Background: Psychological burden among healthcare providers in precision oncology affects workforce sustainability. In regional settings with limited genetic counseling resources, providers face compounded stress disclosing hereditary tumor findings to cancer patients. This implementation study, supported by an MSD Medical Education Grant for advancing genetic medicine understanding in biomarker-based precision oncology, assessed structured communication skills training to address provider psychological burden. **Methods:** We deployed a standardized curriculum across seven regional hospitals in Yamagata Prefecture, Japan, in 2025, integrating SHARE protocol training (Fujimori et al., JCO. 2014) with modules on *BRCA* testing, microsatellite instability, and genomic profiling disclosure. Implementation strategies included professional actors experienced in medical scenarios, facilitated role-playing, and videotaped quality monitoring. This single-arm pre-post intervention study used a mixed-methods evaluation with questionnaire surveys and qualitative inquiries with a modified grounded theory through an inductive thematic analysis until theoretical saturation. **Results:** Among 263 participants (median experience 10 years, range 0-36), including physicians, nurses, genetic counselors, pharmacists, and administrative staff, 93% had baseline psychological burden and 92% reported anxiety when communicating hereditary tumor findings. Psychological burden and anxiety post-intervention decreased in 89% ($p<0.001$) and 84% ($p<0.001$), respectively, with 89% reporting an improved hereditary tumor understanding ($p<0.001$). A qualitative analysis of 18 semi-structured interviews revealed five critical themes: persistent institutional barriers to genetic counseling in resource-limited regions, profound emotional exhaustion from simultaneously managing terminal illness and germline implications, role-play enabling authentic skill rehearsal without patient risk, moral distress balancing patient autonomy against family cascade obligations in limited-prognosis contexts, and the critical need for sustained peer support. **Conclusions:** Multi-site communication skills training including experiential role-play significantly reduced provider psychological burden and anxiety while improving hereditary tumor knowledge across diverse regional healthcare teams. A theory-driven mixed-methods evaluation strengthened intervention rigor. This study supports industry-academic partnerships addressing workforce sustainability while advancing genomic medicine equity in underserved settings. National dissemination with sustained outcome assessment will establish this model as a scalable framework addressing the global workforce crisis in precision oncology. Escape to learn: A team-based gamified educational experience for hematology/oncology fellows. First Author: Emily Wolf, Mayo Clinic Florida, Jacksonville, FL

Background: An escape room is a team-based activity in which participants collaborate to solve puzzles within a fixed time limit and escape. Prior studies demonstrate high learner satisfaction and improved teamwork and communication with medical education escape rooms. To date, no published reports describe an escape room designed specifically for hematology/oncology (hem/onc) fellows. As part of Hem/Onc Curriculum, we designed and implemented a hem/onc-focused escape room and evaluated learner satisfaction and perceived learning impact. **Methods:** The escape room was designed using evidence-based learning science principles (Table 1). Teams worked to solve sequential puzzles, centered on a patient case, addressing key hem/onc concepts, including transfusion medicine, peripheral blood smears, lymphoma classification, and coagulation disorders. Each solved puzzle revealed additional patient laboratory and pathology data. Successful completion required teams to diagnose the patient and select appropriate treatment. Following the activity, teams participated in a facilitator-led debrief focused on team dynamics, communication, and problem solving. Teams observed each other and shared feedback. A larger group debrief co-led by chief fellows and faculty reviewed learning objectives and key takeaways. Learner outcomes were assessed using a post-activity survey evaluating satisfaction, engagement, and impact on learning. **Results:** Eighteen learners participated, including 14 hem/onc fellows, 1 APP hem/onc fellow, and 3 internal medicine residents. Three of four teams escaped within 1 hour (mean completion time, 52 minutes). All participants provided positive verbal feedback. Fifteen learners completed the post-activity survey, and all respondents reported satisfaction with the activity and would recommend it for future fellows. One-word descriptors included “engaging,” “fun,” and “challenging.” Most respondents (93.3%) agreed that the activity reinforced key hem/onc concepts and improved confidence in clinical problem-solving. All learners felt the activity supported learning, and 93.3% reported that collaboration enhanced the learning experience. Participants identified team-based problem solving, clinical application, and interactive puzzles as the most effective components. **Conclusions:** A hem/onc escape room resulted in high learner satisfaction and reinforced hem/onc knowledge and clinical problem-solving. This feasible, fun, and innovative activity complements traditional fellowship education by leveraging adult learning principles through gamified, team-based learning and should be incorporated into training programs’ curriculum. Research Sponsor: None.

Career destination effects of receipt of the American Society of Clinical Oncology Young Investigator Award. First Author: Vince D. Cataldo, Department of General Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Successful funding during training has long been recognized as a predictor for a career in academic medicine.[1] Among hematology and medical oncology fellows, the American Society of Clinical Oncology Young Investigator Award (ASCO YIA) often serves as a fellow’s first attempt to obtain extramural research funding. Whether receipt of the ASCO YIA predicts for an academic career in hematology and medical oncology is unknown. **Methods:** A retrospective, exploratory analysis was conducted using data from 15 consecutive graduating classes from the fellowship program of a large destination cancer center. For each graduate, data regarding submission of an ASCO YIA proposal and the results of each submission were collected. To determine if receipt of the ASCO YIA correlated with an early career and retention in academia, we explored data on each graduate’s initial and current job placement. Correlation of each physician’s area of subspecialization compared to the focus of the ASCO YIA proposal was also investigated. **Results:** From 2011-2025, a total of 214 graduates were identified, and 211 (98.6%) applied for the ASCO YIA. Eighty-three (39%) applicants were awarded the ASCO YIA. Among the entire cohort of applicants for the ASCO YIA, 157 (74%) graduates sought an initial career in academia. Of the fellows who were awarded the ASCO YIA, 74 of 83 (89%) started their careers in academia compared to 83 of 128 (65%) for those who were not awarded the ASCO YIA (odds ratio [OR], 4.46; 95% confidence interval [CI], 2.04 to 9.74; P = 0.0002). Of the fellows awarded the ASCO YIA, 66 of 83 (80%) currently remain in academia compared to 51 of 128 (40%) for those who were not awarded the ASCO YIA (OR, 2.57; 95% CI, 0.29 to 1.60; P = 0.0038). Of the fellows who were awarded the ASCO YIA and sought careers in academia, 69 of 74 (93%) began their academic career in the same subspecialty as the focus of their ASCO YIA proposal, and 59 of 66 (89%) remain in that subspecialty. **Conclusions:** Among applicants for the ASCO YIA, recipients are more likely than non-recipients to begin careers in academic hematology and medical oncology positions and to remain in academia. In addition, early funding through the ASCO YIA predicts for retention of academic hematologists/oncologists in their subspecialty of early research and funding. These results emphasize the need for enhanced funding to support these awards with a goal of promoting early careers in academic hematology and medical oncology. To further validate these results, a multi-institutional analysis is planned. Reference: 1. Brass LF, Akabas MH, Burnley LD, Engman DM, Wiley CA, Andersen OS. Are MD-PhD programs meeting their goals? Oncomovies: Cancer in cinema from early sound film to 2025. First Author: Luciano de Fiore, Il Pensiero Scientifico Editore, Rome, Italy

Background: Cinema has played a relevant role in shaping public representations of cancer, influencing social perceptions of illness, medical care, prognosis, and the patient–physician relationship. Over time, cancer narratives in film have evolved alongside medical knowledge, therapeutic advances, and cultural attitudes toward disease, suffering, and death. Building on previous analyses presented at ESMO (2012) and a systematic review published in 2014, this study provides an updated overview of how cancer has been portrayed in cinema up to 2025. **Methods:** We conducted a cross-sectional descriptive analysis of feature films in which cancer played a prompt, relevant, or plot-driving role. Films were identified through major movie databases (IMDb, AllMovie, MyMovies) and previous curated filmographies. Each film was independently reviewed and coded using a standardized data extraction framework including year of production, country, patient demographics, cancer type and anatomical classification, stage or phase of disease when specified, diagnostic and therapeutic representations, healthcare professionals’ roles, and narrative outcome. Data were aggregated and analyzed descriptively. **Results:** A total of 255 films produced between 1939 and 2025 were included. The majority originated from North America and Western Europe, with a progressive increase in geographic diversity after 2000. Solid tumors accounted for approximately 75% of depicted cancers, followed by hematologic malignancies (about 19%). The most frequently represented cancer types were breast cancer, brain tumors, leukemia, and lung cancer, while several high-incidence cancers in real-world epidemiology remained underrepresented. Central nervous system tumors and breast cancer were the most common anatomical classifications. When reported, cancer was often portrayed at an advanced or metastatic stage. Treatments were shown in most films, with chemotherapy being the most frequently depicted modality, followed by surgery and palliative care. Healthcare professionals appeared in the majority of narratives, though with varying degrees of realism. Death remained a common narrative endpoint. **Conclusions:** This updated analysis confirms persistent narrative patterns in cinematic representations of cancer, including a preference for younger patients, specific tumor types, and dramatic disease trajectories. While recent films show increased attention to diagnostic processes and treatment complexity, discrepancies between cinematic portrayals and epidemiological reality remain substantial. Oncomovies may represent both a valuable cultural resource for medical education and a potential source of misconceptions, underscoring the importance of critical engagement with cancer narratives in film. Research Sponsor: None.

Training fellows in genomic oncology: A pilot team-based workshop. First Author: Lauren O'Loughlin, Beth Israel Deaconess Medical Center, Boston, MA

Background: Genomic oncology (GO) is central to diagnosis and management of patients with cancer. However, GO training is an unmet need for hematology/oncology (H/O) fellows. The Training Fellows in Genomic (TFIG) Working Group developed a team-based GO workshop, with goals of creating a "train-the-trainer" experience for faculty and improving fellows' GO knowledge. **Methods:** Ten North American H/O fellowship programs participated in the TFIG pilot. Cross-disciplinary faculty (H/O fellowship program leaders [PL] with local GO faculty experts) participated in (2) 60-minute virtual "train-the-trainer" sessions on team-based learning (TBL) and GO content. Faculty then led (2) 120-minute case-based TBL workshops for fellows at their home institutions: 1) methodology and selection of cancer gene panels, and 2) result interpretation and clinical utility. Participating faculty and fellows were sent a post-workshop survey. Fellows received an additional follow-up survey seven months after workshop participation. **Results:** 96 fellows and 24 faculty participated in the TFIG workshop. 68 fellows (71%) and 21 faculty (88%) completed the post-workshop survey; 60 fellows (62%) completed the follow-up survey. In addition to H/O PL, workshop faculty included pathologists (n=2), genetic counselors (n=2), laboratory geneticists (n=2), medical geneticists (n=1), and genomics professors (n=1). Most (90%) felt train-the-trainer sessions were helpful for workshop preparation. All agreed/strongly agreed that the workshop will help fellows as practicing oncologists. All would recommend the workshop to other fellowship programs. While most fellows (88%) reported using GO in their clinics, 97% had no prior training during fellowship. The majority reported that their pre-workshop knowledge of GO was poor (31%) or fair (43%). Almost all (91%) agreed/strongly agreed that the workshop will help their clinical practice, and most (88%) would recommend this workshop to other fellows. At seven months post-workshop, more than half (52%) of fellows reported greater interactions with genetics professionals and increased use of web-based GO resources introduced during the workshop; 32% reported using knowledge gained during the workshop to educate others. **Conclusions:** Formalized training in GO is required for H/O practice and remains an unmet need for H/O fellows. Our TFIG pilot demonstrated that an interactive GO workshop is feasible through implementation of standardized faculty training and a case-based TBL format. Faculty found the "train-the-trainer" model helpful and noted TFIG content is effective and recommended for fellows. Fellows reported sustained improvements in GO knowledge, increased use of web-based GO tools explored during the workshop, and greater interdisciplinary engagement with GO experts. These findings support the TFIG model as a scalable and effective means to deliver expert-led, team-based GO training for H/O fellows. Research Sponsor: U.S. National Institutes of Health; R25CA168544.

Experiences of a cancer survivorship elective in a US medical school: The first 10 years. First Author: Lee Dong, Frank H. Netter MD School of Medicine, Quinnipiac University, North Haven, CT

Background: Cancer survivorship care is an increasingly important competency in medical education, but early introduction in medical school curriculum is uncommon, and longitudinal evaluation of survivorship curricula is limited. We report here our 10 years' experience of a dedicated UME cancer survivorship course. **Methods:** A 15-week elective was offered to pre-clerkship Y2 students (5-14 participants /y) annually from 2016-25, including one fully remote class in 2020. Attendees had a year of prior longitudinal clinical experience. Key topics of the curriculum were developed from ASCO and NCCN Survivorship Guidelines. Sessions were facilitated by a clinical oncologist (MCF) and co-hosted by rotating guests with clinical experience in cancer care. These included a primary care physician, survivors, caregivers, a medical geneticist, a palliative care nurse, social workers, a nutritionist, and a PT/OT specialist. The final assessment was a proposed individualized survivorship care plan (SCP), based on a one-to-one interview with a survivor. Students completed pre- and post-course surveys, assessing satisfaction with course structure, change in confidence dealing with topics covered, and the course's influence on specialty choice. Likert scale responses (1-4) were analyzed using paired t-tests and Cohen's d for confidence changes. Descriptive statistics summarized satisfaction and career impact. **Results:** Of 102 students participating over 10 years, 90 returned pre/post surveys (88%). Students overall reported a high level of satisfaction with the course (mean 3.60/4, SD 0.49), particularly valuing guest sessions with survivors (3.84/4), caregivers (3.86/4), and social work (3.91/4). They felt the course was adequately rigorous for the M2 level (3.59/4), provided useful skills for future interprofessional collaboration (3.60/4), and was effectively tested by the final assignment (3.47/4). Multimedia assignments were the most valuable to students (3.47/4). Confidence in speaking to and caring for cancer survivors increased very significantly post-course (mean change +0.75, $t = 7.81$, $p < 0.001$, $d = 1.02$), and students felt that the skills they learned were relevant to their future careers (3.53/4). Over half of students (56%) indicated the course strengthened their interest in pursuing an oncology-focused field while another f26% indicated an interest in remaining committed to cancer-related issues in some capacity. **Conclusions:** A dedicated undergraduate cancer survivorship curriculum is novel, feasible, sustainable, and highly valued by medical students. The course produced significant gains in confidence, increased interest in oncology, and highlighted the educational value of interprofessional, survivor-centered learning. Early integration of survivorship education may improve future physician comfort with holistic cancer care and enhance career interest in the field. Research Sponsor: None.

From pathophysiology to prognosis: An oncology curriculum for interdisciplinary palliative care specialists. First Author: Sinthana Ramsey, University of Pittsburgh Medical Center, Division of General Internal Medicine, Pittsburgh, PA

Background: Integrating specialty palliative care (SPC) improves outcomes for patients with advanced cancer, yet effective collaboration requires a shared understanding of the clinical condition. Oncologists report that SPC professionals lack familiarity with new oncologic therapies and their implications for prognosis and decision-making—a gap that can hinder the quality and timing of communication amongst providers as well as goals of care conversations with patients and surrogates. Addressing this gap may enhance the value of SPC consultations and support more aligned co-management of patients with advanced malignancies. Objective: To design, implement, and evaluate an interdisciplinary oncology curriculum for SPC health science professionals (HSPs) at a single institution, with the goal of enhancing SPC's knowledge and confidence in caring for patients with advanced solid-tumor malignancies. **Methods:** An informal needs assessment was conducted with oncologists and palliative care physicians to inform content development. The topics identified to discuss included oncologic terminology, therapeutics, side effects, and disease trajectories for breast, lung, colon, and pancreatic cancer. The curriculum comprised five synchronous virtual sessions delivered over five months. Sessions incorporated active learning strategies grounded in principles of Andragogy and Self-Determination Theory. Medical oncologists reviewed content and participated in sessions. Electronic flashcards were distributed to provide learners asynchronous background knowledge and for post-session reviews. A paired pre/post survey assessed knowledge (via 19 multiple-choice questions for physicians, APPs, and pharmacists) and SPC's attitudes (via 5-point Likert scale). **Results:** Of 79 invited SPC HSPs across nine sites, 51 participated: 17 APPs, 26 physicians, 1 pharmacist, 7 social workers, and 1 chaplain. 87% of the participants attended at least 4 of the 5 curriculum sessions. 67% of the participants utilized the flashcards. Among the physicians, APPs, and pharmacists completing knowledge assessments (pretest n= 42, posttest n= 35), mean scores improved from 53.9% (SD 13.6) to 67.8% (SD 13.1), $p < 0.001$. Confidence in applying oncology concepts increased from 2.7 (0.8) to 3.5 (0.5), $p < 0.001$. Perceived importance of this education remained high throughout (pre 4.2 [0.6], post 4.1 [0.8], $p = 0.609$). **Conclusions:** This oncologist-informed curriculum significantly improved SPC's oncology knowledge and confidence. By equipping specialty palliative care teams with stronger oncologic foundations, this curriculum offers a scalable approach to enhancing interdisciplinary collaboration—potentially improving consultation quality, communication, and shared decision-making for patients with advanced cancer. Enhancing hematology-oncology education through a structured AI-based board review series: An ASCO Leadership Development Education Scholars initiative. First Author: Manasi Ghatge, Department of Hematology Oncology, The Permanente Medical Group, San Francisco, CA

Background: As an ASCO Leadership Development Education Scholars Initiative, structured board review is essential for hematology–oncology fellows to consolidate knowledge, support examination readiness, and strengthen clinical decision-making in an increasingly complex therapeutic landscape. Existing approaches are often fragmented and insufficiently tailored to trainee-specific knowledge gaps. To address this need, we developed a pilot, structured board review series within a single academic fellowship program integrating peer-led teaching, faculty mentorship, and anonymous question-based learning aligned with board examination content and real-world oncology practice. **Methods:** A longitudinal, fellow-led board review curriculum was implemented within a hematology–oncology fellowship program with subspecialty faculty mentorship to ensure clinical accuracy and guideline-based context. Fellows engaged through weekly anonymous board-style multiple-choice questions distributed via Microsoft Teams polls. Questions were curated from ASCO Self-Evaluation Program materials based on high-yield topics identified from ASCO and ASH in-training examinations, with AI-assisted topic prioritization. Objective knowledge acquisition was assessed using identical pre- and post-session questions. Each topic spanned one month with eight pre-session questions and the same eight questions administered post-session. Across five sessions, five fellows answered eight questions per session, yielding 200 learner responses for both pre- and post-intervention assessments. This initiative was conducted as an educational quality improvement project and did not meet criteria for human subjects research. **Results:** Educational gains were observed across multiple high-yield oncology domains, including molecular biomarker interpretation, guideline-directed therapy selection, toxicity recognition and management, and familiarity with emerging treatment modalities. In the pre-test assessment, 63% of questions were answered correctly (126 of 200 responses). Following the educational intervention, 98% of questions were answered correctly (196 of 200 responses), representing an absolute improvement of 70 correct responses (35%). **Conclusions:** This structured, fellow-led, faculty-supported board review initiative represents a feasible and effective model for delivering high-yield oncology education within hematology–oncology fellowship training. The curriculum demonstrated measurable knowledge gains, high trainee engagement, and successful integration of AI-informed topic selection with in-training examination data, highlighting the potential for learner-centered curricula to modernize subspecialty medical education and expand to more fellowship programs. Research Sponsor: None.

Impact of liquid biopsy training on real-world testing practices for advanced NSCLC across Latin America: The OMEGA (LACOG 0424/GBOT) survey. First Author: Leonardo Gil Santana, Latin American Cooperative Oncology Group (LACOG), Porto Alegre, Brazil

Background: The therapeutic landscape of non-small cell lung cancer (NSCLC) has evolved with advances in genomic profiling and the integration of next-generation sequencing (NGS) platforms. Liquid biopsy (LB) enables minimally invasive biomarker-guided treatment across solid tumors, including NSCLC. However, disparities in physicians' familiarity with these tests and limited access to continuing education can affect their optimal implementation. Despite the potential benefits, access to and utilization of LB testing across LATAM remains unexplored. In this LATAM survey, we evaluated oncologist's attitudes and practices related to LB. **Methods:** A cross-sectional survey was conducted to evaluate oncologists' attitudes, practices, and expectations regarding LB use in NSCLC across LATAM. A 33-item questionnaire was distributed between August and December 2024 through the Brazilian Thoracic Oncology Group (GBOT), the Brazilian Society of Clinical Oncology (SBOC), and the Latin American Consortium for Lung Cancer Research (CLICaP). Descriptive statistics summarized the data, and associations were assessed using chi-square or Fisher's exact tests for categorical variables and Student's t-test or Wilcoxon rank-sum test for continuous variables. **Results:** Among the 178 respondents, 84.8% were from Brazil. Most of the oncologists had completed their oncology training between 5 and 20 years prior (61.2%). In terms of clinical exposure, 43.3% reported treating 10 to 30 new patients with lung cancer annually. While 72.5% reported prior use of LB, only 30.0% expressed confidence in interpreting the results. In addition, 50% of respondents (n = 89) reported no formal training in LB over the past three years. Among those reporting educational updates, the most prevalent source of educational updates was ASCO-affiliated platforms (43.8%). Respondents who had received dedicated training during this period were significantly more likely to request LB testing (87.2% vs 60.7%; $p<0.0001$) and to report confidence in interpreting ctDNA results (86.0% vs 53.9%; $p<0.0001$). The most frequently used techniques were DNA-based NGS (38.8%) and reverse transcription polymerase chain reaction (RT-PCR) (43.5%). Most respondents (96.1%) anticipated an increase in the use of LB over the next five years. **Conclusions:** The OMEGA survey indicates that while LB use is common among LATAM oncologists, formal training remains limited. Educational exposure significantly increased both the likelihood of requesting NSCLC testing and confidence in molecular report interpretation. Thus, future efforts implementing structured educational programs are very needed to support the equitable and effective adoption of liquid biopsy throughout LATAM. Research Sponsor: None.

9030 **Poster Session**

Applying learning science principles (LSP) in a workshop (WS) for hematology and oncology (HemOnc) trainees (HOT) about how to use artificial intelligence (AI) in medical education (MedEd) and clinical practice (CP). First Author: Guilherme Sacchi de Camargo Correia, Medical College of Georgia at Augusta University, Augusta, GA

Background: AI use is ubiquitous among HOT and healthcare workers, but with variable base knowledge and comfort level. Its indiscriminate use may be problematic. To address this educational gap, we developed a WS for HOT to assess their use of AI and educate them on how to employ it in MedEd and patient-centered CP based on LSP. **Methods:** A faculty member developed a WS on how to use AI in MedEd and CP based on LSP of analogy, contrasting cases, elaboration, generation, and question driven learning. The WS was for HOT, but faculty could join. It had 3 sections: introduction to basic concepts of AI; principles of the Health Insurance Portability and Accountability Act and protected health information; AI in MedEd; and AI in CP. Sections had real use case examples of AI, for participants to interact, ask questions, and share their personal use cases. HOT were invited to compare and generate examples during the WS, based on their educational and clinical experience and needs. Participants' AI use and self-perceived and objective knowledge about it were assessed in a pre activity survey, a post WS survey, and a post 8 week survey to evaluate long term learning. **Results:** A 2 hour WS with 9 HOT and 2 faculty was completed successfully. 10 participants completed the pre WS survey, and 11 completed the post WS and the post 8 week surveys. 100% of them used generative AI tools before the WS, while 10% had prior training in AI. 90% used AI in personal life and MedEd, 70% used it in CP, and 30% in academic research. Table 1 shows participants' self-assessed knowledge of AI, comfort level in using AI for MedEd and CP, self-assessed preparedness to implement AI in MedEd and CP, and objective knowledge. 8 weeks post WS, 91% of participants reported increased AI use in CP, leading anywhere from slight to significant decreases in time spent on documentation tasks for 91% of them. In MedEd, 73% reported increased AI use, and 82% described slight to significant improvement in the quality of time dedicated to it. 82% described the WS as extremely relevant to their daily responsibilities, and 91% reported confidence navigating ethical and privacy risks of AI in HemOnc. All participants were interested in having a similar WS in the future. **Conclusions:** An LSP based WS about AI increased the self-perceived and objective knowledge of HOT about using this tool in MedEd and CP. It also increased HOT comfort level, preparedness, and efficiency using AI. With the ubiquitous use of AI by HOT, ongoing education about it focused on supporting high-quality patient care should be a part of fellowship curriculum. Research Sponsor: None.

	Pre WS %	Post WS %	Post 8 week %
Moderately/Very knowledgeable about AI	50	91	100
Comfortable using AI in MedEd	60	82	82
Prepared to implement AI in MedEd	30	91	73
Comfortable using AI in CP	40	73	82
Prepared to implement AI in CP	0	91	73
Correct answers on objective assessment	53	68	71

Enhancing oncology board exam readiness through a longitudinal review curriculum. First Author: Sonia Godbole, Ohio State University Wexner Medical Center, Columbus, OH

Background: Due to the rapid pace of medical advancements in cancer care in recent years, passing the medical oncology board exam is a challenging task, with an average failure rate of 8% for first-time test takers since 2020 (American Board of Internal Medicine – ABIM). A needs assessment performed within our large academic Hematology/Oncology (H/O) fellowship program revealed that only a modest majority of fellows felt adequately prepared for medical oncology and malignant hematology board exam topics (53% and 63%, respectively). To improve fellow satisfaction, confidence, and exam performance, we developed a longitudinal board review curriculum that ran parallel to standard didactics. **Methods:** From August 2024 to May 2025, H/O fellows at The Ohio State University participated in a structured, longitudinal board review series covering medical oncology and malignant hematology topic areas. Faculty led monthly Zoom sessions focused on rapid content review and interactive question practice aligned with high-yield concepts per the ABIM Oncology exam blueprint. Questions from existing board review materials were utilized in session creation. Fellows completed pre- and post-surveys assessing satisfaction with the curriculum and confidence across 20 oncology topic domains using a 5-point Likert scale. Attendance and In-Training Exam (ITE) scores were collected. Analyses included descriptive statistics, correlation, and effect size testing. **Results:** Survey response rates (n = 29) were 72% (pre) and 86% (post). Agreement that the curriculum adequately prepared fellows for medical oncology and malignant hematology content on the board exam increased from 53% to 79% and 63% to 92%, respectively. Fellow confidence improved in all 20 topic domains, with an average increase of 0.57 on a 5-point Likert scale. Paired analysis of individual ITE scores could be performed in 19 fellows and demonstrated a mean gain of +58 points from 2024 to 2025. Larger improvements were observed among those who attended $\geq$50% of the 2024-2025 board review sessions (Cohen's $d \approx 0.85$). A moderate positive correlation was also identified between pre-ITE session attendance and the magnitude of the score increase for an individual fellow ($r = 0.47$). Notably, the correlation between attendance and change in ITE score held true for both second and third-year fellows. **Conclusions:** The implementation of a longitudinal, structured oncology board review series for H/O fellows at our institution improved trainee satisfaction with their preparation and confidence regarding all testable topic areas. Furthermore, improvements in ITE scores pre- and post-intervention were more robust in fellows with higher session attendance, regardless of fellowship year. This intervention strategy offers a model for other fellowship programs, H/O or otherwise, seeking ways to improve board exam readiness for their fellow-level learners. Research Sponsor: None.

Bridging educational and research gaps among young oncologists in Latin America: Results from a multicenter survey. First Author: Sergio Cifuentes-Canaval, Instituto de Cancerología Las Américas, Medellín, Antioquia, Colombia

Background: Strengthening oncology research capacity in LATAM is critical to improving regional cancer outcomes. Early-career oncologists play a central role in clinical research, yet structural barriers limit their engagement. Data on educational access, research opportunities, and training needs in LATAM remain limited. This study describes research involvement among early-career oncologists and assesses access to training, mentorship, and career development opportunities, and key barriers to education and research participation. **Methods:** An international, cross-sectional, web-based survey was conducted between Nov/2025 and Jan/2026 among early-career oncologists in LATAM ($<$40 years or $<$10 years post-training). Data included demographics and professional development indicators related to research and training. **Results:** A total of 105 surveys were included and were mainly from Colombia 37.1%, Mexico 23.8%, Argentina 8.6%, and other LATAM countries 30.5%; 58.1% were female. Most were $\leq$40 years 84.8%, with 43.8% aged 30–35; 19.0% were in training and 55.2% early career. 19% reported no research involvement; 71.4% dedicated $<$25% of professional time to research, and only 9.5% $\geq$26%. Most participants (80.0%) received no research-related compensation. Although 51.4% reported access to educational opportunities, only 29.5% perceived adequate access to clinical research. Institutional encouragement was reported by 23.8%, and 39.0% had a clear career development plan. Main training barriers were cost (63.8%), clinical workload (61.9%), and limited institutional support (49.5%). The leading unmet educational need was clinical trials and research methodology (83.8%), followed by precision medicine (64.8%) and leadership/oncology management (57.1%). Overall, 68.6% had prior research exposure—mainly as collaborators (43.8%)—while only 21.9% reported principal investigator experience. Key research barriers included limited clinical time (58.1%), lack of funding (48.6%), and restricted research networks (42.9%). Only 37.1% reported an active mentor; institutional mentorship was available to 22.9%, and formal leadership training to 30.5%. Despite high motivation, structural barriers—including limited protected time, funding, mentorship, and institutional support—restrict research engagement among young oncologists in LATAM. Clinical trials and research methodology as unmet needs underscores a gap between educational access and effective research capacity development. **Conclusions:** Young oncologists in LATAM face limited opportunities for active research participation. Structural barriers—including workload, funding, restricted networks, and limited mentorship—hinder progression toward independent research and leadership roles, underscoring the need for programs that expand participation pathways beyond education. Research Sponsor: None.

Collaborative education to advance equitable prostate cancer care in geographically diverse communities. First Author: Erica Rusie, Talem Health, Trumbull, CT

Background: Although 15%-19% of the US population resides in rural areas, less than 10% of oncologists practice there, driving significant inequities in prostate cancer care. Community clinicians face barriers including limited subspecialist access, multidisciplinary gaps, biomarker testing delays, and low clinical trial participation. As biomarker testing, imaging, and individualized treatments evolve, targeted education is vital to support evidence-based decision-making and equitable delivery. **Methods:** Talem Health implemented a multicomponent CME/CE-accredited initiative for community oncologists managing prostate cancer across the disease spectrum. The initiative featured a 1-hour virtual session at the 2025 Oncology Congress, a 7-session longitudinal Project ECHO (Extension for Community Healthcare Outcomes) telementoring series, and a 1-hour "lessons learned" online activity. Outcomes were assessed via mixed methods: quantitative pre/post-activity assessments and polling, and qualitative data from ECHO case discussions and interviews. Analyses evaluated changes in knowledge, competence, and planned behaviors using Chi-square tests and effect size calculations. **Results:** Over 600 clinicians participated; 91% were hematology/oncology specialists, 93% practiced in community/non-academic settings, and 90% served rural or underserved populations. Identified barriers included limited testing access (36%), treatment access challenges (27%), multidisciplinary gaps (25%), and guideline unfamiliarity (23%). Statistically significant improvements occurred across all knowledge and competence outcomes ($P < .05$ to $P < .01$). Clinicians reported increased intent to incorporate genomic/germline testing; align nmCRPC decisions with guidelines; utilize combination strategies for mHSPC; personalize mCRPC therapy; and implement shared decision-making. Qualitative findings from the ECHO series emphasized the value of peer-to-peer learning. Participants reported higher confidence in managing complex cases and contextualizing new evidence within real-world practice. Ongoing needs were identified regarding risk stratification, rural access barriers, and artificial intelligence applications. Repeated participation in ECHO sessions enabled clinicians to apply new evidence across multiple patient cases over time, reinforcing clinical decision-making through iterative discussion and shared problem-solving. **Conclusions:** This longitudinal educational design effectively supported community oncologists, yielding meaningful gains in knowledge, confidence, and intended practice behaviors. These results demonstrate that tailored education can expand clinician capacity and improve care for patients with prostate cancer in rural and underserved settings. Research Sponsor: This initiative was supported by an independent educational grant from Astellas and Pfizer, Inc.

Investigating interactions between pharmaceutical industry and oncologists in Africa: A secondary analysis of ONCOTRUST-2 study. First Author: Imène Hadji, EPH Ibn Zohr, Guelma, Algeria

Background: Following the hypothesis-generating ONCOTRUST-1 study, ONCOlogy TRansparency Under Scrutiny and Tracking 2 (ONCOTRUST-2) aimed to compare perceptions, understanding, and behaviors related to conflicts of interest (COI) in oncology between high-income countries (HICs) and low- and middle-income countries. This secondary analysis focuses on African countries versus HICs to explore regional differences in interactions with the pharmaceutical industry. **Methods:** We conducted a cross-sectional, survey-based study over two years (January 2024–January 2026). Participants were oncologists practicing in Africa or HICs. Outcomes included perceptions of industry-oncologists' interactions, recognition of COI scenarios requiring disclosure, and self-reported behaviors. Comparisons used Chi-squared or Fisher's exact tests as appropriate. **Results:** A total of 331 oncologists were included (Africa n=133; HIC n=188; 52% women). Most respondents were specialists (61.3%), followed by professors (22.1%) and trainees (15.1%). HIC oncologists reported better understanding of evidence-based medicine (EBM) than African oncologists (p=0.002). Overall ability to identify all COI scenarios requiring declaration did not differ (p=0.45), but HIC oncologists more frequently recognized consulting/advisory roles, direct payments/honoraria, expert testimony, personal funding, and travel/conference support as declarable COI (all $p<0.01$). No group differences were observed for sample drugs, institutional research funding, gifts, or food/beverage paid by industry (all $p>0.05$). Self-reported COI disclosure prevalence was similar between groups (p=0.67), and travel/conference support from pharmaceutical industry did not differ (p=0.14). African oncologists reported fewer consulting honoraria (p=0.001) and lower amounts ($p<0.001$) and less research funding (p=0.02), but more receipt of drug samples (p=0.001). Compared with HIC peers, African oncologists reported poorer disclosure practices (less reporting in publications when COI existed, p=0.001; less disclosure before presentations, $p<0.0001$). Moreover, African oncologists reported more prescription pressure from industry (p=0.013) and lower perceived objectivity in trial appraisal when COI exist (p=0.056). Interestingly, HIC oncologists more often endorsed adopting new drugs despite weak clinical-trial evidence (p=0.003). Knowledge of COI regulations/policies was lower in Africa ($p<0.0001$). Across both groups, support was strong for clearer COI policies, education, and online COI databases. **Conclusions:** African and HIC oncologists showed difference in recognition of specific COI types, disclosure behavior, and policy awareness. Strengthening COI education and implementing clear enforceable policies are therefore needed. Research Sponsor: None.

Hematology-oncology bootcamp: Educational impact of an interactive, guideline-based "101" curriculum. First Author: Chinmay Jani, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL

Background: Hematology-oncology is a rapidly evolving field, and incoming fellows often face early gaps in foundational knowledge during the transition from internal medicine. Mastery of core principles and guideline-based care is required before complex trial interpretation, yet traditional one-way didactic models may be insufficient. To address this, we implemented a structured, longitudinal bootcamp of ASCO- and ASH-aligned sessions delivered through interactive educational formats for fellows across all training years. **Methods:** Bootcamp curriculum included foundational content in anticancer pharmacology, 4 core-domain "101" sessions, NCCN-based case discussions, clinical trial design, academic career development, workshop on difficult clinical conversations and Kahoot-based heme-path and board review. Content was delivered through 6 different interactive formats over the first 10 weeks of the academic year during a weekly protected half-day. Fellows completed anonymous pre- and post-bootcamp questionnaires assessing self-reported confidence on a 5-point Likert scale. Secondary outcomes included overall knowledge improvement, clinical confidence, satisfaction, and educational format preferences. Pre- and post-intervention scores were compared using Mann-Whitney test. **Results:** Sixteen fellows completed the pre-bootcamp survey and 13 completed the post-bootcamp survey. There was statistically significant improvements across all 4 core-domains: General Oncology and foundations (2.9 to 3.8; $p < 0.01$), Classical Hematology (3.0 to 3.7; $p < 0.05$), Hematologic Malignancies (2.8 to 3.7; $p < 0.05$), and Solid Tumors (2.5 to 3.4; $p < 0.05$). Case-based discussions and chalk-talks were the most effective formats, used in both 101 sessions and communication workshop (Table). Moderate or major improvements in overall knowledge as well as inpatient/outpatient clinical confidence were reported by 92.3% fellows. Quality meal options encouraged in-person attendance for 84.6% fellows. Overall satisfaction with the bootcamp was high, with 84.6% fellows reporting agreement or strong agreement. **Conclusions:** Early delivery of foundational concepts through interactive, case-based "101" curricula improves fellows' knowledge and clinical confidence. While traditional lectures remain important for trial interpretation, incorporating interactive formats enhance confidence and satisfaction for fellows. This structured, guideline-based bootcamp represents a scalable model for fellowship training. Research Sponsor: None.

Educational format effectiveness.

Educational Format	Mean Effectiveness Score (1-5) ± SD
Chalk-talks	4.2 ± 0.7
Case-based scenarios	4.2 ± 0.6
Kahoot-based interactive rounds	3.9 ± 0.6
PowerPoint	3.6 ± 0.7
Group-discussions	3.3 ± 1.1
Online Modules	2.5 ± 0.8

Empowering educators: An international virtual mentorship program for hematology/oncology medical educators. First Author: Audrey M. Sigmund, The Ohio State University - The James Cancer Hospital and Solove Research Institute, Columbus, OH

Background: Mentorship is a cornerstone of physician career development, linked to improved well-being, job satisfaction, research productivity, and faculty retention. Clinician educators often cite lack of mentorship as a major barrier to career advancement. We developed and piloted a year-long virtual mentorship program (VMP) with the American Society of Clinical Oncology (ASCO) for hematology/oncology (H/O) career development in medical education. **Methods:** We piloted the program during the 2024-2025 ASCO VMP cycle. Mentors and mentees applied via survey and were matched by committee members based on interests and goals. Each pair was required to complete a mentorship plan, including goals in three domains: professional development/course work, administrative/leadership experience, and scholarly output. We conducted an anonymous retrospective survey of participants via Qualtrics upon cycle completion. Surveys assessed: meeting cadence, satisfaction, goal attainment, and perceptions of career trajectory. Confidence in mentoring and knowledge growth related to pursuing a medical education career were assessed using a 5-point Likert scale with retrospective pre–post ratings. Paired scores were analyzed using the Wilcoxon signed-rank test after excluding ties. **Results:** Thirty-eight mentors and 42 mentees participated in the pilot. Survey response rate was 40% (mentors: 36.8%, mentees: 42.9%). Most met monthly (mentors: 35.7%, mentees: 44.4%) or every 2-3 months (mentors: 42.9%, mentees: 38.9%). Satisfaction was high (mentors: 71.4% "very satisfied," 21.4% "satisfied"; mentees: 66.7% "very satisfied," 27.8% "satisfied"), and nearly all would recommend the program (mentors: 100%, mentees 94.4%). The mentorship plan was discussed by all, with the majority reporting goal achievement (mentors: 92.9%, mentees: 88.9%). Most plan for ongoing mentoring after cycle completion (mentors: 78.6%, mentees: 72.2%). All respondents reported improved perceptions of career trajectory, with all mentors and 92.9% of mentees expressing greater interest in medical education careers and all noting a higher perceived likelihood of success. Mentors' confidence in mentoring increased by a mean of 0.29 on a 5-point scale, but the Wilcoxon test was non-significant ($p = 0.22$). Mentees' knowledge of medical education careers increased significantly with a mean gain of 0.57 ($p = 0.016$). **Conclusions:** Our pilot medical education VMP was highly valued, with strong satisfaction, widespread goal attainment, improved perceptions of career trajectory, and plans for sustained relationships beyond the defined mentorship period. These findings support virtual mentorship as a feasible strategy for clinician educator career development within H/O. Collaboration with and organizational support from professional societies will be essential for scalable, sustainable program development. Research Sponsor: None.

Determinants of leadership attainment among ASCO Leadership Development Program, 2009–2025. First Author: Sarah Marie Abraham, Florida International University, Miami, FL

Background: Determinants of leadership attainment among participants in formal leadership development programs remain poorly characterized. We examined the factors associated with leadership attainment among graduates of the ASCO Leadership Development Program (LDP). **Methods:** We conducted a retrospective cohort study of ASCO LDP participants from 2009–2025. Leadership attainment following participation in the ASCO LDP was the primary outcome, defined as cancer Center Director, Division Chair, Subspecialty Chief, or Program Director, as identified through publicly available data. Participant characteristics included gender, medical training (American medical graduate [AMG], international medical graduate [IMG]), education (MD, MD/PhD, MD/Master's), National Cancer Institute (NCI) designation, geographic region (West, Northeast, South, North Central, non-US), and scholarly productivity (h-index). Descriptive analyses were performed overall and by leadership status. Multivariable logistic regression was used to estimate adjusted associations, including gender–NCI designation interaction. Adjusted odds ratios (AORs) with 95% confidence intervals (CIs) were reported. **Results:** Among 216 eligible participants, 165 (76.4%) attained leadership roles. Participants were predominantly female (n=116, 53.7%), AMGs (n=157, 72.7%), MDs (n=129, 59.7%) and affiliated with NCI-designated centers (n=145, 67.1%). Median h-index was 39 (IQR 25–57), and participants were mostly based in the Northeast (n=77, 35.6%) and West (n=53, 24.5%) regions. Compared with non-leaders, leaders demonstrated higher scholarly productivity, with a higher median h-index (42 [IQR 25–59] vs 29 [IQR 20–44], p=0.042). Using NCI-designated females as the reference group, NCI-designated males demonstrated higher odds of leadership attainment in adjusted models (AOR 2.34, 95% CI 0.96–6.06, p=0.067). Compared with participants from the West, those based in the South demonstrated lower odds of leadership attainment (AOR 0.35, 95% CI 0.12–0.98, p=0.050), independent of gender, education, NCI designation, and year. Leadership attainment remained stable over time, with no consistent temporal trends across subgroups. **Conclusions:** Leadership attainment in ASCO LDP was stable over time and associated with scholarly productivity and geographic region rather than gender or institutional setting. Research Sponsor: None.

Adjusted odds of leadership attainment by gender–NCI designation interaction and geographic region.

Variable	Category	Adjusted OR (95% CI)	p value
Gender × NCI	NCI Female	Reference	–
	NCI Male	2.34 (0.96–6.06)	0.069
	Non-NCI Female	2.04 (0.71–6.43)	0.201
	Non-NCI Male	1.17 (0.43–3.32)	0.760
Region	West	Reference	–
	Northeast	0.64 (0.23–1.65)	0.366
	South	0.35 (0.12–0.98)	0.050
	North Central	0.45 (0.14–1.49)	0.183
	Non-US	0.32 (0.07–1.44)	0.141

Gender × NCI modeled as a combined interaction term (ref: NCI female).

Leader-member exchange (LMX) and workforce outcomes in radiation oncology: A preliminary generational comparison. First Author: Christopher Mendez, NYU Langone Hospital - Long Island, Mineola, NY

Background: Job satisfaction and turnover intention remain crucial outcomes for healthcare organizations incurring substantial costs associated with recruiting and training new employees. Continual workplace stressors continue to challenge retention efforts across clerical and clinical settings. Leader-member exchange (LMX) theory provides a relationship-based framework for understanding these outcomes, emphasizing the quality of the manager-employee relationship. As healthcare workforce increasingly spans generational cohorts, differences in career expectations and workplace values may influence how leadership relationships are perceived. This study examines the association between LMX quality, job satisfaction, and turnover intention, with specific attention to generational differences between older (Baby Boomers and Generation X) and younger (Millennials and Generation Z) employees within a Radiation Oncology department. **Methods:** This quantitative study surveyed healthcare professionals ($>$ 18 years) in a Radiation Oncology department at an academic medical center using purposive sampling. An anonymous, web-based survey was distributed via email and included standardized measures of leader-member exchange (LMX-7), job satisfaction, and turnover intention (TIS-6), along with demographic items. After electronic informed consent was obtained, the average for survey completion was 7.5 minutes. Data was collected over three months, de-identified, and analyzed using RStudio. **Results:** The survey achieved a 74% response rate, indicating broad representation of the department. Mean LMX scores were comparable between older (M = 4.04, SD = 1.06) and younger (M = 3.91, SD = 1.13) employees. Job satisfaction was modestly higher among younger respondents (M = 4.18, SD = 0.73) compared with older respondents (M = 4.00, SD = 0.82), whereas turnover intention was slightly higher in the older group (M = 1.56, SD = 0.87 versus M = 1.45, SD = 0.83). LMX was positively correlated with job satisfaction in both older (r = .58, p = .002) and younger (r = .59, p $<$ .001) professionals. LMX demonstrated an inverse association with turnover intention in both groups, reaching statistical significance among older employees (r = -.57, p = .003) but not among younger employees (r = -.32, p = .069). **Conclusions:** Higher-quality LMX was associated with greater job satisfaction and lower turnover intention among both older and younger healthcare professionals. This emphasizes the importance of leadership relationships in workforce development and stability. These findings support the value of authentic leadership practices grounded in mutual respect and trust. Additionally, these findings highlight the need for future analyses to examine individual generational groups (e.g., Generation X versus Millennials) to better understand variations. Research Sponsor: None.

RECON: A trainee-led, needs-informed professional development and global connectivity model for young oncologists in low- and middle-income countries. First Author: Muhammad Nawaz Khan, Aga Khan University Hospital, Karachi, Pakistan

Background: Oncology trainees and early-career oncologists (ECOs) in low- and middle-income countries (LMIC) face persistent gaps in structured mentorship, research exposure, and non-clinical professional skills, limiting academic development and global engagement. In response, the Residents & Early Career Oncologists Network (RECON) was established in 2024 under the Society of Medical Oncology Pakistan as a national, trainee-led, needs-informed initiative delivering scalable, low-cost, collaborative educational interventions aligned with learner priorities. **Methods:** RECON implemented a needs-informed, multi-component professional development framework for oncology trainees and ECOs ($\leq$5 years post-training) across Pakistan. Core components included: (1) structured mentorship; (2) digital education via the Second Opinion Podcast addressing non-clinical competencies; (3) conference-linked outreach workshops on abstract preparation and peer networking; and (4) monthly international virtual oncology case rounds with young oncologists from Türkiye. Engagement was prospectively tracked, and post-session surveys assessed acceptability and self-reported learning outcomes using 5-point Likert scales (1–5). **Results:** RECON enrolled 104 members (79 trainees, 25 ECOs) and engaged 32 national and international faculty mentors. Baseline survey data (n = 104) demonstrated substantial unmet needs across multiple professional domains, with high interest in professional development (83%), research collaboration (80%), mentorship opportunities (61%), and general networking (60%). Digital education initiatives achieved over 10,000 cumulative podcast views, and three national outreach workshops engaged 155 participants. Post-session surveys from the case rounds series (n = 37) demonstrated high acceptability, with 92% rating sessions as very good or excellent. Participants reported greater confidence in international oncology case discussions (84% rating 4–5) and improved ability to critically appraise alternative management approaches (81% rating 4–5). International perspectives were rated as highly relevant to clinical practice. **Conclusions:** This early evaluation demonstrates the feasibility and acceptability of a national, trainee-led, needs-informed initiative in an LMIC setting. RECON's low-cost, digitally enabled model was associated with high engagement and perceived educational value, particularly in fostering global connectivity and professional confidence among oncology trainees and ECOs. Future evaluation will explore longitudinal outcomes and support iterative refinement, with consideration of adaptation across similar resource-limited contexts. Research Sponsor: None.

The role of coaching in enhancing clinical oncology academic performance. First Author: Amanda Woods Herron, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Oncology faculty in academic medicine navigate a multitude of demands spanning clinical care, research, teaching, and administrative pressures. These forces are the impetus for the implementation of targeted interventions to enhance leadership capabilities. Coaching is a robust intervention and has been recognized as well-suited to meet faculty needs. Despite this recognition and increasing adoption, the impact of coaching on key outcomes in both research and clinical spaces remains underexplored. We leveraged Intentional Change Theory (ICT) to guide our evaluation of an internal coaching program within a large academic hospital in the South-Central United States. ICT articulates how alignment of one's ideal self with their professional goals yields sustained personal transformation and is a useful guide for professional coaching. **Methods:** Through this conceptual framework, we employed a quasi-experimental approach to evaluate the impact of coaching on the research outcomes: clinical trials activated and h-index increase, as well as its components (new publications and new citations). Further, we investigated the impact of coaching on the clinical outcomes of Work Adjusted Relative Value Units (RVUs) and patient experience scores (Press Ganey Care Provider Scores). We conducted this study among a sample of clinical oncology faculty who participated in coaching (N = 189) and N = 200 matched peers who were eligible for but had not yet participated in coaching between 2018 and 2022. **Results:** Analyses revealed coaching positively impacted certain research productivity metrics; notably, faculty who participated in coaching were found to have greater increases in h-index (F(1, 379) = 7.27, p = .007, η2 = .02, Coached M = 2.52, SD = 4.16; Comparison M = 1.69, SD = 1.77), new publications (F(1, 318) = 6.26, p = .013, η2 = .02; Coached = M = 10.81, SD = 11.54; Comparison M = 8.06, SD = 10.18), and new citations (F(1, 379) = 7.43, p = .007, η2 = .02; Coached M = 891.79, SD = 1,598.05; Comparison M = 509.47, SD = 1,054.25) in comparison to faculty who had not engaged with a coach. However, no significant differences were detected between groups in regard to clinical outcomes as measured by Work Adjusted Relative Value Units (RVUs) (F(1, 304) = 2.06, p = .15, η2 = .007; Coached M = 6,316.48, SD = 3,558.46; Comparison M = 6,352.38, SD = 3,975.66), and patient experience scores (F(1,150) = 0.91, p = .34, η2 = .006; Coached M = 95.35, SD = 6.41; Comparison M = 96.22, SD = 3.32), or the research outcome of clinical trial activations (F(1,382) = 0.05, p = .83, η2 = .00; Coached M = .73, SD = 1.62; Comparison M = .49, SD = 1.42). **Conclusions:** Findings suggest coaching can be an effective intervention to enhance certain research outcomes reliant on self-regulation and individual motivation. Yet, initial evidence suggests coaching may be less well-positioned to influence outcomes prone to institutional constraints and governance. Research Sponsor: None.

9041 **Poster Session**

Role expansion of advanced practice providers over 5 years at Hawai'i's NCI Community Oncology Research Program. First Author: Christa M. Braun-Inglis, University of Hawai'i Cancer Center, Honolulu, HI

Background: Advanced Practice Providers (APPs), including Nurse Practitioners and Physician Associates, are key members of the oncology team but historically have not been utilized to their full potential in cancer clinical trials. In alignment with NCI policy and guideline changes in 2020 & 2021, the University of Hawai'i Cancer Center & Hawaii NCI Community Oncology Research Program (NCORP) began formally engaging their APPs to maximize clinical trial efforts. The objectives of the current project were to measure the impact of the APP role expansion and identify factors contributing to enhancement of APP role in cancer clinical trials. **Methods:** Data were gathered from the clinical trial management system analyzing APP contributions annually from 2021-2025, including the number of unique APP accruals (enrolling or referring), APPs serving as enrolling/referring investigators, APPs serving as site principal investigator, APPs reviewing trials for feasibility and scientific merit, and trials led by APPs. Informal interviews were conducted to identify the means of APP engagement. **Results:** From 2021 through 2025 the annual number of patients enrolled or referred to trials by APPs increased from 28 to 103, APPs who accrued patients to trials increased from 4 to 13, APPs serving as site PIs increased from 1 to 6, APPs reviewing trials for feasibility and scientific merit increased from 4 to 6, and trials being led by APPs increased from 13 to 30. In 2025, among trials that allowed APP accrual (symptom management and cancer care delivery), APPs accounted for 51% of this site's total accrual. Factors contributing to APP role in cancer clinical trials were identified as APP leadership and engagement, formal and informal mentorship, and APP educational opportunities. **Conclusions:** APPs can significantly contribute to cancer clinical trials in terms of accrual and leadership as evidenced by these results. This project illuminates potential avenues for expanding APP roles in clinical research. This group will engage APPs on neighbor islands and Guam with an ultimate goal of increasing clinical trial access for underserved populations who reside on these islands. Placing oncology and conflicts of interest in a global context: Evidence from the large international ONCOTRUST-2 study. First Author: Khalid El Bairi, Faculty of Medical Sciences, University Mohammed VI Polytechnic, Ben Guerir, Morocco

Background: Conflicts of interest (COIs) arising from relationships between pharmaceutical industry and oncologists can influence clinical practice and research. Still, global patterns of COIs and disclosure practices remain unexplored. In this interim analysis of ONCOTRUST-2 study, we compared self-reported COI-related practices and financial relationships among oncologists practicing in high-income countries (HICs) versus low-/middle-income countries (LMICs). **Methods:** ONCOTRUST-2 is a multinational cross-sectional survey (January 2024–January 2026) targeting oncologists with at >1 year of experience from LMICs and HICs. Data were collected using snowball sampling through established professional networks and scientific societies. Multivariable logistic regression models were fitted, adjusting for years of professional experience, specialty, current position/seniority, frequency of pharmaceutical industry visits, and the presence of local COI regulations/policies. We report adjusted odds ratios (aORs) with 95% confidence intervals, using a significance threshold of $p < 0.05$. Findings are reported in accordance with the CROSS guidelines. **Results:** A total of 678 oncologists responded to the survey (LMICs: 63.9; HICs: 36.1%) mainly in medical oncology (48.7%), clinical oncology (15.9%) and radiation oncology specialties (15.5%). After adjustment for experience, specialty, position, pharma-visit frequency, and local COI policy presence, HIC oncologists reported higher prevalence of higher-profile industry relationships, including consulting/advisory roles (aOR 2.13, CI: 1.45–3.13; $p < 0.001$) and honoraria/consulting payments (aOR 2.77, CI: 1.29–5.98; p = 0.009). Trips/accommodation support was also more common in HICs (aOR 1.52, CI:1.07–2.17; p = 0.021). A marked gradient was observed for payment magnitude. HICs oncologists were less likely to report no money received (aOR 0.37, CI 0.25–0.54; $p < 0.001$) and more likely to report receiving $2,000–$5,000 (aOR 6.96, 95% CI 3.08–15.75; $p < 0.001$) or > $5,000 (aOR 17.23, 95% CI 4.92–60.32; $p < 0.001$). HICs oncologists reported better COIs disclosure in key academic settings. COIs disclosure before presentations was more common in HICs (aOR 2.72, 95% CI 1.81–4.09; $p < 0.001$), and disclosure in publications was also higher (aOR 1.92, CI: 1.32–2.79; $p < 0.001$) than in LMICs. Reporting non-disclosure was also less frequent in HICs (aOR 0.44, 95% CI 0.25–0.77; p = 0.004). **Conclusions:** Oncologists in HICs reported both greater engagement with and better COI disclosure compared with LMICs. These findings suggest that global COI policies and disclosure infrastructures may differ by national economic context and should be strengthened, with attention to equitable, context-appropriate implementation, regulation governance of COI in LMIC settings. Research Sponsor: None.

Separating facts from feeds: An evaluation of social media videos on Barrett's esophagus. First Author: Sean Bowden, UMass Memorial Medical Center, Worcester, MA

Background: Esophageal cancer is subdivided into two types based on histopathology, squamous cell carcinoma and adenocarcinoma (ACE). While the former has declined in incidence within the US, the latter has seen a marked increase. The natural history of ACE begins with metaplastic and dysplastic changes, coined Barrett's esophagus (BE). This pre-malignant condition is treatable if dysplastic changes are detected early. Surveillance endoscopies are recommended every 3-5 years in individuals with BE, yet the adherence to this recommendation remains low. As the incidence of cancer increases in young individuals, clinicians must adapt their methods for disseminating information. In this study, we graded social media videos about BE and compared scores between medical professionals and non-medical professionals. **Methods:** Utilizing a freshly made account to limit algorithmic tailoring, 106 videos were gathered from TikTok (n=60, 56%) and Instagram (n=46, 44%) using the hashtag "#barrettesophagus." Inclusion criteria included videos covering the pathophysiology, clinical features, diagnosis, treatment, or surveillance of BE. Exclusion criteria were videos that did not cover those topics or were not in English. Videos were graded utilizing the CHAI rubric, a verified, 10-point grading rubric for online videos, where 10 is an ideal score. The graded categories are credibility, transparency, content accuracy, accessibility, and relevance. Medical professionals (MP) were defined as MD/DOs, PhDs, RNs, PA/NPs, or RDs. Engagement was defined as cumulative total of likes and comments. Each video was graded by two independent reviewers. Statistical analysis was performed utilizing unpaired, Welch's t-test. **Results:** Out of the 106 videos, 15 were excluded. From those remaining, 52 videos (49%) were made by MP, and 54 videos (51%) were made by non-MP. This latter group was composed of lay individuals (n=12, 11%), non-medical influencers (n=12, 11%), professional organizations (n=3, 2%), and private groups (n=12, 11%). The average CHAI for videos from MP were 9.7, compared to 7.0 from non-MP ($p < 0.01$). Screening guidelines were covered in 21 videos (20%), with MP covering 15 of them (71%), while only 6 were covered by non-MP (29%). Average engagement on MP videos was 2674, contrasted to 183 in the non-MP group. No videos explicitly stated that AI was involved in making the content. **Conclusions:** Medical professionals produced significantly higher-grade content covering BE than non-medical professionals. Additionally, medical professionals were more likely to report on the updated screening guidelines for BE and on average had higher engagement per video. This highlights the benefit of medical professionals within social media and shows the potential of disseminating updated screening guidelines through modern avenues of information sharing. Digital information–seeking behavior in patients with cancer through storytelling. First Author: Samantha Liu, San Mateo High School, San Mateo, CA

Background: Peer support for cancer patients through narrative interventions can have benefits for quality of life, emotional health, and self-efficacy. This support has classically been provided through static text content on websites, but less is known on whether video-based platforms can preferentially drive patient engagement and self-activation. The Patient Story is a multi-channel platform specializing in video-focused patient-led programs and stories designed to reduce emotional burden and drive patient self-advocacy that leads to informed treatment decision-making. We sought to describe engagement between webpage delivery and a video-based version to understand how different digital platforms could drive varying levels of patient reach and activation, including measurable behavioral changes like motivation to ask doctors questions about treatment and care. **Methods:** Site traffic data relative to benchmarks and participant characteristics visiting The Patient Story were prospectively collected (1/1/22–12/31/25) using Google Analytics 4 for the website and YouTube Studio for the videos. A retrospective review was done on a convenience sample of 4,065 digital platform viewers who then participated in high-touch educational webinars led by patient moderators and multidisciplinary health care providers. Impact was assessed via post-program surveys (n=1,452; 36% response rate) measuring shifts in treatment awareness and behavioral intent. **Results:** A higher percentage of patients who viewed the video platform were female (72.9%) compared to the website (64.4%). Video platform participants tended to be older, with 24% 65+ years old compared to 13% of web participants. Mobile devices were most commonly used for websites (71.2%) and video (54.8%) while 24.8% of those who engaged on video platforms used SmartTV. Reach was substantially higher with the video platform, which generated 72.4M views (average duration on video 6:04) compared to 1.8M website views (89.7% engagement rate). Significant shifts were observed: treatment awareness increased from 3.6 to 4.2 (on a 5-pt scale), and 51.5% of respondents reported a specific intent to discuss the webinar topics (treatment and clinical trial education) with their physician. **Conclusions:** Video first-person storytelling is a novel way of helping patients receive peer support and information. Cancer patients increasingly seek information through mobile and video platforms rather than traditional web searches on desktop computers. Health systems should consider multiple methods of digital communication to increase patient engagement. Research Sponsor: None.

Metric	Value (N=1,452)
Topic Pre-Awareness (5pt scale)	3.6
Topic Post-Awareness (5pt scale)	4.2
% Change in Awareness	+16.7%
Intent to Discuss with Doctor	51.5%
Intent to Research Clinical Trials	20.1%

9045 Poster Session

AI-powered social media listening of oncologist conversations at ASCO 2025. First Author: Sandeep Ghosal, The Larvol Group, LLC, San Francisco, CA

Background: Major oncology congresses generate extensive expert-driven discussion on social media around clinical trial data. However, standardized methods to systematically capture, contextualize, and evaluate these conversations remain limited. LARVOL CLIN is an AI-powered platform that analyzes oncology-focused discussions on X (formerly Twitter), enabling systematic evaluation of clinical trial discourse through assessment of trial-level activity, oncologist sentiment, and engagement. **Methods:** This observational, descriptive analysis evaluated oncology-related posts on X associated with ASCO 2025 (from Apr 23, 2024, to Jan 14, 2025). Posts were identified using predefined conference- and trial-specific keywords and underwent manual validation to confirm relevance to oncology clinical trials. Text-based sentiment analysis was conducted exclusively on posts from oncologists, while trial-related images and polls from both oncologist and non-oncologist X accounts were reviewed for relevance. Validated content was analyzed using oncology-trained large language models, based on ChatGPT 5.1, to interpret clinical context, including efficacy, safety, endpoint status, and potential practice relevance. Sentiment was categorized as negative, neutral, positive, or strongly positive. **Results:** A total of 4,621 oncology clinical trial–related X posts from 651 digitally active oncologists were analyzed for ASCO 2025. Sentiment profiles varied across trials (Table 1). Some studies demonstrated a higher proportion of positive or strongly positive sentiment while others were characterized primarily by neutral assessments reflecting cautious clinical interpretation. Neutral sentiment constituted a substantial share of oncologist posts, often reflecting data interpretation, contextual discussion, or pending clinical relevance. Negative sentiment was typically associated with limited efficacy signals, safety considerations, or unmet expectations. **Conclusions:** This ASCO 2025 observational study demonstrates that AI-driven social listening can systematically capture, contextualize, and quantify expert oncology discourse surrounding clinical trial presentations. LARVOL CLIN enables real-time assessment of oncologist sentiment supporting medical affairs, outcomes research, and strategic communication. Research Sponsor: None.

Digital oncologist activity for selected ASCO 2025 trials.

Trial (Abstract ID)	Views (K)	Not Rated	Negative	Neutral	Positive	Strongly Positive	Total X Posts
PACIFIC15 (8516)	798	47	10	14	25	14	110
DESTINY-Breast09 (LBA1008)	477	32	4	14	24	34	108
SERENA-6 (LBA4)	358	36	9	15	39	26	125
ASCENT-04 (LBA109)	355	22	2	5	25	34	88
ATOMIC (LBA1)	290	25	4	8	27	40	104

LARVOL CLIN represents cumulative views across all X posts for each trial. Sentiment categories reflect AI-generated classification of oncologist X posts.

Baseline bone marrow biopsy (BMBx) performance relative to a mastery-level standard: A SIM-BMBx interval analysis. First Author: Max Farber Kelsten, Northwestern University Feinberg School of Medicine, Division of Hematology-Oncology, Chicago, IL

Background: BMBx is the gold standard diagnostic test for many pathologies. Bedside BMBx is frequently performed by advanced practice providers (APPs) and is required of Hematology-Oncology (HO) fellows by the ACGME. Apprenticeship-style instruction is inconsistent and promotes variable practice. Simulation-based mastery learning (SBML) standardizes instruction to a mastery performance standard (MPS) and is known to improve skill acquisition, retention, and performance. We developed an SBML curriculum for BMBx and herein provide a report of baseline performance. **Methods:** We developed a 28-item BMBx checklist based on experience, literature review, and institutional feedback. Eight experts completed a Modified Angoff Method that set the checklist MPS at 27. Maintaining sterile technique was mandatory. HO fellows, HO APPs, and Internal Medicine (IM) residents were invited to participate. Participants completed a survey of their experience and confidence in performing BMBx. Those with $<$ 3 BMBx were considered "novice," and those with $>$ 3 were "experienced." Participants completed a baseline simulated BMBx (B1) using the VATA Bonnie Bone Marrow Biopsy Skills Trainer. Performance was assessed by investigators via the checklist. The first 15 simulations were co-evaluated for consistency. The protocol was exempted by Northwestern University's IRB. The primary endpoint is the change between B1 and post-SBML score. We performed a descriptive analysis of B1 conducted at 50% enrollment. **Results:** Twenty-five participants completed B1, including 10 APPs, 9 fellows, and 6 residents. Nine were novices (3 APPs, 6 residents). The 16 experienced participants (7 APPs, 9 fellows) had all performed 10 or more BMBx. The median B1 score was 17 (range 6 – 27). One participant, an APP, met the MPS at B1 with a score of 27. The median among APPs, fellows, and residents was 17 (8 – 27), 18 (15 – 23), and 8.5 (6 – 14), respectively. The median among novices was 10 (6 – 19) and among experienced was 18 (12 – 27). Baseline confidence scores were numerically higher for experienced participants (Table 1). **Conclusions:** For the vast majority of practitioners, regardless of professional training and experience with the procedure, BMBx performance does not meet an expert-derived MPS. Experienced practitioners have high confidence despite this. More consistent education of BMBx technique and best practices is needed and may be achieved with SBML. Research Sponsor: Northwestern University Lewis Landsberg Society.

Participant B1 confidence scores.

	N	ID Biopsy Site	Anesthetize Site	Obtain Specimen	Self-Assess Performance	Troubleshoot to Obtain Specimen	Post-Procedure Instruction
Novice	9	30 (10-70)	30 (10-60)	0 (0-50)	0 (0-50)	0 (0-50)	10 (0-80)
Experienced	16	80 (0-100)	90 (0-100)	80 (0-90)	80 (0-100)	70 (0-100)	90 (10-100)

Median (range) confidence in performing an activity from 0 (very low) to 10 (very high).

TPS9047 Poster Session

Improving internal medicine residents' confidence in oncology goals-of-care conversations. First Author: Prathyusha Pandu, Mount Sinai St. Luke's, New York, NY

Background: Internal medicine (IM) residents frequently participate in goals-of-care (GOC) discussions for patients with cancer, yet formal training in oncology-specific serious illness communication remains limited across residency programs. As a result, residents often rely on oncology or palliative care teams to lead these conversations, which may delay timely GOC discussions and subsequent care decisions. Prior educational interventions in serious illness communication have demonstrated improvements in resident confidence; however, oncology-specific GOC training tailored to IM residents is underrepresented. We aim to address this educational gap through the development of a brief, case-based curriculum focused on oncology-related GOC conversations. The objective is to evaluate whether a brief, case-based educational intervention improves IM residents' confidence and knowledge in conducting oncology-related goals-of-care discussions. **Methods:** This is a pilot educational intervention involving IM residents (postgraduate years 1–3) at a large academic residency program. The intervention consists of a 60-minute, case-based session delivered during a scheduled conference. Content focuses on key oncology GOC topics, including prognostic uncertainty, transitions to comfort-focused care, transitions to palliative-intent treatment, and use of structured communication frameworks. Participants will complete pre- and post-intervention surveys assessing self-reported confidence in conducting GOC discussions, comfort discussing prognosis and treatment transitions, and knowledge using two brief case-based vignettes. Pre- and post-intervention survey responses will be compared using paired t-tests. Qualitative feedback will be collected and analyzed thematically. Research Sponsor: None.

Individualized neoantigen therapy intismeran autogene (intismeran) plus pembrolizumab (pembro) in resected melanoma: 5-year update of the KEYNOTE-942 study. First Author: Matteo S. Carlino, Westmead and Blacktown Hospitals, Melanoma Institute Australia, and The University of Sydney, Sydney, NSW, Australia

Background: Intismeran is an mRNA-based individualized neoantigen therapy designed to increase endogenous neoantigen-specific antitumor T-cell responses. The phase 2b KEYNOTE-942 study of high-risk resected melanoma showed clinically meaningful improvements in recurrence-free survival (RFS) and distant metastasis–free survival (DMFS) with intismeran + pembro vs pembro alone at primary analysis. Intismeran + pembro had a manageable safety profile without potentiation of immune-related AEs vs pembro alone. Clinical benefits of intismeran + pembro were sustained at 3 y, with a 49% risk reduction of RFS and 62% risk reduction of DMFS. Intismeran + pembro also induced greater novel T-cell clonal expansion vs pembro, which was positively associated with RFS for intismeran + pembro but not pembro alone. We report results from KEYNOTE-942 after 5 y of planned follow-up. **Methods:** Eligible participants (pts; aged ≥18 y) with resected stage IIIB–IV cutaneous melanoma were randomized 2:1 to receive 9 doses of intismeran 1 mg IM Q3W + 18 doses of pembro 200 mg IV Q3W or 18 doses of pembro 200 mg Q3W alone. Primary endpoint was RFS; secondary endpoints included DMFS and safety. Exploratory endpoints included OS. No alpha was assigned to this analysis. **Results:** From Jul 2019 to Sep 2021,157 pts were randomized to intismeran + pembro (n=107) or pembro (n=50). With an additional 2 y of follow-up (data cutoff, Dec 15, 2025; median planned follow-up, 60.3 [range, 50.5–76.4] mo) after the 3-y analysis, minimal new events occurred. RFS risk reduction for intismeran + pembro vs pembro alone was 49% (HR, 0.51; 95% CI, 0.29–0.89), with landmark 5-y RFS rates of 68.8% (95% CI, 56.3%–78.3%) for intismeran + pembro vs 49.1% (95% CI, 33.3%–63.0%) for pembro alone. DMFS risk reduction was 59% (HR, 0.41; 95% CI, 0.20–0.84). In the intismeran + pembro arm, 7 pts (6.5%) died (disease progression, n=4) vs 7 pts (14.0%) in the pembro arm (disease progression, n=6). There was a trend for improved OS (HR, 0.47; 95% CI, 0.17–1.35); 5-y rate was 92.2% (95% CI, 84.2%–96.3%) for intismeran + pembro vs 71.3% (95% CI, 35.4%–89.6%) for pembro alone. The safety profile of intismeran was consistent with prior analyses. **Conclusions:** After a median 5 y of follow-up, intismeran + pembro continued to prolong RFS and DMFS, along with a trend for improved OS vs pembro alone in pts with high-risk resected melanoma. These long-term findings show that intismeran + pembro treatment benefits were sustained and durable over time, despite all pts having completed study treatment before primary analysis (2021). As reported previously, intismeran was well tolerated, with a manageable safety profile for intismeran + pembro. Intismeran + pembro is being evaluated in a phase 3 study of high-risk resected stage II–IV melanoma (INTerpath-001; NCT05933577) and in studies of pts with other malignancies. Clinical trial information: NCT03897881. Research Sponsor: This research was supported by Moderna, Inc., Cambridge, MA, USA, in collaboration with Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

9501 **Oral Abstract Session**

A phase II study of neoadjuvant ipilimumab-nivolumab-relatlimab (INR) combination immunotherapy in high-risk resectable melanoma. First Author: Ahmad Tarhini, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Advances in the neoadjuvant (neo) setting of locoregionally advanced melanoma have recently transformed practice. However, there continues to be a need to enhance efficacy while deescalating the duration of systemic therapy for those who achieve major pathologic (path) responses (MPR). Recent data support an important role for triplet INR checkpoint inhibitor therapy targeting CTLA4, PD1 and LAG3 in the treatment of advanced melanoma. **Methods:** A phase II trial of INR in patients (pts) with resectable clinical AJCC8 stages IIIB-D. It planned to enroll 20 evaluable pts to neo ipilimumab 1 mg/kg x1 dose combined with nivolumab-relatlimab (NR) 480/160 mg every 4 weeks x2 doses, followed by definitive surgery. Primary endpoint was MPR consisting of complete path response (pCR; 0% viable tumor) and near-pCR (< 10%). Secondary endpoints included other path responses, recurrence free survival, overall survival, event-free survival [EFS: disease progression (PD), recurrence or death] and safety. Adjuvant therapy was given in the absence of MPR. Biospecimens for research from consenting pts were banked at baseline, during treatment, at surgery and in follow up. **Results:** The study enrolled 20 pts August 2024-January 2026, including 7 female, 13 male, 16 cutaneous (2 acral) and 4 unknown primary. Median age was 65 (63-80). Baseline clinical stages were 9 IIIB, 9 IIIC, 2 IIID, including 4 pts with in-transit metastases. Among 19 patients who completed the neoadjuvant phase, all received ipilimumab and the median number of neo NR doses was 2. Among 19 pts who initiated treatment, 5 pts (26%) experienced Gr3 related AEs including colitis (1), encephalitis (1), headache (1), hyperglycemia (1), rash (1), and one pt experienced an event of Gr5 myocarditis. Among 18 pts who completed radiologic tumor response assessment, there were 13 (72%) partial response (PR), 4 stable disease (SD) and 1 disease progression (PD) preoperatively. There was 1 event of death before surgery. One patient declined surgery following deep PR, 1 pt is pending surgery and 1 pt continues in the neo phase. Among 16 pts who had surgery, median time from enrollment to surgery was 73 days. Pathologic responses were 5 path non-response (pNR), 1 near-pCR (microscopic residual disease) and 10 pCR (63%; 95% CI, 38.64 – 81.52). MPR rate (pCR + near-pCR) was 11/16 (69%; 95% CI, 44.40 – 85.84) and none of these patients received adjuvant therapy. Median follow up time from enrollment was 9.8 months. Among all pts, no pt experienced recurrence after surgery to date. **Conclusions:** Neoadjuvant INR demonstrated encouraging clinical activity in pts with resectable clinical stages IIIB/IIIC/IIID melanoma, warranting further investigation. The toxicity profile was consistent with reported data of INR and other combinations in this setting. Mechanistic and biomarker studies related to response, resistance and toxicity are underway. Clinical trial information: NCT06295159. Research Sponsor: Bristol Myers Squibb; H. Lee Moffitt Cancer Center and Research Institute.

9502 **Oral Abstract Session**

A phase 2 study of neoadjuvant nivolumab (nivo) + relatlimab (rela) in high-risk stage II cutaneous melanoma (NeoReNi). First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, Royal North Shore Hospital and Mater Hospital, Sydney, Australia

Background: Patients (pts) with stage II melanoma account for ~50% of those who develop metastatic disease. Checkpoint inhibitor neoadjuvant therapy (NAT) is standard for resectable stage III melanoma (NADINA & SWOG 1801) and pathological response correlates with recurrence. Other NAT benefits include personalised prognosis, tailored subsequent management, and collection of translational specimens to explore response and resistance mechanisms. The NeoReNi II trial aimed to determine feasibility, response and safety of NAT nivo+rela in resectable stage II melanoma. **Methods:** Eligible pts had biopsy (partial) confirmed AJCC (v8) clinical stage IIA (T2b, T3a), IIB (T3b, T4a), or IIC (T4b) cutaneous melanoma with residual macroscopic primary disease at enrolment. IIA pts had ≥20% 5 yr recurrence risk according to Melanoma Institute Australia stage II risk calculator (melanomarisk.org.au). All pts underwent sentinel lymph node (SLN) mapping at baseline and perioperatively, and resection (wide excision + SLN biopsy [RES]) at wk 6 following 2 doses of nivo (480 mg, IV) + rela (160 mg, IV). Pts without major pathological response (MPR) had 11 cycles (Q4W) of adjuvant nivo/rela. FDG PET/CT was performed at baseline; CT prior RES; dermoscopy and reflectance confocal microscopy (RCM) baseline, wk 3 and prior to RES. The primary endpoint was the path complete response (pCR) rate. Secondary endpoints included feasibility of NAT in stage II, RECIST response, RFS, OS, safety/tolerability, surgical outcomes, QOL. Exploratory; biomarker, dermoscopy and RCM analyses. **Results:** From 6 Oct 2023 to 21 Oct 2025, 20 pts were recruited and received NAT, demonstrating partial biopsy leaving residual macroscopic stage IIA-C primary melanoma was feasible. Median age 67 yrs (46-81yrs), 9 females, 8 IIA, 8 IIB and 4 IIC. 18 (90%) pts received both NAT doses. 12 (60%) pts had pCR in the primary melanoma, 1 near-pCR (MPR 65%), 1 pPR and 6 (30%) pNR. Drug treatment related adverse events (TRAE) gd ≤ 2 occurred in all 20 pts (100%); 11 (55%) with fatigue, 8 rash (40%) and 5 arthralgia (25%). 3 (15%) pts had gd 3 (secondary adrenal insufficiency, nephritis, pneumonitis). There were no gd 4 or 5 TRAEs. 1 (5%) pt had a gd 3 AE related to surgery (cellulitis). 19 (95%) pts had no change in SLN mapping from pre to RES. 2 pts with pNR in primary melanoma had postitive SLN and 1 pt with pCR had focal fibrosis within a negative SLN, suggestive of possible treatment effect. Dermoscopy showed regression in all 12 MPR (100%) pts; 11 also showed changes in RCM (collagen reorganization and imflammatory infiltrates) concordant with pathology. At datacut off (11 Dec 25) 2 pts recurred, 5 and 11 mo respectively (both pNR);1 died due to melanoma (15 mo after 1st recurrence; 20 mo after enrolement. Positive SLNBx at pNR). **Conclusions:** NAT with nivo + rela in resectable stage II melanoma was feasible and induced a high rate of pCR and MPR in the primary melanoma. Clinical trial information: NCT05418972. Research Sponsor: None.

A phase II, multicenter, single-arm clinical trial of response-adapted definitive radiotherapy and cemiplimab-rwlc immunotherapy for locally advanced, unresectable cutaneous squamous cell carcinoma: RAMPART. First Author: Christopher Andrew Barker, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Locally advanced (T3-4/N+/M0) and unresectable cutaneous squamous cell carcinoma (LAUCSCC) patients (pts) have been historically treated with definitive radiotherapy (RT) +/- chemotherapy, yielding poor outcomes (18m progression-free survival [PFS] rates of ~38%). More recently, anti-PD1 immunotherapy with cemiplimab (cemi) led to an 18m PFS rate of ~55% in locally advanced pts that were not candidates for RT or surgery. In this prospective, multicenter trial, we assessed definitive RT with neoadjuvant, concurrent, and adjuvant cemi for LAUCSCC pts. **Methods:** Pts with T3-4/N+/M0 LAUCSCC according to local multidisciplinary consensus, ECOG $\leq$2, were enrolled and treated with 2 doses of cemi (350 mg IV q3w). Those with progressive disease (PD) after 2 doses received RT (70 Gy/35 fractions). Those without PD received 2 additional doses of cemi followed by response-adapted RT (50-70 Gy/25-35 fractions) with concurrent cemi followed by adjuvant cemi for a maximum of 1y. The primary endpoint was event free survival (EFS) at 18m after cemi start. Secondary endpoints included safety, response (by RECIST v1.1, see table), quality of life, overall survival (OS) and PFS (after RT start). To test the hypothesis that the 18m EFS was 60%, compared to a historic 18m PFS rate after RT of 38% with 80% power and 5% type 1 error rate, 34 pts were planned for enrollment (accounting for 40% attrition). **Results:** 34 pts (median age 77y, 82% men, ECOG 0/1/2 in 41/53/6%) were enrolled with stage III (41%) and IV/M0 (59%) LAUSCC (56% recurrent, 91% head/neck) between 2022-2024. 85% completed 4 doses of neoadjuvant cemi and 94% completed RT as planned. With median follow up of 18m (range 2-36m), 18m EFS is estimated to be 86% (1 sided 95% CI lower bound of 73%) among all pts. Adverse events were consistent with prior studies of cemi or RT. 18m PFS and OS are estimated to be 86% and 92%. Quality of life analyses are in progress. **Conclusions:** The study met its primary endpoint demonstrating the highest rate of EFS, PFS and OS after treatment of LAUCSCC ever reported. As the largest prospective study of definitive RT for LAUCSCC, the data suggest integrating cemi with RT may benefit appropriate pts. Future studies identifying pts who are best served with this approach are warranted. Clinical trial information: NCT05574101. Research Sponsor: Regeneron; National Cancer Institute (US).

Response over time.

	Complete response	Partial response	Stable disease	Progressive disease	Non-response/Non-progression[1]	NA[2]
Time

OBX-115 engineered tumor-infiltrating lymphocyte (TIL) cell therapy with regulatable membrane-bound IL15 (mbIL15) in patients with advanced melanoma that has progressed on/after immune checkpoint inhibitors (ICI): Phase 2 results. First Author: Allison Betof, Stanford University School of Medicine, Stanford, CA

Background: OBX-115 TIL are engineered to express mbIL15 under regulatory control of the small-molecule drug acetazolamide (ACZ); this engineering abrogates the need for toxic high-dose IL2 cytokine support after TIL infusion. Early data demonstrated differentiated safety and promising efficacy at the recommended phase 2 dose (RP2D; Chesney ASCO 2025). We report additional data evaluating OBX-115 in patients (pts) with advanced melanoma treated at the RP2D in the Agni-01 study. **Methods:** This single-arm, open-label, phase 1/2 study (NCT06060613) assesses safety, tolerability, and efficacy of the OBX-115 TIL cell therapy regimen in pts with advanced non-uveal melanoma and NSCLC (Shoushtari AACR 2025); eligibility was not restricted by LDH, HLA, or melanoma subtype. Phase 1 established an RP2D of OBX-115 1–100$\times 10^9$ cells, with ACZ 500 mg/d orally on Days 0–6 (Wk 1) and 14–20 (Wk 3). Phase 2 evaluates efficacy of the regimen at RP2D by RECIST v1.1 per investigator in pts with $\leq$2 prior lines of therapy. OBX-115 is manufactured from pt tumor tissue (core needle biopsy [CNB] or surgical excision) and infused after low-dose (Cy 750 mg/m^2/d $\times$ 3; Flu 30 mg/m^2/d $\times$ 4) lymphodepletion (LD). ACZ is redosed (7 d) after recovery from LD every 6 wks until Wk 24. Primary data cutoff is 19Dec2025; RECIST efficacy was updated on 22Jan2026. **Results:** OBX-115 was successfully manufactured (median dose 83.4$\times 10^9$ cells) and infused at RP2D schema for 15 pts with advanced melanoma progressing on/after ICI (doublet ICI in 93%); 6/8 pts (75%) with BRAF-mut disease had prior BRAF-/MEK-inhibitor exposure. 2 pts (13%) had tumor tissue procurement by CNB; 4 pts (27%) received outpatient LD. Confirmed ORR was 67% (1 CR, 9 PR, 4 SD; DCR 93%). At median study follow-up of 18.6 wks (range 10.1–73.4), median duration of response was not reached (range 4.6+ to 55.1+ wks). There was no dose-limiting toxicity, ICU transfer, or treatment-related mortality. Immune-related adverse events (AEs) included CRS (G3 n=1; G$<$3 n=4) and hypoxia (G3 n=1; G$<$3 n=2), which responded to short-course steroids; no ICANS was observed. 3 pts reported 4 OBX-115–related serious AEs. 13 pts were alive as of the datacut. **Conclusions:** OBX-115 TIL cell therapy at RP2D demonstrated encouraging efficacy in 2/3L advanced non-uveal melanoma, an area of unmet medical need. Unique aspects of the OBX-115 regimen, such as low-dose LD, ACZ-inducible mbIL15 expression, and CNB-enabled manufacturing, were associated with manageable side effects and compare favorably with other adoptive TIL approaches. Data support continued investigation of OBX-115 in the ongoing phase 2 portion of Agni-01 and planned registrational study. Clinical trial information: NCT06060613. Research Sponsor: Obsidian Therapeutics, Inc.

Patient-level clinical response dynamics in advanced melanoma with anzutresgene autoleucel (anzu-cel), a PRAME-directed T-cell receptor (TCR) T-cell therapy. First Author: Diwakar Davar, University of Pittsburgh Medical Center (UPMC) Hillman Cancer Center, Pittsburgh, PA

Background: Pts with advanced melanoma frequently experience progressive disease (PD) with limited long-term survival following available therapies; there is a need for novel systemic treatments that can induce deep and durable responses. PRAME is a cancer-associated antigen expressed in >50 cancers, including melanoma. Anzu-cel (IMA203) is an autologous PRAME-directed TCR T-cell therapy engineered to recognize intracellular PRAME-derived peptides presented by HLA-A*02:01 and mediates a potent and specific anti-tumor immune response (Wermke et al. ASCO, 2025). A registration-directed phase 3 trial (SUPRAME; NCT06743126) is underway. **Methods:** IMA203-101 is an ongoing, multicenter, phase 1/2 trial evaluating anzu-cel in pts with advanced PRAME-positive solid tumors. Pts underwent lymphodepleting (LD) chemotherapy followed by a single infusion of anzu-cel +/- low-dose SUBQ IL-2. This analysis focuses on melanoma pts in phase 1b treated at RP2D. Data cutoff was Sep 24, 2025. Exploratory analyses evaluated lesion-level patterns of progression among pts evaluable per RECIST1.1. **Results:** As of data cutoff, 33 pts with melanoma were evaluable, incl. cutaneous (n=14), uveal (n=16), and other subtypes (n=3). Most frequent AEs were LD-related cytopenias. AEs of special interest included cytokine release syndrome (CRS), immune effector cell–associated neurotoxicity syndrome (ICANS) and hemophagocytic lymphohistiocytosis (HLH). CRS was predominantly low grade (G1: 36%, G2: 46%, G3: 18%) and occurred early after infusion, with incidence and severity decreasing over time. ICANS (G1: 6%, G3: 6%) and HLH (G2: 3%, G3: 3%) were infrequent. Confirmed ORR was 56% (cCR=1, cPR=17) and DCR was 91%. mDOR was 14.6 mos (4.2-38.2+), mPFS was 6.1 mos (1.4-39.6+), and mOS was 16.2 mos (2.4-39.6+). Responses were observed in target and nontarget lesions, with most pts demonstrating initial lesion responses within the first 6 weeks of treatment; median time to BOR of cPR/cCR was 1.4 mo (1.2-2.8). 25 pts were evaluable for patterns of PD. At the time of PD, 68% (17/25) developed new lesions (NL); 1 pt developed new central nervous system (CNS) lesions. PD via growth of existing lesions was observed in 56% (14/25); 24% (6/25) experienced PD by both growth of existing lesions and NLs. No specific pattern of PD was identifiable in those who achieved cPR compared to those who did not. **Conclusions:** Anzu-cel demonstrated favorable tolerability and induced clinically meaningful and durable responses. Exploratory analyses suggest that the CNS was not a common site for relapse. Future analyses will characterize response dynamics and progression patterns to better define scenarios in which progression following cPR remains clinically manageable, potentially supporting individualized decision-making regarding timing and necessity of subsequent systemic therapy. Clinical trial information: NCT06743126. Research Sponsor: Immatics.

Real-world safety of adoptive cellular therapy with lifileucel in patients with advanced melanoma. First Author: Alexandra Haugh, Massachusetts General Hospital Cancer Center, Boston, MA

Background: Although acute toxicities associated with adoptive cellular therapy using lifileucel are well described and largely occur within the first 2 weeks of treatment, adverse events beyond this early window remain incompletely characterized. We sought to characterize treatment-related adverse events (AEs) with emphasis on those starting or persisting ≥2 weeks after lifileucel infusion. **Methods:** We conducted a retrospective multicenter study across three centers (Moffitt Cancer Center, Massachusetts General Hospital, and Mayo Clinic). Patients with advanced melanoma treated with lifileucel were included. The primary endpoint was incidence and characterization of AEs occurring or persisting ≥2 weeks after standard of care lifileucel infusion. **Results:** Among 79 patients (median follow-up 11 months [95% CI, 9.6–15]), median age was 63 years (range 30–79), 59% were male (n = 47), 41% were female (n = 32), and ECOG PS was 0–1 in 98%. Patients received a median of 5 IL-2 doses (range 0–6). Of 79 patients, 78 experienced treatment-related adverse events that either persisted or occurred >2 weeks after cell infusion. A total of 308 delayed treatment-related adverse events were identified; 96 were new events (31%) and 212 (69%) were continued toxicities that started < 2 weeks after cell infusion. Lymphopenia was the most common delayed or persistent toxicity, occurring in a majority of patients (n = 68/79, 86%). Treatment-associated anemia (n = 59/79, 75%), fatigue (n = 56/79, 71%) and thrombocytopenia (n = 24/79, 30%) were also common. Viral infections occurred in 9.0% (n = 7), including CMV/EBV viremia (n = 1) and respiratory or gastrointestinal viral infections (metapneumovirus, parainfluenza, SARS-CoV-2, and norovirus). Hemophagocytic lymphohistiocytosis (HLH) occurred in 2 patients (n = 2/79, 3%) and was fatal in both cases. No other toxicity related deaths were noted. Autoimmune toxicities directly attributable to TIL included vitiligo in 9% (n = 7; median onset 41 days), uveitis in 5% (n = 4; median onset 26 days), and sensorineural hearing loss in 1% (n = 1; onset 28 days). All patients underwent TIL infusion in the inpatient setting; a total of 14 of 79 patients (18%) were re-admitted after discharge due to treatment-related toxicity (median time from infusion 19 days). **Conclusions:** In this multicenter real-world cohort, toxicities persisting beyond two weeks were largely driven by lymphodepleting chemotherapy–associated immunosuppression and cytopenias. These findings highlight the importance of structured post-discharge monitoring and support ongoing efforts to de-intensify lymphodepleting chemotherapy to improve safety while maintaining clinical benefit. Research Sponsor: None.

Immunologic determinants in procured melanoma tissue as drivers of durable response to tumor-infiltrating lymphocyte therapy. First Author: Lilit Karapetyan, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Predictive biomarkers that identify melanoma tumors capable of generating therapeutically effective tumor-infiltrating lymphocytes (TIL) remain inadequately defined. We conducted an integrated spatial and histopathologic evaluation of resected melanoma specimens to characterize tumor microenvironmental features associated with durable clinical benefit (≥12 months) and improved survival following TIL therapy. **Methods:** Data were extracted from early-phase clinical trials conducted at Moffitt Cancer Center enrolling patients with advanced melanoma treated with TIL. Tumor specimens from 45 of 50 patients undergoing TIL manufacturing were evaluable based on tissue availability. Histopathology, multiplex immunofluorescence, and NanoString GeoMx spatial transcriptomics were performed on procured tumors. Tertiary lymphoid structures (TLS) were defined as organized aggregates of $CD3^+$ T cells and $CD20^+$ B cells and classified as immature or mature based on CD21/CD23 expression. Associations with ex vivo TIL expansion, infused product composition, clinical response, progression-free survival (PFS), and overall survival (OS) were assessed. **Results:** Procurement sites included subcutaneous/soft tissue (78%), lymph node (18%), and lung (4%). Viable tumor content and necrosis were not associated with ex vivo TIL expansion or response. TLS were present in 56% (25/45) of tumors and were strongly associated with clinical response (18/45 responders overall; response rate 56% [14/25] in TLS-positive tumors vs 20% [4/20] in TLS-negative tumors; p=0.014), improved PFS after adjusting for procurement site (HR=0.32; p=0.005) and improved OS (p<0.0001). Evaluation of ex vivo TIL expansion demonstrated that TLS presence did not affect the total number of expanded TIL (p = 0.3) but was significantly associated with a higher proportion of $CD8^+$ T cells within the infusion product (83% vs 56%, p=0.027). Spatial transcriptomics of 132 immune-enriched regions of interest demonstrated that responders exhibited marked upregulation of antigen-presentation and interferon-response programs, including MHC I/II genes, *STAT1/2, IFI6,* and *CXCL9*. A patient-level immune activation score derived from the top 25 responder-associated transcripts correlated with improved PFS (p<0.0001). To independently validate the significance of this immune gene set score, we analyzed an external dataset from the Lauss et al., 2017 cohort. Consistent with our findings, the gene set score was significantly higher in TIL responders compared with non-responders (p=0.048). **Conclusions:** TLS and spatial immune activation signatures in procured melanoma tumors are strongly associated with response and survival following TIL therapy. These findings support the integration of tumor microenvironment biomarkers into patient selection and optimization strategies for TIL therapy. Research Sponsor: None.

9512 **Rapid Oral Abstract Session**

Phase 1b study of a brain-penetrant MEK inhibitor, PF-07799544, plus next-generation BRAF dimer inhibitor, PF-07799933, in advanced *BRAF*-mutant melanoma. First Author: Monica F. Chen, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Treatment of *BRAF*-mutant (mut) melanoma has been transformed by targeted inhibition of MEK and BRAF kinases. However, duration of clinical benefit has been limited by de novo and acquired resistance through RAF-kinases signaling as dimers, poor activity in brain metastases (BMs), and paradoxical activation adverse events (AEs) negatively impacting tolerability. PF-07799544 is an oral, brain-penetrant, reversible MEK inhibitor (MEKi). PF-07799933 is an oral, brain-penetrant, selective BRAF dimer inhibitor (BRAFi) with activity against $BRAF^{V600}$ and non-V600 muts. We report initial results of this next-generation BRAFi/MEKi combination from ongoing phase 1 study. **Methods:** This platform study (NCT05538130) is evaluating PF-07799544 as monotherapy or combined with other targeted therapy for *BRAF*-mut melanoma and other solid tumors. Substudy B is an open-label, multicenter study assessing safety, tolerability, pharmacokinetics (PK), pharmacodynamics, and clinical activity of PF-07799544 + PF-07799933. Dose escalation (DE) enrolled into 4 dose levels patients (pts) with *BRAF*-mut advanced melanoma who had progressed on standard therapy, including pts with BMs. Randomized dose optimization (DO) enrolled pts with $BRAF^{V600}$-mut advanced melanoma previously treated with 1-2 immunotherapy (IO) lines and $\leq$1 BRAFi $\pm$ MEKi line; pts with BMs were eligible if asymptomatic. We report pooled baseline characteristics and safety and separate efficacy. **Results:** As of Nov 12, 2025, 60 pts received $\geq$1 dose of study treatment. At baseline: median age, 54.5 years; female, 50%; White, 95%; ECOG PS of 0, 63%; adrenal insufficiency, 25%; BMs, 53%; and $BRAF^{V600}$ mutation, 95%; 77% received $\geq$3 prior systemic anticancer therapies, 100% received prior IO, 100% of pts with $BRAF^{V600}$ mutation received prior BRAFi $\pm$ MEKi, and 73% received BRAFi $\pm$ MEKi $<$6 months before beginning study treatment. Any-grade treatment-emergent AEs (TEAEs) occurred in 95%; most common ($\geq$20%) were rash (40%), fatigue (37%), diarrhea (32%), and peripheral edema (22%). Grade $\geq$3 TEAEs occurred in 67%; most common ($\geq$5%) were rash (7%), disease progression (7%), anemia (5%), and fall (5%). Dose modifications due to TEAEs (any-causality, treatment-related) included reductions (13%, 13%), interruptions (53%, 33%), and discontinuations (10%, 3%). Objective response rate (ORR; including unconfirmed) by investigator was 27% in 41 DE pts and 32% in 19 DO pts. In pts with baseline BMs, intracranial (IC) ORR was 30% in 23 DE pts and 22% in 9 DO pts. PK showed BRAFi/MEKi exposures consistent with preclinical exposures which showed antitumor activity supporting selected DO doses. **Conclusions:** PF-07799544 + PF-07799933 showed manageable safety and promising systemic and IC antitumor activity in heavily pretreated *BRAF*-mut advanced melanoma. Evaluation of dose expansion cohorts is ongoing. Clinical trial information: NCT05538130. Research Sponsor: Pfizer.

9513 **Rapid Oral Abstract Session**

Combination of vemurafenib with cobimetinib in *BRAF* V600E/K mutated melanoma patients to normalize LDH and optimize immunotherapy with nivolumab and ipilimumab (COWBOY): A randomized, open-label phase 2 clinical trial. First Author: Anne Sophie Blokland, Radboud University Medical Center, Nijmegen, Gelderland, Netherlands

Background: Elevated levels of serum lactate dehydrogenase (LDH) in patients (pts) with metastatic melanoma are associated with reduced response to immune checkpoint inhibitors (ICIs). In a phase 2 trial, we investigated whether upfront reduction of tumor burden and normalization of LDH through six weeks of BRAF/MEK inhibitor (BRAF/MEKi) induction, prior to the initiation of ICIs, could improve response rates compared to standard first-line dual ICI. **Methods:** In this two-arm, multicenter, phase 2 trial, treatment naïve pts with unresectable stage III or stage IV BRAFV600E/K mutation-positive melanoma and elevated baseline LDH levels ($<$ 5x upper limit of normal) were randomized 1:1 (stratified by LDH) to one of two treatment arms. Arm A received 6 weeks of induction with vemurafenib 960 mg bid + cobimetinib 60 mg QD on a 21/7-day schedule, directly followed by four courses of ipilimumab 3 mg/kg q3wk (ipi3) plus nivolumab 1 mg/kg q3wk (nivo1). Arm B directly started with four courses of ipi3 + nivo1. Both arms received response-adapted nivolumab maintenance. The primary endpoint was to compare the best overall response rate (BORR) within 18 weeks from the start of treatment between two treatment arms, as assessed by RECIST 1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and the rate of grade 3/4 toxicity. Exploratory endpoints focused on circulating tumor DNA dynamics (ctDNA), blood transcriptome, and tumor immunoprofiling. ClinicalTrials.gov identifier: NCT02968303. **Results:** Between 2017-2021, 71 pts were randomly assigned, 36 to arm A and 35 to arm B. The study was prematurely terminated due to slow patient accrual (planned accrual: 200 pts). The median follow-up time was 27.9 months (IQR 16.8-57.8). In arm A, the BOR was partial response (PR) in 75% of the pts (36.1% had an ongoing response after treatment switch), stable disease (SD) in 22.2%, and progressive disease (PD) in 2.8%. In arm B, 54.3% had PR, 22.9% SD, and 20% PD (1 pt was not evaluable). BRAF/MEKi induction prior to ICI was associated with a significantly shorter median PFS as compared with upfront dual ICI (4.4 months vs 25.0 months, HR 0.52, 95% CI 0.30-0.91; p=0.02). Median OS was also shorter in arm A (13.5 months), whereas the median OS was not reached in arm B (HR 0.38, 95% CI 0.19-0.68; p=0.002). Treatment-related grade $\geq$3 adverse events occurred in 25 of 36 pts (69%) in arm A and 15 of 35 pts (43%) in arm B. When combining both arms, pts with undetected ctDNA at 6-12 weeks after ICI initiation had significantly longer PFS than those with detected ctDNA (HR 2.05, 95% CI 1.05-4.0; p=0.03). **Conclusions:** BRAF/MEKi induction prior to dual ICI did not improve response rates to ICI and was associated with worse PFS and OS in pts with BRAFV600E/K mutated melanoma and elevated LDH compared to upfront dual ICI. Clinical trial information: NCT02968303. Research Sponsor: Bristol-Myers Squibb; Roche; Paul Speth Fund; PAMgene.

A phase II study of neoadjuvant cemiplimab in hedgehog inhibitor (HHI)–naive basal cell carcinoma of the head and neck. First Author: Hannah L. Kenny, Thomas Jefferson University Hospital, Philadelphia, PA

Background: Surgical resection of locally advanced basal cell carcinoma of the head and neck (BCCHN) often carries significant morbidity. This phase II study seeks to investigate the response to neoadjuvant cemiplimab on surgical morbidity in BCCHN patients. **Methods:** In this prospective, nonrandomized, multicenter, phase II trial (NCT05929664), anti-PD1 and HHI-naive patients with resectable BCCHN received 2 to 6 cycles of cemiplimab (350mg IV Q21 days), followed by surgical resection or biopsy. Surgical plan at enrollment required functional organ sacrifice (orbit, eyelid, ear, nose, lip, or facial nerve). RECISTv1.1 tumor measurements were performed every 2 cycles to determine primary endpoints of ORR and DCR. Patients with PD ($>$20% growth) or SD with 5 to 20% growth at any assessment were offered HHI or surgery. Patients with CR at any assessment proceeded to surgery or directed biopsy. Secondary endpoints included: surgical benefit rate (SBR, defined as rate of functional organ preservation, determined by the investigator, comparing surgical resection to surgical plan at time of enrollment), rate of pCR, safety (CTCAEv5.0), and quality of life (FHNSI, FACE-Q and VFQ-25). Correlative studies include examination of the tumor immune microenvironment related to functional changes in immune cell composition. **Results:** Between August 2023 and September 2025, 33 patients were enrolled: 40-89 yo; 22 M/11 F; sites of disease included eyelid (n=17), orbit (n=4), nose(n=5), lip (n=1), facial nerve (n=1), ear (n=1), and scalp or cheek (n=5). 30 were evaluable: 23 (76.7%) completed 6 cycles. Among the remaining 7 patients, 1 experienced CR after 4 cycles; 1 was taken off therapy for grade 3 myalgia; 1 had SD with 5-20% growth and 2 had PD, and were taken to surgery per protocol; 2 chose surgery due to stagnant response after initial PR. 12 patients (40%) experienced a grade 1-2 treatment-related AE. 1 patient (3.33%) experienced a grade 3 treatment-related AE as above. The ORR was 66.67%. The DCR was 90.0%. Based on RECISTv1.1 criteria, 3.33% (n=1) had CR, 63.33% (n=19) had PR, 23.33% (n=7) had SD, and 10.0% (n=3) had PD as best overall response 8 patients (26.67%) achieved pCR. The SBR was 43.3%, with functional preservation of the eyelid (n=7), nose (n=2), lip (n=1), ear (n=1), or orbit (n=1). **Conclusions:** Neoadjuvant cemiplimab had an acceptable safety profile and shows promising efficacy in the treatment of advanced, surgically-resectable BCCHN. This novel approach may alleviate the morbidity of subsequent surgical resection. (NCT05929664 supported by Regeneron Pharmaceuticals, Inc.). Clinical trial information: NCT05929664. Research Sponsor: None.

9516 **Rapid Oral Abstract Session**

Cadonilimab or ivonescimab plus axitinib in metastatic mucosal melanoma: Results from a phase Ib trial. First Author: Lili Mao, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China

Background: Mucosal melanoma (MM) is a rare and aggressive cancer with a poor prognosis. Unlike its more common counterpart, cutaneous melanoma, MM responds poorly to standard single-agent immunotherapy, such as anti-PD-1 monoclonal antibodies (mAbs), limiting treatment options. This clinical challenge underscores the need for more effective strategies, making combination therapies a clear future direction. The aim is to overcome resistance by targeting multiple pathways simultaneously. The main objective of this study is to explore and compare two distinct immunotherapy backbones—targeting the PD-1/CTLA-4 and VEGF pathways—for their potential in future rational combinations against MM. **Methods:** This is a phase Ib, dose de-escalation and cohort-expansion, open-label trial. The combination dose of axitinib will utilize a "3+3" dose de-escalation design. The starting dose is 5 mg. If dose-limiting toxicity (DLT) is observed at this dose level, the dose for subsequent cohorts will be reduced to 3 mg. Patients with metastatic melanoma receive 10 mg/kg cadonilimab Q3W (cohort 1) or 20 mg/kg ivonescimab Q3W (cohort 2) in combination with 5 mg axitinib BID. Primary endpoints are rate of dose-limiting toxicities (DLTs) and safety. Secondary endpoints are objective response rate (ORR) by investigator assessment, duration of response (DOR), progression-free survival (PFS), overall survival (OS) and overall safety. **Results:** As of December 25, 2025, a total of 28 patients have been enrolled in the study (14 cohort 1; 14 cohort 2). Median follow-up of 13 months. The distribution of primary tumor sites was as follows: oral cavity 14.3%, esophagus17.9%, rectum 32.1%, and cervix 35.7%. 21% had elevated LDH. BRAF status, known for 71% of patients, was positive in 25%. No DLT or treatment related death was observed ，Axitinib was selected as 5 mg BID. 71.4% patients experienced treatment related AE (TRAE) and 17.9% patients experienced Grade 3-4 TRAEs. In cohort 1 , the most common TRAEs include hypothyroidism, hypertension, diarrhea, anorexia and rash. In cohort 2, the most common TRAEs include proteinuria, myalgia, hyperthyroidism, hypertension, abnormal transaminase levels, anorexia and hyperlipidemia. No patient discontinued treatment due to TRAE. ORR, DOR, DCR, and median PFS for all cohorts are shown in Table. **Conclusions:** The combination therapy involving cadonilimab or ivonescimab plus axitinib demonstrates a promising safety and efficacy profile. These findings suggest that such dual-antibody-based regimens could provide synergistic anti-tumor activity with an improved therapeutic index, warranting further clinical investigation. Clinical trial information: NCT06424626. Research Sponsor: None.

Secondary Endpoint	Cohort 1 （n=14）	Cohort 2 （n=14）
PR	5	5
SD	4	5
PD	5	4
ORR	35.7%	35.7%
DCR	64.3%	71.4%
DOR (mo)	6.7	6.4
mPFS (mo)	5.8	8.7
mOS (mo)	NA	NA

9518 **Rapid Oral Abstract Session**

A 3-year landmark overall survival analysis of RP1 plus nivolumab in patients with anti–PD-1–failed melanoma from the IGNYTE clinical trial. First Author: Michael K.K. Wong, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Advanced melanoma has a high mortality rate; however, survival for patients (pts) treated with anti–PD-1–based therapy tends to plateau at 3–4 years, suggesting that pts alive at 3 years are likely to have prolonged benefit. This highlights the need for novel therapies that offer increased survival beyond 3-4 years. RP1 (vusolimogene oderparepvec) is an HSV-1–based oncolytic immunotherapy expressing GM-CSF and a fusogenic glycoprotein (GALV-GP-R$^-$). In the IGNYTE trial (data cutoff [DCO]: 15OCT2024), pts with advanced melanoma that had confirmed progression on anti–PD-1 therapy who received RP1 + nivolumab (nivo) had an objective response rate by RECIST 1.1 of 33.6% (16.4% complete response); median duration of response was 24.8 months. Here, we present a 3-year survival analysis of pts treated with RP1 + nivo from IGNYTE (last pt in: 9MAR2023; DCO: 11JUN2025). **Methods:** Pts ≥18 years with advanced melanoma and confirmed progression while being treated for ≥8 weeks with anti–PD-1 ± anti–CTLA-4 as the last prior therapy were enrolled (NCT03767348). An initial dose of RP1 was administered intratumorally (1×10^6 PFU/mL), followed by up to 7 doses every 2 weeks (Q2W; 1×10^7 PFU/mL) in combination with intravenous nivo 240 mg Q2W/480 mg Q4W for up to 2 years; additional RP1 was allowed if protocol-specified criteria were met. This updated analysis evaluated overall survival (OS) using the Kaplan-Meier (KM) method. **Results:** Of 140 enrolled pts, 49.3% had stage IVM1b–d disease, 55.7% had PD-L1–negative tumors, 46.4% had prior anti–PD-1 + anti–CTLA-4 therapy, and 65.0% had primary resistance to prior anti–PD-1 (ie, progression within 6 months of starting the immediate prior course of anti–PD-1). The median (95% CI) OS was 32.2 (25.8, 39.2) months (the median OS follow-up was 3 years by reverse KM method). OS rates (95% CI) at 1, 2, and 3 years were 75.3% (66.9%, 81.9%), 61.6% (52.5%, 69.4%), and 45.5% (35.8%, 54.7%), respectively. Importantly, among responders (n=47), the 3-year OS rate (95% CI) was 81.8% (65.2%, 91.0%) vs 22.5% (12.6%, 34.2%) for non-responders (n=93). The 3-year OS rates were 41.8% in pts with stage IVM1b–d disease (n=69), 37.2% for those with PD-L1–negative tumors (n=78), 37.4% in pts with prior anti–PD-1 + anti–CTLA-4 therapy (n=65), and 44.8% in pts with primary resistance to anti–PD-1 (n=91). The safety profile for RP1 + nivo remained consistent with prior reports; no new safety signals were seen. **Conclusions:** The 3-year landmark OS rate of 45.5% in the overall population and 81.8% among responders provides further evidence that the deep and durable responses provided by RP1 + nivo translate into long term clinical benefit, including extended OS in pts with melanoma post-confirmed progression on prior anti–PD-1–based therapy. Clinical trial information: NCT03767348. Research Sponsor: Replimune, Inc.

9519 **Rapid Oral Abstract Session**

A phase 2 trial of IO102-IO103 and nivolumab-relatlimab in previously untreated, unresectable melanoma. First Author: James William Smithy, Memorial Sloan Kettering Cancer Center, New York, NY

Background: IO102-IO103 is an investigational cancer vaccine that targets both tumor and immune-suppressive cells in the tumor microenvironment. IO102-IO103 has demonstrated clinical activity in combination with anti-PD-1 monotherapy in advanced melanoma, with concordant clonal T cell expansion observed in the tumor and peripheral blood in patients with radiographic response. IO102-IO103 has not yet been assessed in combination with nivolumab-relatlimab (nivo-rela). **Methods:** In this multicenter, phase 2 trial (NCT05912244) patients with unresectable, previously untreated non-uveal melanoma were treated with subcutaneous IO102-IO103 and intravenous nivo-rela for up to two years. IO102-IO103 was administered every two weeks for eight weeks, and every four weeks thereafter. PD-L1 protein expression was assessed using the 28-8 pharmDx assay on pre-treatment tissue. The primary endpoint was best overall response rate (BORR) by RECIST v1.1, with a plan to reject the null hypothesis based on the proportion of patients with ≥1% membranous PD-L1 staining in the tumor compartment. Secondary endpoints included progression-free survival (PFS), safety assessed by Common Terminology Criteria for Adverse Events v 5.0, and duration of response (DOR). PFS and DOR were summarized using Kaplan-Meier methods. Bulk T cell receptor (TCR) sequencing was performed on peripheral blood mononuclear cells using an RNA-based assay at baseline, week 4 and week 8. **Results:** Among 43 evaluable patients, the BORR was 60% (95% confidence interval [CI]: 44-75%), including 19 patients with partial response and 7 patients with complete response. At database lock (Dec 1 2025), median follow up was 10.1 months (interquartile range 6.1-19.3). The median duration of response was not reached (95% CI: 14, NR) and median PFS was 8.2 months (95% CI 6.8, not reached [NR]). Among patients with PD-L1 negative tumors (n = 25), the BORR was 52% (95% CI 31-72%) and median PFS was 8.2 months (4.2, NR). Grade 3-4 treatment-related adverse events occurred in 9 patients (21%), including adrenal insufficiency (2 patients), acute kidney injury (2), aseptic meningitis (1), arthritis (1), maculopapular rash (1), myositis (1), neutropenia (1), and colitis (1). There were no treatment related deaths. T cell clonal expansion was observed at on-treatment time points compared to baseline in patients with and without radiographic response. **Conclusions:** IO102-IO103 in combination with nivo-rela was associated with a higher objective response rate compared to historical data for nivo-rela alone, meeting the trial's primary endpoint. No unexpected safety signals were observed. These findings support the further clinical investigation of IO102-IO103 with nivo-rela as an initial treatment for unresectable melanoma. Clinical trial information: NCT05912244. Research Sponsor: IO Biotech; NCCN Foundation; National Cancer Institute; P30 CA008748.

9520 Rapid Oral Abstract Session

Response-focused analyses of the impact of circadian rhythm on efficacy of first-line immunotherapy in melanoma. First Author: Hemant Khandelia, Department of Medicine/Division of Hematology and Oncology, University of Washington, and Clinical Research Division, Fred Hutchinson Cancer Cancer, Seattle, WA

Background: Several retrospective studies have associated better clinical outcomes with morning infusions of immune-checkpoint inhibitors (ICI), attributing the same to circadian differences in T-cell activity. However, these studies have largely focused on survival endpoints, which are susceptible to confounding by skewed cohort distributions, treatment heterogeneity or other unknown variables. In this study, we explore the impact of timing of ICI infusions by primarily focusing on objective response as a more direct and immediate measure of immunologic activity, and possibly less susceptible to confounding variables. **Methods:** We conducted a single center, retrospective study of patients with advanced melanoma with response-evaluable disease and treated with an ICI regimen in the first-line setting. We recorded baseline patient and tumor characteristics and the start time of the first ICI infusion. Based on the median start time (~1:00 PM) of all ICI infusions in our clinic, we classified patients into "Early" (before 1:00 PM) and "Late" cohorts (1:00 PM & after). We analyzed objective response rate (ORR) per RECIST v1.1, time-to-response (TTR), duration of response (DOR), progression-free survival (PFS), and overall survival (OS), comparing endpoints between cohorts using logistic or Cox regression, with adjustments for variables including age, sex, ECOG score, and disease stage. **Results:** We identified 216 eligible patients treated between 2014 - 2025, including 78 in the Early cohort and 138 in the Late cohort. Median age was 64 years (range 19 - 95) and 69% were male. Median follow-up duration was 27 months (range 6 days - 12 years). There were no significant differences in baseline patient and tumor characteristics between the two cohorts. ORR for the Early cohort was 64.1% (50/78; complete response [CR] - 34.6%, partial response [PR] - 29.5%) and for the Late cohort was 61.6% (85/138; CR - 28.3%, PR - 33.3%) [p = 0.71]. There were no significant differences in TTR and DOR between the cohorts. The distribution of first ICI infusion start-time in the responders mirrored that of all ICI infusions in all patients with melanoma. Adjusted PFS and OS were also similar between the cohorts (see Table). **Conclusions:** Our response-focused analyses do not suggest an association of early timing of ICI infusion to better efficacy outcomes, in contrast to findings from other studies. Our findings are consistent with the known long terminal half-life of ICI agents, which should provide steady availability of ICI antibodies to immune cells throughout the day. Our results do not support implementing time-based ICI infusion strategies in the oncology clinics. Research Sponsor: None.

