p=0.004; mOS: 11.4 vs 21.7 months(mo), HR:1.43 (1.16-1.78), $p<0.001$). However, among RASa/KRASwt tumors, concurrent mutations in STK11/KEAP1/SMARCA4 had no impact on survival outcomes (mPFS: 5.9 vs 4.1 mo., HR:0.79 (0.6-1.02), p=0.07; mOS: 15.8 vs 14.8 mo, HR: 1.02 (0.77-1.35), p=0.89). This differential effect was confirmed by a significant interaction between RAS status and co-mutational status (aHR 1.71, p=0.004). For OS, interaction analysis did not show a differential effect of co-mutations according to RAS status (aHR 1.43; p=0.073). **Conclusions:** Known co-mutations that confer worse outcomes to ICI in KRASm NSCLC do not appear to have the same impact in KRASwt tumors with other RAS activating mutations. RASa/KRASwt tumors with co-mutations behave more similarly to KRAS wild-type NSCLCs, highlighting biological heterogeneity within RAS-driven tumors and potential implications for patient selection for treatment intensification or de-escalation strategies. Research Sponsor: None.

Effect of dual immune checkpoint inhibitors (ICI) by the time of infusion in advanced non–small cell lung cancer (NSCLC): A secondary analysis of CCTG BR34 trial. First Author: Sze Wah Samuel Chan, McMaster University, Hamilton, ON, Canada

Background: There is increasing evidence suggesting the impact of circadian biology on ICI efficacy in solid tumours, though evidence for dual checkpoint blockade is limited. We conducted a secondary analysis of BR.34 to assess whether time of infusion (TOI) correlates with outcomes with durvalumab–tremelimumab ± platinum chemotherapy in advanced EGFR/ALK-negative NSCLC. **Methods:** Patients were classified into the AM group when ≥80% of the PD-1 inhibitor infusions were started before 13:00 (threshold based on prior literature); otherwise, they were placed into the PM group. OS and PFS were analyzed using Cox models adjusted for imbalanced baseline factors. Sensitivity analyses were performed to assess correlations with other TOI thresholds. **Results:** TOI was evaluable for 296/301 patients; 186 were AM and 110 PM. PM infusion was associated with longer median OS (19.1 vs 13.4 months (m); HR 0.58, 95% CI 0.41–0.82) and median PFS (8.3 vs 4.1 m; HR 0.67, 95% CI 0.51–0.88). The improvement in OS associated with the PM group was consistent across both arms. In the multivariable analyses, PM administration remained associated with improved OS (adjusted HR (aHR) 0.62, 95% CI 0.44–0.88) and PFS (aHR 0.73, 95% CI 0.55–0.96). Sensitivity analyses using an alternative threshold of ≥60% of the PD-1 inhibitor infusions started before 1300 yielded consistent trends. Using a median TOI of 11:00 AM as an additional threshold, later infusions were also associated with longer OS (HR 0.77, 95% CI 0.56–1.05), with similar trends across both treatment arms. There was no apparent difference in fatal adverse events (n = 4), with two in the AM and two in the PM group. Serious adverse effects that led to therapy discontinuation also did not significantly differ between AM vs. PM in the IO-alone group (3 vs. 5) or the IO-chemo group (6 vs. 4). **Conclusions:** Afternoon infusion of dual ICI ± chemotherapy was associated with improved survival in BR.34, in contrast to earlier reports with anti-PD-1 therapy. These findings highlight the potential for regimen- and disease-specific chronotherapeutic effects and support the need for prospective trials across tumour types and of different checkpoint inhibitor combinations. A phase 2 study of plinabulin (Plin)/docetaxel (Doc) plus pembrolizumab (Pemb) in metastatic NSCLC (mNSCLC) after acquired resistance (AR) to anti–PD-1/L1 alone or in chemotherapy combination: Efficacy and immunophenotyping. First Author: Yan Xu, Peking Union Medical College Hospital, Beijing, China

Background: PD-1/L1 inhibitors have become a part of 1L treatment for EGFR/ALK wild-type NSCLC. However, >60% patients (pts) develop AR associated with T cell exhaustion and defective antigen presentation. Doc remains a mainstay for pts who relapse after anti-PD-1/L1 therapy, while multiple late-stage clinical trials have failed in comparison. Plin is a first-in-class, brain-penetrating dendritic cell maturation agent with clinically validated potential to restore antigen presentation/T cell function after AR to PD-1/L1 inhibitors. Plin also reduces severe neutropenia and thereby increases Doc tolerability. In a global phase 3 study (Dublin-3, n=559), Plin/Doc outperformed Doc with significant OS/PFS/ORR benefits, doubling of 2-/3-year OS rates, and 80% reduction in G4 neutropenia ($p<0.0001$). The aim of this study was to assess the efficacy/safety of Plin/Doc plus Pemb in mNSCLC after anti-PD-1/L1 based therapy. **Methods:** This single-arm phase 2 trial (NCT05599789; Study 303) enrolled 47 pts after immediate progression on anti-PD-1/L1 alone or combined with platinum doublets. Pts received Plin 30mg/m2, Doc 75mg/m2 and Pemb 200mg, on Day 1 in 21-day cycles. The primary/secondary endpoints at the median follow-up of 20.6 months (mo) are tabulated. For immunophenotyping, whole blood from baseline and post treatment were analyzed by flow cytometry. **Results:** At the data cutoff date of 31-Dec-2025, cORR was 18.2% with 79.5% DCR. mPFS was 7.0 mo, and mDoR at 9.3 mo. While mOS was 34 mo, the 24-mo OS rates were 64.3% (ITT), 71.1% (NSQ), and 52.0% (SQ). In all endpoints assessed, prior Pemb exposure did not reduce the efficacy of this regimen. Whole blood analysis indicated that activated CD4+/CD8+ T cells and proliferating Ki67+CD8 T cells were significantly increased post two cycles of treatment. Also observed were concurrent elevations of Ki67+B cells and CD38+NK cells. **Conclusions:** Plin/doc plus Pemb shows promising efficacy in mNSCLC with AR to anti-PD-1/L1 confirmed by immune activation post-treatment. TRAEs were manageable. These findings along with DUBLIN-3 support a global confirmatory study in EGFR/ALK wild-type NSQ NSCLC following progression on anti-PD1/L1 based therapy. Clinical trial information: NCT05599789. Research Sponsor: BeyondSpring Pharmaceuticals, Inc.

Efficacy endpoints.

Endpoint*	ITT (N=47)	NSQ (N=30)	SQ (N=17)
Primary endpoint			
cORR (RECIST 1.1)	18.2%	13.8%	26.7%
Secondary endpoints			
mPFS (RECIST 1.1)	7.0 mo	7.7 mo	5.5 mo

Efficacy, safety, and cytokine profiling with addition of the toll-like receptor (TLR) 7/8 dual agonist EIK1001 to standard of care (SOC) first-line (1L) therapy: The phase 2 TeLuRide-005 trial in stage 4 NSCLC. First Author: Bo Wang, Sarah Cannon Research Institute at Willamette Valley Cancer Institute and Research Center, Eugene, OR

Background: EIK1001 a TLR 7/8 dual agonist activates dendritic cells via both innate and adaptive pathways. This mechanism of action (MOA) associated with cytokine (CK) release and T-cell differentiation is complementary to immune checkpoint inhibitors (ICIs) that enhance anti-tumor T-cell activity. It provides rationale to add EIK1001 to SOC chemotherapy (chemo) + ICI in Stage 4 NSCLC, a disease with unmet therapeutic needs. **Methods:** TeLuRide-005 (NCT#06246110) is an ongoing multicenter, open-label study of intravenous weekly (wk) EIK1001 combined with SOC q3-wk pembro + chemo in treatment-naïve patients (pts) with Stage 4 NSCLC. The nonsquamous (NSQ) and squamous (SQ) cohorts completed accrual in May '25 and Jan '26, respectively. CK were sampled pre- and post EIK1001 treatment (PT) on Day 1 of Cycle (C) 1 and C4. **Results:** 71 pts (median age: 68, male:73%) were treated. An ORR of 61% and DCR of 90% were observed for the pooled study population. Cytokine release syndrome (CRS) events were of low grade: 4 pts with Grade 1 and 3 pts with Grade 2. For safety, and efficacy by histology, see Table. 71% of NSQ remain progression free at 8 months and despite over 11 months of follow-up, median PFS is not yet accurately estimable. Type 1 and 2 interferons (IFN) and Interleukin 6/8 (IL6/8) increased PT on C1. By C4, baseline IP-10, an IFN inducible protein that is a T-cell chemotactant, was upregulated by a median of 1.6- fold increase from baseline C1D1. Conversely, CRS-associated IL6 and IL8 were reduced or less inducible on C4D1 than on C1D1, consistent with our observation of only one pt. experiencing CRS after C4. **Conclusions:** 1L EIK1001 + SOC demonstrates encouraging efficacy in Stage 4 NSCLC with evidence of durable effect. AEs were similar to SOC alone and CRS events were low-grade. Cytokine data support the MOA of the TLR 7/8 dual agonist, EIK1001, and reduced inducibility of IL6/IL8 PT by C4 may suggest CRS likelihood diminishes with time. Clinical trial information: NCT#06246110. Research Sponsor: None.

SHR-1701 combined with fuzuloparib and chemotherapy as first-line therapy for advanced lung squamous cell carcinoma: Efficacy and safety results from a phase II study. First Author: Yongchang Zhang, Clinical Trials Center, Hunan Cancer Hospital, The Affiliated Cancer Hospital of Xiangya School of Medicine, Changsha, China

Background: Although immune checkpoint inhibitors are established in the treatment of advanced lung squamous cell carcinoma (LUSC), many patients derive limited or no durable benefit, underscoring the need for novel therapeutic strategies. However, poly (ADP-ribose) polymerase inhibitors (PARPi) can upregulate PD-L1 expression and promote immune-mediated response, which may increase the efficacy of anti-PD-(L)1 based therapy. Additionally, blocking TGF-b signaling has the potential to facilitate the recovery from chemo-induced myelosuppression. This phase II study evaluates the efficacy and safety for first-line approach combining SHR-1701, a bifunctional anti–PD-L1/TGF-β trap, with the PARP inhibitor fuzuloparib, combined with standard chemotherapy, which may potentiate anti-tumor immunity. To our knowledge, this is the first clinical investigation of this multi-pathway targeting strategy in advanced LUSC. **Methods:** Treatment-naïve patients with advanced LUSC received induction therapy with SHR-1701 (30 mg/kg IV q3w) plus platinum-based chemotherapy (investigator's choice) for 4 cycles. Patients with disease control proceeded to maintenance therapy with SHR-1701 (same dose) plus oral fuzuloparib (100 mg twice daily) until progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS) by Blinded Independent Review Committee (BIRC) per RECIST v1.1. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety. **Results:** Between February 2023 and June 2025, 71 treatment-naïve advanced LUSC patients were enrolled (median age 65 years; 96% male). As of data cutoff (December 1, 2025; median follow-up 17.4 months), 57 patients (80.3%) had started maintenance therapy (median 12 cycles). Disease progression or death had occurred in 27 of 71 patients (38.0%) by the cutoff date. Median PFS was 11.0 months (95% CI, 8.1 to not estimable). Among 69 response-evaluable patients, best overall response included 1 complete response (1.4%), 56 partial responses (81.2%, including 46 confirmed), and 11 stable disease (15.9%), yielding an unconfirmed ORR of 82.6% (57/69), a confirmed ORR of 68.1% (47/69), and a DCR of 98.6% (68/69). OS data were immature; the 12-month OS rate was 83.0% (95% CI 71.1–90.2). Treatment-related adverse events occurred in 94.4% (67/71) of patients, most commonly anemia (42.3%), increased blood creatinine (19.7%), and proteinuria (18.3%). No new safety signals were observed. **Conclusions:** SHR-1701 plus fuzuloparib and chemotherapy as first-line therapy demonstrated promising anti-tumor activity and a manageable safety profile in patients with advanced LUSC. Clinical trial information: NCT04937972. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

1L olomorasib plus pembrolizumab +/- chemotherapy in *KRAS* G12C-mutant NSCLC patients +/- a prior cycle of SOC: Results from LOXO-RAS 20001 and SUNRAY-01. First Author: Timothy F. Burns, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Real-world data suggests allowing 1 cycle of standard of care (SOC) prior to enrollment into first-line (1L) NSCLC trials of targeted therapies could expand the potential enrollable population by accommodating molecular testing turnaround time and enabling a more representative patient (pt) population. Here, we report results from 1L pts who did or did not receive 1 prior cycle of SOC in LOXO-RAS-20001 and the dose optimization/safety lead-in of SUNRAY-01, which investigated olomorasib, a KRAS G12C inhibitor, with pembrolizumab +/- chemotherapy. **Methods:** Pts with advanced *KRAS* G12C-mutant NSCLC, PD-L1 0-100% and ECOG PS 0-1 were eligible to receive olomorasib (50 or 100 mg, orally BID) with either pembrolizumab (doublet) or pembrolizumab + chemotherapy (quad) at their physician's discretion. One cycle of SOC prior to enrollment was permitted when timely initiation of treatment was clinically indicated, this included pembrolizumab (doublet) and pemetrexed + platinum +/- pembrolizumab, or pembrolizumab alone (quad). ORR was assessed in the efficacy evaluable population, defined as pts with ≥1 post-baseline response assessment or who discontinued treatment before the first response assessment. Safety was assessed across all treated pts. **Results:** As of 6 June 2025, 85 pts received the doublet and 77 pts received the quad; 13 pts (15%) and 23 pts (30%) received 1 prior cycle of SOC, respectively. Baseline characteristics of pts who did and did not receive 1 prior cycle of SOC were comparable. Accounting for small sample sizes, efficacy and safety were broadly similar across both the doublet and the quad among those who did and did not receive a prior cycle of SOC (Table). **Conclusions:** Treatment with 1 cycle of SOC prior to enrollment appeared to have no detrimental effect on safety and efficacy outcomes of olomorasib in combination with pembrolizumab +/- chemotherapy in pts with *KRAS* G12C NSCLC. This is the first analysis of the clinical impact of 1 prior cycle of SOC in a NSCLC clinical trial, allowing early access to treatment if clinically indicated. Implementation of this strategy in SUNRAY-01 and other 1L NSCLC trials may expand enrollment and allow for a more representative pt population. Clinical trial information: NCT04956640, NCT06119581. Research Sponsor: Eli Lilly and Company.

Phase II study of multidisciplinary therapy combined with pembrolizumab for patients with synchronous oligometastatic non-small cell lung cancer: TRAP-OLIGO study (WJOG11118L). First Author: Hideyuki Harada, Division of Radiation and Proton Therapy Center, Shizuoka Cancer Center, Nagaizumi, Japan

Background: Several clinical trials have demonstrated that local ablative therapy (LAT) to all lesions, including primary site, may provide a survival benefit for patients with oligometastatic non-small cell lung cancer (NSCLC). However, few studies have evaluated the efficacy of integrating immune checkpoint inhibitors with chemotherapy and LAT. This study aimed to evaluate the efficacy of multimodal therapy combining platinum-doublet chemotherapy plus pembrolizumab followed by LAT to all sites of disease in patients with synchronous oligometastatic NSCLC. **Methods:** This multicenter, single-arm, phase II trial enrolled treatment-naive patients with stage IV NSCLC and three or fewer metastatic lesions. Patients received 4 cycles of induction therapy consisting of pembrolizumab plus platinum-doublet chemotherapy. Patients then received LAT to all residual lesions, followed by maintenance therapy with pembrolizumab. The primary endpoint was the 24-month progression-free survival (PFS) rate from the initiation of LAT. Secondary endpoints included safety, response to induction therapy, PFS, overall survival (OS), and the proportion of patients who underwent LAT. The threshold and expected 24-month PFS rates were set at 25% and 60%, respectively, with a one-sided alpha of 0.025 and 80% power. **Results:** Between October 30, 2020, and August 12, 2022, 30 patients were enrolled. At enrollment, seven patients had one metastasis (23.3%), 14 had two (46.7%), and 9 had three (30%). Twenty-three patients (76.7%) received LAT to all residual disease sites. The 24-month PFS rate from the initiation of LAT was 56.5% (95% CI, 34.3–79.8%). The median PFS from the initiation of LAT was 25.8 months (95% CI, 11.7–not reached). The OS rates at 24 and 36 months from the initiation of LAT were 78.0% (95% CI, 55.0–90.2%) and 61.6% (95% CI, 37.2–78.9%), respectively. During the LAT phase, grade 3/4 adverse events occurred in 3 patients (13.0%). No treatment-related deaths were observed. **Conclusions:** The TRAP-OLIGO study met its primary endpoint with the lower limit of the 95% CI exceeding the threshold, demonstrating that multimodal therapy combining platinum-based chemotherapy plus pembrolizumab and LAT provides favorable efficacy for patients with synchronous oligometastatic NSCLC. These findings suggest that this integrated approach is a promising treatment strategy for this population. Trial registration: Japan Registry of Clinical Trials, jRCTs041200046. Clinical trial information: jRCTs041200046. Research Sponsor: None.

Immune-related adverse event severity and clinical outcomes with immune checkpoint inhibitor immunotherapy in participants with non–small cell lung cancer: Analysis of the lung MAP sub-studies S1400A, S1400I, S1400F, and S1800A. First Author: Diane Tseng, Fred Hutch Cancer Center, Seattle, WA

Background: Immune checkpoint inhibitors (ICIs) have advanced the treatment paradigm for non-small cell lung cancer (NSCLC), but ICIs are associated with risk of immune-related adverse events (irAEs). There is an unmet need to better understand how the severity of irAE impacts the clinical outcome of NSCLC treated with ICIs. We hypothesized that participants (pts) with lower grade irAEs would have better outcomes than those with higher grade irAEs and those without irAEs. **Methods:** We evaluated outcomes in Lung-MAP pts with advanced NSCLC treated with ICIs in the 2L setting (S1400A [durvalumab vs docetaxel], S1400I [nivolumab +/- ipilimumab], S1400F [durvalumab + tremelimumab], and S1800A [pembrolizumab + ramucirumab vs standard-of-care]), using 6-, 12-, and 24-week landmark analyses of the relationship between irAE severity (Grade(G) 1 or 2 vs G3 or 4 and vs no irAE) and overall survival (OS) from the landmark timepoint. OS was compared between groups using Cox Proportional hazards model with separate analyses for ICI-naïve (S1400A and S1400I) and ICI-exposed (S1400F and S1800A). **Results:** Analyses included 315 ICI-naïve and 127 ICI-refractory pts. In the ICI- naïve cohort, no irAEs and G 3-4 irAEs were associated with inferior OS compared with G1-2 irAEs by 12 wks of treatment (no irAEs: HR 1.68, CI 1.28 – 2.22, $p < 0.0005$ G3-4: HR 2.28, CI 1.47 – 3.53; $p < 0.0005$). This difference in OS between the irAE groups was consistent at the 6 wk ($p = 0.006$) and 24 wk ($p = 0.03$) landmark timepoints. See table for outcomes in the ICI naïve cohort. In the ICI-exposed cohort, there was no difference in OS between the irAE groups at any landmark timepoint (6 weeks: $p = 0.39$; 24 weeks: $p = 0.98$). **Conclusions:** In the ICI-naïve cohort, G1-2 irAEs in were associated with better OS compared to no irAEs and G3-4 irAEs for all landmark times. This association was not observed in the ICI-exposed cohort. Additional analyses will incorporate molecular and immune features evaluating risk and severity of irAEs. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; U10CA18088; National Cancer Institute/U.S. National Institutes of Health; U10CA180819.

Outcomes for ICI naïve cohort.

Landmark Time	irAE Group	N	mOS (95% CI)
6 weeks	No irAE	160	9.0 (7.9-10.9)
	G 1-2	124	14.6 (10.1-19.0)
	G 3-4	20	5.9 (3.5-10.8)
12 weeks	No irAE	124	8.2 (6.5-9.8)
	G 1-2	130	15.4 (11.5-9.8)
	G 3-4	29	5.3 (2.9 - 8.0)
24 weeks	No irAE	77	7.0 (5.8-9.8)

Durable efficacy of first-line necitumumab plus pembrolizumab in PD-L1–high advanced NSCLC: Final results of the phase II K-TAIL-202 study. First Author: Atsushi Horiike, Division of Medical Oncology, Department of Medicine, School of Medicine, Showa Medical University, Tokyo, Japan

Background: Pembrolizumab is a standard 1st line treatment for advanced non–small cell lung cancer (NSCLC) with high PD-L1 expression (tumor proportion score [TPS] $\geq$50%); however, durable benefit is achieved in only a subset of patients. Prior pembrolizumab-based combination strategies (e.g., anti-TIGIT) have inconsistently improved outcomes over pembrolizumab monotherapy in this setting. Epidermal growth factor receptor (EGFR) signaling may promote immune evasion by stabilizing PD-L1 expression and shaping an immunosuppressive tumor microenvironment, providing a rationale for combining the anti-EGFR antibody necitumumab with pembrolizumab. We therefore evaluated the efficacy and safety of necitumumab plus pembrolizumab in treatment-naive patients with PD-L1–high advanced NSCLC. **Methods:** K-TAIL-202 (jRCT2031200248) was an open-label, multicenter, single-arm phase II study conducted in Japan. Eligible patients were aged $\geq$20 years with unresectable stage III/IV or recurrent NSCLC, PD-L1 TPS $\geq$50% (22C3), ECOG PS 0–1, and $\geq$1 measurable lesion. Patients received necitumumab 800 mg IV on days 1 and 8 plus pembrolizumab 200 mg IV on day 1 every 3 weeks for up to 35 cycles or until disease progression or unacceptable toxicity. The primary endpoint was investigator-assessed objective response rate (ORR) per RECIST v1.1; secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. The study assumed an expected ORR of 54.8% and a threshold ORR of 39.0% (one-sided $\alpha = 0.10$; 80% power), requiring enrollment of 50 patients. **Results:** Between December 2020 and March 2023, 50 patients were enrolled (median age, 72 years). The ORR was 68.0% (95% CI, 53.3–80.5) and the disease control rate was 78.0% (95% CI, 64.0–88.5). Complete response, partial response, stable disease, progressive disease, and not evaluable status were observed in 2.0%, 66.0%, 10.0%, 12.0%, and 10.0% of patients, respectively, meeting the primary endpoint. Median PFS was 16.0 months (95% CI, 9.0–24.0), with a 24-month PFS rate of 35.9%. Median OS was not attained (95% CI, 38.0 months–not estimable), and the 24-month OS rate was 71.3%. The most treatment-emergent adverse events included acneiform dermatitis (66.0%), hypomagnesemia (60.0%), and pneumonitis (12.0%). One grade 5 cardiac arrest occurred in 1 patient (2.0%), for which a causal relationship to study treatment could not be ruled out. **Conclusions:** At final analysis, first-line necitumumab plus pembrolizumab demonstrated durable antitumor activity and encouraging long-term survival as a chemotherapy-free regimen in patients with PD-L1–high advanced NSCLC. Toxicities were consistent with the known profiles of EGFR-targeted antibodies and PD-1 inhibitor therapy, underscoring the need for careful monitoring. These findings warrant further confirmation in a randomized phase III clinical trial. Clinical trial information: jRCT2031200248. Research Sponsor: Nippon Kayaku Co; READYFOR (Japan) crowdfunding (public donations).

A phase II study of HB0025 (a PD-L1/VEGF bispecific antibody) in combination with chemotherapy as first-line treatment for non–small cell lung cancer (NSCLC). First Author: Lei Wang, Department of Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Background: HB0025, developed by Huaota, is a novel anti-PD-L1/VEGF bispecific antibody with VEGFR1D2 linked at the N-terminal of anti-PD-L1 antibody. This Phase II study assesses the efficacy and safety of HB0025 combined with chemotherapy in locally advanced unresectable, recurrent or metastatic non-small cell lung cancer (NSCLC). **Methods:** This open-label, multi-center, Phase II trial enrolled previously untreated patients with locally advanced unresectable, recurrent or metastatic NSCLC, without *EGFR* or *ALK* gene alterations. Participants were assigned to two cohorts: Cohort 1 (squamous NSCLC) received 20 mg/kg HB0025 plus carboplatin and paclitaxel every three weeks (Q3W) for 4-6 cycles, followed by HB0025 maintenance; Cohort 2 (non-squamous NSCLC) received 20 mg/kg HB0025 plus carboplatin and pemetrexed Q3W for 4-6 cycles, followed by maintenance with HB0025 and pemetrexed. Primary endpoint was objective response rate (ORR) per RECIST 1.1. **Results:** As of January 5, 2026, 125 patients were enrolled in the study (62 patients in Cohort 1 and 63 patients in Cohort 2). The median age was 65 years old (range: 34, 74). The median follow-up period was 10.55 months (range: 1.0, 17.4). A total of 119 patients had at least one post-baseline tumor assessment. In Cohort 1, ORR was 84.5% (49/58), with subgroup ORRs of 81.3%, 72.2%, and 100% for PD-L1 TPS $<$ 1%, 1–49%, and $\geq$50%, respectively; disease control rate (DCR) was 94.8% (55/58), median progression-free survival (mPFS) was 12.62 months, and median duration of response (mDOR) was immature. In Cohort 2, ORR was 65.6% (40/61), with ORRs uniformly 66.7% across all PD-L1 TPS subgroups; DCR was 96.7% (59/61), mPFS was 14.65 months, and mDOR was 12.06 months. Overall survival data remained immature. The most common immune-related adverse events (irAEs) were hypothyroidism (7.2%), hyperthyroidism (4.8%), increased alanine aminotransferase (4.0%), increased aspartate aminotransferase (3.2%), and increased blood thyroid stimulating hormone (3.2%). Anti-VEGF-related AEs of grade $\geq$3 were proteinuria (8.8%), hypertension (6.4%), hemorrhage (4.0%), and thromboembolism (4.0%). 6 (4.8%) patients discontinued HB0025 due to TRAE, and 2 (1.6%) patients died due to TRAE. **Conclusions:** The combination of HB0025 and chemotherapy has demonstrated promising efficacy and favorable safety as a first-line treatment for patients with locally advanced unresectable, recurrent or metastatic NSCLC. Multi-center, randomized, double-blind, controlled phase III trials in both squamous and non-squamous NSCLC have been initiated. Clinical trial information: NCT06758557. Chronotherapy in metastatic non–small cell lung cancer: Clinical outcomes according to immune checkpoint inhibitor administration time during the day in patients treated with first-line chemoimmunotherapy. First Author: Bahadır Köylü, Department of Medical Oncology, Koç University School of Medicine, Istanbul, Turkey

Background: Although circadian rhythms are known to modulate immune cell function, the effect of immune checkpoint inhibitor (ICI) infusion timing during the day on oncologic outcomes in metastatic non–small cell lung cancer (NSCLC) patients treated with first-line chemoimmunotherapy has not been fully elucidated. **Methods:** We retrospectively analyzed patients with de novo metastatic NSCLC without actionable oncogenic driver alterations who received first-line chemotherapy plus ICI between January 1, 2018, and October 31, 2025, at two centers. Patients receiving platinum-based doublet chemotherapy plus pembrolizumab and/or nivolumab were included, whereas those treated with dual ICIs (nivolumab plus ipilimumab with platinum-based chemotherapy) were excluded. Infusion times for the first four cycles were recorded, and patients were categorized as the early group if they received ≥2 of the first four ICI cycles before 11:00 a.m., and as the late group if they received ≤1 of the first four ICI cycles before 11:00 a.m. Endpoints were objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Results:** We identified 101 eligible patients who met the inclusion criteria, comprising 34 patients in the early group and 67 patients in the late group. Median follow-up was 18.4 months (95% CI 12.4 – 24.4). There were no differences between the early group and the late group in terms of age, gender, body mass index, smoking status, ECOG performance status, stage (IVA vs. IVB), histologic subtype (squamous vs. non-squamous), PD-L1 tumor proportion score (< 1% vs. 1-49% vs. ≥50%), central nervous system metastases, liver metastases, number of metastatic sites (≤2 vs. ≥3 organ systems), and ICI agent (pembrolizumab vs. nivolumab). The early group demonstrated significantly longer median PFS (14.6 vs. 7.1 months; HR = 0.54 [95% CI 0.31 – 0.93]; p = 0.027) and median OS (not reached vs. 27.3 months; HR = 0.28 [95% CI 0.11 – 0.71]; p = 0.008). Both the ORR (97.1% vs. 56.7%; p < 0.001) and the disease control rate (97.1% vs. 64.2%; p < 0.001) were significantly higher in the early group. The majority of patients who experienced primary progression after the first four cycles were in the late group (24 of 25 patients; 96%). In multivariate analysis, only disease stage (IVB vs. IVA; HR = 2.35 [95% CI 1.05 – 5.26]; p = 0.039) and timing-based group assignment according to the number of the first four ICI infusions administered before 11:00 a.m. (late vs. early; HR = 2.97 [95% CI 1.14 – 7.76]; p = 0.026) were independently associated with OS. **Conclusions:** Our findings demonstrated that receiving majority (≥2) of the first four ICI infusions before 11:00 a.m. might be associated with better response rates, improved PFS and OS in patients with de novo metastatic NSCLC treated with first-line chemotherapy plus ICI. Research Sponsor: None.

Multi-omic ctDNA-based MRD for predicting clinical outcomes in advanced NSCLC receiving chemoimmunotherapy. First Author: Yun Fan, Department of Thoracic Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: Immune checkpoint inhibitors (ICIs) have revolutionized treatment for advanced non–small cell lung cancer (aNSCLC); however, many patients achieving radiographic partial or complete response (PR/CR) relapse early. This underscores the need for more precise risk stratification after an initial response. We investigated whether circulating tumor DNA -based minimal residual disease (ctDNA-MRD) assessment could stratify patients with durable benefit versus those at risk of early progression after chemoimmunotherapy (Chemo-IO). **Methods:** We analyzed 152 retrospective and 60 prospective aNSCLC patients who achieved PR/CR after first-line (1L) PD-1-based Chemo-IO. Plasma was collected at the first imaging-confirmed PR/CR (retrospective) or at baseline and Cycle 5 Day 1 (C5D1; prospective). ctDNA-MRD was assessed using a tumor-naïve, mutation-based panel and a fragmentomics model derived from low-pass whole-genome sequencing (LP-WGS). In the retrospective cohort, 89 patients were used for LP-WGS model training and 63 for validation. Risk stratification was evaluated using progression-free (PFS) and overall survival (OS). **Results:** In the retrospective validation cohort (n = 63), both the mutation- and fragmentomic-based assays stratified PFS and OS. For the mutation-based assay, median PFS (mPFS) was 27.0 vs. 10.1 months (negative vs. positive; Hazard ratios [HR] 0.414, 95% confidence intervals [CI] 0.211–0.814, p = 0.008) and median OS (mOS) was not reached (NR) vs. 17.5 months (HR 0.341, 95% CI 0.151–0.768, p = 0.007). For the LP-WGS-based model, mPFS was 27.0 vs. 13.8 months (HR 0.412, 95% CI 0.216–0.785, p = 0.005) and mOS was NR vs. 25.1 months (HR 0.355, 95% CI 0.158–0.795, p = 0.009). Integration using an either-assay-positive definition further improved prognostic discrimination, with mPFS NR vs. 13.8 months (HR 0.379, 95% CI 0.201–0.714, p = 0.002) and mOS NR vs. 25.1 months (HR 0.324, 95% CI 0.143–0.730, p = 0.004). In the prospective cohort (n = 60), both assays at C5D1 identified patients at higher risk of progression: mutation-based mPFS 18.3 vs. 6.1 months (HR 0.184, 95% CI 0.075–0.457, p < 0.0001); LP-WGS-based mPFS NR vs. 5.3 months (HR 0.178, 95% CI 0.070–0.456, p < 0.0001). Integration-based mPFS was NR vs. 6.5 months (HR 0.130, 95% CI 0.039–0.440, p = 0.0001). Multivariable analysis confirmed the independent and complementary prognostic value of both approaches across cohorts. **Conclusions:** Both mutation- and fragmentation-based ctDNA-MRD assays effectively stratified risk among aNSCLC patients with radiographic response to 1L Chemo-IO. Their integration further improved prognostic performance, refining risk beyond imaging-defined PR/CR and informing post-response management decisions. Research Sponsor: None.

8577 Poster Session

Real-world efficacy and safety of bispecific antibody ivonescimab-based regimens in EGFR-TKI–resistant advanced NSCLC. First Author: Chuang Yang, Qilu Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China

Background: Ivonescimab is a first-in-class bispecific monoclonal antibody targeting programmed cell death protein 1 (PD-1) and vascular endothelial growth factor (VEGF)-A. In the phase III HARMONi-A trial, ivonescimab plus chemotherapy significantly improved progression-free survival (PFS) compared with chemotherapy alone in patients with epidermal growth factor receptor (EGFR)-mutant advanced non–small cell lung cancer (NSCLC) after resistance to EGFR tyrosine kinase inhibitors (EGFR-TKIs). However, in real-world clinical practice, ivonescimab is administered across heterogeneous treatment lines after EGFR-TKI resistance, and evidence regarding its effectiveness in these settings remains limited. **Methods:** This real-world study included patients with advanced NSCLC who received ivonescimab plus chemotherapy following progression on EGFR-TKIs. The primary endpoints were median PFS (mPFS) and safety. **Results:** A total of 254 patients were included. At the data cutoff of November 30, 2025, the median follow-up was 8.9 months. The median age was 61 years; 54.3% were female, and 48.0% had brain metastases. The overall objective response rate (ORR) was 47.9%, with a mPFS of 6.9 months (95% CI, 6.2–7.5). A total of 124 patients were treated with ivonescimab plus chemotherapy immediately after EGFR-TKI resistance with HARMONi-A–like sequence and achieved an ORR of 52.9% with a mPFS of 7.0 months (95% CI, 4.5–9.4). The other 130 patients receiving ivonescimab plus chemotherapy after failure of prior immunotherapy-, anti-angiogenic therapy-, and/or chemotherapy-based regimens achieved an ORR of 43.1% with a mPFS of 6.7 months (95% CI, 6.0–7.4). No statistically significant difference in PFS was observed between the two groups (p= 0.269). Grade 3–4 adverse events occurred in 14.6% of patients, including leukopenia (n = 9), neutropenia (n = 7), immune-related pneumonia (n = 6), and checkpoint inhibitor–related myocarditis (n = 5). Given the relatively short follow-up, overall survival data were not mature. **Conclusions:** In this real-world cohort, ivonescimab plus chemotherapy demonstrated clinically meaningful efficacy and a manageable safety profile when administered both immediately after EGFR-TKI resistance and following multiple prior lines of therapy, supporting its use across diverse treatment sequences in patients with EGFR-mutant advanced NSCLC. Research Sponsor: None.

Baseline characteristics of NSCLC first-line immunotherapy super-responders in three European lung cancer centers: An ENDEAVOUR-IMIGO project. First Author: David Lang, Department of Pneumology, Kepler University Hospital, Johannes Kepler University, Linz, Austria

Background: Immune-checkpoint inhibitors (ICI) are part of first-line treatment concepts for most patients with metastatic non-small cell lung cancer (NSCLC) without targetable driver mutations. Still, long-term response is rare and data on predictive biomarkers limited. **Methods:** As part of the Daiichi Sankyo ENDEAVOUR programme supporting young LC researchers, the ENDEAVOUR-IMIGO working group aims to explore novel predictive biomarkers for ICI response with a focus on imaging data. We present the baseline characteristics of first-line ICI "super-responders" with PFS ≥24 months, derived from three independent cohorts from Austria, Italy and the Netherlands. Also, an exploratory single-center analysis compared ICI super- to non-responders (PFS<6M) matched for age, sex, histology, PD-L1 positivity, stage and ECOG performance status. **Results:** The Linz (Austria) cohort reported 50 (12.4%) super-responders out of a total of 402 patients, the Milan cohort (Italy) 45 out of 283 (15.9%), and the Groningen cohort (Netherlands) 46 (10.7%) out of 428. As shown in table 1, all cohorts had a high prevalence of adenocarcinomas, with KRAS mutations present in nearly half of patients and a mean PD-L1 expression of approximately 50%. In the Austrian cohort, matched baseline data showed a higher frequency of systemic steroids among non-responders, and lower absolute neutrophil count as well as neutrophil-to -lymphocyte ratio in super-responders. **Conclusions:** Baseline characteristics of ICI super-responders were similar in three European cohorts, with a majority of high-PD-L1 expressing adenocarcinomas. Exploratory matched analyses from one cohort showed implications of baseline systemic steroid treatment as well as of differential blood cell count. Research Sponsor: None.

Initial safety and efficacy of A2B694, a logic-gated mesothelin (MSLN)–targeted Tmod chimeric antigen receptor T-cell (CAR T) therapy in patients with advanced solid tumors with HLA-A*02 loss of heterozygosity (LOH). First Author: Julian R. Molina, Division of Medical Oncology, Mayo Clinic Rochester, Rochester, MN

Background: LOH may provide a means to target tumor versus normal cells, to augment the efficacy and safety of MSLN-targeted programs (Hecht et al. *JCO*. 2022). A2B694 is an autologous, logic-gated, Tmod CAR T therapy designed to improve tumor selectivity and decrease toxicity by integrating an MSLN CAR activator with an HLA-A*02 blocker (Hamburger et al. *Mol Imm*. 2020). **Methods:** The first-in-human, open-label, phase 1/2 EVEREST-2 (NCT06051695) study of A2B694 in patients with recurrent/metastatic MSLN-expressing cancers with tumor-associated HLA-A*02 LOH. The prescreening study BASECAMP-1 (NCT04981119) identifies eligible patients and cryopreserves leukapheresis product. Upon progression, A2B694 is manufactured and administered after lymphodepletion. Phase 1 primary objective: evaluate the safety and tolerability of A2B694 and identify a recommended phase 2 dose. **Results:** As of 05 January 2026, 13 patients were enrolled: 8 women/5 men, median age 59 years, 11 non-Hispanic White/2 Hispanic with unknown race. Tumor types included colorectal (n = 4), ovarian (n = 3), pancreatic (n = 3), non–small cell lung adenocarcinoma (NSCLC), gastro-esophageal, and mesothelioma (n = 1 each). A2B694 dose level (DL) groups were: DL1: 1×10^8 cells (n = 3), DL2: 2×10^8 cells (n = 4), DL3: 4×10^8 cells (n = 5), and DL4: 6×10^8 cells plus low-dose IL-2 (n = 1). Lymphodepletion prior to administration of A2B694 was well-tolerated, with expected, transient cytopenias. The only adverse event reported in more than 1 patient was grade 3 neutropenia. One patient had grade 3 ICANS and 1 patient had grade 1 CRS. There were no dose-limiting toxicities or new safety signals after up to 17 months follow-up. All 13 patients received A2B694, were efficacy-evaluable, and had A2B694 detected post-infusion in peripheral blood. While A2B694 was not detected in tumor biopsies collected in patients treated at DL1 (0/2), all patients treated at DL2-DL4 with available biopsies (3/3) had detectable A2B694 in the tumor microenvironment. A patient with $KRAS^{G12V}$/STK11 co-mutated NSCLC who had progressed on carboplatin, pemetrexed, and pembrolizumab achieved a complete response (CR) at D90 post-infusion per RECIST 1.1 by central review and had a confirmed CR at D180. In addition, PET-CT scan and ctDNA on D190 demonstrated no evidence of disease. On D243, the patient had a CNS relapse, with an ongoing non-CNS CR per RANO-BM at D284. At M12, the patient's CT showed no new findings and persistence of A2B694 in the blood was confirmed by ddPCR. **Conclusions:** We report the first patient with NSCLC to have a CR after CAR T. Overall, A2B694 demonstrated manageable safety and tolerability in patients with advanced solid MSLN-expressing tumors with tumor-associated HLA-A*02 LOH. The maximum tolerated dose has not been reached; dose-escalation continues. Clinical trial information: NCT06051695. Research Sponsor: A2 Biotherapeutics, Inc.

Phase I study of IMM2510, a PD-L1/ VEGF bispecific antibody, in participants with advanced IO-treated SQ-NSCLC. First Author: Xiaoqing Yu, Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China

Background: Despite advancements in first-line treatments such as immunotherapy and targeted therapies, resistance to these treatments is common, especially those IO-treated and low PD-L1 TPS, creating a significant unmet need for effective second-line therapies. IMM2510 is a bispecific fusion protein targeting PD-L1 and VEGF which can modify tumor microenvironment to overcome resistance and improve sensibility to antitumor agents. The data of dose-escalation phase I was previously reported in ASCO2024. Here we summarize the updated efficacy and safety results of IMM2510 in advanced IO-treated SQ-NSCLC. Part of the data were previously reported in WCLC 2025. **Methods:** The phase I study was designed as a first-in-human, open-label, multi-center study to evaluate the safety, efficacy, PK and PD of IMM2510 in pts with advanced solid tumors. Eligible pts were enrolled to receive IMM2510 via intravenous infusion Q2W. **Results:** As of 31 Dec 2025, 32 pts with advanced IO-treated SQ-NSCLC received IMM2510. The median age was 61 years; 31.3% pts had PD-L1 TPS $<$ 1%; 75.0% pts had ECOG score of 1; the median prior lines of anti-tumor therapy were 2 (range: 1-5). All 32 pts experienced TEAEs. Grade $\geq$3 TEAEs were reported by 17 (53.1%) pts; Grade $\geq$3 TRAEs were reported by 12 (37.5%) pts; TRAEs leading to treatment discontinuation were reported by 1 (3.1%) participant. No participant experienced TRAE leading to death. 22 pts with advanced IO-treated SQ-NSCLC were evaluable for efficacy analysis. The ORR was 27.3% (6/22) and DCR was 81.8% (18/22). The median DoR was 11.1 months. The median PFS was 9.4 months at the median follow-up time of 8.3 months. The median overall survival was not reached. Exposure-response (ER) analysis within the 3 - 20 mg/kg dose range revealed a positive exposure-efficacy relationship in pts with SQ-NSCLC, with higher exposure corresponding to increased ORR or DCR, while a relatively flat ER was observed for Grade 3 or higher TRAE and most common AEs in NSCLC. Thus, 20 mg/kg Q2W was selected as the RP2D with well-balanced efficacy-safety profiles. **Conclusions:** In pts with advanced IO-treated SQ-NSCLC, IMM2510 provides clinical meaningful benefit and supports a favorable benefit-risk profile. The phase III clinical study is being planned. Clinical trial information: NCT05972460. Research Sponsor: None.

First-line serplulimab for locally advanced or metastatic squamous non–small cell lung cancer: Updated survival from the ASTRUM-004R trial. First Author: Bo Shen, The Affiliated Cancer Hospital of Nanjing Medical University & Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research, Nanjing, Jiangsu, China

Background: Although the ASTRUM-004 trial has confirmed that serplulimab plus platinum-based therapy improves survival in patients with locally advanced or metastatic squamous non-small cell lung cancer (sqNSCLC), evidence regarding its efficacy and safety in routine clinical practice remains limited. Previous results from the ASTRUM-004R trial have shown that a serplulimab plus platinum-based therapy exhibits promising antitumor activity in sqNSCLC. Here, we report the updated follow-up results from this study. **Methods:** The ASTRUM-004R trial is a retrospective, real-world study conducted across 14 centers in China. Patients with locally advanced or metastatic sqNSCLC received first-line serplulimab plus platinum-based therapy, followed by serplulimab maintenance treatment until disease progression, intolerable toxicity, or up to 2 years. This update presents the survival outcomes, including progression-free survival (PFS) and overall survival (OS). Additionally, PFS was assessed across various patient subgroups. **Results:** A total of 132 patients were enrolled in the analysis, with a median follow-up of 18 months as of October 31, 2025. The median patient age was 69 years. Overall, 92.4% (n = 122) were male, 71.2% (n = 94) were aged 65 or older, 19.7% (n = 26) had an ECOG performance status of 2, and 47.0% (n = 62) had stage IV disease. Maintenance therapy was administered to 50.8% (n = 67) of the patients. The median PFS for all patients was 14.8 months (95% CI: 11.9-19.6), with a 6-month PFS rate of 78.5% (95% CI: 71.5%-86.2%). The median PFS benefit was comparable between patients receiving nab-paclitaxel and those receiving paclitaxel (17.5 *vs.* 15.2 months, *P*= 0.677), suggesting no significant difference in efficacy between the two groups. Furthermore, a significantly longer median PFS was observed in patients with stage III disease compared to those with stage IV disease (20.4 *vs.* 11.9 months, *P*= 0.009). The median OS for all patients was 29.7 months (95% CI: 29.7-NR), with a 12-month OS rate of 90.1% (95% CI: 84.7%-95.9%). The updated findings confirm sustained antitumor activity, as evidenced by an objective response rate of 66.7% (95% CI: 57.9%-74.6%) and a disease control rate of 95.5% (95% CI: 90.4%-98.3%). Adverse events (AEs) of any grade occurred in 48 patients (36.4%), most of whom had hematological disorders. Immune-related AEs (irAEs) were reported in 35 patients (26.5%), including 9 (6.8%) who experienced grade $\geq$3 irAEs. **Conclusions:** Updated results from the ASTRUM-004R study show that first-line serplulimab platinum-based therapy provides a significant survival benefit with a manageable safety profile in locally advanced or metastatic sqNSCLC, consistent with findings from the ASTRUM-004 trial. The long-term survival benefit warrants further validation with extended follow-up. Research Sponsor: None.