Endpoint	Early cohort	Late cohort	Hazard ratio (95% CI)	P-value
PFS, Median months (95% CI)	12 (9, NR)	16 (9, 28)	1.01 (0.68, 1.50)	0.97
OS, Median months (95% CI)	82 (66, NR)	88 (62, NR)	1.07 (0.61, 1.89)	0.82

CI = Confidence interval; NR = Not reached.

Metabolic signatures of response: 2-hydroxybutyric acid as a biomarker in melanoma patients receiving ipilimumab–nivolumab. First Author: Jean Henri Maselli-Schoueri, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: 2-Hydroxybutyric acid (α-HB) is an established biomarker in metabolic disease of insulin resistance and oxidative stress but its role in immuno-oncology remains unclear. This study conducted an exploratory analysis to evaluate whether α-HB could be used as a biomarker in advanced melanoma patients treated with ipilimumab-nivolumab, and its association with treatment response and toxicity. **Methods:** In this single-center retrospective study, 36 patients with unresectable/metastatic melanoma received ipilimumab-nivolumab. α-HB levels were measured by targeted mass spectrometry and measured relative metabolomic signal intensities. Descriptive statistics assessed α-HB across subgroups defined by age, sex and BRAF status. Associations between α-HB and grade $\geq$3 immune-related toxicity, treatment response, and survival at last contact were tested using univariable logistic regression with α-HB entered as a continuous predictor (log2-transformed). Prespecified sensitivity analyses dichotomized α-HB at the median (1.13) and 75th percentile (1.55). For mortality, we additionally derived an exploratory ROC-based Youden threshold to define a "high α-HB" group and report diagnostic performance (specificity, PPV, NPV) and odds ratios. **Results:** Median age was 53.5; 63.9% were male; 80.6% had cutaneous melanoma; 33.3% were BRAF-mutant; 80.6% received first-line therapy. Baseline α-HB was lower in patients who developed grade $\geq$3 toxicity (mean 1.01 vs 1.54; p=0.013) and in responders (1.09 vs 1.60; p=0.021), while it was higher among those who died (1.49 vs 1.06; p=0.045). In logistic models using log2-transformed α-HB, each doubling in α-HB was associated with reduced odds of grade $\geq$3 toxicity (OR 0.165, 95%CI 0.036–0.744; p=0.019) and response (OR 0.268; 95% CI 0.075–0.961; p=0.043; AUC = 0.79; HL p=0.803, where higher p indicates better fit), consistent with lower α-HB marking both toxicity and response. Higher α-HB trended toward increased death risk (OR 3.3 per doubling; p=0.066). Using a Youden-derived cutoff (α-HB $\geq$1.58), high α-HB defined a high-risk subgroup (OR 10.0; 95% CI 1.09–91.4; p=0.041) with high specificity for death (94%); PPV 89% and NPV 56%. **Conclusions:** Elevated α-HB was associated with reduced response, lower incidence of immune-related toxicity, and higher rates of death, suggesting a metabolically suppressed immune phenotype. Further validation is needed to determine whether metabolic interventions could improve immunotherapy outcomes in selected patients. Research Sponsor: None.

Final results and correlative analysis of entinostat (E) plus pembrolizumab (P) in patients (Pts) with metastatic melanoma (MM) previously treated with anti–PD-(L)1 therapy (Tx). First Author: Stergios J. Moschos, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: PD(L)1 inhibitors have transformed MM tx, yet several pts experience resistance. Preclinical data suggest that epigenetic modifications may overcome this. Here, we present the results of an expansion MM cohort treated with E+P following prior anti-PD(L)1 tx. **Methods:** Pts with unresectable stage III/IV melanoma, progression to anti-PD(L)1 and BRAF-targeted tx (if *BRAF*-mutant) were eligible. Pts were treated with E, 5 mg PO qwk, and P, 200 mg IV q3wks. The primary endpoint was to determine the objective response rate (ORR) per the irRECIST criteria. Secondary endpoints included assessment of the safety of E+P tx, progression-free (PFS), and overall survival (OS). Correlative analyses were performed on baseline and on-tx tissues. **Results:** 53 pts were treated (median [mdn] age, 61 years; 60% male; 55% with ECOG performance status of 0; 64% with visceral metastases; 23% with *BRAFV600* mutation), including 43% with primary resistance to anti-PD(L)1 inhibitors, respectively. The mdn number of prior systemic tx was 3 (range 1-8), and 70% of pts had previous tx with CTLA4 inhibitors. 49% pts developed $\geq$ grade 3/4 toxicity, and 19% pts discontinued at least one drug due to adverse events. 10 pts had a partial (n=9) or complete (n=1) response, for an ORR of 19%. The mdn follow-up was 11.5 months (mon), and the mdn response duration was 23.7 mon (range 2.6-45.6+ mon); 9 pts had stable disease $>$ 6 mon. The mdn PFS and OS were 4.0 and 11.5 mon, respectively. Blood analysis showed that the tx significantly decreased Ki67-PD1+ T cells and T regs and significantly increased Ki67-HLA-DR+ and ICOS+ T cells. Analysis of baseline (n=30) and on-tx (n=10) tumor biopsies using NanoString and/or bulk RNAseq showed increased immune infiltration with tx and increased expression of key genes in antigen presentation (*ß2M*), chemoattraction (*CXCL11* & *13*), and IFNγ. Hallmark gene set enrichment analysis suggests that pts bearing inflamed, non-proliferating baseline tumors had a more durable clinical benefit to tx (i.e., no disease progression for $>$ 6 mon). Exploratory analysis using quantitative multiplex immunohistochemistry showed that pts with more durable clinical benefit had baseline tumors with a higher lymphoid-to-myeloid (L/M) ratio, and higher numbers of tumor-infiltrating (TI) CD4+ and CD8+ cells, particularly CD8+PD1+ cells. With tx, pt tumors with clinical benefit maintained a higher L/M ratio, had lower TI CD8+PD1+ cells, and increased density of TI CD20+ cells. TI CD8+PD1+ cells increased in pt tumors without clinical benefit. **Conclusions:** E+P tx in anti-PD(L)1-resistant MM was associated with durable clinical benefit in a pt subset and was well tolerated. Correlative analysis revealed that tx increased inflammation across most analyzed pt tumors; the most significant benefit, however, was observed in pts with pre-existing inflamed tumors. Clinical trial information: NCT02437136. Research Sponsor: SYNDAX Pharmaceuticals.

Clinical characteristics, molecular features, and treatment of primary central nervous system melanoma. First Author: Alexander Xiao, Mayo Clinic Rochester, Rochester, MN

Background: Primary Central Nervous System (CNS) Melanoma is a rare and aggressive malignancy, comprising 1% of melanoma cases and 0.07% of brain tumors. Due to its rarity, its natural history, molecular features and optimal management remain poorly defined. **Methods:** We retrospectively reviewed patients at our institution between January 1998 and October 2025 with primary CNS melanoma or melanocytoma with melanoma transformation. Clinical characteristics, molecular profiling, treatments and survival outcomes were collected. Overall survival (OS) and progression free survival (PFS) were estimated using Kaplan-Meier curves. **Results:** Nineteen patients were identified, including eight (42%) with melanocytoma to melanoma transformation. Median time of transformation was 34.4 months. Thirteen (68%) patients were female with a median age at diagnosis of 59.3 years. Common presenting symptoms were sensory disturbances (58%), pain (53%), motor deficits (37%) and nausea or vomiting (32%). At diagnosis, location of disease was spinal (n=12), intracranial (n=6) and multifocal (n=1). Thirteen patients had leptomeningeal involvement. Molecular profiling was performed in 15 patients, revealing mutations in *GNAQ* (n=7), *GNA11* (n=3), *CKIT* (n=2), *BAP1* (n=1), *EIF1AX* (n=1), and *BRAF v600* (n=1). Thirteen (68%) patients underwent subtotal resection (STR), five (26%) gross total resection (GTR) and one radiation only. Median resected tumor size was 1.7 cm. Seventeen (94%) patients had recurrence at a median of 9.1 months, and four patients underwent repeat surgery. Fourteen (74%) patients received adjuvant radiation and 14 (74%) received immunotherapy, most commonly ipilimumab with nivolumab (71%). Nine patients received chemotherapy: temozolomide (n=5), bevacizumab (n=2) and one each of intrathecal IL-2, tebentafusp, imatinib and encorafenib with binimetininb. Four patients received chemotherapy before immunotherapy. Median OS from diagnosis of CNS melanocytoma or melanoma was 50.9 months (13.4 – 80). Median OS from time of transformation to melanoma or CNS melanoma diagnosis was 24.0 months (11.9 – NA). One-, three- and five-year OS rates were 73%, 53% and 40% respectively. GTR was associated with increased median OS compared to STR (80.0 vs 19.7 months, p= 0.02). Age at diagnosis, immunotherapy, chemotherapy, adjuvant radiation, STR with or without radiation, disease location, leptomeningeal involvement, tumor size $>$3cm and presence of GNAQ mutation were not associated with survival. Median PFS was 3 months with chemotherapy and 5.7 months with immunotherapy. **Conclusions:** To our knowledge, this is the largest single center study of primary CNS melanoma. Outcomes remain poor, with survival primarily associated with GTR. The predominance of *GNAQ* and *GNA11* alterations with rare *BRAF v600* mutations highlight the distinct biology of primary CNS melanoma and need for novel targeted therapies. A propensity score-matched analysis comparing first-line regional, systemic, and intralesional treatments for melanoma in-transit metastases in a contemporary patient population. First Author: Caitlyn Balsay-Patel, Moffitt Cancer Center, Tampa, FL

Background: Unresectable melanoma in-transit metastases (ITM) can pose a significant clinical challenge. Our recently published data comparing first-line treatments for ITM, isolated limb infusion or perfusion (ILI/ILP), immune checkpoint inhibitors (ICI) and intralesional talimogene laherparepvec (TVEC), found superior outcomes with TVEC. However, TVEC was used more often in patients with lower disease burden and earlier stage (IIIB vs. IIIC/D). Therefore, we sought to better investigate these differences with a propensity score-matched (PSM) analysis. **Methods:** A multi-institutional, international IRB- approved retrospective analysis was conducted for unresectable melanoma ITM from 2016-2022. PSM analysis comparing first-line ILI/ILP, ICI, and TVEC for was performed. Patients were matched for stage, number of ITM, anatomical site, CLND status, gender and age. Kaplan-Meier curves (OS, PFS, DMFS) and Cumulative incidence function (MSS) were used to visualize time-to-event outcomes in the PSM cohort, though both methods do not account for the matched structure. **Results:** 274 patients were identified, 120 female/154 male; 96 treated with ILI/ILP, 111 with ICI, and 67 with TVEC. Median follow-up was 40 months (range, 1-80). PSM was performed and identified 36 TVEC–ICI pairs and 27 TVEC–ILI pairs. These were combined resulting in a final cohort of 108 observations (45 TVEC, 36 ICI and 27 ILI). The groups were well balanced. No statistical difference was found for metastasis-free survival (DMFS), progression-free survival (PFS), melanoma-specific survival (MSS), and overall survival (OS) between treatment modalities. TVEC was associated with significant improvement in local PFS (median was 2.2 years (y) for ILI/ILP, 1.5y for ICI and not reached for TVEC, p=0.048). While not statistically significant, a clinical benefit was seen in PFS being longer for TVEC (2.1y for TVEC vs. 1.2y for ILI/ILP and 1.1y for ICI; p=0.2) and OS (not reached vs 2.9y for ILI/ILP and 5.2y for ICI; p=0.2). On mixed effect Cox regression proportional hazard model using the matched data set, there were no significant differences in any of the survival and recurrence outcomes. **Conclusions:** When patients are propensity-matched, there were no significant differences in first-line treatment modalities for unresectable melanoma ITM. Treatment with TVEC did result in clinically meaningful improved overall and local PFS and OS. This supports that selection of ITM therapy should incorporate an individualized approach, incorporating disease distribution, stage, burden, treatment side effects and patient priorities. Research Sponsor: None.

A phase I/IIa, first-in-human, multicenter, monotherapy and combination therapy with nivolumab dose-finding study of [^{212}Pb]VMT01 melanocortin-1-receptor–targeted, image-guided, alpha-particle therapy in subjects with previously treated unresectable or metastatic melanoma. First Author: Zachary Scott Morris, University of Wisconsin, Madison, WI

Background: Melanocortin-1 receptor (MC1R) is a novel target for radiopharmaceutical therapy and is highly expressed on melanoma tumor cells. VMT01 is an MC1R-targeted peptide. ^{203}Pb is used for patient selection via SPECT imaging. Peptide radiolabeling with ^{212}Pb delivers alpha-particle therapy. Here, we present data on the treatment of adult patients with MC1R-positive metastatic melanoma receiving [^{212}Pb]VMT01 either as a monotherapy or in combination with the programmed death-1 (PD-1) checkpoint inhibitor, nivolumab. **Methods:** This is an ongoing phase I/IIa, first-in-human, prospective, multicenter, open-label, radioactive dose-finding and dose-expansion trial. The objectives are to investigate safety, pharmacokinetics, dosimetry, and efficacy. Participants receive up to 3 treatment cycles with either [^{212}Pb]VMT01 3 mCi, 5 mCi, or 1.5 mCi monotherapy, or combination therapy with [^{212}Pb]VMT01 (1.5 mCi) + nivolumab (480 mg, Q4W) or [^{212}Pb]VMT01 (3 mCi) + nivolumab. Participants are evaluated for any DLTs for the first 6 weeks after cycle 1. Efficacy is assessed by RECIST v1.1 criteria by the investigator. **Results:** As of 24 December 2025, 26 participants (53.8% male; median age: 68 years [range: 27-81]) with MC1R-positive metastatic melanoma were enrolled. The median prior systemic therapies was 4. All 26 enrolled participants received $\geq$1 dose of [^{212}Pb]VMT01. No DLTs were reported. All SAEs (including one grade 5 SAE) were attributed to disease progression. Most TEAEs were grade 1 (19.2%) and grade 2 (34.6%). Grade 3 TEAEs occurred in 8 participants (30.8%), 5 on monotherapy and 3 on combination therapy (3 mCi + nivolumab). Of the 22 evaluable participants, 1 PR, 9 SD, and 12 PD were reported. Four participants had progression-free survival of $\geq$6 months. **Conclusions:** [^{212}Pb]VMT01 as a monotherapy and in combination with nivolumab was generally safe and well-tolerated in 26 enrolled participants, with antitumor activity observed at the 3 mCi dose level. These data may be supplemented with a more complete follow-up at the time of the meeting. Clinical trial information: NCT05655312. Research Sponsor: None.

Imneskibart + low-dose subcutaneous IL-2 ± nivolumab in patients with CPI-refractory cutaneous melanoma: Promising results from an ongoing phase 1/2 study. First Author: Meredith McKean, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN

Background: Imneskibart (AU-007) is an AI designed monoclonal antibody binding to interleukin-2 (IL-2) preventing binding to CD25 in the trimeric IL-2 receptor (IL-2 R), while allowing engagement with the dimeric IL-2R, CD122/CD132. Imneskibart-bound IL-2 expands T effector (Teff) and NK cell populations (dimeric IL-2R) without expanding regulatory T cells (Tregs; trimeric IL-2R). **Methods:** Patients (pts) with locally advanced/metastatic cutaneous melanoma were evaluated in Phase 1 (Ph1) dose escalation and in 2 ongoing Ph2 expansion cohorts. Rigorous eligibility criteria were applied requiring pts to have objective progression after $\geq$ 2 cycles of prior doublet checkpoint inhibitors (CPI, anti-PD-1 + anti-CTLA-4 or anti-LAG-3) with confirmation of progression $\geq$ 4 weeks later. Ph2 Cohort 1 evaluated the recommended Ph2 dose (RP2D) of 9 mg/kg imneskibart IV Q2W. Ph 2 Cohort 2 evaluates the RP2D of imneskibart IV Q2W + nivolumab (nivo) 480 mg Q4W. Both cohorts receive subcutaneous (SC) 135K IU/kg aldesleukin dose on Day 1 of first cycle with additional doses of aldesleukin administered at the beginning of each cycle until at least a partial response (PR) is obtained. Tumor reassessment is performed at the end of each 8-week cycle. **Results:** Fifteen pts received imneskibart + aldesleukin: 2 in Ph1 and 13 in Ph2. Fourteen pts were efficacy evaluable. Nine pts had tumor reductions ranging from -1 to -100% including pts with -100% and -58% reductions (continue treatment at 24 and 18 M respectively), and a -48% reduction (14 M on treatment). The median PFS and duration on treatment were 7.6 and 9 M respectively (9.3 M median follow up); 6 pts continue treatment. Nine of 14 evaluable pts have received imneskibart + IL-2 for a longer duration than their prior CPI doublet therapy. Eight pts enrolled in Ph2 Cohort 2 and 2 of the 6 efficacy evaluable pts to date (33%) had PRs with -35% and -31% tumor reductions and continue treatment. Two of 6 had SD and continue treatment. Overall, 67% had disease control at 4 months. Six pts continue treatment. Imneskibart led to a decrease in peripheral Tregs and increase in CD8 cells leading to CD8/Treg ratio increases up to 2 – 3 fold over BL. CD8/Treg ratio increases $>$ 2 fold over BL were associated with longer median duration on treatment, PFS, and OS. Imneskibart + IL-2 was well-tolerated with Grade 3/4 drug-related adverse events (AE) occurring in only 14% of pts and in 0 of the 8 pts who received this combination + nivo. No patient discontinued treatment due to a drug-related AE. **Conclusions:** Compelling anti-tumor activity is observed with imneskibart + IL-2, with a strong emerging signal of enhanced activity with the nivolumab combination in pts with melanoma refractory to doublet CPI therapy. Imneskibart + IL-2–associated Treg reduction likely drives the high disease control rate, supporting durable benefit with prolonged treatment exposure and PFS. Clinical trial information: NCT05267626. Research Sponsor: Aulos Bioscience.

Phase 1 evaluation of the PRAME-targeted ImmTAC brenetafusp in advanced melanoma (Mel). First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, Sydney, NSW, Australia

Background: Brenetafusp (brene) is an ImmTAC bispecific (PRAME $\times$ CD3) therapy that promotes T cell recruitment into tumors. Initial Phase (Ph) 1 data showed acceptable safety, robust T cell activation at target doses (TD) $\geq$ 20 mcg and promising clinical activity in multiple tumors including heavily pretreated cutaneous melanoma (CM) (Hamid 2022, 2024; NCT04262466]). We present updated monotherapy (mono) and PD1 immune checkpoint inhibitor (ICI) combination (combo) safety and efficacy results supporting brene dose selection in Mel (CM, mucosal [Mu] or acral [Ac]). **Methods:** HLA-A*02:01+ Mel patients (pts) who exhausted standard treatments were eligible. Primary objectives: safety and recommended dose; additional objectives included efficacy, biomarkers and ctDNA response. Brene mono was administered intravenously weekly (QW) with 1-2 step-up doses to TD; TD 40 and 160 mcg were evaluated in expansion. Combo was 160 mcg brene QW + 400 mg pembrolizumab (pembro) Q6W. Molecular response: $\geq$ 0.5 log [68%] ctDNA reduction by week 9 (Hamid 2024). T cell fitness defined as 3-gene (TESPA1, CD28 and GPR183) signature in blood (Sacco 2024). Tumor PD-L1 measured by immunohistochemistry, beta2 microglobulin (B2m) by immunofluorescence. **Results:** As of Oct 2025, 66 pts with Mel (median 2.5 prior lines, 100% prior PD1, 30% PD1 refractory [progression $<$6 mo post start of first anti-PD1], 68% St IV-c/IV-d) received brene mono (TD 40, n=16; TD 160, n=24; other TD 10-320 mcg, n=26). The 40-mcg cohort had more favorable baseline prognostic factors (ECOG PS, tumor burden, ctDNA, prior treatment) and T cell fitness. Ten pts (median 2.5 prior lines, 90% prior PD1, 50% prior BRAF/MEKi, 70% St IV-c/IV-d) received brene + pembro. Safety was similar at TD 40 and 160 mcg with Gr1/2 CRS (56% vs 42%) and rash (44% vs 42%) initially. Gr3/4 events occurred in 25% vs 54%: mainly transient lymphocyte decrease, consistent with mechanism. Of 10 pts with prior ICI Gr3/4 irAE, none had recurrence. Combo profile resembled each agent alone. No new safety signals observed. Disease control, RECISTv1.1 response and ctDNA molecular response rates were numerically higher at 160 vs 40 mcg (Table), with similar rates across subgroups typically less responsive to anti-PD1. Overall survival was associated with baseline T cell fitness and tumor B2m, but not with PD-L1 status. **Conclusions:** Brene shows promising monotherapy activity in late-line Mel, including difficult to treat populations, without causing ICI-like irAEs, and can be safely combined with pembro. Ph1 results support 160 mcg as the selected dose in the Ph3 PRISM-MEL trial evaluating brene with nivolumab versus standard nivolumab regimens (NCT06112314). Clinical trial information: NCT04262466. Research Sponsor: Immunocore Ltd.

	N	DCR% (PR + SD)	ORR%	6mo OS%	ctDNA-evaluable N	ctDNA response%

Comparison of baseline gut microbiome features between response subgroups of patients (pts) with advanced melanoma undergoing immune checkpoint inhibitor (ICI) therapy. First Author: Michelle Ferreira, Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Gut microbiome composition has been implicated as a potential biomarker of response to ICIs in melanoma pts, but it is unclear whether baseline gut microbiome composition may predict emergence of specific ICI resistance subtypes (primary vs. acquired resistance) or immune-related adverse events (irAEs). We sought to define clinical characteristics and baseline gut microbiome features that correlate with ICI resistance subtypes and irAEs in melanoma pts. **Methods:** We identified 90 pts from our institution's fecal biorepository of advanced melanoma pts who received ICIs and who had ≥ 1 pre- or on-treatment fecal sample available for 16S rRNA amplicon sequencing. Pts were categorized into 3 responder subgroups: responder (R, no progression on ICI), primary resistance (pR, progression $<$ 6 months from ICI start), or acquired resistance (aR, progression $\geq$ 6 months from ICI start). Associations between clinical covariates and survival were analyzed using Kaplan-Meier and Cox proportional hazards models. Microbial features were compared using alpha and beta diversity metrics and pairwise comparisons at each taxonomic level using Wilcoxon rank-sum tests. **Results:** Baseline demographic and clinical characteristics were similar between subgroups (R, n = 35; pR, n = 32; aR, n = 23). IrAE occurrence rates significantly differed between responder subgroups (p = 0.048). Pts who developed irAEs had significantly longer progression-free survival (PFS) than those without irAEs (median PFS 1412 vs. 106 days, p = 0.026). Later treatment line and receipt of prior ICI were associated with significantly higher hazard ratios (HRs) for death and progression, while resectable disease and development of any-grade irAE were associated with lower HRs for death and progression. There was no significant difference in baseline alpha diversity between responder subgroups or irAE groups. A trend toward differences in baseline beta diversity between responder subgroups was observed (p = 0.084). Abundance of *Faecalibacterium prausnitzii*, a known butyrate producer, was significantly higher in R than pR ($p < 0.001$, $p_{adj} = 0.029$), aR than pR ($p < 0.001$, $p_{adj} = 0.071$), and in pts who did not develop irAEs (p = 0.02). Other operational taxonomic units more abundant in responders (aR vs. pR, R vs. aR/pR) and pts who did not develop irAEs include the short-chain fatty acid (SCFA) producers *Coprococcus comes*, *Dorea longicatena*, and *Blautia glucerasea* ($p < 0.001$, $p_{adj} = 0.071$). **Conclusions:** Although no significant differences in baseline alpha diversity were observed between responder subgroups or irAE groups, responders and those without irAEs had significantly higher levels of SCFA-producing taxa at baseline, suggesting a potential immunomodulatory role for SCFAs such as butyrate in mediating ICI response and protection from irAEs. Prospective, non-interventional, multisite evaluations of TRAQinform Immuno algorithmic quantitative treatment response analysis on treatment intent decisions in metastatic melanoma. First Author: Ryan J. Sullivan, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Molecular imaging plays a critical role in assessing immunotherapy response in metastatic melanoma, but current assessment methods may not fully leverage imaging data to inform clinical decision-making. This study prospectively evaluated whether integrating TRAQinform Immuno quantitative analysis into clinical assessment would alter oncologists' treatment intent in metastatic melanoma patients receiving checkpoint inhibitor combinations. **Methods:** In this prospective, multisite, non-interventional study (NCT05819255), patients with metastatic melanoma receiving dual-agent immunotherapy were enrolled at the University of Wisconsin Carbone Cancer Center and Massachusetts General Hospital Cancer Center. FDG PET/CT scans were acquired at baseline, 3-4 weeks and 12 weeks. All scans were analyzed using a research version of the TRAQinform IQ (TRAQinform) algorithmic quantitative software. At each timepoint, treating oncology and nuclear medicine teams recorded treatment intent before and after review of the TRAQinform analysis report. A cross-site, blinded review was conducted to assess potential status quo bias. **Results:** Twenty-six patients were enrolled (12F, 14M, mean age 65 years), 25 of whom completed all study scans. At week 3-4, 27% of cases (7/26) showed an intent to change treatment after oncologists reviewed the TRAQinform report, (p=1.0). At the 12-week assessment, 56% of cases (14/25) demonstrated intent to change treatment (p=0.0008). Considering either timepoint, 65% of cases (17/26) exhibited a change in treatment intent compared to baseline (p=0.000006). Cross-site analysis indicated minimal influence of status quo bias on intent decisions. **Conclusions:** In this prospective study assessing intent to treat, TRAQinform analysis of standard-of-care FDG PET/CT images influenced oncologists treatment decision in the majority of metastatic melanoma patients, suggesting it provides clinically actionable information. For oncologists managing patients on dual-agent immunotherapy - where treatment decisions often involve uncertainty and clinical judgment, this study demonstrates that TRAQinform offers an additional data-driven tool to support optimal therapeutic decision-making. Long-term efficacy and safety of first-line (1L) nivolumab plus relatlimab (NIVO + RELA) versus NIVO plus ipilimumab (NIVO + IPI) in advanced melanoma: An updated indirect treatment comparison (ITC) with 5-year follow-up data. First Author: Hussein A. Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: An ITC comparing NIVO + RELA and NIVO + IPI, approved dual immunotherapy treatment options for patients (pts) with advanced melanoma, was previously conducted using pt-level data from the pivotal RELATIVITY-047 (RELA-047; NIVO + RELA vs NIVO) and CheckMate 067 (CM-067; NIVO + IPI or NIVO vs IPI) trials (Long JCO 2024). Here we present updated results using 5-year follow-up data from RELA-047. **Methods:** Inverse probability of treatment weighting was used to adjust for cross-trial imbalances in baseline characteristics. CM-067 follow-up was truncated to best align with the follow-up length in RELA-047. Progression-free survival (PFS) per investigator (INV), confirmed objective response rates (ORRs) per INV, overall survival (OS), and melanoma-specific survival (MSS) were analyzed. Outcomes were also evaluated across key subgroups. The weighted NIVO arms from each trial were compared for validation. **Results:** After weighting, key baseline characteristics were balanced for NIVO + RELA (n = 339) and NIVO + IPI (n = 297). Outcomes after weighting were similar between NIVO + RELA and NIVO + IPI (hazard ratio [HR] [95% CI]: PFS, 1.10 [0.90–1.34]; OS, 0.96 [0.77–1.20]; MSS, 0.88 [0.68–1.12]; table). Grade 3–4 treatment-related adverse event (TRAE) rates were numerically lower with NIVO + RELA than with NIVO + IPI (23% vs 62%, respectively). Across subgroups, efficacy appeared similar between treatments, although trends favoring NIVO + IPI were observed for ORRs among pts with *BRAF* mutant disease (59% vs 48%) or serum lactate dehydrogenase $> 2\times$ the upper limit of normal (33% vs 12%). Among pts progression-free at 3 years, both NIVO + RELA and NIVO + IPI were associated with sustained benefit, with 5-year OS of 96% and 94% and MSS of 100% and 98%, respectively. **Conclusions:** Consistent with earlier findings, this updated ITC with a 5-year minimum follow-up from RELA-047 suggests that 1L treatment with NIVO + RELA may have efficacy comparable to NIVO + IPI in pts with advanced melanoma, overall and across most, but not all, subgroups. Results should be interpreted with caution because of differences in study design and the evolving treatment landscape over time. Research Sponsor: Bristol Myers Squibb.

Transposable elements and homotypic niches as drivers of immune dynamics and resistance in melanoma epigenetic-based immunotherapy. First Author: Teresa Maria Rosaria Maria Rosaria Noviello, University of Miami, Miami, FL

Background: Melanoma plasticity facilitates immune evasion and therapy resistance through dynamic cell-state transitions. While epigenetic remodeling critically influences these processes, its role in reshaping the tumor ecosystem under therapeutic pressure remains unresolved. We investigated the molecular and spatial mechanisms underlying clinical response to epigenetic-based immunotherapy in the phase Ib NIBIT-M4 trial (NCT02608437), which evaluated the DNA methyltransferase inhibitor guadecitabine combined with the anti-CTLA4 antibody ipilimumab. **Methods:** We performed longitudinal single-cell multiome profiling (paired snRNA-seq and snATAC-seq) on tumor biopsies collected at baseline and during treatment (weeks 4 and 12) from five melanoma patients (two responders, three non-responders). To resolve the spatial architecture of cell states, we integrated these data with high-resolution spatial transcriptomics (Visium HD) across nine samples. Analyses focused on defining malignant meta-programs (MPs), tumor microenvironment (TME) remodeling, and the regulatory role of transposable elements (TEs). **Results:** Integrated analysis resolved seven malignant MPs. Responders exhibited progressive enrichment of an Antigen Presentation/Interferon program, coupled by coordinated TME remodeling with T- and B-cell expansion. Conversely, non-responders were enriched for a de-differentiated Neural crest-like state. Spatial modeling revealed that this resistant Neural crest-like program relies on homotypic clustering to form compact, centrally localized niches that stabilize its transcriptional identity. In contrast, Wnt/β-catenin subpopulations displayed a bimodal architecture, existing as either cohesive clusters or dispersed plastic cells. Epigenetic therapy reactivated TEs, which provided regulatory signals priming innate immunity and generated tumor-associated antigens that drove immunoediting in responders. Mechanistically, NFATC2 emerged as a master regulator of the Neural crest-like phenotype, and its inhibition promoted re-differentiation toward immunogenic states. **Conclusions:** Epigenetic-based immunotherapy dynamically reshapes the melanoma ecosystem by modulating TE activity and cell-state plasticity. Clinical response links to TE-driven immune priming, whereas resistance is maintained by spatially consolidated Neural crest-like niches stabilized by NFATC2. These findings identify spatial clustering as a principle of resistance and highlight NFATC2 as a potential therapeutic target. Nivolumab + relatlimab (NIVO + RELA) in advanced melanoma: 5-year update of RELATIVITY-047. First Author: Hussein A. Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: NIVO + RELA improved progression-free survival (PFS) vs NIVO in patients (pts) with advanced melanoma in the randomized, double-blind, phase 3 RELATIVITY-047 trial (NCT03470922), leading to regulatory approval as a fixed-dose combination (FDC). The combination also improved clinically meaningful efficacy outcomes (objective response rate [ORR], overall survival [OS], melanoma-specific survival [MSS]) vs NIVO. Here, we report 5-year trial outcomes that characterize long-term response durability and landmark survival. **Methods:** 714 pts were randomized 1:1 to receive NIVO 480 mg + RELA 160 mg FDC or NIVO 480 mg intravenously every 4 weeks, as previously described. PFS per RECIST v1.1 (primary endpoint) was assessed by blinded independent central review (BICR); secondary endpoints included ORR per BICR and OS. MSS (censoring nonmelanoma-related deaths) was a post hoc analysis. **Results:** At data cutoff (25 Sept 2025), minimum potential follow-up was 57.3 months (mo; time from last pt randomization to clinical cutoff date). NIVO + RELA continued to show a clinically meaningful benefit vs NIVO for PFS, OS, MSS, and ORR (table). Improvements in absolute landmark survival rates were observed over 3, 4, and 5 years as follows: PFS, 4%, 7%, and 10%; OS, 7%, 9%, and 10%; MSS, 9%, 10%, and 13%. In addition, NIVO + RELA demonstrated consistent improvement in efficacy outcomes vs NIVO across the majority of key subgroups. Subsequent systemic therapy was received by 40% of pts treated with NIVO + RELA and 41% with NIVO. Secondary efficacy and biomarker analyses will be presented. Grade 3–4 treatment-related adverse events (TRAEs) occurred in 23% of pts treated with NIVO + RELA and 12% with NIVO; TRAEs (any grade) led to treatment discontinuation in 17% and 10% of pts, respectively. No new treatment-related deaths were reported since the 2-year analysis. **Conclusions:** With a follow-up of 5 years, first-line NIVO + RELA continued to demonstrate durable, clinically meaningful long-term improvements in PFS, OS, ORR, and MSS vs NIVO, with median MSS not reached for the combination. Across landmark timepoints, absolute separations in PFS, OS, and MSS rates were maintained and increased at the 5-year follow-up. Safety remained consistent with prior reports, with no new or unexpected safety signals. Clinical trial information: NCT03470922. Research Sponsor: Bristol Myers Squibb.

Circulating tumor DNA (ctDNA) clearance after immune checkpoint inhibition (ICI) with radiotherapy (RT) as a prognostic indicator for patients with advanced melanoma. First Author: Alyssa K. Steimle, University of Wisconsin Carbone Cancer Center, Madison, WI

Background: ctDNA is becoming a useful biomarker for ICI treatment response assessment in advanced melanoma. RT is capable of producing an abscopal effect, potentially enhancing ICI efficacy. The utility of ctDNA monitoring with concurrent ICI and RT remains incompletely explored. Here, we describe the clinical characteristics and survival outcomes of patients with advanced stage melanoma treated with ICI and palliative RT based on ctDNA dynamics. **Methods:** In this multicenter, retrospective study, patients with unresectable stage III/IV melanoma treated with ICI and palliative RT were identified. Patients had prospectively collected, tumor-informed, exome-based, ctDNA monitoring (Natera). Within 3 months prior to RT, patients had a baseline ctDNA level. Patients were separated into 3 cohorts based on nadir ctDNA dynamics within 3 months after RT. Those with undetectable ctDNA were categorized as "ctDNA cleared." Patients with a positive fold ctDNA change were "increasing ctDNA" and negative fold change were "decreasing ctDNA." Hazard ratios for overall survival (OS) probability were determined via log-rank tests and multivariate analysis (MVA) used cox proportional hazard models. **Results:** 50 patients treated with ICI and palliative RT were analyzed. Median follow up was 8.0 months from RT start. Median age was 65 (24-86) and median baseline ctDNA level was 8.9 MTM/mL (0-11390 MTM/mL). Melanoma primaries included: 82% (41) cutaneous, 10% (5) mucosal, 8% (4) unknown primary. ICI regimens included 70% (35) ipilimumab/nivolumab, 16% (8) nivolumab/relatlimab, 2% (1) anti-PD-1/investigational ICI, 12% (n=6) anti-PD-1 monotherapy. 20 patients had ctDNA clearance, 12 patients had decreasing ctDNA, and 18 patients had increasing ctDNA following RT with ICI. The most common RT sites were the CNS (50%, n=25) and skin/soft tissue (24%, n=12), followed by lymph nodes and bone (each 14%, n=7), and lung and liver (each 6%, n=3). Patients with ctDNA clearance had longer OS (p=0.001) compared to those with increasing or decreasing and detectable ctDNA following RT. One year OS was 85.9% with ctDNA clearance, 30.6% with decreasing ctDNA, 22.0% for increasing ctDNA. In a MVA adjusting for age, M substage, radiation site, and melanoma subtype, both decreasing and increasing ctDNA were associated with worse OS compared with ctDNA clearance (HR 5.08 [95% CI, 1.26–20.48, p=0.022] and HR 9.83 [95% CI, 2.69–35.94, p<0.001], respectively). **Conclusions:** Among patients with advanced melanoma treated with ICI and palliative RT, ctDNA clearance is associated with significantly improved OS compared to patients with detectable ctDNA within 3 months following RT. Ongoing prospective studies are needed to understand the long-term clinical impact of RT on ICI-treated patients with melanoma, and better define the role of ctDNA monitoring for this population. Research Sponsor: None.

Optimal timing of circulating tumor DNA (ctDNA) dynamics to prognosticate immune checkpoint inhibitors (ICI) efficacy in patients with advanced stage melanoma. First Author: Vincent T. Ma, University of Wisconsin Madison, Madison, WI

Background: ctDNA predicts relapse in resected tumors, but its role in advanced disease is less defined. We previously reported that early ctDNA changes at 3-4 weeks after ICI initiation can inform treatment response and survival. In this study, we attempt to identify the optimal timing of ctDNA dynamics within 90 days at various windows to better associate with ORR, PFS, and OS outcomes in patients (pts) with advanced stage melanoma treated with ICI. **Methods:** We performed a multicenter retrospective analysis using a personalized tumor-informed ctDNA assay (Natera) on prospectively collected plasma from pts with unresectable stage III/IV melanoma treated with anti-PD-1-based therapy. ctDNA was assessed at baseline and within 90 days of ICI initiation, stratified by ≤30, 31-60, and 61-90 days. Logistic regression evaluated associations between ctDNA change (decrease/stable vs increase) and ORR. Cox proportional hazards models assessed PFS and OS. Pearson (ORR) and Spearman (PFS, OS) correlations were used for continuous ctDNA analyses. **Results:** Among 182 pts, 80% had cutaneous, 11% mucosal, and 9% unknown primary melanoma; 23% had unresectable stage III and 77% stage IV disease. Treatments included ipilimumab/nivolumab (55%), nivolumab/relatlimab (24%), and anti–PD-1 monotherapy (20%). Median follow-up was 12.1 months. Decreasing/stable ctDNA at all timepoints was strongly associated with ORR (p<0.0001), with the greatest effect at 31-60 days (OR 25.38, 95% CI 7.12-90.45). Similar patterns were observed for survival, with improved PFS across all windows and strongest separation at 61-90 days (HR 0.170, 0.101-0.288). OS was likewise improved, most notably at 61-90 days (HR 0.137, 0.058-0.321). Continuous ctDNA change correlated with ORR (r -0.51 to -0.63) and PFS (ρ -0.35 to -0.47); OS correlations were weaker but significant at 61-90 days (ρ -0.21). See Table 1. **Conclusions:** While ctDNA dynamics within 30 days showed prognostic value, associations with ORR, PFS, and OS were strongest and most consistent at 31–60 and 61–90 days. Prospective studies are needed to validate ctDNA for ICI treatment monitoring. Research Sponsor: The Institute for Clinical and Translational Research KL2 Scholars Program at the University of Wisconsin; UL1TR002373 and KL2TR002374.

Anti–PD-1 (PD-1) monotherapy versus combination with anti–CTLA-4 for metastatic uveal melanoma (MUM) patients (pts). First Author: Ines Esteves Domingues Pires da Silva, Melanoma Institute Australia, The University of Sydney, Sydney, NSW, Australia

Background: MUM carries a poor prognosis with few effective treatments, especially for HLA-A*02:01-negative pts. While a subset of MUM pts responds to immune checkpoint inhibitors, the comparative efficacy of IPI+PD1 versus PD1 monotherapy is unclear. This study compares objective response rate (ORR), progression-free survival (PFS), overall survival (OS), and safety between these regimens in MUM. **Methods:** MUM pts treated with PD1 or IPI+PD1 at 15 major melanoma centres (from Australia, Europe, United States and Israel) were included. Demographics, patient and disease characteristics, and clinical outcomes were examined. Univariate and multivariate (MVA) analyses were performed to identify clinical predictors of response and survival. **Results:** Of 412 MUM pts treated, 150 (36%) had PD1 and 262 (64%) received PD1+IPI. Compared to the PD1 group, PD1+IPI-treated pts were younger (64 vs. 70 years; p<0.001), had higher rate of elevated LDH (44% vs. 31%; p=0.037), and more frequently had prior treatment with tebentafusp (6.5% vs. 1.3%; p=0.031). Median follow-up from commencement of PD1+/-IPI was 4.9 years (95% CI 4.7 – 6.1). ORR was higher in IPI+PD1 group (18%) vs. PD1 (9%) (p=0.008), particularly in males (p=0.009), patients with liver metastases (p=0.018) and with lung metastases (p=0.011), with elevated LDH (p=0.047) and with no prior treatment with tebentafusp (p=0.007). PFS and OS at 1 and 2 years were numerically higher with IPI+PD1 (1- and 2-year PFS: 23% and 15%; 1- and 2-year OS: 63% and 39%) vs. PD1 (1- and 2-year PFS: 17% and 11%; 1- and 2-year OS: 54% and 36%), but these differences were not statistically significant (p>0.05). On MVA, adjusting for predefined variables (age, gender, ECOG PS, LDH, presence/absence of liver/lung metastases, prior treatment with tebentafusp), IPI+PD1 was associated with higher ORR (OR 2.71, 1.30 – 6.05; p=0.01) but not with PFS or OS compared to PD1. Presence of liver metastases (ORR [OR 0.28; 95% CI 0.13 - 0.64], PFS [HR 1.61; 95% CI 1.11 - 2.34], OS [HR 2.02; 95% CI 1.32 - 3.10]), ECOG PS≥2 (PFS [HR 1.82; 95% CI 1.07 - 3.10], OS [HR 2.24; 95% CI 1.25-4.01]), elevated LDH (PFS [HR 1.66; 95% CI 1.30 - 2.11], OS [HR 2.39; 95% CI 1.84-3.10]) and prior tebentafusp treatment (OS [HR 2.36; 95% CI 1.21-4.59]) were also independent predictors of response and/or survival. A higher percentage of pts experienced grade ≥3 immune-related adverse events (irAEs) in the IPI+PD1 group compared to the PD1 group (34% vs 13%, p<0.0001). Most pts ceased treatment due to progression (234, 57%), and more pts stopped due to toxicity in the IPI+PD1 vs. PD1 group (25% vs. 9%, p<0.0001). **Conclusions:** In pts with MUM, IPI+PD1 demonstrated a higher ORR but did not improve survival compared with PD1 alone. IPI+PD1 was more toxic, leading to early treatment discontinuation in one-quarter of pts. These findings may help guide treatment selection in MUM. Research Sponsor: None.

Real-world experience with lifleucel, tumor selection, and dead-in therapy from a single-institution series. First Author: Theresa Medina, University of Colorado, Aurora, CO

Background: Lifileucel is the first approved cellular therapy for persons with metastatic melanoma after upfront treatment with immune checkpoint inhibitor(s) (ICIs) and BRAF-targeted therapy (if applicable). There is not an established consortium to centralize data surrounding procurement and outcomes. Until then we report a single institution series of lifileucel used in the real-world in patients (pts) with previously treated metastatic melanoma. We evaluate whether there are differences in outcomes based on tumor procurement sites, lead-in therapy, and presence of CNS metastases prior to being treated with lifileucel. In addition, for those with progressive disease (PD) will describe the pattern of progression after lifileucel. **Methods:** The University of Colorado and its affiliated hospital UCHealth became an authorized treatment center for TIL in November 2024. Between November 2024 and January 2026, tumor tissue procurement was completed on 27 patients diagnosed with a variety of melanoma subtypes, stages and received bridging therapy. 24 pts have been treated with lifileucel. All pts received prior combination ICIs and, if BRAF-V600mut, most received prior treatment with BRAF/MEK inhibitors. **Results:** 41.7% of pts treated with lifileucel have had at least partial response (PR) as best overall response (BOR). 12% of pts have had a complete response (CR) as BOR. 16.7% had an initial PR but then had PD within 3 mos. 37.5% of pts had PD as BOR. In regard to tumor procurement site, tumor sites were subcutaneous/superficial soft tissue, lymph node, or visceral locations. The response rate from subcutaneous tumors was 16.7%, the response rate from lymph node was 33.3% and the response rate from visceral sites was 42.3%. The response rate from a single tumor used for procurement was 27%. The response rate from combining multiple tumors from different sites was 46%. The most recent therapy prior to lifileucel included: 1) ipilimumab+nivolumab, (5 pts) with 40% response rate, 2) relatlimab+nivolumab, (8 pts) with 75% response rate, 3) anti-PD-1 monotherapy, (3 pts) with 66% response rate, 4) BRAF/MEK inhibitor, (5 pts) with no response to lifileucel. 10 pts had CNS lesions treated prior to lifileucel, 6 pts had CNS lesions treated after lifileucel infusion, 5 were treated with BRAF/MEK prior to receiving lifileucel. 4 pts had PR and 2 had CR of metastatic sites present prior to lifileucel but had PD within 3 mos to new visceral sites. **Conclusions:** From our single-institution series, using lymph node and visceral tumors for lifileucel generation is associated with higher overall response rate. Combining more than one tumor for lifileucel generation is also associated with higher overall response rate. There were 6 patients that had CNS progression after lifileucel but the majority had used BRAF/MEK prior to receiving lifileucel which raises question of what effect this has on lifileucel efficacy. Research Sponsor: None.

Prognostic and therapeutic implications of HRR gene mutations in non-cutaneous melanoma: Association with anti-PD-1 efficacy. First Author: Yue Yang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China

Background: Homologous recombination deficiency (HRD) describes a tumor cell state characterized by impaired DNA double-strand break repair via the homologous recombination repair (HRR) pathway. Deficiencies in this pathway may serve as predictive biomarkers. However, the relevance of HRR gene mutations remains inadequately characterized in non-cutaneous melanoma. In this study, we aimed to delineate the mutational landscape of HRR genes in this population and evaluate their predictive implications for clinical management. **Methods:** We conducted a retrospective analysis of 932 patients with non-cutaneous melanoma treated at Beijing Cancer Hospital from January 2008 to January 2026. Tumor genomic profiling was performed using targeted next-generation sequencing with either an 81- (n=852) or a 425-gene (n=80) panel. Associations between HRR mutation status and survival outcomes were assessed using Kaplan-Meier survival estimates and Cox proportional hazards regression models. **Results:** HRR mutations were identified in 92 patients (9.9%), with the most frequent alterations occurring in ATM (3.5%), ARID1A (3.4%), BRCA2 (2.7%), and BRCA1 (1.8%). Within this HRR-mutated cohort, the primary subtypes were mucosal (44.6%) and acral (29.3%) melanoma. And the disease stages were distributed as follows: stage I, 31 patients (33.7%); stage II, 15 (16.3%); stage III, 22 (23.9%) and stage IV, 24 (25.0%). After a median follow-up of 63.7 months, the median overall survival (OS) was 57.5 months (95% CI: 43.4–71.7), with 1-, 2-, 3-, and 5-year OS rates of 92.1%, 84.9%, 74.7%, and 56.8%, respectively. Multivariate analysis confirmed age ≥65 years as an independent predictor of poorer overall survival (HR 2.7, 95% CI 1.3–5.4, P = 0.005), whereas ATM mutation emerged as a significant protective factor associated with a 68% reduction in mortality risk (HR 0.32, 95% CI 0.1–0.7, P = 0.007). Among 59 HRR-mutated patients who received first-line systemic therapy, 41 were treated with anti-PD-1-based regimens and 18 with non-PD-1-based regimens. In the 54 evaluable patients, median progression-free survival (PFS) was 9.0 months (95% CI: 3.8–14.2) and median OS was 55.0 months (95% CI: 39.0–71.0). The objective response rate (ORR) was 11.1%, and the disease control rate (DCR) was 61.1%. The DCR was 77.8% (21/27) in the mucosal subgroup versus 37.5% (6/16) in the acral subgroup with a statistically significant difference (P = 0.028). In a subgroup analysis, although not statistically significant, anti-PD-1-treated patients trended toward a longer median PFS compared with those not receiving anti-PD-1 therapy (15.0 vs. 6.0 months, P = 0.249). **Conclusions:** HRR mutations define a distinct molecular subset in non-cutaneous melanoma. ATM mutation serves as an important prognostic biomarker, and patients with HRR-mutated melanoma may derive survival benefit from anti-PD-1 immunotherapy. Research Sponsor: None.

Novel adaptive versus continuous dosing of encorafenib and binimetinib in combination with nivolumab in advanced *BRAF V600E* mutant melanoma. First Author: Zeynep Eroglu, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: In BRAF V600 mutant melanoma, continuous treatment with BRAF/MEK inhibitors invariably begets acquired resistance. Preclinical success of intermittent dosing to overcome resistance did not translate to clinical benefit in the randomized SWOG S1320 trial, possibly due to fixed schedule of intermittent dosing (5 wk on/3 wk off cycles). Leveraging intra-tumoral competition dynamics to slow expansion of resistant tumor subpopulations via patient-specific adaptive MAPK therapy may improve outcomes. We hypothesized that adaptive drug scheduling of BRAF/MEKi combined with anti-PD-1 would lead to non-inferior or improved outcomes with less toxicity compared to a continuous triplet regimen. **Methods:** In a pilot prospective trial, pts with advanced BRAF V600E mutant melanoma, naïve to systemic tx in this setting, with detectable plasma circulating tumor DNA (ctDNA) were eligible (using BRAFV600E ctDNA ddPCR). Ten pts were randomized 1:1 to continuous (Arm A) or patient-specific adaptively dosed (Arm B) ENCO plus BINI, with continuous biweekly NIVO in both arms. A mathematical model was calibrated for Arm B using pts' ctDNA values (baseline and biweekly sampling) and standard CT response imaging every 12 weeks. This model was a coupled system of differential equations to guide treatment decisions biweekly by simulating the future response on or off drugs (ENCO+BINI) based on that pt's known ctDNA levels and response data. Therefore, pts in Arm B all had differing lengths of time that they received ENCO+BINI. Primary endpoint was feasibility of the adaptive approach, by adherence to protocol from baseline to week 12. **Results:** Ten pts, median age 59, 70% male, 80% with stage IV melanoma, were randomized. In Arm B, NIVO alone was often effective enough to not trigger resuming ENCO+BINI; in Arm A, pts were on E+B for a median of 61 weeks (89% of time on tx, as drugs could be held for toxicity), while in adaptive Arm B, patients were on E+B for median 11 weeks (24% of time on tx). ORR was 100% in Arm A and 60% in Arm B, all partial responses, with 2 stable disease in Arm B. At median follow-up of 45.5 months, median PFS was 26.9 months (95% CI 5.5-NA) with 3 progressors in Arm A. Median PFS was not reached (17.8-NA) in Arm B and 2 progressed (log-rank p= 0.5). Median OS was 32 months (8.8-NA) in Arm A (2-year OS 60%, 3 pts died). Median OS was not reached (17.8-NA) in Arm B (2-year OS 75%,1 pt died), log-rank p=0.18. In Arm A, there were 16 treatment-related grade 3 adverse events, with only 6 grade 3 AEs in Arm B. **Conclusions:** In this innovative study, we demonstrated the feasibility of patient specific mathematical modeling incorporating ctDNA and imaging, to inform adaptive dosing of ENCO+BINI with concurrent NIVO. The adaptive arm did not compromise efficacy and had lower toxicity. Successful confirmation of this approach in larger trials may favorably impact patient QOL and reduce cost of therapy. Clinical trial information: NCT03543969. Research Sponsor: None.

Pretreatment spatial immune architecture and 1-year clinical benefit to first-line ICB in advanced melanoma. First Author: Karim Amrane, Institut Gustave Roussy, Villejuif, France

Background: Predictive biomarkers for immune checkpoint blockade (ICB) in advanced cutaneous melanoma (CM) remain limited. Imaging mass cytometry (IMC) enables spatially resolved profiling of the tumor microenvironment (TME) and can capture immune–tumor architecture beyond cell density. **Methods:** Patients with advanced CM treated with first-line ICB and available pretreatment FFPE tissue were analyzed using IMC (40-marker panel). The primary endpoint was durable 1-year clinical benefit (1y-CB: metabolic CR/PR or stable metabolic disease ≥12 months by PERCIST on FDG-PET/CT); the secondary endpoint was 1-year progression-free survival (1y-PFS). Cell densities, tumor marker expression, and spatial neighborhood metrics were evaluated. Reproducibility was assessed by re-analyzing an independent published IMC melanoma cohort (PMC8026677). **Results:** Twenty-nine patients (anti–PD-1 n=27; ipilimumab+nivolumab n=2); 15 achieved 1y-CB. 1y-CB was associated with higher leukocyte infiltration and increased densities of B cells, conventional CD4⁺ T cells (Tconv), CD8⁺ T cells, and plasma cells, whereas higher tumor density was associated with lack of benefit and inferior 1y-PFS (HR 10.57; $p<0.001$). Higher CD8⁺ and B-cell densities were associated with improved 1y-PFS (HR 0.26, p=0.013; and HR 0.26, p=0.047). Tumor PD-L1 and HLA-DR expression correlated with 1y-CB (p=0.022 and p=0.040). Spatial metrics further stratified outcomes: increased tumor–tumor proximity was associated with poor 1y-CB (p=0.0016), while increased B–Tconv proximity was associated with 1y-CB and longer 1y-PFS (HR 0.20; p=0.037). The strongest spatial association was macrophage proximity to HLA-DR⁺ tumor cells ($p\leq0.0001$). In the external cohort (n=60), responder enrichment for Tconv/CD8⁺ T cells and macrophage proximity to HLA-DR⁺ tumor cells were reproduced. **Conclusions:** Pretreatment IMC identifies both compositional and spatial TME features associated with durable benefit from first-line ICB in advanced CM. T-cell enrichment and macrophage proximity to HLA-DR⁺ tumor cells emerged as reproducible candidate spatial biomarkers warranting prospective validation. Research Sponsor: European Regional Development Fund (ERDF/FEDER); RU-000950; Pfizer; Novartis.

Main predictors of 1y-CB and 1y-PFS.

Parameters	1y-CB events/N	1y-CB p-value	1y-PFS HR (95% CI)	1y-PFS p-value
B cells ≥9.5	5/15 vs 9/14	0.026	0.26 (0.00–0.99)	0.047
CD8⁺ T cells ≥36	7/20 vs 7/9	0.023	0.26 (0.00–0.76)	0.013
Plasma cells ≥1	3/12 vs 11/17	0.017	0.28 (0.08–1.00)	0.050
Tumor density ≥4194	5/5 vs 9/24	0.006	10.57 (3.08–36.23)	<0.001
B–Tconv proximity ≥13.3%	2/10 vs 10/16	0.018	0.20 (0.00–0.91)	0.037
HLA-DR ≥58.4%	1/7 vs 13/22	0.040	0.17 (0.02–1.28)	0.085
PD-L1 ≥3.3%	8/20 vs 6/9	0.022	0.48 (0.16–1.38)	0.171

A phase III randomized study comparing BCD-201, a pembrolizumab biosimilar candidate, and reference pembrolizumab in patients with advanced melanoma. First Author: Kristina V. Orlova, FSBI "National Medical Research Oncology Center named after N.N. Blokhin" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: The development of clinically comparable biosimilars of key immuno-oncology agents is essential to improving global access to effective therapy. BCD-201 is a proposed pembrolizumab biosimilar that has shown high analytical similarity in preclinical studies, and pharmacokinetic equivalence to the reference pembrolizumab in phase I study (NCT05739006).This phase III trial evaluated the clinical equivalence of BCD-201 versus reference pembrolizumab in patients with advanced melanoma. **Methods:** This international, multicenter, randomized, double-blind phase III study enrolled adult patients with unresectable or metastatic cutaneous melanoma. Patients were randomized 1:1 to receive BCD-201 or reference pembrolizumab 200 mg IV every 3 weeks for 24 weeks. Randomization was stratified by ECOG (0 vs 1), PD-L1 expression ($<$5% vs $\geq$5%), and disease stage (AJCC 7th edition M0/M1a/M1b vs M1c). The primary endpoint was objective response rate (ORR) per RECIST v1.1 assessed by blinded independent central review (BICR) at week 24 in the ITT population. Equivalence was concluded if the 95% confidence interval (CI) for the ORR difference fell within prespecified margins of $-$15% to +15%. Secondary efficacy endpoints included ORR per iRECIST, progression-free survival (PFS), overall survival (OS). **Results:** A total of 479 patients were included in the ITT population (BCD-201, n=234; reference pembrolizumab, n=245), with balanced baseline characteristics. At week 24, ORR was 33.3% in the BCD-201 group and 32.7% in the reference pembrolizumab group in ITT population. The unstratified ORR difference was 0.7% (95% CI $-$7.7 to 9.1), fully within the prespecified equivalence margins. Results were consistent across per-protocol and stratified sensitivity analyses. Secondary efficacy endpoints, including ORR per iRECIST, OS, and DOR, were comparable between groups. At 24 weeks, PFS rates were 51.9% for BCD-201 and 50.5% for reference pembrolizumab per RECIST 1.1. OS rate at 24 week was 90.2% in the BCD-201 group and 89.3% in the reference pembrolizumab group. Longer-term efficacy and safety data will be reported in future analyses. Safety profiles were similar between groups, with grade $\geq$3 AEs reported in 19.7% and 21.9% of patients for BCD-201 and reference pembrolizumab. Main PK parameters (AUC and C_{max}) met equivalence criteria. Immunogenicity was low and comparable between groups, with binding antibodies (Abs) detected in 7 (3.1%) and 6 (2.6%) patients in the BCD-201 and comparator groups, respectively. No neutralizing Abs were detected. **Conclusions:** BCD-201 demonstrated equivalent efficacy to reference pembrolizumab with comparable safety, pharmacokinetics, and immunogenicity in patients with advanced melanoma. These data support BCD-201 as a pembrolizumab biosimilar and highlight its potential to expand access to anti-PD-1 therapy. Clinical trial information: NCT05986331. Research Sponsor: None.

The prognostic and predictive role of FDG PET/CT in melanoma patients treated with immune checkpoint blockade: A meta-analysis. First Author: Isadora Mamede, Faculdade de Governança, Engenharia e Educação de São Paulo - FGE, Chapecó, Brazil

Background: Immune checkpoint blockade (ICB) is standard therapy for advanced melanoma, but many patients derive limited benefit. Biomarkers to guide treatment decisions are needed. FDG PET/CT (PET) shows promise for response assessment, but most studies are small or evaluate a single timepoint. Here, we conducted a meta-analysis to assess the prognostic value of metabolic response for overall survival (OS) and progression-free survival (PFS), and the diagnostic performance of PET-derived parameters. **Methods:** PubMed, Cochrane, and EMBASE were searched for studies including melanoma patients treated with ICB who underwent baseline and follow-up PET. Metabolic response was defined using PERCIST, PERCIST5, or EORTC criteria, dichotomizing patients as responders or non-responders. Random-effects meta-analyses estimated pooled hazard ratios (HRs) for OS and PFS, with subgroup analyses by PET timing (early $\leq$4 months vs late $>$ 4 months). Univariate diagnostic meta-analyses evaluated the accuracy of changes in total lesion glycolysis (TLG) and metabolic tumor volume (MTV) for predicting death or OS, as well as the ability of PET-defined progressive metabolic disease (PMD) to identify clinical or RECIST-based disease progression. **Results:** Of the 15 studies included, 943 pts were included. Interval metabolic response was significantly associated with improved OS (HR 0.22; 95% CI 0.13-0.36; p = 0.02), with no significant difference according to the time of PET assessment early vs late (p for interaction = 0.75). Similarly, metabolic responders experienced significantly longer PFS (HR 0.21; 95% CI 0.11-0.39; p = 0.03). Although the association was statistically significant for late (HR 0.21; 95% CI 0.11-0.41), but not for early assessment (HR 0.13; 95% CI 0.01-1.91), no subgroup difference was observed (p for interaction = 0.73). In diagnostic analyses for OS prediction, changes in TLG demonstrated a pooled sensitivity of 0.70 (95% CI 0.54-0.82) and specificity of 0.79 (95% CI 0.52-0.93). Changes in MTV showed comparable performance, with a sensitivity of approximately 0.70 (95% CI 0.54-0.82) and a specificity of 0.83 (95% CI 0.42-0.97). PET-defined PMD showed good diagnostic accuracy for identifying clinical or RECIST-defined disease progression, with a pooled sensitivity of approximately 0.71 (95% CI 0.42-0.89) and specificity of 0.86 (95% CI 0.69-0.95). **Conclusions:** In our study, metabolic response by PET was associated with improved OS and PFS, irrespective of the timing of imaging. Quantitative changes in TLG and MTV provide moderate accuracy for predicting survival, while PET/CT-defined PMD reliably identified RECIST-based disease progression. These findings support future prospective studies investigating the role of PET dynamics as a minimally invasive prognostic and predictive biomarker for pts with advanced melanoma undergoing treatment with ICB. Research Sponsor: None.

Botensilimab (BOT) ± balstilimab (BAL) in patients (pts) with advanced cutaneous melanoma (cMEL) refractory/resistant (R/R) to anti–PD-(L)1 ± CTLA-4: A phase 2 trial. First Author: Michael B. Atkins, Georgetown Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Background: Pts with advanced cMEL R/R to PD-(L)1–based therapy, including PD-(L)1+CTLA-4, have few treatment options. BOT (Fc-enhanced anti–CTLA-4) augments T-cell priming, depletes Tregs, and activates antigen-presenting cells to overcome immune checkpoint inhibitor (ICI) resistance. BOT ± BAL (anti–PD-1) has shown activity in ICI-R/R and cold tumors. **Methods:** The open-label, global phase 2 C-800-23 trial (NCT05529316) enrolled pts with cMEL (stage III unresectable or IV) R/R to prior anti–PD-(L)1 ± CTLA-4. Part 1: randomized 1:1 to BOT 50 mg or 150 mg every 3 weeks (Q3W; up to 4 doses). Part 2: BOT 75 mg Q3W (up to 4 doses) plus BAL 450 mg Q3W (up to 2 years). Endpoints included confirmed objective response rate (ORR; primary; RECIST 1.1), progression-free survival (PFS), duration of response (DOR), overall survival (OS), and safety. Clinical benefit rate (CBR) was complete or partial response or stable disease for $\geq$24 weeks. **Results:** As of Dec 13, 2025, 138 pts received BOT monotherapy (median follow-up, 12.3 mo; range, 0.2–35+) and 36 pts received BOT+BAL (median follow-up, 13.8 mo; range, 2–26+). Overall, 51% had stage M1c or M1d disease, 29% had *BRAF* mutant disease, and 39% had LDH $>$ULN. In pts R/R to anti–PD-(L)1, 72% (60/83 with pre-trial data available) had primary resistance (best overall response of progressive disease [PD] or PD $\leq$6 mo from most recent course of respective ICI type). In pts R/R to anti–PD-(L)1+CTLA-4, 69% (61/88) had primary PD-(L)1 resistance and 69% (60/87) had primary CTLA-4 resistance. With BOT+BAL, ORR was 22% (95% CI, 10–39), CBR was 33% (95% CI, 19–51), median DOR was not reached (NR; 95% CI, 4.17–NR), 12-mo PFS was 29% (95% CI, 15–44), and median OS was 16.6 mo (95% CI, 9.1–NR; 24-mo OS, 46%; 95% CI, 29–61). ORR with BOT+BAL was numerically higher in PD-(L)1+CTLA-4 R/R pts (29%, 4/14; 95% CI, 8–58; 3/4 responders had primary ICI resistance) vs PD-(L)1–only R/R pts (18%, 4/22; 95% CI, 5–40; all responders had primary ICI resistance). With BOT alone, ORR was 6% (95% CI, 3–11), CBR was 14% (95% CI, 9–21), 12-mo PFS was 7% (95% CI, 3–13), and median OS was 12.9 mo (95% CI, 9.7–16.2; 24-mo OS, 28%; 95% CI, 20–36). Responses were irrespective of Fcγ receptor genotype. Treatment-related adverse events occurred in 81% (grade $\geq$3, 30%) with BOT alone and 94% (grade $\geq$3, 36%) with BOT+BAL; most common was diarrhea (BOT 33%; BOT+BAL 42%). One possibly treatment-related death was reported with BOT monotherapy (immune-mediated enterocolitis). No new safety signals occurred. **Conclusions:** In this ICI-R/R cMEL population enriched with primary ICI-resistant pts, BOT+BAL showed durable responses, encouraging survival, and a stronger signal in pts who had prior conventional anti–CTLA-4. BOT monotherapy also showed activity. This supports a differentiated mechanism for BOT and continued development of BOT+BAL, including for pts with dual ICI-R/R cMEL. Clinical trial information: NCT05529316. Research Sponsor: Agenus Inc.

Final results of the phase III OCTAVA trial: Clinical benefit of low-dose anti–CTLA-4 plus anti–PD-1 combination vs anti–PD-1 monotherapy in unresectable or metastatic melanoma. First Author: Lev V. Demidov, N.N.Blokhin NMRC of Oncology MoH of Russia, Moscow, Russian Federation

Background: BCD-217-2/OCTAVA is an international, multi-center, randomized, double-blind, placebo-controlled phase III study conducted to assess the efficacy and safety of nurulimab +prolgolimab (nuru + prolgo) combination therapy with continued prolgolimab therapy compared to prolgolimab monotherapy at the 1st line treatment of patients (pts) with unresectable or metastatic melanoma (un/mM). BCD-217 is a fixed-dose combination of nurulimab (aCTLA-4, 5 mg/ml) and prolgolimab (aPD-1, 15 mg/ml) which was recently approved for this indication in Russia and Belarus. Here we present efficacy results based on 24 mos of therapy. **Methods:** Treatment-naïve pts with un/mM (stage IIIC–IV) were randomized 1:1 to two arms. The nuru+prolgo arm received a combo of nurulimab (1 mg/kg) and prolgolimab (3 mg/kg) at 0.2 ml/kg Q3W for the first four infusions. The prolgo arm received prolgolimab monotherapy (3 mg/kg Q3W) for the first four infusions. Both arms then received prolgolimab maintenance therapy for up to two years. The primary endpoint of the study was PFS. **Results:** 271 pts were randomized to nuru+prolgo (n=135) or prolgo monotherapy (n=136) arms. After a median follow-up of 24.7 mos the mPFS was 15.4 (95% CI 8.4; NA) mos in the nuru+prolgo arm and 8.3 (95% CI 4.2; 14.8) mos in the prolgo monotherapy arm (HR 0.696, 95% CI 0.502; 0.965), iRECIST, ITT population). The PFS benefit was consistent per RECIST 1.1 (HR 0.717, 95% CI 0.533; 0.964). ORR, DCR and TTR were also higher in nuru+prolgo arm. mOS was not reached in both groups (HR 0.836, 95% CI 0.495; 1.41). 24-mos OS was 76.1% in nuru+prolgo arm and 71.7% in prolgo arm respectively. The mDOR was also not reached in any arm, meaning that more than half of the pts who responded to therapy maintained their response until the end of the FU period. Grade $\geq$3 treatment-related AEs occurred in 17.8% of pts (nuru+prolgo) vs 13.2% (prolgo). Gr $\geq$3 irAEs were 14.1% vs 5.1%, respectively (p=0.0126). Any-grade irAEs were reported in 51.9% vs 33.8% of cases (p=0.0027). Treatment discontinuation due to AEs was 11.1% vs 5.1%. **Conclusions:** The OCTAVA trial results demonstrated a statistically significant and clinically meaningful improvement in PFS for the 1st line low-dose nuru + prolgo combination followed by prolgo maintenance, compared to prolgo monotherapy, in patients with unresectable or metastatic melanoma. This efficacy benefit was accompanied by manageable rate of immune-related AE, consistent with the known profile of CTLA-4/PD-1 combinations. These results support the use of the nuru + prolgo regimen as a valuable 1st line treatment option for this population. Clinical trial information: NCT05732805. Research Sponsor: JSC BIOCAD.

Twenty years of metastatic uveal melanoma management: Real-world experience from a comprehensive cancer center in a low- and middle-income country (LMIC). First Author: Yacob Saleh, King Hussein Cancer Center, Amman, Jordan

Background: Uveal melanoma (UM) is a rare malignancy arising from melanocytes of the uveal tract and accounts for 85% of primary ocular malignancies. Despite effective local control, 10-50% of patients develop metastatic disease, which is associated with poor prognosis and a median overall survival (OS) of approximately one year. Until recently, no effective standard systemic therapy existed for metastatic UM. Real-world data especially from LMICs remain lacking. This study evaluates the clinical characteristics, treatment patterns, and survival outcomes of patients with metastatic UM treated in a LMIC. **Methods:** This retrospective study included adult patients with metastatic UM treated and followed at King Hussein Cancer Center in Amman, Jordan between January 2006 and December 2025. Collected data included baseline demographic and clinical characteristics, metastatic and treatment patterns. Descriptive and survival analyses were conducted using JASP software (version 0.95.4). A two-sided P value <0.05 was considered statistically significant. **Results:** Among 125 patients with UM, 31 (24.8%) had metastatic disease, including two patients with metastasis at initial presentation. Median age at diagnosis was 51 years, and 61.3% were males. ECOG performance status was 0–2 in 81.5% of patients. Hepatic-only metastasis occurred in 51.6% of patients, combined hepatic and extrahepatic in 38.7%, and extrahepatic-only in 9.7%, with 58.6% classified as M1a disease. Median time to distant metastasis was 25 months. Median OS from initial UM diagnosis was 35 months, while median post-metastatic OS (PM-OS) was 10 months. First-line Immunotherapy was associated with significantly improved PM-OS compared to Dacarbazine (median 11 vs 5 months; P = 0.034), with 24-month PM-OS of 44.4% vs 0% respectively. Treatments included Immunotherapy, chemotherapy, Targeted therapy in one patient, local interventions, and best supportive care (Table). **Conclusions:** Metastatic UM remains associated with poor survival outcomes in this real-world cohort. First-line Immunotherapy was associated with longer survival compared to chemotherapy. This study highlights ongoing unmet outcomes needs and underscores disparities in access to emerging therapies, such as Tebentafusp, in LMICs. Broader availability of novel agents and inclusion of patients from LMICs in clinical trials are required. Research Sponsor: None.

Overall survival of patients with mucosal melanoma in the US before and after the advent of PD-1 based immune checkpoint inhibitor treatment. First Author: Olivia First, Department of Medical Education, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Mucosal melanoma (MM) is a rare, aggressive melanoma subtype with poor survival. Prior to 2010, systemic therapy for MM was limited to chemotherapy, adjuvant interferon, and bolus interleukin-2; after 2015, immune checkpoint inhibitors (ICIs), specifically programmed cell death protein-1 (PD-1) based therapies, were widely adopted. The magnitude of overall survival (OS) benefit from ICIs in MM remains poorly defined. **Methods:** We conducted a retrospective cohort study of 8,125 patients with histologically confirmed MM from the National Cancer Database. Patients were stratified by diagnosis era (pre-ICI: diagnosed before 2010; post-ICI: diagnosed after 2015) and receipt of first-line systemic therapy (immunotherapy and/or chemotherapy versus none). Survival analysis was conducted using Kaplan-Meier methods and Cox proportional hazards models. Difference-in-differences (DID) models using Cox regression estimated survival improvements attributable to systemic therapy in the post-ICI era. Multivariable logistic regression was fitted to assess changes in the characteristics of patients receiving systemic therapy between eras. Subgroup analysis included metastatic patients and stratification by primary tumor site (genitourinary [GU], gastrointestinal [GI], head and neck [HN]). Covariates for multivariable models were selected a priori based on clinical relevance. **Results:** Median OS (mOS) significantly improved in the post-ICI era with covariate adjustment (36.2 vs. 25.0 months; HR: 0.63, 95% CI: 0.59-0.66). Adjusted DID analysis demonstrated survival benefits attributable to systemic therapy (HR: 0.86, 95% CI: 0.77-0.97). mOS of metastatic patients also improved in the post-ICI era (12.0 vs. 7.33 months; HR: 0.63, 95% CI: 0.54-0.73). All tumor sites demonstrated significantly longer mOS in the post-ICI era, with GU patients living the longest (49.5 months), followed by HN (34.5 months), and GI (24.4 months). Post-ICI systemic therapy recipients were more likely to be older and publicly insured, to have a high comorbidity burden (Charlson Deyo score), to be ineligible for surgery, and to receive immunotherapy alone compared to pre-ICI patients. **Conclusions:** Survival of MM patients has improved by 37% since the introduction of ICIs. While OS varies by tumor site, all sites showed relative improvement in the post-ICI era. DID analysis suggested that modern survival benefits are driven by ICIs despite an older and more clinically complex treatment population. Health-related quality of life following tumor-infiltrating lymphocyte (TIL) therapy with commercial lifileucel in metastatic melanoma: Real-world longitudinal patient-reported outcomes. First Author: Kimberly Ward, Moffitt Cancer Center - McKinley Campus, Tampa, FL

Background: Although the efficacy of lifileucel has been demonstrated in metastatic melanoma, real-world longitudinal patient-reported outcomes remain limited. We evaluated health-related quality of life (HRQoL) among patients treated with commercial lifileucel at Moffitt Cancer Center using the Functional Assessment of Cancer Therapy–Melanoma (FACT-M) instrument. **Methods:** FACT-M surveys were administered at Baseline, Day +7, Month +6, and End of Treatment (April–December 2025). Scores were calculated using validated procedures. Clinical benefit was defined as complete response/ no evidence of disease or partial response as the best response per RECIST v1.1. Minimally important differences (MID) were defined as 4–7 points for the FACT-G total score and 4–6 points for the FACT-M combined scores. Comparisons used Wilcoxon rank-sum tests. **Results:** Thirty-two patients were enrolled, with 97 surveys completed out of 105 requested (92% completion rate). Median age was 66 years (range 29–78); 56% were male (n=18) and 44% female (n=14). ECOG performance status was 0–1 in 93%. Patients received a median of 5 IL-2 doses (range 1–6), and 53% experienced clinical benefit (n=17). Baseline, Day +7, and Month +6 FACT-M subscale and total scores are presented in Table 1. Among all patients, FACT-M and FACT-G scores remained stable from baseline to Day +7 and demonstrated clinically meaningful improvement exceeding the minimally clinically important difference at Month +6. While baseline HRQoL scores did not differ by treatment outcome (median FACT-G, 87 in both groups; median FACT-M, 108 in patients without clinical benefit and 109 in those with benefit), scores were significantly higher across follow-up assessments among patients with clinical benefit compared with those without. Median FACT-G scores were 102 vs. 76 (p=0.012), and median FACT-M scores were 125 vs. 94 (p=0.017), respectively. **Conclusions:** HRQoL, as measured by FACT-G and FACT-M, was maintained following commercial lifileucel in a real-world metastatic melanoma cohort, supporting the tolerability of TIL therapy. HRQoL outcomes varied according to clinical benefit. Larger studies with extended follow-up are warranted to confirm these findings. Research Sponsor: None.

Real-world outcomes of dual checkpoint inhibition (nivolumab + ipilimumab) versus anti-PD-1 monotherapy in metastatic uveal melanoma: Impact of local therapy and adjusted survival analysis—A multicenter retrospective study in Russia. First Author: Zakhra R. Magomedova,

Background: Metastatic uveal melanoma (mUM) remains a rare and aggressive malignancy. Immune checkpoint inhibitors (ICI) demonstrate modest activity, and real-world evidence comparing dual (nivolumab + ipilimumab) versus anti-PD-1 monotherapy, as well as the additive role of local therapy is limited. **Methods:** Multicenter retrospective observational study conducted in Russia (IRB-approved at participating centers). Outcomes assessed: median progression-free survival (mPFS), median overall survival (mOS), objective response rate (ORR), disease control rate (DCR), and grade $\geq$3 immune-related adverse events (irAEs). Stratified by treatment line, ICI type, and local therapy use. Univariable Cox proportional hazards regression was performed. **Results:** Patients with metastatic uveal melanoma treated between 2019 and 2025 were included (n=262). Of these, 25 patients (9.5%) who did not receive systemic treatment or received only palliative care were excluded. Among the full cohort: 158 (60.3%) were female, median age at primary diagnosis was 55.9 years, median time to metastatic disease was 2.42 years. Liver metastases were present in 90.8%. After exclusion, 237 patients were analyzed for survival. Results are presented in Table 1. Univariable Cox regression (after exclusion n=237): Dual ICI exposure (yes vs no): HR 0.60 (95% CI 0.44–0.84, p=0.003); Any ICI exposure (yes vs no): HR $\approx$0.72 (p=0.102) — non-significant trend. **Conclusions:** Dual ICI (nivolumab + ipilimumab) was associated with improved overall survival (HR 0.60, p=0.003), particularly with combination with local therapy (predominantly IHP, STRT, and TACE), which substantially enhanced ORR, DCR, PFS, and OS across ICI types. Patients who were unable to receive ICI in the first-line setting may be candidates for this option in the second-line; however, this requires further investigation through subgroup comparative analyses. Research Sponsor: None.

The clinical significance of *TET2*-driven clonal hematopoiesis (*TET2*-CH) in ICI-treated melanoma patients. First Author: Mason Nicholas Alford-Holloway, Vanderbilt University Medical Center, Nashville, TN

Background: Clonal hematopoiesis (CH) arises from age-related somatic mutations in hematopoietic stem cells and has been linked to altered immune function and clinical outcomes in solid tumors. While recent studies in colorectal and lung cancers suggest *TET2*-mutant CH may enhance immunotherapy responses, the impact of CH genotype on melanoma outcomes remains unclear and potentially context-dependent. **Methods:** We performed a retrospective cohort study of 361 patients with unresectable stage III/IV melanoma who underwent whole blood sequencing prior to anti-PD-1-based immunotherapy (2014-2024). CH was defined as somatic mutations in CH driver genes with variant allele fraction (VAF) $>$ 2%. Progression-free survival (PFS) and overall survival (OS) were measured from ICI initiation; patients without events were censored at last follow-up. Kaplan-Meier curves and multivariable Cox models adjusted for age, sex, BRAF V600E status, stage, and prior therapy estimated hazard ratios (HRs) compared to patients without CH. Chi-squared analysis assessed CH prevalence among melanoma patients compared to a healthy control cohort (n = 12,346) matched for age and sex. **Results:** CH prevalence was significantly elevated in melanoma patients compared to age and sex-matched healthy controls (27.7% vs. 21.4% χ^2 = 7.94, p = 0.004). Among 361 patients, 32 (8.9%) harbored *TET2*-driven CH, 48 (13.3%) had *DNMT3A*-CH, and 20 (5.5%) had other CH mutations. *TET2*-CH was associated with significantly worse OS compared to patients without CH (HR = 1.79, p = 0.014) and a trend toward inferior PFS (HR = 1.42, p = 0.119). In contrast, neither *DNMT3A*-CH (N = 48) nor other CH genotypes demonstrated significant associations with clinical outcomes (*DNMT3A*-CH: OS HR = 1.38, p = 0.11; PFS HR = 1.21, p = 0.32), establishing genotype-specific effects. **Conclusions:** In this cohort of patients with unresectable Stage III/IV melanoma receiving ICI therapy, *TET2*-CH was associated with inferior survival outcomes, while no significant survival differences were found among patients with *DNMT3A*-CH or other CH genotypes. Incorporating CH genotyping into pre-treatment risk stratification may identify high-risk melanoma patients who could benefit from alternative or intensified therapeutic strategies. Mechanistic studies are warranted to elucidate the biological basis for these genotype-specific effects and explore therapeutic interventions targeting CH-driven immune dysfunction. Research Sponsor: None.

Multivariable PFS and OS hazard ratios by clonal hematopoiesis genotype in ICI-treated melanoma patients.

Survival outcomes of adding stereotactic radiosurgery to dual immune checkpoint blockade in melanoma brain metastases: A systematic review and meta-analysis. First Author: Arturo Ortiz, Universidad Autonoma de Tamaulipas, Matamoros, TM, Mexico

Background: Melanoma brain metastases (MBM) carry a poor prognosis and remain understudied in prospective trials. Dual immune checkpoint blockade (ICB) with nivolumab plus ipilimumab (N+I) achieves durable intracranial responses; stereotactic radiosurgery (SRS) is sometimes added but its survival benefit is unclear. Despite the increasing real-world use of SRS in combination with dual ICB, no prior meta-analysis has compared survival outcomes of N+I + SRS versus N+I alone. **Methods:** A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines.PubMed, Embase, Scopus, and Web of Science were searched for randomized controlled trials (RCTs) and observational/real-world (ORW) studies published from January 2015 to July 1, 2025. Primary outcomes were overall survival (OS) and progression-free survival (PFS).Secondary outcomes included radiologic responses rates assessed by RECIST 1.1 and prognostic biomarkers. Random-effects models were used to pool risk ratios (RRs) and hazard ratios (HRs) with 95%confidence intervals (CIs). Analyses were performed in RevMan and R. **Results:** From 2,972 records, a total of thirteen studies included (ten ORW studies and three RCTs) met our inclusion criteria, including 2,055 patients. Median age was 57.2 years and 64.28% were male. N+I + SRS significantly improved OS compared with N+I alone (HR = 0.56; 95% CI, 0.44–0.71; p$<$0.00001). Two-year OS for N+I + SRS (RR = 1.35;95% CI, 1.17-1.55; p$<$0.0001). Among patients receiving N+I alone, two-year OS was 48% (95% CI, 35–60) and PFS was 52% (95% CI, 45-59). Radiologic response rate with N+I included a complete response rate of 29% (95% CI, 22–37) and a partial response rate of 44% (95% CI,29-59). High lactate dehydrogenase (LDH $>2\times$ upper limit of normal) was observed in 37% of patients (95% CI, 20–58) and was associated with inferior survival outcomes. **Conclusions:** In patients with MBM, the addition of stereotactic radiosurgery with dual immune checkpoint blockade is associated with significant overall survival advantage compared with N+I alone. This first meta-analysis defines the incremental survival benefit of adding SRS to contemporary dual immunotherapy N+I integrating long-term survival outcomes, radiologic response, and prognostic biomarkers. These findings support N+I as the systemic backbone for MBM management and support SRS integration for appropriately selected patients. Prospective trials are warranted to optimize sequencing,timing, and patient selection. Research Sponsor: None.

CD4 T-cell reconstitution and CD4:CD8 inversion following lymphodepleting chemotherapy for tumor-infiltrating lymphocyte therapy in metastatic melanoma. First Author: Arkadiusz Z. Dudek, Mayo Clinic Rochester, Rochester, MN

Background: Lymphodepleting (LD) chemotherapy is required prior to tumor-infiltrating lymphocyte (TIL) therapy, yet the depth, kinetics, and completeness of peripheral T-cell recovery in practice remain poorly defined. Using a pooled, multi-institution cohort, we characterized longitudinal CD4 and CD8 T-cell reconstitution and the prevalence of CD4 lymphopenia following TIL therapy. **Methods:** We conducted a retrospective multicenter study across Mayo Clinic, Moffitt Cancer Center, and Massachusetts General Hospital of patients with metastatic melanoma treated with TIL (N = 41, median follow-up 7.6 months). Absolute CD4 and CD8 T-cell counts and CD4:CD8 ratios were assessed at baseline (pre-LD), week 4, month 3, and month 6 post-TIL. Clinically significant CD4 lymphopenia was defined as CD4 $<$ 200 cells/μL. All patients received Pneumocystis jirovecii and antiviral prophylaxis, with antibacterial and antifungal prophylaxis administered per institutional protocols. Post-TIL infections were recorded. Paired changes from baseline were evaluated using Wilcoxon signed-rank testing. **Results:** Median age was 65 years (range 35-79), and 68% were male. At baseline, 16 patients (39%) had CD4 counts below the institutional lower limit of normal prior to LD. Eighteen patients (44%) received bridging therapy prior to TIL and had lower baseline CD4 and CD8 counts compared with those who did not ($p<$ 0.05 for both); however, post-TIL CD4 and CD8 recovery trajectories did not differ between groups. CD4 counts declined sharply following LD and demonstrated incomplete and heterogeneous recovery. Median CD4 decreased from 490 cells/μL at baseline to 250 at week 4, 290 at month 3, and 220 at month 6, remaining significantly below baseline at all post-TIL timepoints ($p<$ 0.05). Clinically significant CD4 lymphopenia was observed in 45% (10/22) of evaluable patients at month 3 and in 50% (44%, 7/16) at month 6. In contrast, CD8 counts increased early after TIL (median 240 to 590 cells/μL at week 4; p= 0.004) and remained higher than baseline at month 6. The CD4:CD8 ratio inverted from a median of 2.02 at baseline to 0.46 at week 4 and remained below 1.0 through month 6, reflecting sustained CD4 suppression despite CD8 recovery. Post-TIL infections occurred despite widespread prophylaxis, including bacterial (13%), viral (10%), and fungal (4.9%) infections. **Conclusions:** In a multi-institution cohort, LD chemotherapy preceding TIL is associated with profound and prolonged CD4 T-cell suppression, persistent CD4:CD8 inversion, and a high prevalence of CD4 $<$ 200 cells/μL through 6 months. These findings identify delayed immune reconstitution as a common and clinically relevant consequence of TIL therapy and support prospective optimization of antimicrobial prophylaxis duration, vaccination timing, and immune monitoring strategies. Research Sponsor: Mayo Clinic Comprehensive Cancer Center Grant; CA015083.

Real-world outcomes of lifileucel in advanced melanoma: A single-institution experience. First Author: Kelly Mahuron, City of Hope, Duarte, CA

Background: Lifileucel (Amtagvi), an autologous tumor-infiltrating lymphocyte (TIL) therapy, was FDA approval for unresectable or metastatic melanoma after progression on systemic therapy based on clinical trial data. However, real-world data describing early outcomes with lifileucel remain limited. **Methods:** We retrospectively reviewed a prospectively maintained database of patients with unresectable/metastatic melanoma who progressed on immune checkpoint inhibitors (and BRAF $\pm$ MEK therapy if applicable) and received lifileucel per standard protocol at a single institution April 2024–January 2026. Eligible patients received an in-specification TIL product and had evaluable imaging $\geq$12 weeks post-infusion unless progression was detected sooner. Responses were assessed per RECIST v1.1. Endpoints included objective response rate (ORR), disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS), and grade $\geq$3 treatment-related adverse events (TRAEs), excluding lymphodepletion-related cytopenias. Time-to-event endpoints were estimated using Kaplan–Meier methods. **Results:** Of 38 patients who underwent surgical TIL harvest, 32 (84%) received lifileucel, including 5 via the Expanded Access Program due to out-of-specification product. Among 27 patients receiving in-specification lifileucel, 20 had evaluable imaging and were included in the analysis. Patients received a mean of 2.2 prior therapies, and 35% had acral lentiginous or mucosal melanoma. All patients had Stage IV disease, including liver (40%) and brain (30%) metastases. 55% received bridging therapy after surgery prior to infusion. Median follow-up was 5.7 months (range, 0.9–16.9). ORR was 30% (3 CR, 3 PR), and DCR was 45%. Among responders, 67% (4/6) have ongoing response and median DoR was not reached. Median PFS was 3.5 months (95% CI, 2.1–5.3) and median OS was 6.1 months, with 6- and 12-month OS rates of 51% and 44%, respectively. Non-cytopenic grade $\geq$3 TRAEs occurred in 55%. **Conclusions:** In this early real-world experience, lifileucel demonstrated encouraging antitumor activity with ongoing responses in heavily pretreated patients despite high-risk features such as elevated LDH and liver and brain metastases. Additional studies and longer follow-up are warranted to optimize patient selection and define durability of benefit and survival outcomes. Research Sponsor: None.

A phase II trial of olaparib in combination with pembrolizumab in metastatic uveal melanoma. First Author: Nikhil I. Khushalani, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Metastatic uveal melanoma (mUM) has a poor prognosis with modest response to immune checkpoint blockade (ICB). Inactivating mutations in BRCA-1 associated protein 1 (*BAP1*) are common in mUM leading to deficient homologous recombinant DNA repair and increasing reliance on alternate repair pathways, including poly[ADP-ribose] polymerase (PARP). We investigated if the PARP inhibitor olaparib could improve objective response to pembrolizumab (PEM) in mUM (NCT05524935). **Methods:** Key eligibility included mUM with measurable disease, ECOG 0-1, and adequate organ function. Prior liver directed therapy was allowed. Patients (pts) received PEM 200mg IV every 21 days plus oral olaparib 300mg BID till progression, toxicity, or completion of 2 years of treatment. In a Simon 2-stage optimal design, >1 response by RECIST 1.1 in 12 evaluable patients would permit accrual to expand to 37 pts. **Results:** Twelve eligible mUM pts, 6 male and 6 female, median age 59 years (42, 84) were treated in stage 1 of this trial. Most pts (11/12; 92%) had both liver and extra-hepatic metastatic disease; 5 pts had elevated serum LDH at baseline. Seven pts (58%) were naïve to prior systemic therapy; 4 had prior liver directed therapy. There was no objective response observed; best response was stable disease (SD, n=5), remainder (n=7) with progression; disease-control rate was 42%. One patient continues treatment at 13 months with ongoing SD. Of 4 pts who received prior tebentafusp, three had SD lasting greater than 6 months. At median follow-up of 13 months, the median progression-free survival (PFS) was 3.6 months (95% CI: 2.2, 8.3), and median overall survival (OS) was 13.8 months (95% CI: 2.5, 24.3). Six-month PFS and OS were 0.42 (95% CI: 0.15, 0.67) and 0.83 (95% CI: 0.48, 0.96) respectively; one year OS was 0.73 (95% CI: 0.37, 0.91). Most common ($\geq$ 25%) all grade treatment related adverse events (AEs) were fatigue, arthralgia, diarrhea, nausea/vomiting, dyspnea, anemia, abdominal pain, bloating, anorexia, muscle weakness, pruritus, rash, vitiligo, dyspnea, cough, hypertension, muscle weakness, ↑ AST, ↑ alkaline phosphatase, ↓ lymphocyte count, ↑ glucose, ↑ potassium and ↓ albumin. Grade 3 AEs were infrequent; nausea, anorexia, dehydration, hypotension, and muscle weakness (all n=1); there was no treatment related death. 5/12 (42%) pts required a dose reduction for olaparib. **Conclusions:** The addition of olaparib to pembrolizumab was well tolerated but did not result in any objective response in molecularly unselected mUM. Landmark survival results appear clinically meaningful and likely related to disease control with stable metastatic burden. Ongoing biomarker studies of tumor tissue (BAP1, PD-L1, PARP1, TIL) and blood may help discern which patients could benefit from this combination regimen. Optimal sequencing of ICB with tebentafusp in HLA-A*02:01+ mUM should be explored further. Supported by Merck, Inc. Clinical trial information: NCT05524935. Research Sponsor: Merck, Inc.

Stage I results of a phase II study evaluating thymosin α1 combined with toripalimab in elderly patients with advanced melanoma. First Author: Xizhi Wen, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Anti–PD-1 monotherapy yields limited response rates in Chinese patients with melanoma, highlighting the need for effective combination strategies. Elderly patients frequently present with multiple comorbidities and immunosenescence which may compromise both the efficacy and safety of immunotherapy. Thymosin α1 (Tα-1) promotes T-cell activation and survival, potentially enhancing responsiveness to immunotherapy, while exerting immunomodulatory effects during excessive inflammation that may reduce the risk of immune-related adverse events (irAEs). This study aimed to evaluate whether combining Tα-1 with toripalimab could improve efficacy while mitigating irAEs in elderly patients with advanced melanoma. **Methods:** This was a single-arm, open-label, Simon two-stage phase II study. Patients aged $\geq$60 years with pathologically confirmed unresectable stage III or IV melanoma and no prior immune checkpoint inhibitor exposure were enrolled. Treatment consisted of Tα-1 (1.6 mg daily during week 1, then three times weekly during weeks 2–3) plus toripalimab 240 mg intravenously every 3 weeks for up to four cycles, followed by toripalimab maintenance until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Stage I required $\geq$3 responses among 19 evaluable patients to proceed to Stage II. **Results:** Between July 2023 and September 2025, 19 patients were enrolled (median age 72 years, range 60–81). Acral melanoma accounted for 78.9% (n=15). All patients had chronic comorbidities; 63.2% had ECOG $\geq$2 and 47.4% had metastases in $\geq$3 organs. At a median follow-up of 10.5 months, ORR was 47.3% (95% CI, 22.6–72.1). Median PFS was 8.0 months (95% CI, 4.4–11.6), and median OS was not reached. Median PFS was 8.1 vs. 4.5 months in acral versus non-acral cutaneous melanoma (P=0.4). Elevated LDH showed a trend toward shorter PFS (2.8 vs. 8.1 months, P = 0.076). Six grade 1 irAEs were observed (vitiligo n=2, transaminase elevation n=2, thyroiditis n=2). Patients without progressive disease had lower neutrophil-to-lymphocyte ratios and higher lymphocyte percentages than those with PD. **Conclusions:** Tα-1 combined with toripalimab demonstrated promising efficacy and excellent tolerability in elderly patients with advanced melanoma. The prespecified criteria for Stage II expansion were met, and enrollment of an additional 36 patients is ongoing. Research Sponsor: None.

Risk and protective factors for acral, mucosal, and uveal melanoma in a multi-institutional cohort of veterans and civilians. First Author: Marc S. Hurlbert, Melanoma Research Alliance/Fastercures, Washington, DC

Background: Melanoma is the 4th most common cancer among US Veterans. Non-acral cutaneous melanoma has well-established risk factors including history of sunburn, ultraviolet (UV) exposure, fair skin and features. Risk factors for acral (AM), mucosal (MM), or uveal melanoma (UM), are less understood. **Methods:** We conducted a nested case-control study (2000-2024) identifying cases of acral (N=1,292, Veterans only), mucosal (N=520, combined Veteran and civilian cohort), and uveal (N=2,010, combined Veteran and civilian cohort) melanoma using the Veterans Affairs (VA) Cancer Registry, natural language processing applied to pathology reports, and Mass General Brigham Research Patient Data Repository. **Results:** For AM, current smoking was associated with reduced odds, while Agent Orange Exposure (AOE) was associated with increased odds compared to both control populations. Compared to non-melanoma controls, prior nevus, keratinocyte carcinoma (KC), and actinic keratosis (AK) were associated with increased odds of AM. For MM, prior KC was associated with higher odds of MM compared to non-melanoma controls, consistent across anogenital, sinonasal, and upper aerodigestive tract sites. Smoking status was associated with reduced MM odds in the sinonasal cohort. For UM, we conducted a case-control study using data from 3 academic medical centers and the VA. Prior cutaneous and systemic immune disease were protective of UM development compared to CM. Smoking status and prior nevi had higher odds of UM compared to CM and non-cancer controls. **Conclusions:** To our knowledge, this is the largest cohort of AM, MM, and UM cases to date. Our study identified unique factors associated with risk of, or protection from, AM, MM, or UM, compared to CM or non-cancer controls. These findings provide novel insights into potential risks for rare melanomas and can help guide future biologically driven studies. Research Sponsor: CDMRP Department of Defense; W81XWH2110819.

Risk and protective factor associations across rare melanomas.

Melanoma type	Factor type	Both cohorts	CM only	Non-cancer only
Acral	**High risk association factors**	Younger age, female sex, Black race, Hispanic ethnicity, AOE	Asian race	Prior nevus, prior KC, prior AK
	Protective factors	Current smoking	≥2 comorbidities, AUDIT-C positive, prior KC, prior AK	Former smoking

Long term survival outcomes of immune checkpoint inhibitors in metastatic melanoma: Later relapse and long-term outcomes beyond 5 years. First Author: Chantal Saberian, National Institutes of Health, Bethesda, MD

Background: Immune checkpoint inhibitors (ICI) have improved survival outcomes in patients with metastatic melanoma, with a subset achieving durable long term survival outcomes. However, the incidence of late relapse and outcomes among patients who are alive but not progression-free at 5 years remain unknown. **Methods:** This is a multi-institutional retrospective study of patients with metastatic melanoma treated with either single agent anti-PD1 therapy or a combination of anti-PD1/CTLA-4 who started treatment prior to January 1, 2016. We analyzed the following outcomes: progression free survival at 5 years, late relapses (defined as progression $>$ 5 years after ICI initiation), sites of late relapse, and long-term overall survival. **Results:** 206 patients with metastatic melanoma were included; 65% (n = 135) were male. Most patients 86% (n = 177) had cutaneous melanoma and 29% (n = 59) had BRAF V600E/K mutations. In this cohort, 56% (n = 115) received a single agent anti-PD1, while the remaining 44% (n = 91) of patients received a combination of Ipilimumab (IPI) plus anti-PD1. The median follow-up from treatment initiation was 9.1 years. At 5 years, 68% (n = 140) of patients were progression-free. Late relapse, occurring $>$ 5 years after ICI treatment initiation, was seen in 6% (n = 12) of patients, at a median of 8.2 years from ICI treatment initiation. Among 12 patients with melanoma relapses, site of relapses was most commonly at nodal metastases (50%), followed by visceral (17%), brain (17%), and bone/spine (17%), soft tissue (8%), and unspecified sites (8%). Overall, 50% of patients had oligo progression, 33% had metastasis at multiple sites, and 17% unspecified. Following late relapse, 83% (n = 10) were rechallenged with ICI; 50% were rechallenged with the same ICI, 17% switched from IPI plus anti-PD1 to single agent anti-PD1, 17% unspecified, and the other 17% were not rechallenged with ICI. The disease control rate was 75% among patients rechallenged with anti-PD1, 100% among those rechallenged with IPI plus anti-PD1, and 100% among patients who switched from IPI plus anti-PD1 to single agent anti-PD1. At last follow-up, 75% (n = 9) of patients with late relapse were alive. Additional analyses, including Kaplan Meier estimates of progression-free and overall survival and incidence of long term sequalae from immune related adverse events will be reported. **Conclusions:** In this multi-institutional cohort of long-term survivors with metastatic melanoma, late relapse occurred uncommonly. And the outcomes following late relapses were generally favorable, with many patients still experiencing ongoing survival. The findings in our study support continued long-term surveillance beyond 5 years and provide clear expectations in daily clinical practice regarding cure and survivorship following anti-PD1 based therapy in metastatic melanoma Research Sponsor: None.

Influence of peri-dose high-sensitivity troponin on clinically significant cardiac events and IL-2 interruption during post-TIL high-dose IL-2 therapy. First Author: Jabra Zarka, Mayo Clinic Rochester, Rochester, MN

Background: High-dose interleukin-2 (IL-2) is administered following tumor-infiltrating lymphocyte (TIL) therapy, yet cardiotoxicity frequently limits dose delivery. The clinical significance of peri-dose troponin elevations during IL-2 remains poorly defined. We evaluated troponin kinetics during IL-2 dosing and their association with significant cardiac events and IL-2 interruption. **Methods:** We retrospectively analyzed patients with metastatic melanoma treated with TIL therapy followed by inpatient high-dose IL-2 at Mayo Clinic Rochester (N = 24; 87 IL-2 doses). High-sensitivity troponin and ECGs were obtained before and after each IL-2 dose. Clinically significant cardiac events were defined as QTc prolongation $>$ 480 ms, arrhythmias (excluding isolated sinus tachycardia), new ECG abnormalities, vasopressor requirement, or cardiology consultation. Dose-level outcomes included cardiac events and subsequent IL-2 dose interruption. Paired troponin changes were assessed using Wilcoxon signed-rank testing. Dose-level associations were evaluated using clustered logistic regression to account for repeated IL-2 doses within patients. **Results:** 24 patients received 87 IL-2 doses (median 3 [IQR 2 - 5]). Median age was 63 years (IQR 54 - 70), and 58% were male. Baseline troponin median was 11 ng/L (IQR 6 - 21); 38% had baseline troponin $>$ 14 ng/L. Post-dose troponin exceeded 14 ng/L in 16/24 patients (67%) and 48/87 doses (52%). Median delta troponin was 0 ng/L (IQR -1 to 6; range -24 to 133), with post-dose levels higher than pre-dose values (p= 0.02). Clinically significant cardiac events occurred in 33% of patients; no post-IL-2 reductions in left ventricular ejection fraction were observed. At the dose level, cardiac events occurred only when post-dose troponin exceeded 14 ng/L (15/48 [31%] vs 0/39 doses; $p<$ 0.001). In clustered logistic regression, post-dose troponin $\geq$15 ng/L was independently associated with cardiac events (OR 9.6, 95% CI 1.5 - 60.6; p= 0.02) and subsequent IL-2 dose interruption (OR 3.4, 95% CI 1.1 - 10.7; p= 0.04). When modeled continuously, each 1-unit increase in log-transformed post-dose troponin was associated with higher odds of cardiac events (OR 3.3, 95% CI 1.6 - 6.7; p= 0.001) and IL-2 interruption (OR 2.8, 95% CI 1.6 - 4.9; $p<$ 0.001). Baseline troponin correlated with peak post-dose troponin (ρ = 0.44, p= 0.04). **Conclusions:** Peri-dose troponin elevations are common during post-TIL high-dose IL-2; however, higher post-dose troponin independently identifies clinically significant cardiac toxicity and predicts IL-2 interruption after accounting for repeated dosing within patients. Baseline troponin modestly predicts peak elevations, supporting standardized, risk-stratified troponin monitoring and prospective evaluation of toxicity-adaptive IL-2 delivery strategies in TIL therapy. Real-world comparison of ipilimumab–nivolumab dosing strategies in melanoma brain metastases. First Author: Dina Elantably, Mayo Clinic Florida, Jacksonville, FL

Background: Ipilimumab 3 mg/kg plus nivolumab 1 mg/kg (Ipi3+Nivo1) is the standard immunotherapy regimen for metastatic melanoma with brain metastases (MBM) but is associated with significant immune-related toxicity, particularly neurologic toxicity. Ipilimumab 1 mg/kg plus nivolumab 3 mg/kg (Ipi1+Nivo3) has demonstrated improved tolerability in extracranial melanoma, though comparative data in MBM are limited. We compared efficacy and toxicity of these dosing strategies in a multisite real-world cohort. **Methods:** We retrospectively identified patients with MBM treated with ipilimumab plus nivolumab across three Mayo Clinic sites between 2016 and 2024. Patients were classified by induction dosing as Ipi1+Nivo3 or Ipi3+Nivo1. Overall survival (OS) and progression-free survival (PFS) were estimated using the Kaplan–Meier method and compared using log-rank tests. Best overall response (BOR) and toxicity outcomes were summarized descriptively. **Results:** Among 147 patients (Ipi1+Nivo3 n=32; Ipi3+Nivo1 n=115), 144 were evaluable for survival. Median age was higher in the Ipi1+Nivo3 group (69.5 vs 66.0 years); males predominated in both groups (71.9% vs 61.7%), and the cohort was predominantly White ($>$96%). Most patients had ECOG 0–1 in both groups (84.4% in Ipi1+ Nivo3 and 90.4% in Ipi3+Nivo1). BRAF mutation status was balanced between regimens, with approximately half of patients harboring BRAF-mutant disease (51.6% vs 53.2%). Median OS was 18.5 months (95% CI, 5.7–54.7) with Ipi1+Nivo3 versus 10.6 months (95% CI, 6.5–19.1) with Ipi3+Nivo1 (log-rank p=0.25). Two-year OS was 45.9% and 35.0%, and five-year OS was 24.5% and 19.2%, respectively. Median PFS was 7.3 months (95% CI, 1.8–10.9) versus 2.8 months (95% CI, 2.1–4.4) (log-rank p=0.16). BOR was available for 138 patients; objective response rates were 35.5% and 31.8%, respectively. 3–5 adverse events occurred in 24.1% of Ipi1+Nivo3 versus 30.5% of Ipi3+Nivo1 patients. Hospitalizations were less frequent (16.7% vs 36.1%), and neurologic adverse events occurred only with Ipi3+Nivo1 (11.9% vs 0%). **Conclusions:** In this multisite real-world MBM cohort, Ipi1+Nivo3 demonstrated comparable efficacy, numerically longer survival, and a more favorable toxicity profile compared with standard Ipi3+Nivo1. Notably, no neurologic toxicity was observed with the Ipi1+Nivo3 regimen. These findings support further prospective evaluation of lower dose ipilimumab strategies. Research Sponsor: None.

Response and survival outcomes.

Outcome	Ipi1 + Nivo3	Ipi3 + Nivo1
Complete response (CR)	2 / 31 (6.5%)	8 / 107 (7.5%)
Partial response (PR)	9 / 31 (29.0%)	26 / 107 (24.3%)
Objective response rate (ORR = CR+PR)	11 / 31 (35.5%)	34 / 107 (31.8%)
Disease control rate (DCR = CR+PR+SD)	18 / 31 (58.1%)	51 / 107 (47.7%)
Median PFS, months (95% CI)	7.3 (1.8–10.9)	2.8 (2.1–4.4)
2-year PFS	27.6%	22.3%
Median OS, months (95% CI)	18.5 (5.7–54.7)	10.6 (6.5–19.1)
2-year OS	45.9%	35.0%
5-year OS	24.5%	19.2%

Integrated AI-informed morphologic and spatial transcriptomics features from H&E slides to enable risk stratification of primary melanoma patients. First Author: Bhakti Vilas Baheti, Department of Biomedical Engineering, Emory University, Atlanta, GA

Background: Tumor proliferative activity and the tumor-stroma microenvironment are key determinants of melanoma aggressiveness and prognosis, yet their assessment from routine histology remains limited and subjective. Mitotic activity and stromal composition are histologic markers of tumor aggressiveness associated with overall survival (OS). While spatial transcriptomics (ST) can capture tumor biology associated with prognosis, its cost and limited availability restrict clinical use. Recent advances in computational pathology enable inference of spatial gene expression directly from routine hematoxylin and eosin (H&E) whole slide images (WSIs). We evaluated whether integrating AI-informed histologic biomarkers with ST features derived from routine H&E slides improves OS prediction in primary melanoma. **Methods:** Formalin-fixed paraffin-embedded H&E WSIs from TCGA-SKCM primary melanoma cases with available survival data were analyzed (N=291). Automated mitotic index (MI) in tumor region was quantified using a Detectron2-based mitosis detection model, and tumor-stroma ratio (TSR) was computed from automated tissue segmentation. Spatial gene expression for 18 melanoma relevant genes was inferred from WSIs using a pretrained DeepSpot model, and quantified for spatial heterogeneity and clustering. Three Cox regression models were created: i) $M_{Path+Clinical}$ (MI, TSR, age), ii) $M_{AI-ST+Clinical}$ (ST features, age), and iii) $M_{Integrated}$ (MI, TSR, ST features and age). Feature selection was performed on training cohort (N=174), and model performance for 10-year OS prediction was evaluated on holdout test cohort (N=117) using hazard ratio (HR) with 95% confidence interval, C-index, and log-rank tests. Independent contributions of various features were assessed by multivariable analysis. **Results:** In hold-out test cohort, both $M_{Path+Clinical}$ model (C-index = 0.639, p = 0.001, HR = 2.71 [1.49-4.94]), and $M_{AI-ST+Clinical}$ model (C-index = 0.603, p = 0.002, HR = 2.51 [1.37-4.59]) were prognostic for 10 year OS. AI-ST signature consisted of spatial heterogeneity and clustering metrics of ARG1, TFAP2A, and KRT6B genes, along with global gene expression metrics. The integrated model $M_{Integrated}$ resulted in the best OS stratification (C-index = 0.644, p = 0.007, HR = 2.24 [1.23-4.07]). Multivariable analysis demonstrated independent association of MI, ST features and age with OS. **Conclusions:** AI-derived ST features contributed additional prognostic value beyond histologic and clinical features, yielding the strongest OS stratification when integrated into a unified model. By combining established histologic biomarkers with virtual spatial omics, this approach improves survival prediction without additional tissue or molecular assays, supporting its potential clinical utility for risk adapted management of melanoma patients. Systematic evaluation of machine learning optimization strategies for uveal melanoma detection using ultra-widefield photography. First Author: Sanjay Ganesh, College of Medicine, University of Illinois at Chicago, Chicago, IL

Background: Early differentiation of uveal melanoma (UM) from benign intraocular lesions remains clinically challenging, particularly in regions with limited access to specialized ocular oncologists. Diagnostic uncertainty can delay referral and treatment, highlighting a gap between current practice and the desired goal of timely, accurate early UM detection. Machine learning (ML) offers a promising approach to improving diagnostic support with early detection of UM. This study developed, trained, and optimized eight ML classification models for early UM detection using ultrawidefield fundus (UWF) imaging to evaluate methods to increase clinical utility and readiness of current models. **Methods:** 1,592 UWF images from 784 patients were retrospectively collected and labeled into four classes: UM (n = 364), choroidal nevus (n = 824), congenital hypertrophy of the retinal pigment epithelium (CHRPE, n = 102), and healthy controls (n = 302). Images with multiple lesions, significant media opacity, or poor tumor visualization were excluded. All models used a ResNet-50 architecture, and a binary UM/nevus classifier was developed as the control. Optimization strategies included 1) class expansion with healthy control and CHRPE images, 2) training dataset augmentation with multiple images per patient and post-treatment images, and 3) a region of interest (ROI) dilation preprocessing pipeline. A 70/15/15 train/validation/test split was used with patient-level stratification to prevent data leakage. The test set was held constant across all models to ensure fair comparison. Performance was assessed using per-class F1 score and area under the curve (AUC) with 5-fold cross-validation. Grad-CAM images were generated to aid in model interpretability. **Results:** The control model achieved an AUC of 0.94$\pm$0.01 and F1 scores of 0.90$\pm$0.01 for nevus and 0.80$\pm$0.03 for UM. ROI dilation achieved the greatest improvement (AUC 0.99$\pm$0.001; nevus F1 0.98$\pm$0.01; UM F1 0.95$\pm$0.01). Other optimization strategies showed variable impact, with multi-optos yielding the second-best performance (AUC 0.95$\pm$0.02; nevus F1 0.91$\pm$0.02; UM F1 0.83$\pm$0.04). A final model integrating the most effective strategies demonstrated robust performance (AUC 0.95$\pm$0.01; nevus F1 0.91$\pm$0.03; UM F1 0.82$\pm$0.06). Grad-CAM confirmed an appropriate lesion-centered focus. **Conclusions:** Our findings show that targeted ML optimizations can meaningfully improve performance for early UM detection. While ROI dilation preprocessing had the most performance gain, results varied across optimization pathways, indicating room for refinement. Further evaluation on external datasets is needed to assess generalizability, paving the way for end-stage clinical rollout. Machine learning (ML) model integrating cell death pathways as a prognostic and predictive biomarker for patients with melanoma. First Author: Erick F. Saldanha, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Established regulated non-apoptotic cell death mechanisms, including ferroptosis, necroptosis, and pyroptosis, can govern cancer cells' fate. Early reports suggest that these pathways can drive antitumor immune response, and may be associated with survival outcomes for pts treated with checkpoint blocker antibodies (ICB). We developed a ML model based on transcriptomic data (CDPS), integrating these 3 pathways, and interrogated its prognostic and predictive role in pts with melanoma. **Methods:** An ML score based on 148 non-redundant cell-death–related genes was developed and evaluated in patient-level data from TCGA-SKCM and validated in external cohorts of pts with melanoma (GSE65904, MEL-DFCI-2019, GSE98394, GSE54467). Prognostic performance was assessed using C-index, time-dependent ROC, Kaplan–Meier analysis, and univariable Cox models, with pts stratified by cohort-specific medians. Pathway activity was examined using gene set enrichment analysis (MSigDB Hallmark and Reactome gene sets; pathways were significant if FDR < 0.05). Immune infiltration was estimated with MCP-counter as per Cliff'delta (Mann-Whitney test $p < 0.05$). Predictive value was tested in pts treated with ICB (GSE78220, GSE91061, GSE168294), which also included on-treatment samples (GSE91061). **Results:** Across discovery and validation cohorts, a random survival forest model with ridge regression showed consistent prognostic performance (C-index range, 0.58-0.66). 7 genes emerged as dominant contributors during feature selection. The CDPS-high group showed a downregulation of *MLKL* and *GSDMD* (key mediators of necroptosis and pyroptosis, respectively), and an upregulation of *SLC3A2* (a negative regulator of ferroptosis), suggesting suppression of these regulated cell-death pathways. Across all 5 cohorts, CDPS-high pts exhibited significantly worse overall survival ($p < 0.05$), corroborated by time-dependent ROC analyses at 1 (0.61 - 0.72), 3 (0.84 – 0.75), and 5 years (0.58-0.76). Functional pathway analyses revealed statistically significant positive enrichment of proliferative, anabolic, and DNA-repair signalling in the CDPS-high group and negative enrichment of immune-related pathways (FDR < 0.05). Similarly, CDPS-high tumors demonstrated broadly reduced innate and adaptive immune cell infiltration, indicating a less favorable tumor immune microenvironment ($p < 0.05$). CDPS was significantly lower in responders (R) vs non-responders ([NR], p = 0.04) in GSE168294. Notably, a decrease in CDPS levels was observed during treatment for R, whereas remained stable in NR (GSE91061). **Conclusions:** CDPS exhibited robust and consistent performance by combining selected programmed death pathways (ferroptosis, necroptosis, and pyroptosis), especially in pts treated with ICB. Future efforts will aim to validate CDPS in a prospective cohort of pts with melanoma. Research Sponsor: None.

The efficacy and safety of neoadjuvant toripalimab combined with temozolomide in resectable stage III melanoma: A prospective, single-center, phase 2 trial. First Author: Tu Hu, Department of Musculoskeletal Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Neoadjuvant immune checkpoint inhibitors (ICIs) have demonstrated efficacy in resectable cutaneous melanoma and are recommended by current guidelines. Nevertheless, the clinical benefit of combining ICIs with chemotherapy as neoadjuvant setting in Chinese patients remains to be established. This study is being conducted to explore the efficacy and safety of neoadjuvant toripalimab combined with temozolomide in resectable stage III melanoma. **Methods:** This is a prospective, single-center, single-arm clinical trial (ClinicalTrials.gov identifier: NCT05827770). Patients with resectable stage IIIB-IIID acral or cutaneous melanoma and an ECOG performance status of 0-1 were enrolled and received two cycles of neoadjuvant temozolomide 200 mg/m² plus toripalimab 240 mg every 3 weeks, followed by radical surgery. The primary endpoint was the pathologic response rate (pRR). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), recurrence-free survival (RFS), overall survival (OS) and safety. **Results:** As of December 2025, 20 eligible patients with resectable stage IIIB-IIID melanoma were enrolled, with 14 (70%) acral, 5 (25%) cutaneous and 1 (5%) of unknown primary. Of 20 patients underwent surgery, nine achieved pRR (45%), including 3 with near pathologic complete response (near pCR) and 6 with partial pathologic response (pPR). Radiological assessment showed partial response in 5 patients, stable disease in 12 patients, and progressive disease in 3 patients, yielding an objective response rate of 25% (5/20) and a disease control rate of 85% (17/20) according to RECIST criteria. With a median follow-up of 12 months, 8 recurrence-free survival events had been observed; the median RFS and OS had not yet been reached. Notably, one patient who attained near pCR remained relapse free for 27 months. No new safety signals were observed with the combination therapy. We further performed single-cell-resolution spatial transcriptomics and single-cell RNA sequencing in the current cohort. Integrative multi-omics analyses identified a T cell-excluded tumor microenvironment preferentially associated with non-response. Leveraging these features, we robustly distinguished immunotherapy responders from non-responders. **Conclusions:** This study demonstrates the preliminary efficacy and tolerability of toripalimab combined with temozolomide in the neoadjuvant treatment of patients with resectable stage IIIB-IIID acral and cutaneous melanoma. Given the fact that ICIs alone has limited response rate in acral melanoma, further studies are warranted. Clinical trial information: NCT05827770. Research Sponsor: None.

Survival outcomes of stage IIB/IIC cutaneous melanoma treated with wide local excision and adjuvant immunotherapy without sentinel lymph node biopsy. First Author: Mahaasrei Ghosh, University of Iowa Carver College of Medicine, Des Moines, IA

Background: The Multicenter Selective Lymphadenectomy Trial-1 (MSLT-1) reported no significant difference in 10-year overall survival (OS) in patients with thick melanomas who had only wide local excision (WLE) versus WLE and sentinel lymph node biopsy (SLNB). With expanded immunotherapy eligibility for stage IIB/C melanoma per KEYNOTE-716, does omission of sentinel node negatively impact nodal basin disease control? Thus, we studied patients with stage IIB/C cutaneous melanoma treated with WLE and adjuvant pembrolizumab. **Methods:** We performed a single-institution retrospective review and included patients with stage IIB/C cutaneous melanoma treated with only WLE and adjuvant pembrolizumab with at least 6 months of follow-up. The primary endpoints were OS and cumulative incidence of nodal metastasis (CINM). Secondary endpoints were recurrence-free survival (RFS) and nodal metastasis-free survival (NMFS). Survival was estimated via Kaplan-Meier survival analysis and compared to the thick melanoma observation arm of MSLT-1. **Results:** Thirty-three patients met inclusion criteria between 2021-2025. Our sample was 58% male, 100% White, non-Hispanic, and median age at surgery was 59 $\pm$ 13 years. Twenty-sex (79%) patients were clinical group stage IIB. Tumor subtypes included acral lentiginous (3%), desmoplastic (3%), nodular (45%), spindle cell (3%), and superficial spreading (24%). Median follow-up was 24.3 $\pm$ 12.3 months. Four deaths occurred at 11, 17, 32, and 42 months, and OS probability was 96.2% at 12 months and 84.0% at 36 months. We observed 11 recurrences (33.3%). Six occurred in regional lymph nodes at 3, 3, 7, 7, 20, and 34 months, and 5 were distant metastases at 6, 11, 19, 20, and 25 months. At 12 months, RFS probability was 80.4%, 65.9% at 24 months, and 47.9% at 36 months. The probability of NMFS was 87.5% at 12 months, 82.8% at 24 months, and 69.0% at 36 months. Our CINM, over a median follow-up duration of 24.3 $\pm$ 12.3 months, was 18.2%, of which 3 began nivolumab/relatlimab and had complete radiological response and no subsequent recurrence. Of the 5 distant metastases, 3 underwent radiation or surgery for brain lesions and 1 began nivolumab/relatlimab for a chest wall nodule, both groups had complete radiologic response with no recurrence. Per MSLT-1, melanoma-specific survival of thick melanomas was between 76.1 $\pm$ 5.2% and 53.8 $\pm$ 7.6% at 60 months, and CINM was 33.2 $\pm$ 4.5% at 36 months. **Conclusions:** In our cohort, OS and CINM were comparable or better to the thick melanoma observation arm of MSLT-1. Our data suggests that omission of SLNB is highly likely to not negatively impact outcomes and may be offered to patients with significant operative risk. A larger sample with longer follow-up is needed to substantiate this conclusion. Research Sponsor: None.

Intismeran autogene to induce de novo neoantigen-specific T cells as adjuvant therapy in melanoma. First Author: Ryan J. Sullivan, Massachusetts General Hospital, Boston, MA

Background: Intismeran autogene (intismeran) is an individualized mRNA-based neoantigen (neoAg) therapy designed to enhance endogenous antitumor T-cell responses by targeting patient-specific tumor mutations. In the phase 2 KEYNOTE-942 trial of resected high-risk melanoma, intismeran combined with pembrolizumab (pembro) significantly improved recurrence-free survival (RFS) vs pembro alone. Previously, it was shown that the combination induced greater expansion of *de novo* T-cell clonotypes, which correlated with RFS in the intismeran arm. Here, we show that *de novo* T-cell clonotypes are reactive to intismeran-encoded neoAgs. **Methods:** Peripheral leukapheresis samples longitudinally collected from a subset of intismeran plus pembro treated participants (pts) with melanoma from phase 1 and 2 studies (NCT3313778 and NCT03897881) were assessed at single-cell level to characterize neoAg-specific T cells. In 7 pts, functional assessment of neoAg-reactive $CD8^+$ T cells was performed by intracellular cytokine staining and activation-induced marker assays. To define antigen specificity and phenotype of intismeran-induced T cells, we combined longitudinal bulk and single-cell T-cell receptor (TCR) sequencing with functional validation assays from 3 pts. *De novo* expanded TCRs were tested in Jurkat NFAT-luciferase reporter cells for reactivity against pt-specific intismeran mRNA cassettes and individual neoAgs. For reactive TCRs, minimal epitopes were mapped and mutant vs wild-type peptide reactivity was quantified. **Results:** Using the combination of bulk and single-cell TCR sequencing and Jurkat NFAT-luciferase reporter assays in 3 pts, we identified 20 TCRs expanded following intismeran therapy across all pts mapping to 11 neoAgs, providing direct evidence of intismeran-driven polyclonal T-cell expansion. These responses targeted multiple neoAgs with persistence $>$100 days after last intismeran dose. Reactive TCRs showed stronger recognition of mutant vs wild-type peptides, confirming antigen specificity. Functional assessment of T cells from 7 pts showed that neoAg-reactive $CD8^+$ T cells secreted IFNγ and TNFα and coexpressed markers for degranulation/activation upon peptide restimulation, demonstrating functional activity. Flow cytometry–based characterization of neoAg-reactive T cells *ex vivo* revealed that these cells predominantly exhibited an effector-memory phenotype. Upon stimulation, they were polyfunctional ($IFN\gamma^+$ $TNF\alpha^+$), mobilized CD107a, and were granzyme B^+, consistent with cytotoxic effector function relevant to tumor control. **Conclusions:** Complementary sequencing and functional analyses demonstrated that adjuvant therapy with intismeran plus pembro induced durable, polyclonal, neoAg-specific T-cell responses with effector-memory characteristics, providing mechanistic data consistent with the clinical benefit observed in pts with melanoma. Clinical trial information: NCT3313778 & NCT03897881. Outcome of neoadjuvant immunotherapy for patients with resectable stage III/IV cutaneous melanoma: A Swedish nationwide population-based study (NEO-MEL). First Author: Axel Nelson, Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Randomized trials have shown that neoadjuvant immune checkpoint inhibitor (ICI) improves outcomes compared with adjuvant therapy alone in patients with resectable stage III–IV cutaneous melanoma. Furthermore, pathological response was a strong predictor for relapse-free survival (RFS). The translationability to routine real-world patients is unknown. **Methods:** This population-based cohort study included all patients with macroscopic, resectable cutaneous melanoma treated with neoadjuvant immune checkpoint inhibitor(s) across all academic melanoma centers in Sweden between January 1, 2022 and December 30, 2025. Clinical and pathological data were extracted from medical records. **Results:** A total of 279 patients initiated neoadjuvant ICI and received a median of two treatment cycles, 94% received PD1-inhibitor monotherapy, 91% underwent surgery as planned and 251 had evaluable pathological assessment. Among all patients who started treatment, 37% had a complete pathological response (pCR), 6% near pCR, 15% a partial pathological response (pPR) and 32% no pathological response (pNR). At a median follow-up time of 20 months, the estimated 24-month event-free survival was 69% (95% CI, 62-76), distant metastasis-free survival (DMFS) 75% (95% CI, 69-82) and overall survival (OS) 87% (95% CI, 82-92). Among those who underwent surgery and had an evaluable pathological assessment, RFS, DMFS and OS stratified by pathological response are shown in the table. **Conclusions:** Early nationwide implementation of neoadjuvant ICI in patients with resectable cutaneous melanoma resulted in favourable outcomes that closely mirror those reported in randomized clinical trials. Research Sponsor: None.

Pathological response	N	RFS at 24 months % (95% CI)	DMFS at 24 months % (95% CI)	OS at 24 months % (95% CI)
pCR	103	92 (85-100)	93 (86-100)	94 (87-100)
near pCR	17	76 (56-100)	83 (64-100)	90 (73-100)
pPR	41	83 (71-97)	85 (74-98)	92 (81-100)
pNR	90	48 (36-63)	63 (52-78)	81 (70-92)

Adjuvant versus no adjuvant therapy after major pathological response to neoadjuvant immunotherapy in resectable melanoma: A Swedish nationwide population-based study (NEO-MEL). First Author: Axel Nelson, Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Randomized trials have shown that neoadjuvant PD-1–based immunotherapy improves outcomes compared with adjuvant therapy alone in patients with resectable stage III–IV cutaneous melanoma. In trials, patients experiencing a major pathological response (MPR) rarely relapse, and in the NADINA trial, adjuvant therapy was omitted in this group. However, the need for continued adjuvant treatment after MPR has never been prospectively tested, and real-world evidence is limited. **Methods:** This population-based cohort study included all patients with macroscopic, resectable cutaneous melanoma treated with neoadjuvant immune checkpoint inhibitor(s) across all academic melanoma centers in Sweden between January 1, 2022 and December 30, 2025. Clinical and pathological data were extracted from medical records. MPR was defined as pathological complete response (pCR) or near-pCR. Recurrence-free survival (RFS) was estimated using the Kaplan–Meier method and differences assessed with log-rank test. **Results:** A total of 279 patients initiated neoadjuvant treatment; 254 (91%) underwent surgery as planned, and 251 had evaluable pathological assessment. Overall, 103 patients (37%) experienced pCR and 17 (6%) near-pCR, yielding 120 patients (43%) with MPR. At a median follow-up of 19 moths, the estimated 24-month RFS for patients with MPR was 92%. Among MPR patients, 52 (43%) received continued adjuvant immune checkpoint inhibitor therapy, while 68 (57%) received no adjuvant treatment. RFS differed significantly between groups, with estimated 24-month RFS of 96% in patients receiving adjuvant therapy versus 80% in those who did not (P=0.048). In the non-adjuvant group, there were five recurrences (three had pCR and two had near pCR), two were local recurrences and three were distant metastatic events, compared with no recurrence events in the adjuvant group. One unrelated death occurred in the non-adjuvant group and two unrelated deaths in adjuvant group. **Conclusions:** In this nationwide real-world cohort, patients experiencing MPR after neoadjuvant immunotherapy had excellent outcomes overall. However, a small but clinically relevant risk of relapse was observed among patients who did not receive continued adjuvant therapy after MPR. These findings emphasize the need for individualized assessment when considering adjuvant treatment in patients with MPR. Longer follow-up is needed to determine whether additional events emerge and, importantly, whether relapses can be effectively salvaged with immune checkpoint inhibitor rechallenge. ADAPT-M: A tool to predict individualized benefit from adjuvant anti–PD-1 (PD-1) in resected high-risk melanoma. First Author: Ines Esteves Domingues Pires da Silva, Melanoma Institute Australia, The University of Sydney, Sydney, NSW, Australia

Background: Resected stage IIB/C and microscopic stage IIIA/B/C/D melanoma presents a significant risk of recurrence risk of 37 to 62% at 5 years (yrs). While 1 year of adjuvant PD1 therapy reduces this risk by approximately half, the individual patient's baseline risk without treatment and their specific benefit from adjuvant PD1 remain unknown. We aimed to generate two separate predictive models for recurrence – one for untreated and one for treated pts - to calculate the individualised benefit of adjuvant PD1. **Methods:** Pts with resected stage IIB/C or microscopic stage IIIA/B/C/D melanoma, either treated with adjuvant PD1 or untreated at 13 major melanoma centres, and with at least 2 years of follow-up from surgery were included. We analysed pts demographics, disease characteristics, blood parameters, pathological and imaging data at baseline, and clinical outcomes. Propensity scores were estimated using logistic regression with covariates associated with treatment in univariate screening ($p<0.05$). Separate penalised multivariable logistic regression models were built to predict recurrence for treated and untreated pts. A tool based on these models was created to calculate the individual patient benefit from adjuvant PD1. **Results:** A total of 3560 pts was included, divided into untreated (discovery n=2384 and validation n=597) and treated (discovery n=404 and validation n=175) cohorts. The model for untreated pts included age, gender, primary site, histological subtype, Breslow thickness, ulceration, mitosis, number and site of regional lymph nodes (LN), mutation status and LDH (AUC 0.70 in discovery, 0.69 in validation). The model for treated pts included age, gender, Breslow thickness, site of regional LN, and mutation status (AUC 0.69 in discovery, 0.61 in validation). ADAPT-M (ADjuvant Anti-PD-1 Tool for Melanoma) calculates the individualized benefit of adjuvant PD1. For example, patient A, a woman $\leq$45 years old with a primary head & neck melanoma (superficial spreading, thickness $>$1-2 mm, no ulceration, 1 mitosis/mm^2), 2 clinically occult LN metastases in the neck, NRAS mutant, and normal LDH, has a 12-month recurrence risk of 21.9% untreated vs 2.3% treated (benefit 19.6%), and a 24-month risk of 41.1% untreated vs 6.4% treated (benefit 34.7%). While, patient B, a man $\leq$45 years old with a primary melanoma in the lower limb (nodular, thickness $>$1-2 mm, no ulceration, 1 mitosis/mm^2), 2 clinically occult LN metastases in the groin, BRAF V600 mutant, and normal LDH, has a 12-month recurrence risk of 14.2% untreated vs 11.8% treated (benefit 2.5%), and a 24-month risk of 28.0% untreated vs 30.1% treated (no benefit). **Conclusions:** ADAPT-M, a clinical tool that estimate individualized recurrence risks with and without adjuvant anti-PD1 therapy, quantifies the absolute benefit of treatment for pts with high-risk resected melanoma, facilitating personalized adjuvant therapy decisions. Research Sponsor: None.

Assessment of recurrence risk in stage IIB/C melanoma across time: Implications for stratification and surveillance. First Author: Mohammad Saad Farooq, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: Stage IIB/C cutaneous melanoma is associated with high recurrence risk, however stratification of risk in relation to time after surgery has not been comprehensively evaluated. We evaluated recurrence-free survival (RFS) at key time points, stratified by clinicopathologic factors, to identify patients (pts) at higher recurrence risk and personalize postoperative surveillance strategies. **Methods:** In this multi-institutional, international retrospective cohort study from the Sentinel Lymph Node Working Group database, we included pts with pathologic T3b/T4a/T4b and N0 disease who underwent surgical resection and sentinel node biopsy from 1994-2025. The type of first recurrence (local, regional, distant) was characterized based on time category (0-12, 12-24, 24-60, and 60+ months after surgery). Restricted mean survival time (RMST) analysis was used to measure the average survival time up to a specified time point (6-, 12-, 24-, and 60-months after surgery), and associations of clinicopathologic variables (age, sex, Breslow thickness, ulceration and lymphovascular invasion [LVI]) with RFS. **Results:** We included 2514 stage IIB/C pts from 19 sites in 4 countries, with a median follow-up of 53 (stage IIB) and 49 (stage IIC) months. 675 (27%) pts experienced a recurrence (92 [14%] local, 238 [35%] regional and 345 [51%] distant), and 400 (59%) recurrences occurred within 24 months. The proportion of distant recurrences as the first recurrence increased significantly with time, comprising 39%, 50%, 62%, and 59% of recurrences in the 0-12, 12-24, 24-60, and 60+ month time categories respectively (χ^2 $p<0.001$). No significant differences were observed for the included clinicopathologic variables for 6-month RMST estimates. At 12 months, RMST estimates for thickness $\geq$4 mm (11.2 vs 11.6 months for thickness 2-3.99 mm, $p<0.001$) and presence of LVI (10.7 vs 11.4 months, p=0.009) were significantly different. 24-month RMST estimates differed for male sex (20.7 vs 21.5 months vs females, p=0.002), thickness $\geq$4 mm (20.5 vs 21.9 months, $p<0.001$), and presence of LVI (19.0 vs 21.1 months, $p<0.001$). Lastly, 60-month RMST estimates differed for male sex (42.0 vs 45.2 months, p=0.001), thickness $\geq$4 mm (41.5 vs 46.2 months, $p<0.001$), LVI (36.0 vs 43.7 months, $p<0.001$), and age $>$65 years (41.5 vs 46.4 for age $<$42, p=0.022). **Conclusions:** In this real-world, multi-center analysis of pathologic stage IIB/C melanoma pts, recurrence patterns varied based on time after surgery. Breslow thickness, LVI, male sex, and age were significantly associated with earlier recurrence at different time intervals on RMST analysis. Additionally, given that $>$50% of first recurrences 12+ months after surgery were distant, active surveillance for distant relapses may be warranted. Research Sponsor: None.

Real world outcomes of neoadjuvant immune checkpoint blockade (ICB) for resectable stage III melanoma: Pathologic response and FDG PET/CT correlates. First Author: Yang Wang, Peter MacCallum Cancer Centre, Sir Peter MacCallum Department of Oncology, The University of Melbourne, Melbourne, VIC, Australia

Background: Neoadjuvant (NA) ICB is standard of care for resectable stage III melanoma, with major pathological (p) response (R) (MPR, ≤10% viable tumor) strongly predicting relapse free survival (RFS). Imaging biomarkers to predict MPR are lacking. We evaluated the outcomes of patients (pts) treated with NA pembrolizumab (Pem) or nivolumab (NIVO) + ipilimumab (IPI) therapy, focusing on pR and FDG PET/CT metabolic changes. **Methods:** We retrospectively analyzed pts with resectable stage IIIB-D melanoma treated with NA Pem or NIVO + IPI at Peter Mac from March 2022 to Dec 2025. Clinical characteristics, pR, RFS, and treatment-related adverse events (TRAEs) were analyzed. RFS was calculated from date of surgery until day of death, recurrence or last follow up. Maximum standardized uptake value (SUVmax) of the most avid lesion (lymph node (LN) or in-transit metastases (ITM)) at baseline and post NA ICB on FDG PET/CT scans were recorded. **Results:** Of the 130 pts, 100 had LN metastasis only, 19 ITM only and 11 LN + ITM. 77 (59.2%) received Pem and 53 (40.8%) received NIVO + IPI. 117 pts (90.0%) underwent surgery: LN dissection in 40, index LN (ILN) excision in 58, ITM excision in 18 and excision of ITM + ILN in 1. 13 pts did not have surgery, 10 due to progressive disease on FDG PET/CT, complete resolution of ITM in 2, and toxicity in 1. MPR was seen in 74 (63.2%), partial response (pPR) in 7 (6.0%) and pathological non-response (pNR) in 36 (30.8%) pts. A ΔSUVmax decline ≥50% post NA ICB was strongly predictive of MPR, whereas pts without significant metabolic response were more likely to have pNR (sensitivity 93.2%, specificity 60.0%, positive predictive value 71.9%, negative predictive value 88.9% and accuracy 77.4% p=0.005). In ILN disease, 40/43 pts (93.0%) with ≥50% drop in ΔSUVmax achieved MPR ($p<0.0001$). In ITMs, a decline in ΔSUVmax ≥50% resulted in MPR in all 10 pts (table 1). At 12 months (m) median follow up, 14 pts recurred including 4 after MPR. The estimated 12m RFS was 89.0% for Pem and 79.3% for NIVO + IPI. 12m RFS in pts with ΔSUVmax decline ≥50% for Pem was 97% and 82% for NIVO + IPI (p=0.045). Grade ≥3 TRAEs occurred in 12 pts (7.5%), more frequently with NIVO + IPI. **Conclusions:** NA ICB yields high MPR rates in stage III melanoma. Early metabolic response on FDG PET/CT, defined as a ΔSUVmax ≥50% decline is a strong, readily implementable imaging biomarker for predicting MPR following NA ICB, enabling early treatment adaptation and personalized surgical decision-making. Research Sponsor: None.

5-year overall survival after adjuvant treatment for stage III melanoma: An English nationwide registry-based study. First Author: Mouhamad Hussein Ismail, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Adjuvant treatments for stage III cutaneous melanoma were approved based on significant improvement in recurrence free survival (RFS) with both anti-PD-1 and BRAF+MEK inhibitors. However, registration trials have not demonstrated a significant overall survival (OS) benefit to date. Given the potential patient and financial toxicity associated with adjuvant therapy, the effect on OS remains an important consideration. **Methods:** A retrospective study linking national registry data for all patients diagnosed with stage III melanoma in England between 2016 and 2021 were included and divided into two cohorts based on date of initial melanoma diagnostic staging: pre- and post-May 2018, when adjuvant therapy was initially approved in England. Key data collected were: patient age, sex, date of stage III melanoma diagnosis, TNM stage, systemic therapy for melanoma, cause and date of death. Data cut-off for follow-up was 1st August 2025. Melanoma-specific survival (MSS) and OS were calculated using the Kaplan-Meier method and Cox regression analyses. **Results:** A total of 6,297 patients were analysed (pre-May 2018: n=2,089; post-May 2018: n=4,208). Survival outcomes improved significantly in the post-adjuvant cohort. The 5-year overall survival (OS) rose from 60.9% (95% CI: 58.8–63.0) to 64.2% (95% CI: 62.7–65.7), with a hazard ratio of 0.89 (95% CI: 0.82–0.96; p=0.004). Similarly, 5-year melanoma-specific survival (MSS) improved from 70.4% (95% CI: 68.4–72.5) to 72.8% (95% CI: 71.4–74.3), HR 0.89 (95% CI: 0.81–0.99; p=0.025). When stratifying by age, sex or melanoma TNM stage, no significant OS or MSS was observed. **Conclusions:** English national registry data demonstrates a statistically significant improvement in both OS and MSS for patients diagnosed with stage III melanoma after approval of adjuvant therapy for stage III melanoma. This is consistent with published real world data from France, but contrasts with findings in Sweden and the Netherlands. The reduced utilisation of subsequent therapy for metastatic disease likely reflects the established RFS benefit. The OS benefits are modest, so careful discussion of the potential risks and benefits of adjuvant therapy remains central to patient care. Research Sponsor: Melanoma Focus UK.

Neoadjuvant camrelizumab plus apatinib and temozolomide for resectable stage III acral melanoma: Updated CAP 03-NEO trial results and external control comparison. First Author: Xiaoting Wei, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital & Institute, Beijing, China

Background: SWOG1801 and NADINA trials suggested that neoadjuvant therapy may provide greater benefits than adjuvant therapy in melanoma. CAP 03-NEO explores the efficacy and safety of camrelizumab combined with apatinib and temozolomide triple-drug regimen as neoadjuvant therapy in patients (pts) with resectable stage II/III acral melanoma (AM). **Methods:** This two-stage trial (NCT05512481) aimed to enroll 60 pts with resectable stage II/III AM. Pts received two 4-week cycles of neoadjuvant camrelizumab (200 mg IV Q2W), apatinib (250 mg orally QD), and temozolomide (200 mg/m² IV daily D1–5), followed by surgery and 15 cycles of adjuvant camrelizumab (200 mg Q3W). A total of 30 pts were assessed in stage 1, demonstrating stage III AM benefiting more from neoadjuvant therapy (ASCO 2025, abstract 9512). Therefore, stage 2 exclusively enrolled stage III pts. Endpoints included pathological response, EFS, RFS and DMFS. To further evaluate the neoadjuvant benefit, an external contemporary cohort of stage III AM pts treated with upfront surgery and adjuvant PD-1 inhibitor alone was retrospectively collected for comparison. Propensity score matching (PSM 1:1 nearest neighbor method) and inverse probability of treatment weighting (IPTW) were used to minimize bias. Kaplan-Meier method and Cox regression were performed for survival analysis. Stage 2 results and this post-hoc comparison are reported here. **Results:** As of Jan. 26, 2026, thirty-one pts in stage 2 were enrolled, with a median follow-up of 13 months. The median age was 60 years (IQR: 49–68). Of 28 pts undergoing surgery, 18 (64.3%) achieved any pathological response, including 10 with major pathological response (7 with pCR, 3 with near pCR), and 8 with pPR. Surgery was canceled for 2 pts due to progressive disease. Neoadjuvant therapy was still ongoing for one patient. The 12-month rates of EFS, RFS and DMFS were 74.4%, 80.3% and 84.0%, respectively. All median values were not reached. As compared to external control cohort (adjuvant treatment alone), both unadjusted and adjusted analyses showed that pts treated with additional neoadjuvant therapy achieved significantly better EFS, RFS and DMFS (Table 1, all p values <0.05). The safety profile between stage 1 and stage 2 were similar and no new safety signal was identified. **Conclusions:** Stage 2 results and external control comparison of CAP 03-NEO further confirmed the significant benefit of neoadjuvant camrelizumab, apatinib and temozolomide in pts with resectable stage III AM. Clinical trial information: NCT05512481. Research Sponsor: None.

Ultrasensitive ctDNA detection for relapse and response prediction in melanoma patients treated with immunotherapy. First Author: Christoffer Gebhardt, Department of Dermatology/Skin Cancer Center, University Medical Center Hospital Hamburg-Eppendorf, Hamburg, Germany

Background: Immune checkpoint inhibitors (ICIs) have markedly improved outcomes in melanoma and are now standard of care in advanced and adjuvant settings. However, substantial toxicities remain, and up to 50% of patients derive no clinical benefit. Conventional clinicopathological factors lack sufficient precision for risk stratification, resulting in under- and overtreatment. Circulating tumor DNA (ctDNA) has emerged as a highly specific biomarker for molecular residual disease (MRD) detection, enabling real-time, minimally invasive monitoring to guide personalized ICI strategies. **Methods:** We analyzed 847 plasma timepoints from 98 melanoma patients treated with ICI in either the unresectable advanced (metastatic) setting (25 patients) or adjuvant setting following complete resection of the primary and/or loco-regional metastases (73 patients). Plasma samples were analyzed using NeXT Personal, a whole-genome-sequencing-based tumor-informed assay designed to track up to 1,800 patient-specific variants. This ultrasensitive liquid biopsy approach achieves detection limits of down to ~1 part per million (PPM) at high specificity (>99.9%), enabling identification of MRD and early molecular relapse that may inform timely therapeutic intervention. **Results:** Baseline ctDNA was detected in 100% of 25 patients with unresectable melanoma. Within this group, an early molecular response defined by a ≥30% decrease in ctDNA by cycle 3 predicted an 80% reduction in the risk of progression or death (PFS HR 0.2, P=0.01; OS HR 0.2, P=0.03). In the adjuvant cohort, landmark ctDNA positivity at 3 months post-surgery prior to immunotherapy, was 35% and identified patients with significantly inferior outcomes, with a >3-fold increase for the risk of distant metastasis or death (DMFS HR 3.8, P=4.9510−3; OS HR 4.1, P=3.61×10−3). Longitudinal monitoring further established that any ≥20% increase in ctDNA during adjuvant treatment was highly prognostic of poor survival (DMFS HR 3.0, P=0.01; OS HR 3.5, P=0.02). These molecular increases identified recurrences a median of 212 days prior to radiographic detection. The clinical necessity of ultrasensitive assays was underscored by the fact that 71% of these early detections occurred at ultra-low levels below 100 PPM. Real-time variant tracking revealed mutations druggable mutations such as BRAF V600E. **Conclusions:** Detection of MRD with PPM sensitivity represents a major advance in treatment monitoring for both unresectable and completely resected melanoma. Early on-treatment ctDNA decreases identify responders in advanced disease, while postoperative ctDNA positivity identifies adjuvant patients at highest relapse risk. Early MRD-based detection of loco-regional or distant relapse enables timely adaptation of therapeutic strategies. Research Sponsor: Personalis.

Linking T-cell receptor dynamics to outcomes in neoadjuvant-treated melanoma. First Author: Ronen Stoff, Department of Oncology, Mayo Clinic Rochester, Rochester, MN

Background: Clinical Stage III (cSIII) melanoma patients are at high risk of recurrence following therapeutic lymph node dissection (TLND) and adjuvant therapy. Neoadjuvant immunotherapy based regimens have shown promising results in this setting, with pathological response being the best predictor of recurrence free survival (RFS) and distant metastases free survival (DMFS). T-cell Receptor (TCR) abundance and clonality are being explored as biomarkers. **Methods:** In the phase II NeoACTIVATE (NCT03554083) trial, patients were treated based on BRAF status with 12 weeks of neoadjuvant atezolizumab, vemurafenib and cobimetinib (Arm A, BRAF-mutated) or atezolizumab and cobimetinib (Arm B, BRAF wildtype), followed by TLND and 6 months adjuvant atezolizumab. TCR sequencing (n=23) was performed on the pretreatment involved lymph node (iLN) and on the same node, along with an adjacent uninvolved node (uiLN) after TLND. The fraction productive of T cells (fpTC) was defined as the percentage of in-frame TCR sequences (capable of encoding a functional expressed receptor protein) of all TCR sequences identified. Simpson Clonality Index (SCI) was used to measure relative abundance of specific clones, with a higher score indicating a more monoclonal repertoire. Comparisons were made using the Wilcoxon Rank Sum test. **Results:** 30 patients were enrolled, 15 in each arm. 2 patients were not operated on, and one did not receive adjuvant treatment, leaving 27 patients for outcome analysis. 3-year RFS was 55.6% (95% CI 9.5%-77.8%), median of 62.2 months (95% CI 19-NR); DMFS was 64.3% (95% CI 48%-86.3%), median 62.2 months (95% CI 33.9-NR). The fpTC was higher in the pretreatment iLN for those without an RFS event (p=0.04) with a trend in the uiLN as well (p=0.06). Patients without a DMFS event had a higher fpTC in the uiLN (p=0.03) but not in the iLN. The SCI was significantly higher only in the post treatment iLN for patients without an RFS event (p=0.03) and was not significantly different when compared based on DMFS status. When performing pairwise comparisons of nodes based on recurrence status, we found that patients who did not suffer an RFS event had a significantly higher SCI in the post treatment iLN compared to the uiLN (p=0.02). **Conclusions:** Neoadjuvant immunotherapy and targeted therapy for cSIII melanoma can lead to durable RFS. Higher pretreatment fpTC as well as higher post-treatment iLN TCR clonality were both associated with improved RFS. These data indicate that TCR repertoire characteristics within iLN and uiLN may reflect differential immune responses to neoadjuvant therapy and could inform future studies evaluating biomarkers to stratify risk of recurrence and allow personalization of therapy. Clinical trial information: NCT03554083. Research Sponsor: Stand Up to Cancer-Genentech Catalyst Research Grant; SU2C-AACR-CT1017; Mayo Clinic Center for Clinical and Translational Science (cCaTS).

Surgical de-escalation in high-risk resectable melanoma with major pathologic response (MPR) after neoadjuvant immune checkpoint inhibition (ICI). First Author: Meghan J. Mooradian, Mass General Brigham, Marblehead, MA

Background: Neoadjuvant ICI renders MPR in 50-60% of resectable Stage III/IV melanoma. Early data illustrated the ability to de-escalate surgery in cases of MPR in the index lymph node (ILN). However complete lymph node dissection (CLND), a procedure with considerably morbidity, remains the standard of care. Real-world data demonstrating the ability to de-escalate surgery while maintaining disease control, can inform optimal practice. **Methods:** In our retrospective study performed at two academic institutions (MGB/DFCI), patients with resectable, macroscopic Stage III/IV cutaneous melanoma treated with neoadjuvant ICI were identified. Pre-treatment fiducial placement was routinely performed in cases of macroscopic nodal disease to facilitate index node excision (INE). Data pertaining to treatment course, anti-tumor outcomes, and safety were collected. Signatera ctDNA was evaluated as a non-invasive biomarker of early response. **Results:** From 2020-2025, 126 patients received neoadjuvant ICI: 60 anti-PD-1 monotherapy, 62 ipilimumab/nivolumab (I/N) and 4 nivolumab/relatlimab (N/R). The majority had macroscopic stage III disease (95%) and completed the full neoadjuvant course (86%). Ten patients (8%) did not undergo surgery (clinical CR, n = 3; toxicity, n = 1; progression, n = 6). Of the 116 (92%) who underwent surgery; 43 (37%) had an upfront TLND; 52 (45%) had an INE and 21 (18%) excision of N1c or M1a disease. After INE (n = 52), reflex CLND was performed in 7 (13%) all due to non-MPR. The MPR of the total cohort was 54% (n = 63) with a pCR rate of 51% (n = 59). The MPR/pCR rate was similar between ICI regimens. In the MPR cohort, 35 underwent an INE only whereas 17 underwent CLND; the remainder had excision of N1c/M1a disease. Post-operatively, 15 required drain placement, of whom 2 had an INE. Adjuvant ICI was utilized in 23 patients, the majority receiving peri-operative pembrolizumab (n = 20). After a median follow-up of 15.5mths (3.2-68.7mths), in those who underwent surgery, 20% (23/116) have recurred; 3 with a MPR (INE, n = 1; excision, n = 2). Of these, 2 were distant metastases with no nodal recurrence. Notably, 33 patients had pre-operative ctDNA results (Signatera). At the time of surgery, ctDNA was undetectable in the majority of MPR patients (19/20), while the majority of non-MPR patients remained detectable (8/13). Pre-surgery ctDNA assessment prognosticated RFS for the 20 patients who were detectable at baseline (p = 0.035) with ctDNA clearance associated with both MPR and improved RFS. Updated clinical and ctDNA data will be presented at the meeting. **Conclusions:** Similar to published data, patients with a MPR had low rates of recurrence, with no difference between those who underwent INE compared to upfront CLND. Pre-operative ctDNA levels, particularly ctDNA clearance, correlate with clinical outcomes and may inform de-escalation strategies. Research Sponsor: None.

Microbiome-derived bile acids and association with dietary fiber intake to anti-tumor responses in patients with melanoma receiving immune checkpoint blockade (ICB). First Author: Nazli Dizman, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Multiple studies have now linked high fiber diet (HFD) and outcomes with ICBs, however, the clinical actionability and mechanistic basis of this association remain incompletely defined. We investigated whether microbiome-derived metabolites may function as potentially actionable mediators of this interaction. **Methods:** Blood samples from two studies in patients (pts) with melanoma starting ICB were utilized: (1) longitudinal samples from the prospective Phase II DIET clinical trial (NCT04645680), in which pts with melanoma starting ICBs were randomized (2:1) to a HFD [up to 50 g fiber/day (d)] or a healthy control diet (HCD, 20 g/d) and (2) baseline samples from an observational prospective diet/microbiome ICB-treated melanoma cohort. Untargeted and targeted metabolome analysis of bile acids and tryptophan-metabolites were performed via liquid chromatography (LC)- and short-chain fatty acids (SCFAs) via gas chromatography (GC)-mass spectrometry. Circulating metabolite levels were compared between pre- and on-treatment samples in DIET trial by arm and between pts with response (R, assessed by RECIST 1.1) and no response (NR) in the observational cohort. **Results:** A total of 110 pts were included: 45 DIET study pts randomized to HFDI (n=30) vs HCD (n=15), and 65 pts in the observational cohort. As previously reported, response rates were numerically improved in HFD (77% vs 29% in HCD (p=0.06), in the DIET study. Untargeted metabolomics yielded 38 metabolites with statistically significant differences (nominal $p<0.05$) in change over time in the HFD arm vs in the HCD arm, with notable reductions in glycine conjugated bile acids with HFD. Bile acid biosynthesis metabolite sets were the most significantly differentially enriched ($p<0.01$, enrichment ratio >5.0). Targeted metabolomics showed that HFD reduced secondary-to-primary bile acid ratios (deoxycholic acid [DCA] to cholic acid [CA], p=0.02) as well as glycine- and taurine-conjugated to unconjugated bile acid ratios (glycocholic acid [GCA] to CA, taurocholic acid [TCA] to CA, both p=0.03). In the observational cohort, GCA/CA and TCA/CA ratios were significantly lower in R vs NR (p=0.03 and p=0.04, respectively) whereas no difference was seen in DCA/CA ratios. SCFAs and tryptophan metabolites showed neither temporal changes in DIET trial nor response associations in the observational cohort. **Conclusions:** We observed that bile acid deconjugation, a key microbiome-mediated step, was reduced by an HFD intervention and inversely associated with response to ICB in an observational cohort. Building on prior work demonstrating that additional HFD-mediated secondary bile acids can impair T cell function, microbial bile acid metabolism emerges as a potential determinant of anti-tumor response targetable through HFD. Clinical trial information: NCT04645680. Research Sponsor: Conquer Cancer, the ASCO Foundation.

Outcome of adjuvant BRAF and MEK inhibition with dabrafenib and trametinib in BRAF V600K– compared to V600E-mutated melanoma. First Author: Michael Weichenthal, University of Kiel, Kiel, Germany

Background: Patients with resected stage III BRAF V600 mutated melanoma can be treated with combined dabrafenib and trametinib (D/T) with significant improvement of recurrence-free survival (RFS). The results of the pivotal Combi-AD study showed overall survival (OS) improvement only for patients with BRAF V600E mutations, while for V600K there was even an OS impairment as compared to placebo, although not statistically significant. **Methods:** We analysed EUMelaReg data for patients with adjuvant D/T therapy for resected stage III melanoma. Only patients with V600E and V600K mutations were selected, where n=93 from a total of 1,033 patients (9.0 %) harboured V600K. **Results:** Demographics of patients with V600K mutations differed significantly for age (67 vs. 58 years, $p<0.001$) and a higher proportion of males (67.0% vs. 54.6%, p=0.03) at baseline. Other baseline variables, including substage, were not significantly different. One year of treatment was completed in 51.6% for V600K, and 62.8% for V600E, respectively, while with V600K mutations 22.6% of the patients stopped for toxicity (vs. 18.8% with V600E), and 10.8% for disease recurrence (vs. 6.9%), which was not statistically significant. After a median follow-up of 41.7 (V600K) and 41.2 (V600E) months, Kaplan-Meier analysis estimated 4-year overall survival of 75.7% for V600K compared to 77.8% for V600E. The 4-y-RFS estimates were 48.3% for V600K and 47.0% for V600E. These differences were not statistically significant. Cox regression analysis revealed no different results when adjusted for demographic co-variates, including age and sex, for RFS and OS, respectively. **Conclusions:** It appears that V600E and V600K mutations are not associated with a different outcome from adjuvant treatment with combined D/T. The findings offer no explanation for differences found in the Combi-AD trial, although part of these differences also resulted from a different natural course of V600K mutated melanomas the placebo group. A longer follow-up will help to further confirm these results and also analyse the possible role of further treatments in the metastatic setting. Research Sponsor: None.

Longitudinal monitoring for post-surgical molecular residual disease in patients with stage I–IIIB melanoma using a whole-genome sequencing–based ctDNA assay. First Author: Karam Khaddour, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Circulating tumor DNA (ctDNA) is a novel biomarker for detecting molecular residual disease (MRD) and monitoring recurrence risk in melanoma. Personalized, tumor-informed ctDNA assays may enable highly sensitive and specific longitudinal detection of disease burden following curative-intent surgery. Here, we evaluate the prognostic value of whole-genome sequencing (WGS)-based ctDNA detection in patients with resected stage I–IIIB melanoma. **Methods:** This was a retrospective analysis of residual samples from a deidentified real-world dataset. Clinicopathologic information was collected from Natera's commercial database under an IRB-approved protocol (#20-049-ALL). Patients with stage I-IIIB melanoma who underwent surgery between March 2018 to May 2023 were included. Whole genome-based ctDNA assays (Signatera Genome, Natera, Inc.) were designed from the respective patients' matched tumor and normal WGS data. ctDNA was subsequently tracked in the patients' longitudinal blood samples, which were collected postoperatively until recurrence/end of follow-up. The correlation between ctDNA status post-definitive treatment and recurrence-free survival (RFS) was assessed using Cox regression analysis with a time-dependent covariate and the Kaplan-Meier method. **Results:** A total of 103 patients with stage I-IIIB melanoma and residual material available for testing were included with a median of 6 tests per patient (range: 1–23) and a median of 91 days between ctDNA tests. Median follow-up was 25.1 months (range: 8.5–73.4). Stage distribution was: 1.9% (2/103) IA, 3.9% (4/103) IB, 7.8% (8/103) IIA, 39.8% (41/103) IIB, 20.4% (21/103) IIC, 8.7% (9/103) IIIA, and 17.5% (18/103) IIIB, and 38 patients received adjuvant treatment, with the majority 87% (33/38) receiving immunotherapy only. ctDNA results during the post-operative treatment window were available for 95 patients. Among the 15 patients who experienced recurrence after completion of definitive treatment, 12 (80%) were ctDNA-positive prior to or within 2-weeks of clinical recurrence (range: 99 days pre - 12 days post-imaging). Among patients who did not experience recurrence, 97.5% (78/80) were serially ctDNA-negative. ctDNA positivity at any time during post–definitive treatment was associated with significantly shorter RFS compared with persistent ctDNA-negativity (HR 55.3; 95% CI 18.7–163.3; $p < 0.0001$). Analyses are ongoing to characterize ctDNA dynamics (including quantification) and clinical outcomes in an expanded cohort. **Conclusions:** This analysis demonstrates the prognostic value of longitudinal post-operative ctDNA monitoring for the detection of recurrence in patients with stage I–IIIB melanoma using a WGS-based, personalized, tumor-informed assay with implications for optimizing surveillance and improving clinical outcomes. Clinical validation of an AI-based prognostic assay for stage I-II cutaneous melanoma. First Author: Christina Kanaan, Department of Pathology, Gustave Roussy, Villejuif, France

Background: In early-stage cutaneous melanoma (CM), AJCC staging demonstrates limited ability to identify patients at elevated recurrence risk who may benefit from adjuvant therapy or intensified surveillance. We evaluated DiaSurv, an AI-based prognostic assay analyzing standard H&E whole-slide images (WSI) to refine risk stratification in stage I-II melanoma. **Methods:** DiaSurv was validated on a retrospective cohort of 456 stage I-II primary CM patients with 5-year follow-up at Gustave Roussy. The algorithm assigns high- or low-risk scores based solely on primary tumor WSI analysis. Kaplan-Meier analysis estimated 5-year recurrence-free survival (RFS), distant metastasis-free survival (DMFS), and overall survival (OS). Log-rank tests compared survival between risk groups. Multivariable Cox regression assessed independent prognostic value after adjusting for clinicopathological factors (Breslow thickness, ulceration, age, sex, tumor location, histological subtype, mitotic count). **Results:** Among 456 stage I-II patients (109 recurrences, 67 distant metastases, 57 deaths), DiaSurv classified 285 (62.5%) as low-risk and 171 (37.5%) as high-risk. Low-risk patients had significantly better 5-year outcomes compared to high-risk patients: RFS 92% vs 38% (HR = 7.71, 95%CI 4.86-12.23, $p < 0.001$), DMFS 94% vs 55% (HR = 10.39, 95%CI 5.31-20.36, $p < 0.001$), and OS 96% vs 71% (HR = 8.12, 95%CI 4.10-16.07, $p < 0.001$). In multivariable analysis, DiaSurv was independently associated with all endpoints (RFS: HR = 2.43, p = 0.006; DMFS: HR = 3.71, p = 0.002; OS: HR = 3.78, p = 0.003). In the clinically relevant stage I-IIA subgroup (n = 368), DiaSurv identified 86 patients (23.4%) with high-risk profiles despite favorable AJCC staging. These patients had markedly inferior outcomes compared to the 282 low-risk patients: 5-year RFS 71% vs 92% (HR = 4.85, $p < 0.001$), DMFS 77% vs 96% (HR = 5.48, $p < 0.001$), and OS 84% vs 96% (HR = 4.39, $p < 0.001$). The NPV of low-risk classification at 5 years in stage I-IIA was 92.2% for RFS, 96.5% for DMFS, and 96.5% for OS which is in line or superior to some commercially available gene-expression profiling assays. **Conclusions:** In early-stage melanoma (I-IIA), where adjuvant therapy is not currently standard, DiaSurv identifies nearly one-quarter of patients with a high-risk profile and significantly elevated recurrence rates. This AI-based assay provides actionable prognostic information beyond AJCC staging to guide decisions regarding adjuvant therapy consideration, sentinel lymph node biopsy, and surveillance intensity. Research Sponsor: None.

Neoadjuvant anti–PD-1 prolgolimab monotherapy in resectable high-risk melanoma: Pathologic response and early event-free survival in a prospective single-arm phase II CRISTINA study. First Author: Angelina Kuzmenko, Federal State Budgetary Institution "N.N. Blokhin National Medical Research Center of Oncology" of the Ministry of Health of the Russian Federation (N.N. Blokhin NMRCO), Moscow, Russian Federation

Background: In resectable high-risk melanoma, neoadjuvant anti–PD-1 aims to exceed the ~40% MPR benchmark; while combos may deepen response, they add tox, complexity, and cost. Recently reported data for prolgolimab+nurulimab (N = 205) showed pCR 38.5%, near-CR 4.4%, motivating evaluation of prolgolimab mono as a simpler potentially non-inferior approach. **Methods:** MelPRO-0322 (CRISTINA; NCT06299878) is a prospective single-arm study in resectable stage IIIB–IV melanoma: 3 neoadj doses of prolgolimab followed by radiologic assessment followed by surgery (regional lymphadenectomy or M1a-equivalent metastasectomy). Central pathology used INMC criteria. Interim analysis after full enrollment and pathology assessment. **Results:** Pt characteristics (N = 82): Median age 61.5 y (range 23.2–87.3); median BMI 28.2 kg/m² (21.0–46.5). Females 47 (57.3%); ECOG 0/1: 56 (68.3%)/26 (31.7%). Primary melanoma: cutaneous or UPO 73 (89.0%), acral 7 (8.5%), mucosal 2 (2.4%). Stage: IIIB 12 (15.8%), IIIC 54 (71.1%), IIID 3 (3.9%), IV 7 (9.2%); stage missing 6 (7.3%). BRAF V600 mut in 43/74 (58.1%). Median neoadj tx duration 28 d (0–108). Median time from start of neoadj tx to surgery 67 d (29–176). LND/resection performed in 66/82 (80.5%). RECIST 1.1 (ITT, N = 82): ORR 23 (28.0%); CR 5 (6.1%), PR 18 (22.0%), SD 27 (32.9%), PD 24 (29.3%); not evaluable 8 (9.8%). Pathologic response (ITT, N = 82): pCR 28 (34.1%), near-pCR 7 (8.5%), MPR 35 (42.7%); pathology not available in 16 (19.5%). Among evaluable (n = 66): pCR 42.4%, MPR 53.0%. Achieving MPR correlated with better radiologic response by RECIST ($p < 0.001$) and lower nodal tumor burden (fewer positive nodes; p = 0.012). With a median follow-up of 11.8 mo by reverse KM (95% CI 7.5–17.4), EFS in the ITT cohort (N = 82; events = relapse/progression/death) showed 20 events with median EFS 32.2 mo (95% CI not estimable) and RMST 29.8 mo (SE 4.71). In the pathology-evaluable set (n = 66), EFS was longer in pts achieving MPR vs non-MPR/PD (log-rank p = 0.002): median EFS 19.3 mo for non-MPR/PD (n = 31; 10 events) vs not reached for MPR (n = 35; 2 events); RMST 20.3 vs 30.1 mo. In exploratory multivariable Cox models, MPR remained strongly associated with improved EFS (HR 0.043, 95% CI 0.003–0.684; p = 0.026), while higher PLT/LYM ratio (HR 1.029, 95% CI 1.006–1.052; p = 0.015) and male sex (HR 8.74, 95% CI 1.12–68.21; p = 0.039) showed associations with inferior EFS, while time from neoadj start to surgery and receipt of adjuvant therapy were not associated with EFS. **Conclusions:** NST prolgolimab monotherapy achieved MPR rates above the historical benchmark with encouraging early EFS. MPR—especially pCR—was strongly associated with improved EFS, with no progressions observed among pCR pts. In exploratory analyses, neither time from neoadj start to surgery nor receipt of adjuvant therapy appeared to materially affect EFS. Clinical trial information: NCT06299878. Research Sponsor: None.

Non-melanoma skin cancer–related mortality in the United States: A 25-year CDC WONDER analysis. First Author: Shehdev Meghwar, Liaquat University of Medical & Health Sciences, Jamshoro, NA, Pakistan

Background: Non-melanoma skin cancer (NMSC), including basal cell and squamous cell carcinoma, is the most common malignancy worldwide, with rising incidence due to ultraviolet exposure and aging populations. Analyzing two decades of CDC WONDER data provides insights into mortality disparities and geographic variation. **Methods:** Using the CDC WONDER database for adults aged ≥25, we analyzed age-adjusted and crude mortality rates (AAMRs and CMRs) per 100,000 for NMSC (ICD-10 C44.0 to C44.9) by year, sex, race/ethnicity, and geography. Joinpoint regression (version 5.4) estimated average annual percentage change (AAPC) and annual percentage change (APC) with 95% confidence interval (CIs). **Results:** From 1999–2023, NMSC caused 118,792 deaths (female: 36,921; male: 81,871), most occurring at the Decedent's home (37.7%). The AAMR rose 41% from 1.92 in 1999 to 2.72 in 2023 (AAPC: 1.55%; $p<0.001$), with significant increases in 2005–2019 (APC: 1.88, 95% CI: 1.45 to 2.30) and 2019–2023 (APC: 4.92, 95% CI: 2.78 to 7.09). Adults ≥65 had the highest CMR (8.59), rising 1.57% annually ($p<0.001$). Men consistently had higher AAMR about three times that of women in 1999 (3.24 vs. 1.03), and the gap remained in 2023 (4.35 vs. 1.50). Non-Hispanic (NH) Whites had the highest AAMR, rising 2.06% annually ($p<0.001$), while NH Asians or Pacific islanders had the lowest with a slight decline (-0.19%; p=0.81). Regionally, the West had the fastest rise in AAMR at 1.68% annually ($p<0.001$), while the Midwest had the slowest at 1.24% ($p<0.001$). Mortality in rural areas (AAMR: 2.35) rose faster (1.41%; $p<0.001$) than in urban populations (AAMR: 1.93; 0.80%). Oklahoma and West Virginia ranked highest in the top 90th percentile. **Conclusions:** Mortality from NMSC has risen in the United States over the past two decades. However, significant demographic and geographic disparities in mortality continue, emphasizing the need for equitable healthcare access and targeted interventions, particularly among males, NH Whites, and high-burden states and regions. Research Sponsor: None.

Deaths and AAPC for trends related to non-melanoma skin cancer from 1999 to 2023.

Variable	Deaths	AAPC (1999-2023) with CI
Overall	118,792	1.55 (1.01 to 2.09)
Male	81,871	1.29 (0.71 to 1.87)
Female	36,921	1.54 (1.10 to 1.99)
NH White	108,523	2.06 (1.54 to 2.60)
NH Black	4,797	-0.67 (-1.74 to 0.40)
Hispanic	3982	0.76 (0.48 to 2.02)
NH Asians	1,105	-0.20 (-1.87 to 1.51)
Midwest	25,260	1.25 (0.66 to 1.83)
West	27,192	1.54 (1.03 to 2.05)
South	46,442	1.64 (1.12 to 2.17)
Northeast	19,898	1.69 (0.90 to 2.49)

Anti-tumor activity of FF-10850 (liposomal topotecan) in patients with advanced Merkel cell carcinoma. First Author: Vincent T. Ma, Division of Hematology, Medical Oncology, and Palliative Care, Department of Medicine, University of Wisconsin, Madison, WI

Background: FF-10850 is a novel liposomal topotecan with increased intratumoral accumulation and robust pre-clinical activity. The prolonged $t_{1/2}$ (27 hours) supported a twice-monthly dosing schedule in the first in human dose finding trial (NCT04047251), with anti-tumor activity demonstrated in heavily pre-treated patients (pts) with solid tumors; pts remained on study up to 20 months. Common AEs were nausea and fatigue, with manageable hematologic toxicity. A Merkel cell carcinoma (MCC) pt maintained a PR for 33 weeks after progression on prior topotecan and PD-1-directed therapy. Because MCC pts who have progressed or are ineligible for anti-PD-1 therapy have few effective systemic treatment options, we evaluated FF-10850 in an MCC expansion cohort. Results are reported for all MCC pts on study. **Methods:** Pts ≥18 years with advanced MCC were treated with FF-10850 2 mg/m^2 IV on Days 1 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. Pts must have progressed on or have been ineligible for all standard therapy and treated with or ineligible for PD-1 based therapy. In expansion, pts who progressed on camptothecin therapy within 6 months were excluded; prior etoposide was allowed. Response was assessed by RECIST 1.1. **Results:** 12 pts [8M/4F; median age 70 (58-84), ECOG PS 0 (5)/PS 1 (7)] were treated. Baseline disease (n): unresectable stage IIIA (1), IV (10)/IVB (1). The median # of prior therapies was 1 (0-5), 1 had prior topotecan; 2 pts had no prior therapy, one due to rheumatoid arthritis (RA) and another due to solid organ transplant. Common drug-related AEs were anemia (50%), nausea (50%), fatigue (42%), and thrombocytopenia (25%). One pt each had related Gr 3 anemia and neutropenia; no related Gr 4 toxicity was observed. Three pts had infusion-related reactions; one that did not restart treatment. Two pts left study before RECIST evaluation: one withdrew to hospice care, and one died of an unrelated MI after the first dose of FF-10850 following a clinically significant anti-tumor response 2 weeks after the single dose. Best overall response in 10 RECIST evaluable pts was: 1CR, 1 PR, 4 SD and 4 PD; disease control rate (CR+PR+2 consecutive SD) was 50%. Three pts remain on study: one that achieved a CR after 2 cycles maintains CR after 14 cycles, and 2 pts maintain durable SD after 6-12 cycles. The median (range) time on study was 9.4 (3.1-50.9) weeks; median PFS and OS were 7.5 (95% CI:1.2-NR) and 10.7 (95% CI:2.1-NR) months, respectively. **Conclusions:** FF-10850 has demonstrated encouraging preliminary activity in both pre-treated and treatment naïve MCC. The regimen of 2 mg/m^2 every 2 weeks is tolerable with manageable hematologic side effects. PFS and OS in this small study compare favorably with that reported for cytotoxic agents in 2nd line pts of 3 and 10 months, respectively. Further exploration of FF-10850 in MCC may offer a novel treatment option for this rare disease. Clinical trial information: NCT04047251. Research Sponsor: FUJIFILM Pharmaceuticals U.S.A., Inc.

9582 **Poster Session**

Incidence of new keratinocyte cancers during pembrolizumab in resectable cutaneous squamous cell carcinoma: The De-Squamate study. First Author: Rahul Ladwa, Princess Alexandra Hospital, University of Queensland, Brisbane, Australia

Background: Patients with advanced cutaneous squamous cell carcinoma (cSCC) or basal cell carcinoma (BCC) frequently develop new primary keratinocyte cancers (KCs) due to field cancerisation. Emerging data suggest immune checkpoint inhibitors (ICIs) may reduce this burden. We evaluated the incidence of new KCs in a prospective immunotherapy cohort. **Methods:** De-Squamate was a prospective phase II trial evaluating neoadjuvant pembrolizumab using a response-adapted management strategy in resectable cSCC. As part of protocol-mandated safety monitoring, all new primary KCs were prospectively recorded as adverse events. Events included histologically confirmed new cSCCs, BCCs, or other keratinocyte malignancies diagnosed and resected during or after treatment. Person-time was calculated for periods on pembrolizumab and off treatment. Incidence rates were calculated per person-year. Rate ratios were estimated using crude analyses and adjusted models accounting for within-patient clustering. **Results:** Among the 27 patients, 54 new KCs were recorded. Patients contributed 14.9 person-years on pembrolizumab and 33.4 person-years off treatment. KC incidence was lower during active therapy than after discontinuation (73.7 vs 143.6 per 100 person-years). The unadjusted rate ratio for new KC development off treatment versus on treatment was 1.95 (95% CI, 1.01–3.75). Adjusted analyses using negative-binomial modelling produced similar estimates (adjusted rate ratio 1.94; 95% CI, 0.64–5.89). Reductions were most pronounced for BCCs, with more modest effects observed for new primary cSCCs (table 1). **Conclusions:** In this prospective cohort, new KCs occurred at approximately twice the rate after discontinuation of pembrolizumab compared with during active therapy. These findings support the hypothesis that ICIs may suppress carcinogenesis within chronically damaged skin fields. Larger studies are needed to clarify the potential immunopreventative effect of ICIs in patients with field-driven KCs. Clinical trial information: NCT05025813. Research Sponsor: MSD.

Early burden reduction after two doses of cemiplimab in advanced non-melanoma skin cancer. First Author: Lucrezia Raimondi, Medical Oncology - Humanitas Gradenigo, Turin, Italy

Background: Advanced non-melanoma skin cancers (NMSC) frequently impose a high disease-related burden—severe pain, ulceration, intensive wound care—particularly in older and frail patients (pts). While cemiplimab has established antitumor activity, early pts-centered clinical benefit prior to first radiologic evaluation is under-described in routine practice. We quantified early changes in key burden domains after 2 infusions. **Methods:** A retrospective analysis was performed in a real-world cohort of pts with locally advanced/metastatic NMSC treated with cemiplimab. Assessments at T0 (≤7 days pre-treatment) and T1 (day 35–49; after 2 infusions). Pain intensity (0–10 Numeric Rating Scale, NRS), wound-care frequency (dressing changes/week), and analgesic exposure were extracted from structured clinical/nursing documentation; opioid exposure was quantified as daily morphine milligram equivalents (MME) using standard conversion. Primary endpoint: meaningful early pain benefit at T1 (≥2-point NRS decrease without analgesic escalation). Other endpoints: opioid de-escalation, wound-care reduction (≥2 fewer dressing changes/week), and a pragmatic early-burden composite (improvement in ≥2 of: primary pain benefit; opioid de-escalation; wound-care reduction). Paired Wilcoxon signed-rank and McNemar tests were used. Infection status summarized. Confounding-restricted sensitivity analyses excluded pts receiving RT/surgery within 8 weeks of treatment initiation. **Results:** 53 pts included; median age 80yr (IQR 71–88); 81% locally advanced disease; ECOG 0–1 56%. Baseline burden: median pain NRS 7 (IQR 6–8); baseline opioid use 60%; wound-care frequency median 4/week; ulceration G≥2 64.2%. At T1 median pain NRS improved to 3 (IQR 2–4) (median Δ −3; $p<0.001$). The primary endpoint was achieved in 83% (44/53; 95% CI 70.8-90.8). The proportion of pts receiving opioids decreased from 60% (32/53) at T0 to 22.6% (12/53) at T1 (p=0.00024). Median daily MME decreased from 20 mg (IQR 0–33) to 0 mg (IQR 0–14) ($p<0.001$). Among baseline opioid users (n=32), 100% reduced dose and/or discontinued opioids by T1 (32/32; 95% CI 88.6–100). Wound-care frequency decreased from median 4/week to 1/week ($p<0.001$), with wound-care reduction ≥2/week in 67.9% (36/53). The pragmatic early-burden composite was met in 79.2% (42/53). At first radiologic evaluation (median 91 days), RECIST evaluable in 51 pts; ORR was 76.4% (39/51) and disease control was 96.2% (50/52). Any immune-related AE occurred in 34% (18/53), with G≥3 in 1.9% (1/53). Infection decreased from 43% to 3.8% at T1. **Conclusions:** In an elderly, frail real-world population with NMSC and high supportive-care needs, cemiplimab was associated with rapid, meaningful early clinical benefit after two doses. Early burden endpoints may complement radiologic response to better capture patient-centered benefit and inform supportive-care planning in routine pathways. Research Sponsor: None.

Using stage-matched genomic analysis to support molecular similarity of unknown-primary Merkel cell carcinoma and identify ARID1B as a prognostic marker. First Author: Furkan Bahar, Dana-Farber Cancer Institute, Boston, MA

Background: Merkel cell carcinoma (MCC) can present as nodal disease without an identifiable cutaneous primary, termed unknown-primary MCC (UP-MCC). UP-MCC has been reported to have distinct clinical outcomes compared with stage-matched known-primary MCC (KP-MCC), but its underlying biology is poorly understood. We compared the genomic landscapes of UP-MCC and stage IIIB KP-MCC and evaluated whether specific alterations are associated with survival in UP-MCC. **Methods:** A retrospective analysis was performed using the Dana-Farber Cancer Institute MCC repository (2012-2023). UP-MCC was defined as pathologically confirmed MCC without a detectable cutaneous primary; the comparator cohort comprised stage IIIB KP-MCC. Tumors underwent targeted next-generation sequencing (OncoPanel; 447 genes), and tumor mutational burden (TMB) and Merkel cell polyomavirus (MCPyV) status were recorded. Gene-level alteration frequencies were compared using Fisher's exact test, and MCC-specific survival (MCCSS) and overall survival (OS) were assessed using Kaplan-Meier and Cox proportional hazards models. **Results:** Fifty-two patients were included (20 UP-MCC, 32 KP-MCC). UP-MCC and KP-MCC showed highly overlapping genomic landscapes, including similar distributions of MCPyV status, TMB, and recurrent driver alterations, with no gene-level differences detected. Within UP-MCC, *SETBP1* alterations were associated with worse MCCSS (HR 6.74; 95% CI, 1.33–34.07; p=0.030), while ARID1B alterations identified a markedly high-risk UP-MCC subgroup with inferior MCCSS (HR 27.1; 95% CI, 3.02–243.11; $p<0.001$) and OS (HR 16.9; 95% CI, 1.9–152.9; p=0.004). All five *ARID1B*-altered UP-MCC patients died of MCC, compared with 4 of 15 *ARID1B*−wild-type; in multivariable analysis, *ARID1B* remained an independent predictor of worse MCCSS (p=0.003), whereas *SETBP1* did not (p=0.313). In KP-MCC cohort, *ARID1B* was not significantly associated with MCCSS (p=0.1883). **Conclusions:** Stage-matched genomic profiling demonstrates molecular similarity between UP-MCC and KP-MCC, supporting the hypothesis that UP-MCC often represents regressed primary cutaneous tumors. Within UP-MCC, *ARID1B* alterations identify a high-risk subgroup with markedly inferior MCCSS, suggesting that targeted genomic profiling may refine risk stratification, surveillance strategies, and clinical trial design for patients with UP-MCC and these findings warrant validation in larger, multi-institutional cohorts. Research Sponsor: None.

Efficacy and safety of cosibelimab 800 mg every 2 weeks for locally advanced cutaneous squamous cell carcinoma: Updated follow-up from a pivotal study. First Author: Eva Muñoz Couselo, Medical Oncology, Vall d'Hebron Hospital & Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: Cosibelimab, a high-affinity programmed death ligand-1 (PD-L1)–blocking antibody, is approved by the US Food and Drug Administration (FDA) at a recommended dose of 1200 mg every 3 weeks (Q3W) for the treatment of adults with locally advanced or metastatic cutaneous squamous cell carcinoma (laCSCC or mCSCC) who are not candidates for curative radiation or surgery. The CSCC expansion cohort of the pivotal open-label Phase 1 study (NCT03212404) evaluated cosibelimab 800 mg every 2 weeks (Q2W) in patients with laCSCC or mCSCC and 1200 mg Q3W in patients with mCSCC. Results through March 2023 demonstrated robust and sustained responses with cosibelimab 800 mg Q2W. The 800-mg Q2W and 1200-mg Q3W regimens are considered similar based on pharmacokinetic criteria outlined by the FDA for alternative PD-L1–blocking antibody dosing regimens. We present new follow-up data for the 800-mg Q2W laCSCC cohort. **Methods:** Eligible patients were ≥18 years old and had an Eastern Cooperative Oncology Group performance status of 0 or 1 and unresectable laCSCC not amenable to local therapy. Cosibelimab 800 mg was administered intravenously on Day 1 of each 14-day cycle until complete response, worsening disease progression, toxicity, or clinical deterioration. The primary endpoint was objective response rate (ORR; best overall response: complete or partial) by independent central review per RECIST V1.1; duration of response (DOR) was the key secondary endpoint. Follow-up data presented are from investigator assessment. Other secondary endpoints included safety. **Results:** By the January 31, 2025, data cutoff, 64 patients with laCSCC received ≥1 dose of cosibelimab 800 mg Q2W; their median (range) age was 77 (51–95) years, and 66% were male. Patients received a median of 29 (2–89) doses over a median duration of 60 (4–184) weeks. The ORR (95% confidence interval) was 50% (37%, 63%), including 17 complete and 15 partial responses; over a median follow-up duration of 31 (1–59) months the median DOR was not reached. Treatment-emergent adverse events (TEAEs) were reported in 61 (95%) patients and considered treatment-related in 50 (78%) patients; none were fatal. The most common AEs were anemia and diarrhea, recorded in 17 (27%) patients each. Grade ≥3 TEAEs were reported in 26 (41%) patients and considered treatment-related in 7 (11%). Hypertransaminasemia, in 2 (3%) patients, was the only serious treatment-related TEAE reported. Immune-related AEs (irAEs) were recorded in 22 (34%) patients; Grade ≥3 irAEs occurred in 1 (2%) patient and were dermatologic in nature (maculo-papular and pruritic rashes) and considered treatment-related. **Conclusions:** Responses to treatment with cosibelimab 800 mg Q2W remained robust and durable with stable ORR after continued follow-up in a larger cohort of patients with laCSCC, with no new safety signals identified. Clinical trial information: NCT03212404. Research Sponsor: Sun Pharma.

Final analysis of the efficacy and safety of oral S-1 for locally advanced or recurrent/metastatic cutaneous squamous cell carcinoma: A multicenter retrospective study. First Author: Sadao Inoue, Saitama Medical University International Medical Center, Hidaka, Japan

Background: Anti–PD-1 antibodies are the standard systemic therapy for advanced cutaneous squamous cell carcinoma (cSCC). Recent clinical trials have reported objective response rates (ORRs) of 44–58.3% in locally advanced (LA) disease and 35.2–45.2% in recurrent or metastatic (R/M) disease, with grade ≥3 adverse events occurring in 31.1–34.5% of patients. S-1, an oral fluoropyrimidine, has been suggested as an alternative option with potential advantages, including favorable clinical response, lower toxicity, feasibility of outpatient initiation, and substantially lower cost; however, evidence remains limited to small case series. We therefore conducted a large multicenter retrospective study to evaluate the real-world efficacy and safety of S-1 in patients with advanced cSCC. **Methods:** This multicenter retrospective study included patients with LA or R/M cSCC who received oral S-1 between 2007 and 2024. S-1 was administered for 28 consecutive days, followed by 14 days off (one cycle). The primary endpoint was ORR assessed according to RECIST criteria. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and toxicity. Exploratory subgroup analyses were performed based on concomitant radiotherapy use and primary tumor site. **Results:** A total of 150 patients were analyzed (LA, n = 44; R/M, n = 106). The median age was 76 years (interquartile range, 67–83), and ECOG performance status was 0–1 in 127 patients (85%). Fifty-four patients (36%) had received prior systemic treatment. Among the R/M cohort, 59 patients had nodal metastasis and 47 had distant metastasis. The median follow-up was 13.4 months (LA, 15.0 months; R/M, 12.7 months). ORR was 55% (95% confidence interval [CI], 39–70) in the LA cohort and 40% (95% CI, 30–50) in the R/M cohort. The 12-month PFS and OS rates were 80% and 92% (95% CI, 63–90 and 76–97) in the LA cohort, and 41% and 62% (95% CI, 30–50 and 51–71) in the R/M cohort. Grade ≥3 adverse events occurred in 14% of patients, most commonly anemia (n = 4), thrombocytopenia (n = 3), neutropenia (n = 3), decreased appetite (n = 3), and oral mucositis (n = 3); no grade 5 events were observed. In exploratory analyses, patients receiving concomitant radiotherapy demonstrated higher ORR and PFS compared with those without radiotherapy, while OS was comparable between the groups. Tumors originating in the head and neck region were associated with superior ORR, PFS, and OS compared with other primary sites. **Conclusions:** Oral S-1 demonstrated antitumor activity comparable to that reported for anti–PD-1 antibodies, albeit without direct comparison, with a lower incidence of severe adverse events, suggesting its potential role in selected patients with advanced cSCC. Research Sponsor: None.

Circulating tumor DNA (ctDNA) as a biomarker for pathologic response and clinical outcomes in patients with cutaneous squamous cell carcinoma (CSCC) receiving neoadjuvant anti–PD-1 therapy. First Author: Luke Skyler Vest, Dana-Farber Cancer Institute, Boston, MA

Background: ctDNA is a novel biomarker that can be used to evaluate recurrence and treatment response in multiple cancers. The utility of ctDNA in patients with CSCC receiving neoadjuvant immunotherapy (nIT) is unknown. **Methods:** In this retrospective study, we examined patients with CSCC who received nIT and had ctDNA assay available pre- and post- operatively. Positive ctDNA was defined as a value >0, and ctDNA sensitivity pre-operatively (pre-op) was reported in all patients. Patients with at least two ctDNA measurements pre-op were classified into two cohorts: cohort-A included patients whose ctDNA decreased; Cohort-B included patients whose ctDNA increased. Pathologic response (PR) was defined as complete (pCR) if 0% viable tumor [vt], major (mPR) if vt < or equal to 10%, and no-response (nPR) if vt >10%. The association between ctDNA kinetics during the pre-op period nIT and PR was analyzed using Fisher's exact test. During the post-op period, we used minimal residual disease (MRD) status defined by positive ctDNA measurement within 3 months post-op. Recurrence-free survival (RFS) (landmark analysis with time starting at post-MRD timepoint until recurrence, death or loss-to follow-up) was compared between patients who had detectable MRD (positive ctDNA within 3 months post-op) versus those who had undetectable MRD. **Results:** Forty nine patients were included of which 42 (85.7%) were male, 11 (22.4%) were immunosuppressed, and 31 (63.3%) had AJCC stage IV CSCC. The median follow-up time since starting nIT was 12.9 months. The ctDNA sensitivity at baseline (prior to starting nIT) was 79.6%. The median number of ctDNA collections per patient was 6 (range: 1, 21). Of the 49 patients who underwent surgery, 38 were eligible who had at least 2 ctDNA measurements pre-op. Cohort-A (35 patients) had higher cPR and mPR compared to cohort-B (3 patients) (p=0.05). When excluding 3 patients who did not have kinetic ctDNA changes (ctDNA value was 0 at all pre-op time points), ctDNA decrease was significantly associated with cPR and mPR (p= 0.03). For post-op period, patients with detectable MRD (n=5) had significantly lower RFS compared to those with undetectable MRD (median RFS 11.3 months vs. not reached, HR: 11.9; 95% CI: 2.2-65.8; p< 0.01)(Table). **Conclusions:** ctDNA changes and detectable MRD may be suitable biomarkers for pathologic response assessment and post-op period in patients with CSCC receiving nIT. Further research is essential to confirm these findings. Research Sponsor: None.

Recurrence-free survival according to MRD status.

MRD status	N	Median after 3-month post-op (95% CI) month	6-month RFS after 3-month post-op (95% CI) months	12-month RFS after 3-month post-op (95% CI) months	Hazard ratio (95% CI)

Survival outcomes following resistance to immune checkpoint inhibition in advanced cutaneous squamous cell carcinoma. First Author: Samreen Iqbal, Princess Alexandra Hospital, Woolloongabba, QLD, Australia

Background: Immune checkpoint inhibitors (ICI) are standard first-line therapy for advanced cutaneous squamous cell carcinoma (cSCC); however, 35% of patients experience disease progression. Evidence guiding optimal second-line management remains limited. We evaluated real-world outcomes of second-line treatment strategies in patients with cSCC resistant to ICI. **Methods:** A retrospective analysis of patients with unresectable locally advanced or metastatic cSCC treated with ICI monotherapy at two tertiary centres in Brisbane, Australia, was conducted. Patients with progressive disease (PD) were identified and classified as having primary resistance (PD < 4 months) or acquired resistance (PD ≥4 months). Second-line strategies included local therapy (LT - surgery and/or radiotherapy), systemic therapy +/- LT or best supportive care (BSC). Outcomes included progression-free survival from second-line initiation (PFS2), and overall survival (OS) using Kaplan–Meier estimates. **Results:** Seventy-four patients were identified. Median age was 74 years. Most patients had locoregionally advanced disease (77%), head and neck primary tumours (70%), ECOG performance status 0–1 (76%), and were immunocompetent (70%). Primary resistance occurred in 54% and acquired resistance in 46%, of which 21% progressed after ICI cessation. Locoregional progression was observed in 70% of patients, while 30% progressed with distant disease. Management of ICI resistance included LT (N = 32), systemic therapy +/- LT (N = 16), and BSC (N = 26). An objective response rate of 65% was observed in patients undergoing systemic therapy +/- LT with responses to both ICI rechallenge and/or EGFR targeted therapy (7 of 11 patients). With a median follow up of 46.6m the Median PFS2 was 10.7m. PFS2 was numerically higher in patients undergoing systemic therapy vs LT alone (11.9m vs 8.4m). Of those that underwent LT alone, further PD was seen in 16 patients (50%), with half requiring systemic therapy. Median OS for the overall cohort was 19.0m. OS was numerically reduced in immunocompromised patients (11.6m) and in those with primary ICI resistance (6.9m) vs those who had acquired resistance (22.5m) and progression after ICI cessation (47.1m). **Conclusions:** Selected patients with advanced cSCC, particularly those with acquired resistance, derive meaningful benefit from second-line therapy following ICI progression. Outcomes remain poor for immunosuppressed patients or those with primary resistance, highlighting a major unmet clinical need and the importance of prospective studies in the post-immunotherapy setting. Research Sponsor: None.

Outcomes of neoadjuvant immunotherapy (NeoIO) in Merkel cell carcinoma. First Author: Lacey Mead, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Merkel cell carcinoma (MCC) is an aggressive malignancy with high rate of nodal and distant metastasis, leading to poor overall survival. For clinically detected regional lymph nodes, treatment typically involves node dissection with adjuvant radiotherapy. Evaluation of NeoIO in resectable MCC resulted in a pathological complete response (pCR) rate of 47%; pCR correlated with relapse-free survival (RFS). However, there is no standardized NeoIO regimen. We report our single institutional NeoIO experience in resectable MCC and correlate regimen with clinicopathological response. **Methods:** We retrospectively reviewed pts with resectable MCC who received NeoIO with intent to offer surgery (SX) or radiation (RT), from 2015 to present. Demographic and clinicopathological characteristics were evaluated. Overall Response Rate (ORR), pCR, and Relapse Free Survival (RFS) were computed. Overall survival (OS) was evaluated via a 90-day landmark Kaplan-Meier plot to assess if time to definitive regional treatment impacted OS. **Results:** We identified 25 patients; median age was 77 years old; 75% were male. Majority were clinical stage III (IIIa 20%; IIIb 68%); 12% were stage IIa. 32% had immunosuppression at the time of treatment. 36% had primary MCC on extremity, 36% on head and neck, 8% on trunk, and 20% were of unknown primary origin. 80% of patients received neoadjuvant Pembrolizumab, 16% Avelumab and 4% ipilimumab plus nivolumab. The median number of IO cycles was 3 (1-18); those who completed 1-2 cycles were more likely to receive SX/RT compared to those who received 3 or more cycles (p-value = 0.024). 64% of patients had an adverse effect during therapy; majority (87.5%) had G1/G2 events. 24 patients had post NeoIO imaging to which ORR was 75%. Post NeoIO, 15 underwent SX, 4 had definitive RT, 2 had progression of disease and received systemic therapy, 3 had comorbidities precluding treatment, and 1 was lost to follow up. The median time from beginning of NeoIO to SX or RT was 3 months (1-19mo). Of those who underwent SX, 40% had a complete pathologic response, 20% had a major pathologic response, 33% had a partial response, and 6% had non-response. With a median 23.4 months of follow-up, 8 of the 25 patients (32%) have experienced an event and the median EFS has not been reached. 7 of the 25 (28%) patients have died, 4 due to MCC; median overall survival not reached. Median follow up was 23.4 months. Time to event analysis indicated six patients who received NeoIO, followed with SX or RT within 90 days, had fewer deaths compared with those who received SX/RT after 90 days. Survival was approximately 3.5 years for those who did not receive SX/RT within 90 days and no deaths for those who received SX/RT within 90 days. **Conclusions:** NeoIO for MCC at our single institution achieved an ORR of 75% and a mPR/pCR of 60%. Earlier incorporation of regional therapy post NeoIO appears to improve outcomes, suggesting importance of multimodal management for resectable MCC. Research Sponsor: None.

Characterization of germline pathogenic variants in melanoma patients. First Author: Ye Tong Chua, University of Michigan Medical School, Ann Arbor, MI

Background: Approximately 10% of melanomas arise from hereditary predisposition. NCCN guidelines recommend genetic counseling for patients with ≥3 invasive melanomas, or a mix of invasive melanoma, pancreatic cancer, and/or astrocytoma in an individual or family. However, predictors of germline pathogenic/likely pathogenic variants (P/LPV) in patients undergoing germline testing remain poorly characterized. **Methods:** A retrospective study of all melanoma patients referred for any indication to the University of Michigan Cancer Genetics Clinic from 2015-2024 was performed. Patients who declined testing or had known hereditary cancer syndromes (personal or familial) were excluded. Baseline demographics, referral reasons, melanoma characteristics, and genetic testing results were collected. Chi-square and Fisher's exact tests were used to evaluate associations with P/LPV ($p<0.05$). **Results:** Among 624 patients, median age at melanoma diagnosis was 52 (IQR 38-63); 60.1% were female. The most common referral reasons were new melanoma diagnosis (64.4%), family history of non-melanoma cancers (57.1%), or family history of melanoma (39.4%). Overall, 88 (14.1%) harbored P/LPV (92 variants across 26 genes). P/LPV in established melanoma-risk genes were identified in 42 patients (6.7%): *CDKN2A* (n=16), *MITF* (n=8), *POT1* (n=5), *BRCA1/2* (n=6), *BAP1* (n=3), *TP53* (n=3), and *PTEN* (n=1). The strongest associations with any P/LPV were personal history of ≥2 additional non-skin primary cancers (OR 2.35; p=0.014) and ≥2 primary melanomas (OR 1.80; p=0.017). Diagnostic category (in situ, invasive, metastatic) and subtype (cutaneous, uveal, mucosal, acral, unknown primary) showed statistical significance with P/LPV ($p<0.001$), though effect sizes were modest. Age at diagnosis (<45, <55, <65), sex, and family history of melanoma or pancreatic cancer in 1˚ or 2˚ relatives were not associated with P/LPV. In a secondary analysis restricted to established melanoma-risk genes (n=42), ≥2 primary melanomas remained strongly predictive (OR 4.11; $p<0.001$) and 1˚ family history of melanoma became significant (OR 2.01; p=0.03), while ≥2 additional non-skin primary cancers was not associated (p=0.40). **Conclusions:** In this melanoma cohort excluding patients with known hereditary syndromes, 14.1% had a P/LPV. Personal tumor burden, not family history, was the strongest predictor of a positive test, suggesting current NCCN criteria may miss high-risk individuals by emphasizing family history. For established melanoma-risk genes specifically, both personal history of multiple melanomas and 1˚ family history of melanoma were predictive, supporting a gene-specific approach to risk assessment. These findings support expanding referral criteria to include patients with ≥2 primary melanomas or ≥2 additional non-skin primary cancers, agnostic of family history, to better identify individuals most likely to benefit from germline testing. ctDNA clearance durability and progression-free survival in unresectable or metastatic cutaneous malignancies. First Author: Joshua Espinola, University of Virginia, Charlottesville, VA

Background: Circulating tumor DNA (ctDNA) has emerged as a sensitive biomarker for disease monitoring and prognostication across malignancies. Yet, the clinical relevance of sustained ctDNA negativity ("clearance") as a guide for immunotherapy duration in advanced cutaneous cancers remains poorly defined. This study evaluated the prognostic impact of durable ctDNA clearance in patients with unresectable or metastatic skin cancers treated with immune checkpoint inhibitors (ICIs). **Methods:** A single-institution retrospective study was performed using a personalized ctDNA assay (Signatera, Natera Inc.) on prospectively collected plasma from patients with stage III–IV unresectable cutaneous malignancies receiving ICIs every 3-6 weeks. ctDNA clearance was defined as a change from ctDNA-positive to ctDNA-negative on at least two consecutive samples obtained ≥4 weeks apart during ICI therapy and categorized as transient (<12 months) or sustained (≥12 months). Demographics and clinical characteristics were summarized with descriptive statistics; progression-free survival (PFS) was estimated using the Kaplan-Meier method, and hazard ratios (HRs) were calculated with Cox proportional hazards models. **Results:** Among 75 patients (stage III: 23%, stage IV: 77%), most were male (72%) and had melanoma (87%), with a median age of 72 years and median follow-up of 20.4 months. Median ICI treatment duration was 6.9 months; all patients received ICIs, most commonly relatlimab/nivolumab (49%) or pembrolizumab (40%). Median ctDNA clearance duration was 8.2 months. Patients with sustained ctDNA clearance (n=25) experienced markedly improved 12-month PFS compared with those with transient clearance (n=50) (92.0% [95% CI, 71.6–97.9] vs 58.1% [95% CI, 42.6–70.8]). In a multivariable model adjusting for age, malignancy type, and treatment regimen, transient ctDNA clearance was associated with significantly worse PFS than sustained clearance (HR 12.1; 95% CI, 2.7-53.4). **Conclusions:** Sustained ctDNA clearance (≥12 months) is strongly associated with superior PFS in advanced cutaneous malignancies treated with ICIs, underscoring its potential as a dynamic biomarker to inform the treatment duration. Validation in larger, multi-institutional cohorts is warranted to confirm these findings and refine cDNA-guided immunotherapy strategies. Research Sponsor: None.

Long-term survivorship rates among previously treated advanced melanoma patients achieving objective response (OR) with lifileucel. First Author: Peter Mohr, Elbe Klinikum Buxtehude, Buxtehude, Germany

Background: Durability of response and associated long-term survival benefits of modern cancer therapies are often manifested as plateaus in duration of response (DoR) and overall survival (OS) curves for responders. In the single-arm, Phase 2 C-144-01 trial, unresectable/metastatic melanoma patients who progressed on immune checkpoint inhibitors (ICIs) showed durable clinical responses to lifileucel—an FDA-approved autologous T-cell therapy. This analysis evaluated the association between achieving an OR with lifileucel and possibility of being a long-term survivor (LTS) in the C-144-01 study. **Methods:** Mixture cure models (MCMs) were applied to analyze OS and DoR outcomes for patients who achieved confirmed OR by committee review among those receiving lifileucel within commercial specifications in Cohorts 2 and 4 (overall cohort; n=106, median follow-up: 47.4 months, OR rate 35.8%). In both analyses, LTS were subject to only non–melanoma-related mortality whereas non-LTS were subject to both melanoma- and non–melanoma-related mortality. In the DoR analysis, LTS were also assumed to remain in response until death. For LTS, OS/DoR outcomes were assumed to follow the survival trend of age- and sex-adjusted US general population, and derived from published lifetables whereas for non-LTS, they are modeled by parametric distributions. Fraction of LTS and OS/DoR distributions for non-LTS were estimated simultaneously via maximum likelihood methods. Candidate MCMs were evaluated based on statistical fit criteria, visual agreement with observed OS/DoR data, and underlying hazards. **Results:** Exponential MCM and gamma MCM provided best fits to the observed DoR and OS data, respectively, and estimated the fractions of LTS (95% CI) among responders as 52% (34.0%–69.4%) and 50.4% (31.3%–66.7%) from the OS and DoR data, respectively. Estimated fractions of LTS across clinically plausible models ranged between 48.4%–52.9% in the OS analysis and 50.4%–51.1% in the DoR analysis. Best-fitting MCMs projected 10-year mean OS and DoR as 70.7 and 62.2 months, respectively, and 10-year OS and DoR rates as 46.7% and 45.3%, respectively. Smoothed OS and DoR hazards derived from the observed data displayed convergence to general population mortality rates by the end of follow-up indicating maturity and suitability of data for modeling with MCMs. **Conclusions:** Responders had significantly higher fraction of LTS than the overall cohort, underscoring the importance of achieving OR to lifileucel for its long-term survival benefit. Estimated fractions of LTS from OS and DoR were robust to model choice, consistent with each other, and when scaled by OR rate, aligned with previously reported fractions of LTS from progression-free survival and OS for the overall cohort. Results support clinical potential of lifileucel for addressing unmet need in post-ICI advanced melanoma. Research Sponsor: Iovance Biotherapeutics, Inc.

Incidence and survival rates in pediatric and adolescent melanoma in the United States, 2001-2022. First Author: Maimoona Maheen, Rawalpindi Medical University, Rawalpindi, Pakistan

Background: Melanoma represents a significant malignancy in children, adolescents, and young adults. Recent trends in incidence and outcomes in this population have not been comprehensively characterized. We analyzed population-based data to evaluate temporal trends in melanoma incidence and survival among patients aged <40 years. **Methods:** Data from the North American Association of Central Cancer Registries (NAACR) and SEER registries (representing up to 76% of U.S. children, adolescents, and young adults) were analyzed for patients aged <40 years diagnosed between 2001-2022. Age-adjusted incidence rates per 1,000,000 were calculated and standardized to the 2000 U.S. population. Five-year relative survival rates were assessed for diagnoses from 2001-2020. Annual Percent Change (APC) and Average Annual Percent Change (AAPC) were calculated using Joinpoint Trend Analysis Software. **Results:** Melanoma incidence in patients aged <40 years demonstrated a consistent declining trend from 2001 to 2022. Incidence rates decreased from approximately 47-50 per 1,000,000 in the early 2000s to approximately 38 per 1,000,000 by 2022, representing approximately a 20% reduction over the study period. The decline was particularly notable after 2005, with a steady downward trajectory through 2022. Despite this declining incidence, 5-year relative survival rates remained consistently excellent throughout the entire study period at 95-97%, with a slight upward trend from approximately 95% in 2001 to approximately 97% in 2017-2020. Survival outcomes showed no statistically significant variation over time, remaining stable in the 95-97% range. **Conclusions:** This analysis reveals an encouraging 20% decline in melanoma incidence among children, adolescents, and young adults over two decades, likely reflecting the success of public health initiatives promoting sun protection, sunscreen use, and reduced indoor tanning. The sustained decrease in incidence, particularly among younger populations, suggests that prevention efforts have had measurable impact. Simultaneously, the consistently excellent 5-year relative survival rates exceeding 95% demonstrate the effectiveness of current diagnostic and therapeutic approaches for melanoma in this age group. The stable survival coupled with declining incidence represents a dual public health success, with both primary prevention reducing disease burden and clinical management maintaining excellent outcomes. These findings underscore the importance of continued emphasis on melanoma prevention strategies while supporting ongoing efforts to optimize early detection and treatment protocols in pediatric and young adult populations. A propensity score–matched real-world analysis of immune checkpoint inhibitors in melanoma patients with autoimmune disease. First Author: Shanawar Ali Waris, West Virginia University School of Medicine, Department of Internal Medicine, Morgantown, WV

Background: Immune checkpoint inhibitors (ICIs) are foundational in the treatment of melanoma. However, patients with pre-existing autoimmune diseases (AD) have been excluded from pivotal ICI clinical trials and remain underrepresented in real-world outcome data. We conducted a propensity score–matched cohort study to evaluate the impact of pre-existing AD on clinical outcomes among melanoma patients treated with ICIs. **Methods:** A retrospective cohort study was performed using the TriNetX Research Network, including adult patients with melanoma treated with ICIs. ICI regimens included PD-1, PD-L1, and CTLA-4–based therapies. Patients with documented pre-existing AD were compared with patients without AD using 1:1 propensity score matching (PSM) for demographics, baseline corticosteroid use, laboratory values, and comorbidities. Outcomes included overall survival (OS) at 1 and 3 years; infections, corticosteroid exposure, and non-steroidal immunosuppressant exposure within 90 days of ICI initiation; and immune-related adverse events (irAEs), analyzed as a composite outcome and stratified by organ system (cardiac, pulmonary, endocrine, and dermatologic) within 180 days. Outcomes were assessed using hazard ratios (HRs), risk ratios (RRs), and 95% confidence intervals (CIs). **Results:** A total of 21,236 patients met inclusion criteria, including 3,372 with pre-existing AD and 17,863 without. After PSM, 3,372 patients were included in each cohort. Patients with AD demonstrated improved overall survival at both 1 and 3 years compared with those without AD (1-year HR 0.70, 95% CI 0.62-0.79; 3-year HR 0.76, 95% CI 0.70-0.84). Patients with AD were at increased risk for composite irAEs (RR 1.66, 95% CI 1.47–1.87). Organ-specific analyses demonstrated higher risks of cardiac (RR 3.29, 95% CI 2.02–5.34), endocrine (RR 1.48, 95% CI 1.22–1.81), and dermatologic irAEs (RR 1.46, 95% CI 1.22–1.73) among patients with AD. Patients with AD also had higher rates of corticosteroid (RR 1.23, 95% CI 1.18–1.28) and non-steroidal immunosuppressant exposure (RR 4.96, 95% CI 3.73–6.61), as well as increased risk of infection (RR 1.28, 95% CI 1.13–1.44). **Conclusions:** In this large real-world analysis, melanoma patients with pre-existing AD treated with ICIs demonstrated improved overall survival despite increased irAEs, immunosuppressant exposure, and infection. These findings challenge excluding patients with AD from receiving ICI therapy and support inclusion in future clinical trials. Research Sponsor: None.

Outcome	AD [n= 3,372]	No-AD [n= 3,372]	HR/RR [95% CI]
1-year OS	85.2%	79.8%	0.70 [0.62-0.79]
3-year OS	71.1%	65.2%	0.76 [0.70-0.84]
Any irAE (180 days)	19.6%	11.8%	1.66 [1.47-1.87]
Cardiac irAE	2.1%	0.6%	3.29 [2.02-5.34]
Pulmonary irAE	0.8%	0.6%	1.34 [0.76-2.35]
Endocrine irAE	7.0%	4.7%	1.48 [1.22-1.81]
Dermatologic irAE	9.2%	6.3%	1.46 [1.22-1.73]
Infection (90 days)	15.9%	12.6%	1.28 [1.13-1.44]

First 1000 patients report of global practice patterns and clinical outcomes in the Collaborative Ocular Melanoma Natural History (OMNi) real-world database (NCT04588662). First Author: Anthony M. Joshua, Kinghorn Cancer Centre, St Vincent's Hospital, Sydney, NSW, Australia

Background: OMNi (NCT04588662) is an ambispective natural history database developed to provide contemporary real-world data of UM. The overall objectives of OMNi are to characterize regional/international UM management practice patterns and associated clinical outcomes in an effort to inform best practice recommendations and provide real world evidence. Here we present characteristics, demographics and practice patterns in the first 1000 patients enrolled globally. **Methods:** OMNi utilizes the Pulse Infoframe Healthie platform, enabling the longitudinal structured collection of data mapped to Observational Medical Outcomes Partnership. **Results:** Median age at diagnosis was 60 (15-94), with 47% of patients were female. Enrolment was from Australia (309), UK (93), USA (121) and Canada (477). When known, family history of UM was present in 2% (15/733). Recorded primary treatment modalities included plaque brachytherapy 44%, Enucleation 18%, Stereotactic radiotherapy 9%, Proton beam 3%, other radiotherapy 1%, other/ unknown 23%. Within the cohort, 30 patients were diagnosed with de novo metastatic disease and 343 patients had metastatic disease at any time. Of those, metastatic location was 166 extrahepatic and hepatic, 154 hepatic only, 18 extrahepatic only. HLA-A2 status was *0201 in 172/ 297(58%). Systemic treatments were administered to 176 patients first line– Tebentafusp (71 fist line); Ipi/Nivo (58); Ipi (7); PD-1 inh (15). The total number of patients receiving systemic treatments were Tebentafusp 108; Ipi/Nivo 90; Ipi 22; PD-1 (82). In total, 133 patients received liver directed therapy. At last follow up, where available 29% of patients had died from UM (179/611). Data to be presented will include genetic profiling summaries. **Conclusions:** The OMNi dataset can serve and aid in interpretation of clinical trial outcomes in the real-world, and accelerate the development of diagnostics and therapeutics to provide comparative data. Research Sponsor: None.

Clinical trial in progress: Phase I/II study of tebentafusp in combination with liver-directed therapies for the treatment of metastatic uveal melanoma. First Author: Rino S. Seedor, Sidney Kimmel Comprehensive Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: Uveal melanoma (UM) has a high rate of metastasis, most commonly to the liver. Tebentafusp-tebn (Tebe) is a first-in class immune-mobilizing monoclonal T cell receptor against cancer (ImmTAC) that gained regulatory approval after it showed significantly improved overall survival (OS) compared to single-agent investigator's choice in a pivotal randomized phase III trial. For patients with oligometastatic liver disease, liver-directed therapies (LDT) such as hepatic immunoembolization (IE) and chemoembolization (CE) have been used with success. LDT and Tebe may have therapeutic limitations when administered independently, but combining the two approaches is a potentially beneficial strategy that could provide both short-term hepatic disease control and long-term systemic disease control. **Methods:** This is an investigator-initiated, multicenter, open-label phase I/ randomized phase II trial to assess the safety and clinical efficacy of Tebe in combination with LDT in HLA-A*02:01 positive patients with metastatic UM [NCT06626516]. In Part 1 of the study, we will investigate the safety and efficacy of Tebe + IE in patients with low to moderate hepatic disease burden (M1a or M1b disease with largest tumor ≤ 5 cm, AND < 50% liver involvement). In Part 2, we will investigate the safety and efficacy of Tebe + CE in patients with bulky hepatic disease (M1b disease with largest tumor > 5cm, M1c disease, or >50% liver involvement). Patients must be 18 years or older, HLA-A*02:01 with metastatic UM in the liver. Extra-hepatic disease is allowed. Patients must be treatment naïve in the metastatic setting for Part 1 and must have no more than two prior lines of treatment (systemic or liver directed) for Part 2. Patients will receive Tebe at the approved step-up dosing regimen (20 mcg IV on C1D1, 30 mcg IV on C1D8, then 68 mcg on C1D15 and weekly thereafter). Patients in Part 1 will receive IE with GM-CSF 1500mcg every 4 weeks (starting at week 5) for the first four treatments and then 4 weeks as maintenance if clinically indicated. Part 1 has a phase I safety lead-in (Part 1A), followed by a phase II trial (Part 1B) where patients are randomized 2:1 to receive Tebe + IE or Tebe alone. Patients in Part 2 will receive CE with BCNU 300mg every 4 weeks for a total of 2 (unilobar disease) or 4 (bilobar disease) treatments followed by weekly Tebe. Eighteen patients, 52 patients, and 39 patients will be enrolled in Part 1A, Part 1B, and Part 2, respectively (total 109 patients). Primary endpoints for Part 1A is safety lead-in and 6-month progression-free survival (PFS), 6-month PFS for Part 1B, and 6-month PFS for Part 2. Secondary endpoints include overall response rate, liver-specific PFS, OS, and toxicity. Enrollment for Part 1A began in October 2025 at Thomas Jefferson University Hospital. Clinical trial information: NCT06626516. Research Sponsor: Immunocore, Ltd.

TPS9597 **Poster Session**

A randomized, controlled, multicenter, phase 3 study of RP1 (vusolimogene oderparepvec) combined with nivolumab vs physician's choice of therapy in patients with advanced melanoma that has progressed on anti–PD-1 and anti–CTLA-4 therapy (IGNYTE-3). First Author: Yana G. Najjar, UPMC Hillman Cancer Center, Pittsburgh, PA

Background: Melanoma is the fifth most common cancer, with over 100,000 new cases and 8000 related deaths projected in the US for 2025. First-line systemic treatment with immune checkpoint inhibitors (ICIs) improves the objective response rate (ORR) and extends progression-free survival (PFS) and overall survival (OS) for patients with advanced disease. Among available treatments, combination anti–PD-1 (nivolumab) + anti–CTLA-4 (ipilimumab) therapy is associated with the highest ORR and best PFS and OS. However, only around half of patients respond to treatment, and limited options exist for patients whose melanoma then progresses following anti–PD-(L)1 ± anti–CTLA-4. RP1 (vusolimogene oderparepvec) is a herpes simplex virus type 1–based oncolytic immunotherapy that expresses human granulocyte-macrophage colony-stimulating factor and a fusogenic glycoprotein (GALV-GP-R$^-$). IGNYTE-3 will evaluate the OS and clinical benefit of RP1 + nivolumab for patients with advanced cutaneous melanoma whose disease has progressed after anti–PD-1 and anti–CTLA-4 therapy (or who are ineligible for anti–CTLA-4 therapy) vs physician's choice. RP1 + nivolumab has demonstrated durable, clinically meaningful anti-tumor activity (ORR, 33.% per independent central review), with minimal toxicity (NCT03767348). Repetitive intralesional and intravisceral injections were well tolerated in advanced ICI-refractory melanoma. All patients had confirmed progression on prior anti–PD-1 therapy. **Methods:** IGNYTE-3 (NCT06264180) is a global, randomized, controlled, phase 3 trial. Key eligibility criteria include age ≥12 years, stage IIIB–IVM1a–M1d cutaneous melanoma, disease progression on ≥12 weeks of an anti–PD-1 and anti–CTLA-4 treatment (administered in combination or in sequence, with anti–PD-1 last), ≥1 measurable and injectable tumor, and adequate hematologic, hepatic, and renal function. Patients who are not candidates for anti–CTLA-4 therapy may enroll following progression on anti–PD-1 therapy alone. Patients with *BRAF* V600-mutant melanoma should have received anti–BRAF ± anti–MEK–targeted therapy prior to enrollment, where appropriate. Patients (N ≈ 400) will receive RP1 + nivolumab or physician's choice (nivolumab + relatlimab, anti–PD-1 monotherapy rechallenge [nivolumab or pembrolizumab], or single-agent chemotherapy [dacarbazine, temozolomide, or paclitaxel/albumin-bound paclitaxel]). The primary endpoint of the study is OS; the key secondary endpoints are PFS and ORR per RECIST 1.1. Clinical trial information: NCT06264180. Research Sponsor: Replimune, Inc.

TPS9598 **Poster Session**

A randomized, phase 2/3 clinical trial investigating RP2 plus nivolumab vs ipilimumab plus nivolumab in immune checkpoint inhibitor–naïve patients with metastatic uveal melanoma. First Author: Marlana M. Orloff, Thomas Jefferson University Hospital, Philadelphia, PA

Background: Uveal melanoma (UM) is the most common primary intraocular malignancy, accounting for ~90% of ocular melanomas and 5% of all melanomas. Half of patients with UM develop metastases, most commonly in the liver (~90%). The prognosis for patients with metastatic UM (mUM) is poor, with a median overall survival (OS) of ~1 year. Effective treatment options for mUM are limited, as it responds poorly to single-agent immune checkpoint inhibitors (ICIs; <10% response rate). Response rates are slightly higher with combination therapies (12%–18%), but these often have increased toxicity. Tebentafusp is FDA-approved for mUM based on survival benefit but is restricted to patients who are HLA-A*02:01 positive, and only ~10% of patients achieve an objective response. RP2 is a selectively replication-competent herpes simplex virus type 1–based oncolytic immunotherapy expressing GM-CSF, a fusogenic glycoprotein (GALV-GP-R$^-$), and an anti–CTLA-4 antibody-like molecule. Prior preliminary clinical data of intratumoral RP2 as monotherapy or in combination with nivolumab demonstrated a promising safety profile and anti-tumor activity with an overall response rate (ORR) of 29.4% and disease control rate of 58.8% in 17 patients with mUM, most of whom had received prior ICIs. This study will assess the efficacy and safety of RP2 + nivolumab vs ipilimumab + nivolumab in patients with ICI-naïve mUM. **Methods:** This is a multicenter, randomized, controlled, phase 2/3 study (NCT06581406; RP2-202). Key eligibility criteria include age ≥18 years and confirmed unresectable mUM with at least 1 lesion amenable to injection; up to 1 prior line of therapy in the metastatic setting is allowed. Patients with prior exposure to ICIs since the time of mUM diagnosis, >50% liver involvement, or previous selected liver-directed therapies are not eligible. Enrolled patients (N = ~280) will be randomized 1:1 to receive either RP2 + nivolumab or ipilimumab + nivolumab. In the RP2 + nivolumab arm, RP2 will be given intratumorally initially at 1×10^6 plaque-forming units (PFU)/mL, then every 2 weeks (Q2W) at 1×10^7 PFU/mL for 7 doses in combination with intravenous (IV) nivolumab (240 mg). In the ipilimumab + nivolumab arm, patients will receive IV ipilimumab (3 mg/kg) and IV nivolumab (1 mg/kg) Q3W for 4 doses. Patients in both arms may then receive IV nivolumab at 240 mg Q2W or 480 mg Q4W for up to 2 years. The co-primary endpoints are OS and progression-free survival by independent central review using RECIST 1.1. Secondary endpoints are ORR, duration of response, disease control rate, clinical benefit rate, duration of clinical benefit, and safety, including incidence of treatment-emergent adverse events (AEs), serious AEs, and immune-mediated AEs. Clinical trial information: NCT06581406. Research Sponsor: Replimune, Inc.

TPS9599 **Poster Session**

Phase 2 study of metronomic cyclophosphamide with pembrolizumab in checkpoint inhibitor–refractory melanoma. First Author: Poorva Vaidya, Chao Family Comprehensive Cancer Center, University of California, Irvine, Orange, CA

Background: Immune checkpoint inhibitors (ICI) are standard of care treatment in advanced, metastatic melanoma as well as adjuvant treatment of resected high-risk disease. However, approximately 50% of patients do not respond to primary anti-programmed death ligand-1 (anti-PD1) treatment (primary resistance) or progress after initial response (secondary resistance). Second line treatments in this setting include addition of the anti-cytotoxic T-lymphocyte associated protein 4 (anti-CTLA-4) drug ipilimumab or targeted treatment in BRAF mutant melanomas. However, CTLA-4 blockade can confer significant immune-mediated toxicity in a low performance status (PS) population, and not all patients are eligible for BRAF/MEK inhibition. There remains an unmet clinical need to optimize ICI efficacy and overcome resistance. It is hypothesized that suppressive regulatory T-cells (T_{reg})may inhibit the anti-tumor effect of ICI. Cyclophosphamide (CTX) is an alkylating anticancer agent. Prior studies in patients with recurrent ovarian cancer and soft tissue sarcoma have demonstrated that the combination of anti-PD1 agents with metronomic, or low dose, frequent, CTX was effective with no new safety signals. **Methods:** This phase 2, single-center, single-arm study explores the efficacy of adding oral metronomic CTX to intravenous pembrolizumab in patients with ICI-refractory locally advanced or metastatic melanoma. Key inclusion criteria are measurable disease by RECIST v.1.1 and receipt of investigational treatment within 9 weeks of last ICI treatment. Patients may have previously received single agent pembrolizumab or dual ICI with anti-LAG3 and anti-PD1 (relatlimab/nivolumab). Key exclusion criteria are symptomatic, untreated brain metastases, BRAF V600 mutation without prior receipt of BRAF/MEK inhibition, or prior grade 3 or greater immune-related adverse event (irAE). The primary endpoint is objective response rate (RR) as defined by complete response (CR) + partial response (PR) by RECIST v 1.1. A Simon's minimax two-stage design will be used, with the null hypothesis that the true response rate is .05 and the alternative hypothesis that true response rate is 0.3. In Stage I, a total number of 7 patients will be accrued. If there are 0 responses among 7 patients, the study will be stopped; otherwise, an additional 7 patients will be accrued to Stage II. 3 of 14 planned patients have been enrolled. This trial was approved by the UC Irvine Institutional Review Board; approval number is 6168. Trial registration NCT06771544. Clinical trial information: NCT06771544. Research Sponsor: University of California, Irvine; University of California, Irvine; UCI Melanoma Program.

TPS9600 **Poster Session**

Phase 1b/2 trial of melphalan-percutaneous hepatic perfusion (PHP) therapy and nivolumab/relatlimab in patients with metastatic melanoma and liver metastasis. First Author: Vincent T. Ma, University of Wisconsin Madison, Madison, WI

Background: Despite advances with immune checkpoint inhibitors (ICIs), patients with metastatic melanoma and liver metastases (LM) experience poorer outcomes. In the CheckMate-067 subanalysis, patients with LM treated with nivolumab/ipilimumab had shorter median PFS (4.4 vs 18.1 months) and OS (28.2 months vs not reached) than those without LM, confirming its negative prognostic role. Nivolumab/ipilimumab and nivolumab/relatlimab show comparable efficacy; however, the latter is increasingly used for its improved safety profile (grade ≥3 adverse events: 59% vs 21%). Melphalan-PHP (Hepzato), a liver-directed therapy delivering high-dose melphalan through a closed filtration circuit, concentrates treatment in the liver while minimizing systemic exposure. Research by Yu et al. demonstrated that LM reduces peripheral and tumoral CD8+ T cells, creating an immune desert, while combining liver-directed therapy with ICIs can reactivate systemic immune responses. Based on these insights and the CHOPIN trial's safety data, the proposed Phase 1b/2 study will assess the safety, tolerability, and preliminary efficacy of melphalan-PHP plus nivolumab/relatlimab for first line treatment of metastatic non-uveal melanoma patients with LM. **Methods:** Phase 1b/2, single-center, single-arm study will use a Simon two-stage (5+10) design (n=15). Patients will receive nivolumab/relatlimab on Day 1 of each 28-day cycle for up to 2 years and receive melphalan-PHP on Day 15 of Cycle 1 and Cycle 3. Eligible participants must have histologically or cytologically confirmed metastatic melanoma involving the liver and be systemic treatment-naïve in the metastatic setting. Prior adjuvant ICI is permitted provided it was completed >6 months prior to study enrollment. Key exclusions include metastatic uveal melanoma, prior treatment with melphalan-PHP or ICI combinations, uncontrolled or symptomatic brain metastases, prior grade 3+ adverse events from ICI requiring treatment discontinuation, ongoing immunosuppressive therapy, contraindications to anesthesia, and significant cardiac, hepatic (Child-Pugh B/C), or pulmonary disease. The co-primary objectives/endpoints in stage 1 are to assess the safety and tolerability as measured by 2 or less DLTs (any treatment-related grade 4+ non-hematologic event lasting >3 days); and preliminary efficacy as measured by 2 or more objective responses in hepatic and non-hepatic lesions. Secondary objectives include: disease control rate (DCR), progression-free survival (PFS), overall survival (OS), duration of response (DOR), and any tumor reduction. Open for enrollment in January 2026. Clinical trial registry number: NCT07281924. Clinical trial information: NCT07281924. Research Sponsor: Delcath.

TPS9601 **Poster Session**

Adaptive phase 2/3 study of EIK1001, a TLR7/8 dual agonist, in combination with pembrolizumab, as first-line therapy in participants with advanced melanoma (TeLuRide-006). First Author: Bernardo Leon Rapoport, The Clinical and Translational Research Unit of the Medical Oncology Centre of Rosebank, Saxonwold, Johannesburg; Department of Immunology, Faculty of Health Sciences, University of Pretoria, Prinshof, South Africa

Background: Immune checkpoint inhibitors (ICIs), including anti-PD-1 antibodies, reverse tumor induced immune suppression and promote effective anti-tumor T-cell responses. They have drastically improved outcome in advanced melanoma therapy, yielding durable improvements in progression-free survival (PFS) and overall survival (OS). Although adding anti-CTLA-4 or anti-LAG-3 enhances efficacy beyond anti-PD-1 alone, these approaches do not directly target dominant myeloid-mediated resistance mechanisms within the tumor microenvironment, and new agents targeting this axis are needed. EIK1001, a TLR7/8 dual-agonist, activates myeloid and plasmacytoid dendritic cells to stimulate innate inflammation and adaptive immunity. Across multiple studies, EIK1001 has been well tolerated and has demonstrated clinical activity both as monotherapy and in combination with ICIs. **Methods:** TeLuRide-006 (NCT#06697301) is a global, multicenter, randomized, double-blind, adaptive Phase 2/3 trial of EIK1001 or placebo, in combination with pembrolizumab (pembro), as first-line therapy for participants (pts) with advanced cutaneous melanoma. Approximately 740 pts will be randomized, including a dose-optimization (DO) stage in which pts are randomized 1:1:1 to two EIK1001 dose levels or placebo, each administered with pembro, followed by Phase 2/3 expansion evaluating the selected EIK1001 dose versus placebo, with pembro. Interim analyses will guide progression from DO to Phase 2 and subsequently to Phase 3. EIK1001 or placebo is administered IV QW until the end of Week 27 then Q3W; while pembro is administered IV Q3W. Pts are stratified by prior anti-PD-1 adjuvant therapy, LDH level, and BRAF mutational status. Key eligibility criteria include patients $\geq$12 years (with country-specific variations), life expectancy $\geq$3 months, unresectable Stage III or Stage IV melanoma, known BRAF V600 status, at least one RECIST v1.1–measurable lesion, and no prior or current pneumonitis/interstitial lung disease. Primary objectives are to assess the efficacy and safety of two EIK1001 doses with pembro in DO, and to compare PFS (RECIST v1.1 by blinded independent central review [BICR]) and OS between the selected EIK1001 dose and placebo in combination with pembro. Secondary objectives include safety and tolerability of either EIK1001 dose with pembro, objective response rate and duration of response per RECIST v1.1 by BICR. Exploratory objectives include time to response, EIK1001 exposure-response relationships, and health-related quality of life. This study enrolled (randomized) its first participant on 5/21/2025 and is activated at 91 sites in 22 countries at the time of abstract submission. Research Sponsor: None.