Impact of genomic HLA class I allelic imbalance on enduring immunotherapy response in advanced non–small cell lung cancer. First Author: Yiting Dong, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Human leukocyte antigen class I (HLA-I) molecules are essential for neoantigen presentation and T cell recognition, yet the clinical significance of allelic imbalance within HLA-I genes (HLA-AI) in immune checkpoint inhibitors (ICIs) therapy remains undefined. **Methods:** Here, we established haplotype-specific, coverage-based (cHLA-AI) compatible with routine biopsy-derived sequencing, based on 292 fully heterozygous non–small cell lung cancer (NSCLC) patients with paired tumor samples from the phase III CHOICE-01 trial and confirmed in RATIONALE-304 and real-world NCC cohorts, covering both first- and later-line immunochemotherapy as well as ICI monotherapy, and complemented by analyses in surgical, pan-cancer, and longitudinal datasets to assess immune correlates and evolutionary dynamics. **Results:** Patients with tumor mutational burden (TMB)–low and cHLA-AI derived no benefit from first-line immunochemotherapy, whereas all other patients achieved significant survival gains (TMB-low and cHLA-AI vs. others: immunochemotherapy arm: mOS 16.53 vs. 29.57 months, HR = 2.29, 95% CI 1.59–3.30, p $<$ 0.001,interaction P = 0.019; mPFS 5.59 vs. 9.92 months, HR = 2.02, 95% CI 1.43–2.90, p $<$ 0.001, interaction P = 0.016). These findings were validated in the RATIONALE-304 and RATIONALE-307 trials and independent real-world cohorts. Incorporating cHLA-AI with pathology, PD-L1 and TMB significantly improved 2-year OS prediction (DeLong's P = 0.003). Multi-omic profiling linked cHLA-AI to active DNA damage response signalings, high TMB -intratumor heterogeneity (ITH) -chromosomal instability (CIN) phenotype, immune-cold microenvironments, and failure of on-treatment TCR clone expansion, while longitudinal sampling revealed its late, branching emergence under immune pressure. Pan-cancer profiling (N = 5,989) demonstrated consistent associations with high TMB-ITH-CIN phenotype and proliferative activity (Ki-67 index). **Conclusions:** Collectively, these results establish cHLA-AI as a pivotal biomarker bridging genomic instability, immune evasion, and therapeutic outcomes, providing a framework for stratified immunotherapy response in non–small cell lung cancer and beyond. Research Sponsor: None.

Concomitant radiotherapy, tremelimumab, and durvalumab for advanced NSCLC patients progressing on first-line immunotherapy: A phase 2 study (CORAL-Lung). First Author: Jair Bar, Jusidman Cancer Center, Sheba Medical Center, Ramat Gan, Israel; The Gray Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel

Background: The optimal treatment for advanced NSCLC that developed resistance to immune checkpoint inhibitors (CPIs) remains undefined. We hypothesized that combining anti-PD-L1, anti-CTLA-4 (at an effective dose) and radiotherapy could be effective against CPI-resistant tumors. **Methods:** This open-label, single-arm, phase 2a trial evaluated two CPIs plus radiotherapy in patients with advanced/metastatic NSCLC who progressed on/after 1L CPI given alone or in combination with chemotherapy. Co-Primary endpoints were safety and response rate (RR; by RECIST 1.1). Secondary endpoints were to evaluate progression free survival (PFS) and overall survival (OS). The study included a safety run-in cohort and a Simon two-step design expansion. RR $\geq$ 20% in non-irradiated lesions was required to advance from the initial efficacy to expansion cohort. Patients with prior anti-CTLA-4 treatment were excluded. At least one measurable non-irradiated lesion was required. Treatment included tremelimumab at a fixed dose of 300 mg at D1 and 12 weeks later and 1500 mg Durvalumab q4w (starting from D1). This dosing was based on PK and pharmacodyamic data from study D4190C00006, suggesting tremelimumab of dose greater than 1 mg/kg with a higher peak exposure may be associated with a higher pharmacodynamic effect. On D21, patients began radiotherapy: 11 fractions of 3 Gy (total of 33 Gy), selected based on our real-world database analysis (Onn et al, Cancers 2021, 13(11), 2800). The study was sponsored by Sheba MC and funded by AstraZeneca Pharmaceuticals. NIH trials registry identifier: NCT05000710. **Results:** Ten patients were enrolled, median age was 71 (range 51-82); 50% males; all stage IV; 50% adenocarcinoma; 50% with PD-L1 $<$ 1%; 80% past/current smokers; none had actionable driver mutations. Previous treatment lines were 1/2 in 80%/20% respectively; all patients received prior pembrolizumab and platinum-based doublet. Median (range) durvalumab and tremelimumab cycles administered were 2 (1-7), 1(1-3). Median radiotherapy dose was 33 Gy, in 78% targeting lung lesions. Nine patients were included in the safety run-in, three experienced treatment-related toxicities leading to treatment discontinuation (all grade 3 diarrhea), remaining below the predefined 40% threshold and permitting continuation. All other treatment-related toxicities were grade 2 or lower. The initial efficacy cohort (n = 10) RR was 10%, leading to the study closure. Median PFS was 2.2 months, median OS was 13.9 months. The study was terminated on Dec 31, 2024. **Conclusions:** In unselected patients with advanced CPI-resistant NSCLC, the combination of anti-PD-L1, anti-CTLA4 at a high dose and radiotherapy did not demonstrate a meaningful response rate. Toxicity of a high dose of anti-CTLA-4 is not negligible. Better patient selection might lead to higher efficacy and lower toxicity. Clinical trial information: NCT05000710. Research Sponsor: AstraZeneca.

Final analysis of the biomarker-directed, randomized, phase 2 KEYNOTE-495/KeyImPaCT study of pembrolizumab (P)—based combination therapy for non—small cell lung cancer (NSCLC). First Author: Martin Gutierrez, Hackensack University Medical Center, Hackensack, NJ

Background: KEYNOTE-495/KeyImPaCT (NCT03516981) evaluated 3 P-based regimens in participants (pts) with advanced NSCLC across 4 prospectively defined biomarker subgroups based on T-cell–inflamed gene expression profile ($Tcell_{inf}GEP$) and tumor mutational burden (TMB). In interim analysis, ORR with P + lenvatinib (L) in the $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$ subgroup met the prespecified efficacy threshold. We report final analysis results. **Methods:** Pts with previously untreated NSCLC were assessed for $Tcell_{inf}GEP$ (non-low, ≥ -0.16; low, < -0.16) and TMB (high, $\geq$5 mut/Mb; non-high, $<$5 mut/Mb; $\approx$175 mut/exome by WES and 10 mut/Mb on FoundationOne CDx). Pts were assigned to 1 of 4 subgroups ($Tcell_{inf}GEP^{low}TMB^{non\text{-}high}$, $Tcell_{inf}GEP^{low}TMB^{high}$, $Tcell_{inf}GEP^{non\text{-}low}TMB^{non\text{-}high}$, and $Tcell_{inf}GEP^{non\text{-}low}TMB^{high}$) and adaptively randomized 1:1:1 to P (200 mg IV Q3W) + either L (20 mg PO QD), quavonlimab (Q; 25 mg IV Q6W), or favezelimab (F; 200 mg or 800 mg IV Q3W). The primary end point was ORR per RECIST v1.1 by investigator. Secondary end points included PFS, OS, and safety. Data cutoff: July 30, 2025. **Results:** 243 pts were treated (P + L, 80; P + Q, 82; P + F 200 mg, 30; P + F 800 mg, 51). Median follow-up was 66.5 mo (range, 43.0-81.2). The $Tcell_{inf}GEP^{non\text{-}low}TMB^{non\text{-}high}$ subgroup treated with P + L met the prespecified efficacy threshold ($\geq$95% posterior probability of true ORR $>$20%); PFS and OS were generally consistent with anticipated results among biomarker-defined subgroups (Table). Safety profile of each combination was consistent with the known profiles of each therapy. **Conclusions:** With longer follow-up, OS benefit was comparable across the 4 biomarker subgroups for the 3 combination therapies, with no new safety signals. These data continue to show the feasibility of prospective biomarker assessment to evaluate P-based therapies in advanced NSCLC. Clinical trial information: NCT03516981. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Single-cell spatial analysis of the tumor immune microenvironment in NSCLC primary tumors and brain metastases. First Author: Lauren Julia Brown, The University of Sydney, Faculty of Medicine and Health, Westmead, NSW, Australia

Background: Brain metastases (BrM) are associated with poor prognosis in non-small cell lung cancer (NSCLC). Although immune checkpoint inhibitors (ICIs) demonstrate intracranial activity, intracranial progression remains common, especially in patients with driver-negative NSCLC. To define mechanisms of intracranial immune resistance, we applied imaging mass cytometry to profile the tumor immune microenvironment (TIME) in BrM and primary lung tumors. **Methods:** Forty-four patients with advanced driver-negative NSCLC were included; 39 (89%) were treated with ICIs. A 40-marker antibody panel enabled site-specific immune phenotyping of primary lung tumors and BrM, with all samples obtained prior to initiation of systemic immunotherapy. Three regions of interest per sample (two intratumoral, one peritumoral) were analyzed using a Hyperion imaging mass cytometer. Single-cell segmentation was performed using Mesmer with immune phenotypes defined by marker expression. Spatial neighborhoods were identified using unsupervised k-means clustering of nearest-neighbor-derived local cellular compositions. **Results:** Compared with primary lung tumors, BrM demonstrated significantly reduced $CD4^+$ and $CD8^+$ T cells ($p < 0.001$), B cells ($p = 0.017$) and endothelial markers ($p < 0.001$). Despite reduced overall $CD4^+$ infiltration, BrM exhibited higher proportions of regulatory T cells (Tregs; $p = 0.017$), $Ki67^+CD4^+$ T cells ($p = 0.002$) and $Ki67^+$ Tregs ($p = 0.017$). BrM were enriched for CD206-high immunosuppressive macrophages, whereas primary tumors demonstrated predominance of CD11c-high inflammatory myeloid cells ($p = 0.006$). Spatial analysis demonstrated increased proximity of $CD8^+$ T cells ($p = 0.039$) and Tregs ($p = 0.020$) to M2-like macrophages in BrM. Neighborhood analysis revealed site-specific immune organization, with primary tumors enriched for adaptive immune-dominant niches containing mixed $CD4^+$, $CD8^+$ and B-cell populations. In contrast, BrM were characterized by myeloid-T-cell interface neighborhoods marked by close spatial coupling of T cells with macrophages and monocytes. In primary tumors, durable immunotherapy benefit ($\geq$24-month PFS and OS) was associated with significantly higher $CD8^+$ and $CD4^+$ T cells, B cells, dendritic cells, monocytes and macrophages. In BrM, no consistent immune correlates of long-term benefit were observed. **Conclusions:** NSCLC BrM exhibit a distinct TIME characterized by depleted adaptive immune infiltration, CD206-high macrophage dominance and myeloid-T-cell spatial organization. While primary lung tumors display adaptive immune signatures predictive of durable ICI benefit, BrM lack consistent immune correlates of response. These site-specific compositional and spatial differences provide a mechanistic framework for the attenuated and less durable intracranial responses to immune checkpoint blockade. Research Sponsor: Western Sydney Local Heath District.

IBI363 (TAK-928) plus chemotherapy as first-line (1L) treatment for advanced non—small cell lung cancer (NSCLC). First Author: HaiYan Tu, Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Southern Medical University, Guangzhou, Guangdong, China

Background: IBI363 is a first-in-class, PD-1/IL-$2^{\alpha\text{-bias}}$ bispecific antibody fusion protein with great potential for immune-cold and immunotherapy (IO)-resistant tumors. Previously, IBI363 monotherapy demonstrated encouraging and durable efficacy in patients (pts) with IO-treated advanced NSCLC (2025 ASCO #8509). Here, we report a phase 1 study evaluating IBI363 plus platinum-based doublet-chemotherapy (PDC, pemetrexed/paclitaxel plus platinum) in 1L NSCLC. **Methods:** Previously untreated pts with advanced NSCLC, without sensitizing EGFR, ALK, or ROS1 alterations were enrolled. The safety lead-in evaluated IBI363 at 1.5 or 3 mg/kg Q3W plus PDC. In dose optimization (PD-L1 TPS $<$ 50% required), pts were randomized 1:1:1 to 3 cohorts: 3-1.5 mg/kg (IBI363 3 mg/kg plus PDC in cycle 1, then 1.5 mg/kg Q3W plus PDC in subsequent cycles), 3 mg/kg (IBI363 3 mg/kg Q3W plus PDC) and 1.5 mg/kg (IBI363 1.5 mg/kg Q3W plus PDC). Stratification factors were squamous vs non-squamous, and PD-L1 TPS $<$ 1% vs 1-49%. Primary endpoints were safety and efficacy assessed by investigators per RECIST v1.1. Secondary endpoints included pharmacokinetics (PK) and immunogenicity. **Results:** As of December 22, 2025, 80 pts were enrolled in safety lead-in (N = 11) and dose optimization (N = 69) with median follow-up (mFU) of 5.8 months (range: 0.9-9.5). Baseline characteristics (median age: 64 years, male: 88.8%, ECOG PS 1: 81.3%, stage IV: 72.5%, sqNSCLC: 66.3%) were balanced among 3-1.5 mg/kg (N = 23), 1.5 mg/kg (N = 28) and 3 mg/kg (N = 29) cohorts. Median treatment duration of IBI363 was 25.0 weeks (range: 4.0-41.1) while 65.0% pts with ongoing treatment, and 88.9% pts having completed $\geq$4 cycles of PDC. Grade$\geq$3 (G3+) treatment-emergent adverse events (TEAEs) occurred in 81.3% pts including 65.2% for 3-1.5 mg/kg, 82.1% for 1.5 mg/kg and 93.1% for 3 mg/kg cohorts. Common TEAEs were anemia (any grades 78.8%, G3+ 18.8%), neutrophil count decrease (75.0%, G3+ 42.5%), white blood cell count decrease (63.8%, G3+ 20.0%), arthralgia (51.3%, G3+ 2.5%), and platelet count decrease (45.0%, G3+ 17.5%). IBI363-related AEs led to corresponding treatment discontinuation and death in 6.3% and 1.3% pts. In dose optimization, 65.2% pts had PD-L1 TPS $<$ 1 and 34.8% had TPS 1-49%. Efficacy was evaluable in 62 pts with at least 1 tumor assessment. For 3-1.5 mg/kg cohort (N = 22), ORR was 86.4% (95% CI: 65.1-97.1, confirmed ORR [cORR]: 81.8%) and DCR was 100% (95% CI: 84.6-100). ORR was 85.7% for sqNSCLC (N = 14) and 87.5% for non-sqNSCLC (N = 8). For the 1.5 mg/kg (N = 19) and 3 mg/kg cohorts (N = 21), ORR was 57.9% (cORR: 42.1%) and 66.7% (cORR: 57.1%). PFS was immature (events 28.8%). Clinical PK data also supported an optimal benefit-risk profile based on efficacy and safety observed at 3-1.5 mg/kg. **Conclusions:** IBI363 plus PDC was well tolerated and showed encouraging efficacy in advanced NSCLC. Safety, efficacy, and PK data supported 3-1.5 mg/kg as the recommended dose. Clinical trial information: NCT06468098. Research Sponsor: None.

Immunonutrition intervention in driver gene–negative non–small cell lung cancer patients with sarcopenia: A randomized controlled trial. First Author: Xiangliang Liu, The First Hospital of Jilin University, Cancer Center, Changchun, Jilin, China

Background: Cancer-related sarcopenia impairs treatment tolerance and survival in advanced NSCLC. This Phase II trial evaluated IMPACT (arginine and omega-3 enriched formula) in driver gene-negative advanced NSCLC patients receiving chemo-immunotherapy. **Methods:** Single-center, open-label, randomized Phase II study. Eligible patients: driver gene-negative advanced NSCLC with sarcopenia (AWGS criteria). Randomization 1:1 to IMPACT plus chemoimmunotherapy (Arm A, n=59) versus chemoimmunotherapy alone (Arm B, n=49). IMPACT administered continuously during treatment. Primary endpoint: PFS. Secondary endpoints: body composition (BIA, CT-L3), inflammatory markers (NLR), nutritional status (PG-SGA), safety. Statistical design: 80% power, HR=0.60, alpha=0.05. Dropouts: 7 (11.9%) in Arm A, 5 (10.2%) in Arm B. Modified ITT: 96 patients (52 vs 44). **Results:** Baseline characteristics balanced. Median PFS: not reached (Arm A) versus 7.0 months (95% CI: 5.2-8.8, Arm B); HR=0.45 (95% CI: 0.23-0.88), P=0.018. Six-month PFS: 82.7% versus 54.5%; 12-month PFS: 59.6% versus 31.8%. NLR change: -1.28 versus +0.16 (P=0.0045). Lean mass change: +0.59 kg versus -1.00 kg ($P<0.05$). L3 skeletal muscle density: +1.93 HU versus +0.37 HU ($P<0.05$). PG-SGA improved in Arm A (9.1 ± 5.6 to 6.4 ± 5.1, $P<0.001$) but not Arm B (8.9 ± 5.8 to 8.2 ± 5.5, P=0.156). Elderly subgroup (≥65y) showed enhanced benefit: HR=0.23 (95% CI: 0.06-0.95), P=0.043. Grade 3-4 AEs: 38.5% versus 52.3% (P=0.156). No IMPACT-related SAEs. **Conclusions:** IMPACT immunonutrition with chemoimmunotherapy significantly improved PFS, preserved lean mass, reduced inflammation, and enhanced nutritional status in driver gene-negative advanced NSCLC with sarcopenia. Well-tolerated with favorable safety. Phase III evaluation warranted. Clinical trial information: ChiCTR2300078741. Research Sponsor: Beijing Xisike Clinical Oncology Research Foundation; Y-NESTLE2022ZD–0517.

Efficacy outcomes in first-line (1L) non–small cell lung cancer (NSCLC) with maintenance of immune competence: QUILT-2.023 randomized phase 3 study of IL-15R agonist nogapendekin alfa inbakicept (NAI) with checkpoint inhibitor (CPI) ± chemotherapy. First Author: John M. Wrangle, Medical University of South Carolina, Charleston, SC

Background: Baseline and treatment-induced lymphopenia are adverse prognostic factors in NSCLC and may limit CPI durability. CPI and chemo-IO can reduce peripheral absolute lymphocyte counts (ALC) over time. NAI expands NK and effector/memory T cells and increases ALC, a biological marker of immune competence. In QUILT-3.055 (≥2L NSCLC after CPI failure), sustained ALC increases were associated with prolonged overall survival (OS). QUILT-2.023 tests whether preserving immune competence with NAI improves response rate, progression-free survival (PFS), and OS when added to 1L standards of care (SOC). To inform the design of the ongoing registrational-intent QUILT-2.023 study, results from 98 enrolled subjects were unblinded for exploratory analysis. **Methods:** QUILT-2.023 (NCT03520686) is an ongoing randomized multicohort phase 3 trial in untreated advanced/metastatic NSCLC (ECOG 0–1; squamous or nonsquamous). Cohort A (PD-L1 TPS ≥1%) was randomized 1:1 to CPI+NAI vs CPI; ALC over time was analyzed using a mixed model for repeated measures. The primary efficacy endpoint was PFS with hierarchical testing (TPS ≥50% then TPS ≥1%). PFS was analyzed at 8 months to evaluate the temporal relationship of ALC through 27 weeks of CPI alone versus CPI+NAI. Cohorts B (squamous) and C (nonsquamous), with any PD-L1 TPS, were randomized 1:1 to SOC platinum chemo-IO ± NAI; pooled Cohort B+C efficacy (ORR, DCR, PFS, OS) was assessed per RECIST v1.1. **Results:** Cohort A (N = 63): baseline ALC was comparable between arms; CPI+NAI showed significant, sustained ALC increase vs CPI alone over 27 weeks (P = 0.0065), regardless of PD-L1 TPS. In TPS ≥50% (N = 45), ALC over time significantly improved with CPI+NAI vs CPI alone (P = 0.0420). Correlating with this increased ALC, PFS in the CPI+NAI arm demonstrated median PFS of 7.0 vs 2.2 months (HR 0.40; 95% CI 0.17–0.94; p = 0.0298). Grade ≥3 CPI-related TEAEs occurred in 16% of subjects in both arms. In pooled Cohorts B+C (ITT N = 36), ORR (CR+PR) was 56% with chemo-IO+NAI vs 33% chemo-IO alone; DCR was 83% vs 78%. Median PFS was 18.9 vs 10.6 months (HR 0.48; 95% CI 0.19–1.23; p = 0.1192) and median OS reached significance of 34.7 vs 20.2 months (HR 0.38; 95% CI 0.15–0.98; p = 0.0394). **Conclusions:** Adding NAI to CPI-based SOC increased ALC and improved PFS in PD-L1 TPS ≥50% 1L NSCLC, with manageable safety. In platinum chemo-IO cohorts, pooled efficacy shows improved response and a significant OS signal, consistent with immune-competence preservation as a modifiable determinant of CPI durability. Enrollment and follow-up are ongoing. These interim findings are consistent with the single-arm trial QUILT-3.055 and support continued accrual in QUILT-2.023 and ResQ201A (NCT06745908), randomized NAI+CPI studies across 1L and ≥2L advanced NSCLC. Clinical trial information: NCT03520686. Research Sponsor: ImmunityBio.

Response to cancer immunotherapy for p53 antibody-positive non-small cell lung cancer according to treatment regimen. First Author: Tetsuo Shimizu, Division of Respiratory Medicine, Department of Internal Medicine, Nihon University School of Medicine, Tokyo, Japan

Background: Cancer immunotherapy has enabled long-term survival in advanced non-small cell lung cancer (NSCLC), but there are some patients with resistance to cancer immunotherapy. Mutations in the p53 gene have been reported to suppress immunity in the tumor immune microenvironment and influence resistance to cancer immunotherapy. Serum p53 antibody is an autoantibody produced in association with p53 gene mutations. However, it is unclear whether p53 antibody-positive NSCLC correlates with treatment response to cancer immunotherapy, particularly whether treatment response differs according to the treatment regimen. **Methods:** Participants were patients with advanced NSCLC who received immune checkpoint inhibitors (ICI) with or without chemotherapy at our hospital from November 2018 to June 2024. Blood samples were obtained before and after treatment with ICI and serum p53 antibody levels were measured. We compared the serum anti-p53 antibody and treatment response (early progressive disease, progression-free survival, and overall survival). Furthermore, we investigated whether treatment response of cancer immunotherapy in p53 antibody-positive NSCLC differs according to the treatment regimen. **Results:** A total of 173 patients were enrolled (mean age 69.4 years, 76.7% male, 58.4% adenocarcinoma). The regimen of ICI with chemotherapy was more common in 130 cases (75.1%) than ICI alone. There were 70 patients (40.4%) who were positive for serum p53 antibody before treatment. The p53-positive group had a significantly higher early progressive disease than the p53-negative group in the patients who received ICI with chemotherapy (28.6% vs 15.5%, p = 0.04). Multivariate analysis showed that serum p53 antibody was the only factor significantly associated with early progressive disease (HR 3.11, 95%CI 1.19-8.50, p = 0.02). PFS was significantly shorter in the p53-positive group than in the p53-negative group in patients with PD-L1 low expression (0-49%) (3.7m vs 7.2m, p = 0.01). Regarding the impact of treatment regimens on treatment response, there was no difference based on ICIs with or without chemotherapy. However, the group that combined anti-VEGF antibodies with ICIs had a significantly lower early progressive disease rate than the group that did not combine them (14.3% vs 30.2%, p = 0.03). **Conclusions:** Serum p53 antibody influenced the therapeutic efficacy of cancer immunotherapy in NSCLC. p53 antibody-positive NSCLC demonstrated differing treatment responses depending on therapeutic regimen. We believe that the combination of ICIs and anti-VEGF antibodies is a promising treatment option for p53 mutation-positive NSCLC. Research Sponsor: None.

Indefinite versus 2 years fixed duration of immune checkpoint inhibition in metastatic non–small cell lung cancer. First Author: Biagio Ricciuti, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Clinical trials of immune checkpoint inhibitors (ICIs) in metastatic non-small cell lung cancer (mNSCLC) limited treatment duration to 2 years despite the absence of evidence defining the optimal time on therapy. In routine clinical practice, however, many patients receive ICIs for more than 2 years. We evaluated survival outcomes in patients treated with 2 years versus > 2 years of therapy. **Methods:** We conducted a global, retrospective cohort study of patients with mNSCLC treated with ICIs for at least 2 years. Patients were classified as receiving fixed-duration ICI (discontinued at 2 years) or indefinite ICI therapy. Outcomes included progression-free survival (PFS), and overall survival (OS) from ICI start. Multivariable Cox regression, propensity score matching, and 2-year landmark analyses with inverse probability weighting (IPW) were used to address time-dependent biases and adjust for relevant covariates. **Results:** Among 889 patients who received at least 24 months of ICI therapy, median age was 65.5 years; 45.6% were women; 92.8% had a smoking history; 80.2% had adenocarcinoma histology; 70% of patients received ICI as first-line therapy and median PD-L1 tumor proportion score was 60%. Overall, 58.8% received indefinite ICI and 41.2% discontinued at 2 years. Median PFS and OS for the overall cohort were 5.7 years and 8.1 years, respectively. Baseline clinicopathologic characteristics, including age, sex, histology, PD-L1 expression, ECOG performance status, and smoking history, were well balanced between groups. Indefinite ICI therapy was associated with significantly longer PFS (HR 0.75, $p < 0.01$) and OS (HR 0.62, $p < 0.001$) compared to 2 years of therapy. These findings were consistent in a propensity-matched analyses (PFS HR 0.62, $p < 0.01$; OS HR 0.60, $p < 0.001$) and multivariable models (adjusted PFS HR 0.75, p = 0.02; adjusted OS HR 0.57, $p < 0.001$). In 24-month landmark analyses with IPW, indefinite ICI remained associated with improved PFS (HR 0.74, p = 0.02) and OS (HR 0.56, $p < 0.001$). Benefit with indefinite therapy was observed across all predefined subgroups, including age, sex, histology, PD-L1 strata, ECOG performance status, smoking history. Among 98 patients who received ICI rechallenge at disease progression, the objective response rate was 45%, with a median PFS of 12.9 months and a median OS of 30.2 months. **Conclusions:** Continuation of ICI therapy beyond 2 years was consistently associated with superior PFS and OS compared with treatment limited to 2 years across subgroups and sensitivity analyses. These findings highlight the limitations of arbitrary treatment caps in clinical trial design, support individualized duration decisions, and underscore the need for prospective trials to define the optimal duration of ICI therapy in NSCLC. Research Sponsor: None.

Comparison of a highly sensitive, tumor-informed Illumina whole genome sequencing research assay and a tumor-informed bespoke whole exome sequencing assay for molecular residual disease detection in CheckMate-77T (NCT 04025879). First Author: Jonathan Beer, Bristol Myers Squibb, Cambridge, MA

Background: In CheckMate 77T (NCT 04025879), nivolumab showed clinically meaningful improvements in event free survival and pathologic complete response *vs* placebo in 461 patients with resectable (stage IIA-IIIB) NSCLC. Previously, circulating tumor DNA (ctDNA) clearance rates of 66% in NIVO and 38% in PBO of the neoadjuvant period (C1D1 to definitive surgery) had been reported from 130 patients by Provencio et. al. (LBA50, ESMO 2024). In this study, we aim to extend on the previous exploratory study by using a highly sensitive whole genome sequencing (WGS) minimal residual disease (MRD) assay to detect ctDNA clearance rates and compare to those measured using a tumor-informed whole exome sequencing (WES) MRD assay. **Methods:** Residual samples (tumor FFPE tissue/isolated DNA, normal, cfDNA) from 61 of the 130 participants previously reported comprised this study. The Illumina WGS MRD assay employs WGS of tumor and matched normal to generate tumor fingerprints which were bioinformatically monitored in plasma using low-pass WGS (lp-WGS). All samples were prepared using Illumina's WGS Oncology Prep (research use only) and analyzed with DRAGEN MRD pipeline. A comparison of the operational complexity and turn-around-time (TAT) between tumor-informed WES MRD assays and the Illumina WGS MRD assay was performed. **Results:** Detection rates at C1D1 were greater in this study than previously reported, 91% for WGS *vs* 86% for WES, supporting the hypothesis that WGS MRD is more sensitive than WES MRD assays. Using the WES MRD results as reference, the Illumina WGS assay demonstrated a high concordance with positive percent agreement of 100%, negative percent agreement of 63% and overall percent agreement of 95%. Clearance rates of ctDNA in both study arms were calculated, summarized and compared to previous results by Provencio et. al. Compared to tumor-informed MRD assays, the Illumina WGS MRD assay significantly reduced operational complexity and TAT, as it eliminated the need for bespoke panel design, including analysis, manufacturing and assay validation. The Illumina Oncology WGS Prep uses a single streamlined workflow for all MRD sample types. The lpWGS testing of plasma cfDNA required only 2-5 ng cfDNA which can be obtained from a single tube of whole blood compared to 2 tubes of whole blood as required for many tumor-informed MRD assays. The total TAT of the WGS MRD workflow, including both tissue and plasma testing, was 1-2 weeks, substantially shorter than the 4-6 weeks required for most tumor-informed MRD assays. **Conclusions:** This study found the Illumina WGS MRD research assay to be highly concordant with previous tumor-informed WES MRD results for MRD positive results, with improved sensitivity, reduced TAT, lower cfDNA input requirements and decreased operational complexity. Clinical trial information: NCT04025879. Research Sponsor: Bristol Myers Squibb; Illumina.

Efficacy and safety of anamorelin in patients with non–small cell lung cancer and cancer cachexia undergoing chemoimmunotherapy: A real-world prospective cohort study (SPIRAL-ANA). First Author: Kenji Morimoto, Kyoto Prefectual Univeresity of Medicine, Kyoto, Japan

Background: The efficacy and safety of combining anamorelin with chemo-immunotherapy for non–small cell lung cancer (NSCLC) complicated by cancer cachexia remain unclear. This study aims to clarify the potential clinical benefits of combining anamorelin with standard first-line treatment in this challenging patient subpopulation. **Methods:** We prospectively enrolled patients with advanced NSCLC who had cancer cachexia and were scheduled to initiate anamorelin together with chemo-immunotherapy. Cancer cachexia was defined according to the eligibility criteria for anamorelin administration in Japan. Anamorelin is indicated for patients with body weight loss of $\geq$5% within the previous 6 months and with anorexia, who meet at least two of the following criteria: 1) fatigue or malaise, 2) generalized muscle weakness, or 3) C-reactive protein level $>$0.5 mg/dL, or albumin level $<$3.2 g/dL, or hemoglobin level $<$12 g/dL. Progression-free survival (PFS) from start of chemoimmunotherapy was the primary endpoint. **Results:** Overall, 123 patients were enrolled, of whom 118 comprised the safety analysis set and 114 comprised the full analysis set. The median duration of anamorelin treatment was 13.15 weeks. Median age, body weight, and body mass index were 73 years (range: 42–89 years), 53.2 kg (range: 32.5–79.4 kg), and 20.2 kg/m^2 (range: 15.0–29.1 kg/m^2), respectively. Among these patients, 20 (17.5%) had an Eastern Cooperative Oncology Group performance status of 2. At week 12, 62 patients (54.4%) were still being treated with anamorelin. The median PFS and overall survival (OS) were 6.2 months and 18.5 months, respectively, and the study did not meet the prespecified PFS endpoint. In a 12-week landmark analysis stratified by cachexia status at week 12, OS was significantly longer in patients who had achieved cachexia improvement by week 12 than in those who remained cachectic (19.9 months versus 7.1 months, log-rank p = 0.0098; hazard ratio for death, 2.19; 95% confidence interval, 1.19–4.02). The safety profile was manageable, with grade $\geq$3 neutropenia and hyperglycemia occurring in 31.4% and 5.1% of patients, respectively, and no deaths were considered related to anamorelin. **Conclusions:** In this prospective real-world cohort of patients with NSCLC and cancer cachexia receiving first-line chemoimmunotherapy, anamorelin was associated with a manageable safety profile but did not achieve the primary endpoint of PFS prolongation. Cachexia improvement at week 12 was observed in a substantial proportion of patients and was associated with longer OS. These findings suggest that the clinical value of anamorelin in this setting may lie in facilitating cachexia improvement. Research Sponsor: Ono Pharmaceutical.

Disaggregated lung cancer mortality trends in Asian American, Native Hawaiian, and Pacific Islander (AANHPI) patients by key sociodemographic features including sex, age, and smoking status. First Author: Diya Jayram, University of Miami Miller School of Medicine, Miami, FL

Background: Lung cancer is a leading cause of death in AANHPI populations, yet studies aggregate patients with diverse cultural backgrounds and immigration histories into an "Asian American" monolith, obscuring high-risk subgroups. Prior national disaggregation work has not captured key demographic variables important to understanding epidemiologic trends. **Methods:** This study analyzed the US Multiple Cause of Death database for deaths from lung cancer from 2018–2023, sociodemographic information included age at death, sex, race/ethnicity, smoking status, and education. Disaggregated AANHPI subgroup trends were evaluated using ACS 1-year estimates; other analyses used CDC WONDER bridged-race populations. Joinpoint estimated annual percent change in mortality(APC)/AdjustedAPC by race and sex. Pearson's Chi-squared test tested comparisons. **Results:** From 2018-2023, there were 430,703 deaths due to lung cancer in males, of which 2.7% (n=11,441) were in AANHPI males; there were 379,199 deaths in females, of which 2.5% (n=9397) were in AANHPI females. There were demographic differences in deaths within AANHPI subgroups and compared against white patients. For example, 0.5% of deaths in white male and females occurred in those aged 25-44, but this younger age group had 2.1% (male) and 4.3% (female) of Indian American deaths and 1.2% (male) and 1.7% (female) of Chinese American deaths. Deaths in white patients were associated with smoking in 48% (male) and 43% (female) of cases, but in far less of Chinese American (17% male, 4.4% female) and Filipino American (21% male, 9.7% female) lung cancer deaths ($p<0.001$ comparison). From 2018–2023, adjusted AANHPI male lung cancer mortality significantly declined -1.63% (95% CI -1.87 to -1.38; $p<0.0001$) but this was not seen AANHPI females (AAPC -1.20%; -2.86 to 0.79; p=0.22). The magnitude of AANHPI mortality decreases were smaller than in White (male -3.95, -4.43 to -3.24, female -2.35, -3.64 to -1.10; $p<0.0001$ both) and Black (male -4.35, -5.22 to -3.52, female -2.99, -3.99 to -2.96) adults during the same time period ($p<0.0001$ both). Disaggregation showed rising lung cancer mortality in Filipino women (AAPC +1.99%; 95% CI 0.59–3.54; p=0.006) and upward trends in Vietnamese women (AAPC +2.29%; 95% CI -1.05 to 5.81), whereas most AANHPI men had stable or modestly declining mortality. **Conclusions:** Despite large gains in lung cancer mortality over time, AANHPI populations —especially AANHPI women— show slower improvements despite high never-smoker prevalence, underscoring the need for disaggregated research. Rising lung cancer mortality in specific unique populations like Filipino women should motivate further research and guide targeted community outreach so that all populations benefit from improvements in early diagnosis and precision oncology. 8594 **Poster Session**

A phase 2 study of docetaxel (D), ramucirumab (R), and pembrolizumab (P) for patients with metastatic or recurrent non–small cell lung cancer (NSCLC) who progressed on platinum-doublet and PD-1/PD-L1 blockade. First Author: Badi Edmond El Osta, Winship Cancer Institute of Emory University, Atlanta, GA

Background: NSCLC treatment (trt) efficacy remains modest after progression on platinum and immune checkpoint inhibitors (ICI). Salvage trt with D + R has a 6-month progression-free survival (PFS) rate of 37%. **Methods:** We conducted a phase 2, single-arm study of D (75mg/m^2), R (10mg/kg), P (200mg) given intravenously in 21-day cycles until disease progression or unacceptable toxicity. Eligibility: metastatic or recurrent NSCLC, progression on concurrent or sequential platinum and ICI, no prior exposure to D or R, ECOG 0-1, measurable disease, adequate organ function. A safety run-in cohort was performed followed by efficacy evaluation using Simon's two-stage design. The null hypothesis (H_0) of 6-month PFS rate of 37% was tested against a one-sided alternative hypothesis with a rate $>$62% (α 0.1, power 80%). H_0 will be rejected if $\geq$11 of 21 patients (pts) remain free of progression or death by 6 months (m) with planned sample size of 30 to accommodate early dropout. PFS and overall survival (OS) were estimated using Kaplan Meier method. **Results:** 30 pts were enrolled. Median (range) age = 66.5 (57-84) years. 20 (67%) were white, 11 (37%) female, 25 (83%) ever-smoker, 23 (77%) non-squamous, 23 (77%) PD-L1 $<$50%, 29 (97%) received platinum + ICI concurrently, 19 (63%) progressed after 6m on prior ICI, 10 (33%) had brain metastases (mets), and 7 (23%) had liver mets. 28 pts completed at least one cycle of trt: 22 were evaluable for 6-month PFS (primary endpoint), 6 early dropouts $<$6m on trt w/o progression (including 1 prior to first imaging). No dose limiting toxicities were observed in the first month on trt. 14 (64%) of 22 pts were free of progression by 6m. Median PFS = 7.3m (95CI, 5.6-9.9); median OS = 15m (95CI, 8.4-18.9); ORR = 37%; 10 partial responses; median duration of response = 5.9m (95CI, 1.6-7.2); disease control rate = 96%; clinical benefit = 67%. Nine (31%) pts had trt-related serious adverse event (trSAE) including 1 (3%) death (Table 1). Median (range) cycles for D, R, P were 6 (1-11), 8 (1-23), 8 (1-23), respectively. Two pts remain on trt. Number of D cycles was associated with improved OS (HR 0.73; p= 0.01) and PFS (HR 0.83; p= 0.01). Presence of brain or liver mets (HR 3.13; p= 0.03) and progression in $<$3m on prior ICI (HR 5.42; p= 0.02) were associated with shorter OS. **Conclusions:** The study met its primary endpoint and demonstrated a manageable safety profile and a promising efficacy of this regimen. Clinical trial information: NCT04340882. Research Sponsor: Merck; 58866.

Trends in lung cancer mortality among U.S. adults aged ≥55 before and after the introduction of immunotherapy: A CDC WONDER Joinpoint-style analysis. First Author: Aura Calderon, The University of Texas Rio Grande Valley, Mcallen, TX

Background: Lung cancer remains the leading cause of cancer-related mortality in the United States. Although sustained reductions in tobacco use have contributed to gradual declines in incidence and mortality, recent therapeutic advances have transformed the management of non–small cell lung cancer. The introduction of immune checkpoint inhibitors (ICIs) in the early 2010s led to substantial survival gains in clinical trials and shifted treatment paradigms toward frontline and perioperative settings. Whether these advances have translated into accelerated reductions in lung cancer mortality at the population level remains incompletely characterized. **Methods:** We conducted a nationwide population-based analysis using the CDC WONDER Underlying Cause of Death database from 1999 to 2020. Lung cancer deaths were identified using ICD-10 codes C34.0–C34.9. Annual age-adjusted mortality rates per 100,000 population standardized to the 2000 U.S. population were analyzed. Among adults aged ≥55 years, joinpoint-style segmented log-linear regression was used to identify inflection points and estimate annual percent changes (APC) before and after the identified breakpoint. **Results:** From 1999 to 2020, age-adjusted lung cancer mortality declined substantially. Among adults aged ≥55 years, segmented regression identified a significant inflection point in 2011. Prior to 2011, mortality declined at −1.52% per year, whereas after 2011 the decline accelerated to −3.88% per year ($p < 0.001$ for change in slope). In the overall population, mortality declined from 55.4 to 48.8 per 100,000 between 1999 and 2014 (APC −0.7%/year) and decreased more rapidly from 47.8 to 41.3 per 100,000 between 2015 and 2020 (APC −2.9%/year), representing more than a fourfold acceleration. **Conclusions:** In this nationwide age-adjusted analysis, lung cancer mortality demonstrated a sustained decline over two decades, with a marked acceleration beginning in the early 2010s. Although reductions in tobacco use remain an important contributor, the timing and magnitude of this acceleration, particularly among adults aged ≥55 years, are consistent with population-level benefits associated with advances in systemic therapy, including immune checkpoint inhibitors. These findings suggest that rapid clinical adoption of immunotherapy may have contributed to meaningful real-world improvements in lung cancer mortality. Research Sponsor: None.

Age-adjusted U.S. lung cancer mortality before and after immunotherapy integration, 1999–2020.

Era	Years	Start rate	End rate	Percent decline	APC (% per year)
Pre-immunotherapy	1999-2014	55.4	48.8	-10.5%	-0.7
Immunotherapy era	2015-2020	47.8	47.8	-13.6%	-2.9

APC = annual percent change. Rates are age-adjusted to the 2000 U.S. standard population.

8596 Poster Session

Impact on overall survival after adjusting for treatment crossover in first-line metastatic NSCLC trials for pembrolizumab plus chemotherapy. First Author: Ying Zhang, MSD Europe, Brussels, Belgium

Background: High crossover rates were observed in the chemotherapy alone arm in KEYNOTE(KN)-189 and KEYNOTE-407, attributable to protocol-permitted crossover to pembrolizumab monotherapy and subsequent anti-PD1/PD-L1 therapies per clinical practice. The objective was to assess the impact on overall survival (OS) by adjusting for treatment crossover. **Methods:** The analysis used pooled data from KN-189 global (NCT02578680; cut-off date: 08MAR2022) and Japan extension (NCT03950674; cut-off date: 07FEB2023), and pooled data from KN-407 global (NCT02775435; cut-off date: 23FEB2022) and China extension (NCT03875092; cut-off date: 10FEB2023). The survival time of participants (pts) in the chemotherapy alone arm who crossed over to pembrolizumab or subsequent anti-PD1/PD-L1 therapy was adjusted using a Two-Stage Estimation model (TSE) and Rank-Preserving Structural Failure Time model (RPSFT). Subsequently, a stratified Cox regression model was used to estimate the treatment effect of pembrolizumab+chemotherapy (P+C) relative to chemotherapy. **Results:** Overall, 646 and 669 patients were included in the analysis for KN-189 & KN-407 with a median follow-up of 64.6 months (range, 59.3-82.8) and 56.7 months (range, 50.1-69.3), respectively. In KN-189, adjusting OS for 56.3% pts who crossed over from the chemotherapy arm resulted in a larger treatment effect estimate for P+C relative to chemotherapy than observed in the unadjusted Intention-to-Treat (ITT) analysis. Similarly, for KN-407, after adjusting OS for 53.7% pts who crossed over, compared with chemotherapy alone, P+C showed more pronounced benefit than in the unadjusted ITT approach. The greater treatment effect for P+C was consistently demonstrated in both studies regardless of the PD-L1 TPS cutoff values. **Conclusions:** After adjusting for treatment crossover, pembrolizumab + chemotherapy demonstrated greater magnitude of OS benefit versus chemotherapy alone in both trials. TSE and RPSFT analyses support the robustness of these findings showing similar direction and magnitude of treatment effects across PD-L1 TPS cut-offs. Clinical trial information: NCT02578680; NCT03950674; NCT02775435; NCT03875092. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Early lipid-lowering therapy initiation after lorlatinib and clinical outcomes in non–small cell lung cancer: A propensity-matched real-world analysis. First Author: Sooraj Srirangadhamu Gopu, New York Medical College, Landmark Medical Center, Woonsocket, RI

Background: Lorlatinib improves outcomes in NSCLC but commonly causes marked hyperlipidemia, prompting initiation of lipid-lowering therapy (LLT). Beyond lipid control, LLT may be associated with vascular events; however, its association with thromboembolism, healthcare utilization, and mortality among lorlatinib-treated patients has not been characterized in real-world cohorts. **Methods:** Using TriNetX, we identified adults with NSCLC who received lorlatinib (index = first lorlatinib record). Patients were grouped by early LLT initiation within 30 days of index versus no LLT within 30 days. LLT included statins, ezetimibe, PCSK9 inhibitors, or fibrates. Cohorts were balanced 1:1 using propensity score matching on demographics and baseline comorbidities. Outcomes were assessed through 365 days; patients with prior outcome documentation were excluded. **Results:** After matching, 387 patients per cohort were analyzed. Early LLT was associated with lower all-cause mortality at 365 days (16.1% vs 26.4%; risk ratio [RR] 0.61, 95% CI 0.46-0.81; p=0.0004) and improved time to death (hazard ratio 0.60, 95% CI 0.44-0.82). Early LLT was also associated with lower venous thromboembolism (6.2% vs 12.1%; RR 0.51, 95% CI 0.30-0.86; p=0.0093) and fewer inpatient hospitalizations (14.6% vs 23.6%; RR 0.62, 95% CI 0.40-0.97; p=0.0320). Emergency department visits were numerically lower (8.3% vs 13.9%; RR 0.59, 95% CI 0.35-1.00; p=0.0467). No significant differences were observed for acute kidney injury or major adverse cardiovascular events. **Conclusions:** In a real-world propensity-matched cohort of lorlatinib-treated NSCLC patients, LLT initiated within 30 days was associated with lower 1-year mortality, venous thromboembolism, and hospitalization. Given the frequency of lorlatinib-associated dyslipidemia, these findings support early lipid monitoring and timely LLT initiation in practice. Prospective studies are warranted to confirm these associations. Research Sponsor: None.

365-day outcomes after matching.