TPS9602 **Poster Session**

A phase I/II clinical study of DOC1021 (dubodencel) dendritic cell immunotherapy for refractory melanoma. First Author: Alexandra Haugh, Massachusetts General Hospital Cancer Center, Boston, MA

Background: DOC1021 is an autologous dendritic cell (DC)-based immunotherapy. Loading of DC in tandem with both patient autologous tumor protein and amplified mRNA induces p38MAPK and mTORC1 signaling cascades that initiate cDC1-like skewing of monocyte-derived DC, generating downstream development of highly cytolytic memory effectors. This approach targets the multitude of antigens in a patient's own tumor, does not require myeloablative chemotherapy and has demonstrated a favorable safety profile in Phase I glioblastoma (NCT04552886) and pancreatic cancer trials (NCT04157127). Pre-clinical studies in a variety of animal models, including melanoma (subcutaneous B16F0-OVA tumors), have also shown improved tumor responses and evidence of antigen-specific immunity. While immune checkpoint inhibitors (ICI) have improved clinical outcomes in melanoma, many patients ultimately develop resistance, resulting in refractory disease. We hypothesize that DOC1021 may overcome ICI resistance in refractory melanoma through the generation of durable T cell responses with novel specificities, promoting long-term anti-tumor T cell surveillance and improved survival. **Methods:** This is a prospective, multi-center, open-label Phase I/II study in patients with refractory cutaneous melanoma, unresectable or metastatic, with progression following $\geq$1 prior systemic therapies including anti-PD-1. The study consists of two components: an initial Phase I study to confirm safety/tolerability of DOC1021 in refractory melanoma, and subsequently, a single-arm Phase II cohort to assess efficacy. Up to 12 patients will be enrolled in Phase I, and up to 35 evaluable patients will be enrolled in Phase II using a Simon's optimal two-stage design. DOC1021 will be prepared from mobilized peripheral blood mononuclear cells (PBMC), loaded with autologous tumor lysate and amplified tumor mRNA. All patients will receive 2 courses of DOC1021 (12×10^6 cells per administration) 2 weeks apart via perinodal injections near active disease sites, plus peg-interferon (pIFN) adjuvant on the day of each DOC1021 administration and 1 week after for 4 total doses. An optional DOC1021 booster course may also be given approximately 6 months after the first DOC1021 administration. The primary endpoint of the Phase I study is dose-limiting toxicities of DOC1021, while the primary endpoint of the Phase II study is the overall response rate per RECIST 1.1 criteria. This study will also evaluate survival, tumor responses, changes in circulating tumor DNA, as well as further investigate DOC1021's mechanism of action through biomarker-rich analyses of serial tumor biopsies and blood sampling. The first patient to enroll in the Phase I safety study is planned for early 2026. Clinical trial information: NCT07288112. Research Sponsor: Diakonos Oncology; Cancer Prevention and Research Institute of Texas (CPRIT).

TPS9603 **Poster Session**

Phase I/IIa dose finding study of triplet regimen of relatlimab (RELA) ipilimumab (IPI), and nivolumab (NIVO) in first-line therapy of metastatic melanoma (MM) (TRINITY). First Author: Elizabeth M. Burton, Department of Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Approved immune checkpoint blockade (ICB) agents for the treatment (tx) advanced, unresectable metastatic melanoma (MM) include NIVO (anti-PD1) alone or in combination with IPI (anti-CTLA-4) or RELA (anti-LAG3) and have transformed outcomes for patients with this disease. While doublet combinations induce higher rates of durable disease control and modestly improved survival vs single agent, higher doses of IPI induce higher objective response rates (ORR) also increase grade $\geq$3 immune-related adverse events. Notably, there is no established dose-response relationship for NIVO or RELA. IPI has a demonstrated role in expanding the T-cell receptor (TCR) repertoire, modulating suppressive T cell populations. NIVO+RELA regulates exhaustion of activated T cells, improving effector function. Together, these suggest potential synergy with triplet ICB. Results reported in RELATIVITY-048 (NIVO 480 mg Q4W + RELA 160 mg Q4W + IPI 1 mg/kg Q8W) demonstrated impressive efficacy (ORR 59%) and seemingly improved progression free and overall survival (PFS, OS) over previously reported doublet tx. The RELATIVITY-048 study design did not include dose escalation (DE) of IPI. Our team seeks to identify the optimal dose and schedule if IPI to combine with NIVO+RELA, identify the recommended phase II dose (RP2D) for this triplet ICB treatment and, ultimately, seeking to maximize the clinical benefit while maintaining a toxicity profile comparable to approved doublet regimens. **Methods:** In this single center, investigator initiated, PhI/IIa study, our team is evaluating triplet ICB (NCT06683755) in untreated, unresectable MM pts. Pts will receive NIVO 480mg + RELA 160mg IV Q4W (FDA approved dose). IPI DE will begin at 0.5mg/kg Q4W, escalating to 2mg/kg Q4W x4 induction doses. Pts will receive maintenance tx with NIVO+RELA Q4W at the approved dose. The maximum tolerated dose and the RP2D will be determined using a Bayesian optimal interval design, accruing 12-18 pts in DE. An additional 12-18 pts will be enrolled at RP2D to determine the ORR (primary objective) by RECIST 1.1. Secondary objectives include PFS, OS, and correlative analysis. Non IPI containing prior adjuvant or neoadjuvant tx is allowed if the last dose has been $>$6 months. Pts with asymptomatic brain metastasis on $\leq$10mg corticosteroids are allowed. Safely biopsiable lesions are required for pts enrolled in the PhII portion. By optimizing the dose and schedule of IPI in combination with NIVO+RELA, we seek to maximize clinical benefit while maintaining a toxicity profile comparable to approved regimens. This study is currently accruing at MD Anderson Cancer Center. Clinical trial information: NCT06683755. Research Sponsor: BMS.

TPS9604 **Poster Session**

TrioMBM: A multicenter, phase II trial of relatlimab, nivolumab, and ipilimumab in patients with asymptomatic and symptomatic melanoma brain metastases. First Author: Allison Betof, Stanford University School of Medicine, Stanford, CA

Background: Melanoma brain metastases (MBM) are a leading cause of morbidity and mortality for patients (pts) with advanced melanoma. Modern systemic therapies including immune checkpoint blockade (ICB) are insufficient at controlling MBM, particularly in patients with who are symptomatic and/or require corticosteroids. The CheckMate 204 study established nivolumab (NIVO) 1 mg/kg + ipilimumab (IPI) 3mg/kg followed by maintenance NIVO as the standard treatment (tx) for pts with MBM based on intracranial IC) objective response rate (ORR) of 55% and 6-month progression-free survival (PFS) of 64% in the asymptomatic cohort (*Tawbi et al. NEJM 2018*). In symptomatic pts, intracranial benefit rate (iCBR) was only 22% and median PFS was 1.2 mos (*Tawbi et al. Neuro Oncol 2021*). Triplet tx with the addition of LAG-3 inhibition with relatlimab (RELA) is now being explored as a mechanistically-driven means to improve efficacy of ICB. Arm 2B of RELATIVITY-048 (NIVO 480 mg Q4W + RELA 160 mg Q4W + IPI 1 mg/kg Q8W) reported promising efficacy (ORR 59%, 3y PFS 52%) and 2 of 3 (67%) pts with MBM had confirmed responses (*Ascierto et al. ASCO 2024*) further justifying the need to explore this combination in this population. We hypothesize that triplet ICB will be more effective than NIVO+IPI for the tx of symptomatic and asymptomatic MBM. **Methods:** In this multicenter, investigator initiated, phase II study evaluating triplet ICB (NCT06712927) pts with MBM will be assigned to one of two cohorts: Cohort A (asymptomatic, n=40) and Cohort B (symptomatic, n=20) defined as having symptoms attributable to brain metastases and/or requiring steroids $>$10 mg prednisone/day or equivalent. All pts will receive NIVO 480mg + RELA 160mg IV Q4W (FDA approved dose) plus IPI 1mg/kg IV Q8W. Pts must have $\geq$1 untreated intracranial lesion (5-40mm) and no prior ICB for unresectable stage III/IV melanoma ($>$6 mo since neoadjuvant or adjuvant ICB). Primary endpoint is iCBR (CR+PR+SD $\geq$6 mo) determined by modified RECIST 1.1; secondary endpoints include safety, ORR, duration of response, and PFS. Extensive correlative analyses of peripheral blood mononuclear cells, plasma, tumors, and cerebrospinal fluid are planned. The study is currently enrolling at Stanford Cancer Center with multisite expansion underway. Clinical trial information: NCT06712927. Research Sponsor: Bristol-Myers Squibb; National Cancer Institute; P30CA124435.

TPS9605 **Poster Session**

Phase 2 sequential treatment of percutaneous hepatic perfusion with melphalan/hepatic delivery system followed by tebentafusp in the treatment of metastatic uveal melanoma. First Author: Jonathan S. Zager, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Metastatic uveal melanoma (mUM) typically has a poor prognosis with limited treatment options. Tebentafusp (TEBE) is the only approved systemic agent for HLA-A*02:01 positive mUM, and percutaneous hepatic perfusion (PHP) is FDA approved for patients with mUM in the liver (solely or predominantly). Combining PHP with nivolumab plus ipilimumab in the randomized phase 2 CHOPIN trial significantly improved overall response (ORR), progression-free survival (PFS) and overall survival (OS) compared to PHP alone, but with significantly higher grade 3 or greater adverse events. In the phase 3 TEBE clinical trial there was a modest ORR of 11%, and improved OS compared to investigator choice therapy. We hypothesize that PHP causes antigen release and changes in the hepatic tumor microenvironment that may enhance response to TEBE. In this investigator-initiated trial, we aim to explore the combination of sequential regional and systemic therapy in HLA-A*02:01 positive mUM patients. **Methods:** This is a single institution phase 2 clinical trial combining PHP using the melphalan hepatic delivery system for 2 cycles followed sequentially by intravenous TEBE at approved dosage for up to 1 year of therapy. For patients with unequivocal progression on TEBE, up to 4 additional cycles of PHP will be considered if they continue to meet standard eligibility for PHP. The primary objective is to assess the PFS in uveal melanoma patients who have isolated or liver dominant metastases with landmark analyses at 6 months, 12 months and 24 months. Secondary objectives include (1) toxicity, (2) objective response and duration of response, (3) hepatic and extra-hepatic PFS, (4) OS, (5) biomarker discovery, RNA sequencing and spatial immunofluorescence analysis of the tumor microenvironment through core biopsies performed pre-PHP, after PHP number 2, and post-TEBE treatment. Blood samples for immune panel analysis will be collected at these timepoints. Response assessments are undertaken with standard cross-sectional imaging every 12 weeks for 36 months. Planned accrual is 18 patients with an interim futility analysis after 10 patients are treated to assess the 6-month PFS for the cohort. Primary analysis will be performed using the Kaplan-Meier method. Salient eligibility criteria include: (1) age $\geq$18 years, (2) histologically confirmed metastatic UM, HLA-A*02:01 positive, (3) measurable disease per RECIST v1.1, (4) ECOG performance status of $\leq$1, (5) adequate marrow, renal and hepatic function; (6) no more than 50% of liver involvement by tumor. Limited extrahepatic disease is allowed. This study opened for enrollment in November 2025, and two patients have been treated to date (NCT07276386). This study is supported by Delcath Systems, Inc. Clinical trial information: NCT07276386. Research Sponsor: Delcath Systems.

TPS9606 **Poster Session**

SILVER (supplementing tebentafusp with subcutaneous IL-2 to verifiably eradicate radiological progression): A phase 1/2 trial of IL-2 with tebentafusp upon first radiological progression on first-line tebentafusp alone. First Author: Anthony M. Joshua, Kinghorn Cancer Centre, St Vincent's Hospital, Sydney, NSW, Australia

Background: Metastatic uveal melanoma (mUM) remains a disease with a profound unmet clinical need. Tebentafusp, a bispecific T-cell receptor–anti-CD3 ImmTAC targeting gp100 is the first systemic therapy to demonstrate a reproducible overall survival benefit and is now the standard of care in eligible patients. Despite this advance, most patients ultimately develop radiological progression on tebentafusp, highlighting the need for rational combination strategies that can augment or restore antitumour immune activity. Interleukin-2 (IL-2) has long been recognised as a potent T-cell growth and activation factor. Pre-clinical data demonstrate that IL-2 enhances tebentafusp-mediated tumour cell killing by expanding and priming effector T-cell populations. These effects are mechanistically linked to increased cytotoxic function and improved immune synapse formation (Guc et al., 2025). Importantly, low-dose IL-2 administered subcutaneously has been shown in prior clinical studies to achieve biologically relevant serum concentrations with a substantially improved safety profile compared with historical high-dose intravenous regimens. Collectively, these data provide a strong biological and clinical rationale for combining tebentafusp with low-dose subcutaneous IL-2 in patients with mUM progressing on tebentafusp monotherapy. **Methods:** SILVER is an investigator-initiated, single-arm phase Ib study evaluating the safety, tolerability and preliminary efficacy of tebentafusp in combination with low-dose subcutaneous IL-2 in HLA-A*02:01–positive patients with metastatic or unresectable uveal melanoma who have RECIST-defined progression on tebentafusp alone. Patients receive IL-2 at 125,000 IU/kg subcutaneously, administered for three consecutive days prior to the initial tebentafusp dose, and then weekly 24 hours before each subsequent tebentafusp infusion. Tebentafusp is administered intravenously with step-up dosing in cycle 1, followed by standard weekly dosing thereafter. The primary endpoint is best overall response by iRECIST. Secondary endpoints include RECIST 1.1 response rate, clinical benefit rate, progression-free survival, overall survival, safety and tolerability (CTCAE v5.0), and quality of life. Extensive translational endpoints include serial diffusion-weighted MRI, ctDNA kinetics, and deep immune profiling from blood and tumour biopsies. Early treatment cycles incorporate inpatient monitoring to manage cytokine-mediated toxicities. **Conclusion:** By integrating robust pre-clinical rationale, an established and pragmatic IL-2 dosing strategy, and comprehensive translational analyses, this study aims to enhance tebentafusp activity and improving outcomes for patients with progressive mUM. Clinical trial information: NCT07063875. Research Sponsor: Immunocore; Department of Defence; ME230190 HT9425-24-1-0996.

TPS9607 **Poster Session**

Clinical trial in progress: Phase II trial of neoadjuvant tebentafusp in patients with locally advanced primary uveal melanoma. First Author: Rino S. Seedor, Sidney Kimmel Comprehensive Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background: Uveal melanoma (UM) is the most common intraocular malignant tumor in adults. Primary UM are effectively treated by plaque radiotherapy or enucleation; however, up to 50% of UM patients ultimately succumb to advanced disease. Tebentafusp-tebn is a bispecific gp100 peptide human leukocyte antigen (HLA)-directed cluster of differentiation 3 (CD3) T-cell engager that became the first FDA approved treatment for unresectable or metastatic UM. Among the metastatic UM patients who received tebentafusp on clinical trial (IMCgp100-01 (n=19), IMCgp100-102 (n=146), and IMCgp100-202 (n=245)), 12 patients had recurrent orbital tumors. All orbital lesions were stable or had achieved shrinkage with tebentafusp. The best percentage changes from baseline were reported as -3 to -40% reduction in intra-ocular target lesions. All intraocular non-target lesions were stable or achieved a complete response after tebentafusp treatments. These preliminary data indicate that tebentafusp may have potential for treating surgically unresectable primary UM. **Methods:** This is an investigator-initiated, prospective, single arm phase II trial evaluating neoadjuvant tebentafusp in patients with locally advanced primary UM [NCT06414590]. Patients must be 18 years or older, HLA-A*02:01 with a primary UM with T3 or T4 category tumor size. Patients cannot have a symptomatic UM that requires immediate ophthalmological intervention such as enucleation. Patients will be treated with up to 8 weeks of neoadjuvant tebentafusp, followed by radioactive plaque or enucleation. Tebentafusp will be administered as follows: 20mcg on Day 1, 30mcg on Day 8, 68 mcg on Day 15, and weekly doses of 68 mcg thereafter. The first three treatments will require inpatient hospitalization for overnight observation. The primary endpoint of the study is regression (defined as $\geq$ 20% reduction in tumor volume) of primary UM after tebentafusp treatment in 20% of treated patients. Secondary endpoints include toxicity assessment and ctDNA analysis in both blood and aqueous humor. Exploratory endpoints include changes to visual acuity, radiation dose to the fovea, and treatment (enucleation to plaque brachytherapy). The efficacy of this combination treatment will be assessed using the Simon's two stage design. In stage I, a total number of 8 patients are accrued and if there are 0 responses among these 8 patients, further enrollment of patients may be stopped. Otherwise, an additional 11 patients will be accrued in stage II, resulting in a total sample size of 19 patients. Enrollment began in September 2025 at Thomas Jefferson University Hospital, in conjunction with Wills Eye Hospital. Clinical trial information: NCT06414590. Research Sponsor: Immunocore, Ltd.

TPS9608 **Poster Session**

Neoadjuvant darovasertib in uveal melanoma patients undergoing primary local therapy (OptimUM-10): Phase 3 trial. First Author: J. William Harbour, UT Southwestern Medical Center, Dallas, TX

Background: Uveal melanoma (UM) is the most common intraocular malignancy and has high risk of metastatic progression and poor long-term survival. Standard treatment of the primary tumor includes enucleation (eye-removal), and radiation therapy including plaque brachytherapy (PB) and proton beam therapy, which can result in vision loss or removal of the eye. No approved neoadjuvant therapies exist that shrink the tumor or improve visual outcomes. Almost all UM tumors harbor *GNAQ/GNA11* initiating mutations with downstream constitutive activation of protein kinase C (PKC). Darovasertib, a first-in-class oral PKC inhibitor tested in study OptimUM-09, has demonstrated the ability to reduce UM tumor size resulting in enucleation sparing in patients with large tumors, and radiation reduction in patients with medium sized tumors requiring PB. In addition, visual improvements have been observed not only during neoadjuvant therapy but also in the predicted risk of legal blindness post PB using a vision prognostication tool. **Methods:** OptimUM-10 is an ongoing phase 3, randomized, multicenter, open-label trial enrolling patients with primary non-metastatic UM. Eligible patients must have high metastatic risk (class 2 gene-expression profile, monosomy 3, or AJCC stage 3). Additionally, for the PB cohort, moderate to high risk of vision loss ($>$ 30Gy predicted radiation dose to key visual structures) is required for eligibility. Major exclusion criteria include metastatic disease or extraocular tumor extension, prior UM primary treatment, attributes necessitating immediate enucleation, and relevant ocular comorbidities. The trial has two cohorts: Cohort 1 (n=330) includes patients with medium UM tumors where PB is the standard treatment. Cohort 2 (n=120) includes patients with large UM tumors where enucleation is the standard treatment. In each cohort, eligible patients are randomized 2:1 to receive neoadjuvant darovasertib (300 mg twice daily for up to six 28-day cycles) or standard-of-care treatment with PB (cohort 1) or enucleation (cohort 2). The primary endpoint for cohort 1 is the proportion of patients with loss of Early Treatment Diabetic Retinopathy Study Best-Corrected Visual Acuity of $\geq$15 letters (%VL15) from randomization, while in cohort 2 it is eye preservation rate. Across cohorts, the key secondary objective is to evaluate response rate with neoadjuvant darovasertib. Additional secondary endpoints include event-free survival and safety, as assessed by treatment-emergent adverse events and serious adverse events. Enrollment is ongoing, and results will determine whether OptimUM-10 may establish darovasertib prior to definitive PB as the first neoadjuvant treatment for primary UM to meaningfully reduce tumor burden and expand vision- and eye-preserving treatment options for patients. Clinical trial information: NCT07015190. Research Sponsor: IDEAYA Biosciences, South San Francisco, CA USA.

TPS9609 Poster Session

A phase 3, international, multicenter, randomized, controlled trial of selective index lymph node resection versus therapeutic lymph node dissection after neoadjuvant immunotherapy for stage IIIB-D melanoma (MSLT-3/S2601/EORTC2519). First Author: Maria Gonzalez, Melanoma Institute Australia, Sydney, NSW, Australia

Background: Neoadjuvant immunotherapy (NAT) with immune checkpoint inhibitors (ICI) is a standard therapy for resectable stage III melanoma, with randomized trials demonstrating superior outcomes compared to adjuvant therapy alone. The phase 2 SWOG-1801 trial showed 72% EFS at 2 yrs for NAT & 49% for adjuvant PEMBRO (P=0.004), while the phase 3 NADINA trial confirmed superiority of NAT IPI/NIVO over adjuvant NIVO (2-year RFS 83.7% vs 57.2%, HR 0.32). Pathological response, particularly major pathological response (MPR; ≤10% viable tumor), strongly correlates with improved outcomes, with the International Neoadjuvant Melanoma Consortium (INMC) pooled analysis (N=610 ICI patients) demonstrating 3-yr RFS of 93% for MPR patients (pts) vs 41% for those with no pathological response. The PRADO trial demonstrated that selective index lymph node (ILN) resection (RES) can safely de-escalate surgery in MPR pts, with only 4/60 (6.7%) MPR pts recurring after median follow-up of 28.1 months, all locoregionally. ILN RES significantly reduced surgical morbidity & improved quality of life compared to therapeutic lymph node dissection (TLND). However, PRADO was a single-arm proof-of-concept study. An international survey of 117 melanoma experts showed 71% believe a phase 3 randomized controlled trial is needed to change practice. The MSLT-3 trial will definitively establish whether ILN RES is non-inferior to standard TLND for MPR pts. **Methods:** This phase 3, international, multicenter, randomized, non-inferiority trial will enroll approximately 1,574 pts with resectable stage IIIB-D cutaneous melanoma to identify 496 with MPR following NAT. Eligible pts must have cytologically/histologically confirmed resectable stage IIIB-D melanoma with at least one macroscopic lymph node in groin, axilla or neck basins. All pts are randomized 1:1 to ILN RES or TLND, stratified by continent/region, AJCC stage, & NAT regimen. Prior to NAT, all pts undergo radiological placement of a marker in the largest metastatic lymph node. Pts receive NAT per institutional standard of care (minimum one PD-(L)-1 checkpoint inhibitor, maximum 6 weeks duration) followed by surgery at weeks 6-9 according to randomized arm. Pathological response is assessed per INMC criteria. Pts with MPR in the ILN arm undergo surveillance only; non-MPR pts in the ILN arm proceed to TLND within 3 weeks. Primary endpoint is 2-year recurrence-free survival in MPR pts (non-inferiority margin -5%). Secondary endpoints include escalation to TLND for isolated nodal recurrence, salvage therapy rates, distant metastasis-free survival, event-free survival, overall survival, surgery-related AEs, quality of life (QLQ-C30, EQ-5D-5L, FACT-M), concordance of imaging/ctDNA with pathology & health economics. Clinical trial information: NCT07049276. Research Sponsor: Australian Commonwealth Government.

TPS9610 Poster Session

NeoIRENIE: A phase 2 randomized trial of intensified neoadjuvant therapy for melanoma patients with multi-omic biomarker or clinically predicted poor response to standard immune checkpoint inhibitor (ICI) therapy. First Author: Maria Gonzalez, Melanoma Institute Australia, Sydney, NSW, Australia

Background: Neoadjuvant immunotherapy (NAT) with immune checkpoint inhibitors (ICI) has emerged as superior treatment for stage III melanoma, demonstrating improved outcomes compared to adjuvant therapy. The SWOG-1801 trial showed 23% EFS benefit at 2 years for NAT versus adjuvant PEMBRO (72% vs 49%, P=0.004), while the NADINA trial confirmed superiority of NAT IPI/NIVO over adjuvant NIVO (2-year RFS 83.7% vs 57.2%, HR 0.32). Pathological response, particularly major pathological response (MPR; ≤10% viable tumor), strongly correlates with improved outcomes, with the International Neoadjuvant Melanoma Consortium pooled analysis (N=610 ICI patients) demonstrating 3-year RFS of 93% for MPR patients versus 41% for those with no pathological response. However, standard NAT with IPI (1mg/kg) and NIVO (3mg/kg) achieves MPR in only ~60% of patients. Multi-omic biomarkers can predict poor response to anti-PD-1 therapy, identifying patients who may benefit from intensified ICI therapy. The NeoIRENIE trial evaluates whether intensified ICI regimens improve pathological response in poor prognosis patients identified by biomarker prediction, treatment failure, or mucosal histology. **Methods:** Phase 2, non-comparative, multicenter, randomized trial with 3 cohorts (N=493, Table 1). All pts undergo therapeutic lymph node dissection/completion surgery at week 6 with path response evaluation per INMC criteria. Cohorts 1a, 2 and 3 pts without MPR receive adjuvant NIVO 480mg Q4W for 11 doses. CT, MRI brain and FDG PET/CT performed at baseline, pre-surgery and during 10-year follow-up. Tumor, blood and stool samples collected at baseline, wk 3, surgery and recurrence. Primary endpoint: path response rate in each INMC response category. Secondary endpoints: event-free survival, RECIST response rate, metabolic response rate, overall survival, safety/tolerability, surgical outcomes and quality of life. Exploratory endpoints: biomarker analyses and validation of multi-omic predictive model. Clinical trial information: NCT06999980. Research Sponsor: None.

Cohort	N	Resectable Melanoma Patient Population	*Arms (Randomization)
1a	168	Stage IIIB/C/D cutaneous; biomarker-predicted poor responders; treatment-naive	A-D (1:1:1:1)
1b	154	Stage IIIB/C/D cutaneous; biomarker-predicted high responders; treatment-naive	E-F (1:1)
2	111	Stage IIIB/C/D cutaneous; recurrence within 6 months of adjuvant or NAT ICI therapy	A-C (1:1:1)
3	60	Any stage mucosal melanoma; treatment-naïve	A-B (1:1)

*Arms:
A=IPI 3mg/kg + NIVO 1mg/kg Q3W x2.
B=NIVO 480mg + RELA 160mg + IPI 1mg/kg Q4W x2.
C=NIVO 480mg + RELA 160mg Q4W x2.
D=IPI 1mg/kg + NIVO 3mg/kg Q3W x2.
E=IPI 1mg/kg + NIVO 3mg/kg Q3W x2.
F=PEMBRO 200mg Q3W x2.

TPS9611 Poster Session

EA6232: A phase II double-blind trial of sulforaphane for therapeutic prevention of melanoma in patients with multiple atypical nevi and a prior history of melanoma. First Author: John M. Kirkwood, UPMC Hillman Cancer Center, Pittsburgh, PA

Background: A significant risk factor for melanoma is presence of atypical/dysplastic nevi (A/DN), and evidence suggests a 10-fold increased risk of new primary melanoma with A/DN.[1] Patients with prior melanoma and multiple A/DN are thus reasonable targets for therapeutic prevention due to high risk of additional melanoma. Currently, no preventative systemic agent for melanoma is approved. Sulforaphane, an isothiocyanate of cruciferous vegetables, demonstrates therapeutic prevention potential in multiple clinical trials.[2,3] Topical sulforaphane mitigates effects of UV radiation, a primary driver of melanoma development, in mouse and human skin.[4] The proposed mechanism involves alterations of transcription factor Nrf2, an antioxidant modulator, and IL-6/STAT-3 pathways in A/DN and melanoma.[5,6,7] Our team conducted a phase I trial of oral sulforaphane for 28 days in 17 patients with prior melanoma and ≥ 2 A/DN.[8] Statistically significant decreases in several serum pro-inflammatory cytokines were reported with no dose-limiting toxicities. This phase II trial aims to elucidate effects of daily sulforaphane on A/DN lesions and compare pigmentation change to placebo over one year. We hypothesize sulforaphane will demonstrate a greater decrease in total area of pigmented nevocellular nevi (both A/DN and banal nevi) *vs.* placebo as documented by serial digital photography. **Methods:** This phase II trial (NCT07040280) will assess impact of daily sulforaphane for 12 months *vs.* placebo on total area, quantity, and features of A/DN. Patients with ≥ 3 clinical A/DN (≥ 5 mm diameter with macular component, and ≥2 features of ill-defined borders, color variegation, uneven contour, or erythema) and a history of early stage-melanoma are eligible. Enrolled patients will undergo a baseline clinical skin exam and scheduled follow-up exams every 3 months. Photography of index A/DN and a standardized area of the posterior trunk, excisional biopsy of an A/DN, and peripheral blood sampling will be performed at baseline, 3 months, and 12 months. The primary endpoint is effect of sulforaphane *vs.* placebo on change in total area of pigmented nevocellular nevi on the posterior trunk at 12 months, calculated by Derma-AI image analysis software.[9] Secondary endpoints are number of posterior truncal nevi with moderate to significant changes in area, changes in A/DN features/area, and assessment of the safety/tolerability of sulforaphane. Exploratory endpoints include effects on circulating cytokine and chemokine levels assessed by multiplex technology, impact on A/DN immune cell infiltration by histopathology and immunochemistry, and evaluation of prespecified A/DN features at each timepoint. Outcome measures will be compared between arms over serial timepoints by Wilcoxon rank sum test. The study is open for enrollment with accrual goal of 120 patients. Research Sponsor: None.

TPS9612 Poster Session

A multicenter, randomized phase Ib trial to evaluate neoadjuvant immunotherapy combination of nivolumab alone or plus ipilimumab with the IL-2 superkine MDNA11 alone or with tocilizumab in patients with high-risk, surgically resectable melanoma: The NEO-CYT trial. First Author: Margaret Ottaviano, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy

Background: Neoadjuvant immunotherapy, administered upfront of surgery in patients with resectable stage III melanoma, has shown superior efficacy in recent trials compared to post-surgical adjuvant treatment, due to enhanced anti-tumor immunity when the tumor microenvironment is intact. A pre-operative regimen of 2 cycles of ipilimumab plus nivolumab followed by surgery and response-driven adjuvant therapy (as per NADINA trial) results in substantially improved event-free survival. However, even with this regimen 41% of patients did not achieve a Major Pathologic Response (MPR), with 8% having a partial pathological response and 26.4% showing pathological non-response. Previous analyses have shown a 'cold' CD4-IL-2 signature being associated with no-response, which could be overcome by the addition of IL-2. MDNA11 is a long-acting engineered interleukin (IL)-2 albumin fusion protein, with enhanced affinity for IL-2 receptor β (IL-2Rβ/CD122) and no binding to IL-2Rα (CD25). This design enhances the stimulation of IL-2Rβ-expressing CD8+ T cells and NK cells whilst diminishing the activation of Tregs constitutively expressing the heterotrimeric receptor containing IL-2Rα. Thus, we hypothesize that MDNA11 combination with nivolumab +/- ipilimumab may further enhance clinical outcomes of neoadjuvant standard therapy. **Methods:** This is a phase Ib, prospective, open-label, randomised study where a 6- week neoadjuvant phase is followed by a 7-week surgery/post-surgery phase and a 49-week adjuvant phase as per clinical practice. The study population will include adult patients of either sex aged ≥ 18 years with surgically resectable stage IIIB/C/D cutaneous melanoma. Twenty patients will be enrolled in each arm for a total of up to 80 patients. The ARM A is the control one with Ipilimumab 80 mg plus Nivolumab 240 mg administered every 3 weeks for 2 cycles as for NADINA trial; the ARM B includes Nivolumab 240 mg every 3 weeks for 2 cycles plus MDNA11 at 30 μg/kg on week 0 followed by MDNA11 at 60 μg/kg on week 2 and week 4; the ARM C includes Ipilimumab 80 mg plus Nivolumab 240 mg administered every 3 weeks for 2 cycles plus MDNA11 at 30 μg/kg on week 0 followed by MDNA11 at 60 μg/kg on week 2 and week 4; the ARM D adds tocilizumab 4 mg/Kg on week 0 at the same schedule of the ARM C. The study's primary endpoint is the Major Pathologic Response (MPR) rate at surgery, defined as ≤10% viable tumor in the treated tumor bed. Co-primary endpoints include the incidence, severity, and duration of treatment-related adverse events, particularly immune-related, as per CTCAE v5.0. Health-related quality of life will be analyzed using longitudinal models. Exploratory analyses will investigate biomarker associations with outcomes to generate hypotheses. Clinical trial information: 2024-519010-31-00. Research Sponsor: None.

TPS9613 **Poster Session**

A phase 2 study of neoadjuvant nivolumab + relatlimab versus nivolumab in patients with resectable high-risk basal cell carcinoma. First Author: Soo J. Park, Division of Hematology and Oncology, University of California San Diego, San Diego, CA

Background: The high response rate of neoadjuvant anti-PD-1 has changed the management of locally advanced cutaneous squamous cell carcinoma. However, little is known about the benefit of neoadjuvant immunotherapy for basal cell carcinoma (BCC). Anti-PD-1 is approved second line for advanced BCC where it has modest response rates compared to the first line setting. High LAG-3 expression within the BCC tumor microenvironment may function as a subdominant checkpoint to synergize with anti-PD-1. The current randomized prospective multicenter phase 2 trial evaluates the safety and efficacy of neoadjuvant nivolumab (anti-PD-1) + relatlimab (anti-LAG-3) versus nivolumab alone in resectable high-risk BCC. **Methods:** This multicenter study conducted across the University of California Melanoma and Skin Cancer Consortium will enroll up to 30 patients with resectable high-risk BCC. High-risk BCC is defined by size 2.0 cm or greater in the head and neck region or 4.0 cm or greater for the trunk and extremities. All patients must have surgically resectable disease that is at increased risk for cosmetic disfigurement, functional defects, poor oncologic control, or anticipated to require skin grafting or free flap reconstruction. Patients must also be checkpoint and hedgehog inhibitor naïve with ECOG performance status of <2. Key exclusion criteria include recent radiation therapy and any prior history of myocarditis. Patients will be randomized in 2:1 fashion to receive nivolumab 480 mg + relatlimab 160 mg or nivolumab 480 mg IV every 4 weeks for up to 4 doses. Patients may forgo surgery and continue beyond 4 doses for up to 1 year in cases of ongoing clinical benefit. Tumor tissue and peripheral blood will be interrogated for immune cell subsets and checkpoint expression before and after neoadjuvant treatment. The trial's primary endpoint is the combined rate of pathological complete response, major pathologic response, and clinical response following neoadjuvant therapy with secondary endpoints including surgical de-escalation, safety, duration of response, and recurrence-free survival. This trial uses a Simon's minimax two-stage design for the nivolumab + relatlimab cohort. Eleven patients will be enrolled in the first stage. If $\geq$2 patients respond to nivolumab + relatlimab, the study will continue enrollment for a total of 20 patients. This design yields a type I error rate of 0.1 and power of 0.8. This study was approved by UC San Diego's Institutional Review Board; approval number is 810617. Trial Registration NCT06624475. Clinical trial information: NCT06624475. Research Sponsor: Bristol Myers Squibb.

TPS9614 **Poster Session**

Spino-RT: A multicenter, randomized controlled phase III study of adjuvant radiotherapy versus surveillance in patients with cutaneous squamous cell carcinoma (cSCC) at high risk of recurrence. First Author: Adeline Pêtre, Centre Léon Bérard, Lyon, France

Background: cSCC is the second most common skin cancer, predominantly affecting elderly individuals. Most cSCCs are diagnosed at an early stage and cured with surgery. Recurrences are usually detected during routine clinical examinations or imaging (lymph-node ultrasound, cervicothoracic CT scan). In patients considered at high-risk, local recurrence rates may reach up to 30%. To date, no randomized trial has established the optimal management of cSCCs at high risk of recurrence after complete resection, and indications for adjuvant radiotherapy are only based on local practices or retrospective studies showing variable and contradictory results. **Methods:** This ongoing randomized phase III trial (NCT06692556) compares the efficacy and safety of two commonly used strategies (adjuvant radiotherapy versus surveillance) in patients with cSCC at high risk of recurrence. Key eligibility criteria include age $\geq$ 18 years, histologically confirmed localized cSCC, complete surgical resection and high-risk of recurrence, defined as: 1) microscopic peri nerval involvement (PNI) with or without one additional risk factor, or 2) the presence of two or three risk factors (excluding microscopic PNI): immunosuppression, tumor diameter $>$ 20 mm, specific location (lip/ear/temple), deep invasion (thickness $>$ 6 mm or invasion beyond the subcutaneous fat), poor differentiation or desmoplasia. The primary endpoint is recurrence free-survival, defined as the time from the date of randomization to the date of first documented relapse (local, regional or metastatic) or the date of death. Secondary endpoints include local and metastatic recurrence-free survival, overall survival, safety and quality of life (EORTC QLQ-C30 and QLQ-ELD14). Exploratory objectives include progression-free survival after treatment for local recurrence in the surveillance arm. A total of 120 events will provide 80% power to detect a significant improvement of the recurrence-free survival in favor of the radiotherapy arm (HR=0.6) at a 2-sided alpha risk of 5%. Considering a two-years recurrence-free survival rate of 60% in the control arm, an accrual period of 18 months, 36 months follow-up for the last patient, and 10% of non-evaluable patients, a total of 266 patients is required (133 par arm). Since the start of recruitment (February 2025), 38 patients have been randomized. 35 French health institutions will contribute to recruitment. Clinical trial information: NCT06692556. Research Sponsor: Ligue Nationale contre le Cancer; 2023.

TPS9615 **Poster Session**

Phase 2 study of ivonescimab in patients with cutaneous squamous cell carcinoma. First Author: Neal Akhave, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Cutaneous squamous cell carcinoma (CSCC) is the second most common skin cancer. In the setting of unresectable locally advanced or metastatic disease, checkpoint inhibitors are standard of care and are associated with robust response rates and durable disease control. However, in those who do not respond or progress on immunotherapy, there are limited available standard therapies. Ivonescimab is a tetravalent bispecific antibody targeting programmed cell death protein 1 (PD-1) and vascular endothelial growth factor A (VEGF-A) that has shown promising activity in multiple tumor types. VEGF-mediated activities include driving angiogenesis creating a tortuous tumor vasculature and decreasing effector T-cells within the tumor microenvironment. Herein, we hypothesize that dual targeting of PD-1 and VEGF-A may overcome resistance to checkpoint inhibitors and extend the benefit of immunotherapy in CSCC. **Methods:** This phase 2, single-arm study will enroll up to 24 patients and will be conducted using a Bayesian optimal phase 2 (BOP2) design. Prespecified activity goal for the first stage of accrual was met; second stage accrual began in January 2026. Patients will receive Ivonescimab 20mg/kg intravenously every 3 weeks until progression, death, or intolerance. The main inclusion criteria include unresectable locally advanced or metastatic CSCC that is refractory to prior checkpoint inhibitors, Eastern Cooperative Oncology group performance score of 0-1, and measurable disease by RECIST version 1.1. Primary exclusion criteria comprise prior severe immunotherapy-associated toxicities, prior organ transplant, or major blood vessel invasion. There are no limits on lines of therapy. Primary objective and endpoint is objective response rate in CSCC. Key secondary endpoints include duration of response, disease control rate, progression free survival, and safety. Additional exploratory objectives include evaluating predictive biomarkers of treatment response or resistance utilizing a mandatory biopsy performed both pre-and on-treatment, with correlatives including whole exome sequencing, RNA sequencing, multiplex IHC. Active recruitment and enrollment are ongoing at The University of Texas MD Anderson Cancer Center, Houston, Texas. Copyright © 2026 AACR. Originally presented at AACR 2026. Reprinted with permission. Clinical trial information: NCT06567314. Research Sponsor: Summit Therapeutics.

TPS9616 **Poster Session**

A feasibility study of tumor-infiltrating lymphocytes (TIL) in patients with cutaneous squamous cell carcinoma and Merkel cell carcinoma after anti–PD-1 therapy. First Author: Karam Khaddour, Dana-Farber Cancer Institute, Boston, MA

Background: Tumor infiltrating lymphocyte (TIL) therapy is an autologous cellular therapy isolated from a patient's tumor. Clinical data demonstrated that TIL therapy in heavily pretreated melanoma patients yielded an objective response rate (ORR) in 30% of patients with 5-year overall survival (OS) of approximately 20%. TILs were approved by the FDA in February 2024 for the treatment of metastatic or unresectable melanoma that have progressed on anti-PD-1 therapy and BRAF+MEK inhibitors (in patients with *BRAFV600* mutation). Non-melanoma skin cancers, including cutaneous squamous cell cancer (CSCC) and Merkel cell cancer (MCC), share biologic features with melanoma, including an "inflamed" tumor microenvironment and high responsiveness to anti-PD-1 therapy. However, approximately, a third of patients will experience disease progression after anti-PD-1 therapy or will discontinue treatment due to toxicity and subsequently experience disease progression. Given the overlap between melanoma and CSCC/MCC, we hypothesize that TIL therapy may induce immune response against non-melanoma skin cancers. Because some of these tumors are superficial and are often ulcerated and can contain polymicrobial contamination, this trial will also assess the feasibility of TIL production in this unique patient population, alongside its safety and efficacy. **Methods:** Ten patients with CSCC (Cohort A) and 4 patients with MCC (Cohort B) adults will be eligible for TIL if they have disease progression after anti-PD-1 therapy. Eligible patients should have adequate organ function and be able to receive dose-reduced non-myeloablative lymphodepletion (NMA-LD) and interlukin-2 (IL-2). Following tumor harvest and TIL manufacturing, patients will receive NMA-LD including cyclophosphamide (30 mg/kg on days −5 and −4), and fludarabine (25 mg/m2 on days −5 to −1). Subsequently, patients will receive TIL on day 0 followed by IL-2 (600,000 IU/kg) for up to 6 doses. The primary objective is to evaluate feasibility and safety of TIL production and administration in cohorts A and B (defined by successful tumor harvest that leads to a TIL product that contains $\geq$ 1 x 10^9 cells, administration of NMA-LD, infusion of TIL therapy and complete at least 1 dose administered of IL-2). Secondary objectives include ORR, progression-free survival, duration of response, OS and correlative studies. Within Cohort A, efforts will be made to achieve an approximately equal distribution of ulcerated and non-ulcerated lesions. To maintain this balance, ulceration status will be monitored throughout the enrollment process, and eligibility criteria may be modified as necessary to ensure proportional representation of each subtype. Clinical trial information: NCT07288073. Research Sponsor: Iovance.

10000 **Oral Abstract Session**

Tisagenlecleucel (tisa-cel) in pediatric and young adult patients with high-risk (HR) B-cell acute lymphoblastic leukemia (B-ALL) and minimal residual disease (MRD) at the end of frontline consolidation (EOC). First Author: Shannon L. Maude, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Persistent MRD portends a high risk of relapse in B-ALL. In the Children's Oncology Group (COG) AALL0232 frontline trial for HR B-ALL, children and young adults with MRD ≥0.01% at the EOC had poor 5 y disease-free survival (DFS) of 39% (Borowitz, *Blood*, 2015). We report the primary analysis of a phase 2 trial, in collaboration with COG, of tisa-cel, a CD19-directed chimeric antigen receptor (CAR) T cell therapy, in this very high-risk (VHR) population. **Methods:** COG AALL1721/CASSIOPEIA (NCT03876769) is a global (34 sites in the US/Canada, 10 sites in EU/UK) phase 2 study of tisa-cel in patients (pts) aged 1-25 y with National Cancer Institute HR B-ALL and persistent MRD ≥0.01% by flow cytometry at EOC. A single dose of tisa-cel ($0.2\text{-}5\times10^6$ CAR+ T cells/kg for pts ≤50 kg or $0.1\text{-}2.5\times10^8$ CAR+ T cells for pts >50 kg) was given after standard lymphodepleting chemotherapy. Reinfusion was available for pts with B-cell recovery within 6 mo and/or MRD ≥0.01% at any time. Primary endpoints were 4 y overall survival (OS) and 5 y DFS, defined as time from first infusion to morphologic relapse, secondary malignancy, or death, without censoring for new anticancer therapy, including stem cell transplant (SCT). Secondary endpoints included DFS with censoring, MRD negative rate (MRD <0.01%) at 3 mo, and safety. **Results:** The primary analysis included 121 infused pts; 1 pt was not infused due to adverse event. Median age was 14 y (range: 1-24 y), 67% were male, 6% had trisomy 21. As of August 20, 2025, median time from infusion to last follow-up was 38 mo. OS at 4 y was 85% (95% CI: 76-90%). DFS (95% CI) at 3 y and 5 y without censoring for new therapy was 71% (61-79%) and 64% (53-73%). DFS (95% CI) at 3 y and 5 y with censoring was 69% (55-79%) and 62% (46-74%). MRD negative rate at day 29 and 3 mo post infusion was 95% and 86%. Relapse occurred in 31 pts, of which 7 occurred after new therapy/SCT. 41 (34%) pts received a second infusion. 58 (48%) pts received new anticancer therapy/SCT without prior relapse. Median duration of B-cell aplasia was 5.6 mo. Probability (95% CI) of ongoing remission and B-cell aplasia at 3, 6, and 12 mo was 76% (67-83%), 47% (38-56%), and 31% (23-41%). Following first infusion, cytokine release syndrome (CRS) occurred in 37% (grade ≥3, 2%), immune effector cell–associated neurotoxicity syndrome (ICANS) in 3% (grade ≥3, 1%). There were 18 deaths, all post new therapy/SCT and/or relapse. **Conclusions:** Durable remissions, with very low rates of severe CRS/ICANS, were achieved with tisa-cel in a VHR population with persistent MRD in frontline therapy, who historically have low 5 y DFS. Nearly 50% of pts received new anticancer therapy, including SCT, without prior relapse. Longer follow-up is needed to confirm 5 y DFS. Clinical trial information: NCT03876769. Research Sponsor: Novartis Pharmaceuticals.

10001 **Oral Abstract Session**

SPARTO: A phase I study of PD-1 inhibitor spartalizumab (PDR001) in combination with low dose of pazopanib in pediatric relapsed/refractory tumors. First Author: Jordane Chaix, CHU Bordeaux, Department of Paediatric Hematology and Oncology, Bordeaux, France

Background: The initial results of immunotherapy in children with refractory/relapsed tumors have been disappointing. Modulation of angiogenesis with anti-VEGF may enhance immunotherapy penetration and promote lymphocytes T infiltration. In this context, we propose combining immunotherapy with low doses of pazopanib to enhance therapeutic efficacy in pediatric patients. **Methods:** Pediatric part of the SPARTO trial (NCT05210413) was a multicenter, open-label, dose-finding phase I clinical trial conducted in France. Pediatric patients with recurrent/refractory solid tumors were eligible to receive pazopanib at a fixed low dose of 225 mg/m²/d combined to anti-PD1 spartalizumab at three candidate doses (2, 3, 4 mg/kg/q4w). Dose-finding was guided by Bayesian Optimal Interval design based on dose-limiting toxicities (DLTs) in cycle 1, with a target toxicity level of 25%. Recommended phase 2 dose (RP2D) was determined on the basis of DLTs and blood exposure of pazopanib and spartalizumab. Toxicities were evaluated using CTCAE v5.0 and responses were evaluated by clinical and radiologic assessment (RECIST1.1 or RANO for brain tumors). **Results:** From May 2022 to June 2025, 41 patients were enrolled at 8 sites (median age: 13.9y; range: 7-25). Among 39 evaluable patients, 4 DLTs occurred in 1/9 patients at 2 mg/kg of spartalizumab (DL0), 1/6 patients at 3 mg/kg (DL1) and 2/24 patients at 4 mg/kg (DL2). Three patients experienced macrophagic activation syndrome (grade 3 at DL0 and DL2, grade 4 at DL1) and one patient experienced liver enzymes increase grade > 3 at DL2. A total of 58 grade 3–4 adverse events were reported in 26 patients, predominantly hepatic and hematologic toxicities. Median area under the serum concentration-time of spartalizumab from 0 to 28 days post-infusion at cycle 1, were 12.9 g.h/L (IQR 10.7-15.8), 17.2 g.h/L (IQR 15.5-20.0) and 19.5 g.h/L (IQR 16.9-23.6), respectively for DL0, DL1 and DL2. Median trough concentration of pazopanib was 23.1 mg/L (IQR 15.8-32.1). DL2 was identified as the RP2D. Of 40 evaluable patients, one patient with osteosarcoma presented complete response, 4 had partial responses (2 osteosarcoma, 1 chordoma, 1 carcinoma) and 8 had stable disease (including 4 for more than 4 months). The median duration of treatment was 68 days (IQR 57–106); one patient completed 24 cycles and two were still on treatment at data cut-off (at cycle 16 and cycle 23). **Conclusions:** Spartalizumab combined with low dose pazopanib was well tolerated leading to a RP2D of 4 mg/kg/q4w. The regimen shows evidence of anti-tumor activity in pediatric sarcoma, especially osteosarcoma. Further investigations are ongoing to select the subpopulation who could benefit of this combination. Funded by INCa and ARC Foundation (call for project CLIP2 "Novartis Innovative Molecules, INCa-ARC_14820"). Clinical trial information: NCT05210413. Research Sponsor: Institut National du Cancer (INCa) et Fondation ARC.

10002 **Oral Abstract Session**

Targeting metastatic sites with radiation and outcomes in high-risk pediatric rhabdomyosarcoma. First Author: Rachel Mendelson, St. Jude Children's Research Hospital, Memphis, TN

Background: Outcomes for pediatric patients with metastatic rhabdomyosarcoma (RMS) remain poor despite therapy intensification and novel agents. RMS13 (NCT01871766) was a phase II prospective multicenter trial evaluating a response-based approach to metastatic site radiotherapy (RT). We report outcomes related to metastatic disease management in this high-risk (HR) population. **Methods:** Event-free survival (EFS) and metastatic site control were analyzed for HR patients treated with interval compressed chemotherapy, risk-adapted RT to primary and metastatic site, and maintenance therapy. EFS was defined from therapy start to relapse, progression, death or last follow-up. Metastatic RT was delivered between interval-compressed and maintenance therapy for non–bone marrow metastatic sites without complete response (CR). RT omission criteria included PET negativity, lesion size <1 cm, or complete surgical resection with negative margins. Metastatic RT used protons: 25 Gy in 5 or 50.4 Gy in 28 fractions, by lesion size. Primary tumor control consisted primarily of proton RT, with limited use of surgery plus adjuvant RT. **Results:** From 2015 to 2020, 39 HR patients were enrolled (median age 9.5 years). Most patients were FOXO1 fusion–positive (64%), had nodal involvement (74%), and an Oberlin score >1 (67%). Median follow-up was 23.1 months overall (78.5 months for non-progressors). Five-year EFS was 31.6% (95% CI, 19.7-50.6%), differing by Oberlin score >1 – 16.2% (95% CI, 6.6–39.8%), ≤1 - 61.5% (95% CI, 40-94.6%). Twenty-six patients relapsed: 22 had distant failure (DF), 6 had local failure (LF), and 2 had both DF and LF. The 5-year cumulative incidence of LF was 14.4% (95% CI, 5–28), and 54% for DF (95% CI, 36–69), establishing DF as the predominant pattern of failure. Twenty-six patients reached the protocol window for metastatic-site RT (weeks 47–54): 11 soft-tissue metastases, 6 bone, 8 both, and 1 bone marrow only, with a 5-year EFS of 42.3% (95% CI 23.3-61.3%). Among 21 patients achieving CR at metastatic sites without RT, 5-year EFS was 38.1% (95% CI 17.3–58.9%), and cumulative incidence of any DF was 57.1% (95% CI 35.9–78.3%). Seven patients (33%) recurred at initially involved metastatic sites, primarily soft tissue. In-site recurrence occurred in 7/17 (41%) non-irradiated soft-tissue sites versus 1/12 (8%) bony sites. Only one recurrence occurred among irradiated soft-tissue sites. **Conclusions:** Soft-tissue metastatic sites in CR that were not irradiated had high recurrence rates, while bony sites achieved durable control without RT. Future trials should consider consolidative RT for soft-tissue metastases regardless of response in HR RMS. Clinical trial information: NCT01871766. Research Sponsor: None.

Recurrence by metastatic site.

	CR, no RT (N)	Recurrence, non-RT, N(%)	PR, RT (N)	Recurrence, No RT, N (%)
Bone metastases (n=14)	12	1 (8)	2	0
Soft-tissue metastases (n=19)	17	7 (41)	2	1 (5.9)

CR, complete response; PR, partial response; RT, radiotherapy.

10003 **Oral Abstract Session**

Digital health intervention for comorbid insomnia and neurocognitive impairment in adult survivors of childhood cancer: Results from a randomized clinical trial. First Author: Tara M. Brinkman, St. Jude Children's Research Hospital, Memphis, TN

Background: Survivors of childhood cancer are at risk of developing both insomnia and cognitive impairment, which may persist decades following treatment. Cognitive behavioral therapy for insomnia (CBT-I) is the gold-standard treatment for insomnia, yet the impact of improved sleep on comorbid cognitive dysfunction has not been evaluated in survivors. **Methods:** Survivors enrolled in the Childhood Cancer Survivor Study (CCSS; median age 44 [range 23-66] years; 73% female; 37% leukemia, 23% lymphoma, 18% sarcoma, 14% Wilms, 8% neuroblastoma) with comorbid insomnia and neurocognitive impairment were randomized 1:1 to 9-week digital CBT-I vs. online sleep education (SE). Insomnia severity index (ISI), neurocognitive problems (CCSS-Neurocognitive Questionnaire [NCQ]), emotional health (Patient Health Questionnaire/Generalized Anxiety Disorder), and quality of life (PROMIS) were measured at baseline and 9-week and 6-month follow-ups. Intent-to-treat models estimated treatment effects for ISI (mean difference [MD] between CBT-I and SE of change from baseline to follow-ups) adjusted for age, sex, and cranial radiation. Cohen's *d* estimated effect size. Additional models estimated treatment effects on secondary outcomes and mediation by improved ISI. **Results:** 439 of 541 randomized survivors completed baseline assessments and started the intervention (82% CBT-I; 81% SE); 353 of those completed 9-week (76% CBT-I; 85% SE) and 305 completed 6-month (61% CBT-I; 78% SE) post-intervention assessments. Survivors randomized to CBT-I reported improved ISI scores at 9 weeks (MD=-2.4[95%CI -3.4, -1.4]; Cohen's *d*=0.50) and 6 months post-intervention (MD=- 3.5[-4.6, -2.4]; *d*=0.72) vs. SE (both p's<0.001). Survivors randomized to CBT-I reported greater improvement in memory (9wks: MD=-0.3SD [-0.5, -0.1], p=0.003; 6mos: MD=-0.5SD [-0.7, -0.3], p<0.001) and task efficiency (9wks: MD=-0.3SD [-0.5, -0.1], p=0.003; 6mos: MD=-0.5SD [-0.7, -0.3], p<0.001) vs. SE. Effects of CBT-I on cognitive function were mediated by improved ISI scores (42-65% mediated, all p's <0.001). Insomnia responders (those who reported a change in ISI from >8 [mild to severe insomnia] to <8 [no insomnia]) also reported improved quality of life (9wks: mental beta=1.7[95%CI 0.4, 3.0], physical=2.1 [1.0, 3.1]; 6mos: mental=3.5 [2.0, 5.0], physical=3.3 [2.1, 4.5]), and emotional health (9wks: anxiety beta=-1.3 [-2.1,-0.5], depression=-1.8[-2.6, -1.0]; 6mos: anxiety=-1.8 [-2.7, -0.8], depression=-2.4 [-3.4, -1.4]). **Conclusions:** Use of a fully automated digital health treatment of insomnia confers immediate and long-term benefits to comorbid cognitive impairment and quality of life in survivors of childhood cancer. Given its efficacy and availability, digital CBT-I should be considered for the behavioral treatment of insomnia and comorbid symptoms in survivors. Clinical trial information: NCT04317742. Research Sponsor: National Cancer Institute; R01 CA239689.

10004 **Oral Abstract Session**

The ASPIRES study: Promoting colorectal cancer surveillance in childhood cancer survivors—A randomized intervention trial from the Childhood Cancer Survivor study (CCSS). First Author: Tara O. Henderson, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL

Background: Survivors of childhood cancer exposed to abdominal, pelvic, spinal, or total-body radiotherapy (RT) are at elevated risk for subsequent treatment-related colorectal cancer (CRC). However, adherence to recommended CRC surveillance screening is only ~37%, leaving survivors vulnerable to potentially preventable cancer. Innovative interventions are needed to improve screening uptake. **Methods:** We conducted a three-arm randomized controlled trial comparing mHealth-based patient activation (PA) and patient plus primary care provider activation (PA+PCP) with a control arm that received a survivorship care plan with screening recommendations. Nested within the CCSS, eligible participants were 5-year survivors diagnosed before age 21 who had received abdominal, pelvic, spinal, or total-body radiotherapy and were not up to date with surveillance. Participants (n = 300) were randomized in a 1:1:1 ratio, stratified by age at enrollment (30–44 vs $\geq$45 years). The primary outcome was the proportion of participants who completed CRC surveillance within 12 months. Each intervention arm was compared with the control in an intent-to-treat analysis using the Cochran-Mantel-Haenszel test (α = 0.025/comparison). In secondary analyses, logistic regression, adjusted for age at enrollment, was used to estimate odds ratios (ORs) to identify moderators of the relationship between the intervention (grouping PA with PA+PCP) and the outcome. **Results:** Participants were 45% male and 8% non-white, with a median age of 41 years (range: 30 – 67 years). At 12 months, survivors in the PA group were significantly more likely than controls to have completed surveillance screening: 32/99 (32%) vs 14/102 (14%) [p = 0.003]. Surveillance screening completion was also higher in the PA+PCP group than in controls, but this difference did not meet the prespecified α (0.025): 26/99 (26%) vs 14/102 (14%) [p = 0.041]. Secondary analyses suggested the intervention was more effective among survivors without a chronic health condition (without: OR = 3.6; 95%CI 1.5, 10.1 vs. with: OR=1.9; 95%CI 0.8, 4.8) and with $\leq$ high school education ($\leq$ high school OR=4.4; 95%CI 1.3, 20.2 vs. $>$ high school OR=2.2; 95%CI 1.1, 4.7). **Conclusions:** An mHealth-based patient activation intervention more than doubled adherence to CRC surveillance compared with a survivorship care plan with surveillance recommendations alone. While patient plus PCP activation showed improvement, adding PCP activation did not confer a significant benefit compared with the control. Intervention effectiveness varied across subgroups, underscoring the importance of tailored approaches. As digital technologies continue to advance, mHealth strategies offer a promising and scalable pathway to improving surveillance screening among high-risk survivors of childhood cancer. Clinical trial information: NCT05084833. Research Sponsor: National Cancer Institute R01CA255269; National Cancer Institute U24CA55727.

10005 **Oral Abstract Session**

Prediction of anthracycline-related cardiomyopathy in long-term childhood cancer survivors: The power of survivor-specific polygenic risk score—A COG-ALTE03N1 study. First Author: Noha Sharafeldin, Division of Hematology & Oncology, Heersink School of Medicine, The University of Alabama at Birmingham, Birmingham, AL

Background: Cardiomyopathy is a major dose-limiting toxicity of anthracyclines in the treatment of childhood cancer. Inter-patient variability in cardiomyopathy risk suggests an underlying genetic susceptibility, providing an opportunity to identify survivors at high risk and enable personalized interventions. We evaluated whether addition of a curated survivor-specific PRS for anthracycline-related cardiomyopathy (PRS-S) or general population PRSs for heart failure (PRS-G) to a clinical model improved cardiomyopathy risk classification in CCS. **Methods:** In a matched case-control study of CCS (COG-ALTE03N1: matched on cancer diagnosis and year of diagnosis; controls followed at least as long as cases), anthracycline-exposed non-Hispanic White CCS were randomly split (80/20) into training (cases: n=106; controls: n=180) and test (cases: n=27; controls: n=44) sets. From $>$100 published genetic variants associated with anthracycline-related cardiomyopathy, we selected a prioritized list of 8 independently validated variants with demonstrated biologic plausibility (reduced drug efflux [*ABCC2*], altered drug metabolism [*SLC22A17, SLC28A3, UGT1A6*], reduced antioxidant capacity [*HAS3*], impaired TOP2B-mediated DNA damage response [*RARG*], alternative splicing of *TNNT2*, reducing cardiac pumping efficiency [*CELF4*], and cardiac profibrotic pathway [*ROBO2*]) to construct a standardized weighted survivor-specific PRS (PRS-S). Area under the receiver operating characteristic curve (AUC) was used to compare the performance of a clinical model (age at cancer diagnosis, sex, anthracycline dose, chest radiation (Y/N)) *v* combined models incorporating either PRS-S or PRS-Gs. All models included PRS $\times$ anthracycline dose interaction terms and adjusted for matching variables. Risk scores derived from training model were applied to the test set for risk classification. **Results:** Median age at cancer diagnosis was 7.1y for cases and 8.6y for controls. Cases received higher anthracycline doses (median: 330 *v* 240 mg/m^2) and were more likely to have received chest radiation (24.8% *v* 19.2%). In the test set, PRS-S combined model significantly outperformed the clinical model ($AUC_{clin+PRS8}$=0.70, 95%CI=0.57-0.82 *v* AUC_{clin}=0.63, 95%CI=0.50-0.76, p=0.04); 85% of all cases were classified as high risk and the adjusted negative predictive value was 95.1%. Importantly, none of the 11 PRS-G combined models (AUCs: 0.60-0.65) out-performed the clinical model. **Conclusions:** Integrating a survivor-specific PRS derived from a parsimonious set of biologically plausible genetic variants with readily-available clinical factors informs cardiomyopathy risk classification in CCS and provides an opportunity to develop personalized screening recommendations and behavioral/therapeutic interventions. Primary breast malignancies in adolescents and young adults: The MD Anderson Cancer Center experience. First Author: Samanta Catueno, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Primary malignancies of the breast rarely affect adolescents and are uncommon in young adults. Limited information is available about their clinicopathologic characteristics and outcomes. The 5-year overall survival (OS) for women with breast cancer, not including ductal carcinoma in situ, exceeds 90%. However, it remains unclear whether adolescents and young adults experience similar outcomes compared with older patients. **Methods:** We conducted a retrospective study of all patients aged 0–25 years with primary breast malignancies seen at MD Anderson Cancer Center between 2000 and 2024. Demographics, histology, staging, treatment, and outcome data were collected. Event-free survival (EFS) and OS were estimated using the Kaplan–Meier method. Log-rank test was used to analyze patient outcomes by histology. **Results:** A total of 110 patients were identified. Median age at diagnosis was 23.9 years (range, 15.7–25.5). Two patients were male, 44.9% were White, 27.7% Hispanic, and 15.9% Black. The most common tumor histology was invasive ductal carcinoma (n=83, 75.5%), followed by sarcoma and malignant phyllodes tumors (n=14, 12.7%), carcinoma in situ (n=7, 6.4%), and rare histologic subtypes (n=6, 5.5%). Family history of breast cancer was present in 53.6% of patients and ovarian cancer in 9%. Of 81 patients with germline genetic testing, 25 (30.9%) had a cancer predisposition syndrome: Li-Fraumeni (n=9), BRCA1 (n=8), BRCA2 (n=4), ATM (n=2), other (n=2). Eleven patients (10%) had metastatic disease at presentation to bone, lung, distant lymph nodes, and liver. Among the 96 carcinoma cases, 36 (37.5%) were estrogen or progesterone receptor-positive and HER2-negative; 25 (26%) were HER2+, and 32 (33%) were triple-negative. Of the 110 patients, 69 (62.7%) received neoadjuvant chemotherapy, 37.6% of whom achieved a pathologic complete response, and 46.3% a partial response. Most patients (92.7%) had surgery (mastectomy 87.2% or lumpectomy 9.8%), 67.2% received radiotherapy, and 25.4% targeted therapy. Following treatment, 56 (51%) patients received adjuvant endocrine therapy. The 5-year EFS and OS for the cohort were 30% (95% CI, 22.6-39.9) and 71.8% (95% CI 62.9-82), respectively, and are presented by histology in the table. EFS (p=0.023) but not OS (p=0.36) was associated with histologic type. **Conclusions:** Primary breast malignancies in adolescents and young adults have distinct characteristics with a high frequency of family history and genetic predisposition syndromes and appear to be associated with lower survival compared with breast cancer in older patients. Research Sponsor: None.

Histology	No. of patients	5-year EFS (%) (95% CI)	5-year OS (%) (95% CI)
Invasive ductal carcinoma	83	31.3 (22.8, 43.1)	68 (57.9, 80)
Sarcoma and malignant phyllodes tumors	14	28.6 (12.5, 65.4)	82.1 (62.1, 100)
Carcinoma in situ	7	42.9 (18.2, 100)	100 (100, 100)
Rare histologic subtypes	6	NA	100 (100, 100)

10007 **Rapid Oral Abstract Session**

Characteristics and survival of 4N and non-4N metastatic neuroblastoma across treatment eras: A report from the International Neuroblastoma Risk Group Task Force. First Author: Michael Mitchell, The University of Texas Dell Medical School, Austin, TX

Background: Patients with metastatic neuroblastoma confined to distant lymph nodes (4N) were identified as a subgroup with superior outcomes to those with metastases to other sites. Over the past two decades, outcomes for high-risk neuroblastoma have improved from increasingly effective and intense therapy, while intermediate-risk patients have maintained excellent outcomes with biology and response-based therapy. We aimed to determine if 4N patients remained a favorable subgroup with contemporary therapy. **Methods:** Patients with International Neuroblastoma Staging System (INSS) stage 4 disease in the International Neuroblastoma Risk Group Data Commons diagnosed between 1990-2020 were evaluated. Those with metastases only to the distant lymph nodes were defined as 4N. All other patients were defined as non-4N. Treatment eras included: 1999 and prior, 2000-2009, 2010 and later which correspond to standardization of multimodal therapy, stem cell transplant, and anti-GD2 immunotherapy for high-risk patients. Differences between 4N and non-4N patients were assessed with chi-square, Wilcoxon rank sum, and t-tests. Five-year Kaplan-Meier estimates of survival with 95% confidence intervals and multivariable Cox proportional hazards modeling were used to evaluate event-free (EFS) and overall (OS) survival. **Results:** The analytic cohort included 107 4N and 5976 non-4N patients. There were no clinical differences between 4N and non-4N patients apart from unfavorable histology (74.2% [4N] versus 60.1% [non-4N]; p=0.02). 5-year EFS and OS were higher for 4N compared to non-4N patients (p=0.001 and 0.001, respectively). Though survival estimates for 4N were higher in each era, the difference was not statistically significant for patients diagnosed from 2000-2009 nor 2010 and beyond; (1999 and prior: EFS 58.7% (40.9-72.7%) versus 31.8% (29.7-33.9%) p=0.001; OS, 66.2% (48.1-79.3%) versus 37.9% (35.7-40.1%) p=0.002, 2000-2009: EFS, 47.9% (34.0-60.5%) versus 36% (34.1-37.9%) p=0.179; OS, 55.4% (40.7-67.8%) versus 45.1% (43.1-47.1%) p=0.122, and 2010 and later: EFS, 63.6% (29.7-84.5%) versus 42.8% (39.9-45.6%) p=0.178; OS, 71.6% (35.0-89.9%) versus 52.3% (49.2-55.3%) p=0.207. Log-rank calculations may have been underpowered in part due to small sample sizes (n=39, 56, and 12) of each 4N subgroup, respectively. 4N patients had superior EFS (HR=0.48; p=0.0004) and OS (HR=0.49; p=0.0009) in a model which included age, *MYCN*-amplification status, treatment era, ferritin, and LDH. A sensitivity analysis using only high-risk patients age $>$18 months yielded similar results. **Conclusions:** Patients with stage 4N neuroblastoma are a rare subgroup which appears to continue to have favorable outcomes with contemporary therapy. Additional studies to identify opportunities to reduce therapy intensity for this subgroup are warranted. Research Sponsor: None.

Real-world experience of a pediatric precision oncology protocol utilizing paired somatic and germline sequencing at a single institution: Interim analysis. First Author: Joshua Goldman, C.S. Mott Children's Hospital/ University of Michigan, Ann Arbor, MI

Background: While most pediatric oncology patients are cured with upfront therapy, outcomes for patients with metastatic and relapsed/refractory disease remain poor. Salvage therapy is toxic and has marginal success rates, necessitating novel, personalized approaches. We established our pediatric precision oncology program based on integrative clinical sequencing (ICS) in 2012 and present an interim outcomes analysis of this single institution cohort. **Methods:** Pediatric and AYA oncology patients (age 0-25 years) underwent paired somatic and germline sequencing, including whole exome and transcriptomic analysis. Results were annotated with longitudinal clinical data extracted from the medical record using the NCI-supported tool EMERSE, which has been enhanced by the addition of a beta version of a large language models (LLM) integrated "Chatbot" to implement more efficient data abstraction from clinical notes. **Results:** Of the 1000 patients enrolled, 925 (92.5%) were sequenced successfully. We present interim analysis of the first 435 patients. Within this interim cohort, 233 (53.56%) of patients were male and 79.8% were non-Hispanic white. Hematologic malignancies accounted for 110 (25.3%) diagnoses, brain tumors 75 (17.2%), and non-brain solid tumors 250 (57.5%). ICS succeeded for 400/435 (92.0%) patients. Overall, 471 actionable alterations (AA) were discovered in 266 (66.5%) patients (mean 1.77 AA/patient). These included 62 actionable germline alterations in 60 patients (15%). There were 195 single nucleotide variants (SNV) in 142 patients, 69 gene fusions in 62 patients, and 145 copy number alterations (CNA) in 92 patients. Actionable findings guided the use of targeted therapies (TT) supported by NCI-MATCH criteria in 116 patients (29.0%) with a total of 209 targeted therapies given (mean 1.80 /patient). Thirty-two patients (8.0%) enrolled on therapeutic clinical trials featuring an identified targeted therapy. Sixteen (4.0%) patients without AAs received 22 TTs based on clinician preference. Additionally, 166 patients (41.5%) did not receive TT despite at least one AA due to lack of availability of a suitable formulation, pursuit of alternative therapy, or death prior to therapy initiation. Repeat ICS (range 1-4) was completed for 115 patients (28.8%), among which 8 (7.0%) had additional AAs identified and 5 (4.4%) received TT based on repeat ICS. **Conclusions:** This study highlights the importance of ICS based precision oncology with 67% of patients having AAs and 29% receiving TTs. Analyses are ongoing to study the most frequently altered signaling pathways, frequency of targeted agents used, impact of ICS and TT on the clinical outcomes for these patients, barriers in receiving TT despite having AAs, role of longitudinal sequencing, and the impact of LLM based "Chatbot" on data extraction efficiency. 10009 **Rapid Oral Abstract Session**

Harnessing OMOP-CDM for multisite collaborations to measure cardiovascular risk factors and cardiovascular disease in the early survivorship period for children, adolescents, and young adults. First Author: David H. Noyd, University of Washington, Seattle, WA

Background: The Observational Medical Outcomes Partnership Common Data Model (OMOP-CDM) is an international effort to leverage data standards to cultivate multi-institutional collaborations and generate reproducible evidence using real-world data. Four institutions mapped their electronic health records data to the OMOP-CDM. Cardiovascular risk factors (CVRFs) and their impact on risk for cardiovascular disease (CVD) among survivors of childhood cancer merit further investigation into cardiotoxicity during the early survivorship period. **Methods:** Eligible patients from Seattle Children's with at least one condition contained within the ancestor concept "malignant neoplastic disease" (concept ID 443392) and an index date defined as the initial administration of a medication contained within the ancestor concept "antineoplastic agents" (concept ID 21601387) were included. Clinically computable phenotypes from OMOP-CDM data were constructed in alignment with the Common Terminology Criteria for Adverse Events (version 6.0) for hypertension, diabetes, obesity, and hyperlipidemia within one year of the index date. The primary outcome was CVD, defined as the incidence of cardiomyopathy, heart failure, atrial fibrillation, and ventricular arrhythmias within 1-5 years of the index data. **Results:** Among 1195 survivors, the incidence rate of any CVD from non-cardiotoxic therapy was 0.11 per 100-person-years (95% Confidence Interval 0.04-0.25), compared to 0.43 (95% CI 0.25-0.71) and 1.6 (95% CI 0.08-7.88) for survivors treated with cardiotoxic therapy and cardiotoxic therapy plus targeted or immunotherapy, respectively. Validation of results and sharing of coding for multi-site meta-analysis is ongoing. **Conclusions:** OMOP-CDM represents a feasible approach to explore CVRFs and CVD in the early survivorship period among contemporary cohorts treated with traditional cardiotoxic chemotherapy, targeted therapy, and immunotherapy. Research Sponsor: None.

Association of neighborhood-level vulnerability with health behavior patterns in survivors of childhood cancer: A report from the St. Jude Lifetime Cohort (SJLIFE). First Author: Amy Berkman, St. Jude Children's Research Hospital, Memphis, TN

Background: Childhood cancer survivors face elevated risks for chronic health conditions and premature mortality. Engaging in healthy behaviors may mitigate these risks, yet neighborhood-level vulnerability may constrain survivors' ability to adopt or sustain them. **Methods:** Among survivors (n=3,303) and community controls (n=652) in SJLIFE, neighborhood-level vulnerability was measured using census tract level overall and domain-specific (i.e. socioeconomic status, household composition, minority status, housing type and transportation) Social Vulnerability Index (SVI) scores, with higher values indicating higher vulnerability, and the U.S. Department of Agriculture's persistent poverty measure. Health behaviors, including sedentary time/physical activity, smoking, alcohol, and illicit drug/marijuana use, were categorized as healthy, moderately unhealthy (1-2 unhealthy behaviors), and unhealthy ($\geq$3 unhealthy behaviors). Multinomial logistic regression evaluated associations between neighborhood-level vulnerability at enrollment and health behavior patterns at most recent evaluation among survivors, adjusted for sociodemographic and cancer treatment factors as determined by backward selection. Interaction models compared associations between survivors and controls. **Results:** Survivors were 53.1% male, 82.5% non-Hispanic White, with a median age of 31.0 years (interquartile range: 23.5 – 38.5) at health behavior assessment. The most common childhood cancer diagnosis was acute lymphoblastic leukemia (28.8%). Survivors in the highest vs. lowest SVI tertile had higher odds of reporting moderately unhealthy (Odds Ratio [OR]: 1.46, 95% Confidence Interval [95% CI]: 1.08 – 1.98) or unhealthy (OR: 1.70, 95% CI: 1.13 – 2.56) behavior patterns, compared to a healthy behavior pattern. Socioeconomic and housing type SVI domains drove these associations, with survivors in the highest tertiles more likely than those in the lowest to have an unhealthy rather than healthy behavior pattern (Socioeconomic OR: 1.55, 95% CI: 1.02 – 2.35; Housing type OR: 1.53, 95% CI: 1.03 – 2.27). Persistent poverty was associated with greater odds of a moderately unhealthy behavior pattern (OR: 1.70, 95% CI: 1.09 – 2.66) in survivors. Housing type vulnerability was associated with disproportionately higher odds of an unhealthy behavior pattern among survivors compared to controls (ratio of ORs: 2.80, 95% CI: 1.19 – 6.60). **Conclusions:** Neighborhood-level vulnerability was associated with higher likelihood of unhealthy behavior patterns in childhood cancer survivors with housing type vulnerability having a greater impact on health behaviors in survivors compared to controls. Effective interventions to improve survivors' health behaviors should incorporate neighborhood-level factors. 10011 **Rapid Oral Abstract Session**

Thematic game intervention as a novel psychosocial support to reduce sedation needs and anxiety in pediatric neuro-oncology patients during radiotherapy: A prospective cohort study (2020–2025). First Author: Fuqiang Zhang, Department of Oncology, Guangdong Sanjiu Brain Hospital, Guangzhou, China

Background: Pediatric neuro-oncology patients undergoing radiotherapy frequently require sedation/anesthesia due to severe anxiety (mYPAS $>$15 in $>$80% cases) and treatment non-compliance. Conventional psychosocial interventions show limited efficacy in reducing sedation dependence, which incurs costs and clinical risks (e.g., respiratory depression). **Methods:** A prospective cohort study (2020–2025) of 246 children (3–5 years) receiving varied radiotherapy regimens (average course: ~30 fractions). Non-randomized allocation with propensity score matching for age, tumor stage, and sedation history: 1. Intervention group (n=122): Structured game-based intervention ("Radiation Warrior Training Camp"). 2. Control group (n=124): Standard psychological support. Primary outcomes: mYPAS anxiety scores, sedation/analgesia usage, treatment compliance, and cost savings (calculated at ¥376/session). **Results:** Sedation avoidance rate : 0% in intervention group vs. 41.1% in controls (OR=0.08, 95% CI [0.03–0.22], p$<$0.001). mYPAS score (median): 8.5 [6.8–3] vs. 17.1 [14.2–19.8] (β=-7.9, [-9.5,-6.3], p$<$0.001). Cost savings: ¥5,512/patient (derived from 82% relative sedation reduction $\times$ 30 fractions $\times$¥376/session). Treatment duration deviation reduced by 29% (p=0.011).Key Findings: 1. 92% of intervention patients completed radiotherapy without sedation. 2. Dose-dependent efficacy: Anxiety reduction correlated with gameplay duration (r=-0.71). 3. Developmental gradient: 5-year-olds achieved 9.2-point mYPAS reduction vs. 6.5-point in younger children. **Conclusions:** Game intervention eliminated sedation needs in 92% of patients, reducing anxiety by 7.9 mYPAS points and yielding ¥5,512/patient cost savings. This model demonstrates high clinical utility and economic efficiency for pediatric radiotherapy support. Research Sponsor: None.

10012 Rapid Oral Abstract Session

Alrizomadlin (APG-115) alone or in combination with lisaftoclax (APG-2575) for the treatment of pediatric patients with relapsed/metastatic rhabdomyosarcoma (RMS) or other soft-tissue sarcomas (STSs). First Author: Yizhuo Zhang, Department of Pediatric Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China

Background: Pediatric tumors rarely harbor *TP53* mutations but often overexpress anti-apoptotic BCL-2 family proteins (BCL-2, BCL-XL, MCL-1), making MDM2 and BCL-2 inhibitors attractive therapeutic approaches. Preclinical data have shown that dual targeting these proteins results in synthetic lethality, which may overcome chemoresistance in pediatric patients with STSs. The study evaluated the safety and preliminary efficacy of alrizomadlin alone or combined with lisaftoclax in heavily pretreated relapsed/metastatic pediatric RMS, neuroblastoma (NB) and other STSs. **Methods:** This Chinese multicenter trial (NCT05701306; APG115XC103) assessed alrizomadlin (± lisaftoclax) in children with heavily pretreated relapsed/metastatic RMS, Ewing sarcoma (EWS), NB, or other STSs; Lansky or Karnofsky PS ≥ 50; and no CNS metastases. Alrizomadlin alone was administered orally at 30, 60, or 90 mg/m^2 QOD (2 weeks on, 1 week off). When combined with lisaftoclax (250, 375, or 500 mg/m^2 oral QD), alrizomadlin dose was 90 mg/m^2 QOD in 21-day cycles until progression or toxicity. The primary endpoints were safety and RP2D for the combination. ORR was assessed per INRC for NB or RECIST v1.1 for other solid tumors. **Results:** As of January 16, 2025, 16 pediatric patients received alrizomadlin monotherapy at 30 (n = 5), 60 (n = 4), or 90 mg/m^2 (n = 7). No DLT was observed; the recommended dose was 90 mg/m^2 when combined with lisaftoclax. Most common TRAEs were gastrointestinal and hematologic. Grade ≥ 3 TRAEs included thrombocytopenia (42.9%) and neutropenia (28.6%). One patient (14.3%) experienced treatment-related SAEs (thrombocytopenia, febrile neutropenia, and leukopenia). No treatment-related discontinuation or death occurred. In the combination arm, 18 patients were treated with alrizomadlin (90 mg/m^2) combined with lisaftoclax at 250 (n = 13) or 375 mg/m^2 (n = 5). No DLT was observed. Most common TRAEs were gastrointestinal and hematologic. Grade ≥ 3 TRAEs included thrombocytopenia (38.9%), neutropenia (33.3%), leukopenia (27.8%), and anemia (27.8%). One (5.6%) treatment-related SAE of thrombocytopenia was reported. No treatment-related discontinuation or death occurred. In monotherapy, 1 patient with refractory RMS achieved CR; 2 patients with STSs maintained stable disease. In the combination arm, 10 patients were evaluable for response, showing 1 CR (EWS), 1 PR among 4 patients with RMS, and 1 PR among 3 patients with NB. ORR (CR + PR) was 30% and DCR 80%. **Conclusions:** Alrizomadlin alone or in combination with lisaftoclax showed a manageable safety profile, with preliminary antitumor activity in heavily pretreated R/R RMS, EWS, and NB. The potential mechanisms, safety, and efficacy of alrizomadlin combined with lisaftoclax for pediatric RMS and other STSs warrant further investigation. Clinical trial information: NCT05701306. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

10013 Rapid Oral Abstract Session

RAPID: A pilot feasibility study of rapid dinutuximab infusion in patients with relapsed/refractory (RR) high-risk neuroblastoma (HRNBL). First Author: Sara-Jane N. Onyeama, Cancer and Blood Disease Institute, Children's Hospital Los Angeles; Keck School of Medicine, University of Southern California, Los Angeles, CA

Background: Dinutuximab is a key component of therapy for HRNBL and is widely used in the RR setting. Standard administration requires inpatient infusions of ~10 hours daily. Emerging pediatric and adult data support shorter infusion durations. Evaluating rapid infusion of dinutuximab (RID) with chemotherapy may reduce pain, facilitate outpatient delivery, and decrease healthcare burden. **Methods:** This prospective, single-institution pilot study enrolled patients from 11/2022-12/2025 following IRB approval. Eligible patients included those ≥1 year old with RR-NBL, adequate organ function, and prior dinutuximab exposure. Patients received chemoimmunotherapy consisting of dinutuximab 17.5 mg/m²/day for 4 days (over 2-4 hours) combined with irinotecan/temozolomide (ITD) or cyclophosphamide/topotecan (CTD) for up to 6 cycles. Outpatient administration was permitted after cycle 1 if tolerated. The primary feasibility endpoint was successful dinutuximab administration over ≤5 hours with ≤1 patient experiencing unacceptable toxicity (UT) during cycle 1 in a 10-patient cohort. Secondary and exploratory endpoints included infusion duration, serial pain scores assessed during and post-infusion, opioid use in morphine milligram equivalents (MME), toxicity, feasibility of outpatient administration, pharmacokinetics (PK) and human anti-chimeric antibody (HACA). Changes in MME were compared using a one-sample t-test. **Results:** Eleven patients (median age 14 years, range: 3-24) received ITD (n=6) or CTD (n=5). All patients met the primary feasibility endpoint. Median infusion time was 2 hours (range 2-4) across all cycles. One patient (3 years old), enrolled in the early post-transplant period developed UT (grade 3 ventricular dysfunction). The protocol was amended to exclude patients within 6 months of transplant, require dinutuximab tolerance within 2 months, and extend cycle 1 infusion to 4 hours for patients <12 years of age; this patient was replaced per protocol. Across cycles 1-6, mean pain score was 0.4 (SD 0.46), and mean opioid usage was 0.04mg/kg MME (SD 0.07), reflecting a 78% reduction of opioid use in cycle 1 RID compared to the pre-enrollment standard-infusion cycle ($p<0.001$). Outpatient RID was administered in seven patients without hospital admission; 1 patient was admitted for chemotherapy-related toxicity, 3 patients remained inpatient (social reasons). RID showed expected PK levels; HACA was noted in 1 patient. Most common grade 3 toxicities (27%): increased ALT and hypokalemia; 1 patient (with UT) had grade 4 toxicity (dyspnea, hypocalcemia). **Conclusions:** RID was feasible and well tolerated, including in the outpatient setting. Pain control was achieved with standard premedication and significantly reduced opioid requirements compared with standard infusion. These data support planned multi-institutional evaluation of RID. Clinical trial information: NCT05421897. Research Sponsor: United Therapeutics.

10014 Rapid Oral Abstract Session

Interim analysis of CaboMain: A prospective, single-arm phase 2 clinical trial of cabozantinib as maintenance therapy for patients with "ultra-high-risk" pediatric solid tumors. First Author: Nilay Shah, Nationwide Children's Hospital, Columbus, OH

Background: There are patients with pediatric solid tumors, including those with relapsed/refractory disease, with "ultra-high" risk (UHR) disease (1-year progression free survival (1-yr PFS) <25%) even when achieving disease control. Most pediatric solid tumors do not have a therapeutically-targetable oncogenic driver, limiting treatment options for maintenance therapy. Cabozantinib is a multitargeted tyrosine kinase inhibitor with demonstrated activity against many solid tumors, with a defined safety profile and dosing in pediatric and young adult patients. We hypothesize that use of cabozantinib for 1 year, after achieving disease control, can improve 1-yr PFS to ≥ 45%. **Methods:** We are performing a multisite, open-label, single-arm Phase 2 clinical trial for patients with pediatric solid tumors with 4 strata; Stratum A, primary stratum for analysis, enrolls patients with UHR disease. Patients must have completed prior therapy at least 4 weeks and no longer than 12 weeks before enrollment with stable disease or better at time of enrollment. Enrolled patients receive cabozantinib as per dosing nomogram at 40 mg/m^2/day, taken for up to 365 days from start of therapy. Primary outcome is 1-yr PFS, with Bayesian time-to-event optimal phase 2 design for analysis. Interim analysis follows the rules: assuming a Beta (0.25,0.75) prior distribution for efficacy and 88% statistical power, at interim at least 5/18 evaluable patients must have achieved 1-yr PFS to justify ongoing enrollment. Interim analysis reporting has been recommended by the Data Safety and Monitoring Committee. **Results:** We report the interim results as of 11/1/2025, which includes all enrolled patients on Stratum A who have reached 1 year after start of therapy (n=13). Eight of thirteen patients reached 1-yr PFS; by diagnosis, neuroblastoma (NBL) = 2, Ewing sarcoma (EWS)= 3, osteosarcoma (OST)= 3. Of those not reaching the one-year time point, 2 patients progressed after voluntarily discontinuing cabozantinib (1 NBL, 1 month after discontinuation; 1 OST, 5 months after discontinuation), 1 NBL elected radiation therapy and was removed from study, and 2 OST progressed on study treatment. Having reached the interim analysis benchmark, enrollment continues. Three additional strata (metastatic EWS, metastatic OST, and fusion-positive metastatic rhabdomyosarcoma, each at end of 1st line therapy) also continue to enroll, as secondary endpoints. Longer-term PFS and overall survival, patient reported outcomes, and exploratory biological measures continue to be tabulated for later analysis. **Conclusions:** Use of cabozantinib as maintenance therapy, after prior treatment and achievement of stable disease or better response, has been determined to be feasible to demonstrate improvement of 1-yr PFS by at least 20%, and ongoing enrollment is justified. Clinical trial information: NCT05135975. Research Sponsor: Exelixis, Inc.

Phase II trial of olaparib and ceralasertib in patients with recurrent osteosarcoma: Lung-only resectable cohort efficacy and correlative biomarker results. First Author: Suzanne J. Forrest, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Patients with osteosarcoma recurrence have limited treatment options and poor outcomes. The observed response to cisplatin in osteosarcoma, in vitro susceptibility of osteosarcoma cell lines to ATR and PARP inhibitors, and the presence of mutations in genes involved in DDR served as the basis for the development of this trial. **Methods:** We conducted a phase II trial of olaparib and ceralasertib in patients aged 12-40 with recurrent osteosarcoma. The primary endpoint for patients with resectable disease limited to the lung (Cohort 2) was submission of paired pre- and post-treatment tumor samples. Secondary endpoints for Cohort 2 included event-free status at 12-months, event-free survival (EFS) and overall survival (OS). Patients received Olaparib 150mg twice a day on days 1-28 and ceralasertib 80mg twice a day on days 1-14 of a 28-day cycle. Patients with unilateral disease received 2 cycles of treatment prior to surgery. Patients with bilateral disease had one side resected, then received 2 cycles of treatment followed by surgery of the contralateral side. Tumor, blood and plasma samples were obtained from Cohort 1 (measurable unresectable disease, efficacy results previously reported) and Cohort 2 patients for correlative studies. **Results:** Between 3/2021-9/2024, 10 patients from 4 centers were enrolled in Cohort 2. Four patients had bilateral and six had unilateral lung metastases. Median age was 19.3 (range 15.7-24.6). Patients had received a median of three prior therapy regimens. Seven patients (70%, 95%CI: 35%-93%) underwent planned thoracic surgery and had paired pre- and post-treatment tumor samples submitted for correlative studies. Four patients (40%, 95%CI: 12%-74%) were event-free at 12 months and received >12 cycles of olaparib and ceralasertib. The 12-month EFS±SE and OS±SE were 40±15.5% and 90±9.5%, respectively. Initial review of clinical sequencing on a subset of Cohort 1 and 2 patients suggests therapy resistance may be associated with high-risk genomic features, like MYC amplification. **Conclusions:** Patients with recurrent resectable osteosarcoma limited to the lung parenchyma can be included as a separate cohort in phase II trials of novel agents. In this cohort, it is feasible to incorporate pre-surgical treatment with experimental agents followed by surgical resection of pulmonary nodules and collection of pre- and post-treatment tumor samples, enabling correlative biology. 12-month EFS was 40% but with a wide confidence interval crossing the confidence interval of historical 12-month EFS of 20% from prior COG studies. Sequencing and ctDNA analyses for all enrolled patients (both cohorts) with available samples (N=40 patients with tumor samples and N=48 patients with ctNDA samples) are underway to further assess potential biomarkers of treatment response. Clinical trial information: NCT04417062. Research Sponsor: St. Baldrick's Foundation; Osteosarcoma Institute; Alex's Lemonade Stand.

10016 Rapid Oral Abstract Session

Characterization and validation of a methylation signature as a prognostic marker in osteosarcoma. First Author: Rachel M. Hurley, Children's Hospital of Philadelphia, Philadelphia, PA

Background: Despite extensive research efforts, outcomes for patients with osteosarcoma have not substantially improved since the 1980s. Moreover, no prognostic features are used clinically to risk adapt therapy. Here, we performed methylation and RNA sequencing of pre-treatment osteosarcoma tumor samples to identify distinct features of tumor biology and to generate and validate a prognostic signature. **Methods:** All patients diagnosed with osteosarcoma at the Children's Hospital of Philadelphia (CHOP) before March 15, 2024 with tissue available for analysis were eligible. Of the 100 eligible patients, three were excluded for lack of clinical data and one for initial diagnostic uncertainty. Methylation and RNA sequencing were performed on DNA and RNA extracted from FFPE or frozen tumor. Unsupervised analyses characterized global methylation structure and differential methylation analyses compared differences between progression groups. Tumor and immune cell fractions were estimated using a reference-based deconvolution algorithm. CpGs were filtered using an unsupervised variability criterion (top 20% MAD) and a ridge-penalized Cox model was used to derive a methylation risk score as a linear predictor. The publicly available TARGET-OS cohort was used for validation with median-based risk stratification defined in the CHOP cohort. **Results:** Of 96 patients, 44 patients had pre-treatment samples that passed methylation QC and 13 passed RNA sequencing QC. Within the CHOP cohort, 34/44 (77%) had localized disease with a median age of 13 years. Variability in methylation profiles was driven by leukocyte infiltration, supported by strong correlations between global methylation levels and mitotic index estimates. Tumors from patients with progressive disease displayed 12,338 significantly different CpGs (FDR < 0.01) and enriched for hypomethylated CpGs. A methylation-derived risk score was established for overall survival (OS) in the CHOP cohort. In multivariable Cox models, the methylation risk score remained significantly associated with OS (HR 1.54 [1.05–2.26]; p = 0.026) together with metastatic status (HR 5.13 [2.49–10.59]; $p < 0.001$), yielding improved model discrimination (C-index 0.77 [0.70–0.83]). This was replicated in event-free survival (EFS, HR 2.49 [1.49,4.19], $p<0.01$). In the TARGET-OS cohort, after adjustment for metastatic status, methylation risk score remained independently associated with EFS (HR 1.6 [1.15, 2.23], p = 0.005). and OS (HR 1.54 [1.05, 2.26], p = 0.003). **Conclusions:** In this single-institution cohort analysis, a methylation-based risk score predicts survival and adds prognostic value when combined with metastasis status. Integration of CpG methylation with downstream pathway activation via RNA sequencing is ongoing and will be reported. Further validation of this prognostic signature should be considered in future osteosarcoma trials. Dexamethasone-free antiemetic prophylaxis with olanzapine in children and adolescents receiving highly emetogenic chemotherapy: A multicenter, phase III non-inferiority randomized trial. First Author: Venkatraman Radhakrishnan, Cancer Institute (WIA), Chennai, India

Background: Dexamethasone, with a 5-HT3 receptor antagonist and a neurokinin-1 antagonist, is the guideline-recommended prophylaxis for chemotherapy-induced nausea and vomiting (CINV) in children and adolescents receiving highly emetogenic chemotherapy (HEC), but is associated with clinically relevant toxicities. The role of olanzapine as a dexamethasone-sparing agent for pediatric CINV prophylaxis remains uncertain. **Methods:** This investigator-initiated, multicenter, open label, phase III randomized non-inferiority (NI) trial (INPHOG-SUPP-22-03) enrolled patients aged 4–18 years receiving single or multi-day HEC. Patients were randomized 1:1 (single chemotherapy cycle) to receive dexamethasone, palonosetron, and fosaprepitant (DEX; standard-of-care) or olanzapine, palonosetron, and fosaprepitant (OLANZ; dexamethasone-free). The primary endpoint was complete response (CR) to vomiting (no vomiting and no rescue anti-emetics) during the overall period (0–120 h after the last chemotherapy dose). A NI margin of -15% was prespecified based on adult dexamethasone-sparing trials. Assuming a control CR rate of 70% from prior pediatric studies, 310 patients provided 80% power at a one-sided α of 0.025, allowing for 5% dropout. Absolute differences in CR rates were analyzed using the Miettinen–Nurminen method; NI was concluded if the lower bound of the 95% confidence interval (CI) was above -15%. **Results:** Between December 2022 and January 2026, 310 patients were randomized (DEX, n=156; OLANZ, n=154). The per-protocol (PP) population included 299 patients (DEX, n=151; OLANZ, n=148). Median age was 13 years; 62.2% were male, and 56.8% received multi-day HEC. In the PP population, the CR rate for vomiting during the overall period was 56.9% in the DEX arm and 63.5% in the OLANZ arm (absolute difference, 6.6%; 95% CI, -4.5% to 17.7%). Non-inferiority was demonstrated, as the lower 95% CI (-4.5%) was above -15%. Results were consistent in the intention-to-treat population. For secondary endpoints, CR to vomiting during the acute period (0-24 h) was 64.2% vs 68.9%, and during the delayed period (24-120 h) 78.8% vs 79.1%, in the DEX and OLANZ arms, respectively. CR to nausea during the overall period was 54.3% vs 53.4%, during the acute period 59.6% vs 59.5%, and during the delayed period 69.5% vs 68.9%, respectively. Grade $\geq$2 non-hematologic and hematologic laboratory toxicities were uncommon and similar between arms. Any-grade somnolence was significantly higher with OLANZ than DEX (52.0% vs 25.8%), with all events being $\leq$ grade 2. **Conclusions:** A dexamethasone-free antiemetic regimen was non-inferior to standard dexamethasone-based prophylaxis for prevention of vomiting in children and adolescents receiving HEC. These findings support the use of olanzapine as an effective steroid-sparing alternative. Clinical trial information: CTRI/2022/08/045009. Integrating genomics, imaging, and clinical data for late-onset cardiomyopathy prediction in pediatric cancer survivors: A multi-modal machine-learning comparison using St. Jude Cloud. First Author: Masab Mansoor, Edward Via College of Osteopathic Medicine, Monroe, LA

Background: Pediatric cancer survivors face substantial risk of anthracycline- and radiation therapy (RT)-related cardiomyopathy (CM). Current risk stratification using clinical factors alone demonstrates suboptimal discriminative capacity. We hypothesized that integrating multi-modal data (clinical, genomic, and cardiac imaging/electrocardiography) would enhance predictive accuracy for late-onset CM beyond single-modality models. **Methods:** We analyzed data from 1,217 adult survivors of childhood cancer enrolled in the St. Jude Lifetime Cohort (SJLIFE), accessed via St. Jude Cloud. The primary endpoint was CM, defined as left ventricular ejection fraction (LVEF) $<$50% or $\geq$10% absolute decline from baseline. Four progressively complex feature sets were evaluated: (1) Clinical-Only (anthracycline/RT dose, age at diagnosis, sex); (2) Clinical+Genomic (adding 31 protective variants from PeCan); (3) Clinical+ECG/Imaging (adding 86 signal-processed ECG features and global longitudinal strain [GLS]); and (4) Multi-Modal (comprehensive integration). Logistic regression, random forest (RF), and extreme gradient boosting (XGBoost) algorithms were compared using 5-fold stratified cross-validation. Model interpretability was assessed via SHapley Additive exPlanations (SHAP) analysis. **Results:** Clinical-Only models demonstrated limited discrimination (AUC 0.70; 95% CI, 0.65-0.75). Incremental addition of genomic data (AUC 0.85) or ECG/GLS parameters (AUC 0.89) substantially improved performance. The Multi-Modal XGBoost model achieved superior predictive accuracy (AUC 0.93; 95% CI, 0.90-0.95; sensitivity 0.88; specificity 0.89), marginally outperforming RF (AUC 0.91). SHAP analysis identified GLS as the dominant predictor, followed by cumulative anthracycline dose and protective genomic variants, demonstrating synergistic contribution of multi-modal features. **Conclusions:** Multi-modal machine learning integration using open-source St. Jude Cloud data enables highly accurate prediction of late-onset CM in pediatric cancer survivors (AUC 0.93). The demonstrated superiority over single-modality approaches supports a paradigm shift toward comprehensive risk stratification. This XGBoost-based model could facilitate precision survivorship care, enabling risk-adapted surveillance intensification and early cardioprotective intervention for high-risk patients. Research Sponsor: None.

Comparative performance of machine learning models for 10-year cardiomyopathy risk prediction.

Model Type	Algorithm	AUC (95% CI)	Sensitivity	Specificity
Clinical-Only	Log. Reg.	0.70 (0.65-0.75)	0.62	0.66
Clinical + Genomic	Random Forest	0.85 (0.81-0.89)	0.79	0.82
Clinical + ECG/GLS	XGBoost	0.89 (0.86-0.91)	0.78	0.81
Multi-Modal (Full)	XGBoost	0.93 (0.90-0.95)	0.88	0.89

Longitudinal genomic characterization of pediatric acute myeloid leukemia at diagnosis and relapse. First Author: Jagdish Prasad Meena, All India Institute of Medical Sciences, New Delhi, India

Background: Relapse remains the leading cause of treatment failure and mortality in pediatric acute myeloid leukemia (pAML). In AML, relapse is common and is increasingly recognized as a consequence of therapy-driven clonal evolution rather than mere persistence of the diagnostic clone. This study aimed to delineate mutational trajectories from diagnosis to relapse and identify relapse-associated genomic alterations of potential clinical relevance. **Methods:** This prospective study was conducted from July 2021 to December 2025. Bone marrow or peripheral blood samples were collected from children $\leq$18 years at diagnosis and relapse. Genomic DNA from paired samples was sequenced exomically to identify somatic mutations. Longitudinal comparative analyses assessed clonal persistence, emergence of relapse-specific mutations, and pathway-level enrichment. **Results:** A total of 100 children with AML were enrolled. Paired longitudinal analysis (n=18) identified 133 mutated genes. Seventy-nine (59.4%) were shared between diagnosis and relapse, forming a conserved truncal genomic backbone. Fifty genes (37.6%) were exclusive to diagnosis, while only four (3.0%) were exclusive to relapse, suggesting strong therapeutic selection pressure rather than widespread genomic diversification. At diagnosis, missense variants predominated (88.4%), followed by in-frame insertions/deletions (6.5%), nonsense (2.4%), and frameshift alterations (2.5%). Relapse samples showed further enrichment of missense variants (90.5%) and a relative depletion of truncating events, consistent with selection for functionally adaptive mutations. Truncal alterations were consistently observed in epigenetic regulators TET2 and KMT2C, supporting their role as early leukemogenic events. In contrast, relapse samples showed enrichment of signaling and transcriptional regulators, including FLT3 and PTPN11, along with relapse-exclusive emergence of WNT pathway components (FZD7, LEF1) and the PI3K regulator PIK3R1. Functional enrichment analysis revealed that diagnostic samples were primarily enriched for DNA damage response, p53 signaling, apoptosis, and cell-cycle checkpoint pathways ($p<0.05$). At relapse, these core programs persisted alongside marked enrichment of oncogenic signaling pathways (WNT, PI3K–AKT, FLT3) and metabolic processes, including glycolysis and ATP generation. Reactome analysis highlighted convergence on FLT3- and AKT-driven signaling, TP53-mediated DNA repair, and escape from apoptosis. **Conclusions:** Longitudinal genomic profiling demonstrates that pAML relapse is driven by the persistence of early truncal mutations, coupled with the selective expansion of signaling- and metabolism-adapted subclones. Enrichment of WNT, PI3K–AKT, and FLT3-associated pathways at relapse reveals potential targets for relapse-directed precision strategies. Research Sponsor: Indian Council of Medical Research.

Distinct immunologic vs progenitor landscapes in myeloid leukemia recurrence: Adaptive immune persistence in pediatrics vs niche exhaustion in adults. First Author: Karen Dong-Tran, UNR School of Medicine, Reno, NV

Background: Recurrent myeloid leukemia remains a therapeutic challenge with distinct clinical trajectories across age groups. While our parallel study identified a "universal adipogenic shift" in the marrow stroma common to all ages, the specific cellular drivers distinguishing pediatric from adult relapse remain undefined. We hypothesized that against this shared stromal background, the mechanism of recurrence diverges: the pediatric marrow mounts an adaptive immune response, whereas the aging adult marrow suffers from hematopoietic reservoir depletion. **Methods:** We analyzed the tumor microenvironment (TME) of 2,378 myeloid leukemia samples (2,007 primary, 371 recurrent) using xCell transcriptomic deconvolution. The cohort was stratified into Pediatric ($<$ 18y, n = 2,071) and Adult ($\geq$ 18y, n = 307) subgroups to control for ontogenic baselines. We compared differential expression rankings between primary and recurrent states using Mann-Whitney U tests with Bonferroni correction (Padj) to identify age-specific dominance in TME remodeling. **Results:** Comparative analysis revealed divergent TME landscapes between age groups. In pediatrics, recurrence was characterized by an "Immune-Adaptive" program; CD4+ Memory T-cells were the dominant signature (rank 4, $p < 10^{-27}$), alongside significant increases in Preadipocytes ($p < 10^{-49}$) and pro-B cells. Conversely, adult recurrence exhibited "Niche Exhaustion," primarily losing hematopoietic progenitors (CMP/GMP, $p < 10^{-7}$) and mesenchymal stem cells (MSC, $p < 10^{-9}$). While CD4+ Memory T-cells increased in adults, the signal was less prominent (rank 18, $p < 10^{-5}$). Both groups shared significant vascular collapse (Pericyte loss, $p < 10^{-7}$), identifying it as a universal hallmark of relapse. **Conclusions:** Myeloid leukemia recurrence is driven by age-distinct microenvironmental remodeling. Pediatric relapse is defined by immune adaptation and adipogenesis, while adult relapse is characterized by progenitor and niche exhaustion. Vascular collapse represents a universal therapeutic target. These findings suggest that immunotherapy and niche-directed treatments must be tailored to the patient's age-specific TME landscape to improve outcomes. Research Sponsor: None.

Top age-specific trends in recurrent vs. primary myeloid leukemias.

Cohort	Cell Type	Direction	Mean Diff (Rec - Pri)	Padj
Pediatric (<18y)	Pericytes	Primary- High	-0.085	$P < 0.05$
	Preadipocytes	Recurrence- High	+0.064	$P < 0.05$
	MSC	Primary- High	-0.099	$P < 0.05$
	CD4+ Memory T-cells	Recurrence- High	+0.849	$P < 0.05$
	pro-B cells	Recurrence- High	+0.301	$P < 0.05$
Adult (≥18y)	MSC	Primary- High	-0.165	$P < 0.05$
	Pericytes	Primary- High	-0.078	$P < 0.05$
	CMP	Primary- High	-0.526	$P < 0.05$
	Smooth muscle	Primary- High	-0.094	$P < 0.05$

The burden of childhood cancers in the South Asian Association for Regional Cooperation (SAARC) region: A GLOBOCAN 2022 analysis. First Author: Tara Pattilachan Menon, Virginia Tech Carilion School of Medicine, Roanoke, VA

Background: Countries of the South Asian Association for Regional Cooperation (SAARC) are home to approximately 600 million children aged 0–14 years, representing a quarter of the global child population. We report incidence and mortality for childhood cancers among South Asia's eight nations to inform priority setting for research, programming for health services, and policy for childhood cancers. **Methods:** Incidence and mortality of new childhood cancer diagnoses for all cancers combined and for selected leading diagnostic groups were retrieved from the GLOBOCAN 2022 database of Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka. Age-standardized incidence rates (ASR) and mortality-to-incidence ratios (MIR) were calculated, together with statistical examination of cross-country variation in diagnostic structure and survival trends. **Results:** In SAARC nations, 37,716 new childhood cancer diagnoses and 17,700 deaths were estimated in 2022. India contributed 68.7% of subregional cases (25,939), and Pakistan contributed 20.8% (7,841). Age-standardized rates differed and were greatest in Sri Lanka (10.4/100,000) and Pakistan (10.1) and lowest in Bhutan (2.3) and Bangladesh (3.7). Boys represented 60% of cases overall, with significant cross-country variation in sex distribution (χ^2=18.0, p=0.012). Leukemia was the most common cancer in all countries (35–50%), followed by central nervous system (CNS) tumors. MIR ranged from 0.30 (Sri Lanka) to 0.57 (Afghanistan), reflecting extreme survival differences, with CNS tumors demonstrating disproportionately high mortality relative to incidence. **Conclusions:** SAARC childhood cancer trends reflect both population size influences and health system capacity, with a preponderance of leukemia but alarming survival gaps, particularly for CNS cancers. These findings highlight actionable priorities, including strengthening population-based childhood cancer registries, centralizing care pathways for CNS tumors, expanding standardized leukemia treatment protocols with abandonment-prevention strategies, and improving equitable access to specialty care through subregional collaboration. 10023 Poster Session

A capacity assessment of pediatric oncology research biorepositories across a regional collaborative group in the Middle East, North Africa, and Asia. First Author: Sushmitha Grama Srinivasan, Stanford University School of Medicine, Palo Alto, CA

Background: Biobanks advance translational research in pediatric oncology. Understanding the existing biobanking infrastructure is critical for fostering collaboration and improving research capacity in low- and middle-income countries (LMICs). **Methods:** A previous research capacity survey within institutions of the Pediatric Oncology East and Mediterranean (POEM) Group collaborative network identified 26 out of 69 institutions across 23 countries, with access to clinical tissue specimens for research use. We surveyed these centers regarding sample/data management, patient population, governance, standard operating procedures (SOPs), quality systems, and funding. This study was determined non-human subjects research by the Stanford IRB. Biobanking capacity and participation were evaluated using descriptive statistics (medians, ranges, and frequencies). **Results:** Fifteen of the 26 (58%) institutions confirmed that they have a research-specific biobank; 10 of 15 (67%) participated. All surveyed biobanks collect cancer samples using broad consent, and have ongoing funding through institutional support, external collaborations or both. Principal investigators lead 20% of the biobanks, the others are institution-based and led. A median of 7 staff are involved in biobanking activities per institution (range, 3–28). Most institutions (80%) rely on Microsoft Excel for sample tracking. A quality management system is implemented in 7 of 10 (70%) of institutions, with most adhering to ISBER best practices. Five of 10 (50%) of the biobanks lack disaster management SOPs. Eight of 10 (80%) biobanks are capable of sharing samples and associated clinical data with other institutions through material/data sharing agreements. A median of 3500 samples (range, 368–6000) are stored yearly with a median of 300 samples (range, 100–1000) released for authorized research. While most biobanks viewed their national legal frameworks as supportive, 2 biobanks (20%) indicated that national regulations constrain biobanking activities. All the respondents indicated a need to improve their national regulation to support ethical biobanking practices – specifically need for improved regulation for cross-border collaborations, data privacy, and intellectual property (60%, 40% and 30%, respectively). **Conclusions:** Biobanks exist in 21.7% (15 of 69) centers within the POEM group. Biobanks in the region have robust consenting and sample collection procedures. Significant opportunities exist to enhance capacity through implementation of international quality standards, and improved disaster preparedness. Further understanding of the determinants of successful initiation and maintenance of these biobanking efforts in LMICs will guide targeted initiatives to further expand regional biobanking infrastructure and augment research collaborations. Cancer outcome among adolescents in Canada. First Author: Samuel Sassine, Division of Pediatric Hematology-Oncology, Department of Pediatrics, Charles-Bruneau Cancer Center, CHU Sainte-Justine, Montreal, QC, Canada

Background: Adolescents and young adults (AYA) with cancer, commonly defined as patients aged 15–39 years at diagnosis, experience higher morbidity and mortality compared with other age groups. In this study, we compared outcomes of adolescents with newly diagnosed cancer treated at Canadian pediatric oncology centers with those of younger children. **Methods:** We conducted a retrospective cohort study using the population-based CYP-C database, including children aged 1–18 years with newly diagnosed cancer across Canada (2015–2020). Event-free survival (EFS) and overall survival (OS) were compared between adolescents (15–18 years) and younger children (1 to $<$15 years) across cancer subtypes using Kaplan–Meier analyses and univariable and multivariable Cox proportional hazards models. **Results:** Of the 6,794 patients, adolescents aged 15–18 years comprised 16% (n=1,075) of the cohort. Median age at diagnosis was 16 years (IQR: 15.7–17.2), and among those with solid tumors, 26% (n=150) had metastatic disease at diagnosis. The most frequent adolescent cancers were Hodgkin lymphoma (20%), gliomas and other glioneuronal tumors (12%), acute lymphoblastic leukemia (11%), osteosarcoma (6%), thyroid carcinoma (6%), malignant extracranial germ cell tumors (5%), and Ewing sarcoma (4%). Adolescents with leukemia had comparable 5-year EFS (71% vs. 79%; p=0.06) and OS (83% vs. 89%; p=0.07) to younger children, as did those with non-central nervous system (CNS) solid tumors for EFS (65% vs. 65%; p=0.55) and OS (74% vs. 75%; p=0.23). Among patients with sarcomas, adolescents had similar 5-year EFS (50.7% vs. 52.0%, p=0.55) and OS (55.6 vs. 59.7%, p=0.14) to younger children. Adolescents with CNS tumors had superior EFS (83% vs. 66%; p=0.005) and OS (89% vs. 73%; p=0.006), primarily driven by ependymoma and choroid plexus tumors, and other gliomas/glioneuronal tumors excluding pilocytic astrocytoma. **Conclusions:** Although AYA with cancer are often reported to have poorer outcomes, adolescents aged 15–18 years treated exclusively in Canadian pediatric oncology centers did not have inferior outcomes to younger children, underscoring the effectiveness of pediatric treatment approaches. Research Sponsor: None.

5-year EFS and 5-year OS of adolescents (≥15 years-old) vs. younger children (1 to < 15 years old) across major cancer categories.

-	Adolescents 5-year EFS (%) [95% CI]	Younger children 5-year EFS (%) [95% CI]	p-value	Adolescents 5-year OS (%) [95% CI]	Younger children 5-year OS (%) [95% CI]	p-value
All cancers	76.4 [72.8-79.9]	72.6 [70.8-74.3]	0.12	84.7 [81.4-87.4]	81.1 [79.6-82.7]	0.13

Beyond translation: Leveraging interpreter expertise to enhance clinician training and language equity in pediatric oncology. First Author: Joseph S. Kang, Stanford University School of Medicine, Palo Alto, CA

Background: Medical interpreters play a critical role in pediatric oncology beyond translation by guiding conversations, interpreting cultural and emotional cues, and ensuring families with limited English proficiency (LEP) can access medical information. Yet few clinician training resources focus on interpreter-mediated communication. This study aimed to (1) identify communication best practices and challenges from the perspective of professional medical interpreters and (2) develop an educational toolkit for clinicians to promote equitable, patient-centered communication for families with LEP. **Methods:** We conducted semi-structured individual interviews and a focus group with Spanish medical interpreters from six freestanding children's hospitals across the United States between 12/2024-10/2025. Verbatim transcripts were thematically analyzed in Dedoose, and resulting themes directly informed creation of an educational toolkit. **Results:** Sixteen interpreters (15 female, 1 male) who provide in-person interpretation participated. Benefits of in-person professional interpretation included perceiving non-verbal communication cues, serving as patient/family advocates, providing cultural and linguistic tailoring, explaining idiomatic or metaphorical clinical language, and continuity of interpreters across visits. Challenges included fragmented communication across medical teams, limited clinician understanding of cultural nuance, exclusion of parents from conversations, and remote interpreting. Based on these themes, we developed recommendations for clinicians focused on building collaborative relationships with interpreters, allowing time for interpretation, and actively checking patient and family understanding. We then designed a toolkit comprising three resources for clinicians working with interpreters: a badge reference card with a pre-, during-, and post-visit checklist; a decision-making learning module with case-based, first-person scenarios navigating interpreter-mediated encounters; and a self-paced modular course with structured lessons for in-depth learning. **Conclusions:** Interpreters identified concrete practices that enhance patient-centered care, with particular strengths evident during in-person interpretation, and challenges that undermine equitable communication. These insights informed a clinician-facing educational toolkit to improve interpreter-clinician encounters. Future studies will pilot the toolkit with ongoing, iterative refinement guided by interpreter input. Research Sponsor: Conquer Cancer, the ASCO Foundation; 2023CDA-5176592918.

Immunogenicity profiles in pediatric extra-cranial rhabdoid tumors: A framework for future risk stratification. First Author: Omnia Al Qadi, Department of Pediatric Oncology, Children Cancer Hospital Egypt, Cairo, Egypt

Background: Malignant rhabdoid tumors (MRTs) are highly aggressive pediatric cancers driven by SMARCB1 loss. Emerging evidence suggests that the tumor immune microenvironment may influence the biological behavior of tumors. However, data on immune patterns in extra-cranial MRTs remain extremely limited, particularly in low- and middle-income settings. This study characterizes immune marker expression and immune phenotypes in a large single-center cohort to explore their potential relevance for future risk stratification. **Methods:** Formalin-fixed paraffin-embedded specimens from pediatric extra-cranial MRTs were evaluated for $CD4^+$, $CD8^+$, and $CD68^+$ immune infiltrates using immunohistochemistry. Marker expression was categorized as high or low. Tumor immune phenotypes were subsequently classified based on the balance of infiltrating populations into: (immune-cold (uniformly low), mixed (variable across markers), and inflamed (uniformly high). Associations between immune phenotypes, clinicopathologic features, and survival trends were explored to determine whether immune architecture could serve as a biologically meaningful correlate of clinical behavior. **Results:** Individually, none of the immune markers (CD4, CD8, CD68) showed statistically significant correlation with overall survival. However, higher $CD4^+$ and $CD8^+$ T-cell infiltration demonstrated a consistent trend toward improved clinical outcomes. The most informative observation emerged at the phenotype level: tumors with a mixed immune profile exhibited more favorable survival trends and delayed progression compared with immune-cold tumors, whereas fully inflamed tumors were rare. These findings suggest that the equilibrium and interaction of immune infiltrates—rather than absolute immune cell density—may shape clinical behavior. **Conclusions:** Pediatric extra-cranial MRTs demonstrate distinct immune microenvironment patterns that are readily identifiable using routine immunohistochemistry. Although individual immune markers did not independently predict survival, immune-cold versus mixed phenotypes reflected meaningful biological divergence and aligned with clinical outcomes. Integrating immune phenotyping into diagnostic workflows may provide a pragmatic foundation for future risk stratification and help identify patients most likely to benefit from emerging immuno-epigenetic treatment strategies. Statement of Clinical Significance: Immune profiling using routine immunohistochemistry can classify pediatric extra-cranial rhabdoid tumors into clinically relevant immune phenotypes. Identifying immune-cold versus mixed tumors may support future risk stratification and guide biologically informed treatment selection. Research Sponsor: None.

Peptide receptor radionuclide therapy with ^{177}Lu-DOTATATE in pediatric, adolescent, and young adult neuroendocrine tumors: A single-center experience from Bambino Gesù Children's Hospital. First Author: Maria Debora De Pasquale, Bambino Gesù Children's Hospital (IRCCS), Rome, Italy

Background: Neuroendocrine tumors (NETs) in pediatric, adolescent, and young adult (AYA) patients are rare and often associated with hereditary syndromes such as Von Hippel Lindau (VHL) and type 1 neurofibromatosis (NF1). Peptide receptor radionuclide therapy (PRRT) with ^177Lu-DOTATATE is well established in adults with somatostatin receptor–positive NETs, but data in younger populations remain limited. We report our single-center experience evaluating feasibility, safety, and efficacy of PRRT in this age group. **Methods:** We retrospectively analyzed patients $<$20 years treated with ^177Lu-DOTATATE at Bambino Gesù Children's Hospital between 2019 and 2025. Eligibility required somatostatin receptor expression confirmed by PET-DOTA imaging (Krenning score $\geq$2). Data included demographics, age at diagnosis and PRRT, tumor characteristics, prior therapies, PRRT cycles, cumulative dose, toxicity, and best response per RECIST. Follow-up status was assessed at last visit. **Results:** Six patients (median age at diagnosis 11 years, range 7–16; median age at PRRT 15 years, range 10–19) received PRRT for metastatic or unresectable NETs (pheochromocytoma/paraganglioma, n=5; bronchial carcinoid, n=1). All completed 4 cycles of ^177Lu-DOTATATE (median cumulative dose ~30 GBq). Prior treatments included surgery, chemotherapy (temozolomide), and MIBG therapy. No grade $\geq$3 hematologic or renal toxicity occurred; treatment was well tolerated. Best responses: 4 partial responses (PR), and 2 stable disease (SD). At a median follow-up of 18 months, all patients were alive: one in complete remission after surgery, others with stable disease or ongoing therapy. Genetic predisposition was present in 3 patients (VHL, NF1). SUVmax on baseline PET ranged from 1.2 to 43.8, correlating with Krenning score $\geq$2 in all cases. **Conclusions:** PRRT with ^177Lu-DOTATATE is feasible and well tolerated in pediatric, adolescent, and young adult patients with somatostatin receptor–positive NETs, achieving meaningful disease control with minimal toxicity. This single-center experience supports PRRT as a valuable option in selected cases and highlights the need for prospective studies and age-specific guidelines. Research Sponsor: None.

Clinical impact of panel-based next-generation sequencing in a real-world cohort of neuroblastoma patients. First Author: Samantha Martin, Dana-Farber/Boston Children's Cancer and Blood Disorders Center; Harvard Medical School, Boston, MA

Background: Neuroblastoma is a malignant childhood tumor with a low somatic mutation rate, making targeted therapy challenging. Using a targeted NGS panel in a large real-world cohort, we identified recurrent variants and assessed the clinical impact of NGS for this disease. **Methods:** A real-world cohort of 185 peripheral neuroblastic tumor samples from 181 patients were sequenced with a targeted NGS assay (OncoPanel). Samples were either obtained at baseline ("diagnostic") or at relapse/progression ("relapse"). Variants include SNVs, CNAs, and SVs and were manually curated for pathogenicity. Recurrently altered genes were those curated as Pathogenic/Likely Pathogenic and occurring in more than 4% of samples. Clinically impactful findings were those with therapeutic implications (e.g., targetable *ALK* aberration) and those with prognostic implications at diagnosis (e.g. *MYCN* amplifications or segmental chromosomal aberrations (SCAs) included in the Children's Oncology Group (COG) risk stratification system). SCAs were defined as regions of loss or gain of at least 3Mb. Mutual exclusivity analyses utilized false-discovery rate corrected Fisher exact tests. **Results:** All COG risk groups were represented. At time of last follow-up (median 65.9 months), 103 (59%) were alive with no disease, 31 (18%) were alive with disease or unknown disease status, and 41 (23%) were deceased. Of the diagnostic cohort (n=144), 78 (54%) had at least one clinically impactful alteration (n=42 prognostic only, n=13 therapeutic only, n=23 both). Of the relapse cohort (n=41), 14 (34%) had a therapeutically impactful variant. Recurrently altered genes in the diagnostic samples included *MYCN*, *ALK*, *ATRX* and *MYCN*, *ALK*, *ATRX*, *BRAF*, *CREBBP*, *MLH3*, *PHOX2B* and *TERT* in the relapse samples. The most commonly observed SCA was 17q gain. Among the 144 diagnostic samples, no patients were observed to have both *MYCN* amplification and an ATRX variant nor *MYCN* amplification and 11q loss; this mutual exclusivity was statistically significant for *MYCN* amplification and 11q loss (adjusted p $<$0.001). **Conclusions:** Targeted NGS panels provided clinically impactful results in a majority of cases in a real-world cohort of children with neuroblastoma. Future analyses will include survival analysis by genomic features and comparison of NGS to standard clinical testing. Research Sponsor: None.

Key genomic findings across clinical cohorts.

	Diagnosis (n=144)	Relapse (n=41)	High-risk (HR)(n=53)	Non-HR(n=62)
***ALK* variant**	29 (20.1%)	8 (19.5%)	14 (26.4%)	9 (14.5%)
***ATRX* variant**	7 (4.9%)	3 (7.3%)	5 (9.4%)	1 (1.6%)
***BRAF* variant**	1 (0.7%)	3 (7.3%)	0 (0%)	1 (1.6%)

Results of a phase II trial of nivolumab and ipilimumab in children and young adults with relapsed or refractory INI1-deficient cancers. First Author: Suzanne J. Forrest, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA

Background: Several aggressive pediatric and young adult cancers are characterized by loss of INI1 expression, including malignant rhabdoid tumor, ATRT, epithelioid sarcoma and poorly differentiated chordoma. These cancers have a poor prognosis and limited effective treatments for relapsed or refractory disease. Prior data nominated immune checkpoint inhibition as a potential strategy for INI1-deficient tumors. **Methods:** In this phase II multicenter trial of nivolumab and ipilimumab, patients 6 months to 40 years with relapsed or refractory INI1-deficient cancers were enrolled in two strata: extracranial solid tumors (Stratum 1) and CNS tumors (Stratum 2). The primary endpoint was objective response ≥partial response (PR) by RECIST v1.1 (Stratum 1) or RANO (Stratum 2). Secondary endpoints included progression-free survival, overall survival and 12-month disease control rate. Patients received nivolumab 3mg/kg and ipilimumab 1mg/kg every 3 weeks for 4 cycles followed by nivolumab 3mg/kg every 2 weeks for up to 1 year. A Simon's two-stage design targeted a response rate >25%, with each stratum assessed separately. Interim analysis at Stage 1 required ≥1 of 10 patients to have response ≥PR to proceed to Stage 2; at Stage 2, ≥3 of 20 patients with response ≥PR for evidence of efficacy. Evaluable patients received study treatment and were assessed for response or had progressive disease. **Results:** Thirty patients from six centers enrolled across both Strata from 8/2020 to 5/2025 and 27 were evaluable for the primary endpoint. Three inevaluable Stratum 1 patients were replaced per protocol. In Stratum 1, 1 patient (with poorly-differentiated chordoma) of 20 evaluable patients had ≥PR (ORR: 5%; 95% CI: 0.1-25%). In Stratum 1 (n=20), the 3-month EFS±SE and OS±SE were 20%±9% and 60%±11%, respectively, and the proportion of patients who were progression-free at 12-months was 5% (95%CI=0.1%-25%). Stratum 2 closed early with 7 patients enrolled, too few for Stage 1 interim analysis. No Stratum 2 patients had ≥PR [ORR: 0% (n=7)]. Patients received a median of 2 cycles of study treatment. The most common ≥ grade 3 treatment-related adverse events were decreased lymphocyte count (n=3), increased AST (n=3) anemia (n=2), and pneumonitis (n=2). **Conclusions:** The study did not meet the predetermined threshold for efficacy for Stratum 1. Immune checkpoint inhibitor therapy could warrant further exploration in poorly differentiated chordoma. Clinical trial information: NCT04416568. Research Sponsor: Gateway for Cancer Research; Alex's Lemonade Stand Foundation for Childhood Cancer.

Safety and feasibility of cabozantinib (CABO) in combination with cisplatin, doxorubicin, and high-dose methotrexate (MAP) in patients with newly diagnosed high-risk osteosarcoma (OS). First Author: Michael W. Bishop, Arkansas Children's Hospital, Little Rock, AR

Background: CABO is a multi-targeted kinase inhibitor of VEGFR2, c-MET, AXL and RET and has shown clinical evidence of activity in two prior studies of adult and pediatric patients with advanced OS. We report results of a feasibility cohort of CABO + MAP chemotherapy in patients with newly diagnosed high-risk OS. **Methods:** Patients <40 years, body surface area ≥ 0.8 m^2 and new diagnosis of high-grade OS with metastatic disease and resectable primary tumor were eligible. Patients were enrolled to two CABO dose levels (Dose Level 1 (DL1) 25 mg/m^2/day, maximum 40 mg/day; Dose Level 2 (DL2) 35 mg/m^2/day; maximum 60 mg/day) using a modified IQ 3+3 design. CABO was orally administered concomitantly with six 35-day cycles of MAP (cisplatin 60 mg/m^2 on days 1-2 (cycles 1-4), doxorubicin 37.5 mg/m^2 on days 1-2 (with dexrazoxane), methotrexate 12 g/m^2 on days 22, 29) and for 24 weeks as maintenance monotherapy. CABO was held after 7 weeks and resumed during 4th MAP cycle to allow for primary tumor resection and metastatic surgeries. Dose-limiting toxicities (DLT) were assessed during weeks 1-6 of treatment; additional monitoring for post-surgical complications was conducted through completion of 4th MAP cycle. The primary endpoint for this cohort was feasibility of combination therapy. **Results:** Ten patients (median age 11.5 years, 70% male) were enrolled and treated with CABO + MAP (DL1, n=4; DL2, n=6). Median cumulative doses of all MAP agents were maintained throughout treatment with no dose reductions. Concomitant dosing of CABO with MAP was tolerated with no protocol-specified DLTs occurring during the evaluation period. DL2 (35 mg/m^2) was established as the recommended dose for further study of combination therapy. Commonly reported adverse events included hematologic toxicities, febrile neutropenia, and alanine/aspartate aminotransferase (AST/ALT) elevation. Interruption of CABO was required in 6 patients for Grade 3+ AST/ALT elevation following methotrexate (n=3), wound complications (n=3), and Grade 3 pneumothorax (n=1). Wounds included two Grade 3 port site events and one Grade 1 primary tumor resection site; two patients later resumed CABO after healing without wound recurrence. Dose reduction of CABO was required in one patient for Grade 4 amylase elevation. **Conclusions:** The combination of CABO + MAP is feasible with no protocol-specified DLTs during the evaluation period. Generalizability is limited based on cohort size. Further evaluation of CABO + MAP is ongoing in a phase II/III randomized efficacy study in newly diagnosed standard and high-risk patients using CABO dose of 35 mg/m^2/day (max 60 mg), with delayed initiation of CABO in patients with port placement and early safety monitoring for wound-related events, as well as full study monitoring of dose delivery, wound complications and systemic toxicity. Clinical trial information: NCT05691478. Research Sponsor: Children's Oncology Group.

10031 Poster Session

Long term effects of treatment with dabrafenib (D) and/or trametinib (T) in pediatric patients with MAPK pathway-activated tumors. First Author: Eric Bouffet, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada

Background: Studies have shown the clinical benefits of D and T, in combination and as monotherapy, to treat adult and pediatric patients with *BRAF* V600 mutation-positive cancers. Here, we report the interim results from a long-term, follow-up study for patients from previously completed clinical trials that assessed the use of D and/or T in pediatric patients with MAPK pathway-activated tumors. **Methods:** This ongoing, global, open-label, multi-center study evaluated the long-term effects (general health, growth and development) of D and/or T in pediatric patients with tumors with MAPK pathway activation from previous studies that assessed (1) safety, tolerability and pharmacokinetics of D in solid tumors (NCT01677741); (2) pharmacodynamics and clinical activity of T or D+T in cancer or plexiform neurofibromas (NCT02124772); and (3) safety and efficacy of D+T in glioma (NCT02684058). The patients in this study followed the same treatment as at the end of the parent study. The duration of this study is 7 years after the first patient first visit (FPFV) (November 2019). The primary objective is to assess the long-term safety of the treatment. **Results:** Of a total 165 patients, 157 received the study treatment (D [n=28], T [n=21], D+T [n=108]) and 8 patients were for observation only. Most patients with low-grade glioma (LGG) and high-grade glioma (HGG) had *BRAF* V600 mutation (n=129). The median duration of exposure was approximately 21 months. From FPFV to the data cut-off (October 2024), most of the patients (94.3%) experienced at least one adverse event (AE) with 28% patients experiencing serious AEs. The most common AE was pyrexia (36.9%). AEs leading to treatment discontinuation occurred in 3.8% of total patients (D [3.6%], T [9.5%], D+T [2.8%]). One on-treatment death was reported in the D+T arm due to convulsion (not related to the study treatment). No clinically meaningful changes were observed in hematological or biochemical parameters in the D+T arm. Grade ≥ 3 abnormalities were infrequent and were reported in <2% of patients, except creatine kinase increase (5.7%). Assessment of vital signs, growth, electrocardiography, bone age and Tanner staging did not reveal any new safety signals. In the D+T arm, as per investigator assessment, overall response (complete + partial) was 27.7% for patients with BRAF *V600E* mutation positive LGG (stable disease: 63.9% patients) and 41.2% for patients with BRAF *V600E* mutation positive HGG. The median progression-free survival and median overall survival were not reached. **Conclusions:** In this long-term study, reported AEs were in line with established safety profile of D and/or T. Except more than normal increase in weight, no significant impact of D and/or T was observed on growth, sexual maturation and skeletal development. The benefit-risk remained favorable toward D and/or T therapy in pediatric patients with MAPK pathway-activated tumors. Clinical trial information: NCT03975829. Research Sponsor: Novartis Pharma AG.

10032 Poster Session

Comprehensive genomic landscape of osteosarcoma: Systematic review and analysis of 1,058 patients across 20 studies with therapeutic implications from the Fight Osteosarcoma Through European Research (FOSTER) Consortium. First Author: Emanuela Palmerini, Osteoncologia, Sarcomi dell'Osso e dei Tessuti Molli, e Terapie Innovative - IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy

Background: Osteosarcoma exhibits profound genomic complexity, complicating biomarker discovery. Although advances in multi-omics profiling have improved biological understanding, genomic data remain fragmented across heterogeneous cohorts, and actionable alterations are rarely reported. **Methods:** A systematic review identified 20 studies published between 2005 and 2022, spanning heterogeneous sequencing technologies (whole-genome/exome/RNA sequencing, methylome, and targeted gene panels) and reporting genetic drivers and/or potentially actionable mutations. Mutation data were manually extracted from the published results (e.g., tables, figures, oncoplots) and integrated into a binary Mutation Annotation Format - like matrix (1,041 samples, 471 genes) to provide a comprehensive overview of variants reported to date. **Results:** 1058 patients were included, with tissue derivation (primary, metastatic, recurrent) described in about 10% of the cases. 3816 germlines or somatic SNVs, CNVs or structural alterations were reported in 471 genes. *TP53* (40%), RB1 (18%), and *CDKN2A/B* (17%) were the most frequently altered genes, alongside with recurrent changes in cell cycle regulators (*CCND* family) and angiogenesis-related genes (*VEGFA*). Potentially actionable variants were less common: *MYC* (13%, all amplifications), *CDK4* (10%), *PDGFRA* (8%); single agent activity against such targets is either lacking or not yet available. Potentially actionable epigenetic targets were rarely identified: *TET2* (0.2%), *IDH2* (0.3%), *DNMT3A* (0.7%). TCGA-based pathway analysis revealed consistent involvement of TP53, cell cycle, RTK-RAS, PI3K, and MYC signaling. Co-occurrences detected were *TP53* with *MAP2K4*, *RICTOR*, *PTPRD* and *RB1* genes, and structural rearrangements affecting RTK-RAS and PI3K pathways. There was relative exclusivity between mutations of *RB1* and *CDK4*. **Conclusions:** The analysis identifies a small number of recurrently mutated genes and a large number of rarely affected, though potentially actionable, mutations, encoding proteins involved in cell surface, nuclear and epigenetic interactions. Lack of harmonization in data processing, mutation calling and definition of 'over' and 'under' expression, together with absent descriptions of tissue derivation hamper effective large scale analysis and phenotypic subgrouping. *TP53* mutation co-occurrences such as *RICTOR* or *RB1* were also identified, with potential therapeutic implications including WEE1 and mTOR inhibitors. Tumors with overactive CDK4/6 typically have functional RB1 and might be sensitive to CDK inhibitors. Harmonization of multi-omic methods and collaborative international analyses are essential to advance precision medicine in osteosarcoma and to inform future trials. Research Sponsor: None.

Association of response with survival in patients with relapsed/refractory high-risk neuroblastoma: A report from NANT Consortium. First Author: Michael Migotsky, Children's Hospital Los Angeles; Keck School of Medicine, University of Southern California, Los Angeles, CA

Background: Patients with relapsed/refractory (RR) high-risk neuroblastoma (HR-NB) have poor survival. Tumor response may be an early predictive endpoint, though response may not reflect long term survival. We evaluated the association between NANT Response Criteria (NANTRC) v1.2/2.0 with event-free survival (EFS) and overall survival (OS) in patients with RR-NB treated on contemporary NANT Phase 1/2 trials. **Methods:** Patients enrolled on 8 NANT trials from 2013 to 2022 were included. For patients enrolled on more than one trial, the first trial data was included. NANTRC were utilized to grade individual response components (soft tissue [ST], bone/MIBG, bone marrow [BM]) and overall response (complete [CR], partial [PR], minor [MR] response, stable disease [SD], or progressive disease [PD]). Patient/tumor characteristics, prior therapy and relapse, and disease at enrollment were analyzed for association with best overall response (BOR). Component and BOR were analyzed for association with EFS and OS from trial treatment initiation. EFS and OS were compared with the log-rank test and estimated by the Kaplan-Meier methods. **Results:** Among 244 patients, 3-year OS was 52% (95% confidence interval [CI] 46-58%), and EFS was 22% (95% CI 14-32%). OS differed significantly by best overall response ($p<0.001$), driven primarily by inferior outcomes of patients with PD. The 3-year OS was 16% (95% CI 9-29%) for patients with PD. Patients achieving objective response (CR/PR/MR) had an OS of 63% (95% CI 55-74%) and EFS 25% (95% CI 15-43%), while those achieving disease control (CR/PR/MR/SD) had very similar OS of 63% (95% CI 57-71%) and EFS 29% (95% CI 20-43%). Among patients with response of CR, PR, MR, or SD, OS and EFS were not significantly different. For individual components, a similar impact on OS was seen for PD vs no PD (all $p<0.001$), with BOR of PD in MIBG/bone and ST having OS <10%. Patients lacking either BM or bone/MIBG involvement (but not ST) at baseline and remained not involved in those components demonstrated superior OS (both $p<0.001$). Patients with BOR of PD had shorter time from diagnosis to first progression (median of 1.4 vs 1.8 years, $p=0.035$), and higher incidence of *MYCN*-amplified disease (46% vs. 14%, $p<0.001$) and prior history of progression (95% vs 73%, $p<0.001$). **Conclusions:** In RR-HRNB treated on contemporary NANT trials, BOR of PD is associated with inferior OS. Patients achieving disease control (CR/PR/MR/SD) experienced comparable outcomes regardless of response achieved. These findings support disease-control as a clinically meaningful efficacy endpoint for early-phase neuroblastoma trials. Research Sponsor: National Cancer Institute; P01 CA217959; V Foundation for Cancer Research; St. Baldrick's Foundation; United Therapeutics; Pfizer; Band of Parents; Anonymous.

3-year survival by component response.

Component	Response	N	OS % (95% CI)	EFS* % (95% CI)
BM	Non-PD	100	47 (38, 58)	17 (7, 38)
	PD	18	29 (14, 61)	-
Bone/MIBG	Non-PD	180	59 (52, 66)	22 (13, 35)
	PD	30	7 (2, 26)	-

HopeMove: Feasibility and acceptability of a mobile exercise app for pediatric patients undergoing cancer treatment. First Author: Rejin Kebudi, Istanbul University, Oncology Institute & American Hospital-Koc University, Pediatric Hematology-Oncology, Istanbul, Turkey

Background: Cancer related fatigue and reduced physical activity are common during pediatric cancer treatment and negatively affect daily functioning and quality of life. Although exercise is recommended as supportive care, maintaining regular physical activity during active treatment is challenging. Digitally delivered exercise programs may offer flexible and safe supportive care options. This study evaluated the feasibility, acceptability, usability, and safety of the HopeMove mobile exercise app and explored preliminary changes in fatigue among adolescents undergoing cancer treatment. **Methods:** This prospective, single center pilot feasibility study included adolescents aged 13-18 years undergoing active cancer treatment (N=15). Participants completed 45 minute video guided exercise sessions at least three times per week for eight weeks. The intervention was developed through a multidisciplinary collaboration involving pediatric oncology clinicians, pediatric nurses, physiotherapists, and engineers. Exercise sessions included warm-up, aerobic, strengthening, flexibility, and cool down components, with seated and standing options tailored to individual clinical needs. Prior to patient implementation, the HopeMove mobile application was evaluated by 10 clinical experts using the Mobile Application Usability Scale (MAUS). Feasibility outcomes included recruitment, retention, adherence, and technical performance. Adherence was defined as completing at least 75% of planned exercise sessions. Participant satisfaction was measured with a Visual Analog Scale (VAS). Before the intervention, adolescents completed brief application evaluation questions. Fatigue was assessed before and after the intervention using a validated pediatric oncology specific fatigue scale. Safety was monitored throughout the study. **Results:** All eligible adolescents agreed to participate and completed the intervention, resulting in 100% recruitment and retention. Twelve participants (80%) met adherence criteria. The application showed high usability (mean MAUS score 6.55 ± 0.49) and high satisfaction (VAS mean 6.66 ± 0.48). Participants reported the application to be easy to use and age appropriate. Fatigue scores improved significantly after the intervention, increasing from 100.06 ± 22.28 at baseline to 139.26 ± 18.89 post-intervention ($p<0.001$). Significant improvements were observed across fatigue subdomains (all $p<0.01$). No exercise related adverse events, injuries, falls, or treatment interruptions were reported. **Conclusions:** HopeMove was feasible, acceptable, and safe for adolescents undergoing active cancer treatment. High adherence, favorable usability, and improved fatigue outcomes suggest that mobile, video guided exercise interventions may support supportive care in pediatric oncology. Larger controlled studies are warranted. Clinical trial information: NCT07274358. Research Sponsor: None.

Concurrent RNA- and DNA-NGS testing for the detection of clinically-relevant fusions in pediatric solid-tumor patients. First Author: Lisa Gai, Tempus AI, Chicago, IL

Background: Identifying structural rearrangements and gene fusions is critical to providing high quality, precision-driven clinical care for many types of pediatric cancers. RNA next-generation sequencing (NGS) provides a functional readout of the genome that enables superior detection of chimeric transcripts and novel driver fusions, particularly when genomic breakpoints reside in complex intronic regions. This study demonstrates the benefit of concurrent DNA- and RNA-NGS for fusion detection in a real world pediatric cohort of 1,050 patients, one of the largest such studies to date. **Methods:** We used the Tempus de-identified multimodal database to select a cohort of pediatric solid tumor cancer patients (all stages) who received successful DNA (Tempus xT, 648 gene panel with enhanced detection of structural variants [SVs] in 22 genes) and RNA (Tempus xR, whole-transcriptome) NGS sequencing. All patients had a minimum tumor purity of 20% and were aged 0-21 at the time of sample collection (n=1,050). All assessed fusions appeared on clinical reports. **Results:** Overall, we detected a fusion in 35.1% of patients (n=369). The top 3 cancer types in our cohort were soft tissue sarcoma (n=321), brain/CNS cancer (n=280), and bone cancer (n=120), and fusion prevalence in these types was 53% (n=170), 30.4% (n=82) and 30% (n=36), respectively. The fusion types with the highest overall prevalence were: EWSR1 (9.0%, n=95), BRAF (6.1%, n=64), PAX3-FOXO1 (2.7%, n=28), ALK (2.2%, n=23), and RET (2.0%, n=21) fusions. In assessing the subset of genes that appear on both the DNA-NGS and RNA-NGS panel, 303 patients harbored one of these fusions and 38.6% (117/303) of those fusions were detected only via RNA-NGS. Among fusions with highest prevalence, the percentage detected only via RNA-NGS ranged from 3.1% (EWSR1 fusions) to 100% (PAX3-FOXO1); BRAF (53/64, 82.8%) and ALK (4/23, 17.4%) fusions both had comparatively high proportions detected only via RNA-NGS. RNA-NGS alone detected gene fusions in 65 additional patients where neither partner appears on the DNA-NGS panel. Considering only fusions associated with an indication-matched FDA-approved targeted therapy, we observed a prevalence of 9.0% (94/1050), and of these, 46.8% (44/94) were detected only by RNA-NGS. Overall, 49.3% (182/369) of fusion-positive patients would have been missed if RNA-NGS were not performed, representing 17.3% of the total cohort. **Conclusions:** Pediatric solid tumors are frequently driven by structural rearrangements and gene fusions that are difficult to characterize using DNA sequencing alone. This study demonstrates that performing combined DNA-NGS and RNA-NGS substantially improves the identification of patients with a clinically relevant fusion in a large real-world data set. Precision oncology in practice: Real-world multicenter experience with larotrectinib in pediatric extracranial NTRK fusion–positive tumors. First Author: Rejin Kebudi, Istanbul University, Oncology Institute & American Hospital-Koc University, Pediatric Hematology-Oncology, Istanbul, Turkey

Background: Gene fusions involving *NTRK1/2/3* represent actionable oncogenic drivers across a spectrum of rare pediatric solid tumors. Larotrectinib, a highly selective TRK inhibitor, has demonstrated robust efficacy and a favorable safety profile in clinical trials. However, real-world data from middle-income countries remain limited. We report a national multicenter real-world experience evaluating outcomes of pediatric patients with NTRK fusion–positive tumors treated with larotrectinib in Türkiye. **Methods:** This retrospective, descriptive multicenter study included pediatric patients (0–18 years) with histologically confirmed solid tumors harboring *NTRK* gene fusions, treated with larotrectinib for ≥1 month between August 2023 and April 2025. Clinical data were collected from 15 tertiary pediatric oncology centers. Treatment response was assessed using RECIST v1.1 or tumor-specific pediatric criteria. Adverse events were graded per CTCAE v5.0. Survival outcomes were analyzed descriptively. **Results:** Twenty-two patients were included; median age at diagnosis was 3 months (range, 1 day–182 months), and 59% were female. Infantile fibrosarcoma (IFS) was the most common diagnosis (n=16, 72.7%), followed by rhabdomyosarcoma (RMS), epithelioid sarcoma (ES), desmoplastic small round cell tumor (DSRCT). Six patients (27.3%) had metastatic disease at diagnosis. Larotrectinib was initiated due to disease progression or inadequate response to prior therapy in 86% of patients, treatment-related toxicity in 9%, and as maintenance therapy in one patient. After a median follow-up of 24 months, 10 patients achieved complete response, 6 had partial response or stable disease, and 4 experienced progression; 3 patients later relapsed. One patient died due to progressive disease. The 24-month overall survival rate was 95.5%, and 82% of patients remained event-free. No treatment-limiting adverse events were observed. **Conclusions:** In this national real-world cohort, larotrectinib demonstrated high efficacy, durable disease control, and an excellent safety profile in pediatric patients with NTRK fusion–positive solid tumors, particularly IFS. These findings support early integration of molecular diagnostics and TRK inhibition into routine pediatric oncology practice and provide valuable real-world evidence from a middle-income country setting. *Larotrectinib was provided through the early access to medicines program for humanitarian purposes and the data reflects real world data and does not reflect phase research data. The pharmaceutical company did not provide any kind of support in the planning/reporting/publication of the study. Research Sponsor: None.

Dinutuximab beta in combination with chemotherapy in patients with refractory or relapsed neuroblastoma: A national prospective study (2020/ABM/01/00055). First Author: Aleksandra Wieczorek, Jagiellonian University Medical College, Department of Pediatric Oncology and Hematology, Krakow, Poland

Background: The ChIm-NB-PL phase IIa trial (EudraCT: 2021-003832-96) evaluated the safety and efficacy of dinutuximab beta (DB) combined with chemotherapy (Cht) in children with relapsed or refractory high-risk neuroblastoma (RR-HRNB), a population with limited therapeutic options and poor prognosis. **Methods:** Twenty-eight patients aged 1–18 years with RR-HRNB received DB combined with temozolomide/irinotecan (TemIri) or with N5/N6 chemotherapy of the German Pediatric Oncology and Hematology Group (GPOH) protocol. DB was administered as a 5-day continuous infusion (10 mg/m²/day) every 21 days, concurrently with TemIri or sequentially after GPOH. Treatment allocation and number of cycles were individualized based on prior therapy, disease dynamics, metastatic burden, and toxicity. Responses were assessed after 3 and 5–7 cycles. The primary endpoint was safety and best response (complete or partial response); secondary endpoints included progression-free survival (PFS) and overall survival (OS). **Results:** Between 2021 and 2025, 28 patients were enrolled (25% female). Median follow-up was 28.4 months. Median age was 40.9 months at diagnosis and 51.0 months at study entry. Eleven patients had refractory disease (Group 1), while 17 had relapsed or progressive disease (Group 2; 12 early and 5 late relapses). MYCN amplification was present in 9 patients, and 12 had involvement of more than one metastatic compartment. In Group 1, best response rate (BRR) was 91.7%, end-of-treatment response rate 75.0%, and metastatic complete response 58.3%; 1-year PFS was 0.67 $\pm$ 0.13. In Group 2, BRR was 87.5% (CR 56.3%, PR 31.3%), with higher BRR in late versus early relapse (100% vs 80%); 1-year PFS was 0.81 $\pm$ 0.09. Overall, 71.4% of patients were alive at last follow-up; 1-year PFS and OS were 0.75 $\pm$ 0.08 and 0.82 $\pm$ 0.07, respectively. Grade $\geq$3 non-hematologic toxicities occurred 42 times with TemIri and 35 times with GPOH (CTCAE v4.0). Neurotoxicity, pain, capillary leak syndrome, and cytokine release syndrome were comparable between regimens and consistent with DB monotherapy. **Conclusions:** DB combined with TemIri or GPOH chemotherapy demonstrates high antitumor activity with acceptable and manageable toxicity in children with RR-HRNB. Response-adapted sequencing and individualized chemotherapy selection may improve disease control, including metastatic responses, in this high-risk population. Clinical trial information: 2021-003832-96. Research Sponsor: Medical Research Agency; 2020/ABM/01/00055.

A study of the safety, efficacy, and pharmacokinetics of SPJ-101CA as maintenance therapy for newly diagnosed high-risk neuroblastoma. First Author: Atsushi Makimoto, Tokyo Metropolitan Children's Medical Center, Fuchu, Japan

Background: Isotretinoin (ISO), an oral vitamin A derivative, induces differentiation of neuroblastoma (NB) cells and is used as maintenance therapy. SPJ-101CA (Sun Pharma Ltd.), a novel ISO formulation developed with microparticle technology to enhance absorption, is designed to achieve adequate systemic exposure at 80% of the conventional dose. As ISO is an off-label treatment for NB worldwide, the present, registration-directed clinical trial was conducted to evaluate the safety, efficacy, and pharmacokinetics (PK) of SPJ-101CA in pediatric patients. **Methods:** This open-label, multicenter phase 2 trial enrolled 16 patients aged 1-18 years with newly diagnosed, high-risk NB who had completed the standard, multidisciplinary therapy without progression. Eligibility required an ECOG performance status of 0-2 and adequate organ function. The exclusion criteria were other active malignancies, gelatin allergy, pregnancy or breastfeeding, psychiatric disorder, and intolerance to the study treatment. Written informed consent was obtained from the patients' legal guardians, and assent was provided by the patients when appropriate. The patients received oral SPJ-101CA 64 mg/m² twice daily for 14 days in each, 28-day course for a total of six courses. Dinutuximab was permitted only before or after, but not during, SPJ-101CA administration. The primary endpoint was the incidence of serious adverse events (AEs). The secondary endpoints included 1-year event-free and overall survival, the AE incidence, and PK properties. Blood samples were collected on day 14 of the first course at predefined intervals to measure the plasma concentration of ISO and 4-oxo-isotretinoin, and the standard PK parameters were evaluated. **Results:** All 16 patients were included in the full analysis and per-protocol sets. Three serious AEs related to SPJ-101CA occurred in three patients (two and one case of hypertriglyceridemia and hypercalcemia, respectively), for a total incidence of 18.8%. Common, non-serious AEs included upper respiratory inflammation (75.0%), dry skin (62.5%), hypercalcemia (56.3%), eczema (50.0%), hypertriglyceridemia (43.8%), cheilitis (37.5%), pruritus (31.3%), and neutropenia (31.3%). The 1-year event-free survival rate was 93.8%, and the overall survival rate was 100%. PK analysis of 15 patients found that the mean T_{max} of ISO was 3.9 hours and that the 4-oxo-isotretinoin level remained constant and exhibited no distinct peak. The mean ISO C_{max} was approximately 2.3 μg/mL, with a half-life of about 5 hours; 4-oxo-ISO had a higher C_{max} and longer half-life. **Conclusions:** SPJ-101CA was well-tolerated and effective as maintenance therapy following multidisciplinary treatment for high-risk NB. The PK findings were consistent with the known profile of ISO and indicated good absorption of the formulation. Clinical trial information: jRCT2031220687. Research Sponsor: Sun Pharma Japan Ltd.

Phase I study of the LiViT regimen (liposomal irinotecan, vincristine, and temozolomide) in pediatric patients with relapsed/refractory solid tumors. First Author: Feifei Sun, Department of Pediatric Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

Background: Relapsed or refractory solid tumors in children and adolescents remain a major therapeutic challenge with limited effective options. Liposomal irinotecan provides prolonged systemic exposure compared to conventional irinotecan and may offer improved efficacy and tolerability. We conducted a phase I trial to determine the recommended phase II dose (RP2D), safety, and preliminary antitumor activity of the LiViT regimen in patients aged 2–18 years. **Methods:** This single-center, open-label phase I study enrolled patients aged 2–18 years with relapsed/refractory solid tumors. The LiViT regimen consisted of vincristine (1.5 mg/m² IV day 1; max 2 mg), temozolomide (150 mg/m²/day IV days 1–5) and liposomal irinotecan at escalating doses of 40, 50, 65, 80, or 100 mg/m² (IV day 1) every 3 weeks. A standard 3+3 dose-escalation design was used (Ia), followed by an expansion cohort (Ib). **Results:** Twenty-nine patients were enrolled (Ia: 18; Ib: 11). Diagnoses included rhabdomyosarcoma (n=12), neuroblastoma (n=9), desmoplastic small round cell tumor (n=3), Ewing sarcoma (n=2), and others (n=3). In phase Ia, liposomal irinotecan was administered at escalating doses of 40, 50, 65, 80, and 100 mg/m². At 80 mg/m², 1 of the first 3 patients experienced a dose-limiting toxicity (DLT) (grade 3 diarrhea lasting $>$3 days despite loperamide); the cohort was expanded to 6 patients, and no additional DLTs or other grade 3–4 toxicities were observed. No DLTs occurred among patients treated at 100 mg/m² during Ia (n=3) or in the Ib expansion cohort (n=11). The MTD was not reached, and 100 mg/m² was selected as the RP2D based on safety in 14 patients. Across all dose levels, the only grade $\geq$3 treatment-related adverse event was the single episode of grade 3 diarrhea at 80 mg/m²; all other toxicities were grade 1–2. Among 27 evaluable patients, 5 achieved partial response (PR) and 12 had stable disease (SD), yielding an objective response rate (ORR) of 18.5% and a disease control rate (DCR) of 63.0%. **Conclusions:** The LiViT regimen is feasible with a manageable safety profile in pediatric patients with relapsed/refractory solid tumors. The MTD was not reached, and liposomal irinotecan at 100 mg/m²—the highest tested dose—was established as the RP2D. Promising preliminary activity supports phase II evaluation. Clinical trial information: NCT06710821. Research Sponsor: None.

Changes in the incidence of second malignant neoplasms in neuroblastoma over time: An updated SEER database analysis. First Author: Arhanti Sadanand, UT Southwestern, Dallas, TX

Background: To investigate changes in the incidence of second malignant neoplasms (SMN) for patients with neuroblastoma in the era of anti-GD2 immunotherapy, we analyzed patients from the SEER database according to four treatment eras (1: 1975–1989, 2: 1990–1996, 3: 1997–2010, 4: 2011–2018) corresponding to the introduction of multi-agent chemotherapy, risk-based treatment, stem cell transplant, and GD2-directed immunotherapy. We hypothesized that while the GD2-directed immunotherapy would not increase the incidence of SMNs for patients with neuroblastoma, the standardization of tandem autologous transplant would. **Methods:** The SEER database was assessed for patients younger than 30 years of age with neuroblastoma (ICD-O-3 9500) or ganglioneuroblastoma (ICD-O-3 9490). Patient demographic information and characteristics were assessed, including age at diagnosis, sex, race, histology, year of diagnosis, and extent of disease. Data about delivery of chemotherapy or radiotherapy were collected when available. Statistics including the cumulative incidence of SMN, standardized incidence ratios (SIRs), and rates of SMNs between patients in different eras were calculated. **Results:** The analytic cohort included 4,491 patients. Eighty-four patients (1.9%) developed a SMN with a median latency of 10 years. The SIR of all SMNs was 5.5 (95% CI 4.4-9.0). The majority of SMNs were hematologic (n=23; SIR 18.5, 95% CI 11.7-87.0), followed by kidney cancer (n=14; SIR 28, 95% CI 15.2-309.1) and thyroid cancer (n=12; SIR 11.2, 95% CI 5.8-58.6). Patients who developed a SMN were more likely to have received radiation than those who did not (39.3% versus 24.7%; p=0.002). There was no significant difference in median age, sex, race, or ethnicity between patients who did or did not develop a SMN. The cumulative incidence of SMN at 30 years from diagnosis for high-risk patients was 4.1% (95% CI 2.63-5.56) compared to 1.6% (95% CI 1.07-2.12) in non-high-risk patients. There was a trend toward increasing SIRs over time; in Era 1: the SIR was 3.4, with a 95% CI 2.2-7.0; in Era 2: the SIR was 3.2, with a 95% CI 1.4-9.9; in Era 3: the SIR was 8.7, with a 95% CI 6.3-20.3; and in Era 4: 9.2, 95% CI 4.8-42.1. **Conclusions:** High-risk neuroblastoma patients continue to suffer from high rates of SMNs compared to non-high risk neuroblastoma patients in the current era of GD2-directed immunotherapy. Using standardized incidence ratios, there is a trend toward increasing rates of SMNs in our cohort compared to the general population. This increase may be due to the continued addition of cytotoxic therapy. Ongoing monitoring and research into treatment-associated toxicities is needed for neuroblastoma survivors in the modern era of therapy. Research Sponsor: None.

Interrogation of fibrolamellar cancer to provide clinically relevant insights into therapeutic vulnerabilities. First Author: Sabina A. Schneider, Nagourney Cancer Institute, Long Beach, CA

Background: Fibrolamellar carcinoma (FLC) is a rare disease that primarily afflicts young adults. Systemic therapy with surgery is the only curative intervention for advanced disease with 5-year survivals of 45%. We examined 3-dimensional tissue explants from FLC patients to measure the efficacy of cytotoxics, targeted agents and novel combinations. **Methods:** Of 41 FLC specimens; 17 female, 24 male, median age 26 (14-60), 36 (88%) were previously treated, 18/36 (50%) Oxaliplatin & Gemcitabine-Lenvatinib (GEMOX-LEN), 11 (31%) 5FU & Interferon and 18 (50%) Nivolumab. Samples were examined by Ex Vivo Analysis of Programmed Cell Death (EVA/PCD) as previously described. Following disaggregation and 72-hour drug exposures, 5-point dose-response curves were interpolated to provide lethal concentration 50% (LC50) for comparison with 10,000 prior human tumor explant analyses. Drug synergy was evaluated by the method of Chou & Talalay (Chou TC. *Cancer Res* (2010)15;70(2):440-6). Of 24 drugs and combinations selected for testing, FLC yields were sufficient for 18/24 (75%) to be fully analyzed. To explore mechanisms of response/resistance, single agent LC50's compared drug activity against all solid tumors by Z-score. **Results:** By rank order the highest activity for single-agents identified Vorinostat (HDAC), followed by Phenformin (Mitochondrial Complex I) and 6-Diazo-5-Oxo-L-norleucine (Glutaminolysis), then Cobimetinib (MEK) Regorafenib (TKI), KAT (Hexokinase) Lenvatinib (TKI) and Irinotecan (TOPO I). The lowest activity was found for Navitoclax (BH3) followed by Celecoxib (NSAID) and Quercetin (Natural product). Z scores for drug combinations favored GEMOX and 5FU & Interferon compared with other solid tumors. Previously treated tumors were more drug resistant. GEMOX combined with LEN proved synergistic in 40% of samples. Despite low single agent activity, Quercetin showed synergy with Lenvatinib. Discussion: We have previously described the ex vivo study of small molecules as probes of human tumor biology. As FLC uniformly expresses the DNAjb1-PRKACA gene-fusion, we used drugs with known mechanisms of action to interrogate operative pathways and vulnerabilities of the FLC phenotype associated with the DNAjB1-PRKACA genotype. We have previously shown that Vorinostat and Phenformin activities correlate with the MYC-directed BRD-inhibitor JQ1 while Protein Kinase A is known to regulate MYC and glutaminolysis is an established hallmark of MYC activation. **Conclusions:** The results suggest that the DNAjB1-PRKACA reprograms FLC toward a metabolic phenotype that is vulnerable to epigenetic modulation, mitochondrial targeting and glutaminolysis inhibition. The study met its objective to establish a database for the future management of FLC patients. This will allow each patient's tissue to be used to craft novel therapies predicated upon new insights into the biology of FLC. Research Sponsor: None.

Prognostic significance of CD8+T lymphocytes and CD68+ macrophages in assessing pathologic response in pediatric soft tissue sarcomas. First Author: Djamila Polatova, Scientific Practical Medical Center for Pediatric Oncology, Hematology and Immunology, Tashkent, Uzbekistan

Background: The tumor immune microenvironment (TIME) plays a critical role in treatment response in pediatric oncology. Conventional clinical and demographic parameters often fail to accurately predict individual therapeutic outcomes. Increasing evidence suggests that the phenotype and spatial distribution of immune cells within the tumor may provide valuable prognostic information. This study evaluated the prognostic significance of immune markers (CD4, CD8, CD20, CD68) and their localization in predicting therapy-induced pathomorphologic response in pediatric soft tissue sarcomas (STS). **Methods:** A retrospective analysis was conducted in 98 pediatric patients with embryonal and alveolar STS. Immunohistochemical profiling was performed to assess the status, density, and spatial localization (intratumoral vs peritumoral) of CD4+, CD8+, CD20+, and CD68+ immune cells. Treatment response was evaluated based on the degree of therapy-induced pathomorphosis (grades I–IV) and standard imaging criteria. Statistical analysis included Spearman correlation and chi-square testing. **Results:** Intratumoral immune-cell infiltration demonstrated stronger prognostic value than demographic or clinical characteristics. A significant association was observed between CD8+ T-cell positivity and higher grades of pathomorphologic response (grades III–IV; p=0.001). CD68+ macrophage infiltration was also significantly correlated with tumor regression ($p<0.001$). Intratumoral localization of CD8+ (p=0.002) and CD68+ (p=0.021) cells was significantly associated with improved therapeutic response compared with peritumoral localization. No significant associations were identified for age (p=0.771), sex (p=0.775), or histologic subtype (p=0.960). **Conclusions:** Intratumoral CD8+ T lymphocytes and CD68+ macrophages are key predictors of therapeutic response in pediatric STS. These findings support the integration of immunohistochemical profiling into routine clinical practice for response stratification. The results also provide a rationale for combining standard chemotherapy with immunomodulatory strategies to enhance intratumoral immune infiltration. Clinical trial information: B2023.2.DSc/Tib856. Research Sponsor: None.

Utilization and outcomes of minimally invasive resection in patients with neuroblastoma and Wilms tumor in a national cohort. First Author: Courtney N. Day, Mayo Clinic Rochester, Rochester, MN

Background: Tumor resection is a cornerstone of therapy for neuroblastoma (NB) and Wilms tumor (WT). Minimally invasive surgical approaches such as laparoscopic or robotic tumor resection hold promise to reduce surgical morbidity while maintaining excellent oncologic outcomes. This study aims to determine the utilization and outcomes of laparoscopic and robotic resection of NB and WT among children in a national cohort, hypothesizing that utilization is increasing over time and outcomes are not inferior to open resection. **Methods:** A retrospective cohort analysis of patients <18 years old in the 2020-2023 National Cancer Database who underwent resection of NB or WT was performed. Surgical approach trends were assessed via Cochran-Armitage tests. Conversions to open surgery, length of stay (LOS), and readmissions were compared between approaches using Kruskal-Wallis, Chi-square, and Fisher's exact tests. **Results:** Among 1,262 children who underwent resection of NB (n=581) or WT (n=681), open procedures were most common (83.4%), followed by laparoscopic (13.9%), and robotic (2.7%). Utilization of each approach was stable over time aside from increased robotic resection of NB from 0% to 4% (p=.024). Approach did not vary by patient age (Table 1). Median WT size and lymph node yield were similar between approaches (both p>.05). In NB, laparoscopic procedures were performed on smaller tumors than open or robotic (p<.001). There were no robotic conversions to open; 11.4% of laparoscopic procedures were converted without change over time or difference between NB and WT (both p>.05). Median LOS was greater for open procedures than laparoscopic or robotic (p<.001). Readmission rates (p=.64) and margin status (p=.63) were similar between approaches. Outcomes did not vary by diagnosis. **Conclusions:** Utilization of minimally invasive approaches for NB or WT resection remains low despite noninferior or improved outcomes. Efforts to safely increase utilization are needed, especially for robotics, so that survivorship can be improved through reduced surgical morbidity. Research Sponsor: None.

Differences in patient characteristics and outcomes by surgical approach.

Characteristic or Outcome	Open	Laparoscopic	Robotic	p value
Age in years (median, IQR)	3 (1, 4)	3 (1, 5)	3 (1, 7)	0.08
% female	53%	53%	44%	0.59
NB tumor size in mm (median, IQR)	72 (50, 101)	47 (35, 71)	70 (51, 86)	<0.001
WT tumor size in mm (median, IQR)	110 (75, 140)	115 (93, 150)	93 (54, 125)	0.10
% metastatic disease	33%	30%	15%	0.07
% neoadjuvant therapy	35%	27%	22%	0.014
% conversion to open	n/a	11%	0%	0.05
Negative margins	86%	83%	96%	0.63
# Lymph nodes assessed in WT (median, IQR)	5 (3, 8)	6 (3, 10)	4 (3, 9)	0.62
LOS in days (median, IQR)	5 (4, 7)	4 (2, 6)	4 (1, 5)	<0.001
% readmission	15%	14%	9%	0.64

Impact of central review process on response rates in neuroblastoma clinical trials: A report from NANT Consortium. First Author: Michael Migotsky, Children's Hospital Los Angeles; Keck School of Medicine, University of Southern California, Los Angeles, CA

Background: Accurate and reproducible response assessment is critical for evaluating efficacy in clinical trials. Central response review is frequently used to reduce inter-site variability but is resource intensive and may delay data availability. Whether centralized review meaningfully alters response endpoints compared with remote source verification of site assessment remains unclear. **Methods:** We evaluated response assessments from eight NANT phase 1–2 trials conducted between February 2013 and December 2022 in relapsed/refractory high-risk neuroblastoma. Initial investigator-assessed response, remote source-verified response (remote review of radiology/bone marrow [BM] reports), and centrally-reviewed responses (review of radiographic images and BM biopsy slides) were assessed. Each patient's best overall response (BOR) and individual component responses (BM, MIBG/bone, and soft tissue [ST]) at time of BOR as determined by these three review methods were assessed. Only patients with MIBG-avid disease were included in bone response. **Results:** Among 244 evaluable patients, concordance between remote source-verified response and central review response exceeded the concordance between initial investigator-assessed response and central review response (BOR: 89% vs 79%, BM: 91% vs 74%, MIBG/bone: 92% vs 83%, ST: 82% vs 74%). Concordance between initial investigator-assessed response and remote source-verified response was 86% for BOR and similar for component response (BM: 83%, MIBG/bone: 91%, ST: 86%). Remote source-verified assessment compared to central review demonstrated higher level of concordance than initial investigator assessment for complete response (CR) (90.0% vs 81.0%), partial response (PR) (85.7% vs 72.7%), minor response (MR) (80.6% vs 71.0%), and stable disease (SD) (92.1% vs 86.7%), indicating improved response classification consistency across all major BOR categories. Overall, the initial investigator-assessed response for CR, PR, and MR agreed with central review 74.0% of the time, while remote source-verified agreed 84.7%. Most discordance reflects relabeling within adjacent categories (e.g., CR vs PR or PR vs MR). A change in response from CR/PR/MR to SD/PD when compared to central review was uncommon: 9.4% for initial investigator-assessed response, and decreased with remote source verification down to 7.1%. A change from CR/PR to MR/SD/PD was more frequent but also improved with remote source verification (from 20% to 11.3%). **Conclusions:** Remote source verification substantially improves agreement with central review and reduces responder misclassification. These findings demonstrate that structured remote source verification improves response assessment reliability and harmonization with central review, reinforcing its role as an important quality-control mechanism in multicenter trials. Evaluating satisfactory testing versus transcript grade performance between childhood cancer survivors and healthy controls. First Author: Raymond Mailhot Vega, University of Miami Miller School of Medicine-Sylvester Cancer Center, Miami, FL

Background: Substantial evidence suggests that survivors of childhood cancer are at increased risk for poor academic performance including receiving poor or failing course grades. There is a paucity of primary data as many contributing studies have relied on parental reporting of school performance. In the state of Florida, a high school student graduating with a standard diploma must successfully pass required biology and math classes. These classes require taking a standardized state-wide test which constitutes 30% of their final course grade. Our team sought to evaluate the concordance of state testing and course grade performance between pediatric brain tumor survivors and matched healthy controls from Florida. **Methods:** Children who received radiotherapy for intracranial tumors between 2007-2020 who reside in Florida were recruited to this IRB-approved study (N=37). Electronic medical record data was linked to scholastic data provided by the Florida Department of Education. Scholastic data included state testing scores and grade transcripts. For every patient enrolled, the state provided scholastic data matched at a 3:1 ratio (healthy control to survivor), based on age, grade, school district, and eligibility for free or reduced lunch (ERFL). We used Fisher's Exact test to perform an analysis of association of test scores and course grades between survivors and controls based on state-set pass/fail criteria. **Results:** Mean age of survivors was 14 years. Fifty-one percent of the survivors were female, 81% white, 8% Black, and 14% Hispanic. The majority received chemotherapy and were ERFL. Approximately 55% of survivors and controls received satisfactory math test scores (Table 1). However, survivors with unsatisfactory math scores were significantly more likely to pass their math class compared to controls (67% vs 51%; P<0.01). For biology, 79% of survivors vs 45% of controls had a satisfactory state test score; however, survivors with unsatisfactory biology scores were significantly more likely to pass their biology class compared to controls (80% vs 73%; P=0.007). **Conclusions:** We present the first US-based evaluation of primary evidence of childhood cancer survivors' performance in schools looking at transcripts. Our results demonstrate a discordance that if a survivor or control performed unsatisfactorily on the state test, the survivor was significantly more likely to pass the actual course required for a standard diploma. Further work inviting stakeholder participation, including students, caregivers, and educators is needed. Research Sponsor: Florida Department of Health; 21L09.

Comparison of standardized math test score and math course grades.

State Test	Number (%)		P-value
Unsatisfactory test	Control (n=61)	Survivor (n=21)	
Passing course	31 (51)	14 (67)	P<0.01
Failing course	30 (49)	7 (33)	
Satisfactory test	Control (n=73)	Survivor (n=26)	
Passing course	71 (97)	26 (96)	
Failing course	2 (3)	1 (4)

Neurosensory deficits and functional outcomes in childhood cancer survivors: A report from the Childhood Cancer Survivor Study (CCSS). First Author: Chiara Papini, St. Jude Children's Research Hospital, Memphis, TN

Background: Survivors of childhood cancer are at risk for neurosensory deficits secondary to their disease and treatment. Previous research has characterized system-specific (e.g., visual) impairments; however, the prevalence of multisystem neurosensory deficits and their functional impact remain unknown. **Methods:** Adult 5-year survivors (n=20037, median age 36 [range 18-69] years, 53.4% male) and sibling controls (n=4121) reported neurosensory deficits related to vision, hearing, vestibular, and neuropathy. Comorbidities were graded using modified CTCAE v5 and defined as having at least one grade 1 neurosensory deficit in one, two, and three/four systems. Survivors reported neurocognitive function (CCSS Neurocognitive questionnaire; impairment: $<10^{th}$ %ile of sibling distribution), emotional distress (BSI-18; impairment: T score $\geq$63), quality of life (SF-36; impairment: T score $<$40), and functional independence. Multivariable models estimated the prevalence of neurosensory comorbidities, adjusted for age, sex, and race. Multivariable models further adjusted for other chronic conditions and neurotoxic therapies examined associations between comorbidities and functional outcomes in survivors. **Results:** Survivors had higher prevalence of neurosensory deficits in one (31% vs. 24%; prevalence ratio [PR] 1.4, 95% confidence interval [CI] 1.3-1.5), two (14% vs. 8%; 2.2, 1.9-2.5) and three/four systems (9% vs. 3%; 3.3, 2.9-4.1) than siblings. Neurosensory comorbidities were associated with greater risk of neurocognitive impairment (task efficiency and memory), emotional distress (anxiety) and poor quality of life (physical and social function) in a dose-dependent manner in survivors (Table). Similar effects were observed for indicators of functional independence: assistance with personal care/routine needs (one system: relative risk [RR] 2.7, 95% CI 2.2-3.3; two systems: 4.1, 3.3-5.0; three/four systems: 6.5, 5.4-7.9), interference with job/school (2.5, 2.2-3.0; 3.8, 3.2-4.5; 6.1, 5.2-7.1), no driver's license (1.5, 1.3-1.8; 2.4, 2.1-2.8; 3.8, 3.2-4.4), and non-independent living (1.3, 1.2-1.4; 1.8, 1.6-2.0; 2.1, 1.9-2.4). **Conclusions:** Adult survivors of childhood cancer have high rates of comorbid neurosensory deficits that have a dose-dependent impact on functional outcomes. Survivors with multisystem deficits should be prioritized for interventions to support functional independence. Research Sponsor: National Cancer Institute.

Relative risk (95% CI) of impaired outcomes in survivors with neurosensory comorbidities.

Comparison of different metrics for estimating kidney radiation exposure during treatment for childhood cancer: A report from the St. Jude Lifetime Cohort Study. First Author: Daniel M. Green, St. Jude Children's Research Hospital, Memphis, TN

Background: Risk for impaired kidney function varies with radiation therapy (RT). We compared different methods for quantifying RT. **Methods:** Kidney function was graded in 2753 survivors (>10 years post-diagnosis, age $\geq$18 years) and 806 community controls (CC) per the Kidney Disease International Global Outcomes 2012 Clinical Practice Guideline for the Evaluation and Management of Chronic Kidney Disease (CKD). Multivariable logistic regression was used to evaluate the associations between grades 3-5 CKD and demographics and treatment exposures. RT was expressed as percentage of total kidney volume treated with 5 Gray (Gy) or more (V5), 10 Gy or more (V10) Gray, Children's Oncology Group (COG) abdominal RT, or total body irradiation (TBI)/whole abdomen RT (WA). Model discrimination was assessed using area under the receiver operating characteristic curve (AUC). **Results:** 2.1% of survivors had stages 3 to 5 CKD, compared to 0.12% of CC (Odds Ratio (OR): 17.0 (95% confidence interval (CI) 2.9, 682.8), p < 0.001). Significant associations between higher risks of grades 3-5 CKD and demographic and treatment exposures were identified in separate regression models (Table). AUCs were 0.891, 0.888 and 0.896 for V5, V10, and TBI/WA, models respectively. **Conclusions:** TBI/WA is a more readily available exposure designation than V5 or V10. These results inform identification of survivors at highest risk for CKD. Research Sponsor: None.

Opportunities for breast cancer prevention among pediatric lymphoma survivors treated with chest radiation: Projected gap in breast cancer deaths with real-world uptake rates. First Author: Jenna R. Rogers, Interfaculty Initiative in Health Policy, Harvard University, Cambridge, MA

Background: For survivors of pediatric lymphoma previously treated with chest radiotherapy (RT), the Children's Oncology Group recommends initiation of breast cancer screening with mammography and MRI starting at age 25. The National Comprehensive Cancer Network also recommends risk-reducing medications (e.g. tamoxifen) for breast cancer prevention in high-risk women. While low uptake among survivors has been described, the missed opportunity in terms of avoidable breast cancer deaths remains unknown. **Methods:** Using a Cancer Intervention and Surveillance Modeling Network model adapted to reflect the elevated breast cancer risk and competing mortality among 5-year lymphoma survivors previously treated with mediastinal RT, we estimated the number of breast cancer deaths by age 65 versus no screening or tamoxifen for a 20-year-old cohort under three scenarios: i) optimal uptake and adherence (100%) to early initiation of recommended screening (mammography with MRI) at age 25 and standard dose tamoxifen for 5 years at age 25; ii) real-world uptake of screening alone based on Childhood Cancer Survivor Study data (18% at age 25, increasing over time to 60% by age 35, with 50% reporting MRI within 1 year of mammogram); iii) real-world screening uptake as described in scenario 2, plus real-world tamoxifen use based on published estimates (16%). We assumed tamoxifen reduced breast cancer risk for a minimum of 20 years based on follow-up data from clinical trials. Breast cancer deaths averted were calculated as the difference in breast cancer deaths between each scenario and a baseline of no screening or tamoxifen. **Results:** In the absence of screening or tamoxifen, 53.2 breast cancer deaths per 1000 female survivors were projected by age 65. Under optimal uptake, screening averted 28.5 deaths per 1000 women (54%); screening plus tamoxifen increased the number averted to 31.6 deaths per 1000 (59% total reduction). Under real-world uptake, the number of breast cancer deaths averted was only 11.7 per 1000 women with screening alone and 12.6 for screening plus tamoxifen, suggesting only a 19-24% mortality reduction. **Conclusions:** Low real-world uptake of screening and tamoxifen represents a substantial missed opportunity to prevent breast cancer deaths among survivors of pediatric lymphoma treated with chest RT. Strategies to increase uptake are needed to fully realize the mortality benefits of breast cancer control in this high-risk population. Research Sponsor: National Cancer Institute; R01CA261874, U01CA199218, U24CA55727.

Modeled breast cancer mortality at age 65 under optimal and real-world uptake scenarios.

Scenario	Breast Cancer Deaths per 1000	Breast Cancer Deaths Averted per 1000	% Breast Cancer Deaths Averted
No screening or tamoxifen	53.2	-	-
Optimal (100%)			
Mammo/MRI	24.8	28.5	54%
Mammo/MRI + tamoxifen	21.7	31.6	59%
Real-world			
Mammo/MRI	41.5	11.7	19%
Mammo/MRI + tamoxifen	40.7	12.6	24%

Early-onset chronic and metabolic morbidity among survivors of childhood acute lymphoblastic leukemia: Evidence from Middle Eastern real-world data. First Author: Samah Hayek, Tel Aviv University, Tel Aviv, Israel

Background: Survivors of childhood acute lymphoblastic leukemia (ALL) are at increased risk of long-term morbidity; however, limited data describe the *early* onset of metabolic and chronic conditions in contemporary cohorts or their association with treatment intensity in real-world settings. Existing evidence largely reflects European or North American populations, historical treatment eras, and fragmented healthcare systems. Data from Middle Eastern populations, particularly within a national health insurance framework enabling longitudinal follow-up across childhood and adulthood, are scarce. This study addresses these gaps by evaluating early-onset metabolic and chronic morbidity among childhood ALL survivors treated across multiple therapeutic eras within Israel's integrated healthcare system. **Methods:** We conducted a retrospective cohort study using electronic health records from Clalit Health Services, Israel's largest integrated payer–provider healthcare system. Five-year survivors of childhood ALL (diagnosed $<$19 years between 1980–2018) were matched 1:6 to cancer-free controls by age and sex. Chronic conditions were ascertained longitudinally using validated diagnosis codes. Multivariable Cox and logistic regression models estimated associations between ALL survivorship and chronic health outcomes. Among survivors, additional analyses examined associations with treatment intensity, treatment protocol era, and cranial radiation exposure (dose-specific). **Results:** The cohort included 437 childhood ALL survivors and 2,622 matched controls; survivors were 74.6% Jewish, 18.3% Arab, and 7.1% other ethnicities. Compared with controls, ALL survivors had significantly increased risks of central nervous system conditions (HR 3.65, 95% CI 1.71–7.80), thyroid disorders (HR 2.18, 95% CI 1.55–3.05), cardiovascular disease (HR 2.09, 95% CI 1.35–3.22), diabetes (HR 1.83, 95% CI 1.05–3.21), obesity (HR 1.58, 95% CI 1.31–1.91), and metabolic syndrome (OR 2.09, 95% CI 1.53–2.80). No ethnic differences were found across all chronic conditions. Excess morbidity occurred within the first 2-years of survivorship and persisted through 5- years, except for endocrine that became apparent later. Higher treatment intensity, earlier treatment protocols, and hematopoietic stem cells were associated with greater burden. **Conclusions:** Childhood ALL survivors experience early and disproportionate accumulation of chronic conditions, at young ages. Leveraging real-world data, this study provides novel evidence that treatment intensity and protocol era strongly shape early survivorship risk; unrelated to type of healthcare or ethnicity. These findings highlight the need for early, risk-adapted surveillance and targeted metabolic prevention strategies in contemporary ALL survivorship. Symptom-based individual risk prediction for late mortality: A report from the Childhood Cancer Survivor Study study (CCSS). First Author: Elyse Zhang, St. Jude Children's Research Hospital, Memphis, TN

Background: Survivors of childhood cancer face a higher risk of late mortality than the general population. Yet no prior study has integrated patient-reported symptoms and social determinants of health with treatment exposures to predict late mortality risks. **Methods:** A total of 9,569 survivors from the CCSS cohort who completed two surveys (baseline [T1], follow-up [T2]) reported 37 symptoms spanning 10 domains (cardiac, pulmonary, sensory, musculoskeletal, nausea, pain, fatigue, memory, anxiety, depression) at T1 and T2. Additional predictors included sociodemographic and lifestyle factors, address-linked Area Deprivation Index, and treatment exposures. Standardized mortality ratios (SMRs) were calculated, stratified by individual symptoms and domains at T2 and T1-T2 change, to compare mortality rates between survivors and the general population five years after T2. Multivariable Cox proportional hazards models with LASSO regularization were used to predict 5-year health-related and cause-specific late mortality (cardiac, pulmonary, subsequent neoplasm) after T1 and T2. The dataset was randomly split into training and test datasets in a 7:3 ratio, and prediction performance was assessed using the area under the receiver operating characteristic curve (AUC). **Results:** Among 9,569 survivors (52.4% female), the median age at T1 and T2 was 27.1 and 36.9 years; median years from diagnosis to T1 and T2 were 16.6 and 26.3, respectively. Acute lymphoblastic leukemia (31.3%) and Hodgkin lymphoma (15.3%) were the most frequently observed primary diagnoses. Compared with the sex/age/race/calendar year-matched general population, survivors had significantly higher health-related mortality 5 years after T2, with SMR of 4.21 (95%CI 3.76-4.70). Presence of cardiac and pulmonary symptom domains at T2, and their persistence and worsening from T1 to T2, were associated with $>$10-fold higher SMRs. Presence, persistence, and worsening of individual symptoms, including angina pectoris, chronic cough, and trouble breathing, were also associated with SMRs $>$10. For 5-year health-related mortality after T2, the symptom-based model yielded an AUC of 0.79 (95%CI 0.75-0.84), surpassing the symptom-agnostic model (AUC 0.76, 95% CI 0.71-0.81) and the T1 model (AUC 0.73, 95%CI 0.67-0.79). Cause-specific models also showed strong prediction performance, with symptom-based AUCs of 0.87 for cardiac, 0.89 for pulmonary, and 0.78 for subsequent neoplasms mortality. **Conclusions:** Adult survivors of childhood cancer experience elevated SMRs, with the greatest excess late mortality observed in those reporting cardiopulmonary symptoms. Longitudinal symptom-based models yielded the highest predictive performance, outperforming single-time-point and symptom-agnostic models. Incorporating symptom data can strengthen mortality prediction and inform targeted survivorship care. Research Sponsor: U.S. National Institutes of Health; U24 CA55727.

Perceptions of Medicaid coverage and care experiences among long-term survivors of childhood cancer: Qualitative interviews from the Childhood Cancer Survivor study (CCSS). First Author: Xu Ji, Emory University School of Medicine, Atlanta, GA

Background: Childhood cancer survivors require lifelong, risk-based follow-up care. Survivors insured by Medicaid may face barriers to coverage and care unique to this type of insurance. We identified barriers and facilitators related to coverage, access to quality primary and specialty care, and survivor-provider interactions among Medicaid-insured survivors. **Methods:** Between May-November 2024, we conducted 23 in-depth interviews with adult survivors in CCSS currently also enrolled in Medicaid or with Medicaid coverage within the prior two years. Participants were recruited using stratified purposive sampling by state Medicaid expansion status, race/ethnicity, and age group. Interviews were audio-recorded, transcribed, and analyzed using thematic analysis. **Results:** Participants lived in 10 states (6 expansion, 4 non-expansion), 52% rural. At interview, 91% were enrolled in Medicaid. Mean age was 39 years (median 39; range 28-55); 26% were Hispanic and 35% non-Hispanic Black. Cancer types included blood cancers (n=9), brain tumors (n=7), and other solid tumors (n=7). When asked about maintaining coverage, survivors reported barriers including burdensome application/renewal requirements (e.g., in-person processes, extensive documentation); limited navigation guidance; and coverage instability tied to changes in disability status or income. Facilitators included assistance from knowledgeable staff (e.g., social worker), renewal reminder, and auto-renewal tied to Supplemental Security Income eligibility. Survivors expressed a need for hands-on help with application/renewal paperwork. When asked about care access, survivors reported difficulty finding specialists and primary care providers (PCPs) who accept Medicaid and are equipped to address survivor-specific needs (e.g., implement recommended tests in survivorship care plans), appointment delays, and transportation/geographic barriers. Facilitators included long-term relationships with PCPs and effective PCP–specialist communication. When asked about interactions with providers, survivors valued being heard, clear explanations, adequate visit time, and shared decision-making. However, many reported negative specialist encounters—feeling rushed or dismissed, including when new symptoms were repeatedly attributed to childhood cancer history without clear explanation, undermining trust. **Conclusions:** Medicaid-insured survivors reported challenges in maintaining coverage and accessing primary and specialty care. Streamlining enrollment/renewal, strengthening navigation supports, and improving survivor-centered care within Medicaid are critically needed amid the evolving Medicaid policy landscape. Findings inform a larger study designed to quantify policy-relevant gaps in coverage among aging survivors. Effects of delayed sodium thiosulfate on cisplatin-induced ototoxicity in pediatric and adolescent patients with cancer: Results from the Japanese Children's Cancer Group STS-J01 study. First Author: Eiso Hiyama, Hiroshima University Hospital, Hiroshima, Japan

Background: Cisplatin is a cornerstone of therapy for pediatric, adolescent, and adult solid tumors but frequently causes irreversible, dose-dependent ototoxicity. Delayed administration of sodium thiosulfate (PEDMARK) has demonstrated otoprotection in Western trials. STS-J01 evaluated the efficacy, safety, and pharmacokinetics of delayed sodium thiosulfate anhydrous in Japanese pediatric and adolescent patients. **Methods:** STS-J01 was an open-label, single-arm phase II study enrolling patients aged 0–18 years with localized solid tumors receiving cisplatin-based chemotherapy. Sodium thiosulfate (12.8 g/m²) was administered intravenously 6 hours after completion of each cisplatin dose. The primary endpoint was incidence of hearing loss by American Speech-Language-Hearing Association (ASHA) criteria in patients aged $\geq$3 years, compared with the observational cohort of ACCL0431. Secondary endpoints included hearing loss by Brock classification, tumor response, safety, and pharmacokinetics. **Results:** Thirty-one patients were enrolled, including 25 evaluable patients in the primary cohort (Table). Hearing was preserved in the majority of patients, with 76% free of ototoxicity by ASHA criteria and 84% with no hearing loss by Brock classification, representing a significant reduction versus historical controls (relative risk 0.42; 95% CI 0.20–0.82; P=0.007). Antitumor efficacy was preserved, with an objective response rate of 95.8% and there was no evidence of treatment interference from sodium thiosulfate. Pharmacokinetic analyses demonstrated no clinically meaningful impact of sodium thiosulfate on cisplatin exposure. No serious adverse events were attributed to sodium thiosulfate transient electrolyte abnormalities were manageable and reversible. **Conclusions:** Delayed administration of sodium thiosulfate significantly reduced cisplatin-induced ototoxicity without compromising antitumor efficacy in Japanese pediatric and adolescent patients, confirming reproducibility of sodium thiosulfate otoprotection across populations. Clinical trial information: jRCT2061220018. Research Sponsor: Japan Agency for Medical Research and Development; Fennec Pharmaceuticals.

Summary of STS-J01 trial.

Age at diagnosis (years)		3–6 (N=4)	7–14 (N=17)	15-18 (N=4)	Total (N=25)
No Hearing Loss by ASHA		2/4(50%)	13/17 (76.4%)	4/4 (100%)	19/25 (76.0%)
Disease	Hepatoblastoma	1/2 (50%)	-	-	1/2 (50.0%)
	Germ Cell Tumors	1/1 (100%)	6/6 (100%)	1/1(100%)	8/8 (100%)
	Bone and Soft Tissue Tumors	-	6/8 (75.0%)	3/3 (100%)	9/11 (81.8%)
	Medulloblastoma	0/1 (0%)	0/1 (0%)	-	0/2 (0%)
	Others	-	1/2 (50.0%)	-	1/2 (50.0%)
Chemotherapy	Responder*	4/4 (100%)	16/16 (100%)	3/4 (75.0%)	23/24 (95.9%)

Olanzapine for weight gain in children undergoing chemotherapy for solid-organ malignancies: An investigator-initiated, open-label, multicenter, phase III randomized controlled trial (SNOWMAN). First Author: Shubham Sahni, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Background: Children receiving intensive chemotherapy for solid-organ malignancies frequently experience deterioration in nutritional status. Olanzapine improves nutritional outcomes in adults with advanced cancer and is guideline-endorsed. Its use in pediatric oncology has been limited by safety concerns and lack of robust data. We conducted this trial to evaluate the efficacy and safety of olanzapine for weight gain in children undergoing chemotherapy for solid-organ malignancies. **Methods:** In this open-label, investigator-initiated, multicenter, phase III randomized trial (CTRI/2024/03/064371), children aged 2-18 years with newly diagnosed solid-organ malignancies were randomized 1:1 to receive olanzapine (1.25-2.5 mg once daily, weight-based) plus standard dietary counseling (SDC) or SDC alone for 12 weeks, stratified by nutritional status. The primary endpoint was the proportion of participants achieving $\geq$5% weight gain at 12 weeks. Secondary endpoints included changes in appetite scores (visual analog scale), anorexia-related quality of life (QoL) (Peds-FAACT), anthropometric measures (weight, body-mass index, and mid-upper arm circumference), dietary intake, health-related QoL (PedsQL Cancer Module v3.0), and safety outcomes (CTCAE v5.0). Exploratory endpoints included longitudinal changes in body composition, using air-displacement plethysmography and skeletal muscle mass assessed by computed-tomography derived L3-L4 psoas muscle area. **Results:** A total of 130 participants were randomized (median age of 11.1 years; 13.9% undernourished), of whom 117 (60 olanzapine plus SDC, 57 SDC) had evaluable outcomes. At 12 weeks, 21/60 (35%) in olanzapine plus SDC and 22/57 (38.6%) in SDC group achieved the primary endpoint, with no significant difference between groups (OR 0.86, 95% CI 0.40-1.82; p=0.69). Longitudinal analyses showed no significant differences between groups in appetite scores, anthropometric measures, dietary intake, and QoL. Exploratory analyses showed no differential impact on skeletal muscle mass or fat proportions. Rates of grade $\geq$3 adverse events were similar between groups. No extrapyramidal symptoms were observed, and no participant required dose modification or discontinuation of olanzapine due to sedation or QTc prolongation. **Conclusions:** The addition of olanzapine to SDC does not increase the proportion of children achieving clinically meaningful weight gain over 12 weeks. The impact of pharmacological nutritional modulation may be limited by the physical hurdles posed by highly intensive pediatric chemotherapy protocols. Olanzapine was well tolerated and these data provide reassurance regarding its short-term safety for other supportive care indications in pediatric oncology. Clinical trial information: CTRI/2024/03/064371. Research Sponsor: CanKids KidsCan National Society for Change for Childhood Cancer in India.

Neuropsychiatric symptom and biomarker changes with electroacupuncture in adolescent and young adult (AYA) cancer survivors: Results from a randomized controlled trial. First Author: Alexandre Chan, School of Pharmacy & Pharmaceutical Sciences, University California Irvine, Irvine, CA

Background: Electroacupuncture (EA) shows promise for managing neuropsychiatric symptoms, yet its role in adolescent and young adult (AYA) cancer survivors remains unclear. We conducted a randomized, controlled, patient- and assessor-blinded pilot trial comparing two EA regimens to evaluate effects on neuropsychiatric symptoms and associated biomarkers in AYA cancer survivors (ClinicalTrials.gov: NCT05283577). **Methods:** AYA cancer survivors aged 16–39 years who self-reported cognitive impairment, fatigue, insomnia, or psychological distress were randomized (1:1) to receive ten weekly EA sessions targeting either neuropsychiatric-specific acupoints (nEA) or non-neuropsychiatric-specific acupoints (sham EA; sEA). Blood collection, neurocognitive testing (CANTAB), and patient-reported outcomes (FACT-Cog, MFSI-SF, EORTC QLQ-C30) were obtained at four timepoints. Sixteen plasma cytokines were measured using ProcartaPlex immunoassays, and brain-derived neurotrophic factor (BDNF) concentrations were quantified using ELISA. Between-group effects were evaluated with linear mixed models and expressed as Cohen's *d* (positive values favor nEA). Adverse events (AEs) were graded using CTCAE v5.0. **Results:** Thirty-four AYAs participated (mean age 20.9 $\pm$ 3.5 years; 59% Hispanic/Latino; 59% hematologic and 21% CNS cancers). Most (82%) reported $\geq$2 neuropsychiatric symptoms at baseline. Completion of all EA sessions was comparable between study arms (nEA: 64.7%; sEA: 70.6%). A positive dose-response relationship was observed, with approximately half reporting at least one improved symptom after 5 weeks of treatment (nEA: 53.8%; sEA: 60.0%) and >80% reporting improvement at 4 weeks post-treatment (nEA: 80.0%; sEA: 92.3%). At 4-week follow-up, greater improvement in self-reported cognitive function favored sEA ($d = -1.017$, $p < 0.05$), accompanied by between-group differences in BDNF ($d = -1.073$, $p < 0.05$), IL-10 ($d = 1.378$, $p < 0.05$), and RANTES ($d = 1.058$, $p < 0.05$). All AEs were grade $\leq$ 2; tremors and pain were the most commonly reported. **Conclusions:** AYAs across both EA regimens demonstrated meaningful improvements in neuropsychiatric symptoms, accompanied by corresponding biomarker changes. However, maximal benefit occurred among participants who completed all scheduled sessions, underscoring the importance of strategies to optimize EA session adherence in this population. These findings support the feasibility of EA in AYAs and inform the design of larger trials. Clinical trial information: NCT05283577. Research Sponsor: University of California Irvine.

Barriers and enablers to pediatric palliative care integration in low- and middle-income countries: A systematic review and meta-synthesis. First Author: Mohd Faizan Siddiqui, Medical Faculty, Osh State University, Osh, Kyrgyzstan

Background: Globally around 21 million children require pediatric palliative care yearly of whom more than 97-98% of the children in greatest need live in low- and middle-income countries. Nevertheless, presently, only around 5-10% of children and their families in those situations receive palliative care while the development of pediatric-specific palliative care frameworks and services remains very much less developed than adult palliative care in many health systems. **Methods:** A systematic search was performed in PubMed database, Embase database and Global Health for studies published between 2015 and 2025 using PRISMA guidelines. Inclusion criteria: Original research on the models of PPC, access to opioids or educational interventions in the context of LMICs. Articles were screened for inclusion by two independent reviewers and were evaluated for quality using the MMAT. Data have been synthesized with the help of a thematic framework. **Results:** Out of the 427 identified records, 48 studies in 32 countries met the inclusion criteria. Important barriers identified were restrictive legislation, and 68% of the studies mentioned "opiophobia" and legal barriers to access of pediatric morphine, median morphine consumption in LMICs less than 1% of high income countries. While workforce deficit only of 12% of LMIC children's or pediatric doctors (pediatricians) reported some type of formal training in PPC during residency. Also, financial toxicity: End-of-life care financial costs for families in LMIC often outweigh cost up to, or more than, 50% of their yearly income. On the other hand, successful enablers were task-shifting to community health workers and integration of PPC into existing oncology protocols. Quantitative synthesis demonstrated the use of integrated hospital in-home models to decrease emergency room visits by 35% in the last month of life. **Conclusions:** Large disparities still exist in PPC provision in LMICs, which is related to regulatory and educational gaps. But some localized "hub-and-spoke" models provide an outline of how to integrate in a sustainable fashion. For ASCO's global mission, these findings indicate that "Zero Pain" initiatives require pediatric specific legislative reform and mandatory oncology palliative training to address the gap in quality of survival. Development and early implementation of a statewide comprehensive childhood cancer network to support pediatric oncology care and research. First Author: Chris Hagemeyer, Live Like Bella Childhood Cancer Foundation, Coral Gables, FL

Background: Although pediatric cancer survival has improved substantially, families continue to face fragmented access to navigation, clinical trials, survivorship care, and psychosocial support. Florida's pediatric oncology system is geographically dispersed and resource-variable, highlighting the need for coordinated statewide infrastructure. **Methods:** The Live Like Bella Comprehensive Childhood Cancer Network (CCCN) was established as a statewide, multi-institutional initiative to address gaps in access, care coordination, and research participation. Phase 1 activities emphasized infrastructure development, stakeholder engagement, and needs assessment. A caregiver survey was distributed to 2,478 families who received pediatric cancer support services between April 2024 and August 2025. Descriptive analyses evaluated barriers to care, information gaps, survivorship education, and clinical trial awareness. Missing survey responses were handled using complete-case analysis for each item, with denominators reported per question. In parallel, CCCN convened children's hospitals, academic centers, advocacy organizations, and researchers to develop collaborative frameworks, digital navigation tools, and consortium-based initiatives. **Results:** Over 170 caregivers responded. Eighty percent reported significant non-clinical care challenges (e.g., housing, utilities, transportation), 67% reported work-related disruptions, and 52% identified unmet caregiver support needs. Thirty-three percent reported difficulty locating services. Only 50–53% rated information about childhood cancer and diagnosis-specific education as comprehensive. Forty-eight percent of families reported being offered a clinical trial; among those, 71% participated. Survivorship education gaps were common, with 22.7% and 26% reporting limited or no information on post-treatment and survivorship care. CCCN established leadership and advisory governance, launched development of a digital navigation and clinical trial matching portal, hosted a statewide research symposium (>250 participants), and initiated multi-institutional grant proposals focused on precision oncology and navigation workforce development. **Conclusions:** Early CCCN implementation demonstrates the feasibility of a statewide, family-centered model to identify care gaps, support research participation, and align pediatric oncology stakeholders. Ongoing evaluation will assess impacts on access, survivorship, and clinical trial engagement. Research Sponsor: Florida Cancer Innovation Fund.

TPS10057 **Poster Session**

A phase 1b study of xaluritamig (a STEAP1 x CD3 T-cell engager) in pediatric, adolescent, and adult patients with relapsed/refractory (R/R) Ewing sarcoma. First Author: Emily K. Slotkin, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Ewing sarcoma (EWS) is an aggressive tumor of the bone and soft tissue primarily affecting adolescents and young adults. For patients with recurrent disease, outcomes remain poor with 5-year survival rates of 10%–15%, highlighting the need for novel approaches. STEAP1 is highly expressed in EWS cell lines, xenograft models, and patient tumor samples[1] and is transcriptionally regulated by *EWSR1*::*FLI1*, the main oncogenic driver in EWS. Xaluritamig, a humanized bispecific XmAb 2+1 T-cell engager targeting STEAP1 and CD3, has demonstrated potent, antigen-dependent T-cell–mediated lysis of STEAP1-expressing EWS cell lines[1] and induced robust in vivo antitumor activity in EWS xenograft models with concomitant CD8+ T-cell activation. In metastatic castration-resistant prostate cancer, another STEAP1-expressing solid malignancy, xaluritamig has shown meaningful antitumor activity and a manageable safety profile[2] supporting its clinical evaluation in R/R EWS. **Methods:** This ongoing, phase 1b, single-arm, open-label, two-part, multicenter study (NCT07297979) is evaluating xaluritamig in pediatric, adolescent, and adult patients with a histologic diagnosis of EWS and an *EWSR1*::*ETS* fusion gene locally confirmed by next-generation sequencing. Patients must have R/R EWS following ≥1 line of systemic therapy and Karnofsky or Lansky performance status ≥70. Part 1 (dose confirmation) consists of cohort 1 (age ≥12 years) and cohort 2 (age ≥2 to <12 years), and part 2 (dose expansion) includes patients aged ≥2 years with no upper age limit at enrollment. This study includes a 21-day screening period, a treatment period, a safety follow-up period, and a long-term follow-up period. Patients receive xaluritamig every 2 weeks once reaching the target dose until radiographic disease progression per RECIST v1.1, clinical disease progression, unacceptable toxicity, initiation of other anticancer therapy not permitted per protocol, withdrawal of consent, death, or end of study as determined by the sponsor, whichever is earlier. Primary endpoints are safety, tolerability, and determination of recommended dose(s) for expansion. Secondary endpoints are pharmacokinetics, preliminary antitumor activity, and immunogenicity. Biomarker evaluation as an exploratory endpoint includes assessment of serum cytokines, other pro-inflammatory markers, immune-cell subsets, circulating tumor DNA, STEAP1 protein expression, and tumor genomic profile and their association with safety and efficacy. CRS mitigation plan includes step-up dosing, steroid premedication, and administration of interleukin-6 inhibitors as needed. Site activation commenced in January 2026 and enrollment is ongoing. 1. Feasibility study of prolonged administration of naxitamab, irinotecan, and temozolomide for patients with relapsed or refractory neuroblastoma. First Author: Samantha Martin, Dana-Farber/Boston Children's Cancer and Blood Disorders Center; Harvard Medical School, Boston, MA

Background: Neuroblastoma is a malignant childhood tumor of the sympathetic nervous system. Cure rates are unsatisfactory for patients with high-risk disease (approximate 3-year EFS 50%) with current standard of care therapy. For patients who relapsed, anti-GD2 based chemoimmunotherapy has become standard, though it often requires in-hospital administration. Naxitamab, a humanized anti-GD2 monoclonal antibody (mAb), is FDA approved for patients with relapsed or refractory (R/R) high-risk neuroblastoma (HR-NB) with metastatic disease restricted to bone or bone marrow (BM), and who have stable disease or minor/partial response to previous therapies. With an infusion duration of 30-60 minutes, grade 3 pain and infusion-related reactions are common (72% and 68% of patients respectively) and necessitate extensive nursing and provider resources that may preclude administration at many centers. Slowing the rate of infusion of naxitamab and other anti-GD2 mAbs is generally associated with lower rates and severity of acute toxicity. We have therefore opened a phase I feasibility trial of prolonged administration of naxitamab in combination with irinotecan and temozolomide. **Methods:** This is a phase 1, single treatment arm, modified 3+3 prospective trial in patients with R/R or progressive HR-NB. The primary objective is to identify a recommended safe and feasible prolonged infusion duration of naxitamab in combination with irinotecan and temozolomide, with a goal of still allowing outpatient administration. Patients are enrolled at the starting total infusion duration of 4 hours, with an escalating infusion rate at pre-defined timepoints; the total infusion duration will be extended or shortened in cohorts of 3-6 patients based on safety and adverse events (AEs) observed in the first cycle. Individual patients will be eligible for duration escalation or de-escalation depending on AEs observed. An expansion cohort will be enrolled at the recommended infusion time. Key eligibility criteria include diagnosis of R/R or progressive HR-NB or ganglioneuroblastoma, age 1-30 years at enrollment, documentation of disease per revised International Neuroblastoma Response Criteria (INRC), adequate performance level, and adequate organ function including BM. Key exclusion criteria include prior receipt of naxitamab, untreated CNS metastatic disease, and discontinuation of prior GD2 immunotherapy due to unacceptable toxicity other than allergic reaction. Secondary endpoints include response rate per revised INRC and survival outcomes. Correlative and exploratory investigations embedded within the trial include PK profiling of prolonged naxitamab infusion durations and evaluation of circulating biomarkers including circulating tumor DNA, tumor cells, and GD2 in the study population during anti-GD2 therapy. Clinical trial information: NCT07027748. Research Sponsor: None.

Allostatic load as a mediator of exposomic risk pathways to early-onset cancer: A cross-cohort validation study. First Author: Ravi Bharat Parikh, Emory University, Atlanta, GA

Background: Early-onset cancer (EoC, defined as any solid tumor diagnosed ≤50 years age) incidence has increased 79% globally since 1990. Traditional risk models focus on isolated exposures or specific rare genetic variants and have limited utility for EoC, as high-penetrance mutations account for <10-20% of cases depending on tumor type. Allostatic load (AL) – the cumulative physiological burden of chronic stress across neuroendocrine, immune, and metabolic systems – may represent a pan-EoC mechanism linking environmental exposures to EoC carcinogenesis. **Methods:** We analyzed 13,745 adults aged ≤50 years (2,749 EoC cases) across two population-based cohorts: UK Biobank (UKB; n=5,100) and NIH All of Us Research Program (AoU; n=8,645). AL was constructed by summing standardized indicators for 8-11 baseline biomarkers representing cardiovascular (blood pressure), metabolic (HbA1c, glucose, cholesterol, BMI), and immune (CRP, WBC, albumin) domains. An exposome score was derived via bifactor analysis of 61 (UKB) and 11 (AoU) baseline exposures spanning diet, lifestyle, neighborhood, and psychosocial factors. Propensity score matching controlled for age, sex, race/ethnicity, and socioeconomic indicators. Mediation analysis estimated indirect effects of exposome on EoC operating through AL. **Results:** Mean age was 43.0 years in UKB and 39.8 years in AoU; 72.5-76.5% were female. For each SD increase in baseline AL, there was 11-18% increased odds of subsequent EoC (AoU OR: 1.18 [95%CI 1.12-1.24]; UKB OR: 1.11 [1.04-1.18]). Exposome score was significantly associated with AL (AoU β=0.09; UKB β=0.08; both p<0.001). Mediation analyses revealed significant indirect effects in both cohorts, with non-significant direct effects (Table). For exposome-related cancers, AL mediated 8.7-15.4% of exposomic risk. **Conclusions:** This is the first multinational population-level study to demonstrate that AL mediates environmental risk pathways to EoC, supporting the hypothesis that cumulative environmental burden promotes carcinogenesis through physiological stress pathways. AL represents a potentially modifiable target for EoC risk stratification. Future research integrating polygenic risk and longitudinal exposome assessments may refine mechanistic understanding and enable precision prevention approaches for this growing public health challenge. Predicting multi-cancer risk from EHR data using multi-agent LLMs. First Author: Sihang Zeng, Truveta Inc., Bellevue, WA

Background: Accurate multi-cancer risk prediction is essential for optimizing screening strategies and yet remains challenging due to heterogeneous and longitudinal electronic health record (EHR) data. Large language models (LLMs) offer a unified framework for multi-cancer risk assessment without disease-specific model training, but single-agent LLMs struggle to reason effectively over long patient histories. **Methods:** We developed a multi-agent system (MAS) composed of chained LLM agents with episodic memory to synthesize longitudinal EHR data into comprehensive cancer risk profiles. The system generates 1-year cancer risk scores (1–10) for individual cancer types. Using Truveta Data, we identified cases for 9 cancer types with clinically recognized precursor signs using clinician-curated diagnostic codes. For each cancer type, 500 cases were randomly sampled and matched 1:1 with controls by 10-year age group and sex. All structured EHR data (conditions, laboratory results, observations, medications, and procedures) up to 1 year before diagnosis or index date were included. Performance was evaluated across cancer types; lung cancer was used as a benchmark cohort for comparison with traditional machine learning (ML) models and a single-agent LLM baseline. **Results:** The MAS demonstrated heterogeneous but clinically meaningful discrimination across cancer types (AUROC range: 0.64 to 0.80), with liver cancer performing the best and colorectal cancer the worst. In the lung cancer cohort, performance (AUROC=0.79) was comparable to that of trained ML models (AUROC: XGBoost 0.82, logistic regression 0.73, k-nearest neighbors 0.58). Beyond risk prediction, the system generated concise patient summaries and interpretable rationales that supported downstream analyses, including cancer real-world evidence generation and exploratory knowledge discovery. Compared with a single-agent LLM, the MAS showed improved temporal coherence and clinical reasoning. **Conclusions:** A multi-agent LLM system can leverage longitudinal EHR data to estimate short-term multi-cancer risk within a unified framework, without cancer-specific model training. These findings support the potential role of LLM-based systems as scalable tools to inform risk stratification and screening strategies in real-world clinical populations. Research Sponsor: Truveta.

Beyond hematologic malignancies: Clonal hematopoiesis of indeterminate potential and the risk of solid tumors in the UK biobank. First Author: Parham Habibzadeh, University of Pittsburgh, Pittsburgh, PA

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is an age-related condition characterized by somatic mutations in hematopoietic stem cells. While CHIP is associated with hematologic malignancies, its relationship with solid tumors remains incompletely characterized. We conducted a comprehensive analysis of CHIP and cancer risk in a large population-based cohort. **Methods:** We analyzed 409,150 UK Biobank participants with whole exome sequencing, including 13,709 (3.4%) with CHIP. CHIP was defined as somatic mutations in myeloid driver genes at variant allele frequency (VAF) ≥2%. Incident cancers were ascertained through registry linkage over median 15.5-year follow-up. We performed propensity score-matched Cox regression adjusting for age, sex, ethnicity, smoking, BMI, diabetes, chronic kidney disease, and family history. Gene-specific, VAF-stratified, and multi-hit analyses were conducted. **Results:** Among 77,695 incident cancers, CHIP was associated with increased risk of any cancer (HR 1.22, 95% CI 1.18-1.27), including both hematologic and solid tumors. Associations were strongest for myeloid neoplasms (HR 10.49, 95% CI 8.64-12.74), including AML (HR 11.09), MDS (HR 9.75), and MPN (HR 8.03). For solid tumors, significant associations were observed for lung cancer (HR 1.50, 95% CI 1.31-1.73), particularly adenocarcinoma (HR 1.79, 95% CI 1.48-2.16), and esophageal cancer (HR 1.52, 95% CI 1.13-2.03). Notably, esophageal squamous cell carcinoma showed particularly elevated risk (HR 2.28, 95% CI 1.37-3.81). VAF-stratified analyses revealed dose-response for esophageal cancer: large clones (defined as VAF ≥20%) conferred HR 2.23 (95% CI 1.32-3.75) and very large clones (defined as VAF ≥30%) HR 2.72 (95% CI 1.39-5.30). Multi-hit CHIP (≥2 mutations) was associated with HR 3.35 (95% CI 1.46-7.71) for esophageal cancer and HR 4.07 (95% CI 1.79-9.21) for esophageal adenocarcinoma. Gene-specific analyses showed TET2 mutations increased esophageal adenocarcinoma risk (HR 2.46, 95% CI 1.21-5.03). Results remained consistent in 5-year landmark analyses. **Conclusions:** CHIP is associated with significantly increased risk of both hematologic and select solid malignancies. We identify esophageal cancer, particularly squamous cell carcinoma, as a novel CHIP-associated malignancy with clear dose-response by clone burden. These findings warrant external validation and, if confirmed, suggest CHIP features may help refine risk stratification strategies for selected solid tumors. Research Sponsor: None.

10503 **Oral Abstract Session**

Effect of type and location of *BRCA2* deleterious variant on prognosis and survival in metastatic prostate cancer: A longitudinal, international, cohort study from hormone-sensitive to castration-resistant settings. First Author: Lorena Incorvaia, Department of Precision Medicine in Medical, Surgical and Critical Care (Me.Pre.C.C.), Section of Medical Oncology, University of Palermo, Palermo, Italy, Italy

Background: Emerging evidence suggests that *BRCA*-altered prostate cancer (PC) is not a unique molecular subtype. However, the prognostic and therapeutic relevance of specific pathogenic/likely pathogenic variant (PV) in metastatic PC (mPC) remains poorly defined. We investigated the impact of *BRCA2* PV type and position on clinical outcomes across across different metastatic settings. **Methods:** This international, hospital-based cohort study (Jan 2020–Apr 2025) included mPC patients (pts) across 29 centers who underwent germline, somatic, and/or ctDNA *BRCA* testing. Analysis included three settings: 1) mHSPC (ADT+docetaxel vs. ADT+ARPi); 2) mCRPC (ARPi vs. taxanes); 3) mCRPC treated with PARP inhibitors (PARPi). Outcomes [Time on Treatment (ToT); Overall Survival (OS)] were analyzed by PV type (frameshift, missense, nonsense, splicing; indels, SNV, CNV) and position: 1) Functional Domains (FDs) (RAD51-BD [AA 900-2000] vs. DBD [AA 2459-3190] vs. Others); 2) The recently identified Prostate Cancer Cluster Regions (PCCR) (c.756-c.1000 and 3' of c.7914 vs. Others). **Results:** Of 2.119 pts included, 401 harbored Homologous Recombination Repair PVs. In the cohort of 1.411 mHSPC pts, *BRCA2*-mutated (n = 201) showed significantly shorter OS vs. wild-type (mOS 63 vs 76 months; HR 1.2, p = 0.02), regardless of first-line therapy. Contrary to previous reports, *BRCA2*-mutated mHSPC pts had superior ToT from ADT+ARPi vs. ADT+docetaxel (55 vs 15 mos; HR 3.5, p < 0.001). Within the *BRCA2* subgroup, PV location was highly prognostic for OS. In mHSPC, PCCR-outside variants (c.756-c.1000/3'of c.7914) and non-FD variants (RAD51-BD/DBD-outside) were associated with shorter OS (PCCR: 57 vs 97 mos, HR 4.0, p = 0.006; FD: 47 vs 88 mos, HR 3.0, p < 0.001). Similar prognostic impacts were confirmed in 684 mCRPC pts (PCCR: 78.0 vs 38.0 mos, HR 3.3, p = 0.01; FD: 64.0 vs 34.0 mos, HR 2.7; p = 0.009). Among 201 pts treated with olaparib, those with RAD51-BD PVs achieved significantly longer ToT (20.0 vs 7.0 mos; p = 0.01) and longer OS. Furthermore, frameshift deletions were associated with shorter OS compared to other PV types (15.9 vs 26.0 mos; p = 0.04). **Conclusions:** This is the largest longitudinal study to demonstrate that *BRCA2* PV type and location are critical determinants of survival and treatment response in mPC. Our findings identify a "high-risk" molecular subgroup (PCCR and RAD51-BD/DBD-outside and frameshift deletions) with significantly poorer outcomes. These results provide a rationale for refined risk-stratification and personalized treatment selection, including early PARPi integration, in *BRCA2*-mutated patients. Research Sponsor: None.

10504 **Oral Abstract Session**

Association between the rs72725854(A>T) allele and prostate cancer in males of African ancestry in a US population-based database. First Author: Jeffrey Shevach, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: Black males have a 70% excess incidence of and two-fold higher mortality from prostate cancer (PCa) compared to White males in the US. The rs72725854(A>T) variant ('T' allele) is a common African ancestry-specific variant that is associated with PCa in large case-control studies in the US and Africa. We measured the association between the 'T' allele and PCa in a unique US population-based cohort. **Methods:** We conducted a retrospective time-to-event cohort study using the *All of Us* database (Duke IRB Pro00117610). We included males of African ancestry who met the following criteria: 1) were at least 35 years old at *All of Us* enrollment; 2) had undergone whole genome sequencing; 3) had linked electronic health record (EHR) data; 4) had no Systemized NOmenclature of MEDicine – Clinical Terms (SNOMED-CT) diagnosis of PCa prior to *All of Us* enrollment. PCa diagnoses were ascertained by the following EHR-based phenotyping algorithm: two PCa SNOMED-CT diagnosis codes plus evidence of PCa treatment with radical prostatectomy, radiotherapy or androgen deprivation therapy. The date of PCa diagnosis was defined as the latter of second diagnosis code date or first treatment date. Individuals were censored at last visit in the EHR if they did not meet the primary endpoint of PCa diagnosis. The association between each additional 'T' allele and time from *All of Us* enrollment to PCa diagnosis was measured using Cox regression methods, adjusting for the top 5 genetic principal components, age, and rare pathogenic variants (RPVs) in PCa predisposition genes (*ATM, BRCA1/2, HOXB13* X285K African-ancestry variant, and *PALB2*). Included RPVs had pathogenic/likely pathogenic designation in ClinVar with at least two stars. **Results:** Our study included 18,846 male participants of African ancestry, with 2,349 (12.5%) and 90 (0.5%) being heterozygous and homozygous for the 'T' allele, respectively. Median age at enrollment was 56.0 years (interquartile range 48.5 – 62.3). There were 91 cases of PCa during a median follow-up of 25.6 months (interquartile range 3.0 – 45.9). For each additional 'T' allele, there was a 3.4-fold increased hazard of PCa (HR 3.38; 95% CI 2.31 – 4.95; p $3.92x10^{-10}$). Age (HR 1.09; 95% CI 1.06 – 1.11; p $2.74x10^{-15}$) and RPVs in *ATM* (HR 7.54; 95% CI 1.84 – 30.90; p $5.03x10^{-3}$) were also significantly associated with increased PCa diagnosis. *BRCA2* RPVs (HR 4.94; 95% CI 0.68 – 35.68; p 0.112) and *HOXB13* X285K (HR 2.61; 95% CI 0.36 – 19.02; p 0.343) were associated with PCa, but did not meet statistical significance. There were no *BRCA1* or *PALB2* RPVs among participants with PCa. **Conclusions:** In a large, US population-based study, we confirmed an association between the common rs72725854(A>T) variant and PCa diagnosis. This variant has a per-allele effect on PCa risk that is similar in magnitude to RPVs in PCa predisposition genes, and should be considered for inclusion in PCa genetic testing panels. Research Sponsor: None.

Prospective prostate cancer screening in germline pathogenic variant carriers: The PATROL study. First Author: Daniel Lee, University of Pennsylvania, Philadelphia, PA

Background: Germline pathogenic variants (gPV) in prostate cancer (PCa) risk genes are associated with aggressive disease, but optimal screening thresholds for this population are unclear. We report early results from the Prostate Cancer Screening for People at Genetic Risk for Aggressive Disease (PATROL) study. **Methods:** PATROL is a multicenter, prospective study enrolling participants ≥40 years with a gPV in at least one of 13 PCa risk genes. Biopsy is recommended using age-specific prostate-specific antigen (PSA) thresholds: > 1.0 ng/mL (< 50y), > 1.5 (50–59y), > 2.0 (≥60y). Prostate multiparametric MRI is encouraged at baseline and within 1 year of biopsy. Clinically significant PCa (csPCa) was defined as Grade Group (GG) ≥2 (NCT04472338). **Results:** As of 12/1/2025, 436 participants were enrolled; 69% carried *BRCA1/2* gPVs (*BRCA2* 46%, *BRCA1* 22%), 12% carried mismatch repair gene variants, and gPVs in other genes were each ≤7%. Overall, 106 participants underwent 119 on-study biopsies (median age 61 [IQR 53–68]) with a median PSA 2.3 ng/mL [IQR 1.3–3.9]). GG1 disease was detected in 21/119 (18%) biopsies and csPCa in 21/119 (18%) biopsies. Among csPCa, the median PSA was 3.2 ng/mL (IQR 2.2-4.1), and 76% (16/21) had a PIRADS 4-5 lesion. Fifteen (71%) and 14 (67%) of GG1 and csPCa, respectively, were identified in participants with *BRCA1/2* gPVs. In multivariable logistic regression adjusting for age, PSA, and genetic status, PI-RADS 4-5 was associated with csPCa (OR 12.2, 95% CI 3.3-45.4). Of the 17 men with GG1 PCa, 11 (65%) elected active surveillance. Of the 11 men on surveillance, median follow up time was 19 months, with one (9%) upgraded to GG ≥2 and who underwent definitive treatment. In total, 25 participants underwent definitive treatment; 18 with initial diagnosis of csPCA, six GG1 who elected for definitive treatment and one enrollee with GG1 upgraded to GG ≥2. Of the 25 patients who elected definitive treatment, 88% (22/25) of underwent surgery, two underwent radiation, and one underwent focal therapy. Of surgery patients, there were no postoperative complications. At a median follow-up time of 16 months, all currently have undetectable PSA, and one patient required salvage radiation therapy. **Conclusions:** Age-specific PSA-driven biopsy in gPV carriers yielded ~20% csPCa detection, with two-thirds occurring at PSA < 4 ng/mL (common biopsy threshold). MRI (PI-RADS 4–5) strongly predicted csPCa and may improve inherited-risk screening algorithms. With limited follow-up, surveillance of low-risk PCa among gPV carriers appears to be feasible, and definitive treatment of gPV carriers found with csPCa is effective. Clinical trial information: NCT04472338. Association of GLP-1 agonists with breast cancer incidence in women. First Author: Elizabeth Susan McDonald, University of Pennsylvania, Philadelphia, PA

Background: Excess weight is a key modifiable risk factor for breast cancer. Glucagon-like peptide-1 receptor agonists (GLP-1) promote weight loss and improve markers of metabolic health. However, the effect of GLP-1 on breast cancer risk among women eligible for breast cancer screening remains unclear. **Methods:** We conducted a retrospective, time-dependent cohort study from January 1, 2022, to June 30, 2025, using electronic health records. We identified 217,025 unique patients who underwent breast imaging, restricting the sample to women aged 45 to 80 years with a BMI greater than 25 and a documented imaging outcome (n=94,827; median age 61). The primary outcome was breast cancer detection. GLP-1 use was defined as a first prescription prior to the exam date and assessed in relation to race, ethnicity, age, and type 2 diabetes. To address potential confounding between these covariates and GLP-1 exposure, we performed one-to-one, case-control matching using propensity scores based on age, race, ethnicity, highest BMI, breast density, and type 2 diabetes diagnosis. **Results:** Among 94,827 women, 2,314 (2.4%) were diagnosed with breast cancer during the study period, while 92,513 (97.6%) were not. Of the total, 15,107 (15.9%) had GLP-1 exposure, and 79,720 (84.1%) did not. Among those exposed to GLP-1, 249 (1.65%) developed breast cancer, while 14,858 (98.4%) did not. Among women without exposure to GLP-1, there were 2065 (2.6%) women with breast cancer and 77,655 (97.4%) of women without breast cancer. GLP-1 exposure was associated with a lower incidence of breast cancer (OR 0.630 (0.552, 0.720); p<0.0001). In the matched logistic regression analysis (30,214 observations; 581 cancer cases), GLP-1 exposure prior to the exam date was associated with a lower incidence of breast cancer (OR 0.746, 95% CI: 0.632–0.880; p<0.0005). **Conclusions:** In this large observational study of women undergoing breast imaging at a major academic center, GLP-1 treatment was associated with a significantly lower incidence of breast cancer after accounting for age, race, ethnicity, BMI, breast density, and type 2 diabetes status. These findings support the need for prospective trials investigating incretin medications for breast cancer prevention. Research Sponsor: Pennsylvania Breast Cancer Coalition.

Matched case-control contingency table for GLP-1 exposure prior to exam date and breast cancer.