Outcome	Early LLT (n=387)	No early LLT (n=387)	RR (95% CI)	HR (95% CI)	p

Glucagon-like peptide-1 receptor agonist use in lung cancer patients receiving immune checkpoint inhibitors: A real-world study. First Author: Wern Lynn Ng, Louisiana State University Health Shreveport, Shreveport, LA

Background: Immune checkpoint inhibitors (ICI) have become a cornerstone of treatment for lung cancer. Glucagon-like peptide-1 receptor agonists (GLP-1 RA) have been associated with improved outcomes in cancer patients in prior studies; however, their impact on outcomes among lung cancer patients receiving immunotherapy remains limited. **Methods:** We conducted a retrospective cohort study using the TriNetX real-world data platform. Adult patients with lung cancer treated with ICIs, including PD-1, PD-L1, or CTLA-4 inhibitors, were included. Patients were stratified based on exposure to GLP-1 RA. Propensity score matching (1:1) was performed to balance baseline demographics and comorbidities, including type 2 diabetes mellitus and body mass index. Primary outcomes included all-cause mortality, intensive care unit (ICU) admission, and hospitalization. Secondary outcomes included immune-related pneumonitis, colitis/enteritis, cachexia, and major adverse cardiovascular events (MACE). **Results:** After matching, 2,013 patients were included in each group, with a median follow-up of 372 days in the GLP-1 RA group and 383 days in the non-GLP-1 RA group. Mean age was 66.8 and 67.2 years, respectively, and approximately 50% of patients were male. Most patients were White (77.2% vs 71.8%), followed by Black (14.1% vs 14.0%) and Asian (2.1% vs 1.8%). GLP-1 RA use was associated with a significantly lower all-cause mortality rate compared with non-use (35.7% vs. 53.4%; $p < 0.0001$), with a hazard ratio of 0.65 (95% CI, 0.59–0.71). Significant reductions were also observed in ICU admissions (22.8% vs 29.0%; p = 0.0001), hospitalizations (64.1% vs 71.8%; p = 0.0001), pneumonitis (5.2% vs 6.8%; p = 0.0457), and MACE (19.9% vs 25.3%; p = 0.0026). No significant differences were observed in colitis/enteritis (9.3% vs 9.4%; p = 0.9704) or cachexia (8.0% vs 9.8%; p = 0.0650). In a subgroup analysis of lung cancer patients not receiving ICI, GLP-1 RA use was similarly associated with lower mortality, ICU admission, hospitalization, and MACE, without differences in immune-related toxicities. **Conclusions:** GLP-1 RA use among lung cancer patients was associated with improved survival, reduced healthcare utilization, and fewer selected adverse events in patients receiving ICI therapy. These associations likely reflect established metabolic and cardiovascular benefits of GLP-1 RA and may also involve antitumor mechanisms suggested in prior studies. Residual confounding related to healthcare access and socioeconomic factors cannot be fully excluded and should be considered when interpreting these findings. Prospective studies are warranted to validate these observations and clarify underlying biological mechanisms. Research Sponsor: None.

A comprehensive evaluation of the effectiveness of the Geriatric 8 screening tool in Japanese patients with non–small cell lung cancer: Results from the ENSURE-GA study, a cluster-randomized phase III clinical trial. First Author: Akihiro Tsukamoto, Department of Respirology, Gifu University,Graduate School of Medicine, Gifu, Japan

Background: The Geriatric 8 (G8) is a widely utilized screening tool globally for assessing functional status in elderly cancer patients, with a score of 14 or lower indicating a positive result. Previous studies have reported that G8-positive patients are at a higher risk of mortality and experiencing Grade 3 or higher adverse events (AEs). At ASCO 2024, we reported that the G8 positivity rate exceeded 80% among Japanese patients aged 75 and older with non-small cell lung cancer (NSCLC), suggesting a potential issue with its sensitivity in this population. In the present study, we conducted a further detailed analysis of the scoring patterns for individual G8 items and their association with the incidence of AEs. **Methods:** The ENSURE-GA study was a cluster-randomized phase III clinical trial involving 1,021 patients aged 75 years and older with non-small cell lung cancer (NSCLC). Participating institutions were cluster-randomized into either the intervention group or the control group. All patients underwent a standardized Geriatric Assessment (GA) prior to the initiation of treatment. From this cohort, 1,001 patients who underwent G8 assessment were identified for analysis. We evaluated the association between the scoring patterns (loss of points) for each G8 item and the frequency and severity of adverse events. **Results:** The ROC curve for G8 regarding the occurrence of grade 3 or higher adverse events in cases receiving cytotoxic chemotherapy yielded an AUC of 0.525, indicating no discriminatory ability. Among the eight components of the G8 screening tool, self-rated health status ("In comparison with other people of the same age, how does the patient consider their health status?") showed the highest rate of point loss at 72.0% (656/911), followed by polypharmacy at 67.5% (615/911) and Body Mass Index (BMI) at 61.9% (564/911).The G8 score did not correlate with the severity of adverse events. **Conclusions:** The G8 is a valuable screening instrument, but our findings suggest the need for optimization, including the establishment of cancer-specific and race-specific cut-offs, as well as the implementation of weighted scoring for its components. Clinical trial information: UMIN0000037590. Research Sponsor: None.

Five-year overall survival in lung adenocarcinoma: Real-world results from three French nationwide cohorts (2000–2010–2020). First Author: Didier Debieuvre, Service de Pneumologie, Groupe Hospitalier de la Région Mulhouse Sud-Alsace, Hôpital Émile-Muller, Mulhouse, France

Background: Long-term (5-year) real-world overall survival (OS) in non–small cell lung cancer (NSCLC) remains poorly documented especially in prospective condition. The French nationwide KBP program comprises prospective cohorts conducted every 10 years since 2000 to evaluate lung cancer prognosis. In 2020, 8,941 patients were included across 81 non-academic public hospitals, with lung adenocarcinoma (LA) representing the most frequent histologic subtype. Building on previously reported 3-year survival results[1], we assessed temporal changes in 5-year OS and described the characteristics of long-term survivors with LC using the 2000, 2010, and 2020 cohorts. **Methods:** Patients with lung cancer, all stages, diagnosed in non-academic public hospitals in 2000, 2010, and 2020 were included in the French nationwide KBP cohorts, all conducted using the same prospective methodology. For the 2020 cohort, patient inclusion occurred between 1 January and 31 December 2020. Vital status was collected during follow-up. Five-year OS was estimated using the Kaplan–Meier method and compared across the 2000, 2010, and 2020 cohorts, overall and stratified by stage at diagnosis. In the 2020 cohort, a descriptive comparative analysis was performed between long-term survivors (≥5 years) and patients who died before this term. In the 2020 cohort, multivariable Cox proportional hazards models are ongoing to identify prognostic factors associated with OS. Prespecified covariates include age, sex, ECOG PS, smoking status, stage at diagnosis. These analyses remain preliminary and will be updated for the conference, as the 5-year vital status follow-up has recently been completed. **Results:** Among the 1,640, 3,199, and 5,009 patients with LA included in the 2000, 2010, and 2020 KBP cohorts, respectively, 5-year vital status was available for 99.3%, 96.2%, and 83.4% of patients. 5-year OS was 29.4% (95% CI, 28.1–30.7) in 2020, compared with 14.4% (95% CI, 13.3–15.7) in 2010 and 4.7% (95% CI, 3.0–7.2) in 2000, corresponding to an absolute improvement of 15.0% over the last decade. In the 2020 cohort, long-term survivors (≥5 years; n = 772) were 47.8% female, only six patients had an ECOG performance status ≥3, 48.2% were current smokers, 19.8% never-smokers and 32.0% former smokers. The distribution of stage at diagnosis among long-term survivors was 37.6% stage I, 9.9% stage II, 20.9% stage III, and 31.6% stage IV. **Conclusions:** 5-year real-world OS in LA has markedly improved over the last two decades with an increasing proportion of long-term survivors. Ongoing stage-stratified and multivariable analyses will further characterize long-term survival patterns. [1] https://evidence.nejm.org/doi/full/10.1056/EVIDoa2400443. Long-term survival outcomes of consolidative local ablative therapy after response to first-line systemic treatment in oligometastatic NSCLC. First Author: Phurin Areesawangkit, Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA

Background: The role of consolidative local ablative therapy (LAT) for patients (pts) with oligometastatic non-small cell lung cancer (NSCLC) who have responded to first line (1L) systemic treatment remains controversial especially after negative results from the NRG LU002 phase II/III trial. Data on long-term survival outcomes remain limited. **Methods:** We retrospectively collected data from EMR records of pts with oligometastatic NSCLC treated with 1L systemic treatment at the University of Pennsylvania Health System (2015–2025). Oligometastasis was defined as ≤4 distant metastases. Eligible pts had either genuine synchronous or induced oligometastatic disease and had achieved partial response (PR) or stable disease (SD) after 1L systemic treatment. We hypothesized that LAT would be associated with improved PFS and OS using time-dependent Cox regression analysis. **Results:** We identified 187 eligible pts. 53% were female; median age was 67 yrs and 31% had PD-L1 expression > 50%. At diagnosis, 90% had genuine oligometastatic disease: 45% with one metastatic lesion, 24% with two, 15% with three, and 11% with four lesions. Median follow- up time was 81 mos. (Reverse Kaplan-Meier). Of 187 pts, 21 received consolidative LAT in addition to maintenance therapy (LAT+) while 166 received maintenance therapy alone (LAT-). The LAT+ group was less likely to have bone metastasis (4.8% vs 34%, P = 0.007) and more likely to have adrenal metastasis (38% vs 19%, P = 0.049). In the LAT+ group, 67% had received chemo-immunotherapy as 1L and 19% had received immunotherapy alone, compared with 58% and 17% in the LAT− group, respectively (P = 0.80, Chi-square). In the LAT+ group, 76% achieved PR and 24% had SD to 1L therapy, compared with 65% and 35% in the LAT− group, respectively (P = 0.30, Chi-square). Median time from diagnosis to LAT delivery was 6 mos. (range, 2 – 24 mos.). The most common LAT modality was radiation (82%). The most common site of LAT was lung (68%). Median PFS was 28 vs 12 mos. and median OS was 98 vs 24 mos. in the LAT+ and LAT− groups, respectively. In time-dependent Cox models treating LAT as time-varying exposure, LAT+ was associated with improved PFS (P = 0.045) and OS (P = 0.003). A multivariable model confirmed the benefit of LAT after adjusting for PD-L1 status, treatment response, brain metastasis, bone metastasis, and nodal status (PFS: HR = 0.38, P = 0.004; OS: HR = 0.27, P = 0.002). Adverse events grade ≥3 were similar in both groups. **Conclusions:** LAT was associated with significantly improved PFS and OS in pts with oligometastatic NSCLC with an objective response or stable disease following 1L systemic treatment. Prospective studies are warranted to define pt characteristics that predict the greatest benefit from and optimal timing of LAT. Research Sponsor: None.

Impact of time-of-day (ToD) of single-agent immune-checkpoint inhibitor (ICI) on survival in advanced non–small cell lung cancer (aNSCLC) with PD-L1 ≥ 50%: Analysis of the NOTCH collaborative REAL-SAIF study. First Author: Alfred Chung Pui So, St Bartholomew's Hospital, London, United Kingdom

Background: There is growing evidence and interest in the role of chrono-immunotherapy. Previous studies showing benefit of earlier ToD were limited by small cohorts with heterogenous groups and ToD cut-offs. Using one of the largest UK cohort, we explored this further. **Methods:** 896 patients treated with 3-weekly ICI monotherapy between 2017-2023 from 16 UK centres were included in this retrospective study. Early 30-day deaths were excluded. Multiple imputations were used for data missing at random (except ToD) with pooled estimates. The primary endpoint was overall survival (OS). A sinusoidal Cox model was used for multivariate analysis to represent the cyclical nature of ToD. **Results:** Median OS and progression-free survival (PFS) were 19.1 (95%CI 17.2-20.9) and 10.1 (95%CI 9.2-11.7) months. Baseline demographics were median age 70-years, 50% male, 77.3% non-squamous histology, and 91% pembrolizumab as ICI of choice. Mean C1 and C2 ToD was 13:18 and 13:12 respectively. 44.1% and 66.5% of patients received C2 within 1 and 4 hours from prior ToD. ToD was not correlated with age or socioeconomic deprivation. Age (HR 1.01; p=0.008), male sex (HR 1.25; p=0.005), performance status (PS) ≥2 (HR 1.22; p=0.038), squamous histology (HR 1.30; p=0.004), liver metastasis (HR 1.51; p=0.001), albumin (HR 0.98; $p<0.001$), and neutrophil-lymphocyte ratio (NLR) (HR 1.60; $p<0.031$) were associated with OS. PS ≥2 (HR 1.23; p=0.026), squamous histology (HR 1.26; p=0.010), albumin (HR 0.98; p=0.001), and PDL1% (HR 0.99; p=0.012) were associated with PFS. There was no correlation between C1 or C2 ToD with OS/PFS. There was a significant interaction between NLR and C1 ToD for both OS (HR 1.48; $p<0.001$) and PFS (HR 1.30; p=0.014), with a change in HR <1.0 for high NLR after 14:00 and 12:30 respectively. **Conclusions:** ToD alone was not associated with survival in aNSCLC ICI monotherapy. NLR has a strong interaction with ToD. A low NLR with early ToD and a high NLR with later ToD were correlated with improved OS/PFS. The relationship of ToD with survival is complex and further research is required before adoption into routine practice. Research Sponsor: None.

Lung cancer burden in AYAs: Global and U.S. trends. First Author: Ruchi Tusharkumar Jani, Smt N.H.L. Municipal Medical College, Gujarat, India

Background: Lung cancer remains a leading cause of cancer-related mortality and is increasingly observed among adolescents and young adults (AYA), with shifting tobacco use and rising air pollution implicated as potential risk factors. This study examines global and U.S. epidemiological and risk factor trends of tracheal, bronchial, and lung cancer (TBLC) in AYA population (20-54 years). **Methods:** We utilized Global Burden of Disease database (1990-2023) for TBLC, to extract Age Specific incidence (ASIR) and mortality rates (ASMR), as well as proportional and absolute ASMRs associated with all risk factors, tobacco use and ambient particulate matter (PM2.5). Joinpoint analysis assessed changes in trends and calculated EAPC (Estimated Annual Percentage Changes). All rates are reported per 100,000 population. **Results:** In 2023, the global ASIR of TBLC among AYAs was 8.69 (n = 167,524) in males and 4.70 (n = 88,569) in females, with absolute incidence increasing by 13% in males and 50% in females. Absolute mortality similarly increased by 9% in males and 39% in females, with ASMRs of 6.99 and 3.52, respectively in 2023. In US, while overall incidence and mortality declined, ASIR in 2023 for females (0.62) was found to be almost similar to males (0.64), whereas ASMR remained higher in males (0.49) than females (0.43). At global level, tobacco remained the leading ASMR contributor in 2023, with higher burden in males (males 4.8, 68.2%; females 1.1, 31%), followed by PM2.5 (males 1.1, 20.5%, females 0.5, 20.8%). No TBLC-related mortality was attributed to household air pollution in 2023. The most significant decline in tobacco- and PM2.5–associated TBLC mortality in males occurred from 2003 to 2020 (tobacco: EAPC −2.66; PM2.5: 2006-2017: EAPC −0.76), and in females between 2008 to 2021 (tobacco: EAPC −3.5, PM2.5: 2017-2020: EAPC -4.8). By 2023, 18.8% of male and 43.1% of female TBLC deaths had no identified risk factors. In the US, ASMR declined continuously across all risk factors in both sexes, and by 2023, 25.4% of male and 32.0% of female TBLC deaths had no identified associated risk factors. Despite overall reductions in ASIR and ASMR globally and in USA, Mortality to Incidence ratio remained largely stable, with only minimal decreases observed globally (males −3.6%, females −7.5%) and in the US (males −2.3%, females −5.8%). **Conclusions:** Our analysis demonstrated an absolute increase in TBLC incidence and mortality globally in both sexes, with males continuing to experience higher mortality. In the USA, the sex-based gap in ASIR has nearly disappeared. Although tobacco-related mortality declined, it remained the leading risk factor. By 2023, 20–25% of AYA males and 30–43% of AYA females TBLC deaths were attributable to non-modifiable risk factors, highlighting the need for screening guidelines that better address AYAs, particularly those without traditional risk factors. Resistance mechanisms and efficacy of first-line alectinib and sequential treatments in advanced *ALK*+ NSCLC: Real-world outcomes from a multicenter, observational study in Japan (ALCURE). First Author: Hirotsugu Kenmotsu, Shizuoka Cancer Center, Shizuoka, Japan

Background: First-line (1L) alectinib has shown superior progression-free survival (PFS) vs crizotinib in advanced *ALK*+ non-small cell lung cancer (NSCLC). We present final data from ALCURE (UMIN000038934), a real-world study exploring resistance mechanisms to 1L alectinib and treatment sequencing in Japanese patients (pts) with advanced *ALK*+ NSCLC. **Methods:** Eligible pts, aged ≥20 years with *ALK*+ NSCLC, were enrolled into 2 cohorts: pts already receiving 1L alectinib before enrollment (cohort A) or treatment-naïve pts starting alectinib (cohort B). Results were reported separately by cohort to address the potential immortal time bias introduced by cohort A (pooled analyses were reported for second-line [2L] treatment since the bias did not apply and the sample size was limited). Clinical samples were collected and analyzed using next-generation sequencing. **Results:** From Jan–Nov 2020, 249 pts were enrolled (cohort A/B, n=200/49). Demographics in cohort A/B were: age ≥75 years, 21%/18%; female, 60%/57%; never smokers, 65%/67%; brain metastases, 22%/31%; *TP53* mutations, 9%/41%. *EML4-ALK* variant 1 was the most common *ALK* variant (50% cohort A, 42% cohort B). Secondary *ALK* mutations at disease progression (PD) or end of 1L treatment were detected in 14/60 pts (23%) in cohort A and 3/25 pts (12%) in cohort B (primarily G1202R or I1171N). Median duration of 1L alectinib before enrolment in cohort A was 24 months (range 1–111). At data cutoff (Nov 6, 2024), median follow-up was 74.1 months (95% CI 11.8–163.3) in cohort A and 48.7 months (95% CI 0.6–56.7) in cohort B. Median PFS (mPFS) was not reached (NR) (95% CI 83.7–NR) in cohort A and 32.9 months (95% CI 11.8–38.5) in cohort B. In pts whose tumors were *TP53* wildtype vs mutant prior to alectinib, mPFS was NR vs NR (HR 0.47, 95% CI 0.15–1.50) in cohort A and 33.6 vs 14.1 months (HR 0.96, 95% CI 0.46–2.00) in cohort B. mPFS in pts with secondary *ALK* mutations detected vs not detected at PD or end of 1L treatment was 14.6 vs 37.1 months (HR 1.68, 95% CI 0.84–3.34) in cohort A and 9.0 vs 11.8 months (HR 1.56, 95% CI 0.35–6.95) in cohort B. Median OS was NR (95% CI NR–NR) in cohort A and 54.7 months (95% CI 54.7–NR) in cohort B. Of the 118/249 pts who discontinued 1L alectinib, 84 received 2L treatment (including 18 who received non-ALK TKIs); mPFS for 2L treatment was 9.9 months (95% CI 7.4–12.1) in the overall cohort. Among these pts, 40 received lorlatinib and had the longest mPFS of all pts receiving 2L treatment (17.2 months). **Conclusions:** The use of 1L alectinib in clinical practice demonstrated efficacy consistent with that seen in clinical trials in pts with *ALK*+ NSCLC and confirms the existence of long-term responders. Lorlatinib may be an effective treatment following 1L alectinib; further research is needed to identify factors that may predict response and inform optimal treatment sequencing strategies. Clinical trial information: UMIN000038934. Afatinib versus osimertinib for non–small cell lung cancer with uncommon epidermal growth factor receptor mutations: Real-world outcomes (HOT-Next001/HOT2501). First Author: Yutaro Nagano, Department of Respiratory Medicine and Allergology, Sapporo Medical University School of Medicine, Sapporo, Japan

Background: Non–small cell lung cancers (NSCLC) with uncommon epidermal growth factor receptor (EGFR) mutations exhibit considerable biological and clinical heterogeneity. Consequently, the optimal first-line EGFR tyrosine kinase inhibitor (EGFR-TKI) and the role of subsequent immune checkpoint inhibitor (ICI)–based regimens remain uncertain. **Methods:** This multicenter retrospective cohort study was conducted at 29 institutions in Japan and included patients with advanced or recurrent non-squamous NSCLC harboring uncommon EGFR mutations who received first-line afatinib or osimertinib between January 2015 and January 2024. Exon 20 insertions and de novo T790M mutations were excluded. Outcomes included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), safety, and the effectiveness of subsequent systemic therapies, including ICI plus platinum doublet chemotherapy (ICI-Chemo) and platinum doublet chemotherapy alone. To adjust for baseline imbalances, analyses used inverse probability of treatment weighting (IPTW) based on covariate-balancing propensity scores. **Results:** Among 162 patients, 95 received afatinib and 67 received osimertinib. After IPTW adjustment, no significant differences were observed in PFS (median, 11.3 vs 5.9 months; hazard ratio [HR], 1.04; 95% confidence interval [CI], 0.60–1.80) or OS (28.0 vs 25.5 months; HR, 1.34; 95% CI, 0.73–2.44). Afatinib yielded a higher ORR (70.2% vs 47.2%) and DCR (93.7% vs 82.5%) than osimertinib, while adverse events requiring dose reduction were more frequent (76.8% vs 31.3%) but generally manageable. Subgroup analyses suggested greater benefit with osimertinib in L861X mutations and with afatinib in compound mutations. In patients with PD-L1 ≥50%, afatinib was associated with significantly longer PFS (15.5 vs 2.6 months; HR, 0.14; 95% CI, 0.04–0.46), whereas OS was numerically longer (30.5 vs 12.9 months; HR, 0.38; 95% CI, 0.07–1.93). Among 56 patients who received subsequent systemic therapy and were chemotherapy- and ICI-naïve, IPTW-adjusted analyses showed that ICI-Chemo did not improve outcomes compared with platinum doublet chemotherapy: median PFS, 6.7 vs 7.3 months (HR, 1.08; 95% CI, 0.53–2.19) and post–EGFR-TKI OS, 14.6 vs 19.7 months (HR, 1.30; 95% CI, 0.63–2.68). **Conclusions:** In one of the largest multicenter real-world cohorts, afatinib and osimertinib demonstrated comparable survival outcomes as first-line EGFR-TKIs in NSCLC with uncommon EGFR mutations, with treatment effects modulated by mutation subtype and PD-L1 expression. ICI-based regimens did not improve outcomes compared with platinum doublet chemotherapy and conferred no meaningful clinical benefit as post–EGFR-TKI therapy in this population. Brigatinib after lorlatinib and/or chemotherapy following first-line alectinib in ALK-rearranged NSCLC: Cohort B of the WJOG11919L/ABRAID study. First Author: Shuhei Teranishi, Department of Thoracic Oncology, Kanagawa Cancer Center, Yokohama, Japan

Background: As survival improves in ALK-rearranged NSCLC, patients increasingly receive multiple lines of therapy; however, evidence to guide later-line ALK-TKI sequencing in the third line and beyond remains limited. Brigatinib has activity against multiple ALK resistance mutations, yet data on its effectiveness after progression on first-line alectinib and subsequent lorlatinib and/or chemotherapy—and on associated plasma ctDNA biomarkers—remain scarce. **Methods:** WJOG11919L/ABRAID Cohort B is a prospective, multicenter observational study enrolling patients with ALK-rearranged NSCLC who received brigatinib after lorlatinib and/or chemotherapy following first-line alectinib. Effectiveness and safety were summarized descriptively. Pretreatment plasma ctDNA was analyzed with the PGDx Elio Plasma Resolve panel. The data cutoff was September 26, 2024. **Results:** Twenty-five patients were analyzed (median age, 64 years; all adenocarcinoma); ECOG PS was 0-1/2-3 in 22 (88.0%)/3 (12.0%). Baseline CNS metastases were present in 10 patients. After alectinib, 13 patients received lorlatinib and 14 received platinum-based chemotherapy (overlap, n=2). Median follow-up was 12.7 months. Efficacy outcomes overall and by prior lorlatinib exposure are summarized in the Table. 23 patients had discontinued brigatinib, including 21 due to PD. Pretreatment ctDNA was evaluable in 24 patients: ALK mutations were detected in 4 (including 3 with prior lorlatinib), and compound ALK mutations (G1202R/I1171M/L1204V and D1203N/L1196M) were identified in 2, both after lorlatinib. In exploratory analyses, among the 3 patients with prior lorlatinib and detectable ALK mutations, all experienced early progression or death within 10 weeks of brigatinib initiation. Pneumonitis/ILD occurred in 1 patient (4%; grade 4). No new safety signals were observed. **Conclusions:** Brigatinib showed clinically meaningful activity with a manageable safety profile, providing durable disease control in a subset of patients previously treated with alectinib followed by lorlatinib and/or chemotherapy. Outcomes appeared less favorable after prior lorlatinib, although some patients derived benefit. In exploratory plasma ctDNA analyses among patients with prior lorlatinib, detectable ALK mutations were associated with less favorable outcomes and should be validated in larger cohorts. Clinical trial information: UMIN000042439. Research Sponsor: Takeda Pharmaceutical Company Limited.

Efficacy outcomes overall and by prior lorlatinib exposure.

Endpoint	Overall (n=25)	Prior lorlatinib (n=13)	No prior lorlatinib (n=12)
ORR, % (95% CI)	32.0 (14.9–53.5)	30.8 (12.7–57.6)	33.3 (13.8–60.9)
DCR, % (95% CI)	60.0 (38.7–78.9)	38.5 (17.7–64.5)	83.3 (55.2–95.3)
mPFS, mo (95% CI)	4.8 (2.2–12.7)	2.2 (1.2–18.8)	8.9 (2.3–15.6)
12-mo PFS, %	32.0	30.8	33.3
mOS, mo (95% CI)	13.7 (7.29–NR)	10.8 (3.7–NR)	16.2 (7.1–NR)
12-mo OS, %	56.0	38.5	75.0

High-dose furmonertinib in *EGFR*-mutated advanced NSCLC with brain metastases after EGFR-TKI resistance: The iFORCE phase II trial. First Author: Mengxing You, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, China

Background: Brain metastases (BM) are common in patients with EGFR-mutated (EGFRm) non-small cell lung cancer (NSCLC) and are associated with poor prognosis. Furmonertinib is a pan-EGFR tyrosine kinase inhibitor (TKI) characterized by high central nervous system penetration and a wide therapeutic window. This study evaluated the efficacy and safety of high-dose furmonertinib (160 mg once daily) in previously EGFR-TKI-treated patients with EGFRm NSCLC and BM. **Methods:** iFORCE was a prospective, single-arm study conducted at a single center. Eligible patients had EGFR exon 19 deletion or L858R-mutant NSCLC with at least one measurable intracranial lesion (≥5 mm) and had received ≥1 prior EGFR-TKI therapy. Patients received furmonertinib 160 mg orally once daily. The primary endpoints were intracranial progression-free survival (iPFS). **Results:** Twenty-three patients were enrolled, with a median follow-up time of 19.7 months (95% confidence interval [CI], 14.5-25.3 months). Median iPFS was 14.6 months (95% CI, 4.2-not reached), with 12- and 24-month iPFS rates of 53.8% and 30.8%, respectively. The intracranial objective response rate (iORR) was 34.8% (95% CI, 16.4-57.3), and the intracranial disease control rate (iDCR) was 91.3% (95% CI, 72.0-98.9). Median systemic progression-free survival (PFS) was 10.7 months (95% CI, 3.9-not reached). Treatment-related adverse events occurred in 13 (56.5%) of patients and were predominantly grade 1; one patient (4.3%) experienced a grade 3 stomatitis. No treatment discontinuations or treatment-related deaths were observed. **Conclusions:** High-dose furmonertinib demonstrated encouraging intracranial efficacy with a manageable safety profile in previously EGFR-TKI-treated patients with EGFRm NSCLC and BM, supporting further investigation in randomized studies. Clinical trial information: NCT05465343. Research Sponsor: None.

Sotorasib vs adagrasib in the 2L+ setting: Outcomes in a large, multi-institutional, real-world database of KRAS-G12C mutated mNSCLC. First Author: Adam Barsouk, Abramson Cancer Center, Philadelphia, PA

Background: KRAS-G12C mutations are found in ~12% of mNSCLC. KRAS-G12C inhibitors sotorasib and adagrasib are approved treatments but have never been compared head-to-head. We report the first large, multi-institutional database analysis comparing efficacy and safety of sotarasib vs adagrasib. **Methods:** Flatiron Health's de-identified electronic health record US database was used to identify patients with KRAS G12C-mutated NSCLC who started treatment 12/2022-10/2025 with either sotorasib or adagrasib in 2L+. Baseline characteristics were abstracted and evaluated using chi-square tests, Wilcoxon rank-sum tests, and a multivariable logistic regression adjusting for practice type, sex, ECOG performance status, age, line of therapy, prior immunotherapy, and brain metastases. Overall survival (OS), progression-free survival (PFS), and time to treatment discontinuation (TTD) were estimated using Kaplan-Meier curves and compared using the log-rank test and Cox regression. Multivariable Cox regression model included sex, age, ECOG, line of therapy, prior immunotherapy, brain metastases, and PD-L1 expression to control for possible confounding. **Results:** Of the 1133 patients identified, 768 (69%) received sotorasib, and 345 (31%) received adagrasib. Sex, age, PD-L1 status and prior immunotherapy exposure did not affect choice of treatment (Table 1). In a multivariable logistic regression analysis, patients with brain metastases were more likely to be treated with adagrasib (HR =0.64; p=0.003), while patients with higher ECOG PS (2+) were more likely to be treated with sotorasib (HR =1.18; p=0.047). There was no difference in OS between sotorasib and adagrasib (HR = 1.01; p = 0.87), and there was no difference in OS on multivariable regression (adjusted HR = 0.96; p=0.02). There was no difference in PFS between sotorasib and adagrasib (HR = 0.91; p=0.15). Sotorasib had longer TTD than adagrasib (mTTD 3.8 vs 3.3m; HR = 0.82; p =0.005); this association persisted in the adjusted model (adjusted HR = 0.80; p=0.006). **Conclusions:** Sotorasib was associated with slightly longer TTD compared with adagrasib, which may suggest better tolerability, but no difference in PFS or OS. Sotorasib was more likely to be used in patients with poor PS while adagrasib was more likely to be used in patients with CNS metastases. Research Sponsor: None.

	Sotorasib (n = 768)	Adagrasib (n = 345)	p-value

Reduction in circulating tumor DNA (ctDNA) in relation to radiographic response and tumor PD-L1 expression in a phase 1 study of PDL1V (PF-08046054) in patients with non-small cell lung cancer (NSCLC). First Author: Ramy Saleh, Department of Medical Oncology, McGill University Health Centre, Montreal, QC, Canada

Background: PDL1V (PF-08046054) is a novel, first-in-class, PD-L1–directed vedotin antibody-drug conjugate that consists of MMAE connected to an anti–PD-L1 antibody. Prior results from the phase 1 study (NCT05208762) showed promising antitumor activity and manageable safety in patients (pts) with refractory (2L+) NSCLC. We present ctDNA results from an exploratory analysis in this study. **Methods:** C5851001 is a phase 1 study in advanced solid tumors. Pts with NSCLC must have prior exposure to platinum and anti–PD-(L)1 agents, targeted therapies for tumors expressing AGAs, and measurable disease per RECIST 1.1. PD-L1 expression status by tumor proportion score (TPS) was reported by local sites. Paired baseline (T0) and on-treatment (T1; C2D15 to C3D1) ctDNA samples were used for ctDNA analyses using a methylation-based tissue-free assay (Guardant Infinity). Tumor fraction (TF) was quantified by methylation score. Changes in ctDNA from T0 to T1 were compared between subgroups using the Wilcoxon test. **Results:** As of Nov 22, 2025, 55 pts with 2L+ NSCLC received PDL1V: median age 63 yrs, 70.9% ECOG PS 1, 29.1% squamous (SQ) histology, 67.3% TPS ≥1%. The median number of prior lines of therapy was 2.0 (range, 1-8). The investigator-assessed confirmed objective response rate (ORR) was 32.4% (95% CI, 18.0-49.8) in pts with TPS ≥1% NSCLC (n=37) and 0% in TPS <1% (n=18). Grade 3-4 TRAEs occurred in 32.6%. Paired T0 and T1 samples were available in 47/55 pts. ctDNA analysis showed 46/47 pts (98%) had detectable ctDNA at baseline. At T1, ctDNA TF decreased in 36/46 pts (78%) and became nondetectable in 7/46 (15%). Pts with complete or partial responses (CR/PR) had a greater median ctDNA reduction from T0 to T1 than nonresponders (−99% vs −37%, p<0.001). Pts with TPS ≥1% NSCLC had a greater median ctDNA reduction than pts with TPS <1% NSCLC (−77% vs −4%, *P*=0.0023). For pts with TPS ≥1% NSCLC, there was no significant difference in median ctDNA reduction between nonsquamous (NSQ) and SQ histology (−73% vs −87%, p=0.48). **Conclusions:** PDL1V monotherapy showed promising antitumor activity with a manageable safety profile in pts with 2L+ TPS ≥1% NSCLC. Most pts had ctDNA reduction with PDL1V treatment, with greater ctDNA reduction in pts with radiographic response and TPS ≥1% NSCLC. These data further support evaluation of PDL1V in the ongoing phase 3 trial in 2L+ PD-L1+ NSCLC, SQ and NSQ (NCT07144280/PADL1NK-005) and the continued use of ctDNA for response monitoring and potential early prediction of clinical benefit. Clinical trial information: NCT05208762. Research Sponsor: Pfizer.

Firmonertinib combined with platinum-based chemotherapy in patients with *EGFR*-mutant advanced NSCLC following disease progression on first-line third-generation EGFR-TKI. First Author: Jialei Wang, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Patients (pts) who have progressed after first-line 3rd-generation EGFR-TKIs treatment exhibit limited therapeutic options. We report the preliminary antitumor activity and safety results of firmonertinib combined with platinum-based chemotherapy (Cohort C) in pts with EGFR-mutant advanced NSCLC who failed first-line 3rd-generation EGFR-TKIs from a prospective multi-cohort phase 2 trial (NCT06652048). **Methods:** Cohort C planned to include 20 pts with advanced NSCLC harboring EGFR-sensitizing mutations who progressed after first-line 3rd-generation EGFR-TKIs. Study treatment was firmonertinib (160 mg once daily) with chemotherapy (pemetrexed [500 mg/m^2] plus either cisplatin [75 mg/m^2] or carboplatin [AUC 5]). The primary endpoint was progression-free survival (PFS) assessed by investigators according to RECIST v1.1. **Results:** Cohort C completed accrual with 18 pts who received at least one dose of study treatment: median age was 64.5 years (range 43 to 80), ten (55.6%) were female, 16 (88.9%) were ECOG PS 1, nine (50%) were exon 21 L858R, six (33.3%) had CNS metastases at baseline. As of 30-Nov-2025, the median PFS was 8.4 months (95%CI 4.2-NR). The objective response rate (ORR) was 50.0% (95%CI 26.0-74.0). The disease control rate (DCR) was 88.9% (95%CI 65.3-98.6). The median duration of response (DOR) was not reached (95%CI 6.2-NR). The 9-month DOR rate was 75.0% (95%CI 12.8-96.1). The median overall survival (OS) was not reached (95%CI 9.1-NR). The 12-month OS rate was 70.0% (95%CI 16.2-93.3). Treatment-emergent adverse events (TEAEs) of any grade/grade≥3 occurred in 88.9%/44.4% of pts. The most common any-grade TEAEs were anemia (66.7%) and white blood cell count decreased (50%). The most common grade≥3 TEAEs were white blood cell count decreased (16.7%), neutrophil count decreased (11.1%) and anemia (11.1%). No TEAE with fatal outcome was reported. **Conclusions:** Firmonertinib combined with chemotherapy showed promising antitumor activity with a manageable safety profile in pts with EGFR-mutant advanced NSCLC following disease progression on first-line 3rd-generation EGFR-TKIs. Clinical trial information: NCT06652048. Research Sponsor: None.

Spatial transcriptomic profiling to identify stroma-based prognostic groups in oncogene-addicted lung cancer. First Author: Helena Bote-de-Cabo, Department of Medical Oncology, Hospital Universitario 12 de Octubre. Health Research Institute Hospital Universitario 12 de Octubre (i+12). Universidad Complutense de Madrid, Madrid, Spain

Background: Driver genomic aberrations determine prognosis and therapy in non-small cell lung cancer (NSCLC). In this context, some other genomic features such as *TP53* mutations confer poor outcomes. However, other mechanisms leading to worse prognosis in patients (pts) sharing the same genomic profile remain incompletely characterized. **Methods:** NSCLC pts from three cohorts based on their molecular profile (*EGFR*-mutated [EGFRm], *KRAS*-mutated [KRASm] and *ALK/ROS1/RET* fusions) were included. Baseline formalin-fixed paraffin-embedded (FFPE) tumor samples were analyzed using NanoString GeoMx Digital Spatial Profiling. Regions of interest (ROIs) were selected based on histopathological features and fluorescently labeled antibodies for tumor (Tm) and stromal (St) areas. RNA expression of >1,800 genes from selected ROIs was assessed using GeoMx Cancer Transcriptome Atlas. Leiden algorithm was used for clustering, and differential gene expression and other statistical analyses were performed using R software. **Results:** A total of 189 pts (100 EGFRm, 56 KRASm, 33 fusions [17 *ALK*, 7 *ROS1* and 9 *RET* rearrangements]) were identified. Separate analysis of Tm and St compartments revealed an association between genotype and transcriptome in the first, whereas the St transcriptome failed to correlate with the molecular profile. Unsupervised clustering of the Tm compartment identified four subgroups with distinct gene expression. Tm Cluster 4 (30 pts) was mainly composed of KRASm pts (86.7%) and presented the poorest prognosis, with a median overall survival (mOS) of 7.5 months (mo) ($p<0.0001$). Within St compartment, four prognostic clusters were also identified. St Cluster 1 (76 pts: 43.4% EGFRm, 40.8% KRASm, 15.8% fusions) and St Cluster 4 (23 pts: 21.7% EGFRm, 52.2% KRASm, 26.1% fusions) included pts from all three cohorts and showed significantly decreased OS (17.4 mo and 15.6 mo, respectively; $p<0.0001$). Genes involved in matrix remodeling and epithelial-mesenchymal transition signaling were overexpressed in St Cluster 1, while St Cluster 4 exhibited a highly immunogenic profile; no correlation with *TP53* mutation status was observed. **Conclusions:** Spatially resolved transcriptomic profiling suggests that stromal composition could identify oncogene-addicted NSCLC pts with poor prognosis regardless of molecular subtype, potentially guiding the development of novel therapeutic strategies. Further validation studies are warranted. Research Sponsor: None.

Profiling patients with *MET* exon 14 (*MET*ex14) skipping NSCLC with a sustained clinical benefit to tepotinib in VISION. First Author: Paul K. Paik, Thoracic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Tepotinib is a highly selective MET inhibitor with clinical activity in patients with *MET*ex14 skipping NSCLC. We previously reported long-term efficacy and safety outcomes of tepotinib from VISION in patients with ≥3-years follow-up (data cut-off: May 20, 2024; Mazieres et al. ELCC 2025 [Poster 81P]). Here, we provide a subset analysis of patients from VISION who achieved long-term responses to tepotinib to identify clinical characteristics associated with durable benefit. **Methods:** Patients with advanced *MET*ex14 skipping NSCLC detected by liquid (L+) and/or tissue (T+) biopsy received tepotinib 500 mg (450 mg active moiety) once daily. The primary endpoint was objective response by independent review using RECIST v1.1. Secondary endpoints included duration of response and safety. Exploratory analyses of baseline and on-treatment liquid biopsy biomarkers were carried out for potential prognostic, predictive, or pharmacodynamic relevance. For this subset analysis, patients with a long-term response were defined as those with a duration of response (DOR) to tepotinib of >36 months. **Results:** Of 313 patients enrolled, 26 patients had a DOR >36 months (range: 36.6–78.9). In these patients, median age was 67.7 years (range: 52–84), 53.8% were male, 50.0% were White and 34.6% were Asian, 92.3% had adenocarcinoma, 53.8% had a history of smoking, and 53.8% were L+ and 65.4% were T+. Median duration of treatment was 50.7 months (range: 15.9–83.1). Seventeen patients received tepotinib as first-line and nine as second-or-later line therapy. Twenty-four patients achieved >50% decrease, while six patients achieved >80% decrease in the sum of longest diameters from baseline. Eighteen patients' cancer had not progressed at the data cut-off of May 20, 2024, and 14 patients were still receiving treatment. In 12 patients who discontinued treatment, reasons for discontinuation were: adverse events (5 patients [peripheral edema in 2 patients]), disease progression per investigator (3 patients), non-compliance (1 patient), consent withdrawal (1 patient), and other reasons (2 patients). Among patients with long-term responses who stopped treatment early due to adverse events (prior to disease progression), continued responses were observed for up to 52 months after tepotinib discontinuation without any further subsequent anticancer treatment. Of nine patients who received treatment prior to tepotinib, four patients received immunotherapy alone, and eight patients received chemotherapy without immunotherapy. Baseline and on-treatment biomarker data will be presented. **Conclusions:** Patients who achieved long-term responses to tepotinib in VISION had similar clinical characteristics and safety outcomes to the overall population of patients from VISION (Mazieres et al. ELCC 2025 [Poster 81P]); ongoing biomarker analyses may help to further characterize these patients. Clinical trial information: NCT02864992. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

COPERNICUS, a pragmatic phase 2b study of first-line (1L) subcutaneous (SC) amivantamab (ami) + lazertinib (laz) with supportive care in *EGFR*-mutated advanced NSCLC: Early safety results. First Author: Sarah B. Goldberg, Yale School of Medicine, New Haven, CT

Background: In MARIPOSA, intravenous (IV) ami + laz significantly prolonged overall survival vs osimertinib (HR, 0.75; *P*=0.005) in 1L *EGFR*-mutated (exon 19 deletion [Ex19del]/L858R) advanced NSCLC. However, extended infusion times, infusion-related reactions (63%), venous thromboembolism (VTE; 36%), and dermatologic adverse events (AEs; paronychia [68%], rash [62%]) were observed, potentially leading to discontinuations of ami due to AEs (34%). Several studies have since identified ways to optimize ami + laz administration. In PALOMA-3/-2, SC ami coformulated with hyaluronidase (rHuPH20) enhanced patient (pt) experience by reducing administration-related reactions (ARRs) and time, as well as VTE with prophylactic anticoagulation, leading to FDA/EMA approval. In COCOON, an enhanced dermatologic regimen reduced grade ≥2 dermatologic AEs vs standard of care. **Methods:** COPERNICUS (NCT06667076) is the first study to combine SC ami, optimized supportive care and a pragmatic design to broaden the pt population and better resemble real-world usage. This is an early report from Cohort 1 on pt demographics and safety of SC ami every 4 weeks (Q4W) + laz daily in pts with 1L *EGFR* Ex19del/L858R advanced NSCLC receiving VTE/dermatologic AE prophylaxis. Pragmatic design included partnering with academic/community sites to enhance pt diversity, allowing 1 cycle of 1L chemotherapy while awaiting biomarker results and using SC ami Q4W to reduce visit frequency. Pts received prophylactic anticoagulation for the first 4 months of treatment. Dermatologic prophylaxis aligned with the regimen described in COCOON. Here we report safety (key secondary endpoint), including incidence/severity of VTE, ARRs and dermatologic AEs. All comparisons to MARIPOSA are descriptive. **Results:** As of data cutoff (02 Jan 2026), Cohort 1 had enrolled 190 pts in the US (target enrollment, 300; median [range] follow-up, 3.9 [0.1–11.7] mo); 92% were still ongoing in the study. Median age was 66 y, with 55% of pts ≥65 y and 21% ≥75 y; 28% were Asian and 9% African American, reflecting broad enrollment. 6 pts had received 1 chemotherapy cycle. AEs were mostly grade 1–2, with no new safety signals; 5% discontinued ami due to AEs. With dermatologic prophylaxis, paronychia and rash were 26% and 22%, respectively, showing numerical reductions vs MARIPOSA. ARRs and VTE (both grouped terms) were also numerically lower at 9% and 7%, respectively. **Conclusions:** Compared with MARIPOSA, SC ami and dermatologic/VTE prophylaxis in COPERNICUS substantially reduced ARRs, dermatologic AEs, VTE, and ami discontinuations, highlighting the impact of early supportive care interventions. Using a pragmatic design, these early safety data support wide use of SC ami Q4W + laz in a diverse population. Given limited follow up, pts will continue to be evaluated for safety and efficacy. Clinical trial information: NCT06667076. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

COPERNICUS, a pragmatic phase 2b study of subcutaneous (SC) amivantamab (ami) + chemotherapy (chemo) with enhanced dermatologic adverse event (AE) prophylaxis in *EGFR*-mutated advanced NSCLC: Interim results. First Author: Ticiana Leal, Winship Cancer Institute, Emory University, Atlanta, GA

Background: In MARIPOSA-2, intravenous ami + carboplatin-pemetrexed chemo significantly prolonged progression-free survival (PFS) vs chemo (HR, 0.48; $P<0.001$) in participants (pts) with *EGFR*-mutated (exon 19 deletion [Ex19del]/L858R) advanced NSCLC after progression on osimertinib. However, longer infusion times, infusion-related reactions (59%), and dermatologic AEs (paronychia [37%], rash [43%]) were observed, with frequent interruptions of ami due to AEs (60%) as a potential result. Numerous studies have since tested ways to optimize ami administration. PALOMA-3/-2 showed reductions in administration-related reactions (ARRs) and administration time with SC ami coformulated with hyaluronidase (rHuPH20), thus enhancing patient experience and leading to approval by the FDA/EMA. COCOON also showed fewer grade ≥2 dermatologic AEs vs standard of care with an enhanced prophylactic regimen. **Methods:** COPERNICUS (NCT06667076) is the first study to combine SC ami and optimized supportive care, using a pragmatic design to broaden the pt population and better resemble real-world usage. We report planned interim results of Cohort 2 for SC ami every 3 weeks (Q3W) + chemo on/after EGFR TKI progression in US pts with *EGFR* Ex19del/L858R NSCLC receiving dermatologic AE prophylaxis aligned with the regimen described in COCOON. Pragmatic design included partnering with academic/community sites and less stringent eligibility criteria to enhance pt diversity. Primary endpoint is PFS by investigator. Key secondary endpoints are overall response rate (ORR) and safety, including incidence/severity of dermatologic AEs and ARRs. All comparisons to MARIPOSA-2 are descriptive. **Results:** As of data cutoff (02 Jan 2026), 29 pts had enrolled in Cohort 2 (target enrollment, 30; median [range] follow-up: 7.6 [0.5+–10.2] mo); 76% were still ongoing in the study. Median age was 62 y, with 45% of pts ≥65 y and 21% ≥75 y; 38% were Asian and 7% African American. Median PFS was 7.4 mo (95% CI, 4.8–NE; Table). AEs were mostly grade 1–2, with no new safety signals; 31% of pts interrupted ami due to AEs. With dermatologic prophylaxis, paronychia and rash occurred in 24% and 14% of pts, respectively, showing numerical reductions vs MARIPOSA-2. ARRs (grouped term) were also numerically lower at 21%. **Conclusions:** Compared with MARIPOSA-2, SC ami and dermatologic prophylaxis in COPERNICUS led to substantial reductions in ARRs, dermatologic AEs, and ami interruptions, establishing the positive effect of early supportive care interventions. These interim data obtained using a pragmatic design support wide use of SC ami Q3W + chemo post-EGFR TKI progression in a diverse population. Clinical trial information: NCT06667076. Research Sponsor: Janssen Research & Development, LLC, a Johnson & Johnson company.

Median PFS, mo (95% CI)	7.4 (4.8–NE)
ORR (95% CI)	24.1% (10.3–43.5)
Partial response	7 (24.1%)
Stable disease	15 (51.7%)
Progressive disease	2 (6.9%)

RET fusion–positive lung adenocarcinoma: Partner-specific clinicopathological characteristics, co-mutation profiles, and implications for targeted and immunotherapy. First Author: Zihan Sun, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: RET fusions represent actionable oncogenic drivers in lung adenocarcinoma (LUAD). However, the clinicopathological features, co-mutation landscape, and therapeutic outcomes across different RET fusion partners remain incompletely characterized. **Methods:** We retrospectively analyzed 268 patients with RET fusion–positive LUAD diagnosed between July 2017 and December 2024. Clinicopathological characteristics, metastatic patterns, and concomitant mutations were compared between KIF5B and non-KIF5B subgroups. Treatment outcomes of selective RET inhibitors, multikinase inhibitors (MKIs), and immunotherapy combined with chemotherapy were assessed, with subgroup analyses according to RET fusion partners. **Results:** The median age at diagnosis was 58 years, and most patients were female (57.0%) and never/light smokers (60.8%). Bone (12.3%), pleural (11.9%), and brain metastases (6.7%) were the most common metastatic sites. KIF5B-RET fusions were more frequently detected in earlier disease stages compared with non-KIF5B fusions (p = 0.0531). Among 274 RET fusion events, KIF5B-RET was predominant (65%), followed by CCDC6-RET (16%) and NCOA4-RET (1%). Concomitant mutations were identified in 28.7% of patients, most commonly TP53 (39.0%) and CDKN2A (13.0%), with CDKN2A more enriched in the non-KIF5B group (p = 0.0393). Nineteen patients received targeted therapy, including pralsetinib (n=12), selpercatinib (n=2), and cabozantinib (n=5), achieving an overall ORR of 57.9% and median PFS of 12.0 months. Notably, non-KIF5B patients demonstrated longer median PFS than KIF5B patients under pralsetinib (17.0 vs. 5.5 months, p = 0.0473). Fifteen patients received first-line immunochemotherapy, achieving a median PFS of 17.0 months, ORR of 40.0%, and DCR of 80.0%, comparable to targeted therapy (p = 0.3871). PD-L1 expression showed no correlation with outcomes. **Conclusions:** RET fusion–positive LUAD comprises biologically heterogeneous subsets defined by fusion partners. KIF5B-RET fusions tend to occur at earlier stages, whereas non-KIF5B fusions are more frequently associated with CDKN2A co-mutations and appear to derive greater benefit from selective RET inhibition. Immunochemotherapy demonstrates comparable efficacy regardless of fusion partner, highlighting the need for partner-specific therapeutic strategies in RET fusion–positive LUAD. Research Sponsor: None.

PRO results from the Beamion LUNG-1 trial in treatment-naïve patients with *HER2*-mutant advanced NSCLC. First Author: Joshua K. Sabari, Perlmutter Cancer Center, New York University Langone Health, New York, NY

Background: Zongertinib is an irreversible tyrosine kinase inhibitor that selectively inhibits HER2 while sparing wild-type EGFR, thereby minimizing associated toxicities. Here, we report patient-reported outcomes (PROs) on NSCLC-related symptoms, physical functioning, symptomatic adverse events (AEs) and their burden, from patients who were given 120 mg zongertinib QD as first-line in Cohort 2 of the Phase Ib Beamion LUNG-1 trial (NCT04886804). **Methods:** EORTC QLQ-C30 physical functioning scale, NSCLC-SAQ (domains: cough, dyspnea, pain, fatigue and poor appetite), EORTC IL46 (overall side effect burden) and nine PRO-CTCAE symptoms (mouth and/or throat sores, taste changes, nausea, vomiting, diarrhea, rash, skin dryness, itching, and numbness/tingling) were collected at cycle 1: days 1, 8 and 15, and day 1 of cycles 2, 3, 5, 7 and 9, each cycle being 21 days. Change from baseline (CFB) in EORTC QLQ-C30 physical functioning and NSCLC-SAQ total score were analyzed using mixed model repeated measures. The proportion of patients regarded as responders was defined as patients meeting within-patient meaningful improvements in PRO score or maintaining low levels of baseline symptomatology/high functioning. EORTC IL46 (1 = 'Not at all', 4 = 'Very much') and PRO-CTCAE (for frequency/severity/interference items: 0 "Never"/ "None"/ "Not at all" to 4 "Almost Constantly"/ "Very Severe"/ "Very much") were analyzed descriptively. **Results:** The PRO analysis set included 71 patients. High completion rates were observed, over 85% up to cycle 7. Patients had low levels of symptomatology and high levels of physical functioning at baseline. Mean CFB analysis showed patients reported rapid within-patient improvements in EORTC QLQ-C30 physical functioning and NSCLC-SAQ total score after the first week of treatment (from cycle 1, day 8), which were sustained over time. A high proportion of patients responded to treatment in terms of their PRO score; at cycle 5, 70% of patients were responders for physical functioning, and 47% of patients for NSCLC-SAQ total score. There was low side-effect burden; at any post-baseline timepoint a maximum of 8.4% of patients [n=6] reported being troubled with side-effects of treatment 'Quite a bit' or worse; supported by low proportions of patients reporting symptomatic adverse events via PRO-CTCAE. **Conclusions:** Patients treated with first-line zongertinib reported a rapid improvement followed by stability in physical functioning and NSCLC-SAQ total score, with high proportions of patients qualifying as PRO responders. Zongertinib was well tolerated, as reflected by the low overall side effect burden and the low incidence and mild nature of patient-reported symptomatic adverse events. Clinical trial information: NCT04886804. Research Sponsor: Boehringer Ingelheim.

Safety and efficacy of APS03118, a next-generation RET inhibitor, in patients with non-small cell lung cancer (NSCLC): Results from a phase I clinical trial. First Author: Shun Lu, Shanghai Chest Hospital, Shanghai, Jiao Tong University, School of Medicine, Shanghai, China

Background: Acquired resistance to first-generation selective RET inhibitors (SRIs) remains a significant clinical challenge in the treatment of RET fusion-positive NSCLC. APS03118 is a next-generation, highly selective RET inhibitor also with additional potent inhibitory activity against YES1, a SRC family kinases. This Phase I study evaluated the safety, tolerability, pharmacokinetics, and preliminary efficacy of APS03118 treatment in patients with advanced RET fusion-positive NSCLC. **Methods:** This multicenter Phase I trial enrolled 108 patients, including 85 patients with NSCLC harboring RET aberrations. In the dose escalation stage (Ia), APS03118 was administered orally at doses ranging from 40 mg once daily to 120 mg twice daily (BID) 28 days a cycle in 29 patients with solid tumors. In the expansion stage (Ib), 79 patients received 80 mg BID and 100 mg BID, including 66 patients of NSCLC with RET fusions. Efficacy was assessed per RECIST v1.1 every 2 cycles (4 weeks/cycle). Safety was evaluated according to CTCAE v5. Molecular profiling was performed using next-generation sequencing on blood and, when available, tumor tissue. This report focuses mainly on the NSCLC cohorts, including treatment-naïve and previously treated patients with 1-4 lines of therapy, including six different SRIs, (e.g., pralsetinib and selpercatinib). **Results:** Out of 85 NSCLC patients (Ia+Ib), the Objective Response Rate (ORR) was 80% (confirmed) in 20 (20/22) evaluable treatment-naïve patients. The median Progression-Free Survival (mPFS) is not reached, with 10 patients up to or over the 16 cycles at the data cutoff date. In 22 (22/25) evaluable patients with prior systemic therapy not including the SRIs, the ORR was 55%. There were 38 patients in the cohort of prior SRIs treatment failure. Among 22 (22/26) evaluable patients without known bypass pathway mutations, ORR was 23% with 14 patients' PFS up to or over 6 cycles and 10 patients up to or over 8 cycles (data cutoff date). Promising anti-tumor action was observed in the two patients with G810S and G810C mutations, who experienced tumor shrinkage of up to 50%. Grade ≥3 TRAEs occurred in 50.9% of patients. The most common AEs were creatine phosphokinase, AST and ALT elevation, which were reversible and mostly observed within cycle 1-3 and rarely after cycle 5. Dose reductions in 22.2%, and permanent discontinuation in 4.6%. Overall, APS03118 demonstrated a manageable and predictable safety profile. **Conclusions:** APS03118 shows highly promising clinical activity in both treatment-naïve and SRI failed NSCLC patients harboring RET fusions. Its survival benefit may result from potent inhibition of RET and YES1. The safety profile is manageable, characterized primarily by reversible enzyme elevations. Further development in NSCLC patients harboring RET fusion is warranted. Clinical trial information: NCT05653869. Research Sponsor: None.

Efficacy and safety of larotrectinib in patients with *TRK* fusion lung cancer: An updated analysis. First Author: Jessica Jiyeong Lin, Mass General Brigham Cancer Institute, Boston, MA

Background: *NTRK* gene fusions are oncogenic drivers in various tumor types, including lung cancer. Larotrectinib is the first-in-class, highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumor-agnostic use in patients with TRK fusion cancer based on a robust and durable objective response rate in patients with various cancers. Here, we report updated long-term efficacy and safety data in the subset of patients with TRK fusion lung cancer treated with larotrectinib after 1 additional year of follow-up. **Methods:** Patients with TRK fusion lung cancer enrolled in 2 larotrectinib clinical trials (NCT02122913, NCT02576431 [NAVIGATE]) were included. Larotrectinib was administered at 100 mg twice daily. In NCT02122913, primary endpoints were safety and the minimum tolerated and recommended dose; secondary endpoints included pharmacokinetics, overall response rate (ORR), and duration of response (DoR). In NCT02576431, the primary endpoint was best overall response; secondary endpoints included DoR, survival, and safety. Responses were independent review committee-assessed per Response Evaluation Criteria in Solid Tumors version 1.1. The data cutoff was July 20, 2025. **Results:** A total of 32 patients with measurable disease were treated, including 12 with known CNS metastases at baseline. Median age was 56 years (range 25–81). One patient (3%) was systemic treatment-naïve in the metastatic/unresectable setting; 19 (59%) had received ≥2 prior therapies. All *NTRK* gene fusions were identified by next-generation sequencing (NGS). The ORR was 69% (95% confidence interval [CI] 50–84): 4 (13%) complete responses, 18 (56%) partial responses, 6 (19%) stable disease, 2 (6%) progressive disease, and 2 (6%) not evaluable or undefined. Median duration of treatment was 20 months (range 2–81); at data cutoff, no patients remained on treatment. Median time to response was 1.8 months (range 1.5–7.3). Median DoR, progression-free survival (PFS), and overall survival (OS) were 20 months (95% CI 13–67), 19 months (95% CI 10–36), and 41 months (95% CI 17—not estimable), respectively, with median follow-ups of 53, 49, and 58 months. The 4-year rates for DoR, PFS, and OS were 34% (95% CI 12–57), 26% (95% CI 8–44), and 49% (95% CI 30–69), respectively. Treatment-related adverse events (TRAEs) were predominantly Grade 1/2. Grade 3/4 TRAEs were reported in 10 (31%) patients. One patient (3%) discontinued treatment due to TRAEs (alanine aminotransferase, aspartate aminotransferase, and gamma-glutamyltransferase increased). **Conclusions:** Larotrectinib continues to demonstrate rapid and durable responses, extended clinical benefit, and a favorable safety profile in patients with advanced TRK fusion lung cancer. These results support the wider adoption of NGS panels that include *NTRK* gene fusions in patients with lung cancer to identify those who may benefit from TRK inhibitor therapy. Clinical trial information: NCT02122913, NCT02576431. Research Sponsor: Bayer HealthCare Pharmaceuticals, Inc.

First-in-human dose-escalation study of the selective EGFR/HER2 exon 20 inhibitor PFL-721 in patients with locally advanced or metastatic NSCLC. First Author: Anas Gazzah, Gustave Roussy, Villejuif, France

Background: PFL-721 is a highly selective, orally bioavailable tyrosine kinase inhibitor (TKI) targeting activating EGFR & ERBB2 exon 20 (ex20) mutations while sparing wild-type (WT) EGFR. Preclinical studies demonstrate potent inhibition of diverse ex20 variants, >20-fold selectivity over WT EGFR, and robust antitumor activity in xenograft models. **Methods:** PFL-721 is investigated in an ongoing phase I study in patients (pts) with advanced NSCLC and EGFR/ERBB2 ex20 alterations (Clinical trial identifier: NCT06043817). PFL-721 is administered once daily (QD) in continuous 28-day cycles. Assessments included adverse events (AEs), dose-limiting toxicities (DLTs), PK, and antitumor activity by RECIST v1.1. Key eligibility criteria included locally documented EGFR/ERBB2 ex20 alterations on solid or liquid tumor biopsy, ECOG 0–1, and adequate organ function. Molecular responses were based on EGFR/ERBB2 ex20 alterations variant allele frequency decrease in ctDNA. **Results:** A total of 45 pts were dosed , with a median age of 63 years. Pts had received a median of 3 prior treatment lines. Thirty-one pts had EGFR ex20 alterations, 13 had ERBB2 ex20 insertion mutations, and one had both. Dose levels evaluated were 30, 60, 120, 240, 360, 480, and 600 mg QD. Dose escalation was completed with the identification of the maximum tolerated dose at 480 mg. AEs were reported in 43 pts (96%), including gastro-intestinal AEs in 39 pts (87%). Commonly observed grade ≥3 AEs included diarrhea (n=10/45, 22% of pts), hypokalemia (n=4/45 , 9%), and increased blood creatinine (n=3/45, 7%). One grade 3 rash was observed. Six DLT events occurred in 39 evaluable pts, including grade 3 diarrhea (at 360 mg QD, n=2; 480 mg QD, n=1, 600 mg QD, n=1), grade 3 fatigue (600 mg QD, n=1), and grade 4 hypokalemia (600 mg QD, n=1). PK analyses showed dose-proportional exposure and achievement of plasma concentrations predicted to be effective based on preclinical models, at doses of ≥240 mg QD. Among efficacy population (n=42), partial responses (PRs) were observed in 15 / 28 pts at doses of ≥360 mg QD . The overall response and disease control rates at doses ≥360 mg QD were 54% (95%CI [33. 9-72.5]) and 79% (95%CI [59.0-97.7]), respectively. Among 25 evaluable pts, molecular responses (ctDNA decrease >50%) were observed in 12 at doses ≥120 mg. **Conclusions:** In this dose escalation study, class-effect local gastrointestinal AEs were observed in nearly all pts while the frequency of systemic skin toxicity was low, in line with the selectivity of the molecule for mutant EGFR. Antitumor activity was reported in 54% of pts at doses ≥360 mg QD in a heavily pretreated population, including with prior EGFR/ERBB2 ex20 TKI. Consistent with tumor shrinkage, ctDNA clearance was observed in 48% of evaluable pts. The randomized dose-optimization part is ongoing, with three dose regimens: 360 mg QD, 480 mg QD, and 240 mg BID. Clinical trial information: NCT06043817. Research Sponsor: Pierre Fabre Medicament.

Safety and efficacy results of the phase 2 study of silevertinib (BDTX-1535) in previously treated patients with non-small cell lung cancer with non-classical and C797S EGFR mutations. First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Despite significant benefit from FDA-approved EGFR tyrosine kinase inhibitors (TKIs), patients with classical EGFR mutation positive non-small cell lung cancer (NSCLC) ultimately develop progressive disease due to mechanisms of resistance, including alterations of the EGFR pathway. A broad group of non-classical EGFR mutations (NCM), including P-loop and αC-helix compressing (PACC) mutations, and acquired C797S are major mechanisms of EGFR resistance. Silevertinib (BDTX-1535) is a fourth-generation covalent EGFR TKI with high CNS penetrance that targets classical mutations, NCM, and C797S mutations. Antitumor activity and safety of silevertinib in advanced NSCLC were evaluated in an open-label Phase 2 trial (NCT05256290). **Methods:** Patients (pts) with recurrent NSCLC following ≤ 2 lines of therapy with only 1 prior EGFR TKI (osimertinib preferred) and tumors positive for NCM (NCM Cohort) or C797S mutation (C797S Cohort) were enrolled based on a local molecular test. Based on dose optimization of silevertinib at 100 mg and 200 mg orally once daily, all patients after May 2024 received 200 mg once daily. The primary endpoint was ORR by RECIST v1.1, and secondary endpoints included progression-free survival (PFS), duration of response (DOR), dose optimization, and safety. **Results:** From August 2023 to January 2025, 41 pts were treated in the NCM Cohort (100 mg, n=11; 200 mg, n=30; 80% female; 56% white; 49% with CNS metastases) and 42 pts were treated in the C797S Cohort (100mg, n=9; 200mg, n=33; 62% female; 48% white; 31% with CNS metastases). In both cohorts, 29% of pts had received 2 prior therapies. As of November 3, 2025, median follow-up was 9.5 months for pts treated with the 200 mg dose. ORR and median duration of treatment (DoT) are shown in the table. Alterations of other oncogenic pathways (e.g. MET, RET, RAS, and RAF) were observed at baseline in approximately 20% of pts in post hoc analyses. For the 200 mg dose, serious treatment-related adverse events (TRAEs) were reported in 7 (11%) pts, and 5 (8%) of pts discontinued treatment due to TRAEs. The most common TRAEs at 200 mg included rash (13%, grade 3), diarrhea (8%, grade 3), stomatitis (2%, grade 3), and paronychia (2%, grade 3). Available PFS, DOR, and dose optimization results will be presented. **Conclusions:** Silevertinib demonstrated antitumor activity at 200 mg orally once daily in patients with recurrent NSCLC, EGFR NCMs, and acquired resistance C797S mutation with a safety profile consistent with the EGFR TKI class. Clinical trial information: NCT05256290. Research Sponsor: Black Diamond Therapeutics.

Cohort	Dose	n	ORR (%, 95% CI)	Median duration of treatment, mo (range)
NCM Cohort	200 mg	30	16.7% (5.6–34.7)	4.99 (0.99-11.47)
PACC mutations	200 mg	23	21.7% (7.5–43.7)	4.86 (1.28-11.47)
C797S Cohort	200 mg	33	36.4% (20.4–54.9)	4.76 (0.46-12.55)

Cost-effectiveness of amivantamab plus lazertinib versus osimertinib plus chemotherapy for first-line treatment of *EGFR*-mutated advanced non–small cell lung cancer. First Author: Pooja Gokhale, Clinical and Administrative Pharmacy, University of Georgia College of Pharmacy, Athens, GA

Background: Amivantamab plus lazertinib and osimertinib plus chemotherapy are guideline-recommended first-line treatment options for patients with advanced non-small cell lung cancer (NSCLC) harboring EGFR exon 19 deletion or exon 21 L858R mutations. Although both treatments are first-line options, their relative economic value has not been evaluated. This study evaluated the cost-effectiveness of amivantamab plus lazertinib versus osimertinib plus chemotherapy from a United States payer perspective. **Methods:** A partitioned survival model (PSM) and a three-state Markov model were developed to compare the two treatment strategies over a lifetime horizon. Clinical efficacy inputs were derived from the MARIPOSA and FLAURA2 trials. Direct medical costs and health state utilities were obtained from published sources. Outcomes included total costs, life years (LYs), and quality-adjusted life years (QALYs). One-way and probabilistic sensitivity analyses were conducted to assess model robustness using a willingness-to-pay threshold of $150,000 per QALY or LY gained. **Results:** Across both modeling approaches, osimertinib plus chemotherapy was associated with greater effectiveness and lower costs compared with amivantamab plus lazertinib. In the partitioned survival model, osimertinib plus chemotherapy resulted in 1.68 additional QALYs and 2.18 additional LYs with cost savings of $34,799, indicating dominance. Similar findings were observed in the Markov model, with gains of 2.05 QALYs and 2.74 LYs and cost savings of $46,620. Sensitivity analyses identified survival extrapolation parameters and the discount rate as the primary drivers of uncertainty. In probabilistic sensitivity analysis, osimertinib plus chemotherapy was favored in approximately 82% of simulations. **Conclusions:** From the United States perspective, osimertinib plus chemotherapy was dominant over amivantamab plus lazertinib as first-line treatment for EGFR-mutated advanced NSCLC in this model-based economic evaluation. These findings highlight the importance of integrating clinical efficacy and economic value in first-line treatment selection. Future studies should compare all recommended first-line strategies using mature survival data and incorporate real-world treatment patterns and patient-centered outcomes. Research Sponsor: None.

SOHO-01: Updated safety and efficacy of sevabertinib in patients with advanced *HER2*-mutant non-small cell lung cancer (NSCLC). First Author: Herbert H. Loong, Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Sevabertinib, a potent, reversible, oral tyrosine kinase inhibitor, received FDA accelerated approval for pretreated patients with advanced NSCLC harboring *HER2* tyrosine kinase domain-activating mutations. Sevabertinib demonstrated significant antitumor activity and manageable safety in patients with *HER2*-mutant NSCLC who had previously received treatment (Cohort D) or were treatment-naïve (Cohort F) in the ongoing, open-label, multicenter, Phase I/II SOHO-01 trial (NCT05099172) (Le X et al. *N Engl J Med* 2025). Here, we report updated safety and efficacy data from Cohorts D and F. **Methods:** Patients with *HER2*-mutant NSCLC received sevabertinib 20 mg twice daily in both cohorts: patients previously treated with systemic therapy but naïve to HER2-targeted therapy (Cohort D) and treatment-naïve patients (Cohort F). The primary endpoint was objective response rate (ORR) assessed by blinded independent central review (BICR) per RECIST v1.1. Other key prespecified and secondary endpoints included duration of response (DoR) and progression-free survival (PFS) assessed by BICR per RECIST v1.1, and safety per MedDRA v28.0 and CTCAE v5.0. **Results:** In total, 154 patients (n=81, D; n=73, F) received sevabertinib in the two cohorts; median follow-up was 19.5 (D) and 15.0 (F) months. Median age was 60 (D) and 65 (F) years; 61.7% (D) and 63.0% (F) were female; 61.7% (D) and 78.1% (F) had never smoked. As of November 17, 2025, ORR (95% CI) was 66.7% (55.3, 76.8; D) and 75.3% (63.9, 84.7; F); disease control rate (confirmed response or stable disease for ≥12 weeks; 95% CI) was 81.5% (71.3, 89.2; D) and 89.0% (79.5, 95.1; F). Median (95% CI) DoR was 9.5 (6.3, 13.5; D) and 12.2 (8.8, not estimable; F) months; median (95% CI) PFS was 8.3 (6.9, 12.3; D) and 13.5 (10.0, not estimable; F) months. Treatment-related adverse events (TRAEs) in both cohorts were consistent with previous reports. Grade 3 or higher TRAEs occurred in 39.5% (D) and 24.7% (F) of patients. Diarrhea was reported in 86.4% (D) and 87.7% (F) of patients; grade 3 diarrhea occurred in 23.5% (D) and 5.5% (F) of patients. No cases of interstitial lung disease or grade 4 diarrhea, discontinuations due to diarrhea, or new safety signals were observed. **Conclusions:** Sevabertinib demonstrated sustained efficacy with a manageable safety profile in treatment-naïve and pretreated patients with advanced *HER2*-mutant NSCLC. These data further support the rapid and durable responses of sevabertinib for patients with *HER2*-mutant NSCLC. Clinical trial information: NCT05099172. Research Sponsor: Bayer AG.

Safety and antitumor activity of VRN110755, a brain-penetrant, selective EGFR inhibitor, in patients with EGFR-driven non–small cell lung cancer. First Author: Min Hee Hong, Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea

Background: Third-generation EGFR tyrosine kinase inhibitors (TKIs) have improved outcomes in EGFR-mutant non–small cell lung cancer (NSCLC); however, acquired resistance, including EGFR C797S mutations, and central nervous system (CNS) progression remain major unmet medical needs. VRN110755 is an orally available, highly selective EGFR inhibitor designed to target a broad spectrum of EGFR mutations, including C797S, and has demonstrated robust brain penetration in preclinical models. **Methods:** This ongoing, open-label, multicenter Phase I/II study evaluates the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of VRN110755 in patients with EGFR-mutant NSCLC who progressed on prior third-generation EGFR TKIs and had no remaining standard treatment options. A dose-escalation phase (10–480 mg once daily) followed by protocol-defined backfill cohorts (80–400 mg) was conducted. Patients with stable, asymptomatic brain metastases and/or leptomeningeal metastases were eligible. This abstract reports data available at the time of analysis to characterize emerging safety, PK, and antitumor activity and to inform ongoing dose optimization and cohort expansion under protocol-defined safety monitoring. Early reporting was undertaken due to emerging systemic and intracranial activity in a population with high unmet medical need; enrollment and follow-up are ongoing. **Results:** As of January 18, 2026, 63 patients were enrolled. VRN110755 demonstrated dose-proportional PK. At 320 mg, target engagement (C_{trough}/IC_{50}) against common EGFR mutations exceeded that of osimertinib 80 mg by approximately four-fold. Treatment-related adverse events were predominantly low grade (grade 1: 37%; grade 2: 20%; grade 3: 2%), with no dose-limiting toxicities observed; the most common event was grade 1 rash (16%). Low rates of diarrhea were reported, with no interstitial lung disease or clinically meaningful QTc prolongation observed to date. Among 38 response-evaluable patients treated at doses $\geq$160 mg following progression on prior EGFR TKIs, 7 (18.4%) achieved partial responses and 28 (73.7%) achieved stable disease, yielding a disease control rate of 92.1%; approximately half remained on treatment beyond 7.5 months, suggesting durable disease control. In patients with baseline EGFR C797S mutations (n=7), the overall response rate was 85.7% (6/7), with ctDNA clearance of C797S observed in 83.3% (5/6) of responders. Complete intracranial responses were observed in two patients, and a $K_{p,uu,CSF}$ of 2.0 was documented at the 160 mg dose. **Conclusions:** VRN110755 demonstrated favorable PK, a manageable safety profile, and encouraging systemic and CNS antitumor activity in heavily pretreated EGFR-mutant NSCLC, including C797S-positive disease, supporting continued clinical development. Clinical trial information: VRN110755_01. Research Sponsor: Voronoi, inc.

Wait or treat? managing asymptomatic brain metastases in oncogene-mutated NSCLC: Results of a phase-III randomized controlled trial. First Author: Anil Ramakant Tibdewal, Tata Memorial Hospital, Tata Memorial Centre, Homi Bhabha National Institute, Mumbai, India

Background: The timing of brain radiation therapy (RT) in patients with oncogene-mutated NSCLC with asymptomatic brain metastases (ABM) has been a matter of debate. No level 1 evidence supports delayed brain RT in ABM. This phase III, open-label, RCT (NCT05236946) evaluates Upfront Cranial RT (U-CRT) versus Delayed CRT (D-CRT) in ABM of oncogene-mutated NSCLC. **Methods:** Eligible patients ($\geq$18 years, ECOG $\leq$2), with EGFR mutation or ALK gene rearrangement and completely ABM, were randomized to U-CRT vs D-CRT at intracranial progression (ICP), stratified by GPA score (0-2 vs $>$ 2) and BM presentation (Synchronous vs Metachronous). Key exclusions include symptomatic BM, brainstem metastases, and prior cranial RT. All pts received standard systemic therapy (TKI $\pm$ CT). The primary endpoint is intracranial PFS with death treated as a competing event. Secondary endpoints included OS, PFS, and treatment toxicity. All patients underwent MRI brain every 3 months for 1st year and 6 months thereafter, unless indicated clinically. Cumulative incidence functions were estimated, and subdistribution hazards were compared using the Fine and Gray model. With a planned enrollment of 208 patients and 139 target events, the study had 80% power to detect a hazard ratio of 0.62 at a two-sided alpha of 0.05. The icPFS was analyzed in intention-to-treat populations using Kaplan-Meier estimates and log-rank tests. **Results:** A total of 208 patients were randomized (105-U-CRT; 103-D-CRT). Baseline characteristics were well-balanced in both arms. The median age was 53 years (range, 26-83). EGFR and ALK mutations were seen in 87.6% and 12.4% in U-CRT and 79.6% & 20.4% in D-CRT arm. 1st/2nd generation TKIs $\pm$ CT were received by 58% & 72% pts, respectively and rest received 3rd generation TKI. In U-CRT, 44.8% received SRS/SRT, 52.4% received WBRT$\pm$ boost, and 3 pts did not receive RT. The median follow-up was 27.4 months (95%CI 26.2 -33). The cumulative incidence of ICP at 1 yr were 8.7% (95%CI 2.9%, 14.5%) & 25.7% (95%CI 16.8%, 34.7%), and at 2-yrs were 21.7% (95%CI 12.6%, 30.8%) & 50% (95%CI 39.2%, 60.9%) with sub-HR = 0.35 (95%CI 0.21, 0.59), p $<$ 0.001. The median icPFS were 18 mo (95%CI 15.8, 23.5) and 14.3 mo (95%CI 12.6, 19.6) with HR-0.84 (95%CI 0.59, 1.20), p = 0.35. There was no difference in median PFS of 11.7 mo (95%CI 9.2, 14.1) & 12.0 mo (95% CI 9.8, 14.9), p = 0.37 and in median OS of 23.3 mo (95% CI 17.7-28.8) & 28.7 mo (95%CI 17.7, 39.7), p = 0.06, respectively. In the D-CRT arm, 39/47 who had ICP received salvage CRT. The incidence of grade $\leq$2 radiation necrosis was 25.4% and grade $>$ 3 in 5.8% in upfront RT arm. **Conclusions:** In asymptomatic BM of oncogene-mutated NSCLC pts, upfront cranial RT significantly reduced the incidence of ICP; however, it did not improve the survival outcomes. The difference in survival may become more apparent as the OS data matures. Data on QOL, neurocognition, and molecular analysis will be reported later. Clinical trial information: NCT05236946. Research Sponsor: Tata Memorial Centre - Research Administrative Council (TRAC); Neuro-Oncology Research Fund of Brain Tumor Foundation (BTF) of India.

Osimertinib combined with bevacizumab and chemotherapy as 1L treatment in EGFR-mutated metastatic non-squamous non-small cell lung cancer (nsq NSCLC) with concurrent mutations. First Author: Liang Liu, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Concurrent mutations in EGFR sensitive mutations (19 del/21 L858R) are associated with poor prognosis. Previous studies have shown that EGFR-TKI combined with chemotherapy or anti-angiogenic drugs confers heterogeneous degrees of benefit in this population. However, the efficacy of concurrent EGFR-TKI, anti-angiogenic agent, and chemotherapy has not been reported. **Methods:** This is a single-center, open-label, phase I clinical trial designed to evaluate the efficacy and safety of osimertinib combined with bevacizumab and chemotherapy as first-line treatment for EGFRm metastatic nsq NSCLC with concurrent mutations (NCT05507606). 4 induction cycles will be administered (Osimertinib, 80 mg/d, d8–21; bevacizumab, 7.5 mg/kg, d1; pemetrexed 500 mg/m², d1; and carboplatin AUC 5, d1; 3 week/cycle), after which carboplatin will be discontinued. Osimertinib combined with bevacizumab and pemetrexed will be continued as maintenance (Osimertinib, 80 mg/d, d1–21; all other remained unchanged). Bevacizumab and pemetrexed will be stopped at 2 years; osimertinib will be continued until disease progression. EGFRm include exon 19 del, L858R, T790M, G719X, L861Q, S768I, exon 20 A763–Y764 insertion, and concurrent mutations are defined as the presence of at least one destructive TP53 mutation in exons 5 to 8. The primary endpoints are safety and objective response rate (ORR). Secondary endpoints include disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). Exploratory endpoints comprise NGS comparative analysis pre-/post-treatment, 19 del/L858R subgroup analysis, ctDNA clearance, and the correlation between efficacy and prognosis. **Results:** 34 patients were enrolled. Males accounted for 29.41%, and the median age was 58.5 years (25-75). Patients with ECOG PS 1 and 2 comprised 97.1% and 2.9%, respectively. The EGFRm profile consisted of 19 del (50.0%), L858R (44.1%), and other mutations (5.9%, including 20 ins and L861Q). All patients have finished the 4 induction cycles. The median follow-up was 36.8 months (95% CI, 24.2–47.4). The ORR was 94.12% (95% CI, 80.32%–99.28%), the DCR was 100% (95% CI, 89.72%–100%). The median PFS and OS were 35.9 m (95% CI, 26.0–NR) with 44.1% maturity and NR with 26.5% maturity, respectively. 19 del: ORR 100%, PFS/OS NR. L858R: ORR 86.7%, mPFS 26.5m (95%CI:16.3-NR), mOS 47.8m (95%CI:22.1-NR). Others: ORR 100%, mPFS 10.8m (95%CI:7.9-NR), mOS 21.1m (95%CI:18.2-NR). Grade $\geq$ 3 AE occurred in 31.25% of patients during the induction phase. No deaths related to toxicity were observed. The discontinuation rate was 9.4%; no patient discontinued treatment because of AE. **Conclusions:** These results demonstrate that the four-drug regimen anchored by osimertinib is well tolerated and active in patients with EGFRm metastatic nsq NSCLC harboring concurrent mutations. Clinical trial information: NCT05507606. Research Sponsor: None.

Clinical utility of repeat next-generation sequencing in patients with driver-negative non-small cell lung cancer: A report from the LC-SCRUM-TRY screening platform. First Author: Hiroki Izumi, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: While precision medicine targeting driver oncogenes has improved clinical outcome of non-small cell lung cancer (NSCLC), the clinical utility of repeat or late-line multiplex genomic profiling remains unclear for patients whose tumors were initially identified as driver-negative. We evaluated the clinical impact of genomic screening for treatment-resistant NSCLC within the nationwide framework (LC-SCRUM-TRY). **Methods:** Between September 2020 and November 2025, a total of 2,088 patients with NSCLC were enrolled into LC-SCRUM-TRY. Of these, this analysis focused on 840 patients who were diagnosed as driver-negative at the time of enrollment. Genomic profiling was performed using Oncomine Precision Assay (ThermoFisher Scientific) for tumor tissue sample, or liquid biopsy (Guardant360 [Guardant Health] or liquid OPA). We compared overall survival (OS) among three groups: (A) Driver-negative, (B) Driver-positive without targeted therapy, and (C) Driver-positive with subsequent corresponding targeted therapy. **Results:** Among the 840 patients, median age at enrollment was 68 years (range 34-86); the majority were male (70%), ever-smokers (79%), and had adenocarcinoma (74%), with good ECOG-PS of 0-1 (91%). Of these, 89% underwent tissue-based NGS using OPA, while 11% underwent liquid biopsy. Actionable driver alterations were identified in 186 patients (22%), without significant difference between tissue- and liquid-based NGS. The detected drivers included EGFR mutation (mut) (n = 60), HER2 mut (n = 33), $KRAS^{G12C}$ mut (n = 31), $BRAF^{V600E}$ mut (n = 7), MET exon 14 skipping (n = 17), RET fusion (fus) (n = 17), ALK fus (n = 9), ROS1 fus (n = 7), and NRG1 fus (n = 5). Of the 186 patients with detected drivers, 74 patients (40%) received subsequent matched targeted therapies (Group C), including 13 patients enrolled in clinical trials. The median OS was 36.2 months in Group A, 34.1 months in Group B, and 70.2 months in Group C, respectively. Patients who received matched targeted therapies (Group C) had significantly longer OS compared to Groups A and B (p $<$ 0.0001). **Conclusions:** Multiplex genomic profiling effectively identified actionable driver oncogenes in 22% of NSCLC patients previously considered driver-negative. Access to matched targeted therapies based on these results more than doubled the median OS (70.2 vs. 34.1 months), highlighting the critical importance of a multiplex genomic re-screening approach in this population. Clinical trial information: UMIN000041957. First-line (1L) olomorasib + pembrolizumab in patients with *KRAS* G12C–mutant advanced NSCLC, and PD-L1 expression 0-49%, from the dose optimization cohorts of LOXO-RAS-20001 and SUNRAY-01. First Author: Bryan Anthony Chan, Sunshine Coast Hospital and Health Service, Birtinya, Australia

Background: For patients (pts) with 1L *KRAS* G12C-mutant advanced NSCLC and PD-L1 expression <50%, the current SOC is pembrolizumab + platinum-based chemotherapy. Combining olomorasib, a KRAS G12C inhibitor, with pembrolizumab may overcome the limited efficacy of single-agent pembrolizumab in this population, while offering a chemotherapy-sparing targeted approach. Here we report an integrated analysis of 1L pts with PD-L1 expression 0-49% (<1% and 1-49%) who received olomorasib + pembrolizumab from the dose optimization cohorts of LOXO-RAS-20001 and SUNRAY-01. **Methods:** Pts with advanced *KRAS* G12C-mutant NSCLC, known PD-L1 expression and ECOG PS 0-1 were randomized to olomorasib (50 or 100 mg, orally BID) with pembrolizumab (200 mg Q3W). One cycle of SOC pembrolizumab prior to enrollment was permitted. Objective response rate (ORR) was assessed in the efficacy evaluable population, with PD-L1 0-49% Other efficacy endpoints included best overall response (BOR) and disease control rate (DCR). Safety was assessed across all treated pts (PD-L1 0-100%). **Results:** As of 6 June 2025, 85 pts received olomorasib + pembrolizumab, of which 31 pts had tumors with PD-L1 expression 0-49% (<1%: n=13; 1-49%: n=18). In pts with PD-L1 expression <1%, no pts received a prior cycle of SOC, 23% of pts had baseline brain metastases, and 38% had an ECOG score of 1. For the pts with PD-L1 expression of 1-49%, 17% received 1 prior cycle of SOC, 17% had baseline brain metastases, and 56% had an ECOG score of 1. The ORR was 58% in pts with PD-L1 <1%, 67% in pts with PD-L1 1-49% (Table). Across all treated pts the most common any grade treatment-related adverse events (TRAEs) were diarrhea (31%) and ALT/AST increased (26/24%). TRAEs led to permanent discontinuation of study treatment in 12% of pts (n=10). **Conclusions:** Olomorasib + pembrolizumab demonstrated promising efficacy in pts with 1L *KRAS* G12C-mutant advanced NSCLC, and PD-L1 expression <1% and 1-49% with ORRs that compare favorably with historical outcomes for pembrolizumab and chemo-immunotherapy in unselected advanced NSCLC. Olomorasib + pembrolizumab is under evaluation in pts with 1L *KRAS* G12C-mutant metastatic NSCLC (SUNRAY-01, NCT06119581) and early-stage NSCLC (SUNRAY-02, NCT06890598). Clinical trial information: NCT04956640, NCT06119581. Research Sponsor: Eli Lilly and Company.

Patient-reported outcomes (PROs) and health-related quality of life (HRQoL) with taletrectinib in advanced ROS1+ non-small cell lung cancer (NSCLC) from the TRUST-II study. First Author: Yasir Y. Elamin, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Taletrectinib is a next-generation, CNS-active, selective ROS1 tyrosine kinase inhibitor (TKI) approved by the US FDA for the treatment of patients with locally advanced or metastatic ROS1+ NSCLC based on results from two Phase 2 studies, TRUST-I (NCT04395677) and TRUST-II (NCT04919811). Here we report PROs with taletrectinib from TRUST-II. **Methods:** Patients with locally advanced or metastatic ROS1+ NSCLC were treated with taletrectinib 600 mg once daily in 21-day cycles. HRQoL and PROs for cancer-specific symptoms were evaluated using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire 30-item core module (QLQ-C30) and 13-item lung cancer module (QLQ-LC13). Questionnaires were only distributed to patients from North America and Europe. Data were collected at screening, then subsequently on Day (D)1 of every cycle (C) until C9D1, on D1 of every three cycles until C27D1, and every four cycles thereafter until the end of treatment (within 7 days of last dose). Changes from baseline over time were summarized using descriptive statistics. A change in score of $\geq$10 points from baseline was considered clinically meaningful. Time to first improvement (TFI) was assessed using Kaplan–Meier methods. **Results:** At data cutoff (August 31, 2025), the analysis set included 69 patients (23 TKI-naïve and 46 TKI-pretreated). Mean changes from baseline improved or remained stable for most domains across both questionnaires. For global health status/quality of life, the majority of patients showed clinically meaningful improvement or remained stable at multiple timepoints assessed (e.g. 74% of patients at C7). Mean cognitive function score improved or remained stable throughout treatment, with the majority (63–77%) of patients showing improvement or stability and only 9–23% of patients showing worsening at various assessment times. Common disease-related symptoms, including pain and fatigue (QLQ-C30), and dyspnea and coughing (QLQ-LC13), showed consistent clinically meaningful improvement throughout treatment, with a median TFI of 1–3 months across all patients. Coughing was particularly improved in TKI-naïve patients, with a median TFI of < 1 month. **Conclusions:** Taletrectinib was associated with improved or stable HRQoL in the majority of patients and with rapid relief of disease-related symptoms. In contrast to other ROS1 TKIs, taletrectinib demonstrated preservation of cognitive function over time. Together with the efficacy and safety results, these data further support the use of taletrectinib for patients with ROS1+ NSCLC. Clinical trial information: NCT04919811. Hi-C sequencing to identify clinically actionable fusions in non–small cell lung cancer missed by other sequencing technologies. First Author: Kevin Max Levine, University of Washington/Fred Hutchinson Cancer Center, Seattle, WA

Background: For a patient with non-small lung cancer (NSCLC) to benefit from targeted therapy, an actionable driver alteration needs to be identified. DNA-based next-generation sequencing (NGS) is the standard across many clinical laboratories, however, there are known limitations in the detection of structural rearrangements. RNA-based NGS is now being increasingly utilized in cases with negative DNA NGS testing, but it is currently unknown how many driver alterations are missed with RNA NGS. Hi-C, high-throughput chromosome conformation capture, is a newer NGS method that can be performed on formalin-fixed paraffin-embedded (FFPE) tissue to detect pairwise interactions between DNA regions and may have increased sensitivity for fusion detection. **Methods:** We collected FFPE tissue from NSCLC cases that were previously deemed to be negative for driver mutations through standard DNA and/or RNA based NGS. We performed Hi-C sequencing on these samples with the Arima Aventa FusionPlus test. This involves digestion of DNA in situ followed by religating to nearby DNA regions and sequencing pairs of DNA tags that reveal proximal DNA sequences. RNA-Sequencing was performed via multiple commercial testing labs using either panel based or whole transcriptome sequencing. **Results:** In 118 NSCLC specimens that were negative on prior NGS testing, 6 samples (5%) tested positive on Hi-C sequencing for a clinically actionable alteration, including 5 samples that were negative with both DNA and RNA-based NGS. Among these 6 samples were 5 cases of NRG1 fusions and one case of an NTRK2 fusion. All cases with NRG1 fusions have breakpoints proximal to exon 2 and therefore are expected to have expression of the full EGF-like domain. RNA-Sequencing of several of these cases confirmed high expression of NRG1. As an example, one patient had prior negative sequencing with tissue-based panel DNA NGS, ctDNA NGS, an RNA fusion panel, and whole transcriptome RNA-Seq. This patient's Hi-C sequencing identified a non-canonical NRG1 fusion with an intergenic region fused upstream of exon 2 of NRG1. After progression on chemo-immunotherapy, the patient was treated with zenocutuzumab, a recently approved bispecific antibody that blocks NRG1 from activating HER2/HER3 signaling. A CT Chest scan 6 weeks after initiation showed near complete resolution of the diffuse miliary metastases. **Conclusions:** Hi-C can identify clinically actionable driver alterations in NSCLC cases that were negative on other sequencing tests, highlighting the potential value of incorporating this technology into clinical practice. Prognostic impact of actionable driver alterations and efficacy of targeted therapy in lung squamous cell carcinoma: A large-scale nationwide genomic screening (LC-SCRUM-Asia). First Author: Tetsuya Sakai, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Precision medicine based on multi-gene analysis improves prognosis and has established multigene analysis as the standard of care in lung adenocarcinoma.However, the clinical utility of multi-gene analysis in lung squamous cell carcinoma (LUSC) remains controversial due to the rarity of actionable driver alterations and the uncertain therapeutic benefits of targeted therapy. This study aimed to elucidate the prognostic value of driver alterations and the efficacy of targeted therapy in LUSC. **Methods:** We have prospectively analyzed patients with non-small cell lung cancer (NSCLC) enrolled in a nationwide genomic screening project in Japan (LC-SCRUM-Asia) using NGS (Oncomine Comprehensive/Precision Assay). We evaluated clinical outcomes in patients with LUSC, comparing overall survival (OS) according to the presence of actionable driver alterations and receipt of targeted therapy. **Results:** From March 2015 to October 2025, 19,357 patients were enrolled, of whom 2,917 had LUSC. Among these LUSC patients, actionable driver alterations were identified in 180 patients (6.2%) cases, including *EGFR* mutations (n = 78), *KRAS* G12C (n = 33), *MET* exon 14 skipping (n = 28), *ALK* fusions (n = 18), *EGFR* exon 20 insertions (n = 7), *RET* fusions (n = 6), *ROS1* fusions (n = 5), *BRAF* V600E (n = 4), and *HER2* exon 20 insertions (n = 1).In the survival analysis of 2,017 patients with advanced/recurrent disease, median OS was significantly longer in patients with actionable driver alterations compared to those without (18.2 vs. 15.0 months; HR 0.79, p = 0.02). However, among patients with actionable driver alterations, there was no significant difference in median OS between patients who received targeted therapies (n = 97) and those who did not (n = 45) (18.3 vs. 17.0 months, p = 0.94). The efficacy of targeted therapies was notably limited; median progression-free survival was 12.4 months for ALK tyrosine kinase inhibitors (TKIs) (n = 17), 8.4 months for EGFR TKIs (n = 46), 4.5 months for KRAS G12C inhibitors (n = 10), 3.6 months for MET TKIs (n = 15), and 3.4 months for ROS1 TKIs (n = 5). Collectively, these outcomes were consistently inferior to those reported in pivotal clinical trials. **Conclusions:** Although actionable driver alterations were identified in approximately 6% of LUSC and were associated with a favorable prognosis, targeted therapy demonstrated limited efficacy and failed to extend overall survival compared to non-targeted approaches. These findings indicate that the clinical utility of multi-gene analysis in LUSC is currently limited, highlighting the need for the development of novel therapeutic strategies specific to this histology. Actionable genomic alterations and outcomes in lung squamous and adenosquamous cell carcinoma. First Author: Simone E. Dekker, Division of Medical Oncology, Clinical Research Division, University of Washington/Fred Hutchinson Cancer Center, Seattle, WA

Background: Actionable genomic alterations (AGA) are uncommon in lung squamous/adenosquamous carcinoma (LUSC/LUASC) and may contribute to poorer survival than lung adenocarcinoma (LUAD). Though a subset of LUSC patients harbor AGA and may benefit from targeted therapy, outcomes are poorly characterized. We hypothesized that AGA-LUSC patients treated with first-line (1L) targeted therapy have superior survival to those receiving chemotherapy and that AGA-LUSC has a distinct immune tumor microenvironment (TME) compared to non-AGA-LUSC. **Methods:** We identified and analyzed LUSC (6,970) and LUASC (227) patients from the Tempus Lens database with DNA (xT, 648-gene) and whole-transcriptome RNA (xR) NGS using the Lens Platform. AGA were defined as *ALK*, *ROS1*, *RET*, *NTRK1*/2/3 fusions, *EGFR*, *KRAS*, *BRAF* p.V600E, *MET* exon 14 skipping, or *ERBB2* alterations. *KRAS*, *BRAF* p.V600E, and *MET* exon 14 skipping were classified as immune-associated AGA. RNA data were quantified as transcripts per million (TPM) and reported as log2(TPM+1). We assessed tumor mutational burden (TMB), *TTF1* and *TP63* gene expression, and TME (via quanTIseq). OS and PFS were measured from 1L treatment initiation to death, progression/death or last follow up, respectively. **Results:** AGA incidence was 7.5% in LUSC and 45% in LUASC. Non-immune AGA had significantly lower median TMB than immune-AGA and non-AGA in both LUSC (5.3 vs 7.4 vs 7.9) and LUASC (3.7 vs 5.5 vs 8.4) (both $p < 0.001$) and had numerically lower CD8 T-cell infiltration in LUSC. *TTF1* expression did not differ among AGA and non-AGA groups; but *TP63* expression was significantly higher in LUSC than LUASC (8.70 vs 6.23, $p < 0.001$) and in non-AGA compared to AGA in both LUSC ($p < 0.001$) and LUASC ($p = 0.027$). In AGA-LUSC, 1L targeted therapy (n = 15) was associated with numerically longer PFS (27.7 mo vs 8.1 mo, p = 0.17) and OS (19.2 mo vs 15.7 mo, p = 0.78) compared with chemoimmunotherapy/chemotherapy. No difference in outcomes was observed between non-AGA and AGA LUSC patients treated with chemoimmunotherapy/chemotherapy. **Conclusions:** Given the observed rates of AGA in both LUSC and LUASC and numerically improved outcomes in AGA-LUSC patients receiving 1L targeted therapy, routine NGS testing is warranted. TME differs between non-immune and immune-AGA, and *TP63* expression is inversely associated with AGA in both tumor types. Research Sponsor: National Cancer Institute; T32CA009515.