		No cancer	Total
GLP-1	249 (1.65%)	14858 (98.35%)	15107
No GLP-1	332 (2.20%)	14775 (97.80%)	15107
Total	581 (1.92%)	29633 (98.08%)	30214

Primary prevention of acute leukemias in high-risk patients: The therapeutic promise of GLP-1 receptor agonists. First Author: Jonathan Dao, Long School of Medicine, University of Texas Health-San Antonio, Frisco, TX

Background: Despite advances in understanding leukemogenesis, no validated primary prevention strategies exist. Obesity is a dose-dependent risk factor for leukemia. Emerging data implicate epigenetic regulators, specifically the histone methyltransferase GLP (EHMT1), as a driver of leukemic survival; its inhibition induces cell death in CLL and promotes differentiation in AML. We present the first real-world analysis evaluating GLP-1 receptor agonists (GLP-1RA) for the primary prevention of leukemia in high-risk populations. **Methods:** Using the TriNetX global research network (150 million patients across 108 healthcare organizations), we identified adults at elevated leukemia risk based on ≥1 factor (prior chemo/radiation, MDS, MPN, family history, genetic syndromes, tobacco use, or BMI ≥30). Patients with ≥2 months of GLP-1RA use were propensity-matched 1:1 to non-users by demographics, comorbidities, and prior chemotherapy. The primary endpoint was the incidence of ALL, AML, CLL, or CML; secondary endpoints were adverse events related to GLP-1RA. Individuals with pre-existing leukemia were excluded. Cox proportional hazards models and sensitivity analyses were used to assess associations. Sensitivity and subgroup analysis confirmed robustness. **Results:** Of 426,670 high-risk individuals, 213,335 were matched to each cohort; standardized mean differences were <0.1 for all covariates. Across >1.2 million person-years of follow-up, GLP-1RA use was associated with a 63% risk reduction in incident AML (47/213,300 vs 75/213,261; HR 0.37, 95% CI 0.26–0.53; p < 0.001) and a 50% reduction in ALL (42/213,304 vs 53/213,277; HR 0.50, 95% CI 0.33–0.75; p = 0.001). The protective effect for AML remained significant when restricted to patients with prior chemotherapy exposure and was independent of baseline BMI. No significant reductions were observed for CML or CLL. While GI adverse events were higher in the GLP-1RA cohort, the protective signal was consistent across age and ethnic subgroups. **Conclusions:** This is the first large-scale study to demonstrate a significant reduction in incident AML and ALL using GLP-1 receptor agonists in high-risk patients. By linking clinical metabolic intervention to the EHMT1 epigenetic pathway, these findings provide a novel, scalable pharmacologic strategy for the primary prevention of acute leukemias, potentially transforming the management of high-risk and obese populations. Comparative analysis of tirzepatide versus metformin and insulin in type 2 diabetes patients across the 13 most common cancers. First Author: Viraj R. Shah, Division of Cardiology, Department of Medicine, Medical College of Georgia at Augusta University, Augusta, GA

Background: Emerging glucose-lowering therapies may influence cancer risk in patients with type 2 diabetes mellitus (T2DM). While several GLP-1 receptor agonists have been evaluated, data on tirzepatide, a dual GLP-1/GIP agonist with established cardiometabolic benefits, remain limited. We assessed the comparative risk of incident cancers and all-cause mortality among T2DM patients treated with tirzepatide versus metformin or insulin. **Methods:** We conducted a retrospective cohort study using TriNetX, a U.S.-based federated electronic health record network. Adults with T2DM initiating tirzepatide, metformin, or insulin between February 28, 2020 and February 28, 2025, without prior cancer, were included. Propensity score matching (1:1, greedy nearest-neighbor) balanced demographics, BMI, HbA1c, diabetes duration, and comorbidities. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for the 13 most common incident cancers and all-cause mortality. **Results:** After 1:1 propensity score matching, baseline demographic, metabolic, diabetes-related, psychosocial, and medication characteristics were well balanced between groups, with minimal residual differences across age, sex, race/ethnicity, HbA1c, obesity severity, diabetes complications, and concomitant glucose-lowering therapies. In the tirzepatide versus insulin comparison, tirzepatide use was associated with significantly lower risks of multiple solid and hematologic malignancies, including lung, pancreatic, liver, colorectal, kidney, and endometrial cancers, as well as non-Hodgkin lymphoma (all log-rank $p < 0.01$), with no significant differences observed for prostate, thyroid, melanoma, bladder cancer, or leukemia. In the tirzepatide versus metformin comparison, tirzepatide was associated with significantly lower risks of lung cancer (HR 0.086, 95% CI 0.020-0.373; $p < 0.001$), pancreatic cancer (HR 0.124, 95% CI 0.015-1.039; $p = 0.022$), and breast cancer (HR 0.462, 95% CI 0.254-0.840; $p = 0.009$), while risks of other malignancies were not significantly different between groups. Across both matched cohorts, tirzepatide was consistently associated with markedly lower all-cause mortality compared with insulin and metformin, with absolute risk reductions of 4.8% and 0.6%, respectively (both $p < 0.001$). **Conclusions:** Among patients with type 2 diabetes, tirzepatide was associated with consistently lower all-cause mortality and reduced incidence of multiple cancers compared with insulin and metformin in a large, propensity-matched real-world analysis. These findings highlight tirzepatide as a glucose-lowering therapy with a potentially favorable oncologic risk profile, warranting prospective validation and mechanistic investigation. Safety and performance results from PATHFINDER 2, a registrational study of a multi-cancer early detection (MCED) test in an intended-use population. First Author: Karthik Giridhar, Mayo Clinic Rochester, Rochester, MN

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2026, issue of the *Journal of Clinical Oncology*.

10510 **Rapid Oral Abstract Session**

A randomized non-inferiority trial of an eHealth delivery alternative for cancer genetic testing for hereditary cancer (eREACH2). First Author: Kimberley T. Lee, University of Pennsylvania, Philadelphia, PA

Background: Germline cancer genetic testing is a standard evidence-based practice, with established risk reduction and cancer screening guidelines for genetic carriers. Yet, many at-risk patients do not have access to genetic services due in part to a workforce shortage of genetic counselors (GC). The randomized non-inferiority eREACH1 study found that digital delivery of pre-test or post-test counseling (e.g. a 1-visit model) was non-inferior 2-visits with a GC and reduced GC time per patient in patients with metastatic cancer. Outcomes with digital alternatives in the broader population of patients with and without cancer who meet criteria for genetic testing is unknown. **Methods:** eREACH2 is a randomized 4-arm non-inferiority trial where traditional pre-test (visit 1) and post-test (visit 2) counseling delivered by a GC are replaced with a patient-centered eHealth (digital) intervention in patients with and without cancer who meet national guidelines for germline genetic testing. GC visits were offered by telehealth in the home. Arms include: A (GC/GC), B (GC/digital), C (digital/GC) and D (digital/digital). Those assigned to a digital visit could request a visit with a GC if preferred. All participants have a designated GC directing their care, even if they complete a digital visit. Surveys were completed at baseline (T0), after visit 1 (T1), visit 2 (T2) and 6 months (T3). The primary outcomes are non-inferiority in uptake of genetic services and change in genetic knowledge and general anxiety from T0-T2. Secondary outcomes included uptake of testing (89-92% across arms) and additional cognitive, affective and behavioral outcomes. We used modified non-inferiority ANOVAs and modified equivalency chi-squared tests for hypothesis testing using an intention-to-treat (ITT) and confirmatory per-protocol analyses. **Results:** 773 participants were recruited from across the US with 49.8% from rural areas and 188-198 per arm. Participants were 20-87 YO (mean 51 YO), 13% were male, 12% were non-white, 29% had less than a college education, and 33% had a personal history of cancer. 584 (76%) patients completed testing (14% had a positive result, 16% had a VUS). In our primary ITT analyses, we met the non-inferiority threshold for uptake of genetic services and all short-term (T0-T2) primary and secondary cognitive and affective outcomes. 3% assigned to digital visit 1 and 9% assigned to digital visit 2 requested a GC. Per-protocol analyses were similar to the ITT results. **Conclusions:** In this large randomized, nationally recruiting trial of representative patients with and without cancer who are candidates for cancer genetic testing, offering patient-centered digital delivery models is non-inferior to two visits with a GC. This patient-centered digital intervention is an evidence-based alternative delivery model to improve access to and efficiency of cancer genetic testing. Clinical trial information: NCT05427240. Impact of population-based testing for pathogenic variants in breast cancer genes on screening recommendations in the WISDOM study. First Author: Yiwey Shieh, University of California, San Francisco, San Francisco, CA

Background: The relative contributions of pathogenic variants (PV) in breast cancer (BC) genes, polygenic risk scores (PRS), and clinical risk factors to inform risk-stratified screening have not been well-studied on the population level. The WISDOM Study, a study of risk-based screening, used panel-based testing for PVs in 9 BC genes and the Breast Cancer Surveillance Consortium risk model modified by PRS (BCSC-PRS) to generate screening recommendations for $>$ 30,000 participants undergoing risk-based screening. Women with PVs in high-penetrance genes were assigned q6 month screening (alternating MRI and mammogram). Those with PVs in moderate-penetrance genes were assigned q6 screening or yearly mammogram depending on family history. To determine the impact of PV detection on screening assignments, we examined the concordance between screening strategies informed by PV status vs. BCSC-PRS only. **Methods:** We analyzed participants with high-penetrance (*BRCA1, BRCA2, TP53, PALB2, STK11, CDH1*), moderate-penetrance (*CHEK2, ATM*), or *CHEK2* low-penetrance (I157T, S428T) PVs. We performed cross-tabulations of hypothetical (based on BCSC-PRS only) vs. actual (which considers PV) screening recommendation. To generate hypothetical screening recommendations, we calculated individual BCSC-PRS 5-year risk and applied the trial's risk-based screening algorithm as if there were no PV. We considered initial (Year 1) screening recommendations to reflect that PV testing occurred at time of enrollment. We stratified analyses by PV category and age. **Results:** Our analysis included 714 women with a PV, of which 32% were high-penetrance, 39% were moderate-penetrance, and 29% were *CHEK2* low-penetrance. Median age was 53 (IQR 45-62) years and 86% self-reported as non-Hispanic White. We found little overlap between screening recommendations based on PV status vs. BCSC-PRS. In women with a high-penetrance PV, 1.3% (3/234) would have received a q6 screening recommendation based on BCSC-PRS. In women with a moderate-penetrance PV, 33% (92/278) were assigned to q6 screening, of whom 6.5% (6/92) would have received the same assignment under BCSC-PRS. Additionally, 65% (182/278) were assigned to yearly mammogram, of whom 2.2% (4/182) would have received the same assignment under BCSC-PRS. In women with PVs aged 40-49, 67% (187/280) would have been recommended no screening until age 50 based on BCSC-PRS. In women with PVs aged 50-74, 90% (390/432) would have been recommended biennial screening. **Conclusions:** Most women with PVs in BC genes would not have otherwise been recommended for enhanced screening based on clinical and PRS risk. Our results highlight the importance of testing for PVs as a cornerstone of risk-based screening on the population level. Future studies will examine opportunities for risk reduction as we integrate genetic and non-genetic risk factors. Clinical trial information: NCT02620852. Real-world evaluation of germline pathogenic variants (PVs) in cancer-predisposition genes among unselected South Asian women with breast or ovarian cancer. First Author: Siddhartha Yadav, Mayo Clinic Rochester, Rochester, MN

Background: Prior reports of high frequency of *BRCA1* and *BRCA2* (*BRCA1/2*) PVs among South Asian women from Bangladesh, India, Nepal, and Pakistan with breast or ovarian cancer require validation in large prospective unselected cohorts. **Methods:** Individual-level anonymized patient data from two prospective cohorts were pooled to evaluate the prevalence of germline PVs among South Asian women: the South Asian Regional Alliance for Hereditary Cancers (SARAH Consortium) in Bangladesh, Nepal, and Pakistan, and the previously reported Nurse-led Genetic Counseling and Awareness (NuGenA) expansion cohort in India. Both studies enrolled consecutive cases of histologically confirmed newly diagnosed breast or epithelial ovarian cancer irrespective of age at diagnosis or family history. In both studies, participants completed questionnaires on personal and family history (first-, second- or third-degree) and provided blood for germline genetic testing after written consent. PVs in cancer predisposition genes including *ATM, BARD1, BRCA1, BRCA2, BRIP1, CHEK2, MLH1, MSH2, MSH6, PALB2, RAD51C, RAD51D,* and *TP53* were identified as part of the studies utilizing a multigene panel and the results were returned to ordering clinicians. The data cutoff date for this analysis was November 30, 2025. **Results:** The analysis included 1,711 South Asian women with breast (n=1,210) or ovarian (n=501) cancer. A family history of breast or ovarian cancer was noted in 177 (10.3%). Among breast cancers, 94% were invasive, 84% were ductal, 35% were triple-negative and over two-thirds presented with nodal involvement. Germline PVs across 13 predisposition genes were observed in 17.7% of breast and 35.9% of ovarian cancers. Notably, *BRCA1/2* PVs accounted for most of these PV (13.6% of breast and 28.3% of ovarian cancer cases) with PVs in all genes except *BRCA1/2* under 1%. The frequency of *BRCA1/2* PVs was 24.4% in triple-negative breast cancer and 8.0% in ER+/HER2-. *BRCA1/2* PV carriers were diagnosed with breast cancer at a younger age than non-carriers (Median age: 42 vs 46 years, P<0.001), with no age difference observed in ovarian cancer (50 vs. 51 years, P=0.79). Notably, among the 306 *BRCA1/2* PV carriers identified, 229 (74.2%) did not report a family history of breast or ovarian cancer. **Conclusions:** We confirm a high prevalence of *BRCA1/2* PVs among unselected South Asian women with either breast or ovarian cancer. The observations of younger age at cancer diagnosis, and low rates of family history support the need for population-specific germline genetic testing and risk management strategies in South Asia. Fine-scaled genomic ancestry clusters to reveal population-specific cancer enrichments in the All of Us Research Program. First Author: Hersh Gupta, Department of Genetics, Albert Einstein College of Medicine, Bronx, NY

Background: Specific populations exhibit known enrichments for certain cancers, such as breast cancer (BC) in Ashkenazi Jewish individuals. However, identification typically relies on self-reported race or broad continental genomic labels, which can obscure risks in understudied or admixed U.S. populations. **Methods:** Using All of Us (AOU) v8 (n=415k), participants with electronic health records (EHR) and whole-genome sequencing (WGS) were grouped into clusters based on genomic segments identical by descent. Clusters were labeled using genomic and anthropological references. We curated clinical data to remove duplicate or mislabeled entries (e.g., misidentifying metastatic lesions as primary tumors). Enrichment was determined via logistic regression, adjusting for age, sex, BMI, socioeconomic status, smoking, and recruitment site, with correction for multiple hypothesis testing using Benjamini-Hochberg. **Results:** A total of 245k individuals with EHR and quality-controlled WGS were assigned to 58 clusters; 41876 individuals were identified with at least one primary cancer diagnosis, spanning 19 broad types. A non-comprehensive selection of model results are presented in Table 1. These include previously established risks, such as BC enrichment in Ashkenazi-Jewish populations and prostate cancer in African Americans compared to Non-Jewish Europeans (NJE). Other, more novel findings include significant BC enrichment in admixed Hawaiians and colorectal cancer (CRC) in Puerto Rican and Dominican groups (not observed in the African American cluster). While individuals of Mexican ancestry showed lower lung cancer enrichment, this was not consistent in other admixed Hispanic populations, such as Colombians. **Conclusions:** Fine-scaled genomic clustering identifies cancer risks with higher precision than race-based or broad ancestral statistics. This methodology facilitates the identification of globally rare, potentially pathogenic variants that are enriched within specific subpopulations. These results underscore the necessity of granular ancestry data in understanding the genetic architecture of complex diseases like cancer. Research Sponsor: None.

Low-dose tamoxifen for pre-cancer and early disease: A pooled analysis by menopausal status. First Author: Andrea De Censi, Champalimaud Clinical Center/ Champalimaud Foundation, Lisbon, Portugal

Background: Adjuvant endocrine prevention reduces the risk of subsequent breast cancer events after ductal carcinoma in situ (DCIS) and precursor lesions, but the toxicity of standard-dose tamoxifen or aromatase inhibitors limits its use. Low-dose tamoxifen (Babytam) has demonstrated a favorable balance of efficacy and tolerability. Whether the magnitude and pattern of benefit vary by menopausal status remains undefined. We performed a pooled analysis of three studies to evaluate Babytam according to menopausal status and type of breast cancer event. **Methods:** Individual patient data from two randomized trials (Trial 007, JCO 2009; 27:3749; Trial Tam-01, JCO 2023; 41: 3116) and one observational study (Int J Cancer 2016; 139:2127) were pooled. Babytam was administered at 5 mg/day (RCTs) or 10 mg every other day (observational). The primary endpoint was recurrence of any breast cancer event, defined as ipsilateral recurrence or new ipsilateral breast cancer, contralateral breast cancer (CBC), distant metastases, or death. Competing risk models were applied for CBC. Multivariable Cox proportional hazards models with study-level random effects were used. Analyses were stratified by menopausal status. **Results:** A total of 1,772 women were included, 1,568 with DCIS, 101 with ADH, 81 with LCIS, and 21 with pT1a. Babytam significantly reduced overall breast cancer events, with differential effects by menopausal status and event type (table). Reduction in any breast cancer event was driven by a marked decrease in ipsilateral events among postmenopausal women, whereas the preventive effect on CBC was confined to premenopausal women. Few distant metastases or deaths occurred. **Conclusions:** In this pooled analysis, Babytam significantly reduced breast cancer events following in situ and microinvasive disease, confirming and extending the preventive efficacy observed in TAM-01. Menopausal status was a key modifier of benefit, with ipsilateral risk reduction predominating in postmenopausal women and CBC prevention in premenopausal women. These findings underscore the biological heterogeneity of early breast neoplasia and support Babytam as a risk-adapted, de-escalated endocrine prevention strategy that enables individualized decision-making balancing efficacy, toxicity, and patient characteristics. Clinical trial information: NCT06982313. Research Sponsor: Breast Cancer Research Foundation AwardGrant No. PPI-23-002.

Effect of low-dose tamoxifen (babytam) on overall recurrence and contralateral breast cancer by menopausal status.

Population	Menopausal status	Babytam events/N	Control events/N	HR (95% CI)	p-value

10516 Rapid Oral Abstract Session

Clinical impact of *MSH3* loss-of-function alterations in patients treated with immune checkpoint blockade across cancer types. First Author: Emily Linda Alouani, Memorial Sloan Kettering Cancer Center, New York, NY

Background: MSH3 is an alternate mismatch repair protein specialized in the recognition of larger indels through its interaction with MSH2 within the MutSβ complex. While monoallelic germline *MSH3* variants are not associated with cancer susceptibility, the impact of *MSH3* loss-of-function (LOF) alteration has not been systematically assessed for immune checkpoint blockade (ICB) sensitivity. **Methods:** Tumors with *MSH3* loss-of-function alterations were identified by next-generation sequencing in the MSKCC IMPACT cohort (discovery cohort). Overall survival (OS) from diagnosis and from ICB initiation was compared between MSH3-altered and wild-type (WT) tumors using 2:1 propensity score matching, adjusting for age, sex, disease stage, and tumor type. Tumors harboring pathogenic *POLE* or *POLD1* mutations were excluded. An independent pan-cancer cohort (Caris) was used for validation. **Results:** Among 65,570 profiled tumors, 767 patients (1.2%) carried *MSH3* LOF alterations, including 46 (6.0%) germline variants. *MSH3* LOF tumors were MMR-deficient (MMRd) in 71.2% of cases, MMR-proficient (MMRp)/ microsatellite instable (MSI) in 2.6% and MMRp/ microsatellite stable (MSS) in 26.2%. In MMRd tumors, *MSH3*-LOF occurred mainly in colorectal (64%), endometrial (20%), and esophagogastric cancers (12%), whereas in MMRp tumors it was most frequent in lung (17.4%), colorectal (12.5%), breast (10.3%), and esophagogastric cancers (4.9%). In MMRd tumors, patients with *MSH3* LOF tumors experienced significantly prolonged OS compared with *MSH3* WT tumors after ICB (mOS NR vs 85.2 months (mo), p = 0.008), attributed to the fact that they were all MSI while discordant cases (MMRd/MSS) were observed only in the absence of *MSH3* LOF. To further assess the impact of *MSH3* LOF on immunogenicity independent of classical MSI, we performed specific analysis in MMRp/MSS tumors. While these tumors remained mostly TMB low (median TMB 7 Mut/Mb vs 5 Mut/Mb, p = 0.14) with a modest but significant increase in MSI score (1.01 vs 0.42, p = 0.013), *MSH3* LOF patients had significantly improved OS following ICB compared with propensity matched WT controls (median OS 33.7 [95% CI 18.4–NR] vs 20.4 mo [95% CI 12.5–24.5]; p = 0.015). In particular, germline and somatic *MSH3* altered tumors were associated with similar benefit (median OS 33.7 [95% CI 14.4–NR] and 31.1 mo [95% CI 17.3–NR], respectively). No survival difference was observed among patients who did not receive ICB (p = 0.91). Predictive value of *MSH3* LOF for improved OS after ICB was independently validated in the Caris cohort. **Conclusions:** Somatic and germline *MSH3* LOF alterations define a unique subset of cancers with enhanced sensitivity to ICB, in particular in MMRp/MSS tumors, where *MSH3* deficiency may drive immunogenicity through mechanisms distinct from classic MSI. These data support *MSH3* LOF as a potential predictive biomarker for immunotherapy benefit. Research Sponsor: None.

Intralesional PD-1 blockade for oral cancer prevention: First-in-class phase 1 trial. First Author: Moran Amit, Department of Head and Neck Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Oral premalignant lesions affect 5% of the global population with transformation rates of 1-8% in mild-moderate dysplasia and up to 36% in severe dysplasia. Current management via surgical excision yields 30-40% recurrence despite negative margins, with cumulative functional morbidity. We hypothesized intralesional delivery would achieve immune remodeling while eliminating systemic exposure. **Methods:** We conducted a phase 1, open-label, dose-escalation trial of intralesional nivolumab in patients with histologically confirmed oral epithelial dysplasia (*NCT05327270*). Twenty-nine patients received 10 mg or 20 mg intralesional nivolumab every three weeks for four cycles. Primary endpoints were safety and tolerability; secondary endpoints included lesion response, progression to carcinoma, pharmacokinetics, spatial immune profiling, and, uniquely for this population, prospective patient-reported outcomes (PROs). **Results:** No dose-limiting toxicities occurred; 94% of adverse events were grade 1-2 with no systemic immune-related toxicities. Plasma nivolumab concentrations remained 10-fold below IV dosing without accumulation. Lesion area decreased 60% across cohorts with 41% histologic downgrading. Twelve-month cancer-free survival was 75.8%; all progression events were detected early and surgically salvageable. We performed the first prospective longitudinal analysis of PROs in oral premalignancy. High study completion (86%) and adherence rates, despite significant travel burden, coupled with stable or improved quality-of-life scores (specifically pain and swallowing), indicate that repeated intralesional injections are a feasible, non-toxic approach associated with no functional adversity. Unlike surgical standards that degrade function, this strategy preserved patient quality-of-life. Mechanistic analyses using spatial transcriptomics and multiplexed immunofluorescence revealed immune activation exclusively in treated lesions: increased CD4+ and CD8+ T cell infiltration, enriched CCR7+ activated dendritic cells, elevated CD103+ tissue-resident CD8+ T cells, and formation of higher-order immune assemblies. Untreated non-index lesions from the same patients showed no immune changes, definitively demonstrating anatomically restricted immune activation. PBMC profiling confirmed absence of systemic immune response. **Conclusions:** This first-in-class trial demonstrates intralesional PD-1 blockade safely reprograms premalignant tissue immunity without systemic toxicity, establishing lesion-directed checkpoint inhibition as a viable cancer interception strategy. These findings have established the foundation for a randomized, placebo-controlled Phase 2 trial currently enrolling at MD Anderson Cancer Center (NCT06561087) and support broader applicability to accessible other epithelial precancers including cervical and anal. Clinical trial information: NCT05327270. Research Sponsor: CPRITRP210176.

10518 Poster Session

Global development and validation of the Lung Cancer Prevention Score (LCPS): A quantitative framework linking policy strength, incidence, and outcomes across 40 countries. First Author: Adarsh Vardhan Tangella, MedStar Washington Hospital Center, Washington, DC

Background: Lung cancer is the leading cause of cancer worldwide. Despite advances in tobacco control, national prevention efforts remain fragmented. We developed and validated the Lung Cancer Prevention Score (LCPS), a 0–100 composite linking prevention policy strength with real-world outcomes for global benchmarking and equity tracking. **Methods:** Two LCPS models were created. Policy LCPS quantified 12 weighted domains: smoke-free laws, TAPS bans, ≥50% pictorial warnings, ≥75% excise tax, plain packaging, legal-age limits, e-cigarette control, LDCT screening, asbestos ban, radon plan, clean-cooking access, and occupational carcinogen controls. Data-Driven LCPS combined age-standardized incidence (ASIR), mortality (ASMR), mortality-to-incidence ratio (MIR), smoking prevalence, GDP, health expenditure, and HDI (normalized 0–1; higher = stronger prevention). Data from GLOBOCAN 2022, WHO GTCR 2023, World Bank, and UNDP HDR 2023 covered 40 countries (G20 + 20 others). Analyses included correlation, regression (adjusted for GDP, HDI), Bland–Altman agreement, and ROC AUC for MIR ≤0.60. **Results:** Among 32 complete datasets, Policy and Data-Driven LCPS correlated moderately (r = 0.31; 95% CI −0.04–0.60). Discrimination of favorable outcomes (MIR ≤0.60) showed AUC 0.68 vs 0.77. High-policy countries (≥75) had lower smoking (17%) and MIR (0.45) than those <60 (27%, 0.65; p <0.001). Policy LCPS inversely correlated with ASIR (r = −0.42; p = 0.004); Data-Driven LCPS showed a stronger link (r = −0.55; p <0.001). Each 10-point LCPS-D increase predicted 2.4 fewer cases per 100 000 (β = −0.24 ± 0.07; p = 0.002). Results were consistent across income tiers. **Conclusions:** LCPS provides a validated, reproducible framework connecting prevention policy to measurable cancer burden. Data-Driven LCPS reflected performance most accurately, while Policy LCPS defined actionable tiers linked to lower smoking, incidence, and MIR. LCPS serves as a quantitative global benchmark for policy evaluation. Research Sponsor: None.

Policy-driven lung cancer prevention score (LCPS-P) and data-driven lung cancer prevention score (LCPS-D): Domains and scoring weights.

Component	Type	Wt	Rule / Effect
Smoke-free law	P	1	Yes = 1
TAPS ban	P	1	Yes = 1; Partial = 0.5
Pictorial ≥ 50 %	P	1	Yes = 1
Excise ≥ 75 %	P	1	Yes = 1
Plain pack	P	0.5	Yes = 1
Legal age	P	0.5	18–19 = 0.5; ≥ 21 = 1
E-cig reg	P	0.5	Full/Prescr = 1; None = 0
LDCT screen	P	2	Nat = 1; Reg = 0.5
Asbestos ban	P	1	Yes = 1
Radon plan	P	1	Yes = 1
Clean-cook > 90 %	P	1	Yes = 1
Occ carcinogen ctrl	P	1.5	Yes = 1
ASIR	D	1	Lower = better (1–scaled ASIR)
ASMR	D	1	Lower = better (1–scaled ASMR)
MIR	D	1	Lower = better (1–scaled MIR)
Smoking prev	D	1	Lower = better
GDP	D	0.5	Higher = better
Health exp	D	0.75	Higher = better
HDI	D	0.5	Higher = better
Scoring	—	—	Policy LCPS = Σ (weight×value)/12×100; Data LCPS = Σ (weighted norm)/Σ weights×100

10519 Poster Session

Family cancer history and perceived value of multi-cancer early detection tests in a national U.S. sample. First Author: Chinenye Egwuonwu, PAR Piedmont, Athens, GA

Background: Family history of cancer has a strong influence on individuals' perceived cancer risk and has been shown to be a key determinant of cancer prevention behaviors. As novel precision-screening technologies such as Multi-Cancer Early Detection (MCED) blood tests emerge, understanding how familial cancer experience shapes public awareness and openness to adoption is essential for equitable implementation. **Methods:** We analyzed data from a nationally representative survey (Health Information National Trends Survey 7), of U.S. adults aged ≥18 years (N = 5,789). Weighted analyses accounted for complex survey design and population structure. The prevalence of awareness and perceived value of MCED tests among individuals with a family history of cancer, as well as population characteristics, including socio-demographics, family history of cancer, and cancer-related beliefs were estimated. Weighted multivariable logistic regression models evaluated associations between family history and two primary outcomes: awareness and perceived acceptability of MCED adjusting for sociodemographic factors, personal cancer beliefs, and perceived cancer risk. **Results:** Of the overall study sample, 74.3% reported a family history of cancer. The sample was 50.6% female, 63.3% Non-Hispanic White, 10.9% Black, 16.1% Hispanic, and 4.9% Asian. In total, 17.3% reported prior awareness of MCED tests and 74.2% perceived MCED as valuable. After adjustment, family history of cancer was not associated with MCED awareness (OR = 0.94; 95% CI = 0.66 –1.34; p = 0.71). However, family history was significantly associated with higher acceptability of MCED testing (OR = 1.50; 95% CI = 1.15–1.96; p = 0.004). **Conclusions:** Adults with a family history of cancer are more willing to adopt Multi-Cancer Early Detection blood tests even without prior awareness. In this study, family history was not associated with MCED awareness but was significantly associated with higher perceived value and acceptability. This contrast suggests that receptivity to MCED may be driven more by perceived risk in the form of prior family history than by knowledge alone. Increasing general awareness may therefore be insufficient to promote broad uptake, highlighting the need to consider differences in risk perception when designing communication strategies as MCED moves toward clinical integration. Research Sponsor: None.

10520 Poster Session

GLP-1 receptor agonists for primary prevention of breast cancer in high-risk women: A real-world analysis of efficacy and safety. First Author: Nico-al Paolo Gotera, Mercy Med Ctr North Iowa, Mason City, IA

Background: Therapeutic options for breast cancer (BC) prevention for high-risk women remain limited, and not all eligible patients opt for endocrine therapy due to concerns related to adverse events (AEs). GLP1RAs are widely used for obesity and type 2 diabetes mellitus; their role in BC primary prevention (PP) in high-risk women with obesity has not been evaluated. **Methods:** Using the TriNetX Global Network (150 million patients, 108 organizations), we analyzed de-identified records of high-risk women aged 18–90 years with a BMI ≥ 30 who had health care encounters between January 1, 2000, and January 1, 2025, identified via ICD-10 codes. High risk was defined as at least one of the following: genetic predisposition to BC, family history of BC, atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma in situ, or dense breasts. Patients were grouped as having GLP1-RA use or no GLP-1RA use. Patients with a prior history of BC or use of endocrine therapy were excluded. GLP-1RA users were propensity score-matched 1:1 with non-users based on demographics, comorbidities, social determinants of health, lifestyle factors, BMI, HbA1c, and prior breast imaging. Incident BC served as the primary endpoint, with key AEs as secondary measures. Kaplan–Meier analysis and Cox proportional hazards models were utilized to assess outcomes, which were further validated through subgroup and sensitivity analyses. **Results:** Among 80,480 high-risk women with a BMI ≥ 30, 46,581 were assigned to each cohort. Baseline demographics were balanced between cohorts (mean age: 46 years, 70% White, 21% Black). Median follow-up was 2,790 vs 2,630 days for GLP-1RA users and non-users, respectively. BC incidence was 2.95% in GLP-1RA users (1,164/39,495 cases) vs 3.01% in non-users (1,200/39,057 cases) (3.27 vs. 3.57 cases per 1,000 person-years; HR 0.844; 95% CI, 0.779–0.915). GLP-1RA users exhibited an increased risk of endometrial cancer (HR 1.273; 95% CI, 1.088–1.491) and osteoporosis (HR 1.124; 95% CI, 1.054–1.199). No significant association was observed for venous thromboembolism. Gastrointestinal AEs were significantly higher in the GLP-1RA cohort. **Conclusions:** GLP-1RA use was associated with a modest reduction in BC incidence among high-risk women with obesity in this real-world study. Prospective randomized trials are needed to validate these associations. Research Sponsor: None.

10521 **Poster Session**

A SEER-based Joinpoint analysis investigating the effect of shared decision-making on prostate cancer stage at diagnosis. First Author: Noah Ritschard, Western University of Health Sciences, Lebanon, OR

Background: Prostate cancer screening recommendations in the United States have evolved over the last two decades. The U.S. Preventive Services Task Force (USPSTF) recommended against routine prostate-specific antigen (PSA) screening for men ≥75 in 2008 and for all men in 2012 (Grade D), followed by a transition to shared decision-making for men ages 55–69 in 2018 (Grade C). These changes have raised concern for later-stage presentation Few analyses have leveraged national data through 2022 to evaluate whether the 2018 guideline modification has affected stage-specific incidence. **Methods:** We queried the Surveillance, Epidemiology, and End Results (SEER) Program for malignant prostate cancer cases diagnosed from 2000–2022 using the SEER 17 Registries Research Data (November 2024 submission), which provides population-based incidence coverage for approximately 26% of the United States. Cases were limited to men aged ≥55 at diagnosis. Age-adjusted incidence rates (per 100,000; 2000 U.S. standard population) were extracted separately for localized and distant Prostate malignancies (Summary Stage 2000+) using SEER*Stat incidence rate sessions. Annual rates and standard errors were exported for analysis. Joinpoint regression (Joinpoint v5.4.0) was used to estimate Annual Percent Change (APC) for each trend segment, with model selection determined by the Bayesian Information Criterion and weighting by standard error. Up to four joinpoints were permitted, and the software automatically selected the optimal number. Average Annual Percent Change (AAPC) was calculated to summarize overall trends. **Results:** Localized prostate cancer incidence declined significantly from 2004–2022 (APC = −3.12%; $p < .05$). Distant prostate cancer incidence decreased from 2000–2010 (APC = −0.95%; $p < .05$), followed by a significant increase from 2010–2022 (APC = +6.04%; $p < .05$). Joinpoint analysis identified a statistically significant inflection point near 2010 that temporally follows USPSTF recommendations discouraging routine PSA screening. No additional joinpoint or attenuation in distant-stage incidence was observed following the 2018 guideline revision. **Conclusions:** Using up-to-date national registry data through 2022, our analysis corroborates prior work demonstrating rising distant-stage prostate cancer incidence following guideline changes that reduced PSA screening. The absence of a joinpoint following the 2018 revision suggests that the shift to shared decision-making has not yet reversed or slowed this trend. Research Sponsor: None.

Glucagon-like peptide-1 receptor agonist for primary prevention of hepatocellular carcinoma in high-risk patients: A real-world analysis across metabolic, viral, alcoholic, and hereditary liver disease. First Author: Colton Jones, The University of Texas San Antonio, San Antonio, TX

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer mortality. While antiviral and metabolic therapies have reduced incidence, scalable pharmacologic strategies for primary prevention (PP) remain a critical unmet need. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have demonstrated preclinical antitumor activity and the potential to mitigate hepatic lipotoxicity while promoting metabolic reprogramming to stabilize cirrhosis. However, while chemoprevention signals are observed in metabolic dysfunction-associated steatotic liver disease (MASLD) and type 2 diabetes, the efficacy of GLP-1RAs for PP across diverse liver disease etiologies remains underexplored. To address this gap, we conducted a global, multicenter analysis on the efficacy and safety of GLP-1RAs for the PP of HCC in a pan-etiology high-risk cohort. **Methods:** A retrospective cohort study was conducted using the TriNetX database (150M patients across 108 health organizations). Adults 18–90 years at elevated HCC risk with ≥ 1 risk factor (chronic viral hepatitis, cirrhosis, MASLD, alcohol use disorder, or hereditary liver disorders) were identified. Cohort A (≥3 months of GLP-1RA) was propensity score-matched 1:1 with Cohort B (non-users) on demographics, HbA1c, BMI, and MELD-Na scores. The primary endpoint was incident HCC, and secondary endpoints were incidence of gastrointestinal (GI) side effects. We employed a 3-month lag period to mitigate immortal time bias. Time-to-event outcomes were assessed via Kaplan-Meier analysis and Cox proportional hazards models. Sensitivity & subgroup analyses were performed to confirm robustness across non-metabolic etiologies. **Results:** After matching, 592,718 patients were analyzed (296,359 per cohort). Median follow-up was 2,450 days for GLP-1RA users vs 2,114 days for non-users. GLP-1RA use was associated with a 73% reduction in incident HCC (140/296,345 events vs 432/296,198) [HR 0.271 (0.224-0.328)], (NNT=1,015). Notably, the protective effect was most pronounced in non-diabetics [HR 0.179 (0.140-0.229)] and lean patients (BMI < 29) [HR 0.161 (0.103-0.252)]. Risk reductions were sustained across all etiologies, including alcohol liver disease (HR 0.379), cirrhosis (HR 0.456), chronic viral hepatitis (HR 0.477), and MASLD (HR 0.605). GLP-1RA use was associated with a significant increase in GI adverse events. **Conclusions:** GLP-1RA use was associated with a 73% reduction in incident HCC, consistent across subgroups. The enhanced benefit in non-diabetic and lean cohorts suggests a direct anti-neoplastic mechanism independent of weight loss or glycemic control. The NNT of 1,015 highlights the substantial public health impact of GLP-1RA therapy in preventing a high-mortality malignancy. These findings warrant prospective validation. Research Sponsor: None.

Integrating multi-cancer early detection into cancer screening programs in the United States: A cost-effectiveness modeling study. First Author: Shuaipeng Geng, Clinical Laboratories, Shenyou Bio, Zhengzhou, China

Background: In 2021, standard-of-care (SoC) screening for breast, cervical, colorectal, lung, and prostate cancers in the United States cost $43.2 billion to detect 197,773 cancers, with colonoscopy—used as a primary colorectal screening modality—accounting for $23.7 billion, the largest share of expenditures (54.9%). Multi-cancer early detection (MCED) blood tests could complement SoC single-cancer early detection (SCED) screening but may substantially increase overall costs if implemented without concurrent redesign of screening pathways. **Methods:** A static decision model used 2021 U.S. SoC screening volumes and costs, 2020 Census data, cancer-specific incidence in high- and low-risk groups, and published SCED and MCED performance to simulate 75.6 million unique screened individuals after adjusting for overlap across programs. We evaluated (1) SoC alone, (2) SoC plus either a low-cost two-step MCED assay (OnceSeek followed by SeekInCare; "OncoSeek Duet", $143/person) or a higher-priced cfDNA methylation-based MCED test (Galleri, $949/person), and (3) a budget-neutral strategy replacing primary colonoscopy with FIT, designated as SCED 2.0, with savings reinvested to fund OncoSeek Duet for all screened individuals. **Results:** SoC alone detected 197,773 cancers (262 per 100,000) with a PPV of 0.7% at a total cost of $43.2 billion, or $218,276 per cancer detected. Adding OncoSeek Duet increased detections to 398,586 (527 per 100,000; 2.0-fold), PPV to 43.3% (61.9-fold increase) and total cost to $54.0 billion (25.0% increase), reducing cost per cancer to $135,429, while expanding detection to 9 additional cancer types beyond the 5 SoC targets. Adding Galleri yielded 572,223 cancers (757 per 100,000; PPV of 60.7%) at $114.9 billion total cost (2.7-fold increase) and $200,823 per cancer, improving yield but with markedly higher budget impact than OncoSeek Duet. SCED 2.0 cut costs to $20.0 billion (2.2-fold decrease), reduced cost per cancer to $106,876, saved $23.1 billion, and yielded 187,509 detections (5.2% decrease). Reinvesting these savings to provide OncoSeek Duet for all restored and expanded detection to 391,022 cancers (2.1-fold increase), maintained a high PPV of 42.9%, incurred $78,899 per cancer and produced a $12.3 billion surplus without increasing overall screening expenditure. **Conclusions:** In this U.S. modeling analysis, integrating MCED into SoC screening substantially increased cancers detected and lowered cost per cancer, particularly when using lower-cost OncoSeek Duet. Optimizing high-cost SCED components, such as colonoscopy, can fully finance population-wide MCED while preserving or improving efficiency, supporting a value-based, budget-neutral path for MCED implementation in national screening programs. Research Sponsor: None.

Time-restricted eating and metformin (TEAM) in invasive breast cancer or DCIS: A randomized, phase IIb, window-of-opportunity presurgical trial. First Author: Parijatham S. Thomas, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Preclinical studies indicate that metformin administered during fasting synergizes with feeding–fasting cycles to suppress tumor growth through activation of the PP2A–GSK3β–MCL1 pathway. The TEAM trial evaluated the feasibility, safety, biological, metabolic, and clinical effects of a short-term metabolic intervention combining prolonged nightly fasting and metformin in operable hormone receptor–positive breast cancer. **Methods:** TEAM is a randomized, phase IIb, presurgical window-of-opportunity trial. Women with hormone receptor-positive operable invasive breast cancer or DCIS were randomized 1:1 to either ≥16-hour nightly fasting plus metformin 750 mg bid and nutritional counseling (experimental [exp] arm) or to healthy WCRF lifestyle recommendations (control arm). Both groups wore a Continuous Glucose Monitor (CGM) per protocol data downloads. Treatment duration was 4–6 weeks before surgery. The primary endpoint is the absolute change in centrally assessed Ki67 between biopsy and surgery in invasive disease or DCIS. A co-primary endpoint was the difference in post-treatment Ki67 in cancer-adjacent DCIS. Analyses were intention-to-treat. **Results:** A total of 120 patients were randomized and completed the study (mean±SD, 32±8.6 days). As of December 31, 2025, 105 were evaluable for paired Ki67 analysis due to tissue availability. Since the complete results will be presented at the meeting, current data are descriptive with no inferential statistics and p-values, as per DSMB recommendation. Median baseline Ki67 was 15% in both arms. Median absolute Ki67 change was −3 percentage points (IQR −7 to 1) in the exp arm versus −2 (IQR −4 to 4) in the control arm. The median absolute change in invasive disease was -3 (-7 to 2) versus -1 (-3 to 4), and Ki67 reduction ≥3% occurred in 53% versus 32%, in the exp and control arm, respectively. Post-treatment Ki67 in cancer-adjacent DCIS was 3.5 (2-8.5) vs 4 (2-7). There were 3 pathological CR in the exp arm and 0 in the control arm during the presurgical window. Median weight decreased by 1.75 kg in the exp arm relative to the control arm. Mean tumor 18F-FDG PET SUV decreased by 22% versus 4% in a subgroup of 25 patients with tumors ≥ 15 mm. Reductions were observed in glucose, HOMA-IR, leptin, C-peptide, insulin and IGF-I. Changes in CIP2A and MCL1 were observed in patients with Ki67 reduction. Median adherence to ≥16-hour fasting was 100% (97.4-100); overall metformin adherence was 95% (85%-99%). No dose-limiting toxicities or grade ≥3 hypoglycemia occurred. **Conclusions:** These preliminary results show that short-term metabolic intervention was feasible, safe, highly compliant, and very inexpensive, and was associated with favorable antiproliferative and metabolic changes that warrant further investigation in breast cancer prevention and treatment. Full results will be presented at the meeting. Clinical trial information: NCT05023967. Research Sponsor: Division of Cancer Prevention, National Cancer Institute; Grant #: UG1CA242609); Italian Ministry of Health; (Grant #: RF-2019-12370733).

Cost-effective colorectal cancer screening in the United States: Comparative analyses of four molecular tests. First Author: Yinyin Chang, Clinical Laboratories, Shenyou Bio, Zhengzhou, China

Background: Colorectal cancer (CRC) screening in the United States is costly, largely driven by expensive colonoscopy procedures. In 2021, 22.3 million screening tests were performed, costing $27.5 billion; colonoscopy alone accounted for 9.2 million tests and $23.7 billion in expenditure (54.8% of the $43.2 billion spent on five major cancers). This study compared available molecular tests to identify an approach that balances performance and cost as a primary alternative to colonoscopy. **Methods:** Four molecular tests were evaluated: two FDA-approved stool-based (fecal immunochemical tests [FIT] and multitarget stool DNA test [Cologuard]) and two blood-based (the FDA-approved cfDNA-based Shield and the multiomics-based SimpleScreen). Performance data came from published literature and clinical trials (NCT04136002, NCT01397747, NCT04369053). Cost analyses used 2021 U.S. screening volumes: FIT, Cologuard, and colonoscopy costs were based on 2021 fee schedules, Shield pricing on Medicare rates; SimpleScreen was excluded due to cost unavailability. **Results:** For CRC, Cologuard had the highest sensitivity (92.3%) but lower specificity (84.4%), whereas FIT showed lower sensitivity (73.8%) but the highest specificity (93.4%). Shield and SimpleScreen showed intermediate sensitivities (83.1%, 79.2%) and specificities (89.2%, 91.1%). For advanced precancerous lesions, blood-based tests showed minimal detection power, with post-test probabilities (equal to PPV) close to pre-test prevalence (Shield 17.4% vs 14.3%; SimpleScreen 13.5% vs 9.5%; post/pre ratios 1.2 and 1.5). In contrast, stool-based tests modestly increased post-test probabilities: Cologuard 20.7% vs 7.6%, post/pre ratios 4.0; and FIT 27.6% vs 7.6%, post/pre ratios 4.4, indicating preventive potential and supporting their use as alternatives to colonoscopy. Cost analysis further identified FIT as the most cost-effective alternative, with the lowest per-case cost of $57, compared to $651 for Cologuard, $2,571 for colonoscopy, and $1,495 for Shield. Replacing colonoscopy with FIT for the 9.2 million current colonoscopy screenings in 2021 would reduce CRC screening expenditures from $27.5 billion to $4.3 billion (84.2% reduction). Comparatively, Cologuard lower costs to $9.8 billion (64.3% reduction) and Shield to $17.6 billion (36.0% reduction). Nationally, the overall cost for the five major cancers was reduced to $20.0 billion, resulting in a saving of $23.2 billion, which could be reallocated to future multi-cancer screening programs to expand population coverage. **Conclusions:** FIT provides the best balance of performance, preventive potential, and cost-effectiveness. By reducing colonoscopy demand and national screening costs while maintaining adequate detection, it supports sustainable population-wide screening and warrants consideration in guidelines and reimbursement policies. Research Sponsor: None.

Using digital screening to increase early identification of hereditary breast and ovarian cancer syndrome: A multicenter cluster-randomized trial. First Author: Dorothee Speiser, Charité – Universitätsmedizin Berlin, Department of Gynecology with Breast Center, Hereditary Breast and Ovarian Cancer Center, Berlin, Germany

Background: Early identification of hereditary breast and ovarian cancer syndrome (HBOCS) in primary gynecological care is essential for timely referral to specialized counseling and risk-adapted prevention. Yet, identification mostly occurs after disease onset, thereby thwarting preventive efforts. To facilitate early identification of healthy HBOCS carriers along the HBOCS care pathway in Germany, we developed a modular cross-sectoral digital care platform (dVP_FAM). This study compared the impact of dVP_FAM with standard care on increasing the proportion of healthy individuals with HBOCS. This project was funded by the Innovation Fund of the German Federal Joint Committee. **Methods:** We conducted a two-arm, cluster-randomized trial including 42 primary gynecological centers (20 intervention, 22 control) in Germany. In the intervention centers, patients filled out a digital HBOCS screening questionnaire based on the inclusion criteria of the German Consortium HBOC. Results were reviewed and validated by primary care gynecologists, who then decided whether to initiate referral to a specialized HBOC center via the digital platform. Control centers followed usual care. A mixed-effects logistic regression model with random intercepts was used to account for clustering at the study center level. Odds ratios (ORs) and 95% confidence intervals were estimated. **Results:** In the intervention centers, 5.534 individuals completed digital screening; 1.116 (20.2%) met inclusion criteria (IC+), and 507 (9.2%) were uncertain about family history. Of these 1.623 individuals, 664 requested an appointment at an HBOC center. A total of 467 individuals (intervention group (IG): n = 329, mean age = 45.6 (SD 12.3), 99.4% female; control group (CG): n = 138, mean age = 46.2 (SD 13.5), 99.3% female) met the primary endpoint. Among IG, 282 participants (85.7%; [83.3%, 88.6%]) were healthy at the initial counseling at the HBOC center compared with 110 participants (79.7%; [73.5%, 84.7%]) in the CG. After adjusting for center effects, the observed odds of healthy counselees were lower in the CG than in the IG (OR = 0.67; 95% CI, 0.28–1.59; p = 0.368). **Conclusions:** The IG showed a higher proportion of healthy individuals at risk for HBOCS. Although not significant, this trend may suggest that supporting primary care physicians with a digital screening platform facilitates early identification of HBOCS within cross-sectoral care pathways. Clinical trial information: DRKS00030371. Research Sponsor: German Federal Joint Committee; 01NVF20002.

Incorporating CA19-9 testing in a prospective study of pancreatic cancer surveillance (PCS) among high-risk individuals (HRIs). First Author: Asaf Maoz, Dana-Farber Cancer Institute/Mass General Brigham/Harvard Medical School, Boston, MA

Background: For individuals at an increased risk of pancreatic cancer (PC), imaging-based PCS is recommended. However, despite PCS among such individuals, when PC is diagnosed, it is found at an advanced stage in over 25% of individuals. Blood-based biomarkers of PC, such as carbohydrate antigen 19-9 (CA19-9) and HbA1C, can be abnormal prior to radiographic findings among individuals with PC. However, it is unknown whether prospective assessment of these biomarkers would allow for earlier detection or interval PC of PC among HRIs undergoing PCS. **Methods:** We conducted a single-institution (Dana-Farber Cancer Institute) prospective study of HRIs undergoing imaging-based PCS with annual MRCP and/or EUS (NCT06122896). All participants signed informed consent; the institutional IRB approved the study. CA19-9 was measured at baseline and every 6 months. Individuals with normal imaging but abnormal CA19-9 value underwent additional imaging, and short-interval repeat CA19-9 measurement. Personalized, genotype-adjusted, CA19-9 reference ranges were calculated based on fucosyltransferase (FUT) enzymes FUT3 and FUT2 variant analysis. Herein, we report outcomes from baseline PCS assessment. We measured the specificity of unadjusted and adjusted CA19-9. **Results:** 231 HRIs (mean age 62, 71% female, 47% with a previous history of cancer) underwent baseline PCS. 105 HRI (46%) had a pathogenic germline variant (PGV) predisposing to PC and met 2023 NCCN eligibility criteria for PCS surveillance, 77 (33%) HRI had a family history of PC without a predisposing PGV; 49 HRI (21%) had other indications for PCS. 153 (66%) HRIs underwent baseline PCS with MRCP [Table]; the remainder underwent an EUS. No HRIs were diagnosed with PC on baseline imaging. 98 (42%) HRI had pancreatic cyst(s) detected on baseline imaging. All abnormal CA19-9 tests (unadjusted = 5, genotype-adjusted = 1) were considered false positives as additional imaging did not reveal additional pancreatic pathology. The specificity of unadjusted and genotype-adjusted CA19-9 was 97.8% (95% CI: 95.0-99.3) and 99.5% (95% CI 97.3-100). Two individuals with concern for a focal lesion on EUS underwent immediate workup with imaging (n=1) and biopsy (n=1), both with reassuring findings. One individual was found to have a paraganglioma. **Conclusions:** Baseline unadjusted CA19-9 testing led to unnecessary follow-up studies in 2% of HRI undergoing imaging-based PCS. Genotype-adjusted CA19-9 may have superior specificity compared to unadjusted CA19-9. Longitudinal biomarker assessment, including serial CA19-9 and HbA1c, is ongoing. Clinical trial information: NCT06122896. Research Sponsor: The Hale Family Centre for Pancreatic Cancer Research.

Characteristic	n (%)
Baseline imaging	231 (100)

Correlates of patient enrollment in a population-based randomized controlled trial of cascade genetic testing in families with hereditary cancer susceptibility. First Author: Steven J. Katz, University of Michigan, Ann Arbor, MI

Background: Clinical trials that enroll patients through virtual approaches are growing but there is little information about the impact on access. The Genetic Information and Family Testing (GIFT) study was a population-based cluster RCT that evaluated an online platform that delivered cancer genetic education and home germline testing to families with hereditary cancer susceptibility. We examined correlates of patient enrollment to address potential barriers to trial access. **Methods:** We identified a random sample of adult patients with any cancer type diagnosed in Georgia or California in 2018-19 who linked to a pathogenic variant (PV) in a cancer susceptibility gene through a SEER-based data infrastructure. We initiated a mailed survey four years after diagnosis. We invited all respondents who recalled a PV on testing to enroll online in GIFT. Enrolled patients could invite their first- and second-degree relatives to enroll through the online platform. The primary endpoint was the proportion of relatives who received testing through the platform. We examined clinical and sociodemographic correlates of patient enrollment. **Results:** 4,300 patients were selected and 2,285 completed the survey (53.1%); 2,006 of 2,285 respondents were eligible and invited to GIFT (87.8) and 412 enrolled (20.5). The Table shows clinical and sociodemographic correlates of patient enrollment for the 1,994 with complete data. There were no substantial differences in enrollment by PV grouping, cancer type, sex, or race/ethnic groups. Enrollment was lower in older patients, those with lower education levels, and those living in census tracts with higher poverty levels. **Conclusions:** GIFT successfully enrolled a diverse patient population through a virtual approach. Moderate sociodemographic gradients observed in GIFT motivate strategies to ensure access to clinical trials that use virtual approaches to patient enrollment. Trial Registration: NCT05552664 at clinicaltrials.gov. Research Sponsor: U.S. National Institutes of Health; U01CA254822; American Cancer Society; RSG-20-025-01.

Clinical characteristics and risk factors of individuals ineligible for lung cancer screening at a tertiary care center. First Author: Julian A. Marin-Acevedo, Indiana University Melvin and Simon Comprehensive Cancer Center, Indianapolis, IN

Background: Lung cancer screening (LCS) reduces mortality, yet many individuals with lung cancer do not meet the 2021 USPSTF eligibility criteria. We compared clinical characteristics and risk factors in individuals with lung cancer who were ineligible and eligible for LCS. **Methods:** We conducted a retrospective study of individuals with a new or prior diagnosis of lung cancer at Indiana University Health from April 1, 2025 - December 4, 2025. We recruited individuals during their clinic visits and used electronic medical records and a patient-completed survey to obtain demographic information, smoking history, and lung cancer risk factors at diagnosis (high-risk lung disease/occupation, first-degree family history of lung cancer, autoimmune disease, prior chest-wall radiation). Individuals were stratified using the 2021USPSTF criteria. Continuous and categorical variables were compared with T-tests and χ^2/Fisher's exact tests. Logistic regression models were used for multivariate analysis. **Results:** 242 individuals were evaluated and 128 (53%) were ineligible for LCS. The median age was 63 among ineligible individuals, 56% were female, 70% were white, and 25% were black (64, 55%, 80%, and 17% respectively among LCS eligible). These individuals were more likely to have adenocarcinoma (80% vs. 56%, $p<0.001$) and present with stage IV disease compared to those eligible for LCS [51% vs. 26%, adjusted OR 2.13 (95% CI, 1.01 – 4.57), $p=0.048$]. Of note, 24 individuals (19%) were <50 or >80 years old and 46 (36%) were never-smokers; however, tobacco exposure was common (64% ever-smokers, 21% used other tobacco products, 56% secondhand exposure). Most of these individuals had high-risk lung disease (61%), Table. Multivariate analysis adjusting for smoking revealed no association between LCS eligibility and secondhand exposure or high-risk occupation, $p=0.340$ and 0.275. Interestingly, 1/3 of individuals in both cohorts had a first-degree relative with lung cancer. **Conclusions:** Most individuals with lung cancer in our cohort were ineligible for LCS using the 2021 USPSTF criteria and were more likely to present with metastatic disease. Many had significant tobacco exposure and other risk factors similar to those eligible for LCS. Our findings suggest the current LCS criteria exclude a large at-risk population and should be re-evaluated to account for risk factors beyond age and pack-years. Research Sponsor: Indiana University School of Medicine.

Risk Factor	Ineligible n=128 (%)	Eligible n=114 (%)	p
Ever-smokers (≥ 100 cigarettes)	82 (64.1)	114 (100)	**<0.001**

Disparities in cancer screening across disease sites for transgender and gender-diverse patients. First Author: Peter James Stanfield, Medical College of Wisconsin, Milwaukee, WI

Background: Over 2 million Americans identify as transgender, nonbinary, or gender-diverse (TGD) and limited data exist on cancer screening in this population. This study examines uptake rates of recommended breast, cervical, colorectal, and prostate cancer screening in TGD persons and reports factors predictive of screening uptake. **Methods:** A cross-sectional single-institution cohort study was conducted at a tertiary referral center with a specialized LGBTQIA+ Inclusion Health Clinic (IHC). Adult patients self-identifying as TGD with a healthcare encounter from January 2023-May 2025 were identified in our Clinical Research Data Warehouse. Demographic, clinical, and screening data for breast, cervical, colorectal, and prostate cancers were collected. The American Cancer Society, National Comprehensive Cancer Network, and UCSF transgender breast cancer screening guidelines were used as standards for screening indications. Multivariable logistic regression was conducted to evaluate factors predictive of guideline-concordant screening uptake. **Results:** We identified 2,478 TGD patients (821 transgender men (TGM), 789 transgender women (TGW), and 868 gender-diverse (GD) patients). Median age was 28 years (range 18-86) and 62% were treated at the IHC. Most patients were White (78.3%) and non-Hispanic (91.1%). Sixty-four percent of patients used private health insurance, 26.2% used government insurance, and 9.2% were uninsured. Average duration of gender-affirming hormone therapy was 4.0 years (IQR 2.0, 6.0), and 31% of patients had received gender-affirming surgery. Fifty-two percent of patients had some family cancer history at any disease site. Rates of guideline-concordant cancer screening uptake are presented in Table 1. On multivariate analyses, GD gender identity (OR 2.55, 95% CI 1.68-3.88, $p<0.001$), age (OR 1.05, 95% CI 1.02-1.08, $p<0.001$), and treatment at the IHC (OR 2.24, 95% CI 1.50-3.40, $p<0.001$) were predictors of cervical cancer screening uptake. No significant predictors were identified of screening uptake for other disease sites. **Conclusions:** Gender-specific medical care is valuable for promoting guideline-concordant cancer screening uptake. Even in a specialized care center, we found poor rates of recommended cancer screening uptake in TGD patients, demonstrating opportunities to improve uptake of gender-specific cancer screening. Research Sponsor: None.

Rates of guideline-concordant cancer screening uptake by disease site and gender identity.

Disease Site	Overall (n=2,478)	TGW (n=789)	TGM (n=821)	GD (n=868)	*p*-value
Breast	49.2%	40.8%	38.5%	60.0%	0.12

Development and validation of a multidimensional cfDNA assay for cancer detection and tissue-of-origin prediction. First Author: Hua Bao, Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Early detection remains a major unmet need in oncology, and multi-cancer early detection assays that analyze circulating cell-free DNA features have shown promise for detecting multiple cancers with high specificity and tissue-of-origin prediction. Here, we leverage whole-genome sequencing (WGS) to extract multiple cfDNA features (genomic, fragmentomic, and estimated methylation) from a single assay to enable multi-cancer early detection and tissue-of-origin (TOO) localization. **Methods:** Plasma samples were collected in a multicenter, prospective case-control study. From 5× low-pass WGS data, multiple cfDNA feature sets were extracted, including fragmentomic, genomic, and inferred epigenetic features. Machine learning models were trained for cancer detection (healthy vs. cancer) and tissue-of-origin (TOO) classification. The training set included 3,577 healthy and 3,578 cancer participants, and the independent validation set included 2,384 healthy and 2,386 cancer participants. Cancer cases spanned 56 cancer types, grouped into 21 cancer classes. **Results:** Age and sex are evenly distributed across healthy and cancer samples in both the training and validation datasets (Table 1). At 99% specificity, cancer detection sensitivity increased with stage and was consistent between training and validation cohorts: Stage I: 70.66% vs 70.89%, Stage II: 80.41% vs 80.27%, Stage III: 89.89% vs 88.58%, and Stage IV: 92.23% vs 91.76%. Across tumor types, sensitivity at 99% specificity varied substantially, ranging from 57.43% (Thyroid tumor) and 63.87% (Kidney cancer) to 95.96% (Lymphoma) and 99.07% (Liver/Biliary cancer). Tissue-of-origin prediction achieved high accuracy in machine-learning predicted cancer-positive samples (Top-1/Top-2: 0.75/0.89 in training; 0.75/0.88 in validation). **Conclusions:** We developed a cost-efficient blood test (CanScan Pro) using multidimensional cfDNA features from low-pass WGS and machine learning that detects cancers at 99% specificity, with sensitivity increasing by stage and similar performance in training and validation cohorts. The model predicts tissue of origin with high accuracy, which may help guide downstream diagnostic evaluation following a positive result and thereby enhance real-world clinical utility. Research Sponsor: None.

Implementation of a multi-cancer early detection (MCED) test in a private practice: Adoption, performance, and repeat-testing patterns. First Author: Eric Sue, Century City Medical Management, Los Angeles, CA

Background: Century City Medical Management (CCMM), a network of private primary care practices, implemented MCED testing as part of their cancer screening program. The MCED test detects a cancer signal in cell-free DNA isolated from peripheral blood and predicts the cancer signal origin (CSO). We describe CCMM's MCED testing workflow and real-world performance. **Methods:** MCED testing is discussed with all CCMM patients as part of routine care, and shared decision-making guides test utilization. Pts with a positive MCED test result (cancer signal detected) are directed to pursue targeted diagnostic evaluation. This analysis reports on data from 1,949 pts who had 2,922 MCED tests, with results returned between 11/29/21 and 11/24/25. Diagnostic evaluations and clinical outcomes were collected through a Quality Assurance Program via follow-up with ordering providers. All data were deidentified in accordance with HIPAA using the Expert Determination method. The cancer signal detection rate (CSDR) was defined as the proportion of positive MCED tests among all tests administered during the first screening round. Among pts with diagnosed cancers and data available, CSO accuracy (top-two predictions) and median time to diagnosis were calculated. Results of MCED retesting after an inconclusive workup and the frequency of annual MCED screening were evaluated. **Results:** At the first MCED test (N = 1,949), median age was 63y (IQR: 55-71), 47.5% were female, and the CSDR was 1.03% (95% CI, 0.63–1.58%; 20/1,949). Across all screening rounds, 24 pts had a positive MCED result; 16/24 had ≥12mo follow-up at data cutoff. Among these 16, 3 had an active cancer at testing. Of the 13 pts with ≥12mo follow-up and no active cancer at testing, 7 were subsequently diagnosed with cancer. CSO accuracy was 100% (7/7). None of the diagnosed cancers had USPSTF A/B-recommended screening. 1 diagnosis (symptomatic pt) occurred before MCED results were returned; median time from test results to diagnosis of the other 6 was 62 days (IQR: 30.5-143). 5 pts with an initial positive test but negative CSO-directed workup had an MCED retest and ≥12-mo follow-up. Among these, 4 pts with a negative retest remained cancer-free through the end of follow-up, and 1 with a positive retest was diagnosed with a cancer matching the initial and retest CSO. Among 996 pts tested with >15mo of follow-up, 686 (69.6%) received ≥2 MCED screening tests. The most common interval between consecutive tests was annual (9-15mo), with <10% exceeding an 18-mo interval. **Conclusions:** MCED testing in a real-world population achieved test performance, CSO accuracy, and diagnostic resolution timelines consistent with prior studies, with high annual screening uptake and clinical utilization of repeat testing after inconclusive CSO-directed workups. The findings support feasible and scalable implementation of MCED testing in primary care. Research Sponsor: GRAIL, Inc.

Generalizable cancer detection from ultra-low-pass whole-genome sequencing of cell-free DNA using a sequentially fine-tuned transformer framework. First Author: Rui Liu, Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Ultra-low-pass whole-genome sequencing (ULP-WGS) of cell-free DNA (cfDNA) provides a cost-effective approach for cancer screening, yet its clinical translation is constrained by extreme data sparsity and poor model generalizability, particularly in low-tumor fraction (TF) settings. **Methods:** We developed Fragmentia-AI WGS, a mutation-independent framework that leverages a transformer-based multiple-instance learning architecture with sequential fine-tuning across TF strata to extract latent cancer-associated signals from ULP-WGS data (~0.02× coverage, ~128k reads). Model performance and generalizability were evaluated across multiple independent cohorts, including a pan-cancer test cohort across 17 cancer types, a public online cohort sequenced on a different platform, and an analytical variability assessment cohort comprising samples processed under heterogeneous technical and pre-analytical conditions. Clinical relevance was further examined by associating prediction scores with progression-free survival (PFS) in patients with advanced non-small cell lung cancer receiving immunotherapy. **Results:** Sequential fine-tuning across all TF strata substantially improved performance in low-TF samples compared with high-TF-only training, yielding a 35.6% relative increase in AUC in the low-TF subgroup (from 0.652 to 0.884 in the validation cohort). In the independent test cohort, the model achieved an overall AUC of 0.930 (95% CI: 0.924 – 0.936), with consistently strong performance across TF levels (high TF: 0.984; medium TF: 0.958; low TF: 0.910) and across cancer types. External validation in the public cohort demonstrated robust cross-platform and cross-population generalizability (AUC: 0.929; sensitivity: 0.78; specificity: 0.92). Prediction scores remained stable across heterogeneous experimental conditions, supporting robustness to technical and pre-analytical variability. Notably, lower model prediction scores were independently associated with prolonged PFS (hazard ratio: 0.49, 95% CI: 0.31 – 0.77; p = 0.002) after adjusting for sex, age, clinical stage, and histologic subtype. **Conclusions:** Fragmentia-AI WGS enables robust and generalizable cancer detection as well as clinically meaningful risk stratification from ultra-sparse cfDNA sequencing, underscoring its potential for scalable and cost-effective liquid biopsy applications. Research Sponsor: None.

Beyond detection: Five-year screening behaviors and patient-reported perceptions in DETECT-A participants. First Author: Tomasz M. Beer, Exact Sciences Corporation, Madison, WI

Background: Multi-cancer early detection (MCED) blood testing may improve early cancer detection. The impact of MCED testing on anxiety and standard of care (SoC) cancer screening adherence is not fully understood. Detecting cancers Earlier Through Elective mutation-based blood Collection and Testing (DETECT-A) enrolled 10,006 women aged 65 to 75 years from the Geisinger Health System (GHS) with no previous history of cancer and assessed a single instance of MCED (CancerSEEK) testing in 9,911 subjects. Herein, we report cancer survey results, and SoC screening adherence over a 5-year follow-up period (5YFU). **Methods:** Medical record review and participant surveys administered at prespecified intervals, including approximately 5 years after enrollment, were used to assess patient experience, anxiety, and commitment to SoC screening. Decision regret/participation was assessed using a 5-item, 5-point agreement scale; perceived impact on anxiety, depression, and intention to adhere to SoC screening were assessed using 3-option directional responses (more/less/no change), with a 'prefer not to answer' option. Observed SoC screening adherence was assessed through August 2024. SoC screening eligibility (U.S. Preventive Services Taskforce criteria) and adherence data were available for DETECT-A subjects. Changes in adherence over time were assessed using a mixed effects model. **Results:** 8,114 subjects completed all survey questions. 97.3% expressed no participation regret; 94.8% noted a willingness to participate again. Most participants reported no changes in anxiety (89.4%) or depression (96.6%) levels since enrollment. 98.7% reported an equal or greater likelihood of adhering to SoC screening. SoC screening adherence was assessed for a subset of DETECT-A subjects who had at least one month of active GHS patient status (Breast and CRC) and were also eligible for screening (Lung, Breast, CRC). DETECT-A subject SoC adherence was high at consent (Lung: 28.0%, Breast: 88.4%, CRC: 73.9%) and remained high at one year (Lung: 38.5%, CRC: 82.3%) or two-year (Breast: 87.7%) follow-up post consent. Adherence remained high throughout the follow-up period. **Conclusions:** DETECT-A subjects were satisfied with study participation and reported little change in anxiety and depression. Reported commitment to SoC screening adherence was high and observed adherence to recommended screening modalities was maintained over the follow-up period. In a controlled setting of a prospective clinical trial, MCED testing did not contribute to anxiety or depression and did not interfere with adherence to SoC screening. Evaluation of a novel blood-based lung cancer screening test in elevated-risk subjects. First Author: Dawn R. Mattoon, Mercy BioAnalytics, Inc., Waltham, MA

Background: Less than 20% of individuals recommended for lung cancer (LC) screening are screened each year by low dose computed tomography (LDCT), highlighting the need for a more acceptable screening modality. Tumor-associated extracellular vesicles and particles (EVPs) are highly abundant in blood and carry surface biomarkers from their tumor cell of origin, providing a readily measurable analyte class for blood-based screening tests. Test sensitivity may be improved by EVP abundance; specificity by simultaneous measurement of multiple co-localized cancer-related markers on a vesicle surface. We report performance of an EVP-based LC Screening Test in plasma samples from elevated risk participants in the National Lung Screening Trial (NLST). **Methods:** The LC Test (biomarkers and classifier) was locked following a training study, after which we validated consistent assay performance in an independent cohort. Here we evaluated the LC Screening Test in a blinded case-control study nested within the ACRIN Biomarker Arm of the NLST. The study included all available incident LC cases for which subject-matched blood samples were available from the year of diagnosis (T) and the year prior (T-1) (n = 48 cases; 96 samples). Controls were age-matched NLST subjects who had no LC detected before or within the trial follow up period (n = 60). LC Test results were determined blinded to case-control status, with unblinding by ECOG-ACRIN. LC Test sensitivity was calculated at a threshold pertaining to 90% specificity, superior to 87% reported specificity for LDCT in NLST (Lung RADS v1.1). LDCT positivity was based on Lung RADS v1.1 interpretation. **Results:** Across two screening encounters (T and T-1), 34.4% sensitivity, similar across stages, was observed for the blood-based LC Screening Test, compared to 39.5% sensitivity for LDCT, p = 0.53 McNemar test, indicating no significant difference in observed sensitivity between LDCT and the blood test. Complementarity in detection was observed between LDCT vs blood-test detected cases across all histologies. A mean 42% increase was observed in LC Screening Test scores from T-1 to T, indicating signal increase may provide additional sensitivity. **Conclusions:** The blood-based LC Screening Test exhibits similar performance to LDCT in detecting preclinical lung cancer in high-risk individuals and detects some LCs not found by LDCT. The data supports further evaluation of the LC Test for LC screening. Research Sponsor: Mercy BioAnalytics.

Next-generation multi-cancer early detection (MCED) assay: Independent blinded validation of a locked serum multi-omics NMR test with stage I sensitivity. First Author: Patrick C. Strasser, Wholomics GmbH, Ried Im Innkreis, Austria

Background: Blood-based MCED assays could complement existing screening, but many approaches show reduced sensitivity in early-stage disease. Wholomics developed a serum multi-omics MCED assay integrating metabolomic, lipidomic, and proteomic features quantified by proprietary NMR-based technology, designed to capture systemic biology associated with early tumor development. We report independent, blinded validation of a locked MCED assay developed on multi-center data; across training and validation, the program included >1,400 individuals and >13 cancer types. The full assay pipeline was locked before application to the independent validation cohort. **Methods:** Model development leveraged prior multi-center data (N = 1,211) from five European centers (669 cancers, 65% were stage 0-II; 442 controls plus precancerous/benign cohorts). We evaluated an independent validation cohort (N = 216) with 116 cancers (50% were stage 0-II [stage I n = 40; stage II n = 16]; cancers included colon, rectal, pancreatic, cervical, uterine, bladder, breast, gastric, renal, ovarian) and 100 controls with screening-relevant conditions (e.g., dyslipidemia, prediabetes, benign prostatic hyperplasia, osteoarthritis, etc.). Samples were analyzed with fully prespecified locked assay pipeline (proprietary NMR profiling according to SOP with predefined QC, data preprocessing, biomarker feature set, machine-learning model, and decision threshold) and applied to blinded outcome labels. Primary endpoints were specificity and sensitivity (overall, stage I, stage III-IV). 95% CIs for sensitivity and specificity were calculated using the Wilson score method; AUC 95% CIs were calculated using DeLong's method. **Results:** The locked MCED assay achieved specificity of 99.0% (99/100; 95% CI 94.6–99.8; false-positive rate 1.0%) and overall sensitivity of 93.1% (108/116; 95% CI 87.0–96.5). Stage I sensitivity was 95.0% (38/40; 95% CI 83.5–98.6), Stage III-IV sensitivity remained high in advanced stages at 93.1% (54/58; 95% CI 83.6–97.3). AUC was 0.991 (95% CI 0.979-1). High overall sensitivity was observed across multiple tumor types, including pancreas, stomach, kidney, colon (each 100% overall) and rectum (92.3% overall). **Conclusions:** In an independent blinded validation, a locked serum multi-omics NMR-based MCED approach demonstrated high specificity and high sensitivity, including strong stage I performance, across multiple solid tumors in a screening-relevant case-control setting. These findings support clinical utility for shifting detection toward earlier, more treatable stages and warrant prospective studies to confirm real-world performance and downstream impact. Research Sponsor: Wholomics GmbH.

Precision risk stratification for lung cancer in COPD: Evidence from the All of Us Program. First Author: Muhammad Rafiqul Islam, University of Chicago, Chicago, IL

Background: Chronic obstructive pulmonary disease (COPD) is a well-established independent risk factor for lung cancer, yet determinants of cancer susceptibility within this high-risk population remain incompletely characterized. Identifying clinical and genomic predictors is essential to improve risk stratification, early detection, and precision prevention strategies. **Methods:** We conducted an age-matched case–control study using de-identified data from the *All of Us* Research Program to evaluate sociodemographic characteristics, comorbidities, and genetic variants associated with lung cancer risk among adults with COPD. Baseline characteristics were summarized using descriptive statistics. Multivariable logistic regression was used to estimate adjusted odds ratios (AORs) controlling for relevant confounders. Genome-wide association studies (GWAS) were performed with rigorous quality control, population stratification adjustment, and correction for multiple testing. **Results:** Among 633,540 participants, 26,570 (4.2%) had COPD, including 2,044 (7.7%) with lung cancer. The mean age was 67.5 $\pm$ 11.4 years; 43.4% were male. In multivariable analysis, Asian ancestry was associated with increased lung cancer risk (AOR 2.25, 95% CI 1.55–3.26). Age 66–95 years conferred a 29% higher risk, and family history of lung cancer increased risk by 34% (95% CI 1.15–1.57). Hypothyroidism (AOR 1.58, 95% CI 1.27–1.97) and hyperlipidemia (AOR 1.32, 95% CI 1.04–1.68) were independently associated with lung cancer. GWAS identified 19 variants significantly associated with lung cancer risk, including rs539223166, rs551676206, rs922466204, rs144626313, rs147989022, and rs74502961. **Conclusions:** Distinct clinical and genetic factors contribute to lung cancer susceptibility among individuals with COPD. Integrating these determinants may enhance risk prediction and inform targeted surveillance strategies. Research Sponsor: None.

Impact of AI-based risk stratification integrating routine laboratory data with age on screening volume and multi-cancer early detection yield. First Author: Mao Mao, SeekIn Inc., Shenzhen, China

Background: Early cancer detection improves survival, yet population-wide screening remains costly and logistically challenging. Traditional cancer risk models, such as lifestyle-based assessments and polygenic risk scores, offer limited predictive performance. Routine laboratory tests (complete blood count, urinalysis, and biochemical panels) are performed in primary care and may harbor latent cancer signals. We developed an AI-based cancer risk assessment (CRA) model using routine laboratory data to enrich cancer cases and improve the cost-effectiveness of downstream multi-cancer early detection (MCED) testing. **Methods:** Routine laboratory data from 7,672 individuals (1,245 cancer; 6,427 non-cancer) across two hospitals were retrospectively collected and used to develop a random forest based CRA model incorporating 56 selected routine laboratory features. Among them, 5,392 (70.3%) also underwent OncoSeek test, a validated MCED assay based on seven protein tumor markers (e.g., AFP, CEA). OncoSeek screening performance was estimated under two enrichment strategies: (1) age-based enrichment ($\geq$50 years), and (2) risk-stratified enrichment using a joint CRA–age model. A two-dimensional CRA–age risk landscape was used to estimate cancer incidence across strata. Strata with a modeled cancer incidence $\geq$0.57%, corresponding to the overall cancer incidence among Chinese adults (GLOBOCAN 2017), were classified as high risk. Performance metrics from both strategies were applied to simulate OncoSeek screening outcomes in a hypothetical cohort of 1,000,000 adults aged $\geq$20 years. **Results:** In the simulated cohort with an overall cancer incidence of 0.57%, direct OncoSeek screening detected 2,450 cancers with a PPV of 5.6%. Age-based screening ($\geq$50 years) required screening 536,206 individuals ($-$46.4%), increased cancer incidence to 0.92%, and detected 2,327 cancers. In contrast, CRA–age risk-stratified screening reduced the screened population to 178,660 individuals ($-$82.1%), enriched cancer incidence to 2.69%, and detected 2,402 cancers. Compared with age-based screening, CRA–age stratification improved PPV from 7.6% to 15.9%, reduced false positives by 55.2% and lowered the cost per cancer detected from $18,436 to $5,950 ($-$67.7%), while preserving overall cancer detection. **Conclusions:** AI-based CRA–age risk stratification enables efficient population-level cancer screening by restricting downstream MCED testing to a high-risk subset comprising approximately one-fifth of the population, while preserving overall cancer detection. This strategy substantially improves PPV, reduces false positives, and lowers the cost per cancer detected. These findings support a risk-stratified MCED screening paradigm as a scalable and economically sustainable alternative to population-wide or age-based population screening. Research Sponsor: None.

Machine learning–optimized multi-biomarker panel for discriminating lung cancer from LDCT-positive benign pulmonary nodules. First Author: Sungjoon Park, Department of Thoracic and Cardiovascular Surgery, Seoul National University Bundang Hospital, Seoul, South Korea

Background: Accurate discrimination between lung cancer and benign pulmonary nodules remains a critical challenge in lung cancer screening, particularly among individuals with positive findings on low-dose computed tomography (LDCT). Blood-based biomarkers with proven biological relevance may improve risk stratification when integrated with advanced analytical approaches. Serum carcinoembryonic antigen (CEA), serum amyloid A (SAA), and osteopontin (OPN) are biomarkers reflecting tumor burden, host inflammatory response, and tumor microenvironmental activity, respectively. The discriminatory performance of these three biomarkers between healthy individuals and lung cancer patients has previously been validated in a cohort exceeding 2,000 subjects (ASCO 2025, Abstract #489322). Building on this foundation, the present study evaluates whether algorithmic integration of these biomarkers can improve discrimination of lung cancer within the clinically challenging population of LDCT-positive pulmonary nodules. **Methods:** Serum CEA, SAA, and OPN levels were quantified by ELISA in patients with histologically confirmed lung cancer and individuals with LDCT-positive benign pulmonary nodules. To enhance discrimination within this high-risk cohort, machine learning–based modeling was applied. Multiple analytical methods were evaluated, and a Random Forest classifier was selected to capture inter-marker correlations and non-linear biological relationships. The dataset was divided into independent training and validation cohorts. Diagnostic performance was assessed using sensitivity, specificity, and area under the receiver operating characteristic curve (AUC). **Results:** In the LDCT-positive pulmonary nodule population, the machine learning–optimized three-biomarker panel demonstrated strong discriminatory performance. In the validation cohort, the model achieved an AUC of 0.879, with a sensitivity of 88.8% and a specificity of 83.3% for differentiating lung cancer from benign nodules. The algorithm consistently outperformed individual biomarkers and linear models, including in early-stage lung cancer. **Conclusions:** Application of machine learning to a biologically complementary three-protein biomarker panel significantly enhances discrimination of lung cancer within LDCT-positive high-risk pulmonary nodule populations. These findings support the clinical utility of this non-invasive approach as an adjunct to LDCT, addressing a key diagnostic gap in lung cancer screening and management. Research Sponsor: None.

Association of high postoperative physical activity with ctDNA MRD positivity and recurrence-free survival across solid tumors: The SCRUM-MONSTAR LIFELOG study. First Author: Shugo Yajima, Department of Urology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Physical activity is associated with improved survival across multiple cancer types, yet its relationship with molecular residual disease (MRD) detected by circulating tumor DNA (ctDNA) remains unclear. We examined whether objectively measured physical activity correlates with postoperative ctDNA status. **Methods:** The LIFELOG study, ancillary to MONSTAR-SCREEN-3, enrolled patients who underwent curative surgery for solid tumors. Participants wore a wrist-based device targeting 1 month during the early postoperative period. Accelerometer and photoplethysmography data were processed to derive metrics including mean acceleration, moderate-to-vigorous physical activity (MVPA) percentage, longest MVPA bout, and high-intensity heart rate zone percentage. K-means clustering (k=3) classified patients into activity phenotypes. ctDNA was assessed serially using an ultrasensitive whole-genome sequencing-based MRD assay (Myriad Genetics). ctDNA positivity at 1 and 3 months postoperatively were compared between activity phenotypes, with overlap weighting used to adjust for potential confounders. **Results:** Of 127 enrolled patients, 4 were excluded due to no device data, leaving 123 for analysis. Adequate wear time ($\geq$10 hours/day on $\geq$3 days/week) was achieved in 113 patients (91.9%). Cancer types included colorectal (n=29), urothelial (n=24), hepatocellular (n=13), gastric (n=11), renal (n=11), and others (n=35). Median age was 70.1 years; 57.7% were male; 46.3% had stage III-IV disease. Clustering identified three phenotypes: Cluster 1 (high activity; n=10), Cluster 2 (moderate; n=53), and Cluster 3 (low; n=60). Activity metrics differed across clusters (any $P<0.001$). Cluster 3 had significantly inferior recurrence-free survival compared with Clusters 1+2 (hazard ratio 4.01; 95% confidence interval, 1.10-14.6; P=0.035). Postoperative ctDNA positivity was significantly higher in Cluster 3 compared with Clusters 1+2 at both 1 month (32.5% vs 6.4%; P=0.002) and 3 months (30.0% vs 2.4%; $P<0.001$). At 3 months, this difference persisted after adjustment for age, sex, adjuvant chemotherapy, stage, and cancer type (P=0.003). Among 80 patients with evaluable ctDNA data at both 1 and 3 months, of 15 patients who were ctDNA-positive at 1 month; conversion to ctDNA-negative at 3 months was observed in 66.7% in Clusters 1+2 versus 16.7% in Cluster 3 (P=0.15). Of 65 patients who were ctDNA-negative at 1 month; conversion to ctDNA-positive at 3 months was observed in 0% in Clusters 1+2 versus 7.7% in Cluster 3 (P=0.16). **Conclusions:** Lower objectively measured physical activity was associated with higher postoperative ctDNA positivity rates and inferior recurrence-free survival. These findings warrant validation in larger cohorts and investigation of exercise-based interventions in postoperative cancer care. The PROFOUND study: A large-scale prospective multicenter case-control trial of a multi-cancer early detection (MCED) test in China. First Author: Kezhong Chen, Thoracic Oncology Institute and Department of Thoracic Surgery, Peking University People's Hospital, Beijing, China

Background: Early cancer detection reduces morbidity and mortality, but current recommended screening in China misses many lethal cancers. Emerging liquid biopsy-based MCED tests have the potential to increase the number of screen-detected cancers when added to recommended screening. In this study, we evaluate the performance of a MCED test tailored to 16 cancer types covering 85% of China's total cancer incidence, including malignancies without recommended screening tests in the large-scale, prospective, multicenter case-control PROFOUND study. **Methods:** A total of 10,541 participants from over 50 sites nationwide were enrolled, with the cohort comprised by a training set (7,487 participants: 4,448 cancer, 3,039 non-cancer) and a test set (3,054 participants: 1,740 cancer, 1,314 non-cancer). It included 16 major cancer types encompassing diverse pathological subtypes, with stage I-III cases accounting for 83.31% of all cancer samples. All cancer cases were confirmed via pathological diagnosis. Blood samples underwent targeted methylation profiling and were analyzed with the Genie-ADLA AI algorithm to train, validate and independently verify the MCED assay, as well as assess its clinical performance (sensitivity, specificity, tissue-of-origin [TOO] prediction accuracy). **Results:** In the validation set, specificity was 99.03% (95% CI: 98.27%–99.51%), overall sensitivity was 70.63% (95% CI: 67.23%–71.67%) and sensitivity for stage I–III cancers was 66.03% (95% CI: 63.53%–68.46%). The overall TOO prediction accuracy reached 85.21% (95% CI: 83.05%–87.20%). For the five highest-mortality cancers (liver, colorectal, esophageal, gastric and lung cancer), sensitivities were 87.85%, 90.48%, 83.78%, 72.85% and 69.54% respectively. Sensitivities of lung adenocarcinoma and non-adenocarcinoma were 48.75% and 92.96%, respectively. Among them, non-adenocarcinoma is more likely to be missed in recommended screening tests. For cancers without recommended screening (pancreatic, ovarian, gallbladder cancer, lymphoma), sensitivities reached 64.75%, 87.88%, 100% and 74.72%, respectively. **Conclusions:** Powered by the Genie-ADLA AI algorithm, the PROFOUND study's MCED assay demonstrated robust performance including high sensitivity, specificity and TOO prediction accuracy for 16 cancer types (including cancers do not have recommended screening). It may serve as a complementary tool to augment recommended screening and revolutionize early cancer detection paradigms. A prospective interventional clinical study covering 16 cancer types will be launched to further validate MCED's clinical effectiveness. Clinical trial information: NCT06217900. Research Sponsor: Shanghai Xiaohe Medical Laboratory Co. Ltd.

Prospective evaluation of the psychological impact of multicancer early detection (MCED) blood testing: A smartphone-based patient-reported outcomes study. First Author: Ronan Joseph Kelly, Baylor University Medical Center, Dallas, TX

Background: Earlier detection may reduce cancer mortality by reducing the number of cancers diagnosed at advanced stages. Prospective data evaluating the emotional impact of MCED testing are limited, particularly when paired with digital engagement tools. Smartphone-based applications offer an opportunity to monitor patient-reported distress in real time and provide scalable support throughout the testing journey. The Falcon registry is a large prospective study evaluating the Exact Sciences MCED test in clinically cancer-free individuals that included evaluation of patient reported outcomes (PRO) using digital tools. **Methods:** Falcon (NCT06589310) is a multi-site registry enrolling up to 25,000 participants, 50-80 years of age. Participants receive the MCED test annually for 3 years and complete PRO measures, including the Generalized Anxiety Disorder-7 (GAD-7) assessment. The assessment is administered via the myBSWHealth digital platform at baseline (T0), ≤14 days of receiving test results (T1), and at approximately 6 months (T2). Reminders encouraged timely survey completion, and adaptive content was delivered based on distress scores. GAD-7 scores are categorized for clinical interpretation of anxiety: 0-4 minimal, 5-9 mild, 10-14 moderate, 15-21 severe. Clinically meaningful changes (+/->4) in anxiety severity at T0-T1 and T0-T2 were assessed. **Results:** 8,977/9,204 (97.5%) enrolled participants from 08/2024-01/2026 across the Baylor Scott & White Health System have an activated MyBSWHealth account. 4125 had the potential for 6-month follow-up at data analysis; 2729 (66.1%) completed ≥1 GAD-7 and 2161 (52.4%) had a T0 score. Most participants (94.9%) had minimal to mild anxiety at T0; however, a subset of participants (5.1%) demonstrated moderate to severe anxiety prior to testing. Overall, GAD-7 scores stayed within the minimal anxiety range over time with medians (interquartile ranges) of 1.00 (4.00), 0.00 (3.00) and 1.00 (4.00) at T0, T1 and T2, respectively. Among the 1219 participants who completed the GAD-7 at both T0 and T1, 86% had no clinically meaningful change in anxiety severity, 7% had a decrease, and 6% had an increase. Among the 989 participants who completed the GAD-7 at both T0 and T2, 85% had no change, 7% had a decrease, and 8% had an increase. **Conclusions:** Digital assessment of anxiety during MCED blood testing gives real-time data on the effects of cancer screening in an average risk population. Despite concerns about the potential for population-based cancer screening to increase anxiety, our preliminary findings suggest low levels of anxiety that remain stable in the majority of participants who completed follow-up assessments after receiving an MCED test result. Additional data for anxiety and distress using the Post-Traumatic Stress Disorder (PTSD) Checklist for DSM-5 (PCL-5) will be presented. Clinical trial information: NCT06589310. Research Sponsor: Exact Sciences Corporation.

Performance of a cfDNA methylation–based MCED test in patients with clinicoradiologic suspicion of cancer. First Author: Elie Massaad, Harbinger Health, Cambridge, MA

Background: Radiographic findings concerning for malignancy frequently prompt extensive diagnostic evaluations that fail to yield a definitive diagnosis, resulting in delayed treatment, persistent uncertainty, and unnecessary interventions. Multi-cancer early detection (MCED) tests based on circulating cell-free DNA (cfDNA) methylation have demonstrated high specificity in asymptomatic screening populations; however, performance in individuals with clinical suspicion of malignancy remains unclear. We compared the performance of a cfDNA methylation–based MCED test in asymptomatic participants and in participants with imaging-based suspicion of malignancy. **Methods:** Adults aged 45–79 years enrolled in CORE-HH (NCT05435066) were evaluated in (1) a case–control cohort (n = 4,137) comprising asymptomatic participants who reported no history of cancer (n = 2,523) and newly diagnosed cancer participants (n = 1,614); and (2) a prospective cohort (n = 209) of individuals with imaging-based suspicion of malignancy undergoing clinical evaluation (cancer confirmed, n = 155; no cancer, n = 54). Cancer types included lung, breast, colorectal, prostate, pancreatic/hepatobiliary, head and neck, gynecologic, and hematologic malignancies. Samples were analyzed using a cfDNA methylation–based MCED test incorporating an AI/ML model, at a pre-specified specificity of 98.5%. Test performance was compared between cohorts among non-cancer participants and among early-stage (stage I–II) and late-stage (stage III–IV) cancer cases using Fisher's exact test (two-sided). **Results:** Among non-cancer participants (n = 2,577), empirical specificity was 98.1% (53/54) in the clinical suspicion cohort and 98.5% (2,485/2,523) in the asymptomatic case–control cohort (OR, 1.23; 95% CI, 0.03–7.6; p = 0.56). Overall sensitivity was 54.8% (85/155) in the clinical suspicion cohort and 53.9% (870/1,614) in newly diagnosed cancer cases from the case–control cohort (OR, 1.04; 95% CI, 0.74–1.47; p = 0.87). Stage I–II sensitivity was 27.7% (18/65) vs 28.7% (204/711) (p = 1.00), and stage III–IV sensitivity was 82.9% (58/70) vs 81.5% (573/703) (p = 0.87), for the clinical suspicion and case–control cohorts, respectively. Overall cancer stage distribution was similar between cohorts (p = 0.89). **Conclusions:** At the prespecified 98.5% specificity threshold, the cfDNA methylation–based MCED test demonstrated comparable specificity and sensitivity in prospectively enrolled participants undergoing evaluation for imaging-based suspicion of malignancy and in a case–control cohort of newly diagnosed cancer cases versus asymptomatic controls. Recognizing the tendency of case–control designs to overestimate test performance, these results describe MCED test performance in a cohort with clinical suspicion of malignancy, extending characterization beyond asymptomatic screening populations. Clinical trial information: NCT05435066. Research Sponsor: None.

A phase II open-label, single-arm study to evaluate the efficacy of pembrolizumab for leukoplakia. First Author: Maria Antonia Velez Velez, Division of Hematology/Oncology, University of California, Los Angeles, Los Angeles, CA

Background: Oral leukoplakia and erythroleukoplakia represent high-risk premalignant lesions of the oral cavity, with malignant transformation to head and neck squamous cell carcinoma reported in up to 36% of cases. Therapies are limited, with surgical resection remaining the standard of care despite high recurrence rates. Immune checkpoint inhibitors (ICIs) have emerged as a potential preventive strategy. We evaluated whether the efficacy of the PD-1 inhibitor pembrolizumab may serve as a preventive strategy to reduce progression to invasive carcinoma in patients (pts) with these premalignant lesions. **Methods:** This nonrandomized, open-label, multi-center phase II clinical trial enrolled pts between June 2019 and December 2025. Eligible pts had oral leukoplakia, erythroleukoplakia, or proliferative verrucous leukoplakia with moderate dysplasia, severe dysplasia, or carcinoma in situ. Patients with previously treated squamous cell carcinoma (SCC) were included. Pts received pembrolizumab 200 mg intravenously every 3 weeks for 6 months. The primary endpoint was clinical response at 6 months, defined as the proportion of patients achieving a complete response (CR) or partial response (PR). CR was defined as complete lesion resolution on visual inspection sustained for ≥4 weeks. PR was defined as a ≥50% reduction in the product of the two largest perpendicular dimensions of a single lesion or the sum of all measurable lesions. The secondary objectives included clinical response rate at 9 and 12 months, and toxicity. **Results:** Sixteen pts received at least one dose of pembrolizumab. The median age was 63.5 years (range, 33–82), and 44% were female. Three patients had previously treated SCC. Baseline pathology demonstrated moderate dysplasia in 31% and severe or high-grade dysplasia in 69% of patients. At 6 months, the clinical response rate was 44% (7/16; 95% CI, 23–67%), including CR in 19% (3/16) and PR in 25% (4/16) of pts. Progressive disease occurred in 38% (6/16) of patients. Clinical response rates were 31% at 9 months (5/16) and 19% at 12 months (3/16). Median follow-up was 9 months. Treatment-related adverse events (TRAE) occurred in 69% of pts, most commonly fatigue (31%), mucositis/oral discomfort (31%), hypothyroidism (25%), and gastrointestinal immune-related events, including diarrhea or colitis (25%). Grade ≥3 treatment-related adverse events occurred in 19%, with no grade 4–5 events or treatment-related deaths. One pt discontinued due to TRAE. **Conclusions:** These findings suggest that PD-1 blockade may represent a feasible preventive approach for high-risk oral premalignant lesions and warrants further investigation as a preventive option. Biomarker evaluation of pre-treatment and on-treatment biopsies are ongoing to inform predictors of response. Clinical trial information: NCT03603223. Research Sponsor: Merck.

Risk prediction models for familial breast cancer: A Cochrane systematic review and meta-analysis. First Author: Sarah A. McGarrigle, St James's Hospital, Trinity St James's Cancer Institute, Dublin, Ireland

Background: Women with a family history of breast cancer (BC) have an increased risk of developing the disease. Several BC risk prediction models are used in clinical practice to estimate future BC risk, however, their comparative performance in women with a family history of BC is uncertain. The aim of this study was to systematically identify, describe, and critically appraise BC risk prediction models developed or validated in women with a family history of BC, and to synthesize their performance in predicting BC occurrence in this population. **Methods:** We searched MEDLINE, Embase, CINAHL, and ISI Web of Science up to February 2022, with a targeted MEDLINE update to 19 December 2024. We included studies that developed or externally validated BC risk prediction models in women with a family history of BC, provided family history was included as a predictor. Data were extracted using the CHARMS checklist, and risk of bias was assessed using PROBAST. Where data from more than three validation studies were available, random-effects meta-analyses of calibration (observed/expected [O/E] ratios) and discrimination (c-statistic) were conducted. **Results:** Forty-five studies were included. Twelve models were externally validated in the target population; four were validated more than three times and included in meta-analyses. Reporting quality was variable, and most studies had high or unclear risk of bias. The Gail (BCRAT) model was well calibrated (pooled O/E 1.06, 95% CI 0.91–1.25) but showed modest discrimination (c-statistic 0.61, 95% CI 0.57–0.66). BOADICEA was also well calibrated (O/E 0.98, 95% CI 0.90–1.17) with modest discrimination (c-statistic 0.65, 95% CI 0.58–0.71). Tyrer-Cuzick (IBIS) overpredicted risk (O/E 0.86, 95% CI 0.74–0.98), while BRCAPRO underpredicted risk (O/E 1.44, 95% CI 1.25–1.62). Discriminatory accuracy was similar across Tyrer-Cuzick v8, BOADICEA, and BRCAPRO, with pooled c-statistics of 0.64 (0.58 to 0.71), 0.65 (0.58 to 0.71),0.64 (0.54 to 0.73) respectively and slightly higher than Gail (pooled c-statistic 0.61 (0.57 to 0.66)) . **Conclusions:** In women with a family history of BC, Gail and BOADICEA are well calibrated, while Tyrer-Cuzick overpredicts and BRCAPRO underpredicts risk. No model demonstrated clearly superior discrimination. Considering both calibration and discrimination, BOADICEA may be useful for clinical risk assessment in this population, although conclusions are limited by study heterogeneity, small numbers of validation studies in the target population, and high or unclear risk of bias. Improved model performance and reporting are needed. This abstract is based on a post-peer review version of a Cochrane Review. Upon acceptance, the final version is expected to be published in the Cochrane Database of Systematic Reviews (www.thecochranelibrary.com). Research Sponsor: Health Research Board.

Evaluating the impact of the 2021 USPSTF age expansion (50–54 years) on racial disparities in early-stage lung cancer diagnosis. First Author: Shubhangi Sharma, Rutgers Health Community Medical Center, Toms River, NJ

Background: In 2021, the USPSTF updated its guidelines to address known racial disparities in lung cancer outcomes. By lowering the screening age to 50 and reducing the pack-year threshold, one of the goals was to better identify Black individuals, who historically develop cancer at younger ages and with lower smoking intensity than their White counterparts. However, despite this expanded eligibility, screening uptake among the newly eligible 50–54 years cohort remains low. Our study evaluates whether these policy changes have translated into a tangible 'stage shift' toward earlier detection among the newly eligible age group and assesses if these benefits are being realized equitably across racial groups. **Methods:** We conducted a retrospective cohort study using SEER November 2024 sub data (21 Registries) for non-small cell lung cancer (NSCLC) cases. We compared the Pre-Guideline (2016–2019) period to the Post-Guideline (2022) period, excluding initial COVID-19 and transition years (2020–2021). A Difference-in-Differences (DiD) approach compared the newly eligible Target Group (50–54 years) against a Control Group (45–49 years) to control for secular staging trends. The primary outcome was the percentage of localized disease at diagnosis, stratified by race. **Results:** In the newly eligible 50–54 cohort, White patients demonstrated a robust stage shift, with localized disease increasing from 23.2% to 28.7% ($p<0.001$). Conversely, Black patients in the target age group experienced a decline in localized detection from 20.1% to 17.5%, with a concurrent rise in distant-stage diagnoses. Notably, Black patients in the younger control group (45–49) showed improved early detection (+3.3%), suggesting the disparity was specific to the guideline implementation in the target cohort. The DiD interaction was significant ($p<0.05$), confirming racially distinct outcomes. Hispanic patients saw a case volume surge without a significant rise in localized disease (22.3% to 22.6%). **Conclusions:** Initial data following the 2021 USPSTF expansion suggests an early stage shift for White patients aged 50–54, while a similar trend was not observed among Black patients in this first year of implementation. This divergence may reflect a temporary implementation lag, variability in provider adoption, or early access delays rather than a definitive failure of the policy. Continued longitudinal surveillance is required to determine whether this gap represents a transient uptake issue or a persistent disparity necessitating targeted structural interventions. Research Sponsor: None.

Impact of age expansion on early detection (% localized disease).

Group	Race	Pre-Guideline (2016-19)	Post-Guideline (2022)	Net Change
Target (50-54 years)	White	23.22%	28.65%	+5.43%
	Black	20.14%	17.53%	-2.61%
	Hispanic	22.33%	22.58%	+0.25%
Control (45-49 years)	White	21.20%	22.44%	+1.24%
	Black	17.79%	21.09%	+3.30%

Evaluation of a novel blood-based lung nodule triage test in elevated-risk subjects. First Author: Dawn R. Mattoon, Mercy BioAnalytics, Waltham, MA

Background: In the National Lung Screening Trial (NLST), 4,354 (6%) of LDCT scans were positive with Lung RADS scores of 3 or 4A, and 162 lung cancers (LCs) were diagnosed within one year of the associated scan. Despite the elevated risk of malignancy, referral for immediate diagnostic (Dx) workup is not recommended; as a result, diagnosis is delayed by an average of 106 days compared with subjects assigned a Lung-RADS 4B or 4X score, who are referred for immediate Dx workup. This delay highlights the need for methods to further risk stratify these subjects and enable more timely evaluation. Tumor-associated extracellular vesicles and particles (EVPs) are highly abundant in blood and carry surface biomarkers from their tumor cell of origin, providing a readily measurable analyte class. We report performance of an EVP-based Lung Nodule Triage Test in detecting LC as a function of Lung RADS score in plasma samples from NLST subjects. **Methods:** The Triage Test (biomarkers and classifier) was locked following a training study. Here we evaluated the Triage Test in a blinded case-control study nested within the ACRIN Biomarker Arm of the NLST. The study included LC cases diagnosed within 24 months of blood draw (n = 51 cases; 99 samples), including longitudinal samples from 48 subjects. Controls were age-matched NLST subjects who had no LC detected before or within the trial follow up period with Lung RADS v1.1 scores of 1 or 2 (n = 60). Triage Test results were determined blinded to case-control status, with unblinding done by ECOG-ACRIN. A static threshold set to 90% specificity was applied to Triage Test scores. **Results:** Among the 99 samples with a diagnosis of LC within 24 months of blood draw, the Triage Test exhibited 34% sensitivity for detection of LC. The Triage Test exhibited 43% sensitivity in samples associated with LDCT-positive screen results not recommended for immediate Dx workup. The projected positive predictive value (PPV) for the Triage Test applied as a reflex test for individuals with Lung RADS 3 and 4A is 13.8% (95% CI: 5.7% - 30.5%, bootstrapping test sensitivity and specificity). **Conclusions:** The blood-based Lung Nodule Triage Test exhibits clinically meaningful performance for detection of LC among subjects with LDCT Lung RADS 3 and 4A scores. The data supports further evaluation of the Triage Test for reflex testing of indeterminant lung nodules. Research Sponsor: Mercy BioAnalytics.

GLP-1 therapy and hormone receptor–positive breast cancer risk and survival: A real-world analysis. First Author: Zunairah Shah, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are increasingly used for weight management and cardiometabolic risk (CMR) reduction, yet their association with breast cancer (BC) incidence and survival in non-diabetic women with elevated BMI remains unclear. We evaluated the relationship between GLP-1 RA exposure and incident BC, as well as overall survival (OS), in a large real-world (RW) cohort of women without laboratory-defined diabetes. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network including female patients (pts) with BMI 25–35 kg/m². Age <50 vs ≥ 50 years served as proxies for pre- and postmenopausal status, with a ≥ 50 sensitivity analysis to assess age/menopause confounding. Pts with HbA1c $\geq 6.5\%$ or prior BC were excluded. Cohorts were propensity score matched (PSM) on age at index, BMI, metformin and statin exposure, BRCA mutation status, hormonal contraceptive use, parity, breastfeeding history, and smoking status. The primary endpoint was incident HR+/HER2− BC, summarized as incidence proportion and risk reduction estimates; secondary analyses evaluated HR+/HER2+, HR−/HER2+, and triple-negative breast cancer (TNBC). OS was evaluated using Kaplan–Meier and Cox regression. **Results:** After PSM, 148,709 pts were included (mean age 45.8 ± 9.54 years in both cohorts). Over a median 36-month follow-up, incident HR+/HER2− BC was lower with GLP-1 RA vs controls (0.29% vs 0.33%), with an absolute difference −0.04% (95% CI −0.081 to −0.001%; P=0.046) and RR 0.88 (95% CI 0.77–0.99). OS was improved with GLP-1 RA vs controls (HR 0.75, 95% CI 0.65–0.86; $P<0.0001$). No difference in BC incidence was found for HR+/HER2+ (RR 0.98, 95% CI 0.86–1.12) or HR− subtypes, including HR−/HER2+ BC (RR 0.83, 95% CI 0.55–1.23) and TNBC (RR 0.68, 95% CI 0.41–1.12). Findings for HR+/HER2− were consistent across menopausal strata (Table). In the postmenopausal cohort (n=91,577; mean age 63.3 ± 6.88 vs 62.4 ± 6.52 years), GLP-1 RA exposure was also associated with lower incidence of HR+/HER2− BC (RR 0.93, 95% CI 0.86–0.99) and improved OS (HR 0.87, 95% CI 0.81–0.94; P=0.0003). **Conclusions:** In a large non-diabetic cohort of women with BMI 25–35 kg/m² and no prior BC, GLP-1 RA exposure was associated with a modest reduction in incident HR+/HER2− BC and improved OS. Despite limited follow-up and age-based menopausal proxies, these findings provide RW evidence supporting prospective validation with standardized exposure definitions and longer follow-up. Future studies should clarify whether GLP-1 RAs confer direct antitumor effects or indirect benefits mediated through weight loss and CMR reduction and identify pts most likely to derive BC risk and survival benefit. Research Sponsor: None.

GLP-1 RA and HR+/HER2− BC outcomes.

	RR (Breast Cancer Incidence)	HR (Overall Survival)
Age <50	0.88 (0.77–0.99)	0.75 (0.65–0.86)
Age ≥50	0.93 (0.86–0.99)	0.87 (0.81–0.94)

Evaluation of intervention strategies to improve follow-up after FIT/FOBT tests: A systematic review and meta-analysis. First Author: Wei Yu Chua, National Cancer Centre Singapore, Singapore, Singapore

Background: Colorectal cancer (CRC) is the third most common cancer worldwide, with the majority of patients diagnosed at advanced stages. Early detection through screenings has been shown to improve morbidity and mortality. However, follow-up after Fecal Immunochemical Test (FIT) / Fecal Occult Blood Test (FOBT) screenings remains low, with 30%-61% compliance to colonoscopy screening and 28-49% compliance to repeat FIT/FOBT surveillance. Our study aims to evaluate 1) interventions targeting colonoscopy completion post-positive FIT/FOBT and improving adherence to follow-up after negative FIT/FOBT, and 2) the rate of colonoscopy completion post-positive FIT/FOBT and the rate of repeat FIT/FOBT adherence after a negative result. **Methods:** We searched MEDLINE, Embase, and Cochrane from inception to December 20, 2025, to identify cohort studies or randomized controlled trials (RCTs) comparing interventions to improve follow-up colonoscopy after positive FIT/FOBT and repeat FIT/FOBT after negative FIT/FOBT. We computed risk ratios (RR) with accompanying 95% confidence Intervals (CIs) for each study and pooled the results using a random-effects meta-analysis. **Results:** Twenty-seven studies involving 30,974 patients were included. 19 studies (11,905 patients) evaluated interventions to improve colonoscopy completion after a positive FIT/FOBT. Patient-level interventions (RR 1.30, 95% CI 1.17–1.44, n=13) and system-level interventions (RR 1.45, 95% CI 1.20–1.77, n=6) significantly increased colonoscopy completion. Patient navigation (RR 1.28, 95% CI 1.15–1.41), patient reminders (RR 1.32, 95% CI 1.04–1.67), and provider reminders (RR 1.45, 95% CI 1.16-1.83) were effective. Patient reminders via messaging (RR 1.55, 95% CI 1.31-1.83) were more effective than calling (RR 1.10, 95% CI 0.91-1.33, p=0.0083). Follow-up colonoscopy increased from 45.8% in controls to 65.9% after interventions. 8 studies (19,069 patients) assessed repeat FIT/FOBT adherence after a negative result. Patient navigation (RR 1.89, 95% CI 1.36–2.63) and patient reminders (RR 1.31, 95% CI 1.01–1.71) significantly improved adherence, increasing rates from 46.0% in controls to 66.5% after interventions. Based on our findings, we developed a protocol to improve colonoscopy completion post-positive FIT/FOBT and adherence to follow-up after negative FIT/FOBT. **Conclusions:** Patient-level and system-level interventions improve adherence to follow-up colonoscopy post FIT/FOBT. Patient navigation and patient reminders increase completion of follow-up colonoscopy and adherence to follow-up FIT/FOBT. Healthcare systems should adopt patient-level and system-level interventions to enhance compliance with follow-up after initial FIT/FOBT testing. Research Sponsor: None.

Contemporary trends in early-stage non–small cell lung cancer diagnosis and disparities, 2018–2022. First Author: Ahmed Minhas, Methodist University Hospital, Memphis, TN

Background: Early detection of non-small cell lung cancer (NSCLC) improves survival. We evaluated stage trends in adults aged 50-80 with NSCLC in SEER 2018-2022 after the 2021 screening expansion and the COVID-19 pandemic. **Methods:** We included 112,183 SEER cases aged 50-80 with primary NSCLC from 2018-2022. Histology was classified as adenocarcinoma, squamous, large cell or other/unknown. Stage at diagnosis was categorized as early (0-II) versus late (III-IV). Early-stage proportions were calculated by year, sex, race, age, income quartile, rurality and histology. Trends were tested using the Cochran–Armitage test. Multivariable logistic regression evaluated associations with early-stage diagnosis. To adjust for changing eligibility, NHIS 2018-2022 data were used to estimate screening-eligible shares by age-sex-race strata and standardize stage distributions. **Results:** Among 112,183 patients (median age 69; 56% male), 39,023 (34.9%) were early stage. Early-stage diagnoses increased modestly from 34.4% in 2018 to 35.6% in 2022, with a dip to 33.8% in 2020 (Table 1). Women had higher early-stage rates (~38%) than men (~32%), and White patients had higher rates (~37%) than Black or American Indian/Alaska Native patients (~29%). Logistic regression showed male sex (OR 0.78) and non-adenocarcinoma histology (ORs 0.16-0.25) were associated with lower odds of early detection; income quartile and rurality were not significant. Eligibility-standardized analyses produced similar trends, suggesting limited impact of the 2021 screening expansion to date. **Conclusions:** Between 2018 and 2022, early-stage NSCLC detection in SEER improved only slightly. Sex and racial disparities persisted. Enhanced outreach, particularly to men and racial/ethnic minorities, and broader low-dose computed tomography implementation are needed to accelerate stage migration. Research Sponsor: None.

Early-stage NSCLC diagnoses by year (ages 50–80).

Year	Total cases	Early-stage cases	Early-stage proportion*
2018	23,482	8,069	34.36%
2019	24,061	8,427	35.02%
2020	20,633	6,965	33.76%
2021	22,099	7,772	35.17%
2022	21,908	7,790	35.56%

*The Cochran–Armitage test indicated a statistically significant upward trend ($p < 0.05$), but the absolute increase was modest.

Oncoseek 2.0: An updated blood-based assay for multi-cancer early detection. First Author: Shiyong Li, SeekIn, Shenzhen, China

Background: Early identification of cancer remains essential for improving survival and reducing downstream treatment costs, yet effective and scalable multi-cancer screening strategies are still limited. OncoSeek is a previously validated, AI-based multi-cancer early detection (MCED) assay integrating protein tumor markers (PTMs) with clinical data, demonstrating 58.4% sensitivity, 92.0% specificity, and 70.6% tissue-of-origin accuracy in > 15,000 participants. To improve detection of specific cancer types and expand cancer-type coverage, we developed OncoSeek 2.0 by incorporating three additional PTMs and evaluated its performance in validation cohort. **Methods:** OncoSeek 2.0 retained the original machine-learning framework of OncoSeek 1.0, with expanded PTM inputs (ProGRP, SCCA, and tPSA). Performance was evaluated in a retrospective validation cohort comprising 1,267 cancer and 355 non-cancer individuals. Overall performance, including cancer-type-specific sensitivity, was assessed and compared with OncoSeek 1.0. **Results:** OncoSeek 2.0 incorporated three additional PTMs (ProGRP, SCCA, and tPSA) to enhance cancer-type–specific detection. ProGRP levels was significantly elevated in small cell lung cancer compared with other cancers and healthy controls; SCCA concentrations were higher in squamous cell carcinomas (esophageal, cervical, and lung) than in non-squamous cancers and controls; and tPSA was selectively increased in prostate cancer (all $P < 0.0001$). Compared with OncoSeek 1.0, OncoSeek 2.0 achieved a higher AUC (0.917 vs 0.860) and improved sensitivity from 65.3% to 77.6% at 90.1% specificity across 15 pre-specified cancer types collectively accounting for 76.5% of global cancer mortality. Sensitivity gains were notable in lung (75.1% → 84.3%), prostate (58.8% → 88.2%), cervical (55.6% → 65.6%), and esophageal (39.6% → 62.4%) cancers. When stratified by tumor stage, OncoSeek 2.0 achieved sensitivities of 54.2% for stage I, 71.7% for stage II, 79.8% for stage III, and 88.4% for stage IV, consistently outperforming OncoSeek 1.0, which achieved sensitivities of 30.2%, 53.8%, 62.3%, and 85.7% for stages I through IV, respectively. **Conclusions:** By integrating three additional cancer-type–specific PTMs, OncoSeek 2.0 substantially improves sensitivity while maintaining high specificity and low reagent cost (~$30 per test). The upgraded assay enhances detection across multiple tumor types and disease stages, with particularly pronounced gains in lung, prostate, cervical, and esophageal cancers. These results support OncoSeek 2.0 as a scalable and clinically actionable MCED approach for population-level early detection, particularly for cancers lacking USPSTF-recommended screening and in low- and middle-income countries. A Korea–USA multicenter study of duodenal pancreatic fluid–derived exosomal CES1 and MAN2A1 as pancreas-proximal biomarkers for early pancreatic cancer detection. First Author: Do Hyun Park, Division of Gastroenterology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Small pancreatic lesions often yield limited tissue via endoscopic ultrasound (EUS)-guided biopsy, and serum CA19-9 provides poor discrimination in high-risk settings. Duodenal pancreatic fluid (DPF), obtained during routine endoscopy/EUS, is a pancreas-proximal, low-noise biofluid that may enrich tumor-derived exosomal signals. We evaluated whether DPF exosomal proteins complement serum CA19-9 to discriminate PDAC from controls. **Methods:** DPF was collected during upper endoscopy/EUS with or without secretin. DPF-derived exosomes (n = 26) were profiled by LC-MS/MS, and CES1/MAN2A1 were prioritized by stage-pattern clustering. Candidates were quantified by ELISA in a Korea–USA multicenter cohort (n = 123, prespecified to detect a target AUC of 0.94; 63 PDAC, 60 controls; 4 Korean sites and 1 US site, combined with serum CA19-9 using a locked stacked ensemble model with LightGBM meta-learner trained only on out-of-fold predictions). High-risk controls included IPMN and chronic pancreatitis. Orthogonal validation used pancreatic juice from surgery or ERCP (PDAC n = 20; chronic pancreatitis n = 20). The primary endpoint was AUC for PDAC versus controls, compared with CA19-9 alone and in the CA19-9–normal subgroup; performance was also assessed in early-stage PDAC versus high-risk controls. 95% confidence intervals (CIs) were estimated by cross-validated resampling. **Results:** LC-MS/MS identified 2,460 proteins; 130 were differentially expressed (> 2-fold, $p < 0.05$). ELISA confirmed higher exosomal CES1 and MAN2A1 in PDAC versus controls ($p < 0.001$). The multi-marker model achieved an AUC of 0.995 (95% CI 0.982–1.000), a sensitivity of 98.33% (95% CI 0.931–1.000), and a specificity of 100% (95% CI 0.925–1.000), outperforming CA19-9 alone (AUC 0.63). In patients with CA19-9 in the normal range (< 37 U/mL), the model maintained high discrimination (AUC 0.931, 95% CI 0.746-1.000) with 100% sensitivity. For early-stage PDAC (stage I–II, n = 23) versus high-risk controls (n = 20, including IPMN), AUC was 0.976 (95% CI 0.924-1.000). In orthogonal validation, CES1/MAN2A1 in pancreatic juice were elevated in PDAC patients ($p < 0.001$) but not in matched serum, supporting pancreas-proximal enrichment. Decision curve analysis showed a higher net benefit than CA19-9 across clinically relevant thresholds. **Conclusions:** A DPF exosome–derived CES1/MAN2A1 signature integrated with CA19-9 using a locked ensemble model showed high diagnostic discrimination and supportive biological plausibility across a Korea–USA multicenter cohort. These results suggest a pancreas-proximal exosomal biomarker that addresses a critical gap in early detection of pancreatic cancer. Clinical trial information: NCT07030348. Clinical outcomes and cumulative cost of preventive surveillance versus treatment in Li–Fraumeni syndrome: Results from the European PREVENTABLE project. First Author: Marion Rolain Jr., Inserm U1245, Cancer And Brain Genomics, Rouen, France

Background: Li-Fraumeni syndrome (LFS), caused by *TP53* pathogenic variants, is one of the most severe hereditary cancer predisposition syndromes, characterized by very early cancer onset, broad tumor spectrum, and a high lifetime risk of multiple cancers. At the European level, no large-scale health economics study has compared LFS proactive cancer preventive management including intensive multiorgan surveillance and early cancer detection, with treatment approaches initiated after the first tumor occurs in individuals at high cancer risk. To address this gap, and within the European PREVENTABLE project, we evaluated healthcare pathways and cumulative costs of proactive prevention versus treatment in LFS European families. **Methods:** We retrospectively collected clinical data from 866 individuals from seven European countries (ERN GENTURIS centers), including 505 *TP53* gene carriers (27% of whom were children) and 361 non-carrier family members. Based on multidisciplinary expertise, we developed a structured LFS care matrix, mapping patient clinical trajectories and clinical procedures across diagnosis, risk reduction strategies, surveillance and treatments. Costs were estimated using standardized French hospital tariffs, and data were collected via a GDPR-compliant digital tool interface developed by the PREVENTABLE consortium. **Results:** From 866 individuals, 155 were *TP53* carriers without a prior cancer diagnosis at the time of genetic testing, defining the preventive arm. During follow-up (median 75 months; range 6–267), 20 individuals developed one or more cancers.The mean prevention cost per patient was €6,046.8 (range €451–€71,854.76). Among the 273 patients with a history of cancer prior to genetic testing, 109 had early-stage disease and 164 had advanced-stage disease (median follow-up 83 months; range 2–468). The mean treatment cost per patient was €53,906 (range €385.50–€440,760.93). Overall cumulative costs were €937,258 for prevention and €15,103,188 for treatment, including €5,245,915 for early-stage cancers and €9,857,273 for advanced-stage cancers. Preventive mastectomy was performed in 24% of women in either prevention or treatment groups. **Conclusions:** This first European cumulative cost analysis demonstrates that treatment costs for LFS far exceed prevention costs (9-fold), providing strong economic evidence in favor of early genetic diagnosis and preventive surveillance. These findings support public health decision-making and the harmonization of care pathways within the framework of precision medicine in Europe. Preventable is funded by the European Union (EU) under Grant no 101095483. Research Sponsor: European Union; 101095483.