Ablation of oligo-residual disease to prolong progression-free survival in *EGFR*-mutant advanced NSCLC patients treated with third-generation EGFR-TKIs. First Author: Jizhong Yin, Shanghai Pulmonary Hospital, Tongji University, Shanghai, China

Background: Combination of EGFR-TKIs with chemotherapy or amivantamab have become the standard of care for EGFR-mutant NSCLC. This study further evaluated the efficacy of ablation in advanced NSCLC patients who develop oligo-residual disease (ORD) after EGFR-TKI. **Methods:** We retrospectively enrolled patients with advanced NSCLC who achieved ORD after first-line third-generation EGFR TKIs therapy in Shanghai Pulmonary Hospital, Tongji University. Ablation, including radiofrequency ablation (RFA) and cryoablation, were administered for residual lung lesions. Using propensity score matching, patients with ORD who received TKIs monotherapy alone were set as the control group. The primary endpoint was progression-free survival (PFS). **Results:** From Jan 2019 to Dec 2023, a total of 292 patients (100 for TKIs plus ablation group and 192 for TKIs group) were included. With a median follow-up of 26.4 months, disease progression or death had occurred in 41 patients (41%) in the TKIs plus ablation group versus 159 patients (83%) in the TKIs group. The addition of ablation significantly improved PFS compared to TKIs alone (median 31.6 vs. 17.9 months; HR 0.36, 95% CI 0.26-0.51; $p < 0.001$). The 2-year PFS rate were 66.1% and 32.5%, respectively. A consistent trend was observed for overall survival (OS) (median OS: not reached; HR 0.36, 95% CI 0.20-0.65; $p < 0.001$). A total of 81 patients (22 for ablation group and 59 for TKIs group) underwent biopsies and NGS testing after resistance. The ablation group showed an increased incidence of MET amplification (17% vs. 7%) and HER2 amplification (8% vs. 4%), while on-target EGFR resistance mutations (C797S mutation or EGFR amplification) were similar. The side effects were similar in the two groups. **Conclusions:** Front-line third-generation EGFR-TKI combined with ablation for ORD led to significantly longer PFS than EGFR-TKIs alone in patients with advanced NSCLC, which provide an alternative strategy as the front line setting and warranting further prospective validation. Clinicogenomic determinants of early progression on first-line osimertinib in *EGFR*-mutant NSCLC. First Author: Federica Pecci, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: With the recent approvals of the FLAURA2 and MARIPOSA regimens in *EGFR*-mutant non-small cell lung cancer (NSCLC), identifying clinicogenomic features predictive of suboptimal outcomes with first-line osimertinib monotherapy is critical in guiding upfront treatment selections. **Methods:** This is a multicenter retrospective study enrolling patients (pts) with advanced NSCLC harboring common *EGFR* mutations (exon 19 deletions [ex19del], L858R) treated with first-line osimertinib monotherapy across 13 centers (Clinical cohort). Comprehensive baseline genomic data on tumor tissue were available for DFCI and MSKCC (Genomic cohort). The association of clinicogenomic features with real-world progression-free survival (rwPFS) was investigated. Time-dependent discrimination for very-early progression (rwPFS $<$ 6 months) was evaluated using Receiver Operating Characteristic (ROC) curve-based Area Under the Curve (AUC). Variable importance was assessed by delta (Δ) AUC after covariate exclusion. Moreover, very-early progression was analyzed with a Cox model censored at 6 months, reporting adjusted hazard ratios (aHR). **Results:** A total of 1488 pts were enrolled in the clinical cohort; at median follow-up of 43.3 months, median rwPFS was 16.3 months (95%CI 15.3-17.4), median overall survival was 36.7 months (95%CI 34.8-39.4). The strongest predictor of very-early rwPFS in a multivariable model, including, age, sex, *EGFR* mutations, PD-L1 tumor proportion score (TPS), concurrent *TP53* mutations, metastatic sites (brain, bone, liver), performance status, was PD-L1 TPS (aHR 2.75 for $\geq$50% versus 0%, $p < 0.0001$), with the largest decrease in the AUC when excluded from the model (ΔAUC = 0.17). Looking at genomic features in the genomic cohort, at median follow up of 38.2 months, loss-of-function mutations in *KMT2D* (HR 7.1, $p < 0.001$), *TP53* (HR 1.4, p = 0.01), *RB1* (HR 1.7, p = 0.01), *RBM10* (HR 1.6, p = 0.01), *CREBBP* (HR 2.7, p = 0.02), *ATM* (HR 2.1, p = 0.04), predicted shorter rwPFS. Next, we investigated the role of concurrent tumor suppressor gene (*TSG*) alterations beyond *TP53*, including in this cathegory those with a $p < 0.1$ for rwPFS and mutated in at least 5 cases *(RBM10, CREBBP, ATM, RB1, KMT2D, TSC2, PTEN). TSG^{MUT}* had shorter rwPFS compared to *TSG^{WT}* (aHR 1.5, p = 0.01), specifically in L858R subgroup (aHR 1.7, p = 0.02), while *$TP53^{MUT}$* had shorter rwPFS compared to *$TP53^{WT}$* in ex19del only (aHR 1.7, p = 0.01). Combining *TP53* with *TSG*, pts with *$TP53^{MUT}$* plus at least one *TSG^{MUT}* and pts with *$TP53^{WT}$-TSG^{MUT}* had shorter rwPFS compared to *$TP53^{WT}$-TSG^{WT}* and *$TP53^{MUT}$-TSG^{WT}* (10.8, 13.1, 21.9, 18.1 months, respectively, p = 0.004). In the genomic cohort, PD-L1 TPS was the strongest predictor of very-early rwPFS (ΔAUC = 0.16), followed by *TP53* combined with *TSG* (ΔAUC = 0.08). **Conclusions:** In this multicenter real-world cohort, baseline PD-L1 and *TP53* combined with *TSG* predict very-early progression to first-line Osimertinib. ***EGFR*-mutated lung cancer: A comparative analysis of common and uncommon variants.** First Author: Anas Mohammad Zayed, King Hussein Cancer Center, Amman, Jordan

Background: Uncommon EGFR mutations represent a heterogeneous subset of EGFR-positive NSCLC with limited characterization. This study compares clinical, molecular, and survival outcomes between common and uncommon EGFR variants in a large real-world cohort. **Methods:** A retrospective analysis of 1,501 EGFR-positive NSCLC cases from MSK-CHORD was performed. Patients were classified as having common (Ex19del, L858R) or uncommon mutations (G719X, L861Q, S768I). Clinical and genomic variables were analysed using Wilcoxon and chi-square tests (significance $p < 0.05$). **Results:** The study included 1,501 EGFR-mutated NSCLC patients, with 195 (13.0%) harboring uncommon and 1,306 (87.0%) harboring common EGFR mutations. Patients with uncommon mutations were older at diagnosis (median 73 vs 69 years; p = 0.003), while sex distribution remained similar (p = 0.868). Race distribution differed (p = 0.005), with more White patients in the uncommon EGFR group (80.3% vs. 69.5%) and fewer Asian patients (11.8% vs. 25.5%), while Black patient proportions were similar (7.9% vs. 5.0%). Smoking history also varied ($p < 0.005$), with substantially fewer never-smokers among patients with uncommon mutations (25.6% vs 59.6%). Uncommon mutations were associated with higher genomic burden, including elevated TMB (median 4.92 vs 3.46 mut/Mb; $p < 0.001$) and mutation count (median 6 vs 4; $p < 0.001$). Stage at diagnosis did not differ (p = 0.3), nor did metastatic site distributions (p = 0.477). Median OS was significantly shorter for patients with uncommon EGFR mutations (36.69 vs 56.52 months), with HR 1.425 ($p < 0.005$). In Stage IV patients receiving osimertinib, OS was numerically shorter for uncommon mutations but not statistically significant (29.98 vs 34.32 months; HR 1.351; p = 0.08). Among Stage IV patients with uncommon mutations, OS was comparable between afatinib and osimertinib (25.48 vs 26.70 months; p = 0.88). *KRAS* co-mutations were significantly more frequent in the uncommon group (4.62% vs 1.15%; $p = 1.985 \times 10^{-3}$). **Conclusions:** Uncommon EGFR mutations exhibit distinct clinical and genomic features and poorer survival compared with common variants, highlighting their heterogeneity and the need for tailored therapeutic strategies. Research Sponsor: None.

The effect of glucagon-like peptide-1 (GLP-1) receptor agonists on outcomes in metastatic non-small cell lung cancer (mNSCLC) patients treated with tyrosine kinase inhibitors (TKIs): Real-world retrospective analysis. First Author: Khvaramze Shaverdashvili, Thomas Jefferson University, Philadelphia, PA

Background: The therapeutic landscape of mNSCLC has rapidly evolved, with multiple oncogenic alterations now targetable by approved TKIs used in first-line settings, leading to substantial survival gains. However, several TKIs are associated with metabolic toxicities, including weight gain and hyperlipidemia, particularly with ALK inhibitors (e.g., lorlatinib) and selective RET inhibitors. As use of GLP-1 has increased among patients with cancer, their impact on outcomes in oncogene-driven mNSCLC treated with TKIs remains unknown. We evaluated the association between GLP-1 use and survival outcomes in TKI-treated mNSCLC using real-world data. **Methods:** We conducted a retrospective analysis using TriNetX, a Global Collaborative electronic health record with $>$ 190 million patients and $>$ 170 healthcare organizations, from 2010-2025. Adults ($\geq$18 years) with mNSCLC, metabolic comorbidities (T2DM, obesity, or hyperlipidemia), and treatment with first line-approved TKIs (EGFR, ALK, ROS1, RET, NTRK, BRAF, MET) were included. Patients were stratified by concomitant GLP-1 use and matched 1:1 using propensity scores based on demographics, ECOG performance status, cardiometabolic comorbidities, tobacco and alcohol use, and outpatient healthcare utilization. 5 year overall survival (OS) was assessed. **Results:** A total of 25,008 patients met inclusion criteria, including 24,459 (97.8%) non-GLP1 users and 549 (2.2%) in GLP-1 users. After 1:1 propensity score matching (PSM), 546 patients were included per group. Amongst both cohorts average age was 64, 61% were female, 60% were White, 13% were Asian. In the overall mNSCLC TKI-treated patients, GLP-1 use was associated with significantly improved 5-year OS compared with non-use (63% vs 40%; HR 0.45, 95% CI 0.36-0.57; $p < 0.001$). In subgroup analyses, patients treated with ALK TKIs (lorlatinib or alectinib; n = 128/group) demonstrated improved 5 year OS with GLP-1 use 85% vs 48% in non-users (HR, 0.18; 95% CI, 0.09 - 0.36; $p < 0.0001$). Furthermore, GLP-1 use was also associated with improved 5-year OS among EGFR TKI-treated patients (54% vs 44%; HR 0.60, 95% CI 0.44-0.82; p = 0.001) and BRAF TKI-treated patients (41% vs 35%; HR 0.52, 95% CI 0.30-0.91; p = 0.02). Other TKI groups comprised relatively small numbers of patients and therefore were not analyzed separately. **Conclusions:** In this large real-world analysis, GLP-1 use was associated with significantly improved survival in patients with oncogene-driven mNSCLC treated with TKIs, with consistent benefit across ALK, EGFR, and BRAF-driven mNSCLC. To our knowledge, this is the first study to link the impact of the GLP-1 agonists on the outcomes of TKI treated mNSCLC. Further prospective studies are needed to validate these findings and to identify underlying mechanisms. Research Sponsor: None.

Plasma epigenomic profiling for identification of mechanisms of sensitivity, primary and acquired resistance to tepotinib in METex14 skipping metastatic NSCLC. First Author: Sunny Das, Precede Biosciences, Boston, MA

Background: *MET* exon 14 skipping mutations (METex14) are an actionable biomarker in a subset (3-4%) of advanced/metastatic NSCLC patients, with an approved oral and highly selective MET TKI, tepotinib. However, heterogenous clinical responses in patients warrant additional biomarkers of response and resistance. We applied Precede's epigenomic liquid biopsy platform to explore the feasibility of identifying transcriptional programs associated with sensitivity and resistance to tepotinib in patients with METex14 NSCLC. **Methods:** A total of 144 baseline, on-treatment (OT), and end-of-treatment (EOT) samples from patients with METex14 NSCLC from the VISION study (NCT02864992) were profiled using Precede's assay using 1mL of plasma. ctDNA fraction was independently estimated. Genome-wide differential epigenomic activity and pathway analyses compared PFS-stratified responders (top tertile PFS) vs. non-responders at baseline (bottom tertile PFS), and paired baseline vs. EOT samples to identify acquired resistance programs. SCLC/neuroendocrine transformation was assessed in all samples using an independent Precede lineage classifier. Plasma-inferred gene expression models, based on Precede's proprietary algorithms identified additional therapeutic targets. **Results:** At baseline, responders showed higher epigenomic activity in pathways underlying addiction to METex14 signaling, including the FAK-integrin axis, ECM remodeling and EMT/invasion. Non-responders displayed increased translational/intrinsic proliferative programs, altered metabolic fitness, and inflammatory/immune signaling, implicating these programs in intrinsic resistance to tepotinib. These METex14 signaling-associated pathway scores stratified clinical outcomes, highlighting their potential in patient selection. Paired analyses revealed EOT samples had increased activity of regulators of lineage plasticity and neuroendocrine differentiation, relative to baseline. Correspondingly, SCLC scores were elevated in OT and EOT samples, with a subset of baseline samples already harboring neuroendocrine features. Epigenomic activity of GD2 synthase (*B4GALNT1*) significantly increased with treatment, underscoring a potential rationale for combination therapies using anti-GD2 ADCs. **Conclusions:** Precede's comprehensive epigenomic liquid biopsy platform resolved METex14 skipping NSCLC biology associated with response and identified programs associated with intrinsic and acquired resistance to tepotinib, including emergence of neuroendocrine differentiation and induction of GD2 synthase. These findings support the use of plasma-based epigenomic profiling to inform therapy selection for patients at baseline and progression and non-invasively monitor resistance mechanisms in METex14 NSCLC. Efficacy and safety of deulorlatinib (TGRX-326) in patients with locally advanced or metastatic ALK+ non–small cell lung cancer: A multicenter, open-label, pivotal phase 2 trial. First Author: Yunpeng Yang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Treatment options are limited for anaplastic lymphoma kinase positive (ALK+) non-small cell lung cancer (NSCLC) patients (pts) who have developed resistance to second-generation ALK inhibitors. Deulorlatinib is a highly potent third-generation ALK inhibitor. The Previous phase 1 study (NCT05441956) found that deulorlatinib had a high overall and intracranial response rate in pts who had progressed on second-generation inhibitors, with encouraging activity against the G1202R mutation and favorable tolerability. **Methods:** This is a multicenter, open-label pivotal phase 2 study. Pts with locally advanced or metastatic ALK+ NSCLC who had progressed on second-generation inhibitors received deulorlatinib 60 mg orally once daily. The primary endpoint was objective response rate (ORR) per RECIST v1.1 by independent review committee (IRC). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. The ORR in patients harboring the G1202R mutation was also assessed. **Results:** Between Jan 18, 2023 and Dec 29, 2023, a total of 163 patients were enrolled and 158 were evaluable for efficacy. Of these pts, the median age was 53.5 years old, 53.2% were female, 95.6% had adenocarcinoma, and 56.2% had baseline brain metastasis; 56.3% of these pts had progressed on alectinib. As of December 16, 2025, the median follow-up was 28.7 months and 44 pts were still on deulorlatinib. The IRC assessed confirmed ORR was 43.7% (95%CI 35.8, 51.8). The median DoR and PFS was 20.7 months (95%CI 15.4, NR) and 13.8 months (95%CI 8.3, 16.5), respectively; median OS was not reached. Of the 43 pts with measurable baseline CNS lesions, confirmed ORR was 55.8% (95%CI 39.9, 70.9). In pts with the G1202R mutation, the ORR was 62.5% (95%CI 24.5, 91.5). Treatment-related adverse events (TRAEs) were reported in 96.3% of pts. The most common TRAEs were hypercholesterolaemia (77.9%), hypertriglyceridaemia (71.2%), and weight gain (52.8%). Grade $\geq$3 TRAEs were reported in 51.5% of pts. Of note, only 1.2% of pts had Grade $\geq$3 CNS TRAEs. **Conclusions:** Deulorlatinib produced robust and durable responses in locally advanced or metastatic ALK+ NSCLC pts with progression on second-generation inhibitors, including those with the G1202R mutation, with low incidence of Grade $\geq$3 CNS TRAEs. Although across trials comparisons must be interpreted cautiously, deulorlatinib might have a better safety profile than lorlatinib. Altogether these findings suggest that deulorlatinib has a favourable risk benefit ratio and support its further development, particularly in the first-line setting. Clinical trial information: NCT05955391. Research Sponsor: Shenzhen TargetRx, Inc.

Clinical efficacy and tolerability of the selective RET inhibitor soxaltalinib (SY-5007) in advanced *RET* fusion–positive non–small cell lung cancer (NSCLC): Primary findings from a confirmatory phase III trial. First Author: Anwen Xiong, Department of Oncology, Shanghai East Hospital, Tongji University, Shanghai, China

Background: Oncogenic RET gene fusions represent a clinically validated molecular driver occurring in approximately 1–2% of all NSCLC cases, establishing a critical need for targeted therapeutic strategies. Soxaltalinib is a novel, orally bioavailable, and highly selective small-molecule inhibitor of RET kinase. Its anti-tumor potency and safety have been previously reported in a phase I/II study. Here we confirmed its clinical value in a pivotal phase III study. **Methods:** This multicenter, single-arm Phase III clinical trial was designed to evaluate the efficacy and safety of Soxaltalinib in patients with RET fusion–positive NSCLC who were previously untreated for advanced disease. The primary endpoint was the confirmed Objective Response Rate (ORR), as determined by Blinded Independent Central Review (BICR) per RECIST v1.1. The secondary endpoints included investigator-assessed ORR, Disease Control Rate (DCR), Duration of Response (DOR), Progression-Free Survival (PFS), Overall Survival (OS), and safety. **Results:** At the data cutoff (April 10, 2025), the Per-Protocol Population (PPP) comprised 95 patients, 61 of whom were Key efficacy population (KEP) for statistical hypothesis. Soxaltalinib demonstrated profound anti-tumor efficacy. The primary endpoint was met. The BICR-confirmed ORR was 90.0% (95%CI: 79.5, 96.2) for KEP and 87.4% (95%CI: 79.0, 93.3) for PPP. The overall DCR was 96.7% (95%CI: 88.5, 99.6) for KEP and 93.7% (95%CI: 86.8, 97.6) for PPP. The median PFS and DOR had not yet been reached, with an estimated 15-month PFS rate of 68.9% (95%CI: 54.3, 79.7) and 65.0% (95%CI: 51.5, 75.6) and 12-month DOR rate of 73.8% (95%CI: 58.2, 84.4) and 69.1% (95%CI: 53.8, 80.1), respectively for KEP and PPP. The OS data remained immature. The safety analysis population comprised 96 patients who received at least one dose of Soxaltalinib. The most common Grade $\geq$3 treatment-emergent adverse events (TEAEs) were hypertension (22.9%), diarrhea (16.7%), Aspartate aminotransferase increased (6.3%), Alanine aminotransferase increased (5.2%), and hyponatraemia (5.2%). These events were predominantly manageable. None of the patients permanently discontinued treatment due to a treatment-related adverse event. No patient died due to TEAE that was definitely related, probably related, or possibly related to Soxaltalinib. **Conclusions:** The primary analysis of this Phase III trial confirmed Soxaltalinib as a highly effective and well-tolerated therapeutic agent for patients with RET fusion–positive NSCLC in the first-line setting. This observed high response rates and durable disease control benefit underscored its potential as a best-in-class RET inhibitor. The adverse event profile was predictable and manageable, supporting its feasibility for long-term administration. Clinical trial information: NCT06031558. Research Sponsor: Shouyao Holdings (Beijing) Co. Ltd.

Results from OCEAN II: A phase II study of encorafenib + binimetinib combination in Chinese patients with *BRAF*^{V600E} mutated metastatic non-small cell lung cancer. First Author: Huaqiang Zhou, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Lung cancer is the most common cause of cancer and cancer death in China. Patients (pts) with *BRAF*^{V600E} mutant metastatic non-small cell lung cancer (mNSCLC) can benefit from targeted treatments such as encorafenib + binimetinib (E+B). E+B is approved in Western countries (PHAROS: NCT03915951); however, evidence of efficacy and safety in Chinese pts is lacking. OCEAN II (NCT05195632) is the 1st study to specifically evaluate the efficacy, safety and pharmacokinetic of this targeted combination in Chinese pts with *BRAF*^{V600E} mutant mNSCLC. **Methods:** OCEAN II is an ongoing multicenter, open-label, phase 2 (P2) study with a Safety Lead-in (SLI). Eligible pts had unresectable stage IV *BRAF*^{V600E} mutant NSCLC, were treatment-naive or had received systemic therapy, excluding BRAF/MEK inhibitors. Pts received E 450 mg once daily + B 45 mg twice daily. Primary endpoints were dose-limiting toxicities (DLT) during the 1st 28 days (SLI) and confirmed objective response rate (cORR) by independent central review (ICR) (P2). Secondary endpoints (P2) were disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Between June 2022 and October 2023, 63 pts were enrolled (SLI = 15, P2 = 48): median age 65 yrs (range 52–82), 49% female, 75% with ECOG score = 1. There was only 1 DLT (non-serious grade 3 lipase increased) during SLI, supporting P2 initiation. At the primary analysis cut-off date (27 May 2024), the primary endpoint was met; cORR by ICR was 59.3% (95% confidence interval [CI] 45.0–72.4) in the Efficacy set, with pre-defined statistical significance criteria met. An *ad hoc* analysis (cut-off 27 March 2025) was conducted when all pts had ≥12 months (mo) follow up. cORR by ICR was 61.1% (95% CI 46.9–74.1), with 6 (11%) complete and 27 (50%) partial responses, and DCR of 87.0% (95% CI 75.1–94.6). Median time to response was 1.8 mo (range 1.7–13.7), median DoR 17.5 mo (95% CI 12.9–NR), median PFS 13.8 mo (95% CI 7.5–NR) and median OS 27.9 mo (95% CI 14.7–30.0). DoR and OS are not yet mature (median follow-up for OS: 21 months). Median treatment duration was 32.3 weeks, with 7 (11%) pts receiving treatment for > 2 years, and 10 (15.9%) remaining on treatment. Treatment-emergent adverse events (TEAEs) ≥ grade 3 occurred in 56% of pts. Related TEAEs in ≥25% were anemia (36%), increased aspartate aminotransferase (33%), increased alanine aminotransferase (30%), increased creatine kinase (29%), vomiting (27%), increased creatinine (25%). Nine (14%) pts discontinued any drug due to AEs. **Conclusions:** The data confirm the clinical benefit of E+B in Chinese pts with *BRAF*^{V600E} mutant mNSCLC, a population with distinct genomic and disease characteristics. No new safety concern was identified in the Chinese population. These data can support regulatory decisions and clinical practice guidelines in China. Clinical trial information: NCT03915951. Research Sponsor: Pierre Fabre Medicament.

8641 **Poster Session**

A phase 2 multicenter, open-label, parallel cohort study to evaluate the efficacy, safety, and pharmacokinetic profile of ABN401 in patients with advanced solid tumors harboring c-MET dysregulation. First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Vabametkib is a small-molecule, tyrosine kinase inhibitor (TKI) that is a highly selective type I inhibitor of c-MET kinase, for the treatment of solid tumors harboring c-MET gene dysregulation. **Methods:** Phase 2 trial is an open-label, global study designed to evaluate the safety and efficacy of vabametkib in patients with NSCLC harboring MET exon 14 skipping mutations confirmed by NGS. Patients received oral vabametkib at a dose of 800 mg once daily (QD) until disease progression or unacceptable toxicity. The primary endpoint was ORR as assessed by blinded independent central review. Secondary endpoints included pharmacokinetics, DoR, DCR, PFS and OS. Exposure–response relationships of vabametkib were evaluated in enrolled patients to explore the optimal dose and dosing regimen to support further clinical development. **Results:** Forty-two (42) efficacy patients enrolled and median age were 76 years; 78 years in treatment naive and 75 years in the prior treated patients. Median follow-up duration was 14.1 months overall; 14.6 months for treatment naive and 13.5 months for prior treated patients. BICR confirmed ORR was 55% overall, with comparable response rate in both treatment-naive patients (52%) and prior-treated patients (57%). The median DoR assessed by BICR was 14.5 months with 19.9 months in treatment naive patients and 11.7 months in prior treated patients. Median PFS by BICR was 8.8 months overall, with 10.2 months in treatment naive patients and 7.3 months in prior treated patients. TRAE were experienced in 89% patients, 11% patients experienced Grade ≥3 TRAEs and no Grade 4 TRAE was reported. The most common TRAEs included nausea (75%), diarrhea (34%), hypoalbuminemia (25%), rash (18%), vomiting (18%), peripheral edema (16%), fatigue (14%), and elevated ALT and AST (14%). The most common Grade ≥3 TRAE was pneumonitis (4.5%). TRAEs led to dose reductions in 22.7% of patients, most commonly due to rash (6.8%), nausea (4.5%) and stomatitis (4.5%). TRAEs resulted in dose interruptions in 36.4% of patients most frequently due to nausea (9.1%), vomiting (9.1%), rash (6.8%), and fatigue (4.5%). Median AUC_{inf} values were highest in the PR group (2,946 ng·h/mL) compared to the SD (2,021ng·h/mL) and PD groups (988 ng·h/mL) with a statistically significant difference (p = 0.0347 by Kruskal-Wallis). PK simulation demonstrated BID dosing more effectively maintained EC_{90} coverage than QD dosing; sustaining drug conc above EC_{90} for 93% of the dosing interval and increasing $AUC_{0\text{-}24hr}$ by 35.3% thereby increasing likelihood of achieving exposure observed in the PR patients. **Conclusions:** Alternative 350mg BID of Vabametkib had been selected to continue the clinical development. Clinical trial information: NCT05541822. Research Sponsor: AbionBio; Korean Drug Development Fund.

Comprehensive epigenomic profiling of plasma for non-invasive detection of MET activation to uncover MET-associated biology in patients with *EGFR*-mutated advanced NSCLC and progression on osimertinib. First Author: Jonathan W. Riess, UC Davis Comprehensive Cancer Center, Sacramento, CA

Background: Genomic overexpression or amplification of *MET* is an established bypass resistance mechanism in EGFR-mutated (EGFRm) NSCLC, observed in up to 34% of patients whose tumors progress on osimertinib. Savolitinib, an oral, highly selective MET TKI, demonstrates clinical activity in tumors classified as MET-high by tissue-based IHC or FISH. However, tissue at progression is often inaccessible or insufficient for repeated assessment, constraining dynamic characterization of MET pathway dependence and emerging resistance mechanisms. To overcome these limitations, we applied an epigenomic liquid biopsy platform to a subset of patients enrolled in the Phase II SAVANNAH trial that combined osimertinib and savolitinib after progression on 1L osimertinib (NCT03778229), where we evaluated the feasibility of capturing MET activity and additional resistance markers from plasma. **Methods:** Baseline samples from 40 patients enrolled in the SAVANNAH trial with progression on 1L osimertinib, were profiled using an epigenomic assay (Precede Biosciences, Boston MA) on 1mL of plasma. Tissue-based analysis from the SAVANNAH cohort scored 15/40 tumors as MET-high/+ (FISH 10+, IHC 3+ ≥90%+) and 25 samples as MET-low/- (FISH < 10, IHC 3+ < 90%). A plasma-based MET classifier integrating comprehensive epigenomic features was applied to these samples and its performance evaluated against tissue MET status. ctDNA fraction was independently estimated. Pathway analyses on genome-wide differential epigenomic activity were performed to define MET-associated biology and infer tumor gene expression from plasma. **Results:** The plasma-based MET classifier demonstrated strong agreement with tissue-based MET status (AUC 0.97; balanced accuracy 88%), with an estimated limit of quantification (LoQ) of ~0.8% ctDNA. MET+ samples displayed enrichment of epigenomic signatures consistent with MET-dependence, including MYC targets, metabolic signatures, and invasive and developmental programs. In contrast, MET-negative (MET-) samples were enriched for IFN-driven immune pathways and apoptotic priming. Gene expression models across multiple ADC targets applied to patient plasma samples from SAVANNAH also identified elevated EGFR and HER2 expression in select cases. **Conclusions:** Comprehensive epigenomic profiling of plasma demonstrated high concordance with tissue-based approaches, identifying MET pathway activation and additional putative resistance-associated targets, from 1 mL of plasma in EGFRm NSCLC patients. This provides an accessible and scalable blood-based test to increase identification of patients post-EGFR inhibitor treatment, who may benefit from MET-targeted therapy, resistance monitoring, and informing future combination or sequential MET-directed strategies. Research Sponsor: AstraZeneca, Boston, USA.

Clinical significance of *EGFR* amplification in patients with *EGFR*-mutated metastatic non–small cell lung cancer receiving first-line osimertinib. First Author: Alessandro Di Federico, University of Bologna, Bologna, Italy

Background: With rapidly expanding first-line options for patients (pts) with *EGFR*-mutated non-small cell lung cancer (NSCLC), identifying biomarkers that may assist treatment selection is critical. The impact of *EGFR* amplification (*EGFR*^{AMP}) on osimertinib outcomes is unclear. **Methods:** Pts with stage IV NSCLC and *EGFR* exon 19 deletions (ex19del) or the L858R mutation who received first-line osimertinib monotherapy at 5 centres across Italy and the United States and had undergone baseline next-generation sequencing (NGS) that included *EGFR*^{AMP} assessment were included in this analysis. *EGFR*^{AMP} was defined as an *EGFR* copy number (CN) ≥6. The predominantly amplified allele was inferred by INCOMMON, a biostatistical classifier, as previously described. **Results:** Among 473 pts, 81 (17.1%) had *EGFR*^{AMP}. Compared to pts with non-amplified *EGFR* (*EGFR*$^{Non\text{-}AMP}$, n = 392), pts with *EGFR*^{AMP} more frequently had *TP53* co-mutations (80% vs 55%, p < 0.001) and baseline brain (51% vs 34%, p = 0.008), liver (26% vs 13%, p = 0.009), and bone metastasis (65% vs 51%, p = 0.03). When treated with osimertinib, pts with *EGFR*^{AMP} achieved similar objective response rate (ORR) (88% vs 83%, p = 0.23), but shorter median progression-free survival (mPFS) (11.6 vs 19.0 months, HR 1.77, p < 0.0001) and overall survival (mOS) (34.0 vs 40.1 months, HR 1.40; p = 0.040). In a multivariable Cox-regression model, *EGFR*^{AMP} retained its association with worse PFS (HR 1.36, p = 0.04), but not OS. *EGFR*^{AMP} correlated with shorter PFS in both *TP53* co-mutated (n = 269) (11.7 vs 15.0 months, HR 1.43, p = 0.02) and *TP53* wild-type (n = 181) (10.4 vs 21.9 months, HR 2.38, p < 0.001) cases, despite similar ORR and mOS. Among pts with ex19del, *EGFR*^{AMP} (n = 44) showed similar ORR compared to *EGFR*$^{Non\text{-}AMP}$ (n = 241), but shorter mPFS (14.2 vs 20.2 months, HR 2.01, p < 0.001) and mOS (35.4 vs 44.9 months, HR 1.62, p = 0.04). In contrast, no difference was observed in the L858R-mutated subgroup between *EGFR*^{AMP} (n = 39) and *EGFR*$^{Non\text{-}AMP}$ (n = 150) cases (ORR 86% vs 75%, p = 0.14; mPFS 11.4 vs 14.3 months, HR 1.47, p = 0.06; mOS 33.2 vs 36.0 months, HR 1.19, p = 0.5). Within *EGFR*^{AMP} cases, increasing *EGFR* CN (*EGFR*$^{Non\text{-}AMP}$ vs CN≥6 < 15 vs CN 15-30 vs CN > 30) correlated with a stepwise reduction of mPFS (19.0, 16.7, 10.3, and 8.7 months, respectively; log-rank p < 0.001) and mOS (40.1, 37.5, 38.8, and 15.3 months, respectively; log-rank p = 0.02). Moreover, amplification of the mutant allele, as opposed to wild-type amplification, correlated with inferior mPFS (8.3 vs 12.1 months, HR 2.72, p = 0.002) and mOS (17.3 vs 39.7 months, HR 2.08, p = 0.046). Among pts with paired NGS before and after acquired osimertinib resistance (n = 113), those with baseline *EGFR*^{AMP} more frequently showed acquired *MET* alterations (29% vs 12%, p = 0.04). **Conclusions:** *EGFR*^{AMP} is associated with distinctive characteristics and worse outcomes to osimertinib among pts with stage IV *EGFR*-mutated NSCLC. Research Sponsor: None.

Leptomeningeal disease in ALK-positive NSCLC: Survival impact of third-generation ALK inhibitors. First Author: Kelsey Pan, Emory University Hospital/Winship Cancer Institute, Raleigh, NC

Background: As survival outcomes for patients with ALK-positive non-small cell lung cancer (NSCLC) continue to improve with successive generations of ALK tyrosine kinase inhibitors (TKIs), leptomeningeal disease (LMD) has emerged as a growing and critical area of unmet need. While next-generation ALK TKIs were developed to enhance central nervous system (CNS) penetration and improve control of parenchymal brain metastases, their role in the treatment of LMD remains less well defined. **Methods:** We performed a global multi-center retrospective analysis of 141 patients with a diagnosis of ALK-positive NSCLC and radiographically or cytologically confirmed LMD at 5 academic centers across the United States and China (MD Anderson Cancer Center, Zhejiang University, Guandong Lung Cancer Institute, National Cancer Centre Singapore, and Union Hospital at Tongji Medical College) between 2007-2024. Baseline clinical characteristics, treatment history, and outcomes were collected, and subgroup analyses were performed to identify clinical and treatment-related factors associated with leptomeningeal overall survival (LMOS). **Results:** Of the 141 patients with ALK+ NSCLC, most patients had radiographic LMD (79.4%), while 41.1% had positive CSF cytology and 59.6% were neurologically symptomatic. The median time from metastatic lung cancer to LMD diagnosis was 40.6 months among patients who were previously treated with a 3rd generation (3G) ALK TKI (lorlatinib), compared to 23.7 months among those without prior lorlatinib treatment ($p < 0.001$). The median overall survival following LMD diagnosis (LMOS) was 22.5 months. Use of a 3G ALK TKI following LMD diagnosis was associated with improved LMOS in both treatment-naïve patients and those previously treated with earlier-generation TKIs. Among TKI-naïve patients, LMOS was 42.4 months with second-generation (2G) TKI alone, 49.6 months with escalation from 2G to 3G TKI, and not reached with 3G TKI alone ($p < 0.001$). Among patients previously treated with a 2G TKI, LMOS was significantly improved with 3G TKI (32.6 months) compared with an alternative 2G TKI (7.0 months) or no ALK TKI (6.8 months; p = 0.01). Whole-brain radiotherapy, intrathecal therapy, and VEGF inhibition were not associated with improved LMOS. On multivariable analysis, ECOG performance status < 2 and female sex were associated with prolonged LMOS. **Conclusions:** This study represents the largest multi-institutional analysis of LMD in patients with ALK+ NSCLC. Highly CNS-penetrant 3G ALK TKIs are associated with delayed LMD development and significantly improved survival following LMD diagnosis, whereas WBRT and intrathecal therapies confer limited benefit. These findings support the need for potent CNS-active ALK TKIs and prospective studies including patients with LMD in ALK-driven NSCLC. Research Sponsor: None.

Real-world effectiveness of MET inhibitors versus immunotherapy ± chemotherapy in 1L for patients with MET exon 14 skipping mutations in non-small cell lung cancer. First Author: Pranoti Pradhan, ConcertAI, LLC, Cambridge, MA

Background: Metastatic non-small cell lung cancer (mNSCLC) remains a leading cause of cancer-related deaths, with MET exon 14 skipping mutations (METex14) identified as a key oncogenic driver in 1%–4% of cases. MET tyrosine kinase inhibitors (TKI) such as capmatinib and tepotinib have demonstrated efficacy in clinical trials, leading to FDA approval in any treatment line. This study aims to compare first-line (1L) survival outcomes with MET TKI versus immune checkpoint inhibitors ± chemotherapy (IO ± Chemo). **Methods:** Patient characteristics and survival outcomes were retrospectively analyzed for METex14 mNSCLC patients who received 1L therapy with either (1) MET TKI (tepotinib and capmatinib) or (2) IO ± Chemo. Patients were excluded if they had EGFR alterations. Data were sourced from ConcertAI's Patient360 and RWD360, datasets sourced from oncology EHR in the US. **Results:** Among a total of 344 patients, 174 (50.6%) were > 80 years of age, 94 (87.9%) had non-squamous mNSCLC, 176 (51.2%) were female, and 71 (20.6%) had ECOG PS ≥2. As 1L, 202 received MET TKI, 61 received IO + Chemo, and 81 received IO only. Baseline clinicopathologic features were balanced except for a slightly higher proportion of patients with TPS PD-L1 ≥50 in the IO ± Chemo group ($p < 0.05$). At a median follow up of 40.7 months (mo), in the overall group median progression-free survival (mPFS) was 6.6 mo (95% CI: 5.8–8.8) and median overall survival (mOS) was 15.5 mo (95% CI: 14.4–18.3). MET TKI yielded a mPFS of 7.8 mo (95% CI: 6.2–9.1) and a mOS of 13.8 mo (95% CI: 11.4–17.6). IO ± Chemo resulted in a mPFS of 5.1 mo (95% CI: 3.7–8.2) and a mOS of 21.9 months (95% CI: 15.5–25.8). The mPFS did not differ significantly between groups (p =0.38), while mOS favored IO ± chemotherapy (p= 0.03). Objective response rate was 61.0% with MET TKI and 50.7% with IO ± Chemo (p= 0.74); disease control rate was significantly higher with MET TKI (77.0% vs 64.8%; p= 0.03). In subgroup analysis, among patients with PD-L1 ≥50, OS was significantly longer with 1L IO ± Chemo compared with MET TKI (22.0 mo, 95% CI: 7.5–34.3 vs. 8.5 mo, 95% CI: 6.6–16.5; $p < 0.02$). In contrast, among patients with PD-L1 < 50, MET TKI was associated with longer PFS (9.2 mo, 95% CI: 4.2–11.7 vs. 4.9 mo, 95% CI: 2.1–11.0; p= 0.07) although OS was similar (17.6 mo, 95% CI: 9.6–29.6 vs. 14.5 mo, 95% CI: 4.0–23.2; p= 0.57). **Conclusions:** Among patients with METex14 mNSCLC, those treated with 1L IO ± Chemo had a better OS compared to those treated with MET TKI. This seems especially valid for patients with PD-L1 ≥50, for whom IO ± Chemo significantly improved OS. However, patients with PD-L1 < 50 showed prolonged PFS when treated with MET TKI. This highlights the need for personalized treatment patterns in this patient population. Research Sponsor: ConcertAI, LLC.

ALFA score as a predictor of long-term benefit with frontline brigatinib in *ALK*+ advanced NSCLC: A ctDNA-based composite biomarker from ALTA-1L. First Author: Laura Mezquita, Hospital Clinic - IDIBAPS, Barcelona, Spain

Background: Optimal sequencing of ALK-TKI in 1st-line *ALK+* NSCLC remains controversial. Although 3rd-generation (G) TKI are increasingly used upfront, a subset of patients (pts) may achieve prolonged outcomes with 2ndG TKI. However, baseline (B) biomarkers to identify these pts are lacking. We evaluated whether a composite clinical-molecular score integrating (B) ctDNA and biological parameters could predict systemic and intracranial outcomes with upfront brigatinib. **Methods:** Post hoc analysis of pts with *ALK+* NSCLC from the ALTA-1L trial with available (B) ctDNA NGS. *ALK* variants, co-occurring genomic alterations (co-GAs), and clinical/biological variables (PS, albumin, derived neutrophil-to-lymphocyte ratio [dNLR], and metastatic sites) were analyzed. Independent prognostic factors for progression-free survival (PFS) and intracranial PFS (IC-PFS) were identified by multivariable Cox models. A composite score (ALFA), based on the Cox models' coefficients was developed. **Results:** Among 124 pts, ctDNA detected *ALK* variant in 53% (n = 66), mostly *EML4::ALK* (V1 n = 25, V3 n = 24, V2 n = 7, V5 n = 4). co-GAs were present in 46%, including suppressor gene alt. in 35%. High dNLR was observed in 34% and hypoalbuminemia in 21%. In multivariable analysis, high dNLR (HR 1.67, 95% CI 1.02–2.73; p = 0.04), low albumin (HR 0.34, CI 0.20-0.57; $p < 0.001$) and suppressor co-GAs (HR 2.24, CI 1.32-3.79; p = 0.003) were independently associated with shorter PFS. Non-V1 variants showed a trend toward inferior PFS (HR 1.73; p = 0.05). For IC-PFS, high dNLR (HR 1.52; p = 0.03), brain metastases (HR 2.98; $p < 0.001$), and suppressor co-GAs (HR 2.41; p = 0.002) remained independently prognostic. The ALFA score stratified pts into low- (59%), intermediate- (27%), and high-risk (14%) groups, with median PFS of 35.5, 11.1, and 5.5 months (mo.), respectively ($p < 0.0001$; c-index 0.72). A similar separation was observed for intracranial PFS (IC-PFS; $p < 0.0001$), with median IC-PFS not reached in the low-risk group, 21.1 mo in the intermediate-risk group, and 5.5 mo. in the high-risk group (c-index 0.72). Overall survival (OS) showed consistent and significant discrimination across ALFA risk groups (log-rank $p < 0.0001$) with a median OS NR in low-risk, 44.3 mo. in intermediate-risk, and 19.3 mo. in high-risk pts. **Conclusions:** The ALFA score integrates baseline ctDNA-derived molecular features with routine blood-based parameters to robustly stratify clinical outcomes in *ALK+* pts treated with frontline brigatinib. This composite score identifies a subset of patients with durable systemic and intracranial benefit from second-generation ALK inhibitors, supporting its potential role as a practical risk stratification tool in routine clinical practice. Research Sponsor: None.

Genomic determinants of resistance to BRAF/MEK inhibitors in *BRAF*^{V600E}–mutant non–small cell lung cancer. First Author: Eleonora Gariazzo, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: *BRAF* V600E mutations occur in approximately 2–3% of non–small cell lung cancer (NSCLC). BRAF/MEK inhibition (BRAFi+MEKi) yields high response rates and durable clinical benefit but acquired resistance is inevitable. BRAFi+MEKi therapy may select for resistant tumor clones, induce secondary genomic alterations, and drive changes in the tumor immunophenotype. However, the landscape of resistance mechanisms to BRAFi+MEKi in NSCLC remains largely unknown. **Methods:** We conducted a global, multicenter analysis of patients with advanced *BRAF* V600E–mutant NSCLC treated with BRAFi±MEKi across multiple academic centers and available public datasets. Eligible patients had matched pre- and post-treatment next-generation sequencing (NGS). Analyses were restricted to oncogenic or likely oncogenic alterations per OncoKB and/or ClinVar. **Results:** Among 33 patients with matched pre- and post– BRAFi±MEKi samples, median age was 66 years; 39.4% were women, 67.7% had a history of tobacco use, and 97.0% had adenocarcinoma at diagnosis. Objective response to BRAFi±MEKi in this cohort was 81.8%, while median progression-free survival was 8 months; only 3 patients (9.1%) had primary resistance. Acquired resistance mechanisms were diverse, encompassing reactivation of the RAS/RAF/ERK signaling pathway (via *BRAF*-dependent and *BRAF*-independent mechanisms), activation of alternative bypass pathways (e.g. PI3K/AKT and HIPPO), and alterations associated with cell-cycle dysregulation. Concurrent resistance mechanisms were identified in 12.1% of cases, and one patient developed histologic transformation to small-cell lung cancer (SCLC). No identifiable resistance mechanism was detected in 11 patients (33.3%). The most common acquired genomic alterations were *RAS* mutations, observed in 21.2% of cases (*NRAS* Q61K, n = 1; *NRAS* Q61R, n = 1; *KRAS* G12D, n = 1; *KRAS* G12V, n = 1; *KRAS* Q61R, n = 1; *NRAS* Q61R + *KRAS* 61H, n = 1; *KRAS* G12V + *KRAS* Q61H, n = 1), followed by *MET* amplifications (12.1%, n = 4). Additional acquired events included *BRAF* kinase-domain duplication, *MAP2K1* and *NF2* mutations, and *FGFR4* amplification. Putative resistance alterations involving DNA damage repair genes (e.g., CHEK2, BRIP1) were also identified. Clinically, one patient with acquired *MET* amplification showed loss of the *MET*-amplified clone on liquid biopsy after adding crizotinib to BRAFi+MEKi, without grade≥3 adverse events, suggesting a potentially targetable resistance mechanism with therapeutic implications. **Conclusions:** Our findings define the genomic landscape of acquired resistance to BRAFi+MEKi in *BRAF* V600E–mutant NSCLC and highlight the emergence of diverse resistance mechanisms, including SCLC transformation, *MET* amplification, and *RAS* mutations, several of which are potentially actionable and may inform rational post-BRAFi/MEKi therapeutic strategies. A phase Ib study of osimertinib and tegavivint as first-line therapy in patients with metastatic *EGFR*-mutated non–small cell lung cancer (NSCLC). First Author: Regan Michelle Memmott, Department of Internal Medicine, The Ohio State University - James Comprehensive Cancer Center, Columbus, OH

Background: EGFR TKIs improve clinical outcomes for patients with EGFR-mutated NSCLC. However, they are not curative even when combined with chemotherapy or antibody-based therapies because of slow-cycling, drug-tolerant cells that persist due to transcriptional reprogramming. This inevitably leads to tumor resistance and disease progression. Our preclinical studies showed that EGFR-mutated NSCLC cells enter a persistent state in response to TKIs due to increased transcriptional activity of β-catenin. Treatment of mice bearing EGFR-mutated NSCLC xenografts with an EGFR TKI and a β-catenin inhibitor caused a greater depth and duration of response than treatment with an EGFR TKI alone, which improved overall survival (OS). We also observed that patients with EGFR-mutated NSCLC who had the greatest increase in serum levels of the secreted β-catenin transcriptional target PAI-1 following treatment with a TKI had significantly worse progression free survival (PFS). These data led us to conduct a single-arm phase Ib clinical trial (NCT04780568) that investigated osimertinib in combination with tegavivint, an inhibitor of β-catenin transcriptional activity. **Methods:** Patients with metastatic EGFR-mutated (exon 19 deletion or L858R) NSCLC who had not received prior treatment with an EGFR TKI were eligible. All participants received osimertinib 80mg daily and were enrolled to escalating dose levels of tegavivint, which was administered weekly IV for 16 weeks. The primary objectives were to assess the safety and tolerability of the combination and to determine the recommended phase 2 dose (RP2D) of tegavivint. Secondary objectives measured the objective response rate (ORR), median PFS, and OS. **Results:** Fifteen evaluable patients received treatment on the dose escalation portion of this study, including six patients at the highest dose level of tegavivint (8 mg/kg), which was determined to be the RP2D. No dose limiting toxicities nor drug-related serious adverse events occurred. The adverse events that were observed included hematologic, skin, and GI toxicities, consistent with the known osimertinib toxicity profile. Pharmacokinetic analysis showed a dose-dependent increase in the C_{max} and AUC of tegavivint, and plasma levels of osimertinib were comparable to those seen historically when administered as a single agent. The ORR was 73% with 2 of 15 patients (13%) achieving a complete response. Median PFS was 20.6 months (95% CI: 7-32 months). OS data is still maturing. **Conclusions:** NCT04780568 showed that the combination of osimertinib and tegavivint was safe and tolerable as first-line therapy in patients with metastatic EGFR-mutated NSCLC. This novel combination has the potential to improve the depth and durability of response to EGFR TKIs, without significantly increasing toxicity, by targeting drug-tolerant persistence. Clinical trial information: NCT04780568. Research Sponsor: V Foundation; The Ohio State University Comprehensive Cancer Center Internal Research Program.

Five-year outcomes of osimertinib-based treatment in a phase III study comparing EGFR tyrosine kinase inhibitor (EGFR-TKI) monotherapy and EGFR-TKI with inserted cisplatin plus pemetrexed as a first-line treatment for advanced non-squamous non–small-cell lung cancer harboring *EGFR* mutation (JCOG1404/WJOG8214L). First Author: Shintaro Kanda, Shinshu Cancer Center, Shinshu University Hospital, Matsumoto, Japan

Background: JCOG1404/WJOG8214L was an open label, multicenter, randomized phase III study comparing EGFR-TKI monotherapy (gefitinib [Gef] or osimertinib [Osi]) and EGFR-TKI with inserted cisplatin plus pemetrexed as a first-line treatment for advanced non-squamous non–small-cell lung cancer harboring *EGFR* mutation (*EGFR*-NSqNSCLC). In the primary analysis, the insertion of platinum-doublet chemotherapy after the initial response to EGFR-TKI could improve progression-free survival (PFS), but not overall survival (OS) compared with EGFR-TKI monotherapy (Clin Cancer Res 2025;31:2317-26). This study was commenced using Gef in December 2015 and was switched to Osi in October 2018. 501 patients (pts) (308 in the Gef cohort, 193 in the Osi cohort) were enrolled to October 2020, but it resulted in later accrual and shorter follow-up for the Osi cohort at the time of the primary analysis (data cutoff November 2022; median follow-up of all randomized patients 36.0 months). Therefore, we conducted the five-year (5y) follow-up analysis of the Osi cohort. **Methods:** The key eligibility criteria were pts with advanced or recurrent *EGFR*-NSqNSCLC (exon 19 deletion or exon21 L858R), age 20 to 74 years, and PS 0 or 1. In the standard arm (SA), Gef or Osi was administrated until disease progression. In the experimental arm (EA), Gef or Osi was administered on days 1-56. Then, after a two-week drug-free period, three cycles of cisplatin and pemetrexed were administered on days 71, 92, and 113. Thereafter, Gef or Osi was reinitiated on day 134 and continued until disease progression. **Results:** From October 2018 to October 2020, 193 pts were enrolled in the Osi cohort (97 pts in SA and 96 pts in EA). Median follow-up was 64.8 months. Advanced stage and recurrent disease were 79% and 21%, female and male were 63% and 37%, exon 19 deletion and exon 21 L858R were 54% and 46%, PS 0 and 1 were 50% and 50%, $\geq$ 65 year and $<$ 65 year were 57% and 43%, central nerve metastasis (+) and (-) were 27% and 73%, respectively. Median OS were 54.0 months (95% confidence interval [CI] 44.4 to 66.0) in SA and 50.4 months (95% CI 43.2 to 69.6) in the EA (HR, 0.984; 95% CI, 0.684-1.415; p = 0.9279). 5y OS were 43.9% and 40.4%, respectively. Median PFS were 20.4 months (95% CI 14.4 to 28.8) in SA and 25.2 months (95% CI 18.0 to 33.6) in EA (HR, 0.902; 95% CI, 0.663-1.227; p = 0.5147). 5y PFS were 14.3% and 16.3%, respectively. **Conclusions:** The insertion of platinum-doublet chemotherapy after the initial response to Osi could not improve PFS and OS of pts with advanced *EGFR*-NSqNSCLC. On the other hand, JCOG1404/WJOG8214L demonstrated that Osi-based first-line treatment achieved 5y PFS in approximately 15% of this population, providing a benchmark for emerging Osi-based strategies. Comprehensive profiling of EGFR PACC mutations and their co-mutation landscape in Chinese patients with non–small cell lung cancer: A large-scale NGS study of 2,360 cases. First Author: Yuan Jiang, Hunan Cancer Hospital, Changsha, China

Background: EGFR PACC (P-loop and αC-helix compressing) mutations represent a group of noncanonical alterations located in critical structural regions of the EGFR kinase domain and have recently been implicated in reduced sensitivity to EGFR TKIs and treatment resistance. However, the prevalence, mutational spectrum, and co-mutation landscape of EGFR PACC mutations in Chinese patients with non–small cell lung cancer (NSCLC) remain poorly characterized. This study aimed to systematically delineate the molecular features of EGFR PACC mutations to inform molecular testing strategies and clinical decision-making. **Methods:** A total of 2,360 patients with NSCLC were enrolled. All tumor samples underwent NGS covering 733 cancer-related genes. The overall prevalence of EGFR PACC mutations, the distribution of individual PACC variants, and their co-occurrence with other EGFR alterations and non-EGFR driver mutations were comprehensively analyzed. **Results:** Among the 2,360 NSCLC patients, 112 harbored EGFR PACC mutations, yielding an overall prevalence of 4.74%. EGFR PACC mutations exhibited marked site heterogeneity. The most frequent variants were S768I (18/112), G719A (15/112), G719S (12/112), and G719C (8/112), followed by C797S (6/112), E709A (6/112), E709V (5/112), and E709K (5/112). The remaining PACC variants—including I740_K745dup, R776H, S752_I759del, V774M, E709_T710delinsD, G779F, K757R, L747P, L718V, R776C, A647T, K757M, L718Q, T751_I759delinsN, V769L, and V769M—were low-frequency events, underscoring substantial molecular diversity. In total, 61 PACC-associated co-mutation events were identified. Co-mutation analysis revealed that classic EGFR-sensitizing mutations predominated, with L858R as the most common co-occurring alteration (n = 10), followed by exon 19 deletion E746_A750del (n = 4) and L861Q (n = 3). Notably, T790M (n = 2) co-occurred with C797S PACC mutations, suggesting a potential role of PACC variants in the evolution of EGFR-TKI resistance. Beyond EGFR-intrinsic co-mutations, cross-driver co-mutations were also observed, including ROS1 (V1002A, I1685L), MET (V145A), and NRG1 (V516M) (each n = 2), indicating that a subset of EGFR PACC–mutant tumors may harbor more complex oncogenic signaling. **Conclusions:** EGFR PACC mutations occur at a non-negligible frequency in Chinese patients with NSCLC and display pronounced site heterogeneity. These mutations frequently co-exist with classic EGFR-sensitizing or resistance-associated alterations and, in some cases, with additional non-EGFR driver mutations, highlighting their potential biological and clinical relevance. Our findings underscore the importance of comprehensive NGS-based profiling for accurate detection of EGFR PACC mutations and their co-mutation landscape, thereby supporting precision treatment strategies. Efficacy and safety analysis of furmonertinib in the treatment of *EGFR*-mutated lung adenocarcinoma: A single-center real-world study based on high-risk stratification. First Author: Aliya Aosiman, Xinjiang International Medical Center (Xinjiang International Hospital, Xinjiang Academy of Medical Sciences), Urumqi, China

Background: Real-world data on furmonertinib, a third-generation EGFR-TKI, for high-risk EGFR-mutant NSCLC patients (e.g., with brain metastasis, high tumor burden) are limited. This study evaluated its efficacy and safety via risk stratification. **Methods:** This retrospective study included 98 patients with locally advanced/metastatic EGFR-mutant NSCLC treated with furmonertinib (first-or later-line) from Sep 2021 to Dec 2024. Patients were stratified into high-risk (n = 73) and non-high-risk (n = 25) groups based on predefined criteria (brain/leptomeningeal metastases, high tumor burden, key co-mutations like TP53, or acquired T790M). Primary endpoint was investigator-assessed PFS. Secondary endpoints included ORR, DCR, iORR, iPFS, and OS. Safety assessed TRAEs (CTCAE v5.0). **Results:** Median follow-up was 17.7 months. In first-line group (n = 43), ORR was 69.8%, DCR 83.72%; in later-line group (n = 55), ORR was 64%, DCR 72.73%. PFS did not differ significantly between lines (P = 0.22). Median PFS was not reached overall. High-risk stratification analysis showed median PFS of 26.41 months in non-high-risk group vs not reached in high-risk group, with significant difference (P = 0.009). However, PFS rates showed a time-dependent effect: non-high-risk group had higher early PFS (96.0% vs 76.0% at 6 months), but high-risk group showed higher late PFS (98.6% vs 52.9% at 24 months). A time-dependent model confirmed high-risk features were detrimental early (HR = 33.03, P = 0.016) but protective after 6 months (interaction HR = 0.01, P = 0.001). In patients with measurable brain metastases (n = 39), iORR was 79.5%; median iPFS was not reached. TP53 co-mutation within high-risk group did not affect PFS (P = 0.731). TRAEs occurred in 15.3% (all grade 1-2, most common rash [5.1%] and diarrhea [4.1%]). Grade $\geq$3 events occurred in 6.1%, primarily elevated transaminases. No dose adjustments/discontinuations or fatal toxicities occurred. **Conclusions:** Furmonertinib showed durable efficacy in EGFR-mutant NSCLC, unaffected by line of therapy. Risk stratification had time-dependent prognostic value, with high-risk features transforming into a protective factor for PFS after 6 months. Furmonertinib demonstrated strong intracranial activity (iORR 79.5%). TP53 co-mutation did not confer additional prognostic value in the high-risk subgroup. Furmonertinib was well-tolerated with a favorable safety profile. Research Sponsor: Tianshan Talents Program for the Cultivation of High-Level Talents in Medical and Health Field; TSYC202301A068.

Circulating tumor DNA dynamics following molecularly targeted therapy for non–small cell lung cancer. First Author: Justin Jee, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Biomarkers to guide treatment escalation following suboptimal response to molecular targeted therapy are urgently needed for patients (pts) with non-small cell lung cancer (NSCLC). Circulating tumor DNA (ctDNA) has shown promise for monitoring residual disease following definitive treatment, but ctDNA dynamics following targeted therapy response remain understudied. **Methods:** We examined a real-world, multi-institution cohort of pts with NSCLC undergoing personalized, tumor-informed ctDNA testing (Signatera, Natera, Inc.) and clinical annotations from a deidentified commercial claims dataset (Forian's Hybrid data ecosystem, CHRONOS). Longitudinal ctDNA results were evaluated before and after targeted therapy initiation and summarized by treatment line, clinical context, and demographic and clinicopathologic features as available. **Results:** We identified 839 pts (14.0%, 11.1%, 19.4%, and 55.5% with stages I, II, III, and IV) across 395 US institutions, who had ctDNA profiling and were treated with molecularly targeted agents. Median age was 71 years (range 25-93), 67.0% were female, and 85.3% had tumors with adenocarcinoma histology. Pts underwent a median of 4 ctDNA tests/pt (range: 1–58) over a median follow-up of 9 months (range: 0-75). Amongst ctDNA positive tests (n=1705 tests for 408 pts), median ctDNA levels were 1.20 mean tumor molecules/mL (range 0.01–36,599). Pts received osimertinib (58.5%), alectinib (10.7%), sotorasib (5.6%), adagrasib (3.7%), afatinib (3.7%), and capmatinib (3.0%). ctDNA tests prior to targeted therapy (baseline) were available for 336 patients, of which 49.7% (167/336) had detectable ctDNA ("ctDNA(+)"). Among these ctDNA(+) cases, 123 pts had longitudinal ctDNA assessment. ctDNA clearance observed in 38.2% (47/123); 52.1% (25/48) in stage I-III and 29.3% (22/75) in stage IV. Among the 169 pts with baseline ctDNA(-), 115 pts had ctDNA assessed longitudinally. Of these, 89.6% (103/115) remained serially negative, while 10.4% (12/115) had any time ctDNA(+). Among commonly used targeted therapies, ctDNA clearance was observed across multiple agents, and is summarized in table 1. We further analyzed associations between ctDNA dynamics, during different treatment lines, and clinical outcomes. **Conclusions:** In a multi-institution cohort, ctDNA clearance was observed in pts with NSCLC treated with molecularly targeted therapies. Clearance rates varied by treatment type. The use of ctDNA monitoring to guide treatment escalation in this population warrants further study. Research Sponsor: None.

Targeted Therapy	Pts with ctDNA available pre and post-therapy N	Pts with baseline ctDNA(+) N	Pts with ctDNA clearance N (%)
osimertinib	128	54	26 (48.1)
alectinib	22	7	3 (42.9)
sotorasib	15	14	4 (28.6)
adagrasib	12	10	2 (20.0)

Includes only therapies with more than 10 pts who had pre- and post-treatment ctDNA availability.

8653 Poster Session

Molecular and immune profiling of *BRAF*-mutated (*BRAF*^{MUT}) non-small cell lung cancer (NSCLC). First Author: Roupen Odabashian, Department of Hematology and Oncology, Karmanos Cancer Institute, Wayne State University, Detroit, MI

Background: *BRAF*^{MUT} occur in 6-7% of NSCLC and comprise of biologically distinct classes showing variable therapeutic responses. While Class 1 benefits from targeted therapy, molecular and immune determinants distinguishing *BRAF* classes remain incompletely characterized. We performed comprehensive profiling to identify class-specific biomarkers. **Methods:** 51,692 (BRAF wild-type [*BRAF*^{WT}]: n=48,288; *BRAF*^{MUT}: n=3404) NSCLC specimens underwent DNA (592-gene panel/whole-exome) and/or RNA (whole-transcriptome) sequencing at Caris Life Sciences. *BRAF*^{MUT} tumors were classified into 3 Classes, other pathogenic variants (O^{PV}), and unknown/unclassified variants (VUS). The tumor microenvironment (TME) was estimated using the QuanTIseq method. Overall survival (OS) and IO-associated survival (IO-OS) were derived from insurance claims and calculated from the date of tumor biopsy (OS) or IO initiation (IO-OS) to last contact using Kaplan-Meier estimates. Statistical significance was determined by Fisher's Exact, chi-square, and Mann-Whitney U test with adjustments for multiple comparisons ($P<0.05$). **Results:** Class 1 was significantly enriched for SETD2 mutations (mut) and more frequently PDL1+ (22c3, TPS>=1) while showing a lower prevalence of TMB-high (>=10 mut/Mb), TP53, STK11 and KEAP1 mut (Table). Class 2/3 tumors were moderately PDL1+ and TMB-high and enriched for STK11 and KEAP1 muts (Table). While both OPV and VUS were enriched for TMB-high and not PDL1, OPV was enriched in STK11, and VUS was enriched in TP53 mut (Table). Among BRAFMUT, Class 1 exhibited the highest infiltration of M1 macrophages (1.1-1.3-fold), neutrophils (1.2-1.3-fold) and the lowest infiltration of dendritic cells (0.4-0.8-fold). Class 2 and 3 had largely overlapping immune profiles. In metastatic NSCLC, only Class 1 and VUS demonstrated improved OS and IO-OS (vs BRAFWT, both $p<0.05$, Table). OPV had the poorest outcomes, exhibiting the shortest OS and shorter IO-OS relative to Class 1 and Class 2 (all $p<0.05$, Table). **Conclusions:** *BRAF*^{MUT} classes represent distinct molecular, immune and clinical phenotypes. Improved OS and IO-OS in Class 1 and VUS (vs WT) appears to arise from divergent molecular and immune interactions. These findings underscore the importance of evaluating of *BRAF*^{MUT} NSCLC beyond class 1-3, suggesting the expanded classification may have therapeutic and prognostic consequences. Research Sponsor: None.

Correlation of CT changes, PET response, and histopathologic tumor regression in treated advanced *EGFR*-mutant NSCLC before disease progression. First Author: Pei Hsing Chen, Division of Thoracic Surgery, Department of Surgery, College of Medicine, National Taiwan University Hospital and National Taiwan University, Taipei City, Taiwan

Background: Previous studies have examined the correlation between radiologic and pathologic responses using PET, CT, and histopathologic regression in patients receiving chemotherapy or immunotherapy. However, data on the relationship among these modalities after EGFR-TKI treatment remain limited, particularly in the context of emerging induction EGFR-TKI strategies. **Methods:** We conducted a two-arm, phase II clinical trial (PTR-1) enrolling patients with advanced EGFR-mutant NSCLC. After 12 weeks of EGFR-TKI therapy, participants were randomized (1:1) to either continue TKI treatment or undergo primary tumor resection. Surgery aimed to achieve locoregional control with negative margins, and lymph node dissection was not mandatory. All resected specimens were evaluated for pathologic response according to IASLC recommendations. Radiologic response was assessed by RECIST 1.1, and major pathologic response (MPR) and PET metabolic response were evaluated. **Results:** A total of 91 patients were enrolled, with 72 randomized into two treatment arms; 2 patients declined surgery. The median interval from treatment initiation to surgery was 3.7 months, and 18% of patients underwent resection beyond 4.5 months. Among the 34 resected cases, MPR was achieved in 29.4% (10/34) and pathologic complete response (pCR) in 5.9% (2/34). Patients harboring EGFR exon 19 deletions demonstrated higher rates of pathologic response than those with L858R mutations. The correlation between CT-based tumor regression and histopathologic response was weak (r = 0.30). Pathologic response rates were 24.5% in patients with partial response (PR) and 43.8% in those with stable disease (SD) by RECIST. The correlation coefficients between PR or SD status of the primary tumor and pathologic response were 0.15 and −0.29, respectively. Complete metabolic resolution on FDG-PET corresponded to MPR in 66% of cases. A preoperative SUVmax $<$ 2.5 was associated with a mean pathology residual viable tumor of 20.7% and a 42.8% MPR rate, while patients with $\geq$90% regression in PET signal achieved MPR in 66.6% of cases. **Conclusions:** CT-based tumor regression modestly reflects histopathologic response after EGFR-TKI induction but with poor correlation, particularly in radiologic SD cases. This represents the first trial-based dataset analyzing imaging–pathology correspondence in advanced EGFR-mutant NSCLC prior to disease progression. PET metabolic response demonstrated relatively better discrimination of major pathologic responders, though its predictive accuracy remains limited. These findings underscore the need for refined imaging biomarkers or other NGS data to identify optimal candidates for local consolidation therapy in late stage and future neoadjuvant setting in early stage strategies in EGFR-mutant NSCLC. Clinical trial information: NCT05215548. Research Sponsor: None.

Efbemalenograstim alfa for prophylaxis in non–small cell lung cancer patients patients with chemotherapy-induced febrile neutropenia: A randomized, multicenter, exploratory clinical trial. First Author: Mengjie Li, Tianjin Medical University Cancer Institute and Hospital, Tianjin, Tianjin, China

Background: Neutropenia is a common dose-limiting chemotherapy toxicity, with its severity and duration impairing therapeutic efficacy. In NSCLC management, chemotherapy regimens with high risk febrile neutropenia (FN) are relatively uncommon. However, real-world data show suboptimal prophylactic granulocyte colony-stimulating factor (G-CSF) use in intermediate risk FN patients with additional risk factors. This study evaluated efbemalenograstim alfa's efficacy and safety in maintaining absolute neutrophil count (ANC) during chemotherapy cycles in such NSCLC patients. **Methods:** This was a randomized, multicenter, exploratory clinical trial (NCT06143735) enrolling NSCLC patients receiving intermediate risk FN chemotherapy with additional risk factors. Eligible patients were randomized 2:1 into two groups: primary prophylaxis group (Group A) received subcutaneous efbemalenograstim alfa (20 mg) 48$\pm$4 h post-each chemo cycle starting from Cycle 1; secondary prophylaxis group (Group B) initiated treatment only upon grade $\geq$3 neutropenia (per CTCAE v5.0) in the prior cycle. All patients completed at least four cycles of platinum-based chemotherapy. The primary endpoint was the incidence of grade $\geq$3 neutropenia in Cycle 1 between the two strategies. Secondary endpoints included FN incidence, grade $\geq$3 neutropenia in subsequent cycles, and the occurrence of adverse events (AEs) or serious adverse events (SAEs). **Results:** As of Dec 31, 2025, 99 patients were enrolled; 93 (median age: 69 years; 61.3% with ECOG 0–1; 90.3% male) received $\geq$1 platinum-based chemo cycle; 83 received $\geq$1 efbemalenograstim alfa dose. Specifically, 61 patients were assigned to Group A and 32 to Group B (n = 93). In the first treatment cycle, the incidence of grade $\geq$3 neutropenia was 19.7% (12/61) in Group A vs. 50.0% (16/32) in Group B, representing a relative risk reduction (RRR) of 60.6% (absolute risk reduction: 30.3%; p = 0.002). Across all treatment cycles, the cycle-specific cumulative incidence of grade $\geq$3 neutropenia was 16.2% (32/198) in Group A vs. 25.6% (32/125) in Group B (p = 0.0382). FN occurred in 2 patients in both groups. Regarding safety, the most common adverse events (AEs) were hematological toxicities in both groups, with a numerically lower incidence of anemia, leukopenia, neutropenia, and thrombocytopenia in Group A than in Group B. Grade $\geq$3 AEs (52.5% vs. 43.8%, p = 0.514) and efbemalenograstim alfa-related treatment-emergent adverse events (TRAEs, 31.1% vs. 22.7%, p = 0.587) did not differ significantly. Pain-related TRAEs (mainly ankle pain and neuropathic pain) were reported in only 6 patients (7.2%) overall, with most being grade 1–2 per CTCAE v5.0 criteria. **Conclusions:** Efbemalenograstim alfa effectively reduces the incidence of chemotherapy-induced neutropenia and presents a favorable safety profile. Clinical trial information: NCT06143735. Research Sponsor: None.

Genomic clonality analysis of patients with metastatic lung-limited non–small cell lung carcinoma (NSCLC) who underwent double lung transplantation (DLT) across timepoints and tumor region. First Author: Sang Hwa Kim, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Double lung transplantation (DLT) registry aimed for lung-limited malignancies (DREAM) study (NCT05671887) cohort A evaluates DLT as a therapeutic strategy for patients with advanced bilateral lung-limited NSCLC. This is the first translational report of the genomic clonality analysis of the DREAM study across timepoints and tumor regions. **Methods:** Patients with advanced bilateral lung-limited NSCLC who underwent DLT at Northwestern Memorial Hospital between September 2021 and December 2025 were included in the DREAM study cohort A. Patients with extrapulmonary disease were excluded. The primary indications for DLT were disease refractory to systemic therapies, with or without respiratory failure. Tissue next generation sequencing (tNGS) data was collected from diagnosis, bilateral explant and recurrence samples. Commercial tNGS panels utilized include Altera, Caris, Foundation Medicine, Tempus xT, and PGDx. Truncal genetic mutations were identified from genes that were common to all tNGS panels. **Results:** Among 18 patients enrolled in DREAM study cohort A, 11 patients with bilateral tissue NGS were analyzed. The median age was 55.5 years (range 37-74), 9 (81%) were female, and 5 (45%) had a history of smoking. 6 patients (54%) had invasive mucinous adenocarcinoma histology. All 11 patients harbored common gene mutations in bilateral tumors and had common oncogenic genomic clones indicating a truncal mutation. Details are outlined in Table 1. **Conclusions:** All patients harbored common oncogenic driver mutations across all available specimens, providing definitive genomic evidence of a monoclonal origin. These findings not only distinguish intrapulmonary metastasis from multiple primary tumors but also support a common ancestral tumor clone that has progressed over time and space. Further characterization of tumor evolution in advanced bilateral lung-limited NSCLC is warranted. Clinical trial information: NCT05671887. Research Sponsor: None.

TPS8660 **Poster Session**

SigVie-003: Phase 3 trial of frontline sigvotatug vedotin plus pembrolizumab vs pembrolizumab alone in non-small cell lung cancer (NSCLC) with PD-L1 TPS ≥50%. First Author: Martin Reck, Airway Research Center North, Center for Lung Research, LungenClinic, Grosshansdorf, Germany

Background: Integrin beta-6 (IB6) is a tumor-associated membrane protein linked to poor outcomes in solid tumors, including NSCLC, where it is expressed in >90% of cases. Sigvotatug vedotin (SV), a novel, IB6-directed, vedotin-based, antibody-drug conjugate, has shown manageable safety and encouraging antitumor activity as monotherapy in advanced NSCLC in the phase 1 SGNB6A-001 study (Peters, ASCO 2024). Based on preclinical studies, SV may induce immunogenic cell death and enhance antitumor activity when used in conjunction with pembrolizumab, a PD-1 inhibitor. Therefore, SV plus pembrolizumab is also being evaluated in the SGNB6A-001 study. Initial results of the combination demonstrated promising antitumor activity with a manageable safety profile in advanced NSCLC (Sehgal, ASCO 2025). Based on these results, SV plus pembrolizumab is being investigated in the phase 3 SigVie-003 study. **Methods:** SigVie-003 (NCT06758401) is an open-label, randomized, controlled study evaluating the efficacy of SV plus pembrolizumab vs pembrolizumab monotherapy as first-line treatment in adults with locally advanced, unresectable, or metastatic NSCLC with high PD-L1 expression (tumor proportion score ≥50%). Patients (pts) with nonsquamous histology must have negative documentation for *EGFR*, *ALK*, and *ROS1* mutations and no known actionable genomic alterations with approved first-line treatments per local standard of care. Pts must have an ECOG PS of 0 or 1 and have adequate organ function. Pts with stable, definitively treated, or inactive brain metastases <0.5 cm are eligible. Approximately 714 pts will be randomized at a 1:1 ratio to receive either SV 1.8 mg/kg AiBW (adjusted ideal body weight) intravenously on days 1, 15, and 29 plus pembrolizumab 400 mg intravenously on day 1 of a 42-day cycle (Q6W) or pembrolizumab 400 mg monotherapy Q6W. Randomization will be stratified by histology (nonsquamous vs squamous), ECOG PS (0 vs 1), region (East Asia vs rest of world), and presence or absence of brain metastases. Dual primary endpoints are overall survival and progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1. Secondary endpoints include PFS by investigator per RECIST 1.1, confirmed objective response rate and duration of response by both BICR and investigator per RECIST 1.1, safety, and pharmacokinetics and immunogenicity of SV when combined with pembrolizumab. Enrollment began Jul 23, 2025. A genAI tool (2/27/25; Pfizer; GPT-4o) developed the 1st draft; authors assume content responsibility. Frontline sigvotatug vedotin plus pembrolizumab vs pembrolizumab for non-small cell lung cancer with PD-L1 tumor proportion score ≥50%: phase III study design, Reck M, et al., *Future Oncol*, Dec 13, 2025, Taylor & Francis, reprinted by permission of the publisher Informa UK Limited trading as Taylor & Francis Ltd. Clinical trial information: NCT06758401. Research Sponsor: Pfizer.

TPS8661 **Poster Session**

AndroMETa-Lung-713: A phase 2/3 study of telisotuzumab adizutecan (ABBV-400, Temab-A) vs standard of care (SOC) in patients with epidermal growth factor receptor (*EGFR*)–mutated non–small cell lung cancer (NSCLC). First Author: Adam Rock, Department of Medical Oncology, City of Hope Comprehensive Cancer Center, Duarte, CA

Background: Patients with advanced *EGFR*-mutated NSCLC routinely receive third-generation EGFR TKIs in first-line therapy, such as osimertinib or lazertinib, either as monotherapy or in combination with other agents. Following progression, available options primarily include platinum-doublet chemotherapy or amivantamab + chemotherapy, with country-specific approvals for additional agents including antibody-drug conjugates (ADCs). *MET* gene amplification and c-Met protein (also known as MET protein) overexpression are established mechanisms of acquired resistance to osimertinib. Temab-A is a c-Met–directed ADC composed of the telisotuzumab antibody linked to a potent topoisomerase 1 inhibitor payload and is designed to selectively target c-Met–expressing tumors. In the first-in-human study (NCT05029882), Temab-A demonstrated manageable safety and encouraging efficacy in heavily pretreated *EGFR*-mutated NSCLC (confirmed objective response rate [ORR] 63%; median duration of response 9.8 months; median progression-free survival [PFS] 10.9 months) (Camidge. JCO 2025;43: abstract 8512). **Methods:** AndroMETa-Lung-713 (NCT07155187) is a global, open-label, randomized phase 2/3 study enrolling adults with locally advanced or metastatic non-squamous *EGFR*-mutated NSCLC after progression on 1 prior third-generation EGFR TKI administered in the adjuvant, locally advanced, or metastatic setting, as monotherapy or in combination with other agents. Key eligibility criteria include ECOG PS 0–1, measurable disease per RECIST v1.1, exon 19 deletion or exon 21 L858R mutation, and provision of tumor tissue for c-Met protein immunohistochemistry. In phase 2, approximately 80 patients will be randomized 1:1 to Temab-A dose 1 or dose 2 IV every 3 weeks (Q3W) to select the recommended phase 3 dose (RP3D) on the basis of safety, efficacy, pharmacokinetics (PK), and available biomarker data. In phase 3, approximately 350 patients will be randomized 1:1 to Temab-A RP3D or investigator's-choice SOC (platinum-doublet chemotherapy or amivantamab + chemotherapy). Treatment continues until disease progression, intolerable toxicity, or other protocol-defined discontinuation criteria are met. The primary endpoints are ORR in phase 2 and PFS in phase 3, assessed by blinded independent central review. Tumor assessments are performed Q6W for 2 years, then Q12W. Assessment of PK, immunogenicity, and exploratory biomarker analyses, including c-Met protein expression levels and ctDNA dynamics, will be conducted. Clinical trial information: NCT07155187. Research Sponsor: None.

TPS8662 **Poster Session**

Petosemtamab plus pembrolizumab as first-line (1L) treatment of PD-L1 high metastatic non-small cell lung cancer (NSCLC): Global phase 2 trial. First Author: Paul K. Paik, Thoracic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: NSCLC has a heterogeneous biology frequently including high mutational burden, high EGFR expression and upregulated EGFR signaling that is associated with poor prognosis. In the first-line metastatic setting, combination regimens pairing platinum-based chemotherapy with immune checkpoint blockade are standard of care; however, most patients experience disease progression within the first year. Petosemtamab is a low-fucose human common light chain, IgG1 bispecific antibody targeting EGFR and leucine-rich repeat-containing G-protein coupled receptor 5 (LGR5). Petosemtamab mechanism of action includes inhibition of EGFR ligand binding and downstream signaling, degradation of EGFR via LGR5 internalization in EGFR/LGR5-expressing cells, and immune system activation via enhanced ADCC (Herpers et al. Nat Cancer 2022; Lundberg et al. Cancers 2025). Petosemtamab plus pembrolizumab has previously demonstrated clinically meaningful efficacy and a manageable safety profile in 1L PD-L1-positive recurrent/metastatic head and neck squamous cell carcinoma (van Herpen et al. ASCO 2025). **Methods:** MCLA-158-CL04 (NCT07353957) is an open-label, multicenter, phase 2 trial to investigate petosemtamab in combination with pembrolizumab in squamous (Sq) and non-SqNSCLC. Two cohorts will be evaluated in patients with PD-L1 high (TPS ≥50%) metastatic sqNSCLC and non-sqNSCLC, respectively, with no prior systemic treatment for metastatic disease. Patients will be treated with petosemtamab 1500 mg IV Q2W in combination with pembrolizumab 400 mg IV Q6W. The primary objective is investigator-assessed objective response rate. Enrollment of approximately 80 patients in North America, EU, and Asia-Pacific is planned. Clinical trial information: NCT07353957. Research Sponsor: Merus.

TPS8663 **Poster Session**

Telisotuzumab adizutecan (Temab-A) plus osimertinib (osi) as 1L treatment for unresectable/metastatic NSCLC. First Author: Yasushi Goto, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Most patients (pts) with EGFR-mutated (Mut) NSCLC and 1L osi treatment will eventually develop resistance. Although 1L combination strategies (osi+chemo or amivantamab+lazertinib) show potential long-term benefits, associated toxicities can impact quality of life. Temab-A, an antibody-drug conjugate with a topoisomerase 1 inhibitor payload, targets c-Met protein. *MET* gene amplification and c-Met protein expression are associated with poor survival outcomes in NSCLC. A Ph1 study of Temab-A in pts with refractory EGFR Mut NSCLC reported encouraging activity and a manageable safety profile (NCT05029882). Herein, we describe a Ph2/3 study of Temab-A+osi as 1L in pts with previously untreated, locally advanced or metastatic NSCLC harboring common EGFR Mut. **Methods:** Planned enrollment is ~194 pts in Ph2 and ~500 in Ph3 across ~200 sites in 22 countries. Adults (≥18 years) must have histologically/cytologically confirmed metastatic/locally advanced nonsquamous NSCLC with documented EGFR Mut and measurable disease by RECISTv1.1. Pts with prior EGFR tyrosine kinase inhibitor treatment in the metastatic setting are excluded. During dose escalation (Ph2), pts will receive Temab-A (1.6 or 2.4mg/kg) every 3 weeks (Q3W, 1 cycle) intravenously (IV) + 80mg osi daily. During dose expansion (Ph2), after 1 cycle of osi, pts will be randomized to receive Temab-A (1.6, 2.0, or 2.4mg/kg) Q3W IV + 80mg osi daily, or osi monotherapy, and stratified based on c-Met expression levels and history of CNS involvement. Ph2 primary objectives are safety/tolerability, efficacy as measured by objective response rate of Temab-A+osi, and determination of the recommended Ph3 dose (RP3D). Ph2 primary efficacy endpoint is objective response based on blinded independent central review assessment per RECIST v1.1. In Ph3, randomized pts will receive Temab-A+osi at RP3D or standard of care. Additional details for Ph3 will be confirmed after completion of Ph2. Clinical trial information: NCT05029882. Research Sponsor: None.

TPS8664 **Poster Session**

Combination of tulmimetostat and PD-1 blockade for patients with advanced non–small cell lung cancer who progressed from first or second line of treatments. First Author: Daniel Sanghoon Shin, Division of Hematology/Oncology, Veterans Affairs (VA) Greater Los Angeles Healthcare System, Houston, TX

Background: Immune checkpoint inhibitors (ICIs) have transformed advanced non–small cell lung cancer (NSCLC) treatment, yet many patients exhibit primary ICI resistance or progression after initial response. Epigenetic dysregulation, including aberrant EZH2-mediated trimethylation of histone H3 (H3K27me3), has been implicated in tumor immune evasion and reduced responsiveness to ICIs. Preclinical studies suggest that EZH2 inhibition may enhance antitumor immunity and potentiate PD-1 blockade. Tulmimetostat, a potent dual EZH2/EZH1 inhibitor, demonstrates favorable tolerability and antitumor activity across multiple solid tumors. We hypothesize that the addition of tulmimetostat to pembrolizumab may reverse the resistance to pembrolizumab in patients with ICI-refractory NSCLC. **Methods:** The primary objective of this open-label, single-arm, phase Ib/II study is to evaluate the safety, tolerability, and preliminary efficacy of combining tulmimetostat with pembrolizumab in Veterans with advanced NSCLC who have progressed after first- or second-line therapy, one of which must have included ICI. Key eligibility criteria include measurable disease per RECIST v1.1 and provision of adequate tumor tissue (archive or new). Tulmimetostat (200 mg or 300 mg) is administered orally once daily, beginning with a 7-day run-in period during cycle 1, followed by pembrolizumab 200 mg IV every 3 weeks. Treatment continues until confirmed disease progression, unacceptable toxicity, or withdrawal. Safety assessments include clinical exams, laboratory evaluations, ECGs, and CTCAE v5.0 grading of adverse events. Imaging is performed at baseline and every 9 weeks. Secondary endpoints include disease control rate, progression-free survival, and duration of response. Up to 18 patients will be enrolled in Phase Ib using a BOIN method to determine the dose-limiting toxicities (DLTs) and the recommended phase II dose (RP2D) of tulmimetostat. Phase II is a Simon optimal two-stage design to assess objective response rate (ORR) per RECIST v1.1. Subjects treated at the RP2D during phase Ib will be included in the efficacy analysis. In total, up to 66 patients will be enrolled across multiple VA sites. Optional on-treatment biopsies will be obtained at select timepoints. Biomarker analyses will include an assessment of H3K27me3 (Methyl Mark) and PD-L1 expression in tumor biopsy samples to explore epigenetic and immunologic correlates of treatment response. Correlative biomarker analyses, including H3K27me3 and PD-L1 expression in tumor biopsies, will offer insight into epigenetic and immunologic determinants of treatment response. Findings from this trial may support the development of a novel therapeutic approach for patients with NSCLC who have progressed after on standard immunotherapy or chemo-immunotherapy. Enrollment was initiated in January 2026. Clinical trial information: NCT05467748. Research Sponsor: VA ORD; CX002499-01.

TPS8665 **Poster Session**

Phase 2b randomized, blinded, placebo-controlled trial to investigate the efficacy and safety of visugromab added to pembrolizumab, pemetrexed, and carboplatin in first-line metastatic non-squamous NSCLC: GDFATHER-NSCLC-01. First Author: Martin Reck, Department of Thoracic Oncology, Airway Research Center North, German Center for Lung Research, LungClinic, Grosshansdorf, Germany

Background: Immune checkpoint inhibitors (ICIs) have improved outcomes in NSCLC, yet primary and secondary resistance remain common, limiting durable benefit. Growth differentiation factor 15 (GDF-15) has been implicated in ICI resistance. Clinical data for the anti–GDF-15 antibody visugromab in combination with nivolumab have been presented, demonstrating reinvigoration with deep and durable responses in relapsed/refractory solid tumors and increased efficacy in an ICI-naïve neoadjuvant setting, strongly supporting further evaluation in ICI-naïve NSCLC. This trial estimates the added clinical activity and safety of visugromab with standard chemo-immunotherapy and addresses primary immune resistance in first-line metastatic non-squamous NSCLC. **Methods:** GDFATHER-NSCLC-01 is a phase 2b, multicenter trial with an initial safety-run-in (SRI) followed by a randomized, double-blind, placebo-controlled part, conducted at >40 sites in seven countries across the US and Europe. The SRI employs a 3+3 dose escalation (two predefined visugromab dose levels; DLT window of 21 days) to determine the recommended dose for expansion; an independent data monitoring committee oversees escalation and the selection of the expansion dose. In the randomized part, participants with untreated metastatic non-squamous NSCLC (no actionable driver mutations), ECOG 0–1, are assigned 2:1 to receive visugromab or placebo in combination with pembrolizumab, pemetrexed, and carboplatin (21-day cycles). Brain metastases are allowed if untreated, asymptomatic and clinically stable, or if previously treated and stable per protocol. Patients are stratified according to PD-L1 tumor proportion score (<1% vs 1–49% vs ≥50%). The primary endpoint of the trial is objective response rate (RECIST v1.1). Key secondary endpoints include duration of response, progression-free survival, overall survival, safety, pharmacokinetics, and patient-reported outcomes; exploratory biomarker analyses are planned. The randomized part is not powered for statistical significance; the planned sample size is 90 participants, enabling descriptive estimation of effect sizes to inform future pivotal development. Enrollment status: The SRI has been completed. The randomized part is open to accrual; first patient pending. Clinical trial information: NCT07098988. Research Sponsor: CatalYm GmbH.