Prenatal hormonal imprinting reflected by anogenital distance and risk of breast cancer: A case-control study of 839 women. First Author: Domingo Antonio Sánchez Martínez Sr., Department of Medical Oncology. Virgen de la Arrixaca University Hospital.-IMIB, Murcia, Spain

Background: Anogenital distance (AGD) is a sexually dimorphic, stable anthropometric marker set during fetal development and widely used as a proxy of prenatal androgen/estrogen balance. We hypothesized that AGD is associated with the risk of developing breast cancer (BC), a hormone-dependent disease. **Methods:** We conducted a prospective case–control study in Murcia (Spain) including 422 incident BC cases and 417 controls (2022–2024). Two AGD measures were obtained by trained examiners: ano-clitoral (AGDAC, "long") and ano-fourchette (AGDAF, "short"). Models were adjusted for age and BMI; quintile-based logistic regressions assessed non-linear associations. Stratified analyses were performed by menopausal status. Molecular subtype and Oncotype Recurrence Score (RS) (n=81 luminal tumors) were explored. **Results:** Compared with controls, BC cases showed longer AGDAC (mean 85.0 vs 81.2 mm; $p<0.01$) and shorter AGDAF (28.6 vs 29.8 mm; $p=0.02$). Across AGDAC quintiles, we observed an inverse risk gradient: lowest quintile vs highest, aOR 0.34 (95% CI 0.22–0.54; $p<0.001$). The association was stronger in premenopausal women (Q1 vs Q5 aOR 0.31; 95% CI 0.16–0.59; $p=0.001$). AGD was not associated with tumor subtype (luminal A/B, HER2+, triple-negative) nor with genomic risk (RS>25 vs ≤25). **Conclusions:** AGD, especially AGDAC, emerges as a non-invasive, inexpensive clinical marker of BC susceptibility, independent of molecular subtype and genomic risk. Findings suggest prenatal endocrine programming may prime lifetime BC risk, with a pronounced effect in hormonally active (premenopausal) women. If validated, AGD could enhance risk stratification and early detection pathways in population screening and prevention clinics. Research Sponsor: None.

K-ACCELERATE: A multi-center prospective trial to evaluate the utility of a ctDNA-based assay for accelerating multi-cancer diagnosis among high-risk symptomatic participants. First Author: Le Son Tran, Medical Genetics Institute, Ho Chi Minh City, Viet Nam

Background: In low- and middle-income countries, most cancers are diagnosed after symptom onset, where non-specific symptoms complicate referral and delay diagnosis. We previously developed SPOT-MAS, a multi-cancer early detection test integrating epigenetic, genetic, and fragmentomic features of circulating tumor DNA (ctDNA). Here, we report results from K-ACCELERATE (NCT06391749), a prospective multi-center study evaluating SPOT-MAS as a diagnostic aid in symptomatic individuals. **Methods:** Adults (≥18 years) with symptoms suggestive of colorectal, gastric, breast, liver, or lung cancer were recruited across 13 hospitals in Vietnam from July 2024. All participants underwent SPOT-MAS testing alongside standard-of-care diagnostics and were followed for up to 12 months. Primary endpoints included sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and tissue-of-origin (TOO) accuracy, using imaging and/or biopsy as the reference standard, analyzed overall and by symptomatic pathway. **Results:** Of 972 eligible participants, 862 achieved diagnostic resolution and completed follow-up, including 130 cancer cases and 732 non-cancer cases. Overall sensitivity and specificity of SPOT-MAS were 65.4% (95% CI: 56.9–73.0) and 92.1% (95% CI: 89.9–93.8), respectively. Pathway-specific sensitivity was 58.7% for breast cancer, 62.1% for lung cancer, 64.3% for gastrointestinal cancers, 80.0% for liver cancer, and 100% for multiple-pathway presentations. Among confirmed cancer cases, ctDNA-based tissue-of-origin prediction achieved 82.4% accuracy. Incorporation of ctDNA testing into clinical triage increased PPV from 15.1% to 59.4%, representing a nearly four-fold improvement over symptom-based assessment, while maintaining a high NPV of 93.7%. **Conclusions:** This study provides clinical evidence supporting the feasibility of SPOT-MAS as a non-invasive adjunct diagnostic tool for individuals presenting with cancer-related symptoms in low-resource settings. These findings lay the foundation for future prospective interventional studies to evaluate the clinical impact of ctDNA-guided diagnostic pathways in high-risk symptomatic populations. Clinical trial information: NCT06391749. Research Sponsor: None.

Association of clonal hematopoiesis driven by mosaic chromosomal alterations with epigenetic age in the PLCO trial. First Author: Corey Young, National Cancer Institute, National Institutes of Health, Rockville, MD

Background: Mosaic chromosomal alterations (mCAs) are age-associated clonal events detectable in peripheral blood and have been linked to hematologic malignancy risk and adverse clinical outcomes. Whether mCAs are associated with accelerated biological aging, as measured by DNA methylation–based epigenetic clocks, remains poorly understood. **Methods:** We analyzed peripheral blood DNA methylation data generated using the Illumina EPIC array from 482 participants in the Prostate, Lung, Colorectal, and Ovarian (PLCO) Cancer Screening Trial. mCAs were identified from SNP array data and classified by subtype, including autosomal copy-neutral loss of heterozygosity (CN-LOH), gains, losses, and loss of the sex chromosome . Epigenetic age was estimated using six established DNA methylation clocks: Hannum, Horvath pan-tissue/skin and blood, PhenoAge, GrimAge & DunedinPACE. Associations between mCA presence, mCA subtype, clonal burden, and epigenetic age acceleration were evaluated using multivariable linear regression models adjusted for age, sex, smoking status, body mass index, and genetic ancestry. **Results:** Among 482 participants, 261 were mCA-free and 221 had at least one detectable mCA. Individuals with any detectable mCA exhibited higher epigenetic age acceleration than mCA-free individuals across multiple clocks, with the most consistent effect sizes across mCA subtypes observed for GrimAge. Although age acceleration was directionally higher among individuals with mCAs across all non–rate-based clocks, statistically significant differences were observed only for the Hannum, PhenoAge, and GrimAge clocks. For GrimAge, estimated effects for mCA-positive individuals were uniformly positive, except for gain-only events, with effect sizes ranging from 1.2 to 1.9 years of age acceleration. Age acceleration increased with clonal burden: participants with multiple mCAs (n = 51) exhibited greater age acceleration than those with a single mCA (n = 170), particularly for GrimAge and PhenoAge. Higher cellular fraction was also associated with increased age acceleration, with significant associations observed for GrimAge (β = 2.97, 95% CI 0.82–5.12, p = 0.007) and Hannum (β = 4.25, 95% CI 1.14–7.37, p = 0.008) clocks. **Conclusions:** Mosaic chromosomal alterations, particularly CN-LOH and higher clonal burden states, are associated with accelerated biological aging in peripheral blood leukocytes. Epigenetic age acceleration was most consistently observed using GrimAge, a mortality- and healthspan-associated clock, with more variable and less consistent associations observed for chronological age-trained and rate-based clocks. These findings suggest that epigenetic age acceleration may represent a clinically relevant feature of clonal hematopoiesis, warranting further investigation in aging populations. Use of multiplex digital profiling of DNA methylation heterogeneity to enable sensitive early detection of non–small cell lung cancer from low-volume liquid biopsies. First Author: Christine O'Hersey, Johns Hopkins University, Baltimore, MD

Background: Early detection of non–small cell lung cancer (NSCLC) within liquid biopies remains limited by the extremely low abundance and heterogeneous nature of circulating tumor DNA (ctDNA) in plasma, particularly in patients with indeterminate pulmonary nodules. DNA methylation is an attractive early biomarker; however, conventional PCR- and sequencing-based assays have limited ability to sensitively and cost-effectively assess heterogeneous epiallelic methylation patterns at low variant fractions. We developed a digital microfluidic platform that enables multiplex, single-molecule profiling of DNA methylation heterogeneity to improve early NSCLC detection. **Methods:** We applied REM-DREAMing (Ratiometric-Encoded Multiplex Discrimination of Rare EpiAlleles by Melt), a digital high-resolution melt (dHRM) platform combining nanowell-based digital PCR with ratiometrically encoded, methylation-agnostic probes. Following bisulfite conversion, cfDNA was digitized into >40,000 nanoliter wells, enabling copy-by-copy assessment of methylation density across a five-gene biomarker panel previously associated with NSCLC. Analytical sensitivity and multiplex performance were compared against quantitative methylation-specific PCR (qMSP) and digital MSP (dMSP). Clinical feasibility was evaluated in plasma from patients with CT-detected indeterminate pulmonary nodules. **Results:** REM-DREAMing resolved heterogeneous methylation patterns at single-molecule resolution and detected methylated epialleles at fractions as low as 0.00005% in a high background of unmethylated DNA. In a cohort of 48 low-volume plasma samples, incorporating intermolecular methylation density distributions significantly improved classifier performance relative to binary methylation calls. The five-gene panel achieved 93% sensitivity at 90% specificity for early-stage NSCLC, with an AUC of 0.96. Compared with qMSP and dMSP, REM-DREAMing demonstrated superior sensitivity, multiplex scalability, and discrimination of partially methylated epialleles. **Conclusions:** Multiplex digital profiling of DNA methylation heterogeneity enables sensitive, low-cost detection of early-stage NSCLC from limited plasma input. By capturing epigenetic heterogeneity at the single-molecule level, this platform improves diagnostic performance in clinically challenging early detection settings and provides a scalable foundation for expanded biomarker panels. Development of an oncology generative AI foundation model trained on more than a million longitudinal patient journeys across the United States. First Author: Wilson Lau, Truveta Inc., Bellevue, WA

Background: Incidence of cancer diagnoses continues to increase, while the average cost of cancer screening, such as mammogram or colonoscopy, remains high, ranging from hundreds to over a thousand dollars. This study explores the potential of building an oncology foundation model based on Generative Pre-trained Transformers (GPT) to predict future outcomes for patients. We assess the prediction accuracy and feasibility of leveraging the foundation model to inform when screening should be prioritized, thereby reducing the associated burden of unnecessary procedures. **Methods:** The advancement of generative AI offers the opportunity to model the progression of human disease over time. In this study, we extended the GPT architecture and pre-trained it with a subset of Truveta Data containing the electronic health record (EHR) from the journeys of 1.4 million de-identified patients diagnosed with 4 types of cancer (lung, breast, colorectal, prostate). Each sequence of the patient journey—including demographics (age, gender), conditions, lab results (represented by SNOMED-CT and LOINC codes), and the corresponding event time—was tokenized before passing through the GPT model for training. For validation, 1000 patients were randomly sampled from our test data, in which each type of cancer diagnosis constituted 19%-30% of the samples. We used the model to generate synthetic future patient journeys for the selected patients and compared the predicted outcomes with the actual cancer diagnoses within one year. **Results:** The model achieved sensitivities above 78%, with positive predictive values (PPV) between 66% and 90%. More importantly, it demonstrated high specificities above 91%, with corresponding negative predictive values (NPV) above 90%. **Conclusions:** The high specificities and NPV indicate the feasibility of applying generative foundation model pre-trained with EHR data to predict negative cancer outcomes with high accuracy. Since the percentage of screening tests leading to positive cancer diagnosis is relatively low, the projected negative predictive outcomes offer valuable signals for clinicians, which they can use to complement their expert assessment to avoid unnecessary screening and subsequently reduce the burden of screening costs. Research Sponsor: Truveta.

Performance of the foundation model on cancer outcome prediction.

	Lung	Breast	Colorectal	Prostate
Positive predictive value (PPV)	72.77%	90.11%	65.78%	88.88%
Sensitivity	80.28%	79.00%	78.13%	78.26%
Negative predictive value (NPV)	91.87%	96.29%	90.35%	96.27%
Specificity	94.50%	91.45%	94.56%	92.07%

Clinical impact of GLP-1 receptor agonist use on lung cancer incidence in high-risk patients: A real-world analysis. First Author: Ariana N. Neely, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Lung cancer (LC) is the leading cause of cancer-related mortality in the United States. Lifetime risk is ~7% in the general population but substantially higher among high-risk groups with tobacco use, environmental exposures, or family/genetic predisposition. Despite screening recommendations for select high-risk populations, no pharmacologic prevention is established. Emerging evidence suggests that Glucagon-like peptide-1 receptor agonists (GLP-1RA) may influence cancer risk through anti-proliferative, anti-inflammatory, and immunomodulatory effects, but data on LC remain limited. This study evaluated the association between GLP-1RA use and LC incidence in high-risk patients. **Methods:** This multicenter retrospective study used de-identified electronic health data from TriNetX, a global federated research network. Adults ≥18 with high-risk features of tobacco use, environmental or occupational exposure, chronic lung disease, personal/family cancer history, or radiation were included. Participants were stratified by GLP-1RA use. Propensity score matching (1:1) adjusted for demographics, comorbidities, and medications. The primary endpoint was LC incidence. Participants with LC before the study entry were excluded. Multivariate logistic regression and Cox models assessed associations; results reported as hazard ratios (HRs) with 95% confidence intervals (CIs). **Results:** Before matching, 2,715,963 participants were identified. After matching, 68,374 were analyzed (34,187 per cohort) with similar demographics (mean age 58, 54% female, 46% male; 75% White, 17% Black, 1.5% Asian). Median follow-up was 2,324 days. LC incidence was 2% (688/33,784) in the GLP-1RA cohort vs 2.4% (797/33,369) in controls, yielding an absolute risk reduction of 0.4% and a number needed to treat (NNT) of 250. GLP-1RA use was associated with a 31% reduction in LC incidence [HR 0.687 (0.621–0.761)]. **Conclusions:** In this large retrospective cohort of high-risk individuals, GLP-1RA use was associated with lower LC incidence compared with matched controls. Despite modest absolute risk reduction, relative risk reduction and favorable number needed to treat suggest potential population-level impact in a disease with limited preventive options. Findings are biologically plausible given the anti-inflammatory, metabolic, and immunomodulatory effects of GLP-1RAs. While causal inference is limited by observational design, this study supports further prospective investigation of GLP-1RAs as a pharmacologic strategy for LC prevention in high-risk populations. Multimodal risk phenotyping of early-onset colorectal cancer. First Author: Azza Sarfraz, Miami Cancer Institute, Miami, FL

Background: Early-onset colorectal cancer (EOCRC) is rising rapidly, yet its risk profile is incompletely defined. Prior studies have largely focused on isolated metabolic or lifestyle factors and have rarely integrated broader sociodemographic context or objective functional measures. We performed multimodal phenotyping to characterize integrated clinical, behavioral, cardiometabolic, and wearable-derived profiles among individuals with EOCRC compared with average-onset CRC (AOCRC). **Methods:** Adults with CRC in the NIH All of Us Controlled Tier Dataset v8 were identified (≥2 EHR diagnosis codes ≥3 months apart). The primary exposure was age at diagnosis, defined as EOCRC (<50 years) vs AOCRC (≥50 years). Covariates included sociodemographic factors (sex, race/ethnicity, education, employment, health insurance, household income, marital status, neighborhood deprivation). Outcomes included health behaviors (smoking, alcohol use), anthropometrics (BMI, waist circumference), cardiometabolic conditions (dyslipidemia, metabolic syndrome, diabetes, hypertension), laboratory measures (lipids), and wearable-derived (Fitbit) activity, sleep, and heart rate, anchored to the most recent pre-diagnosis timestamp. **Results:** Among 3,915 CRC participants, 710 (18.1%) had EOCRC. The cohort was predominantly male (54.5%), White (64.4%), unemployed (68.6%), with annual income <$50k (45.5%), and married (53.6%). Participants with EOCRC were less often female (38.7% vs 47.0%) and White (52.7% vs 67.0%) (both $p<0.001$). EOCRC was associated with higher obesity (42.0% vs 37.0%), higher LDL (101 vs 86 mg/dL), and lower HDL (51 vs 54 mg/dL) (all $p<0.001$). Alcohol use (60.6% vs 50.5%, $p<0.001$) and heavy drinking (22.0% vs 16.1%, $p=0.003$) were more common among participants with EOCRC. In the wearable sub-cohort, EOCRC participants had higher heart rate (76.8 vs 73.8 *bpm*, $p=0.03$) and lower sedentary time (773 vs 894 *min/day*, $p=0.016$) with no significant differences in sleep metrics or heart rate variability. Female sex was associated with lower odds of EOCRC (OR 0.45, 95% CI 0.25–0.83; $p=0.01$), while Hispanic ethnicity was associated with higher odds (OR 4.04, 95% CI 1.51–10.86; $p=0.006$). **Conclusions:** EOCRC is characterized by higher obesity, dyslipidemia, and alcohol use, as well as differences in wearable-derived physiologic and behavioral profiles. Integrating real-world clinical data with digital biomarkers offers a scalable framework for refined risk stratification and precision prevention in EOCRC. Research Sponsor: None.

Evidence of clonal stability in a 5-year longitudinal prospective cohort of cancer survivors with serial NGS analysis. First Author: Anmol Goyal, Cleveland Clinic, Cleveland, OH

Background: Hematopoietic stem and progenitor cells with preleukemic mutations (mut^{n}s), collectively termed clonal hematopoiesis (CHIP) serve as the cellular origin of myeloid neoplasms (MN). While risk of MN development varies, its natural history and transformation potential remain poorly defined. We present findings from our ongoing 10-year CHIP protocol using serial NGS to monitor clonal evolution and MN in cancer survivors. **Methods:** Retrospective analysis of 210 prospective pts from March 2020 to June 2024. Mut^{n}s were classified CHIP+ if they had a variant allele frequency (VAF) $\geq$2% (or $\geq$1% for *IDH1*, *IDH2*, and *JAK2*). Clonal evolution was evaluated by annual VAF changes adjusted for age-related increases (e.g. *DNMT3A* increases by ~2%/yr based on published data). Mut^{n}s were classified as slow ($\leq$5%/yr: *DNMT3A, TET2, ASXL1*), intermediate (5-10%/yr: *TP53, PPM1D, IDH1/2, KRAS, NRAS, SF3B1*), or fast-growing ($>$ 10%/yr: *JAK2, SRSF2*). BPearson's Chi-squared, Fisher's exact, and Wilcoxon rank-sum tests were used. **Results:** Of 210 pts, 42 (20%) had at least one CHIP+ mut^n. Median age was higher in CHIP+ vs. CHIP- pts (66 vs. 59 years, $p < 0.001$). CHIP+ was not significantly associated with sex, race, family history, smoking, alcohol use, prior cancer types (e.g., breast, head and neck) or treatment (chemo, radiation, surgery). Of 487 samples, 56 had detectable somatic mut^{n}s. The most frequent mut^n were *DNMT3A* (n = 27), *PPM1D* (n = 10), and *TET2* (n = 9). By expected growth kinetics, 37 (66%) mut^n were slow-growing, 12 (21.4%) intermediate, 2 (3.5%) fast-growing, and 4 (7.14%) of unknown kinetic category.Beyond VAF-kinetics-based progression, 12 pts developed new mut^n in subsequent years - *DNMT3A (n = 8), PPM1D (n = 2).* Some later became undetectable, suggesting transient clones. In total, 12 pts (1 by VAF kinetics, 11 by new mut^n acquisition) clonally progressed over 5 years of this study (5.7%).6 pts regressed by year 2, with gene mut^n VAFs becoming undetectable. These included mut^n in *PPM1D* (n = 2), *CBL* (n = 2), *TP53* (n = 1), and *DNMT3A* (n = 1). Three more pts regressed in year 3, and 1 in year 4. In all, 10 pts showed regression over 5 years (17.8%). Notably, 5 of 10 had received interventions for cardiac comorbidities. Overall, ~94% pts had clonal stability/regression. Slow-growing mut^{n}s - *DNMT3A* and *TET2* had median rates of 0.83% and 2.11%, (historical rates $\leq$5%). Intermediate mut^{n}s like *TP53* and *PPM1D* had median rates of 1.64% and -0.625%, below the expected 5-10% annual rise. *JAK2*, a fast-growing mut^n, also showed a lower rate of 0.19%. **Conclusions:** Despite being a high-risk population due to prior solid malignancy and exposure to chemo/radiation, most pts in our five-year longitudinal study showed clonal stability. Even among those who progressed, VAF kinetics remained stable post-detection. CHIP's inflammatory link to cardiovascular disease suggests preventive cardiology may impact clonal behavior. Research Sponsor: None.

Mammography utilization and male breast cancer in BRCA1/2 carriers. First Author: Meredith Davies, Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA

Background: Males with pathogenic germline variants in *BRCA1*/2 (BRCA+) have a 1-10% lifetime risk of developing breast cancer (MBC). NCCN guidelines recommend that BRCA+ males consider annual mammograms. We have prior shown low rates of mammography uptake in an academic cohort from Penn Medicine (PM). We sought to validate these findings about mammography in a national veteran (VA) cohort and to investigate the clinical characteristics of BRCA+ compared to nonBRCA+ MBC. **Methods:** We performed a retrospective analysis of 327 BRCA+ male veterans with no prior history of MBC. The electronic health record was reviewed to determine indication for and results of mammography episodes. A mammography episode was defined as all breast imaging studies obtained for asymptomatic screening or for symptoms within six months. The first mammogram episode identified was referred to as the "initial" mammogram and all other mammography episodes were "subsequent". To determine BI-RADS PPV, data for 85 PM and 68 VA BRCA+ males were combined and compared to 1819 nonBRCA+ males. To determine clinical characteristics of MBC, data for 30 PM and 18 VA BRCA+ MBC were combined and compared to 104 PM and 122 VA nonBRCA+ MBC. **Results:** Sixty-eight (20%) of VA BRCA+ males underwent an initial mammogram, 57% of which were ordered for screening. Among patients $\geq$50 without mammography, 31% of individuals had no discussion documented and 66% had a shared decision-making discussion against screening with an ordering provider. BI-RADS 4 and 5 findings occurred in six and five mammograms, respectively. MBC was diagnosed in 13% (9/68) after initial and 13% (3/23) after subsequent mammography pooled VA and PM data showed that 95% (21/22) of MBC diagnoses in BRCA+ males were after a symptom-prompted mammogram. BI-RADS 4 PPV was higher in BRCA+ compared to non-BRCA+ men (75% vs 5%, $p < 0.0001$), and BI-RADS 5 PPV was similar (100% vs 67%, p = 0.0661). In an expanded cohort of 48 BRCA+ MBC compared to 226 nonBRCA+ MBC, median (IQR) age of diagnosis was 66 (56-73) vs 66 (59-74) (p = 0.52). The majority of BRCA+ and nonBRCA+ MBC were ER+Her2- (85% and 90%, respectively, p = 0.70). Among those with Oncotype testing, 93% BRCA+ BC had intermediate or high-risk recurrence scores compared to 50% of non-BRCA+ (p = 0.002). However, BRCA+ and non-BRCA+ male patients had similar rates of node positivity (40% vs 41%, p = 0.87) and progression to metastatic disease (19% vs 16%, p = 0.67). **Conclusions:** Analysis of a Veteran cohort of BRCA+ males confirms low rates of mammography as we prior reported in an academic cohort. Counseling and SDM were inconsistently documented, highlighting gaps in guideline implementation. Both BRCA+ and nonBRCA+ MBC were nearly always diagnosed based on symptoms. Both BRCA+ and nonBRCA+ MBC were often node-positive and nearly 20% progressed to metastatic disease. These characteristics suggest the need for prospective evaluation of mammography in high-risk males to reduce rates of advanced disease. Research Sponsor: Basser Center for BRCA; VA ORD1I01CX002710; VA ORD1I01CX002710.

Refining breast cancer risk stratification for selection of women at intermediate to high risk for supplemental MRI screening using artificial intelligence. First Author: Eun Kyung Park, Department of Radiology, Seoul National University Hospital, Seoul, South Korea

Background: Supplemental MRI screening for women at increased breast cancer risk can detect additional cancers that are occult on mammography. However, its adoption is limited by restricted availability and high false-positive rates. Improved risk stratification is therefore needed to optimize the use of supplemental MRI screening. This study aimed to evaluate the feasibility of a mammography-based artificial intelligence (AI) system for stratifying women at intermediate to high risk for supplemental MRI screening. **Methods:** This retrospective study included consecutive women who underwent abbreviated breast MRI following negative mammography between January 2020 and December 2024. The study cohort comprised women at intermediate to high breast cancer risk, including those with known genetic predisposition, personal history of breast cancer, prior benign or high-risk breast biopsy, or family history of breast cancer. A commercially available AI system was applied to all mammograms, generating both exam-level and breast-level scores representing the likelihood of a malignancy on a scale of 0 to 100. MRI outcomes, false-positive examinations, cancer detection, and positive predictive value (PPV) were evaluated. Univariate analyses were performed to explore associations between breast density and AI-based selection results. **Results:** In 1,588 women (median age, 51 years; range, 24-87), 1,804 screening mammograms and MRI examinations were performed. Of these examinations, 220 resulted in recall, yielding 24 mammographically occult breast cancers (12 ductal carcinoma in situ and 12 invasive cancers) diagnosed within one year and 166 false-positive examinations. The AI system achieved an area under the curve (AUC) of 0.694 (95% CI, 0.499-0.888) in women without a personal history of breast cancer and 0.611 (95% CI, 0.430-0.792) in women with a personal history of breast cancer. Using AI-based selection, 239 of 1,588 women (14.9%) were selected for supplemental MRI, resulting in an 81% reduction in false-positive examinations (31 vs 166) and an improvement in PPV to 20.5% (8 of 39). 6 of 8 detected cancers (75%) were invasive. Breast density was not associated with the AI-based selection strategy. **Conclusions:** Mammography-based AI substantially reduced false-positive supplemental MRI examinations while preferentially selecting women at higher risk for invasive breast cancers, without compromising cancer detection. These findings suggest that AI can refine risk stratification and optimize selection of women to improve the efficiency of supplemental MRI screening. Real-world experiences with a multi-cancer detection (MCD) blood test. First Author: Julius Chiang-Boeckmann, Massachusetts General Hospital, Boston, MA

Background: Multi-cancer detection (MCD) blood tests hold promise to screen for multiple cancers simultaneously. MCD tests have been assessed in case-control and prospective studies but have not yet been shown to improve cancer outcomes. Mass General Brigham (MGB) offers a commercially available, non-FDA-approved methylation-based MCD test (Galleri; GRAIL) through our Early Detection & Diagnostics Program. Here, we report our initial experience. **Methods:** In this retrospective, observational study, data were collected from all patients (pts) who underwent MCD testing or were evaluated for a prior positive MCD test at our clinic between May 2023 and December 2024. Pts obtained the test through: 1) self-payment after shared decision making, or 2) an early access demonstration project with GRAIL, Point32Health (insurance company), and MGB whereby pts $\geq$50y with specific insurance products and an MGB primary care physician were invited to receive a cost-free test if they met $\geq$1 of 4 criteria: personal history of cancer, 1st-degree family history of cancer, elevated BMI, or any smoking history in the past 10 years. All pts tested at MGB underwent pre-test consultation with a medical oncologist or nurse practitioner to review the benefits and limitations of testing. Result management was coordinated by our team. Longitudinal outcomes were abstracted from electronic health records. **Results:** 742 pts had MCD testing (125 [17%] self-pay, 617 [83%] demonstration project). Median (med) age was 59 (IQR 55-63); most were White (92%) and up to date on USPSTF-recommended cancer screening (82%). Med follow up (FU) was 469 days (IQR 462-478); 580 (78%) had $>$ 12 months FU. Four pts received a "cancer signal detected" result (+MCD): 2/742 tested at MGB (0.3%) and 2 who presented to workup +MCD tested elsewhere; 2 were true positives (TP), 2 false positives. In total, 16 pts (2.2%) were diagnosed (dx) with cancer during FU; 2/16 (13%) after +MCD, and 14/16 after negative MCD, with med time from MCD to diagnosis 199 days (IQR 92-464). The two TP tests corresponded to stage I breast cancer and stage III follicular lymphoma. The most common cancers dx were prostate (n = 5, with two stage III-IV dx at 128 and 142 days) and breast (n = 4, all mammogram-detected stage I). Other advanced cancers included stage III cholangiocarcinoma and stage IV adenocarcinoma unknown primary (dx at 515 and 475 days, respectively). **Conclusions:** In this real-world cohort, MCD test positivity was rare, and multiple cancers were dx within 18 months of a negative MCD, including some advanced cases. In particular, prostate cancer was dx in multiple pts after negative MCD, consistent with prior reports of limited MCD sensitivity for prostate cancer. Our cohort may be biased by the requirement to either self-pay or carry a specific insurance product. Larger studies with longer FU are needed to better define the added utility of MCD tests to standard cancer screening. Research Sponsor: None.

Spatial organization of immune surveillance by germline mutation status in the Breast Cancer Family Registry. First Author: Marni Blair McClure, Stanford Cancer Institute, Stanford, CA

Background: Germline pathogenic variants (gPVs) are associated with increased immune infiltration in resulting tumors; we previously reported increased CD4+ and CD8+ T-cells in gPV-associated tumors using single-cell spatial profiling. Here, we report the spatial features, including cell-cell co-localization, underlying these immune differences. **Methods:** We analyzed CosMx 6K single-molecule RNA transcriptomics in 222 samples from 144 women in the population-based Northern California Breast Cancer Family Registry. Across 1,083,345 cells and 6,583 genes, multicellular niches were identified by clustering cells based on spatial proximity and cell-type identity using a k-nearest neighbors approach, with the number of niches selected by elbow analysis. Niche proportions were compared between gPV-associated and wild-type tumors using linear models. Linear mixed-effects models were used to identify niche-specific enrichment of cell-type densities and pairwise cell–cell colocalization relative to all other niches. P-values were corrected using Benjamini–Hochberg. **Results:** Of 144 participants, 31 (22%) carried at least one gPV, including BRCA1 (n = 12), BRCA2 (n = 8), PALB2 (n = 3), FANCM (n = 3), ATM (n = 2), and CHEK2, RAD50, and TP53 (n = 1 each). We identified eight cell niches, two of which were enriched in gPV-associated tumors, including within ER/HER2 subtypes: niche 2 (10% of cells in gPV tumors vs 3.7% in non-gPV tumors; Wilcoxon FDR = 0.01) and niche 5 (17% vs 9.4%; FDR = 0.03). Niche 2 and niche 5 proportions were uncorrelated across tumors ($r = -0.13$, FDR = 0.14). Compared with other niches, niche 2 had higher proportions of immature B cells (FDR = 0.006), $CD8^+$ T cells (FDR = 0.03), dendritic cells (FDR < 0.001), and macrophages (FDR < 0.001), with no specific cell-cell colocalization pattern. Niche 5 had higher proportions of $CD4^+$ T cells (FDR < 0.001), myoepithelial cells (FDR < 0.001), and macrophage-derived stem cells (FDR < 0.001); niche 5 demonstrated increased colocalization across 95 cell-type pairs at FDR < 0.1, including cancer cells with macrophage-derived stem cells and pericytes with natural killer cells (FDR = 0.01 each). Comparing BRCA1 to BRCA2 gPV carriers, niche 2 was more prevalent in BRCA1 tumors (16% vs $< 1\%$ in BRCA2; p = 0.01); no significant difference was observed for niche 5. **Conclusions:** In this population-based cohort, gPV-associated breast cancers exhibited distinct spatial immune niches. Niche 2, especially enriched in BRCA1 gPV tumors, appears to reflect an inflamed immune environment, whereas niche 5 may represent a more spatially organized stromal-adaptive immune niche characterized by $CD4^+$ T-cell enrichment and extensive non-random cell-cell interactions. These findings demonstrate that inherited cancer risk is associated with reproducible immune spatial architectures, with implications for immune-based prevention and interception strategies. Quantifying the macroeconomic burden of tobacco-attributable cancers in 2023: Global disparities in value-of-lost-welfare (VLW) in 189 countries. First Author: Mansha Gupta, Midwestern University GME Consortium Program, Cottonwood, AZ

Background: Tobacco use is the leading preventable cause of cancer globally, yet the macroeconomic welfare losses attributable to tobacco-related cancers remain incompletely quantified. We estimated the global economic burden of tobacco-attributable cancers in 2023 using a standardized value-of-lost-welfare (VLW) framework. **Methods:** Country-level disability-adjusted life years (DALYs) attributable to tobacco for all cancers were obtained from the Global Burden of Disease (GBD) 2023 framework. Gross domestic product (GDP; purchasing power parity, current international dollars) and population data were sourced from the World Bank. VLW was calculated as tobacco-attributable cancer DALYs multiplied by country-specific GDP per capita (PPP). Outcomes included total VLW, per-capita VLW, and VLW as a percentage of national GDP. **Results:** In 2023, tobacco-attributable cancers resulted in 48.44 million DALYs globally (95% UI: 41.06–57.06 million), corresponding to a global value of lost welfare (VLW) of USD 1.61 trillion. The largest absolute economic welfare losses were observed in China (USD 415.3 billion), India (USD 262.8 billion), and the United States (USD 219.4 billion), followed by Japan (USD 96.1 billion) and Brazil (USD 63.7 billion). Together, these five countries accounted for 65.9% of the global VLW attributable to tobacco-related cancers. When normalized to national economic output, the highest VLW-to-GDP ratios were observed in India (1.12%), China (0.69%), Egypt (0.61%), Bangladesh (0.58%), and Pakistan (0.52%), indicating substantial macroeconomic vulnerability in several low- and middle-income countries. By cancer type, tracheal, bronchus, and lung cancer accounted for 24.6 million DALYs, corresponding to a VLW of USD 0.82 trillion, followed by esophageal cancer (6.1 million DALYs; USD 0.21 trillion), stomach cancer (5.4 million DALYs; USD 0.18 trillion), liver cancer (4.9 million DALYs; USD 0.16 trillion), and oral cavity cancer (3.2 million DALYs; USD 0.11 trillion). Collectively, these five cancer types accounted for 91.4% of total tobacco-attributable cancer VLW worldwide. **Conclusions:** In 2023 alone, tobacco-attributable cancers resulted in nearly 50 million DALYs and over $1.6 trillion in lost economic welfare worldwide, highlighting tobacco use as a dominant driver of both health loss and macroeconomic harm. Research Sponsor: None.

Regional distribution of disability-adjusted life years (DALYs) and economic welfare loss (VLW) attributable to tobacco-related cancers in 2023.

Region	DALYs (millions)	VLW (USD trillion)	VLW/GDP (%)
High-income	11.6	0.75	1.81
Central Europe, Eastern Europe, and Central Asia	4.58	0.17	1.27
Southeast Asia, East Asia, and Oceania	22.87	0.53	1.14
North Africa and Middle East	2.27	0.05	0.57

Effect of breast density reporting on supplemental MRI and ultrasound use. First Author: Gianna Aliberti, Harvard University School of Public Health, Boston, MA

Background: Mammography has lower sensitivity in women with dense breasts due to masking, as both dense tissue and tumor tissue appears white. Supplemental breast imaging, such as MRI or ultrasound, can increase cancer detection among women with dense breasts, but its use is limited by screening capacity, cost, and potential over-diagnosis. The purpose of this study is to understand the impact of changing breast density on supplemental screening use in a longitudinal cohort of women undergoing screening mammography. **Methods:** Participants are from the Boston Mammography Cohort Study (BMCS), a cohort of women undergoing routine screening mammography within the Mass General Brigham health system in Boston, MA enrolled from 2008-2016, with follow up collected through 2022. Participants completed a questionnaire at enrollment which provided demographic, reproductive, lifestyle and behavioral factors. Electronic medical record review provided dates and results of all breast imaging received within the health system. We performed a longitudinal analysis using generalized estimating equations to evaluate the association between breast density and supplemental MRI and/or ultrasound. Women with a history of breast cancer and those without at least one mammogram with reported BIRADS breast density were excluded from the analysis. **Results:** Of the 2,696 women enrolled in BMCS, 87 were excluded for breast cancer prior to enrollment and 16 were excluded for lack of reported BIRADS breast density, leaving 2,593 in the analytic cohort. Of these women, 37.6% were aged 40-49 at the time of enrollment, 71.5% were non-Hispanic white, 46.5% had a body mass index (BMI) of 18.5-24.9, 51.9% were postmenopausal, and 78.0% had no first-degree relatives with breast cancer. Overall, 1.5% (n = 40) were diagnosed with breast cancer, 3.5% (n = 98) received a breast MRI, and 25.8% (n = 669) received a breast ultrasound. In unadjusted analyses, increased breast density was associated with higher rates of supplemental imaging. Compared with women who never had dense breasts, those who always had dense breasts had higher use of MRI (RR 3.7, $p < 0.001$), while ultrasound use was higher among women who sometimes (RR 1.5, p = 0.0002) and always (RR 1.7, $p < 0.0001$) had dense breasts. After adjusting for age, race, BMI, menopausal status, family history, and mammogram results, the association between breast density and supplemental imaging was attenuated. Women who sometimes had dense breasts remained more likely to undergo ultrasound and any supplemental imaging compared with women who never had dense breasts, but the associations were smaller and did not reach significant statistical significance. Abnormal mammogram results were the strongest predictor across all models. **Conclusions:** These findings suggest that breast density alone may be insufficient to guide supplemental screening guidelines and support more targeted, risk-informed approaches. Research Sponsor: None.

Circulating cadherin-17 (CA17) in blood as a diagnostic biomarker for gastric cancer. First Author: Tsz Chun Hon, Tiberias Technology Limited, Shatin, Hong Kong

Background: The asymptomatic onset of gastric cancer (GC) frequently leads to delayed diagnosis resulting in poor survival. Conventional biomarkers (CA72-4, CEA) lack sensitivity, while emerging cfDNA methods remain costly and complex for routine screening. Our proprietary antigen, Cadherin-17 (CDH17), is selectively overexpressed in gastrointestinal (GI) malignancies. We developed a fully automated, high-throughput Chemiluminescence Immunoassay (CLIA) using proprietary antibodies to monitor the blood circulating levels of CA17 – the soluble form of Cadherin-17 protein in liquid biopsies. CA17 screening offers a complementary minimal invasive diagnostic method that identifies high-risk GC individuals for follow up endoscopy evaluations. **Methods:** A CLIA assay was designed to quantify circulating CA17 protein levels in human serum. The assay was established on the iShine i1910 automated platform, which integrates magnetic microparticle and acridinium ester labelling to generate luminescent signals. Four proprietary monoclonal anti-CA17 antibody clones were evaluated in various capture and detection pair combinations to identify the optimal antibody pairing for assay performance. Serum samples from 114 non-cancer individuals and 113 patients with histologically confirmed gastric cancer were analysed. Assay and biomarker performance was assessed by receiver operating characteristic (ROC) curve analysis to determine assay sensitivity and specificity. **Results:** Four capture/detection antibody pairings were evaluated. The clone 1–clone 2 combination demonstrated superior detection accuracy, yielding an AUC of 0.959 (90.3% sensitivity, 91.4% specificity). This optimal pairing revealed a highly significant difference in CA17 levels between the non-cancer and GC groups (Mann-Whitney test,), confirming its ability to reliably distinguish high-risk individuals. In contrast, the clone 1–clone 3, clone 5–clone 1, and clone 1–clone 4 combinations exhibited inferior performance, with AUCs of 0.784, 0.705, and 0.680, respectively. **Conclusions:** The CA17 CLIA assay demonstrates high sensitivity and specificity for GC detection. As a minimally invasive blood-based test, it enables early identification of high-risk individuals for subsequent confirmatory endoscopy. This cost-effective blood test has the potential to allow screening of GC at the early stages and will significantly impact on patient survival. Research Sponsor: None.

Transdermal drug delivery to the normal and the radiated breast: Determinants of individual variation in skin permeation. First Author: Natalie Pulliam, Department of Surgery, Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Primary prevention of breast cancer with oral drugs causes systemic effects which are unacceptable to 85% of high-risk women. Transdermal delivery through breast skin can minimize systemic exposure, but individual variation of permeation, the effects of breast radiation, or increased dose have not been studied. We report a prospective single-arm trial addressing these aspects, using 4-hydroxytamoxifen (4-OHT) an active metabolite of oral tamoxifen. **Methods:** Women with unilateral breast cancer treated with breast conservation and radiotherapy applied 4-OHT gel to both breasts for 4±1 weeks. In Cohort 1 (2 mg/breast/day) we evaluated inter-individual variation of 4-OHT skin permeation in the non-radiated breast based on demographic and skin characteristics. In Cohort 2 (4 mg/breast/day) we evaluated the effect of increased dose. All participants underwent bilateral post-intervention dermal punch and core needle breast biopsy. Drug concentration in tissue and plasma was measured using liquid chromatography-mass spectroscopy. Multivariable linear regression was used to examine the predictors of drug concentration in tissue and plasma. Stepwise model selection was conducted using AIC criteria, with multicollinearity assessed via variance inflation factor (VIF). **Results:** Of 156 consented women, 120 completed intervention and were evaluable for the primary endpoint (breast tissue drug concentration). On multivariable analysis, breast tissue 4-OHT concentration increased with age and White race. Drug concentration was equivalent in the radiated and the non-radiated breasts and was two-fold higher in Cohort 2 (4 mg/breast/day) compared to Cohort 1 (2 mg/breast/day), (p = 0.001). Plasma drug concentrations were low in both cohorts; 0.27ng/mL in Cohort 1 and 0.15ng/mL in Cohort 2, (p = < 0.001). **Conclusions:** Transdermal delivery of breast cancer prevention drugs is a viable strategy, with higher dose achieving proportional increase in tissue concentration, without increased leakage into the circulation. Further work should pursue formulations of highly active drug metabolites with excellent permeation. Clinical trial information: NCT04009044. Research Sponsor: National Institutes of Health (NIH)/National Cancer Institute (NCI).

Embedding germline genetic testing into African oncology care: Early results from the Genetic Cancer Families (GenCAF) program. First Author: Sulin Wu, University of Chicago Medical Center, Chicago, IL

Background: Breast cancer outcomes in sub-Saharan Africa are marked by early onset, advanced stage at diagnosis, and high mortality. Although prior studies demonstrate a high burden of inherited cancer susceptibility variants in African populations, access to ancestry-informed genetic counseling and testing remains limited due to infrastructure constraints and poor integration into routine oncology care. The GenCAF program was developed to translate prior genomic evidence from Nigeria into a scalable, clinically embedded cancer genomics implementation model in African settings. **Methods:** Consecutive breast cancer patients were prospectively enrolled and offered genetic counseling and testing regardless of age or family history. Germline testing was performed using the Color Hereditary Cancer Test (Color Health Inc). Counseling and result disclosure were delivered by locally trained oncology nurses or breast health specialists using a structured protocol. Clinical and tumor characteristics were correlated with genetic findings. The program was designed for scalability across English- and French-speaking sites. **Results:** Among 263 participants, 235 unrelated index breast cancer cases underwent germline testing. Overall, 43.0% (101/235) had a reportable germline finding, including 21.7% (51/235) with pathogenic or likely pathogenic (P/LP) variants and 21.3% (50/235) with variants of uncertain significance (VUS). Among genes present in ≥5% of cases with variant calls, VUS were most frequent in *APC, ATM, PALB2, PMS2*, and *BRCA2*, with several moderate-penetrance DNA repair genes exhibiting disproportionately high VUS burden, representing key candidates for future reclassification as African-ancestry reference data and gene–environment context expand. P/LP variants were most common in BRCA1 (n = 22), BRCA2 (n = 13), ATM (n = 4), and PALB2 (n = 4). P/LP carriers tended to be diagnosed before age 30 (13.7% vs 7.6%) and were more frequently diagnosed with advanced-stage disease (stage III–IV, 30.6%). Mean age did not differ overall; however, BRCA1 P/LP carriers had an earlier onset (mean age 40.1 years). **Conclusions:** These findings support integrating germline cancer genetics into routine breast cancer care in Africa through a scalable, nurse-led counseling model. The substantial VUS burden underscores the need for ancestry-informed interpretation and future reclassification efforts incorporating population-specific and environmental data. Planned implementation of point-of-care next-generation and long-read sequencing will further strengthen local diagnostic capacity and enable sustainable, locally driven precision prevention and oncology through risk-informed care. Research Sponsor: Breast Cancer Research Foundation; Susan G. Komen; U.S. National Institutes of Health; R01MD013452.

Age Group (yrs)	P/LP (%)	VUS (%)
<30	**13.7**	7.6
30–39	15.7	23.9
40–49	23.5	23.4
50–59	27.5	26.6
≥60	15.6	19.0

Missed by the guidelines: A meta-analysis of USPSTF lung cancer screening ineligibility among patients diagnosed with lung cancer. First Author: Khalid Ahmad Qidwai, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Lung cancer (LC) screening utilizes low-dose CT recommended by the US Preventive Services Task Force (USPSTF) based on age and smoking history. However, the proportion of patients who develop LC but are ineligible for screening at diagnosis remains unclear. We performed a meta-analysis to quantify the burden of LCs missed under USPSTF 2013 and 2021 criteria and identify key reasons for ineligibility. **Methods:** We systematically searched PubMed, Embase, and Scopus to identify studies reporting USPSTF screening eligibility among adults diagnosed with primary LC who ever smoked. Data were pooled using random-effects models. Primary outcomes included pooled proportions (PP) of LC cases ineligible for USPSTF screening using 2013 and 2021 criteria. Secondary analyses evaluated reasons for ineligibility, including age, smoking pack-years (yrs), and quit-yrs. Statistical significance is defined as $p < 0.05$. Heterogeneity was assessed using the I^2 statistic. **Results:** Eight studies comprising 12,487 LC cases utilized the USPSTF 2013 criteria. The PP of screening-ineligible cases was 57.6% (95% CI, 48.94%-66.2%; I^2=97.3%). Under USPSTF 2021 criteria, 11 studies including 20,313 cases were analyzed, yielding a pooled ineligible proportion of 40.9% (95% CI, 31.9%-50.5%; I^2=98.8%). In reason-specific analyses, insufficient smoking exposure (pack-yrs) was the primary cause of ineligibility using both criteria, accounting for 68.2% (2013) and 59.3% (2021) of ineligible cases. Age-based exclusions declined from 34.7% under USPSTF 2013 to 31.8% under USPSTF 2021. Quit-year restrictions contributed to ineligibility under both criteria (25.8% in 2013; 49.6% in 2021), reflecting a greater proportional contribution among remaining ineligible cases under the 2021 criteria. Categories of ineligibility were not mutually exclusive. **Conclusions:** More than half of LCs were ineligible for screening under USPSTF 2013 criteria, and over 40% remain ineligible under current guidelines. Smoking pack-year thresholds remain the primary reason for ineligibility to screen and thereby miss a cancer diagnosis. These findings highlight limitations of current criteria and support the development of alternative risk-based screening strategies. Research Sponsor: None.

Lung cancer screening ineligibility under USPSTF 2013 and 2021 criteria.

	Pooled Proportion (95% CI)	I^2 (%)
USPSTF 2013 Criteria Overall Ineligibility	57.6% (48.4-66.2)	97
Age-based exclusion (<55 or >80 yrs)	34.7% (28.2-41.8)	70
Insufficient pack-yrs (<30)	68.2% (54.6-79.2)	93
Quit-year exclusion (>15 yrs)	25.8% (10.8-49.8)	97
USPSTF 2021 Criteria Overall Ineligibility	40.9% (31.9-50.5)	98
Age-based exclusion (<50 or >80)	31.8% (18.4-49.0)	96
Insufficient pack-yrs (<20)	59.3% (45.6-71.6)	89
Quit-year exclusion (>15 yrs)	49.6% (37.1-62.0)	94

Reproducible modulation of tissue Ki-67 across lung and prostate cancer interception trials. First Author: Sri Pranita Cherukuri, Columbia University, New York, NY

Background: The clinical utility of cancer interception is limited by the lack of validated surrogate endpoints that capture early biological response before histopathologic progression. While morphologic changes often require prolonged follow-up, Ki-67, a nuclear marker of cellular proliferation, provides a dynamic, tissue-based measure of epithelial proliferative activity. However, its reproducibility across high-risk tissue contexts remains debated. We evaluated the consistency of tissue Ki-67 modulation across two independent randomized trials in high-risk lung and prostate epithelia. **Methods:** We analyzed data from two prospective, randomized, placebo-controlled phase II cancer interception trials that prespecified tissue Ki-67 as an endpoint. In the lung cohort (NCT03232138; n=98), high-risk smokers with bronchial dysplasia were randomized to oral sulforaphane (200 μmol/day) or placebo for 6 months. In the prostate cohort (CAPFISH-3; n=58), patients with low-grade prostate cancer on active surveillance were randomized to long-chain omega-3 fatty acids (3 g/day) or placebo for 12 months. Paired tissue biopsies were obtained at baseline and study completion. Ki-67 expression was quantified by immunohistochemistry with central pathology review. **Results:** Baseline Ki-67 indices were comparable between intervention and placebo arms in both cohorts. Following the intervention, a statistically significant divergence in tissue proliferative activity was observed. In the lung cohort, sulforaphane treatment was associated with a 20% reduction in bronchial epithelial Ki-67, whereas the placebo arm demonstrated a 65% increase (P=0.014). In the prostate cohort, omega-3 supplementation resulted in a 15% reduction in intratumoral Ki-67, compared with a 24% increase in the control arm (P=0.043). Sub-analysis by staining intensity demonstrated preferential suppression among high-intensity (3+) Ki-67–positive cells, including a 44% reduction in the lung intervention arm. Ki-67 modulation correlated with baseline proliferative activity but not with baseline histopathologic features. No significant changes in histopathologic grade or dysplasia scores were observed. **Conclusions:** Tissue Ki-67 demonstrates consistent, reproducible modulation across randomized lung and prostate interception trials, preceding detectable morphologic change. These findings support Ki-67 as a practical early biologic endpoint for phase II cancer interception studies. Research Sponsor: None.

Tissue Ki-67 modulation across randomized cancer interception trials.

Cohort (n)	Intervention	Ki-67 change (Tx)	Ki-67 change (Pbo)	P value
Lung (98)	Sulforaphane	−20%	+65%	0.014
Prostate (58)	Omega-3	−15%	+24%	0.043

Elevated red blood cell distribution width-to-albumin ratio and incident cancer risk: A prospective cohort study. First Author: Parham Habibzadeh, Department of Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Cancer remains a leading cause of global morbidity and mortality, underscoring the need for accessible biomarkers for early detection and risk stratification. The red blood cell distribution width-to-albumin ratio (RAR) is an emerging composite index integrating markers of erythropoietic stress and nutritional status/hepatic dysfunction, often dysregulated in malignancy and systemic inflammation. Elevated RAR correlates with worse outcomes in patients with sepsis and various cancers; however, its association with incident cancer risk in large prospective cohorts remains uncharacterized. **Methods:** Using UK Biobank data, we conducted a prospective cohort study with 5:1 propensity score matching, yielding an analytic cohort of 112,107 participants (18,916 with elevated RAR, 93,191 with normal RAR). Elevated RAR was defined as $>$ 95th percentile ($>$ 3.48 %·dL/g) among cancer-free participants at baseline. Matching balanced groups by age, sex, ethnicity, socioeconomic status, BMI, smoking, alcohol use, diabetes, chronic kidney disease, and family history of cancer. Adjusted Cox proportional hazards regression was utilized to assess associations between elevated RAR and incident cancer. We also performed a 2-year landmark analysis to evaluate reverse causation. Hazard ratios (HRs) with 95% confidence intervals (CIs) are reported. **Results:** During median follow-up of 15.4 years (1.55 million person-years), 21,307 incident cancers occurred. Elevated RAR was significantly associated with 23% increased overall cancer risk (HR 1.23; 95% CI 1.18-1.27). Cancer-specific analyses revealed strongest associations for hematologic malignancies (HR 1.91; 95% CI 1.70-2.14), including acute myeloid leukemia (HR 2.22; 95% CI 1.37-3.60) and chronic myeloid leukemia (HR 2.78; 95% CI 1.23-6.31). Significant associations were also observed for gastric (HR 2.12; 95% CI 1.57-2.86), liver (HR 1.90; 95% CI 1.38-2.62), lung (HR 1.45; 95% CI 1.27-1.66), and colon cancer (HR 1.48; 95% CI 1.28-1.72). No significant association was observed for breast (HR 1.06; 95% CI 0.96-1.17) or prostate cancer (HR 0.94; 95% CI 0.84-1.05). A 2-year landmark analysis showed that the association with overall cancer risk remained robust (HR 1.19; 95% CI 1.15-1.24). **Conclusions:** Elevated RAR is independently associated with increased incident cancer risk, particularly for hematologic, gastrointestinal, and lung cancers. These associations persisted in 2 year landmark analyses, supporting a potential prospective relationship and motivates further evaluation of RAR, a readily calculable index from routinely obtained laboratory values, in cancer risk models. Pancreatic cancer incidence and survival in lean and obese adults with type 2 diabetes: A propensity matched analysis. First Author: Vasu Bansal, University of Missouri Kansas City, Kansas City, MO

Background: Type 2 diabetes mellitus (T2DM) and excess adiposity are independent risk factors for pancreatic cancer. Pancreatic cancer risk within T2DM across body-mass index (BMI) strata is heterogeneous in real-world cohorts and lean T2DM individuals may represent a distinct high risk phenotype. We compared pancreatic cancer incidence and post-diagnosis survival across BMI strata. **Methods:** We performed a retrospective comparative outcomes analysis using the TriNetX network. Adults with T2DM (HbA1c $\geq$6.5%) were categorized as obese (BMI $\geq$30 kg/m²) or lean (BMI $<$25 kg/m²). The lean cohort additionally excluded any patient with prior BMI of $>$25 kg/m² to control for cancer associated weight loss. The index event was first T2DM diagnosis, and outcomes were evaluated after a 365-day window. Patients with pancreatic cancer prior to the outcome window were excluded. Propensity score matching was done using the following parameters: age, sex, smoking status, pancreatitis, pancreatic cysts, chronic kidney disease, gallstones, family history of pancreatic cancer, and HbA1c. Outcomes assessed were incident pancreatic cancer over 10 years and all-cause mortality among patients with pancreatic cancer and T2DM. **Results:** Total number of patients in the obese group was 1,759,075 with mean age of 57 $\pm$ 13.4 years and in the lean cohort were 205,193 with a mean age of 61.8 $\pm$ 16.6 years. After propensity score matching, there were 204,086 patients in each group. Mean HbA1c levels were 7.4 $\pm$ 1.8% in the obese group and 7.9 $\pm$ 2.2% in the lean BMI group. The incidence of pancreatic cancer was 0.16% (n = 335) in obese patients as compared to 0.23% in lean (n = 478) patients with a risk difference of 0.07% ($p < 0.001$). Obesity was associated with lower pancreatic cancer risk (RR 0.692, 95% CI 0.603–0.797; $p < 0.001$). In the subgroup analysis of patients diagnosed with pancreatic cancer, obese patients had longer median survival (1,109 vs 651 days) with HR 0.853 (95% CI 0.793 - 0.918; $p < 0.001$). **Conclusions:** Lean adults with T2DM had a higher incidence of pancreatic cancer and worse post-diagnosis survival than obese patients. These results identify lean T2DM as a distinct high-risk phenotype and demonstrate that pancreatic cancer risk within T2DM is heterogeneous and not solely attributable to excess adiposity. Further investigation is needed to elucidate the biological mechanisms underlying this association and its implications for clinical risk assessment. Research Sponsor: None.

Pancreatic cancer incidence and associated risk estimates among obese and lean adults with type 2 diabetes mellitus.

Cohort	Pancreatic cancer incidence	RD	RR
Obese T2DM(n = 204,086)	0.16% (n = 335)	0.07% (95% CI: 0.04 - 0.10), $p < 0.001$	1.44 (95% CI: 1.25 - 1.66)
Lean T2DM(n = 204,086)	0.23% (n = 478)		

Abbreviations: CI, confidence interval; RD, risk difference; RR, relative risk; T2DM, type 2 diabetes mellitus.

Diagnostic accuracy of blood-based cfDNA fragmentomic assays for lung cancer detection: A meta-analysis of clinically validated cohorts. First Author: Khalid Ahmad Qidwai, Miami Cancer Institute, Baptist Health South Florida, Miami, FL

Background: Early detection of lung cancer remains limited by suboptimal sensitivity and specificity of current screening and diagnostic strategies. Blood-based cell-free DNA (cfDNA) fragmentomic assays that leverage genome-wide fragmentation patterns have emerged as a promising noninvasive approach for lung cancer detection. However, reported diagnostic performance varies across studies and clinical settings. A meta-analysis was conducted to evaluate the pooled diagnostic accuracy of cfDNA fragmentomic assays in clinically validated cohorts. **Methods:** We systematically searched PubMed, Cochrane Library, and Scopus for studies evaluating blood-based cfDNA fragmentomic assays for lung cancer detection. Eligible studies were required to be lung cancer-specific, use fragmentomics-based features derived from plasma cfDNA, include an independent validation or test cohort, and report extractable binary diagnostic accuracy data. Training-only studies, multi-omic assays, and studies lacking sensitivity and specificity at a prespecified threshold were excluded. Sensitivity and specificity were jointly pooled using a bivariate random-effects model based on 2$\times$2 contingency tables, accounting for threshold effects and between-study heterogeneity. **Results:** Five studies with independent validation cohorts comprising 725 lung cancer cases and 435 non-cancer controls were included, spanning screening-eligible populations, LDCT-positive pulmonary nodules, early-stage disease, and mixed-risk cohorts. Using a bivariate random-effects model, pooled sensitivity was 87.5% (95% CI, 77.4%–93.4%) and pooled specificity was 85.7% (95% CI, 63.6%–95.4%), corresponding to a pooled positive likelihood ratio of 6.14 (95% CI, 2.34–19.26) and negative likelihood ratio of 0.146 (95% CI, 0.074–0.295), and diagnostic odds ratio of approximately 42. Moderate inter-study heterogeneity was observed (I^2=62%), largely attributable to differences in clinical setting, disease spectrum, and control composition; however, diagnostic performance remained directionally consistent across cohorts. The summary receiver operating characteristic curve demonstrated excellent overall discrimination (AUC 0.92). **Conclusions:** Across clinically validated cohorts, blood-based cfDNA fragmentomic assays demonstrated strong discriminative performance for lung cancer detection. Despite heterogeneity across study populations and clinical use cases, pooled sensitivity and specificity were robust, supporting the potential role of cfDNA fragmentomics as a noninvasive adjunct to existing screening and diagnostic strategies. Research Sponsor: None.

Enterprise-wide implementation of multicancer detection testing across a large academic health system. First Author: Aditya Kumar Ghosh, Mayo Clinic Rochester, Rochester, MN

Background: Multicancer detection (MCD) testing using cell-free DNA methylation patterns is a novel blood-based approach to cancer screening. In 2022, Mayo Clinic implemented offering MCD testing into routine clinical practice. Prior real-world reports have been limited to single-site experiences. We evaluated enterprise-wide implementation of MCD testing across all three Mayo Clinic sites using the Mayo Clinic Platform. **Methods:** We performed a retrospective analysis of de-identified clinical data from Mayo Clinic Platform Discover, including GRAIL Galleri tests performed at Mayo Clinic sites in Rochester, MN; Scottsdale, AZ; and Jacksonville, FL. This activity did not require IRB review per 45 CFR 46.102. Demographics, test results, cancer diagnoses, and prior cancer history were extracted using a privacy-preserving protocol, with data de-identified by expert determination. ICD-10 diagnostic codes were used to identify subsequent cancer diagnoses. **Results:** A total of 8,201 Galleri tests were performed in 7,300 patients; some patients underwent repeat testing. Fifty-seven tests (0.7%) were positive. Among MCD-positive patients, cancer diagnostic codes were identified in 32 patients, yielding a positive predictive value (PPV) of 58.7%. The most common cancers identified were oropharyngeal (34.4%), lymphoid and hematopoietic (34.4%), and gastrointestinal malignancies (18.8%).Among 8,144 MCD-negative tests (99.3% of all testing performed), 423 patients (5.2%) subsequently received a cancer diagnostic code, yielding a negative predictive value of 92.5%. The most commonly identified cancers in this group were male genital organs (36.6%), urinary tract (10.6%), and thyroid or other endocrine glands (7.3%). Overall, 10.1% of patients had a prior cancer history, which was more common in MCD-positive than MCD-negative patients (22.6% vs 10.0%). Patients with positive tests were older (mean age 68.4 vs 61.5 years) and more often male (67% vs 62%). Race distribution was similar. **Conclusions:** Enterprise-wide implementation of MCD testing across diverse clinical settings is feasible within routine workflows. Over half of positive tests were associated with cancer diagnostic codes, supporting the clinical promise of MCD testing. Limitations include incomplete capture of externally diagnosed cancers and lack of cancer signal-of-origin data. The Mayo Clinic Platform enables scalable, secure analytics to support future cancer interception strategies. Research Sponsor: None.

Structural disparities in early-onset colorectal cancer mortality: A national county-level analysis. First Author: Varshini Odayar, University of Michigan Medical School, Ann Arbor, MI

Background: Early-onset colorectal cancer (CRC) incidence and mortality are rising, with significant disparities by geography and socioeconomic status. We examined county-level disparities in early-onset CRC mortality (ages $<$ 55) across the United States to identify modifiable factors associated with mortality rates. **Methods:** We analyzed age-adjusted CRC mortality rates from CDC WONDER. Predictors included rurality (Rural–Urban Continuum Codes 2023: non-metro vs metro), socioeconomic factors (median income, % uninsured, % poverty from County Health Rankings 2025), demographic composition (% non-Hispanic Black, % Hispanic), health behaviors (current smoking, obesity, routine checkup from PLACES 2025), and healthcare access (gastroenterologist, primary care physician, and hospital counts from AHRF 2024–2025). Multivariable linear regression assessed associations between predictors and mortality, with continuous variables standardized to z-scores. Counties with missing or unreliable mortality data were excluded ($p < 0.05$ for significance). **Results:** The final sample included 672 counties. Mean mortality was 4.26 per 100,000 (range 1.7–11.9). Non-metro counties comprised 12.2% (n = 82). The model explained 54.8% of variance in mortality ($F = 66.5$, $p < 0.001$). Current smoking was the strongest predictor ($\beta = 0.54$ per SD, 95% CI: 0.38–0.70, $p < 0.001$), indicating a one-SD increase in smoking prevalence corresponded to a 0.54 per 100,000 higher mortality rate. Non-metro counties had 0.80 more deaths per 100,000 than metro counties (95% CI: 0.56–1.05), a 19% increase relative to the mean. Poverty ($\beta = 0.21$ per SD, $p = 0.011$), uninsured rates ($\beta = 0.20$ per SD, $p < 0.001$), and % Black ($\beta = 0.21$ per SD, $p < 0.001$) were also significant. Higher Hispanic population was associated with lower mortality ($\beta = -0.20$ per SD, $p = 0.001$). Healthcare provider variables (gastroenterologist count, primary care count, hospital count) were not significantly associated ($p \geq 0.051$). **Conclusions:** Geographic, socioeconomic, and health behavior factors accounted for 54.8% of variation in early-onset CRC mortality, with smoking showing the strongest association. Non-metro counties and areas with higher poverty, uninsured rates, and smoking prevalence had higher mortality, though these relationships are not causal. Remaining unexplained variance suggests roles for screening uptake, stage at diagnosis, treatment quality, and genetic susceptibility. Findings identify high-risk counties and highlight the need for future causal analyses to clarify pathways underlying disparities and support targeted interventions. Research Sponsor: None.

Quantifying the macroeconomic burden of cancer: Global disparities in value-of-lost-welfare (VLW). First Author: Sai Varun Gadde, UCF HCA GME Consortium, Orlando, FL

Background: Cancer (CA) remains a leading global driver of disability and premature death, yet its full macroeconomic toll is rarely quantified. In this study, we estimated the global economic welfare loss attributable to all cancers in 2023 across 183 countries using a standardized Value of Lost Welfare (VLW) framework. **Methods:** We obtained country-level disability-adjusted life years (DALYs) for CA from the Global Burden of Disease Study 2023. Corresponding GDP (PPP, current international dollars) and population data were sourced from the World Bank. We calculated VLW by multiplying DALYs by a fixed monetary value of USD 14,403.29 per DALY, yielding estimates of total VLW, per-capita VLW, and VLW/GDP (%). CA-specific estimates were derived using cause-wise DALY distributions across global and regional levels. **Results:** In 2023, CA caused 268.9 million DALYs globally, resulting in a global VLW of USD 3.87 trillion—equivalent to 2.12% of global GDP, with an average per-capita economic loss of 522 billion. The largest absolute economic losses were reported in China (915.5 billion), India (458.7 billion), and the United States, followed by Japan (126.7 billion) and Brazil (108.6 billion). When adjusted for national GDP, the highest VLW-to-GDP ratios were observed in Zimbabwe (4.24%), Cambodia (4.00%), Mongolia (3.45%), India (3.09%), and Egypt (1.63%), reflecting intense economic vulnerability. Across SDI strata, high-SDI countries bore the greatest economic burden, incurring a VLW of 1.80 trillion, followed by high-middle SDI (808.7 billion), low SDI (568.0 billion), low-middle SDI (406.5 billion), and middle SDI (384.9 billion). While absolute losses were highest in high-SDI settings, VLW/GDP ratios were notably elevated in low- and low-middle SDI regions, signaling disproportionate economic strain in resource-limited contexts. By CA type, lung CA led the global burden with 672 billion in welfare losses, followed by colorectal CA (377 billion), breast CA (355 billion), stomach CA (324 billion), and esophageal CA (202 billion). **Conclusions:** The global macroeconomic cost of CA surpassed USD 3.6 trillion in 2023, with marked disparities across countries and regions. High-burden nations such as China, India, and the U.S. faced the steepest absolute losses, while several low-income countries suffered disproportionately high economic strain relative to GDP. The concentration of losses in five major CA types signals an urgent need for enhanced global investments in CA prevention, early detection, and control. Research Sponsor: None.

Regional cancer burden and economic losses in 2023.

Region	DALYs (Millions)	VLW ($ Billion)	VLW/GDP (%)
Sub-Saharan Africa	28.82	415.14	6.64
South Asia	43.72	629.68	3.48
Southeast Asia, East Asia & Oceania	89.19	1284.6	2.76
North Africa & Middle East	14.34	206.6	2.50
Latin America & Caribbean	18.39	264.91	2.36
Central/Eastern Europe & Central Asia	20.89	300.85	2.20
High Income	60.37	869.53	1.25

Multimodal profiling of STIC lesions to identify precursor states with genomic features of high grade serous ovarian cancer. First Author: Duaa Al-Rawi, Memorial Sloan-Sloan Kettering Cancer Center, New York, NY

Background: High-grade serous ovarian cancer (HGSC) is a lethal gynecologic malignancy characterized by near-universal *TP53* inactivation, chromosomal instability (CIN), and frequent whole-genome doubling. Because population screening is ineffective, risk-reducing salpingo-oophorectomy (RRSO) remains the only proven risk-reduction strategy. Nonetheless, some individuals develop primary peritoneal carcinoma (PPC), and identification of serous tubal intraepithelial carcinoma (STIC) at RRSO is associated with $>$ 30-fold higher PPC risk. We sought to define the molecular steps required for HGSC initiation and identify features of high-risk STIC. **Methods:** We assembled a 201-patient cohort spanning stages of HGSC development, including normal fallopian tube epithelium, p53 signatures, STIC, and early- and advanced-stage HGSC. All specimens underwent multiplex immunofluorescence (mpIF). Forty-five samples from 36 patients were profiled using Visium HD spatial transcriptomics ($>$ 20 million 8-μm bins). We analyzed epithelial state transitions using unsupervised clustering and trajectory inference. Copy-number variation (CNV) was inferred using spatial inferCNV; CNV calls were validated with matched formalin-fixed paraffin-embedded (FFPE) single-cell whole-genome sequencing. **Results:** mpIF demonstrated lesion-to-lesion variability in cyclic GMP–AMP synthase (cGAS) staining within STIC, consistent with evolving tolerance to CIN before invasion. Spatial transcriptomic clustering identified distinct, reproducible STIC epithelial programs that mapped to histologic features. STIC programs were enriched for NFκB and TGF-β signaling and lacked evidence of the JAK/STAT activation observed in advanced HGSC. CNV inference showed that normal fallopian tube and p53 signature lesions were chromosomally stable, whereas STIC displayed broad, genome-wide alterations resembling advanced HGSC, including losses encompassing *TP53*, *BRCA1*, and *BRCA2* and amplifications of *MYC* and *CCNE1*. In a germline *BRCA2* carrier, we identified polyclonal STIC with distinct CNV profiles; trajectory analysis suggested early CNV changes within an expanded secretory population, followed by loss of chromosome 17 (*TP53*), loss of chromosome 13 (*BRCA2*), and subsequent oncogene amplifications (e.g., *MYC*). As lesions became invasive, spatial CNV profiling revealed neighborhoods of clonally related invasive cells with distinct microenvironments, including differences in fibroblast states and vascularization. **Conclusions:** A multimodal atlas of fallopian tube transformation supports a model in which *TP53* loss precedes *BRCA1/2* inactivation and indicates that STIC is genomically similar to advanced HGSC. These findings provide a framework to study early HGSC evolution, stratify STIC risk after RRSO, and inform early-interception strategies. Texture and color enhancement imaging (TXI) for polyp detection in colorectal neoplasia screening: A meta-analysis of randomized controlled trials. First Author: Haroon Alamy, Desert Regional Medical Center, Inc., Palm Springs, CA

Background: Colonoscopy remains the gold standard for preventing colorectal cancer; however, variable adenoma detection rates (ADR) among endoscopists highlight the need for improved visualization technologies. Texture and Color Enhancement Imaging (TXI) is a novel image-enhanced endoscopy modality designed to optimize the visibility of mucosal lesions by enhancing surface texture and brightness. This meta-analysis evaluates the efficacy of TXI compared to standard high-definition white-light imaging (HD-WLI) in the detection of colorectal neoplasia, specifically assessing whether enhanced visualization translates to higher detection rates of adenomas and polyps in a randomized controlled setting. **Methods:** We conducted a systematic review and meta-analysis of prospective randomized controlled trials (RCTs) published between 2023 and 2025. The analysis included adult patients undergoing colonoscopy for screening, surveillance, or diagnostic indications where TXI was compared to HD-WLI during the withdrawal phase. Primary outcomes included ADR, polyp detection rate (PDR), and adenomas per colonoscopy (APC). Secondary outcomes included polyps per colonoscopy (PPC) and flat lesion detection. Statistical analysis was performed using a random-effects model (DerSimonian-Laird method). Risk ratios (RR) and mean differences (MD) with 95% confidence intervals (CI) were calculated, with heterogeneity assessed via I^2 statistics. **Results:** The analysis pooled data from four RCTs comprising 2,308 patients. The chief finding was a statistically significant 25.5% increase in the Polyp Detection Rate (PDR) with TXI compared to WLI (pooled RR = 1.255; 95% CI: 1.050–1.498; $p < 0.05$). Regarding the Adenoma Detection Rate (ADR), TXI showed a positive trend with a 22% relative increase (pooled RR = 1.220; 95% CI: 0.981–1.519); however, this did not reach statistical significance ($p > 0.05$). Analysis of Adenomas per Colonoscopy (APC) showed no significant difference (MD = 0.153; $p > 0.05$). Substantial heterogeneity was observed across outcomes ($I^2 > 60\%$), suggesting variability in endoscopist experience or study populations. **Conclusions:** Texture and Color Enhancement Imaging demonstrates clear superiority over white-light imaging for overall polyp detection, establishing it as a promising tool for identifying colorectal neoplasia. While TXI significantly improved PDR, the improvement in ADR showed a strong positive trend that did not reach statistical significance, likely due to high between-study heterogeneity. These findings suggest that TXI enhances lesion visibility, particularly for general polyps, but further large-scale RCTs are necessary to definitively establish its impact on adenoma detection and long-term interval cancer prevention. GLP-1 receptor agonist therapy and cancer risk and mortality in patients with moderate CKD: A national matched cohort study of 58,000 patients. First Author: Muneeb Asad, Texas Tech University Health Sciences Center Paul L. Foster School of Medicine, EL Paso, TX

Background: Glucagon-like peptide 1 receptor agonists (GLP-1 RAs) have been associated with reduced mortality in patients with Type 2 Diabetes Mellitus (T2DM) and may lower cancer risk. However, the impact of GLP-1 RAs on cancer incidence and mortality in patients with chronic kidney disease (CKD) remains understudied. Thus, in this study we evaluated whether GLP-1 RA use modifies cancer risk and mortality in a contemporary national cohort of patients with moderate CKD. **Methods:** We performed a retrospective cohort study using the TriNetX Research Network, identifying adults aged 18–90 years with T2DM and newly diagnosed stage-3 CKD between January 2015 and February 2025. Patients with prior malignant neoplasms or end-stage renal disease were excluded. Exposure was defined as a prescription for a GLP-1 RA within 90 days before CKD diagnosis; controls had no documented GLP-1 RA use. Outcomes were evaluated beginning 90 days after the index CKD diagnosis to reduce reverse-causation and immortal-time bias. Our primary outcome was any malignant neoplasm. Our secondary outcomes were site-specific malignant neoplasms (colorectal, lung, liver, kidney, pancreatic, breast, and prostate) as well as all-cause mortality. We performed 1:1 propensity score matching balancing demographics, comorbidities, laboratory values (hemoglobin A1c and estimated glomerular filtration rate), and cardiometabolic medications. After matching, we calculated absolute risks, risk differences, hazard ratios, risk ratios, and 95% confidence intervals. Statistical significance was defined as $p < 0.05$. **Results:** After matching, 28,948 patients remained in each group. GLP-1 RA use was associated with significantly lower all-cause mortality (8.6% vs 15.0%; HR 0.57; 95% CI, 0.546-0.599; $p < 0.001$). Overall malignant neoplasm incidence was significantly lower with GLP-1 RA use (7.0% vs 7.7%; RR 0.90; $p < 0.001$). Among site-specific malignancies, the GLP-1 RA group demonstrated lower incidence of lung cancer (0.5% vs 0.8%; RR 0.56; $p < 0.001$), colorectal cancer (0.5% vs 0.7%; RR 0.74; p = 0.006), and liver cancer (0.3% vs 0.4%; RR 0.63; p = 0.001). Pancreatic cancer (0.2% vs 0.3%; RR 0.89; p = 0.46), kidney cancer (0.5% vs 0.6%; RR 0.98; p = 0.87), prostate cancer (1.1% vs 1.0%; RR 1.08; p = 0.32), and breast cancer (0.7% vs 0.7%; RR 1.11; p = 0.30) did not differ significantly based on GLP-1 RA receipt. **Conclusions:** In patients with T2DM and stage-3 CKD, GLP-1 RA therapy was associated with substantially lower mortality and reduced incidence of several major malignancies, particularly lung, colorectal, and hepatocellular cancers. These findings highlight a potential role for GLP-1–mediated metabolic modulation in cancer prevention among high-risk populations. Prospective studies are warranted to clarify mechanisms and confirm these observations. Research Sponsor: None.

Non-random patterns of multiple primary malignancies in the era of cancer survival. First Author: Thomas George, Boston University Chobanian & Avedisian School of Medicine and Boston Medical Center, Boston, MA

Background: Improved cancer therapies have increased survival, placing survivors at risk for subsequent primary cancers, yet the epidemiology of multiple primary cancers (MPC) is poorly defined. **Methods:** Using the VA Cancer Registry (2003–2023), we quantified MPC frequency, classified cancers by SEER ICD-O-3 codes and histology, and analyzed incidence and expected versus observed occurrence. **Results:** Among 822,564 veterans with cancer, 11.1% (n=91,279) developed ≥2 primary cancers. The frequencies of patients with 2, 3, 4, or ≥5 MPC were 81715 (9.9%), 8655 (1.1%), 800 (0.1%), and 109 (0.01%), with similar relative risks across successive cancers. Interestingly, the median age at first cancer was similar across groups (67.3 years for 1 cancer; 66.6, 65.8, and 65 years for 2, 3 and 4 cancers). In contrast, intervals between successive cancers progressively shortened (2.7 years – 2 cancers; 2.5 and 1.8 years – 3 cancers; 2.2, 1.9, and 1.4 years – 4 cancers), suggesting prior cancer influences the risk of subsequent cancer. The 7 most common first and subsequent cancers were prostate, bladder, lung, colon, melanoma, kidney, and oral cavity cancers. We identified three etiologic patterns underlying MPC. First, exposure-related cancers, clustered as expected, lung cancer was the most common 2nd and 3rd cancer after bladder (n=1850 and 231) and oral cavity (n=1581 and 148) cancers, suggesting a relationship to smoking. Second, genetically predisposed cancers did not cluster, likely reflecting the older population. Third, therapy-related cancers increased, with acute myeloid leukemia (AML)/acute lymphoblastic leukemia (ALL) standard rates rising from 0.02/0.003 (1st) to 39.01/3.19 (AML) and 5.04/0.03 (ALL) as 2nd and 3rd primary cancers. Interestingly, the frequency of prostate cancer and chronic lymphocytic leukemia (CLL) declined with increasing cancer order, consistent with earlier detection through established screening practices, and in contrast, lung cancer and multiple myeloma (MM) frequency increased as subsequent cancers, suggesting more complex etiologies, including aging-related risk. **Conclusions:** In this large VA registry analysis, over 11% of cancer survivors developed MPC with consistent patterns of occurrence, shortening intercancer intervals, and non-random clustering by exposure-, therapy-, and disease-specific factors. These findings underscore the need for risk-adapted surveillance and long-term survivorship strategies that account for shared etiologies and treatment-related risks rather than assuming stochastic occurrence. Research Sponsor: None.

Frequency of a cancer as MPC.

		1st primary	2nd primary	3rd primary	4th primary
Pts with 2 cancers	Prostate	29.4%	14.1%

Differential risk patterns of secondary breast cancer in medullary versus papillary thyroid carcinoma survivors: A SEER-based analysis. First Author: Li Liu, The Second People's Hospital of Hefei, Hefei, China

Background: Prior studies suggest that thyroid cancer (TC) survivors may have an elevated risk of secondary malignancies. However, whether this risk differs by TC histology, specifically with breast cancer (BC), remains unclear. We aimed to investigate the association between TC subtype—papillary thyroid carcinoma (PTC) versus medullary thyroid carcinoma (MTC)—and subsequent BC risk, adjusting for demographic factors. **Methods:** We conducted a retrospective cohort study using the SEER (2000–2022), including adults with a primary, microscopically confirmed PTC or MTC. Subsequent BC occurrence was defined as a binary outcome (yes/no). Multivariable logistic regression was used to estimate adjusted odds ratios (aORs) for MTC versus PTC, controlling for age (<50 vs ≥50 years), sex, and race. Stratified analyses by age and race were also performed. Stata 15 was used for statistical analyses. **Results:** 14,840 patients (14,563 PTC, 277 MTC) were included. MTC patients were older (mean 59.08±12.66 vs 56.16±12.98 years, p<0.001) and had a higher proportion of males (44.4% vs 29.4%, p<0.001). The overall incidence of secondary BC was lower in MTC patients (7.6% vs 22.5%, p<0.001). In unadjusted logistic regression, MTC was associated with significantly lower BC risk (OR=0.28, 95% CI: 0.18–0.44, p<0.001). After adjustment, MTC remained significantly protective (aOR=0.34, 95% CI: 0.22–0.55, p<0.001). Stratified analyses demonstrated consistent findings across age groups (<50: aOR=0.10, 95% CI: 0.03–0.42; ≥50: aOR=0.34, 95% CI: 0.21–0.54), , as well as white and Hispanic patients. **Conclusions:** Survivors of MTC have a substantially lower risk of developing secondary BC compared to PTC survivors. This association persists after adjustment for age, sex, and race, and is consistent across age and most racial subgroups. However, different BC types were not assessed due to limited number of BC patients among MTC survivors, and the small MTC sample size and potential survival differences between groups may affect the results. These findings highlight a possible effect of TC subtype on BC risk, suggesting the potential influence of underlying biological or genetic mechanisms. Research Sponsor: None.

Association of prior SARS-CoV-2 infection with advanced cancer presentation in newly diagnosed solid tumors: A real-world data analysis. First Author: Anushareddy Muddasani, University of Arkansas for Medical Sciences, Little Rock, AR

Background: Emerging evidence suggests that the impact of SARS-CoV-2 infection may extend beyond acute respiratory illness, with potential implications for cancer biology. Recent proteomic analyses and reviews have highlighted several ways in which SARS-CoV-2 might interact with host pathways relevant to oncogenesis, tumor progression, and cellular plasticity. Taken together, these findings support a plausible biological rationale that COVID-19 infection may influence the clinical behavior or progression of solid tumors, potentially leading to diagnosis at later stages or the emergence of more aggressive phenotypes. In this study, we use real-world data from the TriNetX US Collaborative network to test the hypothesis that patients with solid tumors who have had COVID-19 are more likely to present with advanced-stage disease compared to those without a history of SARS-CoV-2 infection. **Methods:** We conducted a retrospective cohort study of adults (≥18 years) with newly diagnosed solid tumors, including breast, lung, colorectal, and prostate cancers, between January 1, 2021, and December 1, 2025. Patients were categorized based on documented SARS-CoV-2 infection prior to cancer diagnosis (COVID-positive vs COVID-negative), defined using ICD-10 codes and laboratory-confirmed PCR or antigen testing. Patients with any prior cancer diagnosis were excluded. The primary outcome was aggressive presentation, defined as AJCC Stage IV, M1 classification, or ICD-10 codes C77–C79 within 90 days of diagnosis. To reduce confounding, 1:1 propensity score matching was performed based on age, sex, race, ethnicity, cancer type, and comorbidities, including obesity, chronic lung disease, chronic kidney disease, diabetes, and hypertension. **Results:** After 1:1 propensity score matching, 201,131 patients were included in each cohort. Aggressive cancer presentation occurred in 16.8% of COVID-positive patients compared with 15.1% of COVID-negative patients. COVID-positive patients had a higher risk of aggressive disease presentation, corresponding to an absolute risk increase of 1.73% (95% CI, 1.50–1.96) and a relative risk of 1.11 (95% CI, 1.10–1.13). The odds of aggressive presentation were also higher among COVID-positive patients (OR, 1.14; 95% CI, 1.12–1.16; $p < 0.0001$). **Conclusions:** Prior COVID-19 infection was associated with a higher likelihood of advanced and metastatic cancer presentation at diagnosis, even after adjustment for demographic factors and comorbidities. These findings highlight the potential long-term oncologic impact of the COVID-19 pandemic and warrant further investigation. Research Sponsor: None.

Distinct immunogenomic features of cancers arising in solid organ transplant recipients. First Author: Shyfuddin Ahmed, National Cancer Institute, National Institutes of Health, Rockville, MD

Background: Solid organ transplantation recipients (SOTRs) are at increased risk of cancer due to long-term immunosuppressive therapy to prevent organ rejection. However, the immunogenomic characteristics of cancers arising in SOTRs remain poorly defined, limiting evidence-based treatment decisions, particularly regarding immunotherapy. **Methods:** Next-generation sequencing (NGS) of tumor tissue for DNA (592-gene panel/whole exome) and RNA (whole transcriptome) was carried out at Caris Life Sciences for SOTRs (n=1,024) and individuals without a transplant matched by age, sex, and cancer type (10:1 ratio, n=10,240). Immune cell infiltration in the tumor microenvironment (TME) was estimated by quanTIseq. Interferon-gamma (IFN-γ) signaling was assessed by a 10-gene transcriptomic signature. Tumor mutational burden (TMB) was assessed by NGS. Microsatellite instability (MSI) was assessed by immunohistochemistry (IHC) and NGS, and PD-L1 expression by IHC. Among SOTRs treated with immunotherapy, overall survival was assessed from insurance claims and calculated from treatment initiation to last contact. **Results:** The median age at sample collection was 65 years, with kidney recipients comprising the majority of SOTR cases (59.6%). Non-small cell lung cancer (NSCLC) was the most common malignancy (18.5%), followed by colorectal cancer (CRC, 10.5%). For all tumors combined, SOTRs exhibited significantly reduced adaptive immune cell infiltration in the TME, including $CD8^+$ T-cells (SOTR vs non-SOTR median: 0.11% vs 0.23%), regulatory T-cells (1.60% vs 2.10%) and B-cells (3.69% vs 3.91%); no significant differences were observed in innate immune cell fractions except for myeloid dendritic cells (0.64% vs 0.79%). While IFN-γ signatures were similar among all SOTRs and non-SOTRs, SOTRs had significantly lower IFN-γ for NSCLC and cutaneous squamous cell carcinoma (cSCC). Median TMB was significantly higher in SOTRs than non-SOTRs for NSCLC, colorectal cancer (CRC), pancreatic cancer, cSCC, melanoma, and esophageal cancer. MSI was more common in SOTRs overall (4.9% vs 1.9%; $p<0.0001$) and for CRC (15.8% vs. 6.8%; $p<0.0001$). PD-L1 positivity was less common in SOTRs than non-SOTRs (12.4% vs 18.6%; p=0.021). Finally, among SOTRs treated with immunotherapy, those with high TMB ($\geq$10 mutations/Mb) tended to have better survival than those with low TMB (hazard ratio 0.79, 95%CI 0.47-1.34, p=0.374). **Conclusions:** Despite higher prevalence of tumors with high TMB and MSI for select cancer types, SOTRs had lower adaptive immune infiltration and IFN-γ signaling within the TME, likely reflecting the immunosuppressive anti-rejection treatment. Our findings highlight distinct immunogenomic features of transplant-associated cancers and provide biologic rationale for further study of immunotherapy strategies in carefully selected SOTRs. Research Sponsor: None.

PCSK9 inhibitors and association with lower risk of metastasis. First Author: Gin Yi Lee, Brigham and Women's Hospital, Boston, MA

Background: Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a serine protease that regulates degradation of membrane proteins including the low-density lipoprotein (LDL) receptor and major histocompatibility complex class I (MHC-I) independently. Beyond lipid metabolism, preclinical studies have shown that PCSK9 inhibition reduces metastasis in animal models, suggesting potential to suppress tumor cell proliferation, migration, and immune evasion. However, population-level evidence across malignancies is limited. We evaluated whether PCSK9 inhibitor (PCSK9i) use is associated with risk of cancer metastasis in a large real-world cohort. **Methods:** In this new-user, active-comparator cohort study using the TriNetX U.S. Collaborative Network ($\approx$134 million patients), eligible patients were adults who initiated PCSK9i or statins alone for hyperlipidemia between 01/01/2015 and 01/01/2025 and subsequently received a cancer diagnosis. Index date was first prescription of PCSK9i or statin, with follow-up period continued until occurrence of study outcomes. To reduce reverse causation and early detection bias from intensified workup around drug initiation, patients with any cancer diagnosis within 6 months after index were excluded. 1:1 propensity score matching (PSM) balanced pre-index demographics, ASCVD and liver comorbidities, cancer screening procedures (low-dose chest CT, Pap smear, colonoscopy), BMI, and LDL. Primary outcome was time to any metastatic cancer (ICD-10 C77–C79); secondary outcomes were site-specific metastases (liver, lung, bone, brain, lymph node, adrenal gland). Cox proportional hazards models estimated hazard ratios (HRs) with 95% CIs. **Results:** Among 1,149,843 adults newly prescribed PCSK9i or statin (mean age 61.7 years, SD 10.6), median follow-up was 2,926 days. After 1:1 PSM, 8,674 patients remained in each cohort with balanced baseline characteristics (all standardized mean differences <0.1). Metastatic cancer was diagnosed in 435 PCSK9i patients versus 741 statin patients. The overall hazard of metastasis did not differ significantly (HR 0.96, 95% CI 0.85–1.08). In site-specific analyses, PCSK9i use was associated with lower hazards of liver metastasis (HR 0.64, 95% CI 0.50–0.85) and lung metastasis (HR 0.78, 95% CI 0.65–0.94); hazards for lymph node, brain, adrenal, and bone metastases were similar between groups. Sensitivity analyses accounting for competing risk of death showed consistent directionality. **Conclusions:** In this nationwide cohort study, overall metastatic risk was similar between PCSK9i and statin-only users, but PCSK9i use was associated with lower hazards of liver and lung metastases. Further mechanistic and prospective investigation are warranted to elucidate the role of PCSK9 inhibition in tumor progression and metastasis. Research Sponsor: None.

The effects of the COVID-19 pandemic on cancer incidence and cancer-specific mortality. First Author: Reba Dhillon, Trinity Health Ann Arbor, Ypsilanti, MI

Background: The 2020 COVID-19 pandemic had a significant impact on cancer screening rates and cancer-related outcomes. The purpose of our study was to determine how the pandemic has affected cancer incidence, incidence by Surveillance, Epidemiology and End Results (SEER) stage, and cancer-specific mortality for the most common cancers in incidence and cancer-specific mortality. **Methods:** The data for our population-based cohort study was accessed by permission from the SEER dataset. We aggregated data for incidence and cancer-specific mortality regarding the leading ten cancers in incidence and cancer-specific mortality, plus cervical cancer, between January 1, 2017 and December 31, 2022 and further divided this time period into two 36-month pre-pandemic and post-pandemic groups. Demographic variables were collected for stratified analyses. Poisson regression models were used to estimate incidence and mortality rates for each cancer type, incorporating the natural logarithm of the total population as an offset term to account for differences in population size. **Results:** Nine of eleven cancers showed significantly higher IRRs (incidence rate ratios) for distant SEER stages during the 36-month post-pandemic period. Most importantly, several cancers with established screening modalities had significantly increased IRRs for distant SEER stage of disease including prostate cancer (IRR 1.175, 95% CI: 1.155-1.195, $p<0.001$), breast cancer (IRR 1.060, 95% CI: 1.040-1.080, $p<0.001$), and colorectal cancer (IRR 1.034, 95% CI: 1.020-1.048, $p<0.001$). Cancer-specific mortality showed significantly increased post-pandemic mortality rate ratios (MRRs) for pancreatic cancer (MRR 1.049, 95% CI: 1.041-1.056, $p<0.001$), prostate cancer (MRR 1.042, 95% CI: 1.032-1.051, $p<0.001$), and liver cancer (MRR 1.026, 95% CI: 1.016-1.036, $p<0.001$). Lung cancer (MRR 0.931, 95% CI: 0.927-0.935, $p<0.001$), Non-Hodgkin's Lymphoma (MRR 0.972, 95% CI: 0.961-0.983, $p<0.001$) and breast cancer (MRR 0.989, 95% CI: 0.981-0.996, p=0.004) all had significantly lower cancer-specific mortality in our post-pandemic period. **Conclusions:** In this large population-based cohort, we observed a shift towards more distant SEER stage cancer diagnoses in the post–pandemic period. The increase in advanced-stage diseases reflects a higher burden of disease and is particularly concerning for cancers with proven screening benefit. These findings suggest persistent downstream effects of disruptions in routine healthcare and cancer screening which have added to the public health crisis of the COVID-19 pandemic. Association of SGLT2 inhibitors and GLP-1 receptor agonists or DPP-4 inhibitors with incident cancer in patients with type 2 diabetes. First Author: Nikitha Vobugari, University of Minnesota, Minneapolis, MN

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) exert potential anti-tumor effects. Emerging data suggest SGLT2i are associated with reduced cancer incidence in type 2 diabetes (T2D), while incretin-based therapies show mixed results varying by cancer type. Among patients with T2D, we tested that hypothesis that use of SGLT2i, as compared to GLP-1 receptor agonists (GLP-1RA), and dipeptidyl peptidase-4 inhibitors (DPP-4i), would be associated with lower risk of overall and individual cancer types. **Methods:** Matched cohort study using MarketScan US claims database (2016–2022). T2D patients with $\geq$1 metformin prescription and $>$90 days enrollment before 2nd line therapy initiation were included. SGLT2i users were matched with up to 5 users of other therapies by age, sex, enrollment, and 2nd line therapy initiation dates. ICD codes were used to identify cancer. Cox models adjusted for demographics, comorbidities, and medications. **Results:** Among 365,494 matched patients (mean$\pm$SD age 54.2$\pm$10.0 years, 48.5% female), 5,422 incident cancers occurred over median 1.43 (maximum 6.75) years follow-up. Cohort included 133,210 SGLT2i users (empagliflozin 55%, dapagliflozin 32%, canagliflozin 12%) and 232,284 comparators (GLP-1RA 60.4%, DPP-4i 39.6%). SGLT2i users showed modestly lower composite cancer risk versus other therapy users [Hazard ratio (HR) 0.94, 95% CI 0.89-0.99]. Compared with DPP-4i use, SGLT2i use demonstrated 10% lower cancer risk (HR 0.90, 95% CI 0.85-0.97), but showed no significant difference versus GLP-1RA use (HR 0.97, 95% CI 0.91-1.04). Analyses by cancer type revealed no significant differences in HR for breast (0.92, 0.84-1.04), prostate (0.96, 0.84-1.08), colorectal (0.96, 0.82-1.12), lung (0.95, 0.78-1.16), pancreatic (1.04, 0.84-1.28), hepatocellular (1.01, 0.76-1.33), renal cell (0.92, 0.76-1.11), endometrial (1.01, 0.79-1.29), or thyroid cancers (0.84, 0.66-1.06). Cancer risk was comparable across individual SGLT2i($p>0.05$). **Conclusions:** SGLT2i demonstrated a 10% reduction in overall cancer risk versus DPP-4i and comparable efficacy to GLP-1RA, reinforcing SGLT2i's potential oncologic benefits. No associations were observed with individual cancer types, though interpretation is nuanced due to poor precision and short follow-up. Comparable risk among individual SGLT2i suggest a class-wide effect. Future prospective studies with extended follow up are needed to validate these associations and clarify whether SGLT2i offer meaningful cancer risk reduction beyond their established cardiometabolic benefits. Research Sponsor: None.

Hazard ratios (95% CI) for incident cancer, Marketscan databases, 2016-2022.

	N (events / total)	HR (95% CI)
SGLT2i vs. DPP-4i		
SGLT2i	1,559 / 93,494	0.90 (0.85 - 0.97)

Predictors of EGFR-mutant primary lung adenocarcinoma. First Author: Lauren Kriger Groner, University of Miami, Miami, FL

Background: The proportion of lung cancer cases in individuals who have never smoked (INS) is increasing. Most of these cases are adenocarcinoma (AC) harboring Epidermal Growth Factor Receptor (EGFR) mutations. As predictors of AC and mutational status (EGFR positive [EGFRp] vs EGFR negative [EGFRn]) are incompletely elucidated, we sought to identify demographic, clinical, and imaging predictors of EGFRp AC. **Methods:** Data were obtained from Weill Cornell's Lung Cancer Database, integrating EGFR mutation status derived from genomic testing, validated natural language processing of unstructured clinical data, and individual and area-level predictors from a large New York City health system. We included patients with early stage, surgically resected primary lung AC, allowing for uniform, robust pathologic and genomic characterization. Lesions were identified on computed tomography (CT) prior to diagnosis The primary outcome was EGFR positivity. LASSO-penalized logistic regression with 10-fold cross-validation was used to identify key predictors in high-dimensional, correlated data. Model performance was evaluated using cross-validated AUC and classification accuracy. **Results:** Among 1145 adults with primary lung AC (312 subsolid nodules [SSNs] and 833 solid nodules; mean age 69.9 [SD, 9.6]), 58.1% were female and 75.4% had a history of smoking. EGFRp ACs (vs EGFRn) were more likely to present as SSNs (39.3% vs 21.7%, $p<0.001$) and occur in women (63.6% vs 55.7%, p=0.013), Asian patients (32.7% vs 8.4%, $p<0.001$), and INS (44.9% vs 15.3%, $p<0.001$). Those with EGFRp AC were less likely to meet USPSTF lung cancer screening (LCS) criteria (12.5% vs 36.0%, $p<0.001$) and had lower prevalence of chronic obstructive pulmonary disease, other pulmonary disease, and weight loss at presentation; $p<0.05$. LASSO-selected predictors of EGFR positivity included SSN density and >1 SSN on CT, former smoking status, family history of LC, and higher exposure to ambient air pollutants (PM2.5, NO2, O3). The model demonstrated good discrimination (AUC 0.77, 0.77-0.78). In the SSN subgroup, new LASSO-selected features positively associated with EGFR positivity included right middle lobe location and lobulated margins on CT and SO2 exposure. Cystic morphology, reticulation, and a new or growing solid component on CT were inversely associated with EGFR positivity. **Conclusions:** In a robust genomically linked and clinically, radiologically, and environmentally enriched dataset, we identified distinct demographic characteristics (female sex, Asian race, family history of LC), CT features (SSN density, multiplicity, lobulated margins), and environmental exposures (PM2.5, NO2, O3, SO2) that may predict EGFR positivity. Moreover, three-fold fewer adults with EGFRp AC met USPSTF LCS criteria. These findings support integrating imaging and non-tobacco risk factors to inform lung AC risk stratification, genomic testing, and more inclusive screening strategies. Association of sociodemographic, environmental, and health factors with early-onset cancer in a diverse urban cohort. First Author: Devon Kathleen Dietrich, The University of Chicago Pritzker School of Medicine, Chicago, IL

Background: Early onset cancer (EOC; diagnosed before age 50) is rising globally, yet its drivers are incompletely understood, especially in diverse community-based populations. We examined sociodemographic, environmental, and health factors associated with EOC in the community-based Chicago Multiethnic Prevention And Surveillance Study (COMPASS) cohort spanning 72 Chicago neighborhoods. **Methods:** This nested case-control study within COMPASS matched EOC cases to controls without cancer 1:2 by age and sex. Standardized mean differences (SMD) compared sample characteristics. Conditional logistic regressions evaluated EOC associations with odds ratios (OR) and 95% confidence intervals (CI), adjusted for race/ethnicity. Meaningful imbalance was defined as $SMD>0.2$ and statistical significance as $p<0.05$. **Results:** Among 13,309 COMPASS participants, 265 EOC cases were matched to 530 controls. While the full sample was well balanced by sex (51.4% male), cases were predominantly female (72.8%) and non-Hispanic Black (72.3%). Breast (28.3%) and cervical (16.2%) cancers were most reported. A greater proportion of cases identified as unemployed/disabled but were also college educated and with incomes ≥$35,000 (SMD=0.382, 0.326, 0.267). Parental cancer history was more common in cases (SMD=0.504). No imbalances were observed in neighborhood-level characteristics, including area deprivation index, particulate matter concentration, and healthcare access strain. Cases reported more recent mammography and prostate-specific antigen screening (SMD 0.385, 0.407) but not pap smears (SMD=0.195). Cigarette use did not differ (SMD=0.141). Cases had higher prevalence of type 2 diabetes (T2D), anxiety, and depression (SMD=0.216, 0.302, 0.242), and lower prevalence of allergies (SMD=0.229). EOC was associated with parental cancer history (OR=3.62, CI 2.31-5.67, $p<0.001$), T2D (OR=1.65, CI 1.02-2.69, p=0.043), and anxiety (OR=2, CI 1.24-3.23, p=0.005), but not sociodemographic or neighborhood factors. **Conclusions:** In this diverse cohort, EOC was associated with multiple factors, including family cancer history, breast/prostate screening, and select health comorbidities. No associations were observed with reported neighborhood-level environmental metrics, current tobacco use, or cervical cancer screening. Our results highlight challenges in measuring sociodemographic and environmental contributors to EOC. Our results align with existing hypotheses on cancer development: familial risk, the potentially protective role of allergies, and T2D-related cancer risk. While causality cannot be inferred, the observed EOC-screening and EOC-anxiety associations warrant further investigation with longitudinal, multilevel research to better define EOC drivers and inform EOC prevention and detection strategies. Racial differences in clinical, genomic, and survival outcomes in colorectal cancer. First Author: Nour Maher Mustafa, University of Jordan, Amman, Jordan

Background: Racial differences influence colorectal cancer incidence, biology, and survival, but the clinical and genomic drivers remain unclear. This study evaluates race-based variation in clinical features, metastatic patterns, and key mutations in a large real-world cohort to improve risk stratification and promote equitable treatment. **Methods:** Clinical and genomic data were obtained from MSK-CHORD via cBioPortal, including patients identified as Asian, White, or Black. Variables were analysed in RStudio. Group differences were assessed using chi-square, Fisher's exact tests, or Kruskal–Wallis. Survival was analysed with Kaplan–Meier and Cox models. Significance was set at $p < 0.05$. **Results:** Among 5,168 colorectal cancer patients (White 83.9%, Asian 8.8%, Black 7.4%), several clinical and genomic features varied. Age differed significantly ($p < 0.001$), with Asians and Blacks diagnosed younger (median 58 y vs. 61 y) than Whites. Gender distribution was similar (p = 0.303). MSI-instability varied (p = 0.0321), lowest in Asians (7.7%) and Blacks (8.3%), and highest in Whites (11.9%). Right-sided tumours differed ($p < 0.001$), being least common in Asians (23.7%) and most common in Blacks (40.8%). Stage at diagnosis was similar (p = 0.0961). TMB differed modestly (p = 0.042): 5.87 in Asians vs. 6.05 in Black and White patients. FGA showed similarly small variation (p = 0.046): 0.17 in Asians, 0.16 in Blacks, and 0.15 in Whites. Liver metastases varied by race ($p < 0.001$): Asians 52%, Blacks 66%, Whites 56%. Reproductive organ involvement differed (p = 0.012): Asians 25%, Blacks 27%, Whites 20%; all other metastatic sites showed no differences ($p > 0.05$). Overall survival varied significantly ($p < 0.001$), highest in Asians (71.6 months) and Whites (54.3 months) and lowest in Blacks (32.3 months); Asians had similar mortality risk to Whites (HR 0.94), whereas Blacks had higher risk (HR 1.44). Genomic variation was notable: KRAS ($p = 1.6\times10^{-7}$) was highest in Blacks (56.8%), TP53 ($p < 0.001$) was highest in Asians (81.5%), and BRAF (p = 0.0046) was lowest in Blacks (7.1%), with no other genes differing. **Conclusions:** Racial differences were evident across outcomes. Black patients had the highest KRAS mutations and worst survival; Asians had the highest TP53 rates and best survival; Whites had the most MSI-H tumours. Other clinical features were similar. These patterns suggest biologic differences relevant to risk and treatment. Research Sponsor: None.

Progestin-only implant and breast cancer risk in adolescents and premenopausal women: A systematic review and meta-analysis. First Author: Angela Theresa Zuffo Yabrude, Universidade Regional de Blumenau, Blumenau, Santa Catarina, Brazil

Background: Progestin-only long-acting reversible contraception via subdermal etonogestrel implants (Implanon/Nexplanon) is widely used. However, the breast cancer (BC) risk signal potentially attributable to implant exposure remains under-characterized, limiting evidence-based, shared contraceptive counseling. **Methods:** We systematically searched PubMed/MEDLINE, Embase, and the Cochrane Library and screened reference lists for observational cohort and case-control studies comparing etonogestrel/progestin-only implant exposure versus non-use in adolescents and reproductive-aged/premenopausal women (as defined by each study) without prior BC. Studies restricted to hereditary breast cancer predisposition cohorts (BRCA1/2 pathogenic variant carriers) were excluded. The primary endpoint was incident BC (invasive with/without in situ). Maximally adjusted estimates were extracted and harmonized to odds ratios (ORs). Risk of bias was assessed using ROBINS-E. Pooled estimates were generated using inverse-variance random-effects meta-analysis. Heterogeneity was quantified with I2 and Tau2. **Results:** Five studies met inclusion criteria, including three nationwide cohort studies from Denmark/Sweden and two nested case–control studies from the UK and Australia. Across cohort studies, implant exposure contributed 1,659,309 person-years of follow-up with 510 incident BC events. The largest case-control dataset included 67,470 BC cases. Study-specific adjusted ORs ranged from 0.93 to 1.24. In pooled analysis, implant exposure was associated with an increased risk of incident BC (OR 1.23. 95% CI 1.19–1.27, $P < 0.0001$), with no between-study heterogeneity (I2 = 0%, Tau2 = 0). **Conclusions:** In large, contemporary population-based observational studies excluding hereditary breast cancer predisposition cohorts, use of etonogestrel/progestin-only subdermal implants is consistently associated with a modestly increased risk of incident breast cancer (~23%) compared with non-use. While the absolute risk increase is likely small in younger women, the consistent signal across study designs supports its relevance for individualized risk–benefit discussions and shared contraceptive counseling in routine clinical practice. Research Sponsor: None.

Endocrine therapy non-adherence and recurrence risk in patients with breast cancer and major depressive disorder. First Author: Maya Aboumrad, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: We evaluated whether non-adherence to oral endocrine therapy explains the increased hazard of recurrence among women with major depressive disorder (MDD) and estrogen receptor-positive breast cancer. **Methods:** We established a retrospective cohort of veteran women (age ≥18 years), with and without MDD, diagnosed with early-stage invasive estrogen receptor-positive breast cancer between 2010-2019 within the United States Veterans Affairs Healthcare System with follow-up through 2022. We assessed adherence to oral endocrine therapy among continuous users (no treatment gaps ≥ 6 months) over two-years (N = 2,722) and five-years (N = 1,666). Adherence was measured using the proportion of medication days covered and evaluated across thresholds from ≥20%-100%. We used multivariable competing-risks regression to estimate hazard ratios (HR) and 95% confidence intervals (CI) for the statistical interaction between MDD and endocrine therapy adherence on breast cancer recurrence, adjusting for sociodemographic, clinical, and prognostic factors. **Results:** The hazard of breast cancer recurrence significantly differed between adherent and non-adherent women with MDD beginning at adherence thresholds of ≥60% over two-years and ≥40% over five-years. At these minimal adherence thresholds, breast cancer recurrence was higher for women with MDD who were non-adherent to endocrine therapy over two-years (HR = 1.65; 95% CI = 1.02-2.62) and five-years (HR = 2.10; 95% CI = 1.16-3.79) compared with adherent women without MDD. In contrast, women with MDD who remained adherent over two-years (HR = 1.21; 95% CI = 0.91-1.64) and five-years (HR = 1.38; 95% CI = 0.85-2.22) had hazards of breast cancer recurrence comparable to those of adherent women without MDD. **Conclusions:** Our findings identify endocrine therapy adherence as a potentially modifiable clinical factor to reduce breast cancer recurrence among women with MDD and estrogen receptor-positive disease. Research Sponsor: Department of Medical Affairs; National Cancer Institute; The Breast Cancer Research Foundation.