TPS8666 **Poster Session**

FUEL-IT Lung: Fasting to unleash and enhance lung cancer immunotherapy—A VA Lung Precision Oncology Program trial. First Author: Razan Aljaras, Indiana University School of Medicine, Indianapolis, IN

Background: Single-agent PD-(L)1 inhibitors are standard first-line therapy for advanced non-small cell lung cancer (NSCLC) with PD-L1 expression ≥50%, yielding objective response rates of approximately 45% and median overall survival of 20-26 months. However, immune-related adverse events (irAEs) occur in up to 20% of patients. Fasting-mimicking diets (FMD) induce metabolic reprogramming by reducing insulin-like growth factor 1 (IGF-1) and glucose while increasing IGF-binding protein 1. Preclinical data demonstrate that FMD enhances anti-tumor immunity by increasing T-cell mediated tumor cytotoxicity, reducing myeloid-derived suppressor cells, and suppressing T-regulatory cell function. Recent murine models show that FMD combined with anti-PD-L1 therapy prevents or reverses immune-mediated myocardial infiltration, reduces systemic inflammation, and is more effective than anti-PD-L1 alone in delaying tumor growth while reshaping the tumor microenvironment. Our prior feasibility study (IUSCCC-0662) in 10 advanced lung cancer patients demonstrated 80% compliance with FMD, with minimal toxicities. These findings suggest FMD may enhance checkpoint inhibitor efficacy while potentially reducing irAEs. **Methods:** This is an open-label, randomized pilot study evaluating the feasibility and safety of FMD combined with pembrolizumab in Veterans with newly diagnosed stage IV NSCLC and PD-L1 expression ≥50%. Eligible patients must have ECOG performance status 0-2 and adequate organ function. Patients receive pembrolizumab 200 mg IV every 3 weeks. The study employs a partial crossover design: Arm 1 receives regular diet with pembrolizumab for cycles 1-3, then crosses over to FMD with pembrolizumab for cycles 4-6; Arm 2 receives FMD with pembrolizumab for cycles 1-3, followed by regular diet thereafter. FMD consists of a 4-day cycle with calorie restriction (fats:carbs:protein ratio of 50:40:10) administered starting on the day of pembrolizumab infusion, followed by transitional diet on day 5, for 3 consecutive cycles. Primary endpoints include feasibility (proportion completing 3 FMD cycles, target ≥70%) and safety. Secondary endpoints include immune-mediated toxicity rates, objective response rate, disease control rate, and 12-month progression-free survival. Exploratory objectives assess FMD impact on metabolic markers (glucose, ketones, IGF-1, IGFBP-1), immune cell populations, body composition via CT imaging, physical function (Short Physical Performance Battery), and quality of life (FACT-L, EORTC QLQ-C30). Enrollment of 33 patients per arm is planned for total of 66 patients. Accrual began in October 2025. Clinical trial information: NCT06671613, Funded by VA ORD. Research Sponsor: This work is supported by a VA Merit, from the VA Clinical Science Research & Development Program.

TPS8667 **Poster Session**

Phase III study of multidisciplinary therapy combining local ablative therapy with immune-checkpoint inhibitors for patients with synchronous oligometastatic NSCLC (J-OLIGO: WJOG20924L). First Author: Taichi Miyawaki, Department of Respiratory Medicine, Juntendo University Hospital, Tokyo, Japan

Background: The standard of care for stage IV non-small cell lung cancer (NSCLC) patients without actionable driver mutations is immune-checkpoint inhibitors (ICIs) with or without platinum-based chemotherapy. For patients with synchronous oligometastatic disease, local ablative therapy (LAT) to all lesions, including primary sites, may improve survival based on several randomized phase II trials. Furthermore, combining LAT with ICIs may enhance anti-tumor immune responses by reducing tumor burden. However, a recent large phase II/III study failed to demonstrate a survival benefit for adding LAT to systemic therapy in patients with synchronous or induced oligometastatic NSCLC. Consequently, it remains unclear whether LAT provides a survival benefit in synchronous oligometastatic NSCLC. Based on the promising results from our preceding phase II trial (TRAP-OLIGO; WJOG11118L), we initiated this phase III trial to definitively evaluate the benefit of adding LAT to pembrolizumab plus platinum-based chemotherapy specifically for synchronous oligometastatic NSCLC. **Methods:** J-OLIGO is a multicenter, open-label, randomized phase III intergroup trial. Eligible patients have untreated stage IV NSCLC, ECOG PS 0-1, 1–3 metastases, and no actionable driver mutations. During the induction phase, patients receive 4 cycles of pembrolizumab plus platinum-based chemotherapy. Patients who achieve disease control with induction therapy and remain eligible for LAT to all residual lesions are randomized (1:1) to either the LAT group (Intervention) or the standard group (Control). The feasibility and appropriateness of LAT for each patient are evaluated by a multidisciplinary tumor board, consisting of medical oncologists, radiation oncologists, and thoracic surgeons, to ensure definitive treatment of all viable lesions. The LAT group receives definitive surgery and/or definitive radiotherapy to all sites, followed by maintenance pembrolizumab (±pemetrexed). Stratification factors include number of metastases, PD-L1 TPS, histology, and induction response. The primary endpoint is overall survival (OS), defined as the time from randomization. Secondary endpoints include progression-free survival (PFS), objective response rate (ORR), and the safety. Based on results from previous studies, the study has 80% power to detect a hazard ratio of 0.55 for OS (median OS: 20 vs. 36 months) with a one-sided alpha of 0.05. The target sample size is 150 patients for primary registration and 100 for secondary registration. Accrual began in October 2025 and is planned for 4 years, followed by a 4-year follow-up period. This trial is supported by the Japan Agency for Medical Research and Development (AMED) under the Project for Innovative Cancer Research. Clinical trial information: jRCTs041250114. Research Sponsor: Japan Agency for Medical Research and Development.

TPS8668 **Poster Session**

A phase 2/3 study of EIK1001 in combination with pembrolizumab and chemotherapy in participants with stage 4 non–small cell lung cancer (NSCLC) (TeLuRide-008). First Author: Dan Costin, White Plains Hospital, Center for Cancer Care, White Plains, NY

Background: Immune checkpoint inhibitors (ICIs) reverse tumor-induced immune suppression and promote effective anti-tumor T-cell responses. Current standard of care (SOC) for Stage 4 NSCLC combining ICIs (e.g. pembrolizumab [pembro]) plus histology-appropriate chemotherapy (chemo) confers significant clinical benefit over chemo alone, yet many patients progress nonetheless, highlighting a large unmet medical need in this disease. EIK1001, a Toll-like receptor (TLR) 7/8 dual agonist, activates myeloid and plasmacytoid dendritic cells stimulating innate and adaptive immunity. In completed Phase 1 and ongoing Phase 2 studies, EIK1001 exhibits a manageable safety profile and encouraging anti-tumor activity both as monotherapy and in combination with ICIs. **Methods:** TeLuRide-008 (NCT#07365319) is a global, multicenter, randomized, double-blind, placebo-controlled, adaptive Phase 2/3 study of EIK1001 or placebo, in combination with pembro and histology-appropriate chemo in systemic-therapy-naïve pts with stage 4 NSCLC. In Phase 2, pts are randomized 1:1:1 to receive 1 of 2 doses of EIK1001 or placebo, + pembro and chemo (Part 1:Dose optimization; n~120), followed by additional enrollment with 1:1 randomization of new pts (n~160), at the EIK1001 selected dose or placebo (Part 2: Dose Expansion; n~280). If the study proceeds to Phase 3 (Part 3: Confirmatory), ongoing Phase 2 pts to continue treatment, and n~440 new pts will be randomized 1:1 to receive the selected dose of EIK1001 or placebo, + pembro and chemo (n = up to 750). Key eligibility criteria: pts $\geq$ 18 years of age, life expectancy $\geq$ 3 months, stage 4 NSCLC (NSQ or SQ), no actionable mutations requiring targeted therapy, $\geq$ 1 measurable lesion per RECIST v1.1, and no history of symptomatic pneumonitis. Primary objectives: evaluate efficacy and safety of 2 doses of EIK1001 + pembro and chemo for dose optimization and compare PFS (RECIST v1.1 by BICR) and OS between the selected EIK1001 dose and placebo, + pembro and chemo. Secondary objectives: safety and tolerability, ORR and DOR per RECIST v1.1 by BICR. Exploratory objectives: time to response, EIK1001 exposure-response relationships, and health-related quality of life. Clinical trial information: NCT#07365319. Research Sponsor: None.

TPS8669 **Poster Session**

Lung-MAP S1800E: A randomized phase II/III study of docetaxel and ramucirumab with or without cemiplimab for patients previously treated with platinum-based chemotherapy and immunotherapy for stage IV or recurrent non-small cell lung cancer (NSCLC). First Author: Saiama Naheed Waqar, Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Integration of immunotherapy into first line systemic therapy for patients with metastatic NSCLC has led to improvement in survival, but most patients experience disease progression. Blockade of PD-1 and VEGFR2 synergistically inhibits tumor growth by reducing tumor neovascularization and leads to upregulation of proinflammatory cytokines. We hypothesize that continuing second line anti-PD-1 therapy using cemiplimab in combination with docetaxel and ramucirumab may reverse immunotherapy resistance, and lead to improved overall survival (OS) compared to docetaxel and ramucirumab. **Methods:** Lung-MAP is a master protocol for patients with previously treated advanced NSCLC. S1800E is a phase II/III non-match Lung-MAP substudy, in which patients are randomized 1:1 to receive either standard of care treatment with intravenous docetaxel and ramucirumab (arm A) or investigational treatment with intravenous docetaxel and ramucirumab in combination with cemiplimab (arm B). The primary objective is to compare OS between patients assigned to arm A and arm B who have acquired resistance to platinum-based chemotherapy and immunotherapy for Stage IV or recurrent NSCLC. The total enrollment goal is 378 patients based on a design with 90% power to rule out an HR = 1 at the 1-sided 2.5% level, if the true HR = 0.66. The design includes 3 interim analyses, with a safety run-in for the first 10 patients on arm B. The main inclusion criteria are patients who experienced disease progression 84 days or more following initiation of anti-PD-(L)1 immunotherapy, with complete response, partial response or stable disease as their best response, in addition to progression on or following platinum-based chemotherapy. If a known sensitizing molecular alteration for which an FDA-approved targeted therapy for NSCLC exists (e.g., *EGFR, ALK, ROS1, BRAF, RET, NTRK, KRAS, HER2*, and *MET* sensitizing mutations), patients must have previously received at least one line of targeted therapy. Prior docetaxel is not permitted, and there is a washout of 14 days from palliative radiation (shortened to 7 days for bone radiation) and 28 days from major surgery, with no plans for concurrent systemic therapy while on the clinical trial. Patients must have adequate organ and marrow function and ECOG performance status of 0-1. S1800E was activated on 4/28/2025, with first patient registered on 5/22/2025. As of 1/6/2026, 49 of the planned 378 patients have been enrolled. Clinical trial information: NCT06616584. Research Sponsor: NIH/NCI grants; U10CA18088, U10CA180819; Regeneron Pharmaceuticals.

TPS8670 **Poster Session**

INTerpath-013: A phase 2, randomized, double-blind study of intismeran autogene plus pembrolizumab and chemotherapy as first-line treatment for metastatic squamous non–small cell lung cancer. First Author: Enriqueta Felip, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Non–small-cell lung cancer (NSCLC) is the leading cause of cancer mortality worldwide. The anti-PD-1 pembrolizumab plus platinum-based chemotherapy is a recommended treatment for metastatic squamous NSCLC. Despite the inclusion of anti-PD-(L)1 therapies into treatment guidelines, there remains an unmet medical need for further improving patient outcomes. Intismeran autogene (intismeran; formerly V940, mRNA-4157) is an investigational mRNA-based individualized neoantigen therapy (INT) encoding up to 34 neoantigens unique to each patient's tumor and is designed to promote antitumor immune response. INTerpath-013 is a phase 2 study evaluating the addition of intismeran to pembrolizumab plus chemotherapy for previously untreated metastatic squamous NSCLC. **Methods:** This phase 2, randomized, double-blind, placebo-controlled study is enrolling patients aged $\geq$18 years with previously untreated histologically or cytologically confirmed stage IV squamous NSCLC (M1a, M1b, M1c1, or M1c2 per AJCC version 9) and measurable disease per RECIST v1.1 by investigator. Participants are also required to have ECOG PS 0 or 1 and provide a tumor sample for next-generation sequencing. Exclusion criteria include known active CNS metastases and/or carcinomatous meningitis, or untreated or symptomatic brain metastases. Approximately 180 participants will be randomized 2:1 to receive 1 treatment cycle comprising intravenous pembrolizumab 400 mg Q6W (1 dose) plus carboplatin AUC 6 mg/mL/min Q3W (2 doses), with either paclitaxel 200 mg/m^2 Q3W (2 doses) or nab-paclitaxel 100 mg/m^2 QW (6 doses). At week 6 (after cycle 1), tumor imaging will be performed and participants with complete response, partial response, or stable disease per RECIST v1.1 by BICR will continue 1 more treatment cycle and also receive up to 2 cycles of intismeran intramuscularly 1 mg (study arm A) or placebo (arm B) Q3W. All participants who complete the first 2 cycles of treatment will then receive up to 7 additional doses of intismeran or placebo (9 total) plus pembrolizumab up to 15 additional doses (17 total). Any participant with PD at the 6-week scan will have treatment unblinded and those in arm A may receive exploratory treatment with up to 9 doses of intismeran plus docetaxel 75 mg/m^2 Q3W until PD, unacceptable toxicity, or participant/physician decision; those in arm B will not receive further investigational treatment. Randomization will be stratified by PD-L1 tumor proportion score ($<$ 1% vs $\geq$1% to $\leq$49% vs $\geq$50%), ECOG PS (0 vs 1), and the number of metastatic sites (1 vs $>$ 1). Primary endpoints are PFS per RECIST v1.1 by BICR and OS. Secondary endpoints include ORR and duration of response per RECIST v1.1 by BICR and safety. Enrollment began in December 2025 and is ongoing across 55 global sites. Clinical trial information: NCT07221474. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.; N/A

TPS8671 **Poster Session**

Phase 3 trial ResQ201A of nogapendekin alfa inbakicept (NAI) plus tislelizumab and docetaxel vs. docetaxel monotherapy for advanced or metastatic NSCLC resistant to ICI therapy. First Author: Andreas Nicholas Saltos, Moffitt Cancer Center, Tampa, FL

Background: Immune checkpoint inhibitors (ICIs) are approved as monotherapy and in combination with chemotherapy in advanced NSCLC. Most patients experience progression with limited treatment options other than chemotherapy. NAI is a first-in-class IL-15 receptor agonist that induces proliferation and activation of natural killer cells, CD8+ T cells and memory T cells without activating regulatory T cells, enhancing both the innate and adaptive immune system to maximize immunogenic cell death. Phase 2 data demonstrated evidence of NAI prolonging OS when used in combination with an ICI. The rationale for ResQ201A (NCT06745908) is based on the prior QUILT-3.055 study, wherein median OS was prolonged at 14.3 months overall and 21.1 months when ALC≥1.2x10^3 was maintained with NAI as a lymphocyte stimulating agent. Randomized clinical trials have demonstrated that the standard of care docetaxel in the 2L+ NSCLC setting results in a mOS of approximately 9 months. **Methods:** ResQ201A is a randomized, open-label phase 3 global, registrational intent trial where 462 adult participants will be enrolled 2:1 in the experimental arm, consisting of two 3-week induction cycles of NAI [SC 1.2 mg], tislelizumab [IV 200 mg] and docetaxel [IV 75 mg/m^2] followed by maintenance NAI and tislelizumab, or a docetaxel monotherapy control arm [IV 75 mg/m^2] until disease progression or unacceptable toxicity. Participants are stratified based on histology, presence of actionable genomic alterations (AGA), and geographical region. Key inclusion criteria are pathologically confirmed stage IV NSCLC with acquired resistance to an ICI (PD after an initial response OR stable disease ≥ 6 mo. duration) to a single line of ICI with or without chemotherapy, ECOG 0 to 2, and measurable tumor lesions per RECIST v1.1. Key exclusion criteria are systemic autoimmune disease, history of organ transplant, and AGA of ALK. The primary endpoint is OS by KM with treatment arm comparison based on the stratified log-rank test and OS hazard ratio summarized based on the stratified Cox proportional hazard model, both stratified by the randomization strata. Secondary efficacy endpoints include iDCR per iRECIST; PFS, ORR and duration of response. Safety is graded using the NCI CTCAE v5.0. Exploratory analyses will be performed to meet objectives. This trial has enrolled and treated participants. Clinical trial information: NCT06745908. Research Sponsor: None.

TPS8672 **Poster Session**

A phase 3 study of ateganosine (THIO; 6-thio-2′-deoxyguanosine) sequenced with immune checkpoint inhibitor (ICI) versus standard-of-care chemotherapy in ICI-resistant advanced NSCLC: THIO-104 trial in progress. First Author: Tomasz Jankowski, Medical University in Lublin, Lublin, Poland

Background: Despite progress in the treatment of advanced non-small cell lung cancer (NSCLC), therapeutic options remain scarce for patients who have developed resistance to immune checkpoint inhibitors (ICIs). Ateganosine (THIO; 6-thio-2′-deoxyguanosine), a telomere-targeting agent, is selectively recognized by telomerase and integrated into the telomeres of cancer cells. Once incorporated, Ateganosine compromises the telomere structure and function, leading to 'uncapping' of the chromosome ends and thus resulting in rapid tumor cell apoptosis. **Methods:** THIO-104 is a multicenter, open-label, randomized Phase 3 study enrolling approximately 300 subjects with histologically confirmed advanced/metastatic NSCLC. Eligible participants must have received two prior lines of systemic treatment, including at least one line of ICIs and platinum-based chemotherapy. Participants will be randomized 1:1 to receive either THIO 180 mg per cycle (60 mg IV on Days 1-3 of a 3-week cycle) followed by cemiplimab 350 mg IV on Day 5, or single-agent chemotherapy (vinorelbine, gemcitabine, or docetaxel). The primary endpoint is overall survival (OS). Secondary endpoints include objective response rate (ORR), progression-free survival (PFS) and duration of response (DoR). Current Status: Enrollment is ongoing , preliminary safety data and efficacy outcomes will be assessed through scheduled interim analyses. **Conclusion:** THIO-104 will provide critical insights into the potential role of telomere-targeting agents in restoring tumor sensitivity to ICIs in NSCLC. The study will also explore key biomarkers to further characterize Ateganosine's mechanism of action and its potential to predict patient response to therapy. Clinical trial information: 2024-520164-33-00. Research Sponsor: None.

TPS8673 **Poster Session**

Randomized phase 3 study (MarsLight-11) evaluating IBI363 (TAK-928) versus docetaxel in patients (pts) with squamous non-small cell lung cancer (sqNSCLC) after prior chemotherapy (chemo) and immunotherapy (IO). First Author: Roy S. Herbst, Department of Medical Oncology and Hematology, Yale School of Medicine, New Haven, CT

Background: In most series, sqNSCLC has worse clinical outcomes compared with non-squamous NSCLC with IO combinations. After chemo and IO failure, docetaxel±ramucirumab remains the standard of care for advanced sqNSCLC, but offers only short-lived disease control (median progression-free survival [PFS] of approximately 3–4 months), and high rates of severe toxicities. Thus, effective post-chemo and IO options for advanced sqNSCLC remain a significant unmet clinical need. IBI363 is a first-in-class, PD-1/IL-2$^{\alpha\text{-bias}}$ bispecific antibody fusion protein designed to block the PD-1/PD-L1 pathway and simultaneously activate the IL-2 pathway. It selectively expands and rejuvenates exhausted tumor-specific T cells by cis-activating IL-2 receptors. The IL-2 arm of IBI363 is engineered to retain its affinity for IL-2Rα while reducing binding to IL-2Rβ and IL-2Rγ thereby minimizing off-target toxicity. This dual mechanism has shown potential to address the unmet clinical needs of pts with IO-resistant and immune-cold tumors. In prior phase 1/2 studies, IBI363 monotherapy at 3 mg/kg every 3 weeks (Q3W) was well-tolerated and showed encouraging, durable efficacy in pts with advanced, IO-treated NSCLC and other solid tumors (2025 ASCO [8509, 2502 and 104]). Here, we present the trial in progress for MarsLight-11 (NCT07217301), a randomized, open-label, multi-regional Phase 3 study evaluating IBI363 versus docetaxel in pts with sqNSCLC after prior chemo and IO. **Methods:** This study is enrolling eligible pts with unresectable, locally advanced or metastatic sqNSCLC who have progressed on or after platinum-based chemo and anti-PD-1/PD-L1 treatments (defined as radiographic progression per RECIST v1.1 during or within 6 months after discontinuation of IO). Pts with known actionable genomic alterations, active or symptomatic brain metastases are excluded. Pts are randomized 1:1 to IBI363 or docetaxel (control). Stratification factors include the type of IO resistance (primary vs. acquired), the sequence of prior IO and chemo (concurrent vs. sequential), and region (Asia vs. non-Asia). Pts in the experimental arm will receive a priming dose of IBI363 (0.1 mg/kg) seven days prior to the first full dose (3 mg/kg Q3W). The control arm will receive docetaxel (75 mg/m² Q3W). The primary endpoint is overall survival (OS). Secondary endpoints include investigator-assessed PFS, objective response rate, disease control rate, duration of response, and time to response per RECIST v1.1, as well as safety, pharmacokinetics, and immunogenicity. One interim analysis (IA1) and one final analysis are planned for OS. The study plans to enroll approximately 600 pts globally, including sites in China, the United States, Canada, the European Union, the United Kingdom, Japan and South Korea. Clinical trial information: NCT07217301. Research Sponsor: None.

TPS8674 **Poster Session**

A randomized phase III trial of chemo-immunotherapy vs immunotherapy alone for the vulnerable older adult with advanced non–small cell lung cancer: The ACHIEVE study—ECOG-ACRIN EA5221. First Author: Megan Ann Baumgart, University of Rochester, Rochester, NY

Background: Lung cancer disproportionately affects older adults, with 70% of cases diagnosed in patients ≥65 years old, though older adults are often underrepresented in clinical trials.[1,2] KEYNOTE-189[3] and KEYNOTE-407[4] studies established superiority of chemotherapy-immunotherapy (chemo-IO) compared to chemotherapy irrespective of PD-L1 tumor proportion score (TPS) in patients with ECOG PS 0-1. Single-agent pembrolizumab was also shown to be superior to chemotherapy based on KEYNOTE-024[5] and KEYNOTE-042[6] studies. KEYNOTE-189[3]/407[4] studies highlighted synergistic benefit from chemo-IO across TPS subsets while single-agent IO benefit is mostly in the TPS ≥50% population. It is unknown if single-agent IO versus chemo-IO is superior for patients with PD-L1 TPS 1-49%, especially in older adults. There is increased risk for toxicity for adults with co-morbidities and impaired function that is enriched along the age continuum. Use of single-agent IO may limit benefit from synergy. Alternatively, chemo may increase toxicity and adversely impact quality of life (QOL) and survival in older adults. The goal of this study is to evaluate overall survival (OS) in older adults with metastatic NSCLC, PD-L1 TPS 1-49% treated with first-line single-agent IO versus chemo-IO. **Methods:** This phase 3 study randomizes (1:1) patients age ≥70 years old with metastatic NSCLC, PD-L1 TPS 1-49% to treatment with pembrolizumab versus pembrolizumab plus chemotherapy with primary endpoint of OS. Patients undergo an abbreviated baseline geriatric assessment (GA) of function, nutrition, cognition, and QOL with opportunity for modification of chemotherapy regimen and dosing based on results. Patients are treated with 4 cycles of induction pembrolizumab 200 mg IV every 3 weeks (Arm A) or 4 cycles of induction pembrolizumab 200 mg IV every 3 weeks in combination with chemotherapy (Arm B). Chemotherapy is investigator-selected from platinum doublet (carboplatin/pemetrexed, carboplatin/paclitaxel, carboplatin/*nab*-paclitaxel) or single-agent options (pemetrexed, paclitaxel, *nab*-paclitaxel) with dose attenuation per investigator discretion. Induction is followed by up to two years of maintenance pembrolizumab (200 mg IV every 3 weeks or 400 mg IV every 6 weeks) with option for continuing maintenance pemetrexed. Modified GA is repeated at specified time points. Optional stool studies are collected at baseline and after four cycles of therapy. Secondary endpoints include progression-free survival, objective response rate, tolerability and QOL. Exploratory aims evaluate GA metrics as predictors of clinical outcomes and relate gut microbe diversity and abundance to treatment outcomes. Efficacy analyses are conducted on an intention-to-treat basis. Enrollment is ongoing, and current accrual (as of January 6, 2026) is 22 of 304. Clinical trial information: NCT06096844. Research Sponsor: National Cancer Institute.

TPS8675 **Poster Session**

ALPACCA: Phase 3 trial of firmonertinib vs investigator's choice of EGFR inhibitor as first-line treatment for locally advanced or metastatic NSCLC with EGFR P-loop and alpha c-helix compressing (PACC) uncommon mutations (FURMO-006). First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite advances in treatment of NSCLC with EGFR classical mutations, no universally accepted standard-of-care treatment exists for patients with EGFR uncommon mutations including PACC mutations. Treatment options include EGFR tyrosine kinase inhibitors (TKIs) (osimertinib, afatinib), chemotherapy, or other targeted therapies (amivantamab for exon 20 insertion mutations). EGFR PACC mutations comprise approximately 12.5% of all NSCLC EGFR mutations (Robichaux et al 2021, Nilsson et al 2024). Firmonertinib is a once daily oral, highly brain penetrant, broadly active mutant-selective EGFR inhibitor that targets classical and uncommon mutations (Musib et al., NACLC 2022). In the phase 1b FURMO-002 study (FURTHER), first-line locally advanced or metastatic EGFR PACC mutation NSCLC patients treated with firmonertinib 240 mg daily achieved a confirmed ORR of 68.2%, best ORR of 81.8%, disease control rate (DCR) of 100%, and median progression-free survival (mPFS) of 16.5 months by blinded independent central review (BICR) (Le et al., WCLC 2025). Firmonertinib was generally well-tolerated with manageable EGFR TKI-associated adverse events. **Methods:** ALPACCA (FURMO-006; NCT07185997) is a global, phase 3, randomized, open-label study investigating firmonertinib vs investigator's choice of osimertinib or afatinib. Eligible patients have locally advanced or metastatic NSCLC with EGFR PACC mutations. Key inclusion criteria include documented presence of EGFR PACC mutation and measurable disease per RECIST v1.1. Patients with asymptomatic CNS metastases are allowed. Key exclusion criteria include prior systemic anticancer therapy in the locally advanced or metastatic setting or any prior EGFR TKI therapy. Approximately 480 patients will be randomized 1:1 to receive firmonertinib 240 mg daily or investigator's choice of osimertinib 80 mg daily or afatinib 40 mg daily. Primary endpoints are PFS and ORR per RECIST v1.1 by BICR. Key secondary endpoints include OS, investigator assessed PFS and ORR, and safety and tolerability. Enrollment is ongoing. Clinical trial information: NCT07185997. Research Sponsor: ArriVent BioPharma Inc.

TPS8676 **Poster Session**

Randomized phase II study of amivantamab + lazertinib versus afatinib in patients with uncommon/compound *EGFR*-mutated non-small cell lung cancer (WJOG17323L: AGEHA study). First Author: Taichi Miyawaki, Department of Respiratory Medicine, Juntendo University Hospital, Tokyo, Japan

Background: While EGFR tyrosine kinase inhibitors (TKIs) such as afatinib are standard treatments for patients with advanced non-small cell lung cancer (NSCLC) harboring uncommon or compound *EGFR* mutations (excluding exon 20 insertions and T790M), the duration of response is often limited, with a median progression-free survival (PFS) of approximately 8 to 10 months. Amivantamab is an EGFR mesenchymal–epithelial transition factor (MET) bispecific antibody with immune cell–directing activity that has multiple mechanisms of action as defined in preclinical models. For common *EGFR* mutated NSCLC, combination therapy with lazertinib has been approved in several countries based on its superiority in Phase III trial. Although a phase I study of amivantamab plus lazertinib combination therapy showed promising efficacy with a median PFS of 19.5 months in treatment-naïve patients with uncommon or compound *EGFR* mutations, this was a small-scale non-comparative study where efficacy was not the primary endpoint. The AGEHA study (WJOG17323L) is designed to prospectively evaluate whether amivantamab + lazertinib provides superior efficacy and acceptable safety compared to afatinib in patients with treatment-naïve, uncommon or compound *EGFR* mutated NSCLC. **Methods:** This multicenter, randomized, open-label, phase II trial is conducted by the West Japan Oncology Group (WJOG). Eligible patients are randomized in a 1:1 ratio to receive either combination therapy with amivantamab plus lazertinib in Arm A, or afatinib monotherapy in Arm B. The primary objective is to compare PFS between the two treatment arms. Secondary objectives include safety, overall response rate, and overall survival. Additionally, mandatory blood samples are collected at baseline and at the time of disease progression for comprehensive biomarker analysis using the Guardant Health platform to identify molecular predictors of response and resistance mechanisms, including approximately 740 gene alterations and methylation abnormalities. The target sample size is 70 patients (35 per arm). This study is designed with a one-sided alpha of 0.1 and a power of 80% to detect the superiority of amivantamab plus lazertinib over afatinib monotherapy. The primary analysis will compare PFS using a stratified log-rank test, and hazard ratios will be estimated using a Cox proportional hazards model. Key Eligibility Criteria: Patients must be histologically confirmed advanced or recurrent non-squamous NSCLC harboring uncommon or compound *EGFR* mutations, excluding exon 20 insertions and T790M. Participants must be treatment-naïve for advanced disease with an ECOG performance status of 0–1. Patient enrollment began in January 2026, with a recruitment period of two years and a total study duration of five years. Clinical trial information: jRCTs031250560. Research Sponsor: Janssen Pharmaceutical K.K.

TPS8677 **Poster Session**

A randomized phase II study of capmatinib plus osimertinib with or without ramucirumab in patients with *EGFR*-mutant, *MET*-amplified stage IV or recurrent no–small cell lung cancer (Lung-MAP Sub-Study S1900G). First Author: Sarah B. Goldberg, Yale Cancer Center, New Haven, CT

Background: Patients (pts) with advanced *EGFR*-mutant non-small cell lung cancer (NSCLC) typically respond well to first-line tyrosine kinase inhibitor (TKI) therapy, however disease progression is inevitable. A common mechanism of resistance to third-generation EGFR TKIs is *MET* amplification in up to 15% of patients. Prior trials have demonstrated efficacy of combined EGFR and MET TKI for patients with acquired *MET* amplification, however treatment can be limited by toxicity due to peripheral edema. Preclinical evidence demonstrates the benefit of VEGF inhibition combined with an EGFR TKI and MET TKI, both in efficacy and reduced edema. Lung MAP S1900G is a randomized phase II trial of osimertinib and capmatinib plus or minus the VEGFR2 inhibitor ramucirumab in patients with *EGFR*-mutant NSCLC and *MET* amplification after progression on osimertinib. **Methods:** Pts have stage IV or recurrent NSCLC with a sensitizing *EGFR* mutation and have disease progression on osimertinib alone or in combination with other agents. Documentation of *MET* amplification must be determined by tissue- or blood-based assay; testing for *MET* amplification can be done locally or centrally through the LUNGMAP screening process and any level of amplification is allowed. Measurable disease is not required. Patients with asymptomatic treated or untreated brain metastases are eligible. Prior VEGF inhibitor or MET antibody (such as amivantamab) are allowed. Pts are randomly assigned to receive osimertinib 80mg by mouth daily, capmatinib 400mg by mouth twice daily, and ramucirumab 10m/kg intravenously on days 1 and 15 of a 28 day cycle, or osimertinib plus capmatinib alone. Treatment continues until disease progression, symptomatic deterioration, unacceptable toxicity or treatment delay greater than 28 days. Disease assessment per RECIST 1.1 is performed every 8 weeks for the first year and every 12 weeks thereafter. The primary endpoint is investigator-assessed progression-free survival (PFS) and secondary endpoints include toxicity, ORR, duration of response, overall survival, rates of edema, and change in weight. A safety run-in of the first 10 pts in each arm evaluable for dose-limiting toxicity is included due to limited safety data on both the doublet and triplet combinations. The target sample size is 40 eligible pts (20 per arm) which will provide 85% power to rule out no difference at a 1-sided 15% level if the true hazard ratio is 0.5. A hazard ratio of 0.71 or less, equivalent to a 2.4 month difference in median PFS, will be consistent with rejecting the null hypothesis. Accrual is ongoing, with 24 of 40 patients enrolled. S1900G is the first Lung-MAP sub-study that focuses on *EGFR*-mutant lung cancer, representing a new era for this platform trial. Clinical trial information: NCT05642572. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; U10CA18088; National Cancer Institute/U.S. National Institutes of Health; U10CA180819; Novartis; Eli Lilly.

TPS8678 **Poster Session**

First-in-human phase I, open-label, multicenter study of HJ-004, a novel EGFR-PROTAC degrader, in patients with advanced *EGFR*-mutated non–small cell lung cancer. First Author: Xinru Chen, Department of Oncology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China

Background: Despite remarkable progress with 1st- to 3rd-generation epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs), nearly all patients with EGFR-mutated non-small cell lung cancer (NSCLC) eventually develop acquired resistance through secondary EGFR mutations, bypass pathway activation, or histologic transformation. Targeted options that specifically address EGFR-dependent (on-target) resistance after progression on 3rd-generation EGFR-TKIs remain limited. HJ-004 is an orally bioavailable, highly selective proteolysis-targeting chimera (PROTAC) that degrades mutant EGFR by recruiting the cereblon (CRBN) E3 ubiquitin ligase. Preclinically, HJ-004 showed broad activity against classical, uncommon, and osimertinib-resistant EGFR variants with favorable pharmacokinetics (PK) and safety profiles. **Methods:** This first-in-human, phase I, multicenter, open-label study evaluates the safety, tolerability, PK, and preliminary antitumor activity of HJ-004 in patients with recurrent or metastatic EGFR-mutant non-squamous NSCLC. The study comprises two parts: dose escalation and dose expansion. In the dose-escalation phase, oral HJ-004 is administered once daily in 28-day cycles using accelerated titration followed by a conventional 3 + 3 design (planned doses: 12.5, 25, 50, 87.5, 125, and 162.5 mg). Dose-limiting toxicities (DLTs) are assessed during the single-dose (C0D1-C0D3) and first multiple-dose cycle (C1D1-C1D28) periods. The expansion phase will enroll approximately 20-40 participants in two dose cohorts to further evaluate safety, PK, and preliminary efficacy. Key eligibility criteria include measurable disease per RECIST v1.1 and adequate organ function. The trial is currently ongoing and is expected to enroll up to 76 patients. The phase I study initiated in 2025, and site activation and patient screening are currently underway. No safety or efficacy data are yet available. Enrollment is projected to be completed in 2027, and updated enrollment and PK data will be presented at a future meeting. Clinical trial information: NCT07361237. Research Sponsor: None.

TPS8679 **Poster Session**

KEYMAKER-U01J: Calderasib plus pembrolizumab with or without cetuximab as first-line treatment for advanced or metastatic nonsquamous non–small-cell lung cancer (NSCLC) with *KRAS* G12C mutations. First Author: Qing Zhou, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China

Background: The anti–PD-1 pembrolizumab (pembro) + chemotherapy (chemo) is a standard of care first-line therapy for metastatic NSCLC with no *EGFR* or *ALK* alterations. Despite these advances, here remains an unmet need for patients with tumors that have certain mutations, including those in the *KRAS* gene. *KRAS* mutations are associated with poor OS in NSCLC. Calderasib (MK-1084), a next-generation, selective *KRAS* G12C-GDP covalent inhibitor, has previously demonstrated preliminary antitumor activity in combination with pembro ± chemo in *KRAS* G12C–mutant metastatic NSCLC in the phase 1 KANDLELIT-001 study. The anti-EGFR cetuximab has shown promising efficacy in combination therapies in NSCLC with *KRAS* G12C mutations. The phase 2 KEYMAKER-U01J study (NCT07252739) is evaluating the addition of investigational agents to pembro in advanced or metastatic nonsquamous NSCLC with *KRAS* G12C mutations; the treatment arms presented here include pembro + calderasib ± cetuximab. **Methods:** This phase 2, randomized, open-label study is enrolling participants (pts) aged ≥18 years with previously untreated histologically or cytologically confirmed stage IIIB, IIIC, or IV (M1a, M1b, or M1c) nonsquamous NSCLC (AJCC v9), with a *KRAS* G12C mutation that is ineligible for curative resection or chemoradiation. Pts must also have measurable disease per RECIST v1.1, an ECOG PS of 0 or 1, and provide a tumor sample for biomarker analysis. Following a safety lead-in of ~10 pts in arm 3, 1:1:1 randomization of ~120 pts will occur. In arm 1 (control arm), pts will receive up to 18 cycles of pembro 400 mg Q6W intravenously (IV) plus carboplatin AUC 5 mg/mL/min up to 2 cycles and pemetrexed 500 mg/m^2 Q3W until discontinuation criteria are met. Pts in arm 2 (reference arm) will receive up to 18 cycles of pembro 400 mg IV Q6W plus calderasib orally until discontinuation criteria are met. Pts in arm 3 will receive up to 18 cycles of pembro 400 mg IV Q6W plus calderasib with cetuximab 500 mg/m^2 IV Q2W until discontinuation criteria are met. Discontinuation criteria include unacceptable AEs, PD, occurrence/progression of another malignancy, or pt/physician withdrawal. Randomization will be stratified by PD-L1 tumor proportion score (< 50% vs ≥50%). Dual primary endpoints are safety (dose-limiting toxicities, AEs, and AEs leading to study discontinuations) and objective response (CR or PR) per RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints are duration of response and PFS per RECIST v1.1 by BICR, OS, and pharmacokinetic characterization. On-study tumor imaging will occur Q6W until week 24, Q9W until week 51, then Q12W, or more frequently if clinically indicated. AEs will be graded per NCI CTCAE v5.0. Enrollment began in December 2025, with 80–105 sites scheduled to enroll globally. Clinical trial information: NCT07252739. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

TPS8680 **Poster Session**

A phase II study of amivantamab hyaluronidase in *MET* amplification–positive stage IV or recurrent non–small cell lung cancer (Lung-MAP Sub-Study). First Author: Christian Diego Rolfo, Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: *MET* amplification is a known oncogenic driver in non-small cell lung cancer (NSCLC), estimated to occur in approximately 3-4% of non-squamous (nsq) and squamous (sq) cases. While targeted therapies such as tyrosine kinase inhibitors (TKIs) have demonstrated activity in this population, with objective response rates (ORR) approximating 30%, there is a need for novel therapeutic approaches, particularly for patients who have progressed on standard systemic therapies. Amivantamab hyaluronidase is a fully human bispecific antibody targeting *EGFR* and *MET* co-formulated with recombinant human hyaluronidase (rHuPH20) for subcutaneous administration. The mechanism of action involves the inhibition of *EGFR* and *MET* signaling, receptor degradation, and the induction of antibody-dependent cellular cytotoxicity. S1900J is evaluating the efficacy of this subcutaneous formulation in specific histological cohorts. **Methods:** S1900J is a 2-stage, single arm phase II biomarker-driven Lung-MAP substudy. The study includes 2 cohorts of Stage IV or recurrent NSCLC, based on histology (non-squamous and squamous NSCLC). Biomarker eligibility requires documentation of *MET* amplification as primary driver via tissue or ctDNA NGS. Participants must have received at least one prior line of systemic therapy; notably, patients who have received prior *MET* TKI therapy (e.g., crizotinib, capmatinib) or harboring other actionable alterations are excluded. Participants receive amivantamab hyaluronidase via subcutaneous injection weekly during Cycle 1 (Days 1, 8, 15, 22) and every 2 weeks thereafter (Days 1, 15). Dosing is weight-based: 1,600 mg amivantamab/20,000 units hyaluronidase for participants < 80 kg, and 2,240 mg amivantamab/28,000 units hyaluronidase for patients ≥80 kg. The primary endpoint is response. with a goal of 40 evaluable participants per cohort. The study design has 90% power to rule out a 15% ORR at the 1-sided 5% level, if the true ORR is 35%. Secondary objectives include progression-free survival, duration of response, and response rates in the subset with MET amplification by FoundationOne CDx assays. Correlative studies of interest include the evaluation of concordance between tissue-based and liquid biopsy (ctDNA) next-generation sequencing for the detection of *MET* amplification. S1900J opened to accrual on 9/27/2024 and is actively enrolling patients. Clinical trial information: NCT06116682. Research Sponsor: NIH/NCI grants; U10CA18088, U10CA180819.

TPS8681 **Poster Session**

An ongoing phase 1–2a study of EO1001, an oral brain-penetrant pan-ErbB inhibitor, in patients with advanced ErbB-driven solid tumors including CNS disease. First Author: Neil Sankar, Edison Oncology Holding Corp., Menlo Park, CA

Background: Central nervous system (CNS) metastases and primary brain tumors remain a major cause of morbidity and mortality in patients with ErbB-driven malignancies, particularly as improved systemic therapies prolong survival. Aberrations in the ErbB family of receptor tyrosine kinases—including EGFR, HER2, and HER4—are frequently associated with CNS progression, therapeutic resistance, and poor outcomes across multiple tumor types. In glioblastoma and other CNS malignancies, specific EGFR extracellular domain (ECD) alterations, including EGFRvIII and recurrent ECD missense variants, have been previously reported to promote ligand-independent signaling, invasive tumor biology, and resistance to currently available EGFR-targeted therapies. EO1001 is a novel, oral, irreversible pan-ErbB inhibitor designed to achieve sustained CNS exposure and broad ErbB pathway inhibition. This ongoing Phase 1–2a study is evaluating the safety, pharmacokinetics, and preliminary antitumor activity of EO1001 in patients with advanced ErbB-driven solid tumors, including those with CNS involvement. **Methods:** This is a first-in-human, multicenter, open-label Phase 1–2a study of once-daily oral EO1001. The Phase 1 dose-escalation component uses an accelerated titration design transitioning to a standard 3+3 schema following the occurrence of ≥Grade 2 treatment-related toxicity. A Phase 2 expansion component is enrolling patients at or below the recommended Phase 2 dose (RP2D). Eligible patients are adults with advanced or metastatic ErbB-expressing solid tumors that have progressed following standard therapy; patients with treated or untreated CNS disease are eligible. EO1001 is administered once daily in 28-day cycles following an initial single-dose pharmacokinetic assessment. The primary objectives are to evaluate safety and tolerability and to determine the RP2D. Secondary objectives include characterization of the pharmacokinetic profile and assessment of preliminary antitumor activity using RECIST v1.1 and/or RANO criteria, as appropriate. Exploratory objectives include evaluation of pharmacodynamic and molecular biomarkers in available tissue and optional cerebrospinal fluid sampling to further assess CNS exposure and pathway modulation. Current Status: Dose escalation has been completed across multiple dose levels, and enrollment is ongoing in Phase 2 expansion cohorts designed to further characterize safety, pharmacokinetics, and CNS-directed antitumor activity at biologically active dose levels. Clinical trial information: ACTRN12620000583943. Research Sponsor: Edison Oncology Holding Corp.

9000 Clinical Science Symposium

Gaps in patient-facing information on artificial intelligence in cancer care: A cross-sectional analysis. First Author: Pearl Subramanian, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: Artificial intelligence (AI) is increasingly integrated into cancer care and is also widely accessed by patients seeking information about their diagnoses and treatments. While AI has the potential to improve care delivery and patient engagement, inadequate or misleading patient education may introduce safety risks. We assessed the availability, readability, and quality of publicly available online patient-facing information about AI in cancer care. **Methods:** We conducted a cross-sectional analysis of online patient-facing information related to AI in cancer care. Using common cancer- and AI-related keywords identified using Google Trends, we searched Google and YouTube on August 6, 2025. The first 170 webpages and 150 videos were screened for relevance and patient-facing intent; scientific or industry-facing content was excluded. Eligible webpages and videos were independently evaluated by two reviewers with discrepancies resolved by a third. Webpage readability was assessed using validated indices (Flesch–Kincaid [FK], Gunning Fog [GF], and SMOG). Content was evaluated for discussion of key AI safety concepts including clinician oversight, transparency, bias, and hallucination or misinformation risk. Quality of consumer health information was assessed for both webpages and videos using the DISCERN instrument, with scores ≥ 4 (of 5) indicating high quality. Descriptive statistics were used to summarize findings. **Results:** Of the 170 webpages screened, 52 (31%) met inclusion criteria. Most content focused on breast cancer (n=30, 58%) or was pan-tumor (n=22, 42%). Median readability corresponded to a college-level reading standard, with median grade levels of 12.8 (IQR: 11.6-14.1), 14.8 (IQR: 13.5-16.5), and 14.2 (IQR: 13.6-15.6) based on FK, GF, and SMOG indices, respectively. Most webpages discussed clinician oversight (n=41, 79%) and/or transparency (n=41, 79%), and over half addressed bias (n=29, 56%); however, few discussed hallucination or misinformation risk (n=8, 15%). Only 33% (n=17) of webpages met criteria for high-quality information. Of the 150 videos, 29 (19%) met inclusion criteria. Median view count was 127 (IQR: 23-1000). Few (n=11, 38%) were classified as high quality based on DISCERN scores. **Conclusions:** Publicly available, patient-facing information about AI in cancer care is limited, difficult to read, and often of low quality. Inadequate discussion of AI-related risks, particularly hallucinations or misinformation, may leave patients poorly informed as they encounter or independently use AI-based tools. These findings highlight the need for accessible, high-quality educational resources that clearly explain the clinical role of AI in oncology and provide guidance for safe patient engagement. 9001 Clinical Science Symposium

Artificial intelligence (AI) in hematology and oncology fellowship (HOF) training: A multicenter survey of education, attitudes, and clinical use. First Author: Evan Garrad, University of Illinois Chicago, Chicago, IL

Background: A prior national survey of U.S. HOF curricula demonstrated substantial heterogeneity and limited protected time for didactics beyond traditional lecture-based education[1]. More recently, artificial intelligence (AI), including large language models and ambient listening tools, has become increasingly integrated into trainee education and clinical practice[2-5]. We conducted a multi-center survey to assess the use of AI among HOFs. **Methods:** Hematology/oncology (H/O) fellows were recruited via email by program leadership to complete an anonymous survey adapted from our prior study, with added questions on AI education, attitudes, and clinical use. Responses were collected via REDCap and summarized using descriptive statistics. **Results:** A total of 118 H/O fellows responded from 18 of 30 invited U.S. HOF programs (60%), primarily from academic centers (94%), with a near-uniform distribution across fellowship training years. Most fellows (74%) reported using AI tools such as ChatGPT or OpenEvidence. Commonly used resources included NCCN guidelines (92%), UpToDate (86%), faculty lecture slides (70%), primary journals (65%), podcasts (58%), textbooks (29%), and social media (20%). Only 8% reported receiving AI education during HOF training. Most fellows felt AI was useful for medical education (93%) and were confident using AI tools for learning (74%). The majority anticipated increasing AI use over the next 5 years (92%) and expressed interest in AI training during fellowship (82%). Fellows most commonly used large language model–based AI tools to clarify difficult concepts (86%), summarize journal articles (83%), and learn about emerging research (75%), whereas fewer reported use for question generation (31%) or patient case simulations (29%). AI-assisted documentation was the most commonly used clinical AI application (51%). Reported barriers to AI use included (in order of highest concern): uncertainty regarding accuracy, lack of formal training, data privacy concerns, and unclear ethical or institutional guidelines. **Conclusions:** AI tools are widely used and perceived as useful for clinical and educational purposes by current H/O fellows, yet formal training during fellowship remains limited. These findings highlight an unmet need for structured education on effective, safe, and ethical AI use, with opportunities for multi-institutional collaboration to achieve scalable impact aligned with contemporary oncology practice. Research Sponsor: None.

9002 Clinical Science Symposium

Patterns of artificial intelligence use among physicians in Mexico: Implications for oncology practice. First Author: Jeffrey Barragán Ortega, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, DF, Mexico

Background: Artificial intelligence (AI) is increasingly incorporated into medical practice; however, physician-level factors associated with AI adoption and usage patterns, particularly among oncologists practicing in low- and middle-income countries, remain insufficiently characterized. This study aimed to describe patterns of AI use among physicians in Mexico and to explore physician-level factors associated with adoption. **Methods:** We conducted a cross-sectional, anonymous survey among physicians from multiple specialties in a tertiary care center in Mexico to assess AI use, professional activities (clinical care, research, and teaching), training interests, and perceptions regarding AI. The primary outcome was self-reported AI use. Associations between physician characteristics and AI use were evaluated using nonparametric statistics. Among oncologists, AI use patterns, training interests, and perceptions were summarized descriptively. **Results:** Between August and September 2025, 170 physicians completed the survey. Overall, 77.1% were $<$ 40 years old, 50% were women, and 91.7% had $\leq$10 years of professional experience. Clinical specialties predominated (78.8%) over surgical specialties (21.2%). Most respondents were involved in clinical care (94.1%), followed by research (48.4%), and teaching (27.1%). AI use was highly prevalent (88.2%), with generative models being the most commonly used tools (80.0%). Physicians younger than 40 years reported significantly higher AI use than those aged $\geq$40 years (93.1% vs 71.8%, $p<0.001$) and were more likely to use AI in clinical practice (77.9% vs 43.6%, $p<0.001$). No significant age-related differences were observed for research or teaching activities. Use of AI-based data analysis tools varied by specialty and was more frequent among surgical compared with clinical specialties (63.9% vs 37.3%, p=0.004). Among oncologists (n=32), 87.5% reported AI use, primarily in clinical practice (75.0%) and research (50.0%), while use in teaching was less frequent (21.9%). Most oncologists expressed strong interest in formal AI training (84.4%) and ethical considerations (87.5%). The majority agreed that AI could improve quality of care and support clinical decision-making (95.2%), while emphasizing the need for continued physician oversight. Concerns regarding data security were common (84.7%), whereas concerns about loss of medical autonomy were generally moderate (36.4%). **Conclusions:** AI adoption among physicians in Mexico is strongly associated with age and professional activity. Oncologists demonstrate widespread AI use in clinical care and research, high interest in structured and ethical training, and a consistent emphasis on human oversight. These findings support the development of targeted educational and governance strategies to guide responsible AI integration in oncology. Research Sponsor: None.

9003 Rapid Oral Abstract Session

Analyzing county-level factors of oncology fellowship program development from 2015-2025. First Author: Ryan James Crowley, NYU Grossman School of Medicine, New York City, NY

Background: In the United States (US), access to oncology care varies geographically. One factor that may contribute to regional shortages is the distribution of oncology fellowship programs. We aimed to assess urban-rural trends in newly created oncology fellowship programs and to identify county-level factors associated with a higher likelihood of gaining a new oncology fellowship program. **Methods:** Data on all hematology/oncology and oncology fellowship positions in 2015 and 2025 were manually extracted from National Resident Matching Program (NRMP) data. A cross-sectional analysis was performed using data from 3,211 US counties to examine program development from 2015-2025. County metrics came from US Census data and physician density was calculated using the Doctors and Clinicians national downloadable file. A model was developed using Firth's penalized logistic regression with the following predictors using 2015 data: oncologist density per 100,000 population, median household income, percentage of population with insurance, rurality (binary with rural county coded as 1), and state-level Medicaid expansion status in 2015 (binary with expansion state coded as 1). The outcome variable was counties that gained a new oncology fellowship program (n=44). **Results:** In 2015, there were 140 fellowship programs in the US with 1 program in a rural county (0.6%). By 2025, there were 180 fellowship programs with 3 programs in rural counties (1.7%). The total fellowship slots grew from 521 to 773 at a rate of 25.2 new fellowship slots per year. The results from the regression model are shown in Table 1. Higher household median income significantly predicted fellowship establishment (OR 1.62, 95% CI 1.25-2.06, p-value $<$0.001), and rurality significantly predicted no fellowship establishment (OR 0.04, 95% CI 0.01-0.14, p-value $<$ 0.001). **Conclusions:** Despite robust growth in the number of oncology fellowship programs and slots, expansion into rural and underserved areas remains disproportionately small. The majority of new programs continue to cluster in urban centers, suggesting that increases in fellowship capacity have not effectively addressed geographic disparities in care. We found that new oncology fellowship programs systematically emerge in more affluent urban counties with pre-existing oncology workforces. Strategic policy interventions including location-based incentives and rural training tracks should be considered to improve the distribution of fellowship programs. Research Sponsor: None.

Firth logistic regression model results.

Variable	Odds Ratio (OR)	95% Confidence Interval	P-Value
Intercept	0.01	0.01-0.02	$<$0.001
Household Median Income	1.62	1.25-2.06	$<$0.001
Percentage of Population with Insurance	0.74	0.51-1.15	0.17
Oncologist Density (providers per 100,000 population)	1.18	1.05-1.29	0.02
Medicaid Expansion Status	3.13	1.57-6.55	0.001
Rurality (RUCC)	0.04	0.01-0.14	$<$0.001

9004 Rapid Oral Abstract Session

Projecting 2050 oncology workforce through historical regional trends and economic stratification. First Author: Arkadi Asaturyan, Yerevan State Medical University, Yerevan, Armenia

Background: Global oncology workforce planning increasingly relies on predictive modeling to guide policy and investment. However, projections are highly sensitive to baseline stratification. Historical models often use broad geographic regions, which may obscure economic heterogeneity within regions. We analyzed historical workforce trends and compared regional versus income-stratified projection models to quantify how perceptions of the 2050 oncology workforce burden have evolved. **Methods:** We extracted oncology workforce data from peer-reviewed literature, government and ministry of health reports, and datasets from professional organizations, including ESMO and ASCO. Cancer incidence and population projections were obtained from GLOBOCAN and UN sources. Workforce burden was defined as annual new cancer cases per clinical oncologist. Historical burden velocity was estimated using comparative data from 2012–2018 and applied to current scenario to build projections. Two models were evaluated: a regional model based on geographic trends and an economic model stratified by World Bank income groups. **Results:** Retrospective analysis (2012–2018) demonstrated substantial regional divergence. Europe showed relative stability, with workforce burden improving by −0.6% per year, while appearing comparable to Asia in 2018 (275 vs. 248 cases per oncologist). However, Asia's burden increased by +8.6% per year, indicating incidence growth already outpacing workforce expansion despite similar cross-sectional values. Using regional trends, the projected 2050 burden reached 694 cases per oncologist for Africa and 3,499 for Asia. In contrast, income-based stratification revealed a markedly steeper trajectory for the most vulnerable economies. At baseline, high-income countries (HICs) had 30,400 oncologists, upper-middle-income countries (UMICs) 46,140, lower-middle-income countries (LMICs) 6,370, and low-income countries (LICs) only 70 providers combined. Projected through historic trends, 2050 burden reached approximately 295 cases per oncologist in HICs, 1,450 in LMICs, and ~11,500 in LICs. This represents a 16-fold increase when shifting from regional (Africa: 694) to economic (LIC: 11,500) projections, while also revealing lower-than-expected burden in emerging economies . **Conclusions:** Comparing regional and income-stratified projections reveals a profound predictive divergence. Although there is limited workforce data for higher accuracy projections, geographic averaging masks extreme workforce deficits in low-income countries while overstating burden in middle-income settings. Absolute workforce growth alone is insufficient to assess preparedness. Future oncology workforce planning should prioritize income-based stratification to accurately identify and address the most critical global capacity gaps. Research Sponsor: None.

9005 Rapid Oral Abstract Session

Support of academic non-clinical efforts for cancer investigator faculty at Association of American Cancer Institutes. First Author: Paula M. Fracasso, VCU Massey Comprehensive Cancer Center, Virginia Commonwealth University, Richmond, VA

Background: Academic non-clinical time (NCT) for physician scientists (PS) and clinical investigators (CI) is critical in advancing novel scientific findings from the laboratory to the community through clinical trials implemented to improve patient outcomes. CI are uniquely positioned to bridge these bench findings to bedside applications given their dual clinical and research training. However, CI face increasing competing pressures that threaten this career path. The Association of American Cancer Institutes (AACI) Physician Clinical Leadership Initiative (PCLI) conducted a national survey in 2018 to identify trends in academic NCT for the physician-trained researchers across US academic cancer centers involved in basic, translational, or clinical research. We recently reevaluated allocation of academic NCT to support faculty. **Methods:** In 2024, AACI PCLI electronically sent a 20-question descriptive survey to 95 academic cancer centers. Survey items assessed the time commitments of medical oncologists caring for patients with hematologic (including cellular therapy and stem cell transplantation) and solid tumor malignancies, as well as institutional academic NCT policies and incentive structures. Responses were summarized using descriptive statistics for quantitative items and qualitative review for open-ended responses. **Results:** Sixty centers (63%) participated. Clinical effort expectations and the amount of academic NCT varied widely by center and faculty role. The median expected effort was 30% (IQR 18%) clinical research and 50% (IQR 14%) direct patient care for CI, and 70% (IQR 20%) basic/clinical research and 20% (IQR 10%) direct patient care for PS. The most common duration of CI startup academic NCT support was 3 years, but this varied greatly across centers. Most centers required external funding to continue academic NCT (48% for CI and 72% for PS). PS were more likely than CI to receive more sustained support when some degree of extramural funding was obtained. Nearly 80% of CI academic NCT was supported by cancer center funds. Clinical trial accrual was the top priority for academic NCT for faculty engaged in clinical research, while mentoring and teaching ranked among the lowest. Incentive plans for clinically active faculty were common (85% of centers) and were largely work relative value unit (wRVU)-based, with limited incorporation of research or mentoring contributions. **Conclusions:** This survey highlights systemic failures in institutional support for CI, including inconsistent allocation of academic NCT, limited support duration, misaligned incentives, and lack of succession planning. These findings underscore the need for sustainable, multisource funding models, recalibrated incentive structures, and robust mentoring pathways to retain and advance CI for accelerating cancer research through advancing discoveries into the clinic. Research Sponsor: None.

9006 Rapid Oral Abstract Session

Gender representation in first and senior authorship of phase III solid-tumor trials presented at the ASCO Annual Meeting, 2015-2025. First Author: Sarbajit Mukherjee, Miami Cancer Institute, Miami, FL

Background: Authorship in clinical trials reflects access to research infrastructure, funding, and academic advancement. While gender gaps have been described, longitudinal trends and structural correlates remain poorly characterized. We examined temporal trends and determinants of gender representation among first and senior authors of phase III solid-tumor trials presented at the ASCO Annual Meeting. **Methods:** We performed a cross-sectional analysis of all phase III solid-tumor trial abstracts presented at the ASCO Annual Meeting from 2015–2025. Data included year, tumor track (breast, gastrointestinal [GI], other), funding source (industry, academic, other), and first/senior authorship. Countries were classified by World Bank income group (high [HIC], upper-middle [UMIC], lower-middle [LMIC], low-income [LIC]) and global region (North America, Europe & Central Asia, East Asia & Pacific, other). Author gender was assigned using publicly available professional profiles and validated automated tools (≥90% certainty). Temporal trends were assessed using Cochran-Armitage tests. Multivariable logistic regression models evaluated factors associated with women authorship. **Results:** Across 1,517 abstracts (3,034 authorships), women comprised 845 authors (27.9%). Most trials were industry funded (63.7%), focused on GI malignancies (20.1%), and based in HIC (84.9%). Using first author as reference group, senior author had higher odds of being male in multivariable analysis (OR=1.30, p=0.001). Women had lower odds of senior authorship compared with first authorship (aOR 0.77, 95% CI 0.65–0.90). Female authorship increased over time (24.9% in 2015–2020 vs. 30.0% in 2021–2025, p=0.002; aOR 1.34, 95% CI 1.13–1.58), most pronounced among senior authors (aOR 1.55, 95% CI 1.21–1.99; p=0.006). Women authorship varied by tumor track, with lower odds in GI compared with breast trials (aOR 0.49, 95% CI 0.38-0.64). Compared with North America, East Asia and Pacific affiliation was associated with higher odds of women authorship overall (aOR 1.54, 95% CI 1.15–2.07), strongest among first authors (aOR 1.89, 95% CI 1.25–2.91). Among senior authors, LMIC affiliation was associated with lower odds of women authorship compared to HICs (aOR 0.11, 95% CI 0.01–0.56). **Conclusions:** In the largest global oncology conference, women authorship in phase III solid-tumor trials has improved over the past decade but remains uneven, with persistent gaps in senior authorship. Research Sponsor: None.

Authorship role, era, and tumor track by gender.

Characteristic	Women (N=845, 27.9%)	Men (N=2,182, 71.9%)	*P*-value

9007 Rapid Oral Abstract Session

Understanding the impact of gold and silver signals on ERAS applications: A survey of hematology/oncology fellowship program directors. First Author: Courtney Nicole Miller-Chism, Baylor College of Medicine Division of Hematology/Oncology, Houston, TX

Background: Since transition to virtual interviews, application and interview inflation have increased the work burden of GME recruitment. In 2021, AAMC ERAS implemented a process that allows applicants to assign signals to top programs of interest. There is a paucity of guidance on optimal use of ERAS signals (ES), resulting in apprehension and uncertainty amongst applicants and program directors (PD). For the 2026 ERAS cycle, Hematology/Oncology programs (HOP) had the option to participate in ES, in which applicants are provided 5 gold (G) signals and 15 silver (S) signals. First-hand knowledge on how ES was utilized by HOP, as well as PD perceptions about ES, may guide best practices on ES. **Methods:** During the ASCO Oncology Training Program Leadership Retreat in November 2025, an anonymous survey, assessing HOP utilization and perception of ES, and the impact of ES on recruitment practices, was launched. One PD from each HOP was invited to complete the survey while onsite. **Results:** 88 HOP (46% of ACGME HOP) are represented. 97% (n=85) utilized ES. Of HOP who used ES, 74% are academic. 32% are small (1-9 fellows), 43% medium (10-19 fellows), and 25% large (20+ fellows). 79% received 400+ applications. 69% reviewed applications without signals but gave higher consideration to signaled applicants. 25% only reviewed applications with signals. 28% used ES when creating rank list; 45% think ES utilization is appropriate during ranking. 85% reported ES did not alter their approach to applicants requiring visa sponsorship. 78% felt ES made the interview selection process easier. 66% were more satisfied with this year's recruitment process compared to years without ES. The most requested change to ES was reduction of allowed signals, especially silver. 98% will use ES next year. **Conclusions:** Despite limited knowledge on ES impact on recruitment, nearly all surveyed HOP participated in ES this past year and will continue. Most HOP view ES positively though many desire changes, particularly with the number of signals. Most HOP consider all applications regardless of ES. However, some HOP with larger applicant pool are using ES as inclusion criteria for interview consideration. Signals are a strong predictor for interview invitation when internal selection criteria are met. The "borderline" applicant may be the greatest benefactor from ES, viewed similarly to the non-signaled applicant who meets internal selection criteria. Sharing PD perspectives and real-life data from this year's ES process breeds opportunities for further improvement and increased confidence with ES. Research Sponsor: None.

Likelihood HOP offer interview invitation based on quality of application and signals (%, n=85).

9008 Rapid Oral Abstract Session

Advancing career-focused training: Program leader perspectives on professional development pathways in hematology/oncology fellowships. First Author: Lauren O'Loughlin, Beth Israel Deaconess Medical Center, Boston, MA

Background: Hematology/Oncology (H/O) fellows have diverse career opportunities post-graduation. Many fellowship programs have created specialized training pathways for trainees to support career-aligned skill development, defined here as professional development pathways (PDPs). These may include specific training for careers in laboratory/translational research, medical education, and quality improvement. There is limited data regarding utilization and perception of PDPs in H/O fellowship programs. **Methods:** We conducted a national cross-sectional survey of United States (US) H/O fellowship program leaders (PLs) to assess: (1) prevalence of PDPs, (2) perceived value of PDPs, and (3) barriers to implementation. The survey underwent content validation by three experts – program directors (PDs) in different fellowship subspecialties – who reviewed the instrument for clarity, relevance, and comprehensiveness. The survey was distributed electronically to 180 US H/O fellowship programs; responses were anonymous. **Results:** 72 responding PLs completed the survey (40% response rate). Program size ranged from 2 to 16 fellows per year. Programs from all US geographic regions were represented; 78% were affiliated with academic hospitals and 17% with academically affiliated community hospitals. Less than half (45%) report offering PDPs. The majority (78%) of PLs agree/strongly agree that PDPs provide fellows with more focused career-concordant training. Among the 32 programs with PDPs, 84% report PDPs align with fellows' post-graduation careers. Most (66%) have fellows select their PDP during the first year of fellowship; PDP selection is mandatory in 56%. Eleven distinct PDPs were described, most commonly clinical research (84%), clinical practice (69%), and basic science research (63%). Core PDP components include clinical experiences (100%), scholarly projects (88%), and structured mentorship (82%). Among the 40 programs without PDPs, 63% perceive value in adding them. Reported barriers include difficulty integrating PDPs into current fellowship structure (60%), lack of appropriate faculty mentors (55%), and lack of PD bandwidth (53%). Resources identified that would support implementation include dedicated time or support for mentorship (68%), sample curricular or implementation tools (68%), access to non-clinical infrastructure (e.g. research, quality improvement, education) (63%), and funding (45%). **Conclusions:** While most US H/O fellowship PLs view PDPs as valuable for trainee career development, less than half of responding programs currently use them. Addressing institutional and programmatic barriers and providing curricular resources, dedicated time for faculty mentors, and funding may enable wider implementation. Future studies should explore existing PDP structures and define best practices for PDP utilization. Research Sponsor: None.

9009 Rapid Oral Abstract Session

Career fulfillment and intent to leave among oncology physicians: A global survey. First Author: Coral Olazagasti, University of Miami/Sylvester Comprehensive Cancer Center, Miami, FL

Background: Burnout among U.S. oncologists has risen from 34% (2013) to 59% (2023), with global estimates of 32–45%. However, burnout is often studied in isolation rather than alongside fulfillment, distress, and intent to leave, limiting understanding of workforce attrition. With ~20% of US oncologists leaving clinical roles over the past decade, factors driving workforce attrition require a precise evaluation across international settings. **Methods:** An anonymous, cross-sectional global survey distributed via professional email (Oct–Dec 2025) assessed burnout using validated Maslach Burnout Inventory (MBI) items and evaluated associations with professional fulfillment, career regret, and intent to leave clinical practice among oncology physicians. Descriptive statistics were performed, with χ^2/Fisher's exact tests for categorical comparisons and multivariable logistic regression to identify independent factors associated with fulfillment and intent to leave. **Results:** A total of 306 participants were included (156 non-U.S. and 150 U.S.). Clinical workload was substantial: 33.0% reported $\geq$5 clinic half-days per week, and 57.7% reported $\geq$5 inpatient service weeks annually. Administrative burden was also common, with 45.6% independently performing peer-to-peer appeals and 53.8% reporting feeling overwhelmed by this responsibility. Career satisfaction was reported by 70.6%, while job-related stress was highly prevalent (71.9%). Work frequently extended beyond scheduled hours, with 48.0% reporting moderate-to-excessive after-hours electronic medical record use. More than one-quarter of respondents (27.4%) expressed regret about pursuing a career in oncology, most attributed to poor work–life balance (69.3%) and burnout (65.3%). Despite these challenges, 50.5% reported frequent professional fulfillment and 21.7% reported very high fulfillment, particularly among U.S.-based vs. non-U.S. physicians (62.7% vs 25.0%, $P < 0.001$). Overall, 45% reported ever considering leaving practice; frequent intent to leave was higher among U.S.-based physicians (15.3% vs 7.1%, P = 0.034) [Table 1]. **Conclusions:** Oncologists experience a fulfillment–distress paradox, reporting meaningful professional fulfillment despite high stress, administrative burden, career regret, and intent to leave practice. This "professional dissonance" suggests that meaning and identity in oncology may persist despite insufficient institutional support but may remain fragile over time. Systems-level approaches addressing workload, professional culture, and identity formation are needed to improve physician well-being and workforce retention. Research Sponsor: None.

Key outcomes by region.

Outcome (often/always)	Non-US (n=156)	US (n=150)	p-value
Fulfillment high	39 (25.0%)	94 (62.7%)	**<0.001**
Consider leaving high	11 (7.1%)	23 (15.3%)	**0.034**

9010 Rapid Oral Abstract Session

Burnout (BO) among oncology professionals in the Middle East and North Africa (MENA): Meta-analysis of pre–post COVID trends, contributors, and predictive value of single-item screening tool. First Author: Atlal M. Abusanad, Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia

Background: BO among oncology professionals is prevalent and may have changed following the COVID-19 pandemic. We conducted a meta-analysis of MENA studies to evaluate temporal trends in overall burnout and subdomains, identify contributing predictors, and assess the screening performance of thought of quitting oncology (TQ). **Methods:** Ten cross-sectional studies (N = 2,486) reporting Maslach Burnout Inventory (MBI) outcomes were included: six pre-COVID and four post-COVID. Pooled prevalence estimates were generated for emotional exhaustion (EE), depersonalization (DP), personal accomplishment (PA), and overall BO. Study-level meta-regression evaluated the effects of time period (pre- vs post-COVID), demographics, specialty, and their interaction on observed trends. Performance of TQ was assessed as a screening tool with pooled sensitivity, specificity, and predictive values. **Results:** The pooled prevalence of BO was 57.1% (95% CI, 40.6–72.8), increased from 48.2% in the pre-COVID period to 77.2% post-COVID (Δ +29.0 percentage points). High EE increased from 41.3% pre-COVID to 70.9% post-COVID (Δ +29.6 percentage points). DP increased from 36.8% to 55.8% (Δ +19.0 percentage points). Low PA showed minimal change (35.4% pre-COVID vs 35.1% post-COVID; Δ −0.3 percentage points). The heterogeneity estimate was high due to inter-study differences related to time period, setting, and baseline burnout prevalence, which were statistically adjusted for. TQ screening demonstrated reasonable sensitivity (82.4%) and PPV (79.9%), but low specificity (46.5%) and NPV (50.5%). Table 1 shows study-level factors contributing to BO prevalence trends. **Conclusions:** BO among oncology professionals increased post-COVID in the MENA region. The rise was driven by age-dependent effects plus time period. EE increased uniformly, while DP and low PA showed more complex patterns. A single-item question assessing TQ demonstrated strong rule-in screening utility for identifying clinicians at risk. Research Sponsor: None.

Meta-regression analysis of study-level moderators of BO prevalence.

Outcome	Best Predictor(s)	R^2	Pattern
EE	Period + Age + Med Onc. %	86.2%	**Additive effects:** Post-COVID, younger, more Med Onc. independently increase EE
DP	None significant	0.0%	
PA	Period × Age	50.4%	**Moderation:** Age moderates pandemic effect on PA
Overall Burnout	Period × Age	55.3%	**Moderation:** Age moderates pandemic effect on BO

9011 Rapid Oral Abstract Session

Standardized mean differences of primary outcomes found in randomized controlled trials of wellness interventions among medical trainees: A systematic review and meta-analysis. First Author: Andrew Irving Hearn, University of Louisville, Brown Cancer Center, Louisville, KY

Background: In the era of physician shortages, wellness interventions among medical trainees is an area of ongoing research interest in hopes of promoting clinician wellness and preventing burnout as a means of reducing clinician attrition. To our knowledge, there has not been a systematic review and meta-analysis of randomized controlled trials among medical trainees (medical students, residents, and fellows) to characterize the overall efficacy of wellness interventions in this population. **Methods:** A medical librarian searched Embase, MEDLINE, Scopus, Cochrane Central Register of Controlled Trials (CENTRAL), APA PsycINFO, and Clinicaltrials.gov from the earliest timepoint to March 2022 for randomized controlled trials of wellness interventions among medical trainees. Measures of wellness included but were not limited to depression, stress, and anxiety. Outcomes were analyzed using Standardized Mean Differences (SMD) calculated as Hedges' g to correct for small sample bias. To ensure consistent interpretation, effect sizes were adjusted for directionality such that a positive SMD indicates a beneficial outcome for the intervention group regardless of the original scale (e.g., higher happiness or lower stress). **Results:** Our search strategy resulted in 3,806 unique articles. 161 articles passed initial screening of titles and abstracts, and 46 studies were included for data extraction with dates ranging from 1980 to 2022. 23 studies with means and standard deviations reported for the primary outcome were included for meta-analysis purposes. The pooled effect size was 0.017 with a 95% confidence interval of -0.501 to 0.536 with an I^2 heterogeneity of 0.904. **Conclusions:** Our systematic review and meta-analysis of randomized controlled trials of wellness interventions among medical trainees suggest that interventions to promote wellness and prevent burnout in medical trainees, as an aggregate, have been heterogenous in design and with little-to-no overall effect. An updated search of the literature with subgroup analyses by intervention type and/or outcome measure may yield more promising results, inform future research, and better assist training programs in weighing the opportunity cost of wellness interventions, particularly in resource-constrained settings or in fields with significant rates of burnout such as hematology and oncology. Research Sponsor: None.

9012 Poster Session

The hidden struggle? Mental health burden among oncology physicians globally. First Author: Coral Olazagasti, University of Miami/Sylvester Comprehensive Cancer Center, Miami, FL

Background: Oncology physicians face demanding clinical workloads, high emotional labor, and frequent exposure to patient loss, contributing to elevated psychological distress. While burnout has been extensively described, anxiety and depression remain under-recognized and stigmatized within the oncology workforce. **Methods:** A cross-sectional, anonymous, online survey distributed internationally (October–December 2025) assessed indicators aligned to PHQ-9 and GAD-7 constructs, mental-health history, medication use, practice characteristics, and workplace context. Descriptive statistics summarized prevalence; χ^2/Fisher's exact tests compared subgroups; and logistic regression explored independent risk factors for anxiety/depression. **Results:** Among 209 oncology physicians who completed all mental health-related survey items (Table 1), 28.2% reported anxiety and/or depression. Female physicians had a higher prevalence than male physicians (35.4% vs 22.2%, P = 0.037). Anxiety/depression was higher among Hispanic/Latino vs non-Hispanic White physicians (45.5% vs 29.8%, P = 0.015) and among non-U.S. vs U.S.-based physicians (33.3% vs 25.7%, P = 0.025), though these differences attenuated in adjusted models. Medication use was strongly associated with anxiety/depression. Prevalence of anxiety/depression was rare among physicians who had never considered medication (0.9%), but common among those with past (72.7%) or current (92.9%) medication use (P < 0.001). **Conclusions:** Nearly one in three oncology physicians reported anxiety and/or depression, consistent with national estimates for physicians generally. Female physicians demonstrated a significantly higher burden and retained an independent risk after adjustment. These findings underscore the need for confidential and accessible mental health care within oncology professional environments and highlight the importance of addressing structural and occupational contributors to psychological distress. If oncology is to remain a sustainable profession, mental health must be treated as a core component of workforce development rather than an individual responsibility. Research Sponsor: None.

Burnout among early-career oncologists in Latin America: A regional survey. First Author: Sergio Cifuentes-Canaval, Instituto de Cancerología Las Américas, Medellín, Antioquia, Colombia

Background: Burnout in healthcare professionals negatively impacts patient care, job satisfaction, and personal well-being. Early-career oncologists are especially vulnerable due to emotional strain and heavy clinical and administrative demands. These challenges are driven by structural constraints. This study aimed to determine the frequency of burnout among early-career oncologists in LATAM and to describe workload conditions and perceived institutional resources. **Methods:** A multicenter, observational, cross-sectional, voluntary, web-based survey was conducted between Nov/2025 and Jan/2026 among young oncologists in LATAM. Participants were physicians aged <40 years or <10 years of clinical practice. Participants were invited electronically via email and social media. The survey included demographic, professional, and workplace-related variables. An adapted version of the Maslach Burnout Inventory (MBI) was performed. **Results:** A total of 105 surveys were included from oncologists across 15 Latin American countries, with the highest representation from Colombia (37.1%), Mexico (23.8%), and Argentina (8.6%). Fifty-one percent were aged ≥35 years, were female (58.1%), and worked in non-academic settings, including public (36.2%), private (32.4%), or mixed public–private practice (29.5%). 19.1% were trainees. Regarding burnout, 55.2% reported feeling emotionally exhausted due to work at least once per week (median 4; IQR 3–5), and 64.8% reported end-of-day exhaustion at least weekly (median 4; IQR 3–5). Depersonalization symptoms were infrequent (median 1; IQR 0–3), and participants reported generally high levels of personal accomplishment (median 5; IQR 4–6). Overall, 46% of participants reported adequate technological, pharmacological, and institutional support resources. Only 21% indicated that their clinical and administrative workload was manageable; 40% considered it unmanageable. Most respondents reported misalignment between salary and workload, with 61% expressing disagreement. **Conclusions:** This survey provides one of the first regional overviews of working conditions among early-career oncologists in LATAM. A proportion of participants reported limited institutional resources and unmanageable clinical and administrative workloads, highlighting structural challenges within the region's oncology workforce. Research Sponsor: None.

Burnout survey among EOCs in LATAM.

Emotional burnout among oncology clinicians in Russia: Results of a national cross-sectional survey. First Author: Anastasia Danilova, Moscow City Oncology Hospital 62, Moscow, Russian Federation

Background: International reports suggest a high prevalence of burnout in oncology, but contemporary Russian data are limited. **Methods:** Anonymous online survey (June 7-14, 2025) of oncology clinicians and trainees assessing emotional exhaustion in the prior 4 weeks, related symptoms, coping strategies, and free-text views on drivers/mitigation. **Results:** 735 respondents participated (medical oncologists 46.0%, surgical oncologists 23.9%, radiation oncologists 11.6%, trainees 9.0%); 78.5% worked in public hospitals and 69.0% had no managerial role. Emotional exhaustion was reported "often" by 326 (44.4%) and "constantly" by 152 (20.7%); 157 (21.4%) reported episodic exhaustion, 74 (10.1%) rare, and 26 (3.5%) none. Patient detachment was reported sometimes by 291 (39.6%), often by 221 (30.1%), and as near-constant disengagement by 42 (5.7%). Frequent thoughts about leaving clinical work were reported by 275 (37.4%) (additional 243, 33.1% only in exceptionally difficult moments). Excessive workload was perceived often/constantly by 458 (62.3%); lack of time for breaks/recovery by 629 (85.6%) at least sometimes. Common coping strategies included sleep/rest by 592 (80.5%), support from close ones by 437 (59.5%), physical activity by 385 (52.4%), and hobbies by 251 (34.1%); 198 (26.9%) reported alcohol/medications. In free-text drivers (n=569), the most cited themes were leadership/management issues (33.7%), time/workload pressure (21.1%), patient/relative conflict and complaints (19.3%), and paperwork (12.5%); proposed mitigation included protected rest/work-life boundaries (26.3%) and workload reduction/staffing/process optimization (20.8%). **Conclusions:** Two-thirds of respondents reported frequent/constant emotional exhaustion, accompanied by patient detachment and high intent to leave clinical work. Findings support prioritizing organization-level interventions and protected recovery time alongside accessible support resources. Research Sponsor: None.

Inspiring the next generation of medical oncologists: Passion, purpose, and preventing burnout. First Author: Ruth Hutch, St. James's Hospital, Dublin, Ireland

Background: The National Cancer Registry of Ireland projects a doubling of cancer incidence by 2045, with an estimated shortfall of over 100 medical oncologists by 2028. This workforce gap is compounded by rising burnout, with ASCO data showing an increase in oncologists reporting at least one burnout symptom from 34% to 59% over the past decade. Alongside sustained investment in training and recruitment, addressing burnout is essential. This study aimed to identify factors influencing career interest in medical oncology and to explore perceived barriers, informing recruitment strategies and burnout mitigation. **Methods:** A cross-sectional, anonymous electronic survey assessed interest in medical oncology among medical students, interns, and junior doctors. The 20-item questionnaire examined demographics, career preferences, oncology exposure, and perceived barriers. A separate 28-item follow-up survey evaluated burnout among Irish medical oncologists and trainees. **Results:** A total of 183 early-career respondents participated (62.3% female). A response rate of 73%, respectively. Most were aged 25–34 years (69.4%), with junior residents comprising the largest group (42.6%). Key motivators for considering oncology included interest in cancer biology and treatment (54.9%), caring for cancer patients (53.2%), managing complex multidisciplinary cases (52.4%), and the dynamic nature of the specialty (51.6%). Personal experience with cancer did not influence career choice for 54%. Deterrents included high patient mortality and emotional burden (71.6%), concerns regarding burnout and work–life balance (57.5%), and prolonged training (36.1%). Oncology exposure was limited, with 38.5% reporting none; exposure most commonly occurred during junior residency (34.3%) and centered on palliative care, systemic therapies, and chemotherapy. Access to mentorship (73.8%) and increased clinical or research opportunities (62.3%) were identified as key factors to enhance recruitment. Forty-one oncologists completed the burnout survey (responses on-going). Most were aged 35–44 years, female, and working in public hospitals, with 65.9% reporting weekly workloads of 50–59 hours. Over half reported burnout at least monthly, and 75.6% reported inadequate work–life balance. Major stressors included high clinical workload, administrative burden, lack of protected academic time, staffing shortages, and moral distress. Despite high professional satisfaction (82.9%), 43.9% had considered reducing hours or leaving practice due to work-related stress. **Conclusions:** Ireland faces a significant oncology workforce challenge. Early exposure, structured mentorship, and targeted strategies to address workload and burnout are critical to strengthening recruitment and sustaining the oncology workforce. Research Sponsor: None.

Turning silence into rhythm: Outcomes of a school-based *Cancer Olympiad* in India. First Author: Vangipuram Harshil Sai, Department of Undergraduate Education, All India Institute of Medical Sciences (AIIMS), Delhi, India

Background: Late-stage presentation continues to account for nearly 70% of cancer diagnoses in low- and middle-income countries, exposing the gap between medical progress and public participation. Traditional awareness drives often falter in communities shaped by stigma, low literacy, and fear of cost. The *Cancer Olympiad* was conceived as an arts-based, school-centered intervention harnessing creativity, performance, and peer learning to transform knowledge into shared action. By positioning children as credible messengers, it aimed to bridge the emotional and educational distance between health information and household practice. **Methods:** A quasi-experimental, mixed-methods study engaged 25,000 students (grades 1–12) and 2,500 families across 125 urban and rural schools in Udaipur District, North India. Schools implemented structured creative modules—drawings, performances, debates, health exhibitions, reflective writing, and parent–child tasks—culminating in an interschool finale attended by educators, clinicians, and policymakers. Knowledge, attitude, and behavior (KAB) outcomes were measured at baseline and three months post-intervention using validated questionnaires adapted for regional literacy levels. Secondary endpoints included stigma reduction, screening and vaccination uptake, tobacco-cessation behavior, and community-engagement indices such as school-initiated health clubs and family advocacy actions. Qualitative interviews and focus groups explored cultural receptivity, emotional learning, and pathways of sustained engagement. **Results:** Knowledge of cancer risk factors and early-warning signs improved by 23 percentage points ($p < 0.001$), while recognition of curability rose from 58% to 83%. Stigma scores fell by 0.35 SD, and 19% of participating families undertook at least one preventive action—screening, vaccination, quitting tobacco, or seeking medical evaluation—within six months. Primary-health-center screening visits increased by 17% compared with matched control blocks, and teacher-reported health-dialogue frequency in classrooms quadrupled. Qualitative analysis revealed recurring themes of “children as catalysts of credibility,” “art as emotional pedagogy,” and “community pride replacing fear.” Implementation fidelity exceeded 90%, school-level engagement remained high, and more than half the schools adopted the Olympiad as an annual, self-sustained event. **Conclusions:** The *Cancer Olympiad* demonstrates that child-led, arts-integrated education can align biomedical understanding with cultural identity, shifting awareness into collective prevention. When stories and performances enter homes, they humanize cancer knowledge and normalize early action. Embedding narrative and creativity within oncology outreach may extend medicine’s reach beyond clinics—turning silence into rhythm, and rhythm into a movement of lasting change. Research Sponsor: None.

Preparedness of internal medicine residents for oncologic emergencies and end-of-life discussions in a community training environment. First Author: Musa Kiyani, HCA Florida JFK Hospital GME Consortium, Atlantis, FL

Background: Internal medicine (IM) residents often serve as first responders for patients with cancer in community hospitals, where oncologic emergencies frequently present before subspecialty involvement. Yet structured heme-onc and palliative training is limited. Preparedness in community settings - where workflow and resource constraints may heighten gaps between trainee knowledge and confidence - remains under-examined. **Methods:** We conducted a cross-sectional electronic survey of IM residents at a university-affiliated community hospital (Oct 17 - Nov 18, 2025). It included 14 vignette-based knowledge items, 8 confidence ratings (0-10), and questions on demographics, oncology exposure, and perceived barriers. Primary outcomes were total knowledge score (0-14) and composite confidence scores. Multivariable regression assessed associations between resident characteristics, knowledge, and confidence. **Results:** Thirty-three of 58 residents participated; mean age was 30.1 years, and 82% had not completed a hematology-oncology rotation. Knowledge was uniformly high (mean 13.0; SD 1.0) across key domains including febrile neutropenia and hospice eligibility. Confidence, however, was substantially lower and more heterogeneous (emergency mean 5.78; end-of-life mean 5.84). Senior trainees demonstrated greater confidence in both domains (β = 1.62 and 1.60; $P < .001$), and caring for ≥3 oncologic patients in the prior month independently predicted higher communication confidence (β = 1.87; P = .04). Residents identified recurrent barriers: delays in triage (72.7%), limited family availability (72.7%), language barriers (57.6%), and difficulty obtaining early intravenous access (39.4%). Free-text responses emphasized the need for concise reference tools, structured exposure, and simulation-based practice. **Conclusions:** IM residents demonstrated excellent factual knowledge but substantially lower confidence in managing acute oncologic conditions and conducting serious-illness conversations. Confidence was influenced more by experience and workflow realities than by knowledge alone. Our findings highlight an actionable opportunity. Experiential curricula, streamlined clinical pathways, and integrated oncologic teaching may strengthen frontline preparedness for high-stakes cancer care in community settings. Research Sponsor: None.

Resident demographics, clinical exposure, and selected barriers (N = 33).

Selected measure	n/N (%)
Resident sex: male	20/33 (60.6%)
Resident sex: female	11/33 (33.3%)
Training level: PGY-1	15/33 (45.5%)
Training level: PGY-2	8/33 (24.2%)
Training level: PGY-3	10/33 (30.3%)
Oncology exposure: 0–2 cancer patients/month	18/33 (54.5%)
Oncology exposure: ≥3 cancer patients/month	10/33 (30.3%)
Barrier: workload or paging delays	13/33 (39.4%)
Barrier: cultural or linguistic challenges	19/33 (57.6%)

Benefits of utilizing experiential learning in a medical school cancer survivorship course. First Author: Yasheen Gao, Frank H. Netter MD School of Medicine, Quinnipiac University, North Haven, CT

Background: Cancer survivorship care remains underemphasized in medical education despite a growing population of cancer survivors with complex long-term needs. Identifying effective strategies to integrate survivorship education into the medical curriculum is essential. Kolb’s experiential learning theory, which posits that effective learning occurs through iterative cycles of concrete experience, reflective observation, abstract conceptualization, and active experimentation, may offer a structured framework well suited to teaching survivorship care. **Methods:** We evaluated the effectiveness of utilizing repeated Kolb’s cycles to teach a 15-week cancer survivorship course during our 2024 Fall semester. 12 learners (9 pre-clerkship medical students and 3 premedical students) attended weekly sessions mediated by the instructor and invited guests. In-class experiences were paired with reflective homework assignments also tasking students to develop new concepts in 4 domains of interest: patients as survivors (PS), caregivers’ issues (CI), illness experience (IE), and interprofessional care (IPC). Students shared concepts in the next session then began the Kolb’s cycle again. For their final assignment, they interviewed a cancer survivor then created a treatment plan applying the concepts they developed during the course. An anonymous post-course survey assessed learner satisfaction and perceptions of Kolb’s cycle, and a one-year follow-up survey evaluated comfort addressing survivorship issues during clerkships and the course’s impact on survivor care. **Results:** Students generated 259 new concepts (PS: 74; CI: 49; IE: 56; and IPC: 80) across the course and applied an average of ten self-developed concepts per student on the final assignment. On the immediate post-course survey, 12/12 students were highly satisfied with the course and 9/12 students rated all four stages of Kolb’s cycle as extremely or mostly helpful. A year later, 6/9 medical students now on clinical clerkships responded to a follow-up survey. Most reported that the course had a significant lasting impact on their understanding of survivorship issues (4/6) and overall patient management (4/6). Qualitative comments describe greater holistic awareness, comfort with difficult conversations, and attention to survivorship-focused referrals. Students also reported being extremely or mostly confident addressing survivorship issues in the following domains: PS 4/6, CI 3/6, IE 4/6, and IPC 3/6. **Conclusions:** Kolb’s experiential learning theory is an effective framework for teaching a cancer survivorship course to pre-clerkship medical students. Students were highly satisfied with this learning method and able to use this model to successfully develop and apply new concepts. Follow-up during clerkships demonstrated sustained learning and a lasting capacity to apply this material to new patient encounters. Research Sponsor: None.

Utilizing large language models for lung cancer patient education compared to publicly available information. First Author: Samantha Liu, San Mateo High School, San Mateo, CA

Background: The advent of the internet, social media, and more recently of large language model (LLM) platforms has led patients to seek information about cancer directly through digital sources. Complete, readable, and accurate information could reduce physician time clarifying information and increase patient self-activation, especially in low-resource environments. We evaluated the quality of publicly available information provided for the five most common lung cancer questions asked on the internet with information provided by the American Cancer Society (ACS), the National Cancer Institute (NCI), ChatGPT, and Gemini. We hypothesized that LLM platforms could produce readable and information quality equivalent to that found on nationally recognized websites. **Methods:** ChatGPT (OpenAI, logged-out version, accessed 12/14/25) was queried to determine the five most common questions patients with lung cancer ask. These question prompts were used to generate responses in ChatGPT (OpenAI, logged-out version, accessed 1/13/26) and Gemini (Google, version 3 Flash, 1/13/26). Additional passages were extracted from NCI and ACS patient education web pages, and all passages were de-identified and reformatted with links and references removed. The deidentified passages were evaluated by seven providers representing medical oncology (n=4), radiation oncology (n=1), surgical oncology (n=2), and onco-primary care (n=1) using Information Quality Grade, Global Quality Scale, Error Classification, Comprehensibility, and Confabulation. Readability was determined via Flesh-Kincaid grade level. **Results:** Readability was similar between passages, ranging from grade levels 6.9-8.2. LLM’s were rated higher on information quality with fewer total errors. Providers were able to discern LLM content in > 50% of the cases but considered human-generated content as LLM in about one third of cases. The most frequent error reported in LLMs was too little information (n=19) and in websites too much information (n=29). **Conclusions:** LLMs can provide more succinct high-quality information for patients with lung cancer compared to current publicly available websites. The information provided by LLMs is accessible to the public, with potential positive implications for low-resourced populations. Further research is urgently needed to understand the potential of LLMs to improve lung cancer outcomes, such as patient self-activation and adherence. Research Sponsor: None.

Source	Readability (Grade level) *	Info Quality* (1 high - 4 low)	Global Quality Scale* (5 high - 1 low)	% Comprehensibility	% Confabulation	Total # of errors	% Considered LLM
ACS	7.8	1.7	3.7	75.0	7.5	28	30.6
NCI	8.2	1.9	3.1	75.0	7.5	43	35.3
ChatGPT	6.9	1.5	4.3	100.0	2.6	20	63.2
Gemini	8.1	1.5	4.4	52.3	2.6	19	64.1

Psychological burden and burnout among regional healthcare providers communicating hereditary tumor findings: A multi-institutional communication skills training implementation study. First Author: Shuhei Suzuki, Department of Clinical Oncology, Yamagata University, Yamagata, Japan