Hair relaxer use and breast cancer risk by tumor molecular subtypes. First Author: Kaitlin White, National Cancer Institute, National Institutes of Health, Rockville, MD

Background: Women of West African ancestry, including US populations, are disproportionately diagnosed with aggressive breast cancers including triple negative tumors. Previously, hair relaxer use has been associated with increased breast cancer risk in the Ghana Breast Health study (GBHS), with former users at an over 2-fold increased risk compared to never users. We aimed to determine if relaxer use risk associations differed by tumor molecular subtypes suggesting possible biological mechanisms of carcinogenesis. **Methods:** The GBHS is a population-based case-control study conducted 2013–2015 in Accra and Kumasi, with 1,071 pathologically confirmed invasive breast cancer cases (87% had available estrogen receptor (ER) status) and 2,106 matched controls, aged 18-74 years. Molecular subtypes were defined using St Gallen's criteria using molecular marker data for ER, progesterone receptor, human epidermal growth factor receptor-2 (HER2), and grade (G). Molecular tumor subtypes defined as: Lum A (ER/PR+, HER2- and G1/G2, N = 260), Lum B- (ER/PR+, HER2- and G3, N = 468), Lum B+ (ER/PR+, HER2+ and G1/G2, N = 195), HER2-Enriched (ER-, PR- and HER2+, N = 59), Triple-Negative (ER, PR, and HER2-, N = 129). We imputed missing data using chained equations. Polytomous logistic regression models were used to estimate odds ratios (ORs) with 95% confidence intervals (CIs) for associations of relaxer use with breast cancer subtypes. Models were adjusted for matching factors (age, hospital site), and potential confounders: education, parity, age at first birth, and median breastfeeding months per child. Results were combined across imputed datasets. Heterogeneity (p-het) in breast cancer risk by tumor molecular subtypes using polytomous logistic regression case-only models. **Results:** Relaxer use was common (ever-use of relaxers 96% of cases and 94% of controls). Compared to never users, increased risk for former users compared to never users was observed across subtypes. While magnitudes of risk differed (OR_{LumA}= 2.59, 95% CI [1.01—6.60], OR_{LumB+}= 2.69, 95% CI [0.47—15.47], OR_{LumB-}= 1.74, 95% CI [0.33—6.93], $OR_{HER2\text{-}Enriched}$= 3.66, 95% CI [0.75—17.98], $OR_{Triple\text{-}Negative}$= 1.21, 95% CI [0.37—4.00]), there was no statistical evidence of etiologic heterogeneity by subtype (p-het = 0.59). Similarly, other measures of relaxer use (duration, age at first use, lye or non-lye) did not show any evidence of heterogeneity. **Conclusions:** In this population with a high proportion of aggressive tumor subtypes, breast cancer risk associated with relaxer use did not support etiologic heterogeneity by molecular subtype, however, power was limited. These findings suggest that relaxer exposure is unlikely to explain subtype-specific breast cancer risk patterns. Future investigations should pool studies for improved power, evaluate other molecular tumor characteristics and relaxer products' formulations to clarify carcinogenic mechanisms to reduce risk. Prevalence of oral and genital HPV-45 and non–vaccine-targeted HPV-35 among U.S. adults. First Author: Morgan C. Byrd, Duke University School of Medicine, Durham, NC

Background: High-risk human papillomavirus (HPV) types 35 and 45 are oncogenic non-16/18 subtypes that contribute measurably to HPV-attributable genital and oropharyngeal cancers. Unlike HPV-45, HPV-35 is not targeted by the current 9-valent vaccine. Although high prevalence of these subtypes has been reported in some global sub-populations, data on their prevalence and distribution in the U.S. adult population remains limited. **Methods:** We conducted a cross-sectional analysis of adults aged 18-64 years from the National Health and Nutrition Examination Survey (NHANES) cycles 2013-2016. HPV was detected via self-collected oral rinse specimens, vaginal swabs, and penile swabs. HPV vaccination history and sexual behaviors were self-reported. We estimated survey-weighted type-specific HPV prevalence and used survey-weighted Poisson regression to calculate adjusted prevalence ratios (aPRs), accounting for age, sex, race/ethnicity, vaccination status, and number of lifetime sexual partners. **Results:** Oral HPV prevalence was low overall, with HPV-16 remaining the most frequently detected type (0.87%). Genital HPV showed a broader distribution of oncogenic types. Among men, penile HPV-35 (1.93%, 95% CI 1.27-2.60%) and HPV-45 (1.94%, 95% CI 1.37-2.50%) were less prevalent than HPV-16 (3.97%, 95% CI 3.13-4.80%) and slightly more prevalent than HPV-18 (1.71%, 95% CI 1.20-2.22%), though confidence intervals overlapped. Among women, vaginal HPV-35 (1.40%, 95% CI 0.95-1.85%) and HPV-45 (1.71%, 95% CI 1.21-2.21%) were also less common than HPV-16 (2.95%, 95% CI 2.14-3.77%) and comparable to HPV-18 (1.26%, 95% CI 0.88-1.65%), again with overlapping confidence intervals. While there were extremely low rates of dual oral-genital infections, males exhibited slightly higher, though non-significant, dual infection prevalences for HPV-35 (0.03% vs. 0%), HPV-45 (0.21% vs 0.07%), and HPV-16 (0.17% vs. 0.11%) compared to females. Non-Hispanic Black participants had a significantly higher genital prevalence of both HPV-35 (aPR 2.75, 95% CI 1.71-4.42) and HPV-45 (aPR 2.08, 95% CI 1.13-3.85) compared with Non-Hispanic White participants. Prevalence was higher among males than females for both types, although these differences did not reach statistical significance. **Conclusions:** In this nationally representative sample of U.S. adults, we found that HPV-35, a high-risk type not included in the current 9-valent vaccine, showed genital prevalence comparable to vaccine-covered types and marked racial disparities. These findings highlight the importance of continued HPV surveillance and targeted prevention strategies. Additionally, future studies should investigate these subtypes in HPV-associated malignancies. Research Sponsor: None.

Genome-wide association and Mendelian randomization analyses of body mass index and breast cancer risk in women of African ancestry. First Author: Wenji Guo, Section of Hematology & Oncology, Department of Medicine, The University of Chicago, Chicago, IL

Background: The relationship between adiposity and breast cancer risk is complex and incompletely understood, particularly among women of African ancestry. We investigated the association between genetically predicted and excess body mass index (BMI) and breast cancer risk in the African Ancestry Breast Cancer Genetic Consortium (AABCG) using complementary genetic and epidemiologic approaches. **Methods:** We conducted a genome-wide association study (GWAS) of BMI in AABCG. Independent BMI-associated variants were then used as instrumental variables in one-sample Mendelian randomization (MR) analyses, using two-stage residual inclusion with logistic regression to estimate the causal effect of BMI on breast cancer risk. To explore the joint influence of genetic and non-genetic contributions to BMI, we constructed a BMI polygenic risk score and defined the BMI polygenic-measured gap (BMI-PGM) as the difference between the percentile of observed BMI and the percentile of genetically predicted BMI. BMI-PGM was categorized into three groups based on quartile distribution: discordantly low (≤25^{th} percentile), concordant (25^{th}-75^{th} percentile), and discordantly high (≥75^{th} percentile). The association between BMI-PGM and breast cancer risk was evaluated. **Results:** We identified thirteen loci that were associated with BMI at the genome-wide significance level. Of these, seven loci had not been reported in prior GWAS of BMI. In the MR analyses (n = 31,522), genetically predicted BMI was inversely associated with overall breast cancer risk: odds ratio (OR) = 0.92 per 5 kg/m^2 increase, 95% confidence interval (CI) 0.86-0.99, p = 0.028. In stratified analyses, there was a stronger inverse relationship observed for estrogen receptor (ER) negative compared with ER positive breast cancer. Inverse associations with similar effect sizes were observed in analyses stratified by menopausal status. Compared with women whose observed BMI was discordantly low relative to their genetically predicted BMI, those with concordant BMI had a modestly increased risk of breast cancer (OR = 1.08, 95% CI 1.02-1.14, p = 0.0074), while women with discordantly high BMI had a 12% higher risk of breast cancer (OR = 1.12, 95% CI 1.05-1.19, p = 0.00049). **Conclusions:** Genetically predicted higher BMI was associated with lower breast cancer risk, whereas BMI in excess of genetic predisposition was associated with increased risk. These opposing associations highlight a distinction between genetically mediated body size versus excess weight that likely reflects adverse metabolic processes. Together, these results underscore the roles of both genetic susceptibility and modifiable influences on adiposity in breast cancer etiology and highlight the importance of maintaining a healthy weight to reduce breast cancer risk, despite variability in genetic predisposition to adiposity across the population. Genetic correlation and causal associations between metabolic traits and lung cancer risk. First Author: Knightess Oyibo, University of Maryland School of Medicine, Baltimore, MD

Background: Lung cancer is the leading cause of cancer-related mortality worldwide. We evaluated whether associations between metabolic traits and lung cancer risk reflect shared genetic susceptibility or causal effects of metabolic dysregulation. **Methods:** GWAS summary statistics from European-ancestry participants were obtained for lung cancer (TRICL–ILCCO; n = 29,266 cases, 56,450 controls), body mass index (BMI; GIANT; n = 681,275), blood lipids, triglycerides (TG), high-density lipoprotein cholesterol (HDL), and low-density lipoprotein cholesterol (LDL), from the Global Lipids Genetics Consortium (GLGC; n = 1,320,016), and type 2 diabetes (T2D; T2DGGI; n = 242,283 cases, 1,569,734, controls). Genome-wide genetic correlations were estimated using LD score regression. Two-sample Mendelian randomization analyses were conducted with lung cancer as the outcome using inverse-variance weighted models, with weighted median, MR-Egger, and weighted mode sensitivity analyses. Heterogeneity and pleiotropy were assessed using Cochran's Q, MR-Egger intercept, and MR-PRESSO. **Results:** Lung cancer demonstrated significant positive genetic correlations (r_g) with BMI (r_g= 0.16, P = 1.0×10^{-4}), TG (r_g = 0.14, P = 3.0×10^{-4}), and T2D (r_g = 0.09, P = 0.017), and a significant inverse correlation with HDL ($r_g = -0.14$, P = 2.4×10^{-5}). No significant genetic correlation was observed for LDL. In MR analyses, genetically predicted BMI was associated with increased lung cancer risk (475 SNPs; IVW β = 0.23, SE = 0.05, P = 2.0×10^{-6}; OR = 1.26, 95% CI 1.14–1.38), and remained statistically significant after outlier correction (β = 0.21, P = 7.2×10^{-6}), with no evidence of distortion. In contrast, no supporting evidence of causal associations between lung cancer risk and genetically predicted HDL, TG, LDL, or T2D liability across primary and sensitivity estimators (all $P > 0.05$). Cochran's Q tests indicated heterogeneity across genetic instruments; however, MR-Egger intercept tests did not provide evidence of directional horizontal pleiotropy. **Conclusions:** These findings suggest that metabolic health, particularly obesity, may play a clinically meaningful role in lung cancer risk assessment. Considering obesity alongside established smoking-related determinants may enhance lung cancer prevention efforts. Lung cancer incidence and $PM_{2.5}$: Evaluating the association with varying spatial scales and durations of exposure estimates. First Author: George Carey, VA Connecticut Healthcare System, West Haven, CT

Background: Particulate matter with a diameter of 2.5 μm or less ($PM_{2.5}$) is classified as an IARC group 1 carcinogen based on decades of research. However, little is known about how the association between $PM_{2.5}$ and lung cancer incidence is impacted by varying spatial and temporal methods of estimating exposure. **Methods:** We performed a nested case-control analysis using the Department of Veterans Affairs (VA) Clinical Data Warehouse. Patients were eligible for inclusion if they had a recorded date of birth, smoking data, and quarterly location data for 40 or more quarters between 2009 and 2021. Cases were required to have at least 10 years of location data prior to diagnosis; diagnoses and diagnosis dates were identified using the VA Central Cancer Registry. Controls were matched in a 4:1 ratio on age (by birth quarter), smoking status (self-reported, defined as "Smoker" vs. "Never Smoker"), and the specific calendar quarters contributing to the $PM_{2.5}$ average. Modeled daily $PM_{2.5}$ estimates at a spatial resolution of 1 km^2 for the entire contiguous United States (US) were aggregated to quarterly estimates at three US Census geography levels (block group, census tract, and county). After case-control matching, we evaluated the impact of different spatial and temporal measures of $PM_{2.5}$ exposure on the association between $PM_{2.5}$ and lung cancer incidence. Specifically, we evaluated estimates at the block group, census tract, and county level with both 5-year and 10-year averages. Associations were evaluated using conditional logistic regression; model fit was assessed using the Akaike Information Criterion (AIC). **Results:** Approximately 4.7 million veterans met our inclusion criteria. Of these, 8451 veterans developed incident lung cancer at least 10 years after the observation period began; 33,150 matched controls were selected. All models showed a statistically significant increase in the risk of lung cancer with increasing $PM_{2.5}$ exposure, with odds ratios (ORs) ranging from 1.06 (95% CI 1.04-1.09) to 1.13 (95% CI 1.10-1.17) and p-values < 0.001 for all models. In both the 5-year and 10-year analyses, models with larger spatial units (county > census tract > block group) had higher ORs and superior model fit by AIC. All models with 10-year averages had higher ORs and lower AIC values compared to models with 5-year averages. **Conclusions:** Our findings add to the considerable body of research that demonstrates an epidemiologic association between $PM_{2.5}$ and lung cancer incidence. Furthermore, our results demonstrate that this association is robust to various methods of estimating patient $PM_{2.5}$ exposure. Finally, these data suggest that using county-level $PM_{2.5}$ estimates and an estimate duration of at least 10 years may be preferable to finer spatial scales and shorter estimate durations in future studies. Quantifying equol-producing and beta-glucuronidating gut bacteria in breast cancer using 16S rDNA sequencing methods. First Author: Kathryn Zamiela, University of Illinois Chicago, Chicago, IL

Background: Gut bacteria with hormone-modulating potential may influence breast cancer (BC) risk: Equol-producing bacteria convert dietary isoflavones into equol, a phytoestrogen that binds estrogen receptors, while beta-glucosidating bacteria affect glycosides of dietary phytoestrogens, and beta-glucuronidating bacteria regulate the deconjugation and reabsorption of endogenous estrogens. We aimed to investigate whether gut bacterial species that have the potential to affect phytoestrogens or endogenous estrogens can be detected using 16S rDNA sequencing methods, and to what extent this detection may be influenced by the choice of 16S hypervariable region targeted for sequencing. **Methods:** DNA extracted from stool samples of women with BC (n = 112) and healthy controls (n = 171) was subjected to PCR amplification and high-throughput sequencing of the V1-V3 and V3-V4 16S rRNA hypervariable regions, commonly used regions in microbiome research. Data was processed using QIIME, and taxonomy assignment was performed with the SILVA database to the species level. Relative abundance and detection of taxa in cases vs controls were evaluated using Wilcoxon and McNemar's tests in R. Taxa were classified as equol-producing based on Setchell and Clerici (2010) or beta-glucuronidating and beta-glucosidating based on Dabek et al (2008). **Results:** The relative abundance of equol-producing bacteria was significantly higher in the BC group vs controls in the V1–V3 (p = 0.0007); V3–V4 (p = 0.0089) regions, and when both regions were summed (p = 0.0011). Adlercreutzia equolifaciens was detected 29.6% more often in a presence/absence analysis of the V1-V3 region (V1-V3 presence: 93.0%, V3-V4 presence: 63.4%, $p < 0.001$), while Finegoldia magna was detected 21.1% more often in the V3-V4 region (V1-V3 presence: 18.0%, V3-V4 presence: 39.1%, $p < 0.001$). The relative abundance of beta-glucuronidating and beta-glucosidating bacteria was significantly higher in the BC group vs controls in the V1-V3 region (p = 0.0094) and when both regions were summed (p = 0.0254), and approached significance in the V3-V4 region (p = 0.0534) . Presence of Bifidobacterium adolescentis was detected 21.8% more often in the V1-V3 region (V1-V3 presence: 21.8%, V3-V4 presence: 0.00%, $p < 0.001$), and Roseburia inulinivorans was detected 21.1% more often in the V3-V4 region (V1-V3 presence: 63.0%, V3-V4 presence: 83.1%, $p < 0.001$). **Conclusions:** Equol-producing and beta-glucuronidating and beta-glucosidating bacteria appear enriched at the species-level analysis in BC subjects, but detection of specific organisms is sensitive to the 16S region sequenced. Accurate identification of hormone-modulating taxa requires both the V1-V3 and V3-V4 regions, as either alone is insufficient to capture the full range of taxa. Additional analyses with absolute quantification such as qPCR are needed to validate the results. Research Sponsor: University of Illinois Chicago; U.S. National Institutes of Health.

Early lessons from the implementation of a pan-African clinico-genomic cancer platform: The African Cancer Atlas. First Author: Emmanuella Amoako, Yemaachi Biotech, Accra, Ghana

Background: Limited representation of African populations in cancer genomics constrains the clinical applicability of precision oncology. We describe the establishment and early outcomes of The African Cancer Atlas (TACA), a multi-site platform integrating genomics, harmonized clinical data, and community engagement for adult breast cancer research across Africa. **Methods:** TACA, led by Yemaachi Biotech, has so far been implemented across five countries (Ghana, Nigeria, Côte d'Ivoire, Kenya, and Seychelles). In early 2025, foundational activities included institutional review board (IRB) approvals, execution of memoranda of understanding and material transfer agreements, site activation, and structured engagement with clinicians, patient advocates, and community stakeholders through Yemaachi's African Cancer Network to support trust-building and study uptake. Participant recruitment began in July 2025. Breast cancer patients were enrolled following IRB approval, with informed consent supported by site-based education on genomics research. Clinical data were captured in UVOSYO-Yemaachi's clinical database. Peripheral blood was collected at recruitment, and formalin-fixed paraffin-embedded (FFPE) tumor tissue was obtained subsequently and shipped to our central laboratory in Accra. Blood and tissue underwent DNA extraction and quantitative and qualitative quality control (QC) prior to sequencing. **Results:** To date, 236 participants have been recruited across the five TACA sites. Blood-derived DNA demonstrated acceptable quality for downstream sequencing, whereas FFPE tumor tissue quality varied substantially, leading to exclusion of cases that failed QC. Among enrolled participants, 97.9% were female, with a mean age of 50.8 years (SD 13.1). A total of 26.7% reported a family history of cancer, with participants in Seychelles having the most significant family history of 87% ($p < 0.001$) Triple-negative breast cancer accounted for 38.1% of tumors overall, ranging from 21.1% in Kenya to 68.1% in Nigeria. Significant between-country variation was observed for triple-negative breast cancer ($p < 0.001$) and hormone receptor status (all $p < 0.001$). Key implementation challenges included prolonged IRB approval timelines related to limited familiarity with cancer genomics, cross-border biospecimen transport constraints necessitating in-country DNA extraction in some settings, and variability in FFPE tissue quality impacting sequencing yield. **Conclusions:** TACA demonstrates the feasibility of coordinated multi-country recruitment and clinical data harmonization for adult cancer genomics in Africa, while highlighting critical regulatory, logistical, and biospecimen quality barriers. Variants of uncertain significance and contralateral risk-reducing mastectomy in early-stage breast cancer across safety-net and private hospital settings. First Author: Vineeth Reddy Kommidi, Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX

Background: Germline genetic testing informs surgical decisions in early-stage breast cancer. Guidelines recommend considering contralateral risk-reducing mastectomy (RRM) for patients with pathogenic or likely pathogenic variants in high-risk genes, but not for those with variants of uncertain significance (VUS). Despite this, VUS results may still affect surgical decisions. This study examines the impact of VUS on surgical decision-making across two university-affiliated settings: a safety-net hospital and a private hospital. **Methods:** We retrospectively reviewed patients with early-stage invasive breast cancer treated between 2012 and 2022 who underwent germline testing before surgery at both a safety-net and a private hospital. Patients with VUS were compared with genetically negative controls. Logistic regression was used to identify factors associated with RRM. **Results:** The cohort included 86 safety-net VUS patients, 115 safety-net controls, 102 private VUS patients, and 97 private controls. Table 1 highlights demographic differences between the hospitals. RRM was performed in 28 safety-net VUS patients (32.6%), 20 safety-net controls (17.4%), 37 private VUS patients (36.3%), and 45 private controls (46.4%). Stepwise regression analysis of the full cohort showed that treatment at the private hospital was independently associated with higher rates of RRM compared with the safety-net hospital, regardless of VUS status (OR 4.52, 95% CI 2.10 - 9.75, $p < 0.001$). Additional factors associated with higher RRM rates included higher tumor stage, higher tumor grade, and younger age at diagnosis. In hospital-specific analyses, VUS status did not influence RRM decisions at the private hospital. However, at the safety-net hospital, patients with VUS were more likely to undergo RRM than those with negative genetic testing (OR 2.38, 95% CI 1.09 - 5.21, p = 0.031). **Conclusions:** Surgical decision-making for RRM is influenced by multiple clinical and institutional factors. While VUS status did not affect surgical decisions at the private hospital, it was associated with increased RRM rates at the safety-net hospital. This finding suggests that differences in counseling practices and patient perceptions of genetic risk may exist within the safety-net setting, where patients may face more uncertainty about access to future care. Further studies are needed to better characterize these disparities and promote guideline-concordant care. Research Sponsor: None.

A pilot study of a digital, patient-directed consent process for MSK-IMPACT tumor-normal genetic testing in gynecologic cancer. First Author: Varshini Gali, NewYork-Presbyterian Weill Cornell, New York, NY

Background: Although germline and somatic genetic testing is increasingly recommended for many cancers including gynecologic cancers, uptake remains low. Barriers include consenting processes that are time consuming for patients and providers. We sought to test uptake and acceptability of a digital, self-directed genetic testing consent process. **Methods:** We developed a digital, self-guided consenting process for MSK-IMPACT tumor-normal targeted sequencing called "read and sign" (R&S) that included an educational video and information about genetic testing along with a direct digital consent. We performed a pilot study in gynecologic surgery (GYNS) and medical oncology (GMO) clinics to evaluate the uptake of genetic testing and other metrics including time to consent, clinic time saved, and patient satisfaction. Briefly, adults with gynecologic cancers eligible for MSK-IMPACT were sent R&S consent via electronic health record. Research staff followed up with patients at 2, 7, and 14 days. If patients did not consent after 14 days, the clinical team was notified to follow-up. This study was approved under IRBs 12-245 and X25-012. **Results:** Between 10/6/2025 and 12/31/2025, we identified 173 patients (122 GYNS and 51 GMO) eligible for MSK-IMPACT and offered them R&S consent. This represented 8% of total MSK-IMPACT consents across the institution during this time. Median age was 61 years. 106 (61%) patients identified as White, 27 (16%) as Asian, 17 (10%) as Black, and 24 (14%) as Hispanic. Most common cancer types were endometrial (n=75, 43%) and ovarian (n=39, 23%). In GYNS, 102/122 (84%) patients consented with R&S, and 59 (58%) consented on the same day the R&S consent was sent. On average, 8 minutes of in-person clinic time per patient was saved using R&S, but 35 (29%) patients had 0 time saved, and 7 (7%) consents were later completed in-person after initial incomplete R&S attempt. One patient who completed the R&S consent later withdrew consent. In GMO, 50/51 (98%) patients consented via R&S, with 38 (76%) consented on the same day. On average, 14 minutes of clinic time per patient was saved, and 4 (8%) patients ultimately required in-person consent. Average time to consent was 3.3 days in GYNS and 1.7 days in GMO. Among 11 patients who completed surveys, 10 (91%) were very/somewhat satisfied with R&S. More in-depth surveys and semi-structured interviews with a subset of patients and staff are ongoing, and data will be forthcoming. **Conclusions:** A digital, self-guided consent for MSK-IMPACT genetic testing was feasible and acceptable with some differences in workflow between surgical and medical oncology clinics. The R&S consent process empowers patient decision-making and should be scaled to other cancer types. Research Sponsor: U.S. National Institutes of Health.

Germline testing in Asian American and Pacific Islander women with breast cancer. First Author: Jennifer Tseng, City of Hope Orange County, Irvine, CA

Background: Per the American Cancer Society, the overall breast cancer incidence rate rose 1% per year from 2012 to 2021, while it increased 2.7% per year for Asian American and Pacific Islander (AAPI) women. Cases increased by 50% for AAPI women under age 50, on par with White women. This study was conducted to examine rates and results of germline genetic testing in AAPI women with breast cancer. **Methods:** In this retrospective analysis, AAPI women with breast cancer were identified from a non-consecutive dataset of patients undergoing multi-gene panel testing (MGPT) at a national clinical diagnostic laboratory. Descriptive statistics were performed and differences in variant frequencies between groups were assessed using two-proportion z-tests. **Results:** From January 2016 through April 2025, 3.8% of women who underwent germline genetic testing reported AAPI ancestry (50,043/1,320,261). AAPI women made up 4.1% of all women with breast cancer who underwent MGPT. Comparatively, the most recent U.S. Census data from 2024 showed 7.0% of the population self-identified as AAPI women. The median age of AAPI women who underwent germline testing was 54 years and the most frequent pathogenic/likely pathogenic (P/LP) variants in order were BRCA2, BRCA1, ATM, PALB2, TP53, and CHEK2 (56.0% of P/LP variants). Most AAPI women (79%) resided in large metropolitan areas, and more than half (53%) had private insurance. AAPI women with breast cancer had lower rates of P/LP variants compared with White women (6.8% vs. 9.2%; $p<0.0001$) and all non-AAPI women tested (6.8% vs 8.9%; $p<0.0001$). Among women ≤50 years, P/LP rates remained lower in AAPI compared with White women (7.9% vs 10.7%; $p<0.0001$) and all non-AAPI women (7.9% vs 10.5%; $p<0.0001$). Younger AAPI women exhibited higher P/LP rates than older AAPI women (11.2% <40 vs 6.24% >40), consistent with age-associated trends across ethnicities (14.0% all non-AAPI <40 vs 8.45% all non-AAPI >40). **Conclusions:** In this study cohort, AAPI women with breast cancer make up a smaller than expected proportion of all tested women with breast cancer, despite similar breast cancer incidence rates as White women. AAPI women with breast cancer who had genetic testing tended to reside in large metropolitan areas and have private insurance. These factors and others should be considered when thinking about how to broaden access to genetic testing and counseling in the future, especially in younger AAPI women who have comparably higher rates of P/LP variants. Research Sponsor: None.

Impact of germline *BRCA* pathogenic or likely pathogenic variants on fertility potential and reproductive outcomes in young women with breast cancer: A systematic review and meta-analysis. First Author: Luca Arecco, Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Institut Jules Bordet, Bruxelles, Belgium

Background: In young women with a diagnosis of breast cancer (BC), the impact of germline *BRCA* (*gBRCA*) pathogenic or likely pathogenic variants (PVs) on their reproductive reserve and fertility outcomes remains uncertain. This systematic review and meta-analysis assessed the influence of harboring *gBRCA* PVs on ovarian reserve, efficacy of fertility preservation (FP) techniques, and pregnancies after BC diagnosis. **Methods:** A systematic PubMed/MEDLINE search was conducted with no date restrictions up to June 30th, 2025 (CRD420251114990). Eligible studies included retrospective and prospective case-control or cohort studies and clinical trials, comparing at least one of the following outcomes between *gBRCA* carriers vs. non-carriers: ovarian reserve parameters [i.e., anti-Müllerian hormone (AMH) levels or antral follicle count (AFC)] at BC diagnosis (objective 1); efficacy of FP techniques (i.e., number of total and mature retrieved oocytes, and cryopreserved oocytes before chemotherapy) (objective 2); likelihood of conceiving after treatments (objective 3). Pooled mean differences and risk ratios (RRs) with 95% confidence intervals (CI) were calculated using a random-effects model. **Results:** Out of 5,325 screened records, 18 studies met the inclusion criteria and were included in the final analysis (2,631 patients, of whom 737 *gBRCA* carriers). Mean age of patients at BC diagnosis was 32.6 years for *gBRCA* carriers and 33.1 years for non-carriers. Among 12 studies (n=1,529 patients) reporting on objective 1, *gBRCA* carriers (n=399) showed significantly lower AMH levels compared with non-carriers, with a mean difference of -0.5 (95% CI -0.8; -0.2) ng/mL, and a numerically lower AFC count (-0.8; 95% CI -2.3; +0.8). Among the 11 studies (n=1,027 patients) addressing objective 2, *gBRCA* carriers (n=318) had a lower median number of total oocytes (-1.8; 95% CI -3.3; -0.3), retrieved mature oocytes (-1.6; 95% CI -2.8; -0.3), and numerically lower cryopreserved oocytes (-1.1; 95% CI -2.7; +0.6). Subgroup analyses showed that reductions in ovarian reserve and FP outcomes were mainly driven by *BRCA1* carriers (n=184), whereas reproductive outcomes in *BRCA2* carriers (n=125) were comparable to those of non-carriers. Regarding objective 3, only one study (n=75 patients) reported the likelihood of conceiving after BC using assisted reproductive technologies (ART) and showed no differences between *gBRCA* carriers (n=20) and non-carriers (RR 0.28; 95% CI 0.04; 2.04). **Conclusions:** Young patients with BC harboring *gBRCA* PVs showed reduced AMH levels and lower FP efficacy, while no differences were observed in pregnancy rates after BC through ART, although evidence remains limited. Prospective studies are needed to optimize oncofertility counselling young *gBRCA* carriers. Research Sponsor: None.

Longitudinal follow-up after identification of variants of uncertain significance in highly penetrant cancer predisposition genes. First Author: Bridget Kiely, Baylor College of Medicine, Houston, TX

Background: ASCO and the NCCN recommend that patients with variants of uncertain significance (VUS) in hereditary cancer predisposition genes undergo periodic variant reassessment, since reclassification of VUS as pathogenic or likely pathogenic (P/LP) may alter clinical management. However, the extent to which such longitudinal follow-up occurs in practice has not been studied. **Methods:** Data were retrospectively reviewed from patients who underwent germline genetic testing for cancer-related indications from 2015-2025 at an adult genetics clinic in an academic-affiliated, safety-net healthcare system. Analyses were restricted to patients found to have VUS (without P/LP variants) in any of 23 highly-penetrant cancer predisposition (HPCP) genes based on the NCCN guidelines for genetic/familial high-risk assessment: *APC*, *ATM*, *BMPR1A*, *BRCA1*, *BRCA2*, *BRIP1*, *CDH1*, *CDKN2A*, *CHEK2*, *EPCAM*, *HOXB13*, *MLH1*, *MSH2*, *MSH6*, *MUTYH* (biallelic), *PALB2*, *PMS2*, *PTEN*, *RAD51C*, *RAD51D*, *SMAD4*, *STK11*, and *TP53*. The primary outcome of interest was the percent of patients who adhered to clinician recommendations for follow-up after VUS disclosure, excluding those for whom insufficient time had elapsed to assess follow-up status. Chi-square tests were used to assess if follow-up rates differed among patients with VUS that were considered "clinically concordant" (personal history of a tumor consistent with the gene's neoplastic spectrum), "possibly concordant" (history of a relevant neoplasm in a 1st/2nd degree relative but not the patient), or "likely incidental" (no relevant personal or family cancer history). **Results:** Of 2028 tested patients, 25% (n = 501) were found to have one or more cancer-related VUS (without P/LP variants), including 308 with VUS in HPCP genes. At the time of initial result disclosure, 11% of these patients were discharged from further follow-up, while the remaining 89% were advised to return for variant reassessment, typically within 2 years. Adherence to these recommendations was low overall, with only 38% returning for any post-disclosure follow-up. Rates of follow-up were similar among patients with VUS classified as clinically concordant (40%), possibly concordant (34%), or likely incidental (45%); p = 0.47. **Conclusions:** Despite clear clinician guidance to return for variant reassessment, most patients with VUS in highly-penetrant genes did not engage in recommended follow-up, even in the presence of a clinically compatible personal and/or family cancer history. Alternative approaches to longitudinal VUS management - such as automated recontact and/or direct-to-patient notification of variant reclassifications - should be explored to mitigate the risk of loss to follow-up in this population. Intensity of chemotherapy regimens for patients with Lynch syndrome and colorectal cancer. First Author: Christine M. Veenstra, University of Michigan, Ann Arbor, MI

Background: Lynch syndrome (LS), associated with inherited pathogenic variants (PVs) in *MLH1, MSH2, MSH6, PMS2* or *EPCAM*, is the most common inherited colorectal cancer (CRC) syndrome. Nearly all LS-associated CRCs are mismatch repair-deficient and microsatellite instability-high (dMMR/MSI-H), a phenotype associated with low recurrence risk and limited benefit from single-agent chemotherapy. Guidelines recommend no adjuvant chemotherapy for most dMMR/MSI-H stage II CRC. A fluoropyrimidine + oxaliplatin is recommended for all dMMR/MSI-H stage III CRC. **Methods:** We linked SEER registry records from Georgia and Los Angeles to germline genetic testing results from 4 labs. We included patients with resected stage II or III CRC diagnosed 2013-19 who linked to genetic test results. Chemotherapy details were extracted from SEER text fields completed by registrars. Regimens were classified as 1) No adjuvant chemotherapy; 2) Less intensive (5-FU or capecitabine); 3) More intensive (5-FU or capecitabine + oxaliplatin). We examined associations between genetic testing results and intensity of adjuvant chemotherapy. Covariates included age, sex, race, ethnicity, rurality. **Results:** Among 2770 patients, 1176 had stage II and 1594 had stage III CRC; 271 had a LS gene PV. The table shows results of multivariable analysis stratified by stage. Adjuvant chemotherapy intensity did not vary between patients with LS versus negative genetic test results. Older age was associated with receipt of no or less intensive chemotherapy in stage II and III CRC. Hispanic patients with Stage III CRC were more likely to receive no chemotherapy compared to non-Hispanic White patients. **Conclusions:** In this population-based cohort of CRC patients from two states, adjuvant chemotherapy regimen intensity did not vary with germline genetic test results. These findings suggest that patients with LS and stage II CRC are being overtreated. Clinicians may require education about optimizing CRC therapy for patients with LS. Research Sponsor: National Cancer Institute; R37 CA251464.

Clinical implementation of an online family cascade genetic testing platform: The Preventive Risk Outreach and Cascade Testing (PROACT) initiative. First Author: Jennifer Lee Caswell-Jin, Stanford Cancer Institute, Stanford, CA

Background: Cascade genetic testing of relatives in families with hereditary cancer susceptibility is an essential strategy to reduce the burden of cancer through targeted risk reduction. However, current testing rates for eligible relatives are low. A promising strategy is to directly engage relatives of affected patients through an online referral service that delivers genetic risk education and the option for home genetic testing to relatives. In the recent GIFT randomized clinical trial, we evaluated an online cascade testing platform for relatives of cancer patients identified through SEER registries. Here, we asked whether a clinical genetic counseling encounter could extend the reach of this approach. **Methods:** We implemented a pilot project at the Stanford Clinical Cancer Genetics Program that deployed an online hereditary cancer education and germline testing platform for first- and second-degree relatives of patients with a pathogenic or likely pathogenic variant (PV/LPV) in a cancer susceptibility gene. Eligible patients had a germline PV/LPV identified within the past year, spoke English, and had at least one adult first- or second-degree relative in the United States or Canada who had not, to the patient's knowledge, been tested for the PV/LPV. The virtual family referral service was offered to all eligible patients seen over a six-month period. Primary endpoints were the proportions of eligible relatives in the family who 1) were invited by the enrolled patient through the platform; and 2) ordered testing through the platform (processed by Color Health Inc). Here we report preliminary results from the initial project period; we will report results from the six-month project at time of presentation. **Results:** Between October 14, 2025 and January 20, 2026, 58 patients with germline PV/LPVs were offered the online tool and 23 patients (40%) enrolled. For these 23 patients, genetic counselors presumptively identified 191 relatives eligible for testing (70 first-degree and 121 second-degree). Patients invited 113 relatives (59%) of whom 57 (50%) accessed the tool and 50 confirmed their eligibility (no prior testing). Among confirmed eligible relatives who accessed the tool, 33 (66%) ordered testing, representing 17% (33/191) of all presumptively eligible relatives. **Conclusions:** Preliminary results from this clinic-based initiative to deliver cascade genetic testing through an online platform show promise. The findings suggest that an online platform can amplify the clinical genetics encounter and increase cascade testing of relatives in families with hereditary cancer susceptibility. Digital approaches to cascade testing may be particularly impactful for reaching relatives with limited access to care, where traditional cascade testing pathways are challenging. A multi-site clinical trial is planned through the PROACT Initiative. Research Sponsor: Bright Pink.

Initial findings from the PROMISE Registry, a US decentralized, prospective prostate cancer genetic registry. First Author: Heather H. Cheng, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA

Background: The role for genetic testing (GT) for prostate cancer (PCa) patients (pts) has expanded to find pts with germline pathogenic variants (PV) for therapeutic opportunities given FDA-approvals for PARP inhibitors in metastatic PCa as well as understanding familial cancer risk and opportunities for tailored screening and risk reduction. The PROMISE Registry (NCT04995198) was set up as a genetic registry to partner with PCa pts for rapid access to a new standard of care given insurance coverage and clinical implementation were initially major barriers. A second goal is to characterize disease features and treatment outcomes to inform management and provide updates about novel therapeutic clinical trials, both of which remain important to rare genetic variant carriers. **Methods:** PROMISE is a US decentralized prospective PCa genetic registry initiated in 2021 with initial phase to enroll and provide clinical-grade germline genetic testing (30 gene cancer-specific panel) to 5,000 PCa pts to identify ~500 PCa pts with variants of interest (pathogenic variants, PV, and variants of uncertain significance, VUS) in DNA repair genes for long-term clinical follow-up of 15 years (LTFU). Here, we report the initial phase testing results and identification of the LTFU cohort. Study design and enrollment strategy have been reported separately. **Results:** Between 2021-2026, 7,275 pts with any stage PCa across 50 US states self-consented to PROMISE, of which 5,674 (78%) of pts completed genetic testing, indicating feasibility of patient-directed, decentralized enrollment. We have identified 495 (8.7%) pts for LTFU. Baseline data is reported for n=367 (Table 1, will be updated at time of presentation). The most frequently observed PV/LPV variants being in *CHEK2* (25%), *BRCA2* (23%), *ATM* (12%), *and BRCA1* (4.6%). At the time of PCa diagnosis, the majority of LTFU pts had non-metastatic disease, with 47% of pts with Gleason>7, median PSA of 5 ng/mL, and median time from diagnosis to PROMISE GT of 25 months. **Conclusions:** PROMISE is a nationwide decentralized PCa genetic registry that has completed initial goal to recruit 5,000 PCa pts to offer germline genetic testing and recruit a cohort of 500 for LTFU. Data about diagnosis characteristics are reported, and analysis of ongoing disease course, treatment response/outcomes and overall survival is being collected. Clinical trial information: NCT04995198. Research Sponsor: Advancing Cancer Treatment, Inc.; U.S. Department of Defense; W81XWH-18-2-0060, W81XWH-17-2-0043; NIH Pacific Northwest Prostate Cancer SPORE; CA097186.

Actionable germline findings in endometrial cancer from a large multigene panel tested cohort. First Author: Adela Rodriguez Hernandez, Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Although most endometrial cancers (EC) are sporadic, 2–6% arise in the setting of Lynch syndrome (LS) or Cowden syndrome. The prevalence and clinical correlates of other germline pathogenic/likely pathogenic variants (PVs) remain incompletely characterized. We assessed the prevalence of potentially actionable germline PVs in EC and their clinicopathologic associations. **Methods:** This retrospective cohort included 3,844 EC patients (pts) who underwent pan-cancer germline multigene panel testing at a single diagnostic laboratory (2018–2025). Pts $<$ 18 years, with mosaic results, or unclear pathology were excluded. Clinical and pathologic variables were compared between pts with and without PVs using appropriate statistical methods, including multivariable logistic regression. **Results:** The final cohort comprised 3,693 females; 46.6% were non-Hispanic White and 8.3% African American. Median age at testing was 62 years and median age at diagnosis was 57 years. Overall, 20.8% (n = 804) harbored a PV in a high- or moderate-penetrance gene. Among 852 PVs identified, 46.9% occurred in DNA damage response (DDR) genes, 37.0% in LS genes, and 16.1% in other genes. The most frequent DDR PVs were *BRCA2* (12.6%), *CHEK2* (9.2%), *BRCA1* (8.0%), *ATM* (7.5%), *PALB2* (3.1%). *PTEN* accounted for 3.2% of the PV. PV carriers were younger at testing (60 vs 62 years; p = 0.014) and diagnosis (54 vs 57 years; p $<$ 0.001), more often African American (12.4% vs 7.2%; p $<$ 0.001), and had higher rates of colorectal cancer (7.7% vs 3.4%; p $<$ 0.001) and multiple primary cancers (41.7% vs 36.8%; p = 0.012). In multivariable analysis, younger age at EC diagnosis (OR 0.99; p = 0.028) and personal history of colorectal cancer (OR 1.84; p $<$ 0.001) remained independently associated with PV status. Histologic subtype distribution differed between LS and DDR groups (p $<$ 0.001); endometrioid tumors were more frequent in LS (26.6% vs 22.7%), whereas serous carcinoma (7.3% vs 1.1%) and carcinosarcoma (4.2% vs 1.8%) were more frequent in DDR. Among pts with available immunohistochemical (IHC) data (n = 810), 51.2% (n = 415) showed mismatch repair protein loss. Of these, 96 (23.1%) had PVs in LS genes, 13 (3.1%) in DDR genes, and 9 (2.2%) in other genes; 297 (71.6%) had no germline PV. Notably, among 161 pts with MLH1/PMS2 loss and confirmed *MLH1* promoter methylation, 25 (15.5%) still harbored PVs; 4 (2.5%) in LS genes, 16 (9.9%) in DDR genes and 5 (3.1%) in other genes. **Conclusions:** Germline PVs were identified in over 20% of EC cases, extending beyond LS or Cowden syndrome. The presence of PVs in *MLH1*-methylated tumors—traditionally considered sporadic—is a critical finding that challenges current tumor-only triage. These results support universal multigene germline testing in EC. A complementary case–control analysis including cancer-free controls and an independent validation cohort will be presented. Research Sponsor: PROACTIVE study supported by DFCI.

Expanded germline genetic testing of patients with hematologic malignancies to identify high proportion with hereditary cancer predisposition. First Author: Ozge Ceyhan-Birsoy, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Identifying hereditary cancer predisposition in patients with hematologic malignancies is critical for their clinical management, surveillance, donor selection, family, and reproductive counseling. However, genetic testing for patients with hematologic malignancies has been limited, largely due to the difficulty of obtaining suitable DNA samples for germline analysis. Heme Germline-MSK-IMPACT is a clinically validated assay for germline testing using nail or saliva DNA, depending on the patient's cancer type, in a non-invasive, rapid, and high-throughput manner, with the matched tumor analysis supporting results interpretation. **Methods:** Genetic testing was performed on 1300 consecutive patients with a clinical diagnosis or suspicion of a hematologic malignancy on Heme Germline-MSK-IMPACT, targeting 82 hereditary cancer predisposition genes. All individuals receiving somatic testing via paired tumor-normal sequencing on MSK-IMPACT-Heme as part of their clinical care were eligible to consent for germline analysis. **Results:** Germline pathogenic or likely pathogenic variants (gPVs) in hereditary cancer predisposition genes were identified in 16.7% (217/1300) of patients, with 5.8% (76/1300) having high penetrance autosomal dominant gene variants. gPVs known to be associated with hematologic malignancies were detected in *DDX41* (n = 14), *POT1* (n = 3), *RUNX1* (n = 2), *ETV6* (n = 1), *TP53* (n = 1). Additionally, four patients had biallelic variants in genes causing autosomal recessive disorders that confer increased risk for hematologic malignancies (*FANCA* (n = 2), *ATM*, *MSH6*). Other high-risk cancer predisposition genes with gPVs identified in multiple patients were *BRCA2* (n = 16), *BRCA1* (n = 15), *MSH6* (n = 4), *RTEL1* (n = 4), *CDKN2A* (n = 3), and *PALB2* (n = 3). Moderate penetrance gPVs were detected in 6.2% (81/1300) of patients in genes such as *CHEK2* (n = 36), *ATM* (n = 24), and *LZTR1* (n = 8). Twenty-four (1.8%) patients had two or more gPVs identified. **Conclusions:** Germline testing in a broad cohort of individuals with hematologic malignancies detected hereditary cancer predisposition in a substantial proportion of the patients. This ratio is comparable to the rate of cancer predisposition variants identified in patients with solid tumors in recent studies. Matched tumor data analysis is ongoing to uncover second hits and correlations for improving our understanding of the hereditary contribution to hematologic malignancies. Prevalence of microsatellite stable Lynch syndrome and universal germline testing: A pan-cancer analysis of 246,694 patients. First Author: Casey Cosgrove, The Ohio State University, Columbus, OH

Background: Lynch Syndrome (LS) is an inherited cancer syndrome that confers up to a 60% lifetime risk of colorectal (CRC), endometrial (EC), or other cancers, and up to a 40% risk of a second primary cancer. The current standard-of-care includes LS screening upon the diagnosis of CRC or EC (especially in patients $<$ 50 years old or with a strong family history) via immunohistochemistry for mismatch repair (MMR) protein deficiencies or microsatellite instability (MSI) testing algorithms; germline genetic testing is subsequently performed in MMR-deficient cases for confirmation . To assess the concordance between MSI status and LS, we evaluated the proportion of patients with pathogenic or likely pathogenic germline variants in a LS gene (LS-PGVs) who had microsatellite stable (MSS) tumors. **Methods:** We analyzed a pan-cancer cohort (n = 246,694) of patients who underwent personalized ctDNA testing (Signatera, Natera, Inc.), which involved whole exome sequencing (WES) of tumor and matched normal samples. MSI status was assessed in the tumor WES data by the MSISensor2 algorithm (MSI-H was defined as score $\geq$6.5). Germline single-nucleotide variants and short insertions/deletions from germline WES were identified and annotated with Variant Effect Predictor (v.105). The pathogenicity of variants in LS genes (*EPCAM*, *MSH2*, *MSH6*, *MLH1*, and *PMS2*) was determined using classifications available in the ClinVar database. **Results:** The pan-cancer cohort largely consisted of patients with CRC (n = 107,907; 44% of cohort), breast (n = 55,330; 22%), and other cancer types (each $\leq$4% of cohort) including EC (n = 5519; 2%). MSI status was determined in 84% (207,536/246,694) of the cohort, of whom 93% (193,110/207,536) had MSS tumors. LS-PGVs were identified in 1% (2418/207536) of the MSI-scored pan-cancer cohort. Among all pan-cancer patients with LS-PGVs, 36% (862/2418) had MSS tumors. Most patients with *EPCAM* PGVs (91%; 32/35) had MSS tumors. Conversely, only 17% (101/588) of patients with *MLH1* PGVs had MSS tumors. We next assessed concordance between LS-PGVs and MSI status in CRC and EC. Among CRC patients with an MSI score (n = 97,309), 12% (11,752/97,309) had MSI-H and 88% (85,554/97,309) had MSS tumors. Further, LS-PGVs were identified in 2% (1,759/97,309), of whom 25% (437/1,759) had MSS tumors. In EC patients with MSI scores (n = 4,625), 20% (926/4625) had MSI-H and 80% (3699/4625) had MSS tumors. Of these, LS-PGVs were identified in 2% (86/4625) among whom 44% (38/86) had MSS tumors. **Conclusions:** LS-PGV yield was 2% for both CRC and EC, and a substantial proportion of these patients had MSS tumors (CRC: 25%; EC: 44%). Given the high risk for secondary cancers associated with LS and the implications for cascade testing, these findings strengthen the existing recommendation for considering broader germline screening of all EC and CRC patients for LS. Research Sponsor: None.

Spectrum of germline pathogenic and novel BRCA1 and BRCA2 gene mutations in a cohort of 1780 breast and ovarian carcinoma patients from east India. First Author: Amit Roy Chowdhury, JBS Haldane Centre of Molecular Medicine, Silicon University, Odisha, India

Background: Advances in our understanding of the molecular basis of cancer have pushed us in a new era of personalized medicine in oncology. The adoption of personalized medicine in Breast cancer (BC) and Ovarian cancer (OC) care holds significant promise. Homologous recombination repair (HRR) process aids in the restoration of halted replication forks during DNA replication. Where, an effective HRR depends on the normal functioning of oncoproteins, BRCA1 and BRCA2 playing crucial roles. **Methods:** Germline Next Generation Sequencing based BRCA1 & BRCA2 gene panel on ion torrent technology was employed in 1780 diagnosed BC and OC patients for genetic-molecular evaluation. Bioinformatics pipelining and data analysis was performed as per Ion Reporter predesigned stringent workflows for germline variant screening. Variants were called as per ACMG guidelines and framework. **Results:** A total of 993 (55.8%) BC, 673 (37.8%) OC and 114 (6.4%) patients with co-existing BC & OC participated in the study. Out of which, 232 (13%) patients were found to harbour a clinically significant BRCA1 or BRCA2 gene variant. Predominantly, BRCA1 was the most mutated gene (68%; n = 158), followed by BRCA2 (32%; n = 74) across cohort. 48.2% of BRCA variants were noted in BC while 41.7% in OC and 10.1% in co-existing BC & OC patients respectively. Majority of the pathogenic variants (55.4%) were detected in high-grade tumors with mean age of 45.2 years. Exon-10 (33.3%) of BRCA1 and exon-11 (47.2%) of BRCA2 genes were the most mutated regions detected. Additionally, findings revealed 21 (9.1%) novel (14 in BRCA1 and 07 in BRCA2 genes) variants across BRCA genes not reported previously in ClinVar (NCBI) or BIC (Breast Information Core) databases. BRCA1 gene, exon-02, c.68_69del (185delAG) was the most pre-dominant (10.3%) variant in the patient cohort. **Conclusions:** India has emerged as the global cancer capital with BC being the most incidental cancer in women. Investigating the BRCA1, BRCA2 gene status in the current patient cohort has enabled the identification of not only the recurring hotspot pathogenic variants but also novel variants, as per the NCCN guidelines with actionable targets. Among BC, elevated and alarming frequency of TNBC patients (37.5%) was noted. The study findings provide a wide spectrum of BRCA gene variants specific to East-Indian patients with novel gene mutations pertaining to Indian population. These findings support the development of targeted therapeutic strategies by enabling the alignment of individual patients with treatments most likely to confer clinical benefit. Such precision oncology approaches may improve therapeutic efficacy, minimize treatment related toxicity, and ultimately enhance quality of life among cancer patients. Keywords: Breast & Ovarian cancer; BRCA1; BRCA2; NGS; Precision therapeutics. Research Sponsor: None.

10615 **Poster Session**

Association of thymic epithelial tumors (TETs) with Lynch syndrome (LS) per germline genetic testing and molecular tumor analysis. First Author: Megan Dwyer, Dana-Farber Cancer Institute, Boston, MA

Background: LS is a hereditary cancer syndrome that increases risk for gastrointestinal, gynecologic, genitourinary, and other cancers, and is typically characterized by microsatellite instability (MSI-H), mismatch repair-deficiency (MMR-D), and high tumor mutational burden (TMB). TETs, including thymomas and thymic carcinomas, are rare neoplasms not known to be associated with LS and usually show low TMB and microsatellite-stable (MSS) biology. We sought to describe the clinical, pathologic, and molecular characteristics of TETs diagnosed in individuals with LS seen at our institution. **Methods:** We conducted a retrospective, single-institution study to identify TETs among individuals with LS. We queried all LS patients seen in the DFCI Cancer Genetics and Prevention program from 1990 (n = 1,386) and identified those with a TET. We also reviewed TET cases that had paired tumor–germline sequencing between July 2023 and September 2025 (n = 12) to identify additional cases with LS pathogenic germline variants (PGVs). Clinical and molecular data, including MMR immunohistochemistry (IHC), and tumor and germline sequencing reports, were abstracted from the medical record. **Results:** Of the 1,398 cases reviewed, 4 females were identified with TETs (1 thymoma and 3 thymic carcinomas) diagnosed at a median age of 54.0 years (range 23-70 years), all with a confirmed PGV in an MMR gene [Table 1]. All four cases had tumor characteristics consistent with MMR-D. Two TETs were MMR-D by IHC, and one TET had biallelic *MLH1* variants on somatic testing, so MMR-D is inferred. Three TET cases were MSI-H by next generation sequencing, and one was MSS, despite being MMR-D by IHC. Three cases had high TMB and one did not have TMB assessment. One patient received neoadjuvant chemotherapy for two cycles, with the addition of pembrolizumab after discovering the tumor's MSI-H status; this patient had a pathological complete response at surgery. One patient received neoadjuvant chemotherapy, surgery, and adjuvant proton beam radiation; another received neoadjuvant chemoradiotherapy followed by surgery. The fourth underwent resection and plans adjuvant therapy. All four are alive at a median of 34.8 months post-surgery (range 3.6-60.7 months). **Conclusions:** Our data show that TETs in patients with LS frequently demonstrate molecular biology (MMR-D, MSI-H, TMB-H) like other classic LS-associated cancers, suggesting that these may be rare manifestations of LS. Further clarifying the link between LS and TETs may have important implications for treatments. Research Sponsor: None.

Population-based analysis of cancer disparities and social determinants of health in hereditary cancer syndrome carriers: A Healthy Nevada Project study. First Author: Haley Nadone, University of Nevada, Reno School of Medicine - Department of Internal Medicine, Reno, NV

Background: Hereditary cancer syndromes account for approximately 5-10% of all cancers, the most common being Hereditary Breast and Ovarian Cancer (HBOC) and Lynch Syndrome (LS). Despite the availability of genetic testing that can reduce cancer morbidity and mortality in carriers, significant disparities exist across various socioeconomic and racial groups. **Methods:** This retrospective cohort study analyzed participants from the Healthy Nevada Project (HNP) who underwent genetic testing for hereditary cancer syndromes. A study protocol was developed by the research committee prior to implementation. Participants were classified as positive or negative for HBOC syndrome (BRCA1/2 pathogenic variants) and Lynch syndrome (mismatch repair gene pathogenic variants). Race, age and ethnicity were categorized along with census tract-level social determinants of health (SDOH) measures including median household income and percent rural population. Descriptive statistics characterized the cohort by demographic and clinical variables. Associations between SDOH and cancer outcomes including diagnosis and age at diagnosis, were assessed using chi-square and logistic regression analysis to test for significance. Multivariable logistic regression models were constructed to assess independent associations between SDOH factors and cancer outcomes, adjusting for confounding variables. **Results:** A total of 47,737 patients were identified using the HNP database. Genetic testing occurred after cancer diagnosis in 99.6% of participants with cancer (2,542/2,552). Delays differed significantly across racial groups ($p<0.001$). There were no significant bivariate nor multivariate associations between HBOC and gender (p=0.63;0.61), race (p=0.52;0.70), Ethnicity (p=0.36; 0.67), income (p=0.75;0.88) or rurality (p=0.52; 0.63). In multivariable logistic regression, younger age at testing was independently associated with genetic test positivity (OR 0.993 per year; 95% CI 0.988–0.999; p=0.014). **Conclusions:** Population-based studies examining the intersection of hereditary cancer syndromes and SDOH remain limited, particularly in diverse cohorts that reflect real-world demographics. The absence of differences in pathogenic variant prevalence across sociodemographic groups suggests that population-based genetic screening may mitigate traditional disparities in genetic yield. However, observed differences in age at testing indicate persistent inequities in timing of access, which may influence early cancer detection. In fact, delayed post-diagnosis genetic evaluation is common across all SDOH groups in this cohort. Understanding these relationships is essential for developing equitable cancer prevention and control strategies that address both genetic predisposition and the social context in which carriers live. Research Sponsor: None.

Evidence supporting *RPS20* as a colorectal cancer susceptibility gene from a case-control MGPT study. First Author: Sarah Nielsen Young, Labcorp (formerly Invitae Corp.), San Francisco, CA

Background: Ribosomal protein S20 (*RPS20*) is increasingly included in colorectal cancer (CRC) germline multigene panel testing (MGPT) and clinical management guidelines, despite limited evidence of gene-disease association. Germline loss-of-function (LOF) variants in *RPS20* have been observed in a small number of individuals with CRC, without tumor loss-of-heterozygosity, and have typically been classified as variants of uncertain significance (VUS). We conducted a case/control study of individuals heterozygous for *RPS20* LOF variants to evaluate the CRC and colorectal polyp risk compared to controls and cases of established CRC susceptibility genes. **Methods:** Cases and controls underwent MGPT at Invitae (now part of Labcorp) from May 2018-May 2025. Cases included individuals with a single LOF variant in *RPS20* who had no identified pathogenic variants (PV) in other hereditary cancer genes and no VUS in established CRC risk genes; controls consisted of individuals with no PV or VUS identified. To reduce ascertainment bias, cases and controls were identified from requisitioned (clinician-ordered, reported) and unrequisitioned (run on MGPT backbone but unreported) data, under WCG protocol 1167406. Ninety controls were randomly sampled and age/sex matched to cases. CRC/polyp diagnoses were determined by clinician-reported ICD10 codes and keywords and compared between cases and controls utilizing Fisher's exact tests. To compare risk estimates with a well-defined hereditary CRC syndrome, odds of CRC/polyps in cases with *RPS20* LOF variants and in cases with mismatch repair gene PVs (*MLH1, MSH2, MSH6, PMS2*), both compared to controls, were estimated with multivariable logistic regression that included sex, age, requisition status, family history of cancer, and race/ethnicity. **Results:** Twenty-seven heterozygous *RPS20* LOF cases were identified (median age at testing 48 years [IQR 35-37]). CRC prevalence was significantly higher in *RPS20* LOF cases (63.0%) compared with controls (11.1%, p= <0.001), while polyp prevalence did not differ (7.4% vs. 10.0%, p=1). In multivariable analysis, *RPS20* LOF variants were associated with increased odds of CRC compared with controls (odds ratio [OR] 18.0; 95% confidence interval [CI], 5.2–62.1), comparable to odds observed for MMR gene PGV cases (OR 9.5; 95% CI, 6.6–13.7). **Conclusions:** Heterozygous *RPS20* LOF variants identified through MGPT are associated with substantially increased CRC risk. By incorporating age- and sex-matched controls and unrequisitioned testing data, this study reduces ascertainment bias and supports RPS20 as a CRC susceptibility gene. Larger studies are needed to inform clinical management. Research Sponsor: None.

Multivariable logistic regression, *RPS20* LOF cases compared to controls.

Cancer/polyps	OR	CI	p-value

Feasibility of a novel oncologist-led diagnostic algorithm for Lynch syndrome in colorectal cancer patients: The ItaLynch study. First Author: Alberto Puccini, Humanitas University, Pieve Emanuele, IRCCS Humanitas Research Hospital, Humanitas Cancer Center, Milano, Italy

Background: International guidelines recommend universal Lynch syndrome (LS) screening in colorectal cancer (CRC) using tumor mismatch repair deficiency (dMMR) testing. However, LS remains underdiagnosed worldwide, largely due to inconsistent referral for genetic counseling and germline testing. We report the final feasibility results of a novel, mainstreamed, oncologist-led diagnostic algorithm for LS. **Methods:** ItaLynch is a prospective, observational, multicenter Italian study on patients with dMMR CRC (May 2021–Dec 2025; 23 high-volume centers). The pathway includes: (1) universal dMMR screening by immunohistochemistry (IHC) in all CRC; (2) reflex testing and "Lynch alert": MLH1-deficient (dMLH1) tumors undergo BRAFV600E testing and, if wild-type, MLH1 promoter methylation; a Lynch alert is added to all dMMR pathology reports (positive for high LS risk based on reflex testing or non-MLH1 loss; negative for BRAFV600E-mutated or MLH1-hypermethylated cases); (3) oncologist-led mainstream germline testing for patients with positive alert, followed by post-test genetic counseling for carriers of pathogenic variants (PV) or clinically suspicious cases. **Results:** Up to Dec. 31 2025, we enrolled 1,482 pts with dMMR CRC. Overall, 1,316 were eligible for analysis (14 not eligible; 152 not yet filled out). Excluding 104 cases with incomplete data, 1,212 patients were evaluable from somatic to germline testing. Overall, 1033 (85%) completed the ItaLynch diagnostic pathway, demonstrating the strong feasibility of this this algorithm. Of patients with IHC data, 975 (78%) were dMLH1 and 281 (22%) had non-MLH1 loss. BRAF testing was performed in 904/975 (93%) dMLH1 cases; 386/904 (43%) were BRAFwt. MLH1 methylation testing was done in 329/386 (86%); 146/329 (44%) were not hypermethylated. Germline testing was performed in 108/146 (74%), identifying 21 LS-associated PV (19%). Among non-MLH1 loss, 232/281 (83%) underwent germline testing and 115 (50%) were diagnosed with LS. Overall, germline testing was performed in 361/1,033 adherent patients (35%), identifying 143 PV (40% of tests) and 24 VUS; PV prevalence was 14% (143/1,033). Mainstreaming reduced genetic pre-test counseling visits by 54% (196/361 avoided) and, compared with universal germline testing, avoided 672/1,033 tests (65%). Post-test counseling uptake was 83% among PV carriers. Median turnaround time from somatic to germline diagnosis was 217 days for dMLH1 and 73 days for non-MLH1. Among non-adherent patients, 67 underwent germline testing (14 PV, 3 VUS). In the full cohort, 157 PV were identified (MLH1 37, MSH2 57, MSH6 43, PMS2 20). **Conclusions:** This oncologist-led, mainstreamed diagnostic pathway for LS is feasible and optimized use of healthcare resources. Analyses of pathway deviations (15%), cost-effectiveness, and clinical/translational outcomes are ongoing. Research Sponsor: None.

A randomized controlled trial of a multilingual digital genetic cancer risk assessment tool in a diverse patient population. First Author: Tina Karimaghaie, Genetics and Personalized Cancer Prevention Program, Weill Cornell Medicine, New York, NY

Background: Most individuals with hereditary cancer risk remain unidentified, particularly racial, ethnic, and linguistic minorities and those publicly insured. Patient-facing digital tools may improve personal/family history collection and genetic cancer risk assessment (GCRA). In this randomized controlled trial (RCT), we evaluated a multilingual digital GCRA tool in a diverse, predominantly publicly insured population. **Methods:** An IRB-approved RCT (NCT05562778) was conducted among new patients at four urban academic gynecology clinics. Eligible patients (≥ 18 years old, English-, Spanish-, Cantonese-, or Mandarin-speaking, no prior cancer genetic testing (GT)) were randomized to a digital GCRA tool versus usual care. The digital tool collected patient history and generated National Comprehensive Cancer Network (NCCN)-based GT eligibility reports for providers. Usual care relied on clinician assessment of personal/family history. The primary outcome was clinician identification of high-risk patients and recommendation for GT. **Results:** From 10/2023 to 10/2025, 210 patients enrolled in the study; 104 (50%) were randomized to GCRA via digital tool and 106 (50%) via clinician interview. Eighty (38%) patients self-identified as Hispanic, 39 (19%) non-Hispanic White, 40 (19%) non-Hispanic Black, and 51 (24%) Asian; 159 (76%) were English-speaking, 40 (19%) Spanish-speaking, and 11 (5%) Mandarin/Cantonese-speaking. Most were publicly insured (133, 63%), (Table 1). In the intervention arm, 99 (95%) completed the digital tool. Among all patients, 36 (17%) were identified as meeting NCCN criteria for high risk of hereditary cancer and thus eligible for GT (intervention: 14; control: 22). Use of the digital GCRA tool was associated with a higher likelihood of high-risk patients being identified and recommended GT (13 [93%] vs. 3 [14%]; P = < 0.001). Digital tool completion and high-risk identification did not differ by race, ethnicity, or language. **Conclusions:** In a diverse, predominantly publicly insured population, a multilingual digital GCRA tool increased identification and recommended GT for those at elevated risk for hereditary cancer. Integrating such tools may improve detection of at-risk individuals and reduce disparities in genetic service utilization. Clinical trial information: NCT05562778. Age-stratified evaluation of subsequent primary malignancy risk in patients with primary Lynch syndrome–spectrum cancers. First Author: Vinit Singh, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Lynch syndrome spectrum cancers (LSSC) include several of the most common cancers in both men and women. Patients with LS are advised to undergo intensive cancer screening and genetic evaluation. However, most at-risk individuals are not assessed by a cancer geneticist, especially those in middle or older age, despite these cancers often appearing late in life. This study evaluates the incidence and timing of LS-related and non-LS–related subsequent primary malignancy (SPMs) in patients diagnosed with LSSCs. **Methods:** We used SEER data (1992–2021) to identify patients with LSSC – colorectal (CRC), endometrial (EC), gastric, Bladder/GU tract (GUC), Small bowel, ovarian, pancreatic, sebaceous, and brain (BC) by using histology and site code. Demographics, survival data, and SPMs details were extracted. Patient were stratified by age < 40 years, 40-60 years, and > 60 years. We calculated the mortality-related competitive risk-adjusted cumulative incidence (CI) of SPMs at 5 and 10 years for both LSSCs and all cancers. Median follow up were calculated by reverse KM method. We calculated the time to the development of 1st SPM after the index cancer diagnosis. Proportions were compared using chi-square test. **Results:** We identified 774955 patients with LSSC (50.4% Female, mean age 66.2 (SD 13.3) with a median follow-up of 149 months. 74331 (9.6%) patients developed a subsequent malignancy, with 30666 (41.3%) of all SPM had at least 1 LSSC. In < 40 year, 40-60-year, and > 60 years groups, 4.5%, 8.1%, and 10.5 % of total patients with LSSCs had a SPM of which 68.2%, and 43.3%, and 39.9 % patient had at least 1 LSSCs (p < 0.001). Median time to cancers and adjusted CI is given in the table. There was significant difference in distribution of primary (p-value < 0.01) and subsequent (p-value < 0.01) LSSC. CRC was the most common primary LSSC across age group, with Brain, and EC, and GU Cancers were the 2nd most common cancer in < 40, 40-60, and > 60-year age group respectively representing 19.3%, 16.7%, and 22.9% cancers of respective LSSCs. Among SPM, CRC was the most common across all age group (42.8% of LSS SPM) whereas EC was 2nd most common LSS SPM in < 40 years, and GU cancers in both 40-60 (35%), and > 60 (31.8%) years group. **Conclusions:** For LSSC patient, likelihood of developing SPM increased with longer survival, and older patients demonstrated the highest SPM burden for both LSSC and non-LSSCs. These findings suggest that cancer genetics evaluation and robust LS-directed surveillance should be extended beyond younger populations, as older patients remain at significant risk for LS-related SPMs. Research Sponsor: None.

Prevalence, tumor characteristics, and clinical impact of *LZTR1* pathogenic variants in a large, pan-cancer cohort. First Author: Anushri Soni, Department of Medicine, Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY

Background: Heterozygous germline pathogenic/likely pathogenic (P/LP) loss-of-function (LOF) variants in *LZTR1* are associated with hereditary schwannomatosis. To date, the prevalence and penetrance remain poorly defined, and there are currently no well-established surveillance guidelines for individuals with incidental *LZTR1* P/LP variants. We sought to describe the prevalence of *LZTR1* P/LP variants in a large pan-cancer cohort, characterize the tumor genomic profile of patients with these variants, and report the clinical utility of surveillance imaging in asymptomatic carriers diagnosed incidentally. **Methods:** Patients with germline P/LP variants in *LZTR1* were identified from pan-cancer patients who prospectively enrolled in an institutional review board-approved protocol of matched tumor-normal DNA sequencing (MSK-IMPACT). Clinical and tumor characteristics of *LZTR1* carriers were collected from electronic medical records. **Results:** Among 50,537 patients who underwent germline genetic testing via MSK-IMPACT, 157 (0.31%) were found to harbor a heterozygous germline P/LP variant in *LZTR1*. Eight patients presented with a schwannoma diagnosis at the time of genetic testing with an additional three reporting a prior history of schwannoma, for a total of 11 (7.01%) meeting criteria for LZTR1-associated schwannomatosis. In the remaining 146 (93%) of patients, the germline *LZTR1* P/LP variant was an incidental finding. The most common cancer types in those identified incidentally included prostate (23), breast (22), colorectal (21), sarcoma (14), and uterine (9). Of the 6 schwannomas with tumor data available, all exhibited a second somatic mutation in the *NF2* gene, and 5 displayed loss of heterozygosity of the *LZTR1* locus in the tumor favoring the mutant allele. LOH data was available for 117 non-schwannoma tumors. Of these, 33 (28.2%) were found to have LOH favoring the mutant LZTR1 allele. Of patients diagnosed incidentally, 29 underwent MRI of the brain and total spine after detection of the *LZTR1* P/LP variant for schwannoma screening. An additional 104 patients underwent whole body imaging (PET/CT or CT chest, abdomen, and pelvis) for cancer surveillance. All patients were asymptomatic and did not have clinical evidence of schwannomatosis on history or physical exam. Of these 133 asymptomatic *LZTR1* carriers, no (0%) schwannomas were identified. **Conclusions:** The prevalence of *LZTR1* P/LP variants was 0.3% in an unselected pan-cancer population with < 10% meeting criteria for *LZTR1*-associated schwannomatosis, suggesting low penetrance. Imaging performed after variant detection did not identify previously unrecognized disease, suggesting limited clinical utility of routine surveillance in asymptomatic carriers without supportive clinical features. These findings support a more selective, risk-informed approach to management of incidental *LZTR1* variants. Research Sponsor: None.

Diabetes risk reduction diet and mortality outcomes following breast cancer diagnosis in Black women. First Author: Lawrence Deng, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ

Background: Black women continue to experience a ~40% higher breast cancer mortality rate than White women. Type II diabetes (T2D) management-related factors have received increasing attention as contributors to this disparity. Emerging evidence, largely derived from studies conducted among White women, suggests that adherence to the diabetes risk reduction diet (DRRD) may be associated with improved breast cancer outcomes. Despite Black women having more than twice the risk of developing T2D compared with White women, no studies to date have examined the association between the DRRD and mortality among Black breast cancer survivors. **Methods:** We conducted a cohort analysis of 1,732 Black breast cancer survivors from the Women's Circle of Health Follow-Up Study. Participants' prediagnostic intake of DRRD components was calculated from validated food frequency questionnaires that included: cereal fiber, coffee, nuts, whole fruits, polyunsaturated/saturated fat ratio, glycemic index, trans fats, sugar-sweetened beverages, and red/processed meat. Consumption levels for each component were scored 1-5, summed to form a DRRD adherence score (higher scores signify greater adherence), and further categorized into tertiles. Death outcomes and causes were ascertained via linkage to the New Jersey State Cancer Registry. Associations with mortality were evaluated using multivariable-adjusted Cox proportional hazards regression models. **Results:** After a median of 10.8 years of follow-up since diagnosis, 422 total deaths (213 breast cancer-related) were identified. The mean DRRD score was 26 (std 5.5). In the multivariable–adjusted model, women with higher scores had a 34% lower risk of breast cancer-specific mortality (top vs. bottom tertile HR = 0.66; 95% CI = 0.46-0.93; p = 0.02) and a 23% lower risk of overall mortality (HR = 0.77; 95% CI = 0.59-1.00; p = 0.05). The associations were consistent across diabetes and menopausal status, and also across household income subgroups. However, the risk reduction appeared more pronounced among women with early-stage disease (HR = 0.54; 95% CI = 0.34-0.88), luminal tumor subtypes (HR = 0.49; 95% CI = 0.28-0.87), those with a BMI ≥30 kg/m^2 (HR = 0.55; 95% CI = 0.34-0.88), and those in the lower half of the neighborhood socioeconomic status distribution (HR = 0.57; 95% CI = 0.35-0.93), compared with their respective counterparts. **Conclusions:** This study represents the first and largest investigation of DRRD adherence and breast cancer outcomes among Black women. Our findings suggest that greater DRRD adherence may offer a protective effect on both breast cancer-specific and overall mortality in Black women, a population facing the highest breast cancer mortality in the US. More broadly, these results, together with prior evidence, suggest that adhering to dietary patterns consistent with T2D prevention may be important for both White and Black breast cancer survivors. Leisure-time physical activity among US cancer survivors, 2020-2024. First Author: Ruixuan Wang, Dana-Farber Cancer Institute, Boston, MA

Background: Physical activity (PA) after a cancer diagnosis reduces treatment-related side effects and improves quality of life and cancer outcomes. Historical data show that most cancer survivors do not meet recommended levels of aerobic and strength training PA. However, the recent pattern of PA in people with cancer remained unexamined. **Methods:** This pooled cross-sectional study analyzed data from the 2020, 2022, and 2024 National Health Interview Survey to examine the prevalence and predictors of meeting PA guidelines among US cancer survivors vs. non-cancer adults. The analytic sample included adults aged ≥18 years with available cancer history. Data were collected on frequency and duration of aerobic and strength training PA. Age-adjusted prevalence of meeting aerobic (≥150 minutes per week of moderate-intensity activity or ≥75 minutes per week of vigorous-intensity activity) and strength training (≥2 days per week) PA guidelines were estimated across sociodemographic and health characteristics among cancer survivors and non-cancer adults. Multivariable logistic regression models were fitted to identify factors associated with meeting PA guidelines among cancer survivors. **Results:** The final sample included 8,974 cancer survivors (Mean age: 65.7 [SE: 0.21]; 57.3% female) and 79,036 non-cancer adults (Mean age: 46.6 [SE: 0.11]; 51.1% female). After age-adjustment, 44.5% of cancer survivors met guidelines for aerobic exercise (95% CI: 41.8-47.3), 28.9% for strength training (26.3-31.6), and 22.2% for both (19.8-24.7%), significantly lower than the non-cancer group (48.3%, 32.5%, and 26.0%; all $p<0.01$). Patterns of lower prevalence were consistent across aerobic, strength training, and combined guidelines. Among cancer survivors, age-adjusted prevalence of meeting PA guidelines was significantly lower among those who were female, non-Hispanic Black or Hispanic, had lower levels of education or income, lived alone, were unemployed, had BMI ≥ 25, or were current smokers (all $p<0.05$). Survivors of gynecological and lung cancers had significantly lower age-adjusted prevalence of meeting both aerobic and strength training guidelines, while gastrointestinal cancer survivors had lower prevalence of meeting strength training guidelines only (all $p<0.01$). After adjustment for all covariates, not meeting PA guidelines in cancer survivors remained significantly associated with older age, female, lower education level, BMI ≥ 25, current smoking, and presence of cardiovascular disease or diabetes (all $p<0.05$). **Conclusions:** During 2020 and 2024, fewer than 1 in 4 cancer survivors met both aerobic and strength training PA guidelines. These findings underscore a critical need to integrate PA interventions into standard oncology survivorship care, with particular attention to addressing socioeconomic barriers and tailoring programs for survivors with comorbidities and high-risk cancer types. Alcohol-related hospitalizations among patients with cancer in the United States: Trends and associated risk factors. First Author: Anna Mehlich, De-Department of Internal Medicine, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: Alcohol consumption is associated with an increased risk of developing multiple cancers and has been linked to higher cancer-related mortality. Alcohol dependence and harmful alcohol use may also compromise oncologic care and worsen the clinical course. However, little is known about the prevalence and outcomes of alcohol-related hospitalizations among patients with cancer. **Methods:** We analyzed trends and risk factors of alcohol-related hospitalizations among adults with cancer using the National Inpatient Sample database for the years 2016-2021. Alcohol-related admissions were identified using ICD-10 codes for intoxication, withdrawal, alcohol-induced mood and psychotic disorders, and other alcohol-induced disorders. Prevalence estimates were adjusted using discharge-level weights to represent national data. Linear and multivariate logistic regression were used to assess trends in alcohol-related admissions and associations with sociodemographic and clinical characteristics. **Results:** Among 12,027,846 non-elective hospitalizations for patients with cancer, 15,205 (0.13%) were alcohol related. From 2016 to 2021, we observed an average increase of 185 admissions per year (from 2130 to 3200, $P = 0.009$). After adjusting for all non-elective hospitalizations in cancer patients, the linear time trend in alcohol-related admissions increased by an average of 0.008% per year ($P < 0.001$). When stratified by diagnosis type, alcohol withdrawal was the leading cause of alcohol-related admissions (69.4%), followed by alcohol intoxication (22.2%). Factors associated with alcohol-related admissions included male sex, younger age, white race, rural residence, housing instability, opioid use disorder, mood and psychotic disorders (Table 1). **Conclusions:** Alcohol-related hospitalizations are rare among patients with cancer but have shown a significant upward trend in recent years. The factors linked to alcohol-related admissions in this population mirror known risk factors for harmful alcohol use among non-cancer patients. Further research is needed to improve alcohol use disorder screening, prevention, and management strategies for patients with cancer, particularly in high-risk populations. Research Sponsor: None.

Association of proton pump inhibitor use with cancer-specific mortality in a nationally representative U.S. cohort (NHANES, 1999–2018). First Author: Albine Djeagou F., Rutgers Health Community Medical Center, Toms River, NJ

Background: Proton pump inhibitors (PPIs) are widely used and often continued beyond recommended durations. Evidence linking chronic PPI use to adverse cancer outcomes and mortality is mixed. Potential mechanisms include hypergastrinemia, altered gastric mucosa, and microbiome changes that may influence tumor behavior and treatment response. We assessed the association between baseline PPI use and cancer-specific mortality in a nationally representative U.S. cohort. **Methods:** Ten NHANES cycles (1999–2018) linked to the NHANES Linked Mortality Files (1999–2018) were pooled. Adults ≥18 years who were mortality-eligible and had examination follow-up time (PERMTH_EXM) were included. A formal written protocol was not developed; the analysis plan (study objective, exposure, endpoint, covariates, and primary models) was prespecified through discussion with the study team prior to final analyses. Baseline PPI exposure was defined from the 30-day prescription medication inventory (container-verified when available). A curated text algorithm identified PPIs using generic/brand/OTC names and fixed-dose combinations. Cancer death was defined as leading cause of death = malignant neoplasm; non-cancer deaths were censored (cause-specific hazard). Survey-weighted Cox models incorporated strata/PSU and pooled MEC weights (WTMEC2YR/10). Models used complete-case covariates per model. **Results:** Among 56,253 adults (1,850 cancer deaths), baseline PPI use was associated with higher cancer-specific mortality in unadjusted analysis and remained elevated after sequential adjustment (Table). **Conclusions:** PPI use was associated with higher cancer-specific mortality in a nationally representative U.S. cohort. These findings support careful review of PPI indication and duration and reinforce deprescribing when PPIs are not clearly indicated. Residual confounding remains possible, warranting studies using designs that better address this bias. Research Sponsor: None.

Sequentially adjusted survey-weighted Cox models estimating the cause-specific hazard of cancer death associated with PPI use (NHANES 1999–2018).

Model	N	Events	HR (CI)
Model 0: Unadjusted	56253	1850	2.63 (2.21 - 3.12)
Model 1: +Age +Sex	56253	1850	1.36 (1.14 - 1.62)
Model 2: +Race +PIR	51140	1695	1.40 (1.17 - 1.68)
Model 3: +Diabetes +Hypertension +HLD	51140	1695	1.40 (1.18 - 1.67)
Model 4: +log(cotinine)+log(metals)	9538	407	1.45 (1.10 - 1.91)

PIR = Poverty Income Ratio.
HLD = Hyperlipidemia.
Metals = lead, cadmium, mercury.
HRs represent cause-specific hazards for cancer death; non-cancer deaths were treated as censoring events.

The impact of high body-mass index on cancer mortality in the United States: An emerging public health challenge. First Author: Charbel Fadi Matar, The George Washington University, Washington, DC

Background: Obesity prevalence has increased markedly in the United States, yet the contribution of high body-mass index (BMI) to age-standardized mortality rates (ASMR) across cancer types, sex, and age groups over three decades remains poorly defined. We evaluated temporal trends in BMI-associated ASMR to identify cancers and populations most affected and inform prevention and equity-focused strategies. **Methods:** Using Global Burden of Disease (GBD) 2023 data, we extracted U.S. mortality estimates attributable to high BMI for neoplasms overall and selected cancer types from 1990-2023. BMI-associated ASMRs were compared by cancer type and sex, alongside age-specific rates for adults aged 20–54 years and all-age estimates. Age-standardized rates were used to distinguish changes in risk from demographic aging, while age-specific analyses assessed early-onset burden. **Results:** Between 1990-2023, BMI-attributable cancer mortality among adults aged 20–54 years increased by 44% (1.79 to 2.58), indicating a shift in the population-level burden toward earlier life. Overall BMI-attributable ASMR increased from 7.28 to 7.87, while all-age mortality increased from 9.15 to 14.15. Among evaluated cancers, liver, pancreatic, and uterine cancers demonstrated the largest increases in BMI-attributable ASMR. Liver cancer ASMR increased from 0.29 to 1.02 (~250%), pancreatic cancer from 0.13 to 0.40 (~200%), and uterine cancer from 1.02 to 1.74 (~70%). Early-onset BMI-attributable mortality also increased for liver (0.11 to 0.33), pancreatic (0.04 to 0.12), and colon cancer (0.53 to 0.90). Male predominance was observed for liver, pancreatic, kidney, and colon cancers, whereas uterine cancer accounted for the highest BMI-attributable burden among women. Marked geographic heterogeneity was observed, with the highest-to-lowest state BMI-attributable ASMR ratio of approximately 2.36 in 1990 (District of Columbia vs Hawaii) and 1.75 in 2023 (West Virginia vs Hawaii), indicating persistent but shifting geographic disparities. These patterns suggest amplification of existing cancer inequities at the population level over time. **Conclusions:** High BMI represents an increasingly important population-level contributor to cancer mortality burden in the U.S., with rising BMI-attributable ASMRs for metabolically associated malignancies and emerging early-onset burden. These findings underscore the importance of obesity prevention and metabolic risk reduction earlier in life as potential strategies to mitigate future cancer mortality and reduce inequities. Research Sponsor: None.

BMI-associated cancer mortality rates by age group and sex, United States, 1990–2023.

Oxybutynin for vasomotor symptoms across cancer-related and menopause-associated settings: A systematic review and meta-analysis of randomised control trials and observational studies. First Author: Arundhati Sharma, Guthrie Robert Packer Hospital, Sayre, PA

Background: Vasomotor symptoms, including hot flashes, are a frequent and debilitating adverse effect among postmenopausal women and patients receiving cancer-directed hormonal therapies, particularly endocrine therapy in breast cancer and androgen deprivation therapy in prostate cancer. Hormone-based therapies are often contraindicated in cancer populations, underscoring the need for effective non-hormonal treatment strategies. Oxybutynin, an anticholinergic agent approved for overactive bladder, has emerged as a potential non-hormonal therapy for vasomotor symptoms; however, the magnitude of benefit and tolerability across randomized studies in diverse clinical populations has not been comprehensively quantified. **Methods:** A systematic search of PubMed, Embase, Cochrane CENTRAL, and clinical trial registries was performed to identify randomized controlled trials evaluating oxybutynin for vasomotor symptoms in postmenopausal women and cancer populations, including patients receiving endocrine therapy and androgen deprivation therapy. Outcomes included change in hot flash composite score (frequency $\times$ severity), change in hot flash frequency, and discontinuation due to adverse effects. **Results:** 5 studies were identified, including four randomized controlled trials and one observational cohort (409 randomized participants). Oxybutynin was associated with a significant improvement in hot flash composite score compared with control (mean difference 8.81, 95% confidence interval 6.51–11.10; $p < 0.00001$; $I^2 = 54\%$). Subgroup analyses demonstrated greater improvement with higher doses (5 mg twice daily) compared with lower doses (2.5 mg twice daily), although both dose ranges were superior to control. Hot flash frequency was significantly reduced with oxybutynin (mean difference 3.88 episodes per day, 95% confidence interval 2.96–4.80; $p < 0.00001$; $I^2 = 42\%$), with larger reductions observed with higher-dose regimens. Treatment discontinuation due to adverse effects was more frequent with oxybutynin (odds ratio 2.90, 95% confidence interval 1.19–7.10; $p = 0.02$; $I^2 = 0\%$), consistent with a dose-related increase in anticholinergic adverse effects, most commonly dry mouth. **Conclusions:** Across studies in women and men with cancer-related and menopause-associated vasomotor symptoms, oxybutynin was associated with clinically meaningful reductions in symptom frequency and severity, with evidence of a dose-response relationship and a trade-off with increased anticholinergic adverse effects. These findings inform the role of oxybutynin as a non-hormonal therapeutic option in populations in whom hormonal therapies are limited or contraindicated. Research Sponsor: None.

CAMPERR: A multicenter, prospective, observational study to evaluate a cfDNA-based genome-wide methylation enrichment assay for multicancer early detection (MCED), identification of molecular residual disease, and relapse prognostication. First Author: Gregory Idos, City of Hope National Medical Center, Duarte, CA

Background: Despite advances in cancer treatment, a lack of established population-level cancer screening strategies for early detection across cancer types contributes to cancer-related mortality. Emerging MCED liquid biopsy tests represent a screening approach with potential to enable detection of multiple malignancies at earlier stages in the disease process. We previously showed that an initial classifier based on a genome-wide methylome enrichment platform detected 12 cancer types, including early-stage, low-shedding tumors (Park et al. AACR 2023. Abs 1030). However, clinical performance of the platform has not been evaluated prospectively. Thus, the CAMPERR study (NCT05366881) was designed to train and validate a cell-free methylated DNA immunoprecipitation and high throughput sequencing (cfMeDIP-seq)-based test for detection and differentiation of 20 pre-selected cancer types, representing 93% of annual cancer incidence and 88% of annual cancer deaths. Longitudinal follow-up for a subset of participants with lung cancer will enable training and validation for MRD-based recurrence prognostication. **Methods:** This case-control study is enrolling participants with 20 different pre-specified cancer types (n=2400) and those without known cancer (n=3900). Eligible participants are $\geq$40 years of age and not receiving treatment for cancer at the time of enrollment or taking any demethylating/hypomethylating agents. Cases include individuals with newly diagnosed ($\leq$120 days), untreated cancer or recurrence of a cancer originally diagnosed $>$5 years ago. Cancers of interest are stage I-IV bladder, brain, breast, cervical, colorectal, endometrial, esophageal, gastric, head and neck, hepatobiliary, leukemia, lung, lymphoma, multiple myeloma, ovarian, pancreatic, prostate, renal, sarcoma, and thyroid. Participants with stage I-III lung cancer will have clinical follow-up and blood draws after completion of first-line treatment, every 3 mo for the first year thereafter, and every 6 mo for an additional 2 years. Eligible control participants have not been diagnosed with invasive cancer in the last 5 years and will have clinical follow-up $\geq$12 mo from enrollment to evaluate cancer status. Liquid biopsy results will not be returned to clinicians or participants. The primary objective is cancer detection. Secondary objectives include detection of specific cancer types, identification of the tissue of origin, and prognostication of clinical outcomes (eg, recurrence-free survival, overall survival). CAMPERR is currently enrolling at 15 sites. As of December 3, 2025, 2108 of 2400 cancer cases have been enrolled, including prostate (n=225), lung (n=216), colorectal (n=211), breast (n=193), and pancreatic (n=192); controls are fully enrolled. Clinical trial information: NCT05366881. Research Sponsor: Adela, Inc.

TPS10629 **Poster Session**

Cancer recognition and assessment through non-invasive evaluation (CRANE): A prospective clinical validation study of a multi-biomarker class multi-cancer early detection (MCED) test in Japan. First Author: Takeaki Yamazaki, Department of Gastroenterology and Endoscopy, National Cancer Center Hospital East, Kashiwa, Japan

Background: Japan has established screening programs for gastric, colorectal, lung, cervical, and breast cancers. Blood-based multi-cancer early detection (MCED) tests utilize the measurement of shared tumor-derived biomarkers (ctDNA, proteins) and machine learning to simultaneously detect several cancer types. By complementing current cancer screening, MCED testing has the potential to detect a wide range of cancers at earlier stages and expand existing screening efforts. CRANE is a prospectively collected, case-control study of Exact Sciences' MCED test (Cancerguard) to assess the overall sensitivity and specificity of the MCED test in a Japanese population. The secondary objective is to evaluate test performance across cancer types and stages. **Methods:** The study will include Japanese participants aged 45-84 years. Participants must provide written informed consent prior to providing a peripheral blood sample. A cancer cohort of approximately 1,000 participants with newly diagnosed confirmed cancer will be included in the study. Cancer cases will be recruited to obtain a diverse representation of cancer types and stages while also considering prevalence rates by cancer type. Emphasis will be placed on the 16 cancers with the highest incidence in Japan: lung, gastric, prostate, colorectal, breast, liver, pancreatic, bladder/renal pelvis, non-Hodgkin lymphoma, esophageal, kidney, uterine, cervical, ovarian, biliary tract, and head and neck. Approximately 1,000 non-cancer control participants will be included in the study, corresponding to the age and gender distribution from current population estimates reported by the Statistics Bureau of Japan. These participants will have no known cancer at enrollment, with status confirmed based on up-to-date routine cancer screening consistent with Japanese national cancer screening programs and subsequently through a 12-month follow-up after enrollment. Participants are enrolled at clinical sites in Japan, including cancer screening centers affiliated with the Japan Cancer Society. Whole blood will be collected at study sites in LBgard tubes, shipped to a local laboratory, processed to isolate the plasma and buffy coat, and then frozen. The frozen plasma and buffy coat samples will be shipped to the Exact Sciences clinical laboratory (Madison, WI, USA) for analysis. Approximately 300 non-cancer control samples and ~50 cancer case samples will undergo interim testing to assess test logistics and preliminary performance. No protocol modifications or enrollment pauses will occur based on interim testing results. Final testing will occur once all participants have been enrolled. The study duration is expected to be approximately 24 months. This study is funded by Exact Sciences Corporation. Clinical trial information: UMIN000059407. Research Sponsor: Exact Sciences Corporation.

BRCA-P: Can denosumab reduce breast cancer risk in *BRCA1* mutation carriers? First Author: Christian F. Singer, Department of Obstetrics and Gynecology and Center for Breast Health, Comprehensive Cancer Center, Medical University of Vienna and Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria

Background: The likely 'cell-of-origin' that leads to breast cancer in *BRCA1* mutation carriers is a progenitor cell that is highly proliferative and prone to DNA damage. This progenitor cell expresses RANK ligand receptor [RANK] and is hyper-responsive to progesterone through paracrine signaling mediated by RANK ligand [RANKL]. Notably, high tissue expression of RANKL has recently been found in mechanosensitive (stiff) breast tissue and is associated with increased breast density, a recognized breast cancer risk factor. **Methods:** The BRCA-P trial is a randomized, double-blinded, placebo-controlled multi-centre international phase 3 trial evaluating the RANKL inhibitor denosumab as a possible breast cancer risk-reducing agent (EudraCT 2017-002505-35; NCT04711109). The safety profile of denosumab is generally well understood, as it is currently approved for the treatment of osteoporosis, bone metastases and giant cell tumor of bone. The study is led by the ABCSG (Austria), in collaboration with individual country sponsors in seven participating countries. Eligible participants include women age 25-55 years who carry a *BRCA1* pathogenic variant, are unaffected by breast or ovarian cancer, and are not pregnant or currently trying to become pregnant. Participants must also have not undergone prophylactic bilateral mastectomy or be currently taking a chemopreventive agent such as tamoxifen. They are randomised 1:1 to receive either denosumab 120 mg or placebo subcutaneously every 6 months for 5 years. The study primary objective is to evaluate the reduction in the risk of any breast cancer (invasive or DCIS). The safety profile and tolerability of denosumab in this setting will be also studied. Secondary and exploratory objectives include reduction in risk of ovarian, fallopian tube and other cancers, reduction in mammographic breast density, reduction in clinical fractures, effects on bone health and bone turnover markers and quality of life. BRCA-P completed its recruitment phase in December 2024, with 364 participants randomised globally. This investigator-initiated study is supported by Amgen. Clinical trial information: NCT04711109. Research Sponsor: U.S. Department of Defense.

TPS10631 **Poster Session**

Lung cancer screening for early detection of suspicious lung nodules in Latin America (LUCAS-LATAM). First Author: Luis Corrales, Department of Medical Oncology, Centro de Investigacion y Manejo del Cancer (CIMCA), San Jose, Costa Rica

Background: Lung cancer (LC) remains the leading cause of cancer-related death in the Latin American (LATAM) region, accounting for 1 in 10 cancer deaths, attributable to late stage diagnosis in above 85%. Clinical utility of low-dose CT (LDCT) in early detection of LC has been established. However, these trials primarily focus on smokers, excluding non-smokers, who account for over one-third of LC globally. Recent studies document a need to expand screening criteria. Prevalence of light smokers and non-smokers among LC patients in LATAM is high (35% of patients being non-smokers). Geographic and socio-economic barriers hinder early detection of LC. Despite effectiveness, access to LDCT is limited in LATAM. Artificial intelligence (AI) based algorithms have demonstrated improved accuracy in predicting the risk of LC among patients with an incidental pulmonary nodule (IPN) detected on chest radiographs. Qure.ai has developed a model (qXR) that generates a lung nodule malignancy score (LNMS) based on the nodule's characteristics in a chest X-ray (CXR): low risk or high risk. **Methods:** Prospective study to assess LC screening with LDCT in LATAM and prospectively evaluate qXR in CXR at the initial visit correlating with the finding of the initial LDCT in patients with other high risk criteria to develop LC. 2000 patients will be recruited in 4 LATAM countries (Mexico 700 pts, Costa Rica 300 pts, Colombia 500 pts, Argentina 500 pts) Inclusion criteria include patients $\geq$50 years of age with one of the following: a. exposure to wood smoke (at least 100 hours/year), b. family history of LC in a first degree relative, c. COPD and/or emphysema, d. smokers with tobacco index of 10 y or more. Exclusion criteria: a. LC diagnosis or other type of cancer 5 years prior to screening, b. loss of 10% of baseline weight 6 months before, c. ineligible for LDCT, d. life expectancy $\leq$5 years, and e. previous history of pulmonary nodules. The primary objective of the study is the utility of LDCT-based LC screening in identifying suspicious lung nodules in smokers and non-smokers across LATAM, with secondary objectives including: 1- Utility of qXR-LNMS of CXR for LC risk assessment to exclude low risk patients from LDCT screening, 2- Utility of LDCT-based LC screening in subjects with various risk profiles in LATAM, 3- Prevalence of lung nodules in the study population, 4-Mortality rate in the subjects diagnosed with an anomaly in the LDCT (with or without LC diagnosis). Study design: Visit 1: CXR by qXR and LDCT1 Visit 2: LDCT2 : (12/24 months as applicable $\pm$ 2 weeks)(interval of LDCT2 is determined by the findings of the Visit 1) Low risk by qXR and Lung RADS 1 or 2: repeat in 24 months Low risk by qXR and Lung RADS 3, high risk by qXR and Lung RADS 1, 2, 3: repeat in 12 months Telephonic follow-up visits (at 6 month interval post LDCT2 for 2 years) Any Lung RADS 0, 4A, 4B, 4X or S will be assed in a thoracic oncology multidisciplinary team. Research Sponsor: Astra Zeneca.

TPS10632 **Poster Session**

SOLAR: A post-approval study evaluating longitudinal performance of a blood-based test for screening individuals at average risk for colorectal cancer (CRC). First Author: Sam Asgarian, Guardant Health, Palo Alto, CA

Background: CRC is a leading cause of cancer-related mortality; CRC screening has been shown to reduce mortality through detection of early-stage disease, yet adherence to recommended screening remains suboptimal. Shield is a methylation partitioning cell-free DNA (mp-cfDNA) blood-based test indicated for CRC screening in average-risk adults age 45 years or older. This test achieved 83% sensitivity for CRC and 90% specificity for advanced neoplasia in a prospective, observational study that enrolled over 20,000 patients (ECLIPSE), and became the first blood-based screening test approved by the FDA as a primary CRC screening option in July 2024. SOLAR is an FDA-mandated, post-approval study to evaluate longitudinal performance of the blood-based mp-cfDNA test in the intended use population. **Methods:** SOLAR (NCT06880055) is an observational, prospective study supplemented with real-world data to evaluate the mp-cfDNA test following a second round of CRC screening. Patients will receive an initial mp-cfDNA test (Shield, Guardant Health, Palo Alto, CA) at baseline (T0). Deidentified healthcare claims data will be collected to assess overall health and any development of disease at 1 and 2 years following the baseline test (T1 and T2, respectively). Patients with a negative screening result at T0 will receive a screening colonoscopy alongside a blood draw approximately 3 years after baseline screening (T3). Patients with a positive result at T0 will be recommended to receive diagnostic colonoscopy. Individuals aged 45-81 years at average-risk for CRC are eligible for the trial. Individuals who have a personal/family history of CRC or are at high risk for CRC are excluded. Those with a positive result from any of the following CRC screening tests are also excluded: fecal occult blood test or fecal immunochemical test within the last 12 months, multi-target stool DNA test within the last 36 months, mp-cfDNA test within the last 36 months, or another CRC screening method within the last six months. Primary outcome is the performance of the mp-cfDNA test at T3, including sensitivity for CRC or advanced adenoma detection and specificity for advanced neoplasia detection. Enrollment began July 2025. There are currently 29 active study sites across the US. Clinical trial information: NCT06880055. Research Sponsor: Guardant Health.

11000 Oral Abstract Session

The association of GLP-1 receptor agonist use with survival and immune-related adverse events in patients receiving immune checkpoint inhibitors: A multi-institutional real-world analysis. First Author: Salman Jajja, New York Medical College, Landmark Medical Center, Woonsocket, RI

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are increasingly prescribed in patients with cancer for metabolic comorbidities and weight management. However, their impact on outcomes in patients receiving immune checkpoint inhibitors (ICIs) remains poorly characterized. We evaluated the association between concurrent GLP-1 RA use and survival and immune-related adverse events (irAEs) in a large real-world oncology population. **Methods:** We conducted a federated electronic health record–based cohort study using the TriNetX Research Network (113 healthcare organizations). Adult patients with solid and hematologic malignancies treated with PD-1/PD-L1 or CTLA-4 inhibitors were identified. Patients were stratified by exposure to GLP-1 RAs. Propensity score matching was performed to balance demographics, comorbidities, and baseline clinical characteristics. Kaplan–Meier survival analyses and Cox proportional hazards models were used to compare overall survival at 3 and 5 years. Incidence of irAEs, including neutropenia and pyrexia, was assessed using risk and odds ratios. **Results:** A total of 3,807 patients receiving ICIs with concurrent GLP-1 RAs were matched to 173,423 patients receiving ICIs without GLP-1 RAs. At 3 years, GLP-1 RA exposure was associated with improved survival (hazard ratio [HR] 0.69, 95% CI 0.64–0.75; log-rank $p<0.001$). This survival advantage persisted at 5 years (HR 0.71, 95% CI 0.65–0.76; log-rank $p<0.001$). Survival probability at the end of follow-up was higher in the GLP-1 RA cohort across both time horizons. No statistically significant survival benefit was seen at the 1-year end point, (HR 0.65, 95% CI 0.59-0.71; log-rank p=0.521). GLP-1 RA use was associated with a lower incidence of selected irAEs. At 3 years, neutropenia occurred in 5.7% of GLP-1 RA users versus 6.5% of non-users (OR 0.87, 95% CI 0.71–1.06), and pyrexia was significantly reduced (risk difference −2.5%, OR 0.73, 95% CI 0.61–0.87). Similar trends were observed at 5 years, with numerically lower neutropenia rates in the GLP-1 RA cohort (OR 0.84, 95% CI 0.68–1.02). **Conclusions:** In this large real-world analysis, concurrent GLP-1 RA use in patients receiving ICIs was associated with significantly improved long-term survival and a reduced burden of selected immune-related adverse events. These findings suggest a potential synergistic or protective effect of GLP-1 RAs in the immunotherapy setting and warrant prospective investigation to clarify underlying mechanisms and clinical implications. Research Sponsor: None.

11001 Oral Abstract Session

Impact of mRNA SARS-CoV-2 vaccination on CAR T-cell therapy outcomes in hematologic malignancies: A multi-center real-world analysis. First Author: Jowan Al-Nusair, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV

Background: The clinical landscape of hematologic malignancies has been reshaped by Chimeric Antigen Receptor (CAR) T-cell therapies; however, their administration is intrinsically associated with immune-mediated toxicities, specifically cytokine release syndrome (CRS) and Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS). The interaction between the immunogenic stimulus of mRNA SARS-CoV-2 vaccines and the systemic inflammatory milieu of CAR T-cell therapy remains undefined in real-world practice. This study aimed to delineate the impact of mRNA vaccination on survival outcomes and immunotoxicity profiles within this vulnerable patient population. **Methods:** We conducted a retrospective cohort study using the TriNetX global federated health research network. We identified patients with hematologic malignancies who received CAR T-cell therapy using ICD-10 and RXNORM codes. Patients were stratified into two cohorts based on whether they received mRNA-based SARS-CoV-2 vaccines. The cohorts were 1:1 propensity score-matched for age, sex, race, staging, and comorbidities. The primary outcome was all-cause mortality at 3 years, assessed with Hazard Ratios (HR). Secondary outcomes included CRS grade 1/2 and 3/4, and ICANS, both graded per the ASTCT criteria, and assessed with Odds Ratios (OR). **Results:** A total of 3,199 CAR T-cell patients (222 mRNA vaccine recipients and 2,977 without the mRNA vaccine) were identified. After 1:1 propensity score matching, 218 patients remained in each cohort. The 3-year mortality was significantly lower among mRNA SARS-CoV-2 vaccine recipients as compared to non-recipients (HR 0.608; 95% CI, 0.411 - 0.901). The mRNA vaccine group had a higher rate of CRS 1/2 (OR 1.577; 95% CI, 1.056 - 2.356). However, there were not enough cases of CRS 3/4 to compare the two cohorts. Furthermore, there was no significant difference in ICANS between the two cohorts (OR 0.8262; 95% CI, 0.522–1.37). **Conclusions:** In this propensity score-matched analysis of real-world data, mRNA SARS-CoV-2 vaccination was associated with a significantly superior long-term survival among CAR T-cell recipients. These findings build on early pre-clinical data related to SARS-CoV-2 mRNA vaccines demonstrating substantial increase in type I interferon, enabling innate immune cells to prime $CD8^+$ T cells. The results provide early real-world clinical evidence and pave the way for prospective validation. Research Sponsor: None.

Key outcomes in CAR T-cell recipients.

Outcome	Effect of mRNA Vaccination (95% CI)	*p* Value
All-cause mortality (3-year)	HR 0.61 (0.41–0.90)	0.01
CRS grade 1/2	OR 1.58 (1.06–2.36)	0.03
ICANS (any grade)	OR 0.83 (0.52–1.37)	0.41

11002 Oral Abstract Session

Frailty matters: Association of mFI-5 Index with odds of mortality, hospitalization, and toxicities with ADCs, BiTE, and CAR T-cell therapies in real-world data. First Author: Anne-Laure Strong, Penn State College of Medicine, Hershey, PA

Background: Targeted-delivery biopharmaceuticals such as antibody–drug conjugates (ADCs) or BiTE cell therapy are increasingly used in oncology. Recent meta-analyses demonstrate similar survival benefits of ADCs in younger and older patients across tumor types; however, baseline frailty predicts increased mortality, toxicity and hospitalization among patients receiving systemic anticancer therapy. While NCCN guidelines recommend frailty assessment for older adults prior to surgery, no such guidance exists for systemic treatments. **Methods:** We conducted a retrospective cohort study using TriNetX, a federated real-world data network with anonymized EHRs from hundreds of healthcare organizations. We included 46,674 patients with solid tumors, breast and bladder (solid ca) and 15,213 patients with hematologic cancers such as lymphoma, leukemia (heme ca) who initiated ADCs, BiTE-cell therapy, or CAR T-cell therapy. Cohort entry was defined as the first use of the drug class (index date). Toxicities, i.e. cardiotoxicity or cytopenia were outcomes if occurred within 30 days of index; patients without these events or with other outcomes served as comparators. Baseline frailty was measured using the modified Frailty Index-5 (mFI-5), derived from ICD-10 codes for hypertension (I10), care dependency (Z74), diabetes (E08–E13), COPD (J44), and heart failure (I50). Logistic regression estimated associations between frailty and each outcome, with p-values adjusted using the Benjamini–Hochberg false discovery rate. Mortality at pre-specified time points and hospitalization were fitted with a Cox proportional hazards model with frailty category as the primary exposure, controlling for age, and stratifying by cancer group and treatment. **Results:** In heme ca and solid ca, higher mFI-5 relative to mFI=0 was associated with significantly increased odds of toxicities with ADCs, including nausea, thrombocytopenia, anemia, cardiotoxicity, diarrhea, lung disease, and neutropenia (all $p<0.001$). In heme ca, higher mFI-5 was associated with significantly higher odds of toxicities, including anemia and cardiotoxicity (all $p<0.001$) with BiTE therapy and CAR T-cell. Results indicate a strong relationship between frailty severity and mortality risk (Table 1) and hospitalization after controlling for age and accounting for differences in baseline hazard across cancer groups and treatment strata. **Conclusions:** Assessing frailty severity through mFI-5 before initiating targeted systemic therapy in hematologic and solid tumors may help identify patients at increased risk of poor survival odds, adverse effects and facilitate shared treatment decision-making. Research Sponsor: None.

Hazard ratio of mortality relative to mFI=0.

mFI-5 score	Hazard ratio of mortality with 95% CI
1	1.41 [1.34-1.47]
2	1.79 [1.69-1.9]
3	2.45 [2.24-2.69]
4+	2.51 [2.11-2.97]

11003 Oral Abstract Session

Overall survival analysis of eSyM: A cluster randomized trial of an electronic patient-reported outcomes (ePRO)-based symptom management program. First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA

Background: ePRO monitoring can improve outcomes yet remains underutilized in routine cancer care. We conducted a pragmatic type II hybrid effectiveness–implementation trial using a cluster-randomized stepped-wedge design to assess an ePRO-based, EHR-integrated symptom management program (eSyM) across 6 health systems. Our prior analyses demonstrated that eSyM use, but not eSyM deployment, was associated with a significant reduction in emergency department visits and hospitalizations. Here, we report results of the overall survival (OS) analysis. **Methods:** Eligible patients were adults who received chemotherapy (CHEMO) or had surgery (SURG) for a gastrointestinal (GI), gynecologic (GYN), or thoracic (THOR) tumor from Jan 2018-Feb 2023. The outcome was OS 1 year after starting chemotherapy or postoperative discharge. The primary analysis compared patients treated pre- versus post-deployment of eSyM. A secondary analysis compared patients who were treated post-deployment and did versus did not use eSyM, where users were those who reported ePROs via eSyM at least once. Cox regression models accounted for sociodemographic, clinical, and health system factors. Analyses were stratified by treatment modality to account for heterogeneity of effect. **Results:** Health systems contributed data on 39,895 patients (selected characteristics in Table). After eSyM deployment, 45% of CHEMO and 53% of SURG patients used eSyM to report ePROs. Multivariable Cox regression analyses identified significant associations between eSyM deployment and OS for CHEMO (HR 1.11, 95%CI 1.03-1.21; P=0.007) and SURG (HR 0.86, 95% CI 0.76-0.98; P=0.026) patients. The adjusted absolute difference in 12-month OS probability for patients treated post-deployment vs. pre-deployment was -2.4% (P<.001) for CHEMO and 0.7% (P<0.031) for SURG. Comparing eSyM users vs. non-users from the post-deployment cohort only, OS was significantly better among CHEMO (HR 0.63, 95%CI 0.57-0.69; P<0.001; 12m OS diff 10.2%) and SURG (HR 0.58, 95%CI 0.49-0.69; P<0.001; 12m OS diff 2.8%) patients. **Conclusions:** Deployment of eSyM was associated with statistically significant but clinically marginal differences in OS. After eSyM was deployed, use of ePROs was associated with statistically significant and potentially meaningful improvements in OS. Considering that ePRO monitoring with eSyM decreases the need for acute care and may be associated with longer survival, strategies to improve adoption and implementation of ePRO-based symptom management programs may be warranted. Clinical trial information: NCT03850912. Research Sponsor: National Cancer Institute; 1UM1CA233080-01.

Multicenter open-label randomized trial of the utility of electronic patient-reported outcome monitoring system in patients with advanced solid tumors (PRO-MOTE). First Author: Naomi Kiyota, Kobe University Hospital, Kobe, Japan

Background: Randomized trials have suggested that electronic patient-reported outcome (ePRO) monitoring during systemic therapy may improve health-related quality of life (HR-QOL) and overall survival (OS) in patients with advanced cancer. However, evidence remains limited outside Western healthcare settings. Here, we evaluated the utility of ePRO monitoring for OS and HR-QOL in Japanese patients with advanced solid tumors receiving systemic therapy. **Methods:** This multicenter, open-label, randomized trial enrolled patients aged ≥18 years with advanced solid tumors, ECOG performance status (PS) 0–2, and receiving systemic therapy. Patients were randomized 1:1 to ePRO monitoring plus usual care or usual care alone. In the ePRO monitoring group, patients completed weekly symptom monitoring using PRO-CTCAE. Predefined severity thresholds were applied, and symptom reports exceeding thresholds automatically generated e-mail alerts to the study physicians. Primary endpoints were OS and global health status (GHS) assessed by EORTC QLQ-C30. Superiority for GHS was tested at a two-sided α of 4%, and for OS at α=5% if GHS was significant or α=1% otherwise. Based on a linear mixed-effects model, 400 patients provided 91% power to detect a 5-point between-group difference in GHS. Target sample size was set at 500, allowing for 20% attrition. **Results:** Between June 2021 and February 2024, 501 patients were enrolled (control n=250; ePRO n=251), with a median age of 63 years (21–82) and ECOG PS 0/1/2 of 362/127/12. Major cancer types included colorectal (27%), lung (22%), breast (19%), and gastric cancer (17%). QOL analysis was conducted in 485 patients due to missing baseline data in 16. Questionnaire completion rates were high (QLQ-C30: baseline 97%, week 24: 92%). In the ePRO group, weekly PRO-CTCAE completion rates were 86% at baseline and 85% at week 24, generating 13,500 symptom reports and 1,918 alerts (14%), with a median of 4 alerts per patient. At the planned interim analysis, between-group difference in change in GHS over 24 weeks was −0.61 (95% CI −3.03 to 1.82; p=0.625), showing no superiority of ePRO monitoring. OS did not differ between groups (HR 0.91; 95% CI 0.70–1.19; p=0.240). Bayesian predictive power of eventual OS benefit was 0.3%, below the futility threshold of 10%, and the trial was terminated early. **Conclusions:** In contrast to previous reports from Western countries, PRO-MOTE failed to demonstrate the superiority of ePRO monitoring for GHS or OS in patients with advanced solid tumors receiving systemic therapy in Japan. Despite high feasibility, the clinical benefit of ePRO monitoring might depend on cancer type, treatment context, or healthcare system. Further subgroup and exploratory analyses are ongoing. Clinical trial information: NCT05931445. Research Sponsor: None.

Impact of remote therapeutic monitoring with patient-reported outcomes on hospitalization in real-world patients receiving therapy for metastatic solid tumors. First Author: James H. Essell, Cincinnati Cancer Advisors, Cincinnati, OH

Background: Remote therapeutic monitoring (RTM) using electronic patient-reported outcomes (ePROs) may help care teams respond earlier to patient needs and potentially avoid acute care events, but evidence from real-world practice is limited. This study evaluates the impact of using the Canopy ePRO-based RTM platform on acute care events. **Methods:** We studied 1,549 patients with metastatic solid tumor malignancies receiving systemic treatment at 5 community oncology sites between Jan 1, 2024 until July 20, 2025. Patients were invited to complete weekly ePRO symptom surveys. Symptoms that exceeded pre-specified severity thresholds triggered notifications to a dedicated triage nursing staff for evaluation and consideration of telephonic triage, urgent outpatient office evaluation or referral to the emergency department or hospital. Patients who enrolled and submitted ≥ 2 ePRO surveys within 45 days of first treatment were included in the RTM group, while those not enrolled or who did not submit 2 or more reports were in the control group. Hospitalization events were extracted from the Arkansas health information exchange. Inverse probability of treatment weighting was used to account for potential non-random selection of patients into the RTM group when performing statistical tests of difference, and achieved cohort balance in terms of age at index, time from first cancer diagnosis to treatment, site of cancer, sex, and race. **Results:** Over 18 months following first anticancer treatment through data cutoff date, 558 patients were in the RTM group compared to 991 patients in the control group. Among patients in the RTM group, 9.0% had a record of hospitalization compared to 13% in the control group, representing a 28% reduction (risk difference: -3.63, 95% CI -7.06 to -0.39, p: 0.032); 12% of patients in the RTM group had record of ED visit compared to 13% in the control group (risk difference: -1.77, 95% CI: -5.24 to 1.63, p: 0.310). The estimated cost savings per 1,000 patients/years utilizing RTM during treatment was $3,192,789 for hospitalizations and $93,330 for emergency department visits. **Conclusions:** RTM utilization with Canopy is associated with fewer hospitalizations and potentially fewer emergency visits compared to traditional outpatient management of patients with metastatic solid tumors, potentially reducing the cost of care. Prompt notification of patient symptoms resulting in preemptive treatment may help patients avoid acute care events. Research Sponsor: None.

Randomized, double-blind phase 3 trial of the fixed-dose combination fosrolapitant/palonosetron (HR20013) plus dexamethasone for prevention of nausea and vomiting in patients receiving moderately emetogenic chemotherapy. First Author: Li Zhang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Despite antiemetic guidelines, ~50% of patients (pts) receiving moderately emetogenic chemotherapy (MEC) still experience chemotherapy-induced nausea and vomiting (CINV), mainly in the delayed phase (DP, 24-120 h). HR20013 is a fixed-dose IV formulation providing dual NK1 and 5-HT3 receptor blockade in a single dose and showed efficacy in preventing CINV following highly emetogenic chemotherapy in the phase 3 PROFIT trial (Zhou et al., JCO 2025). This study is the first pivotal phase 3 trial to evaluate the efficacy and safety of single-dose HR20013 plus dexamethasone (DEX) in the MEC setting. **Methods:** In this multicenter, randomized, double-blind, active-controlled phase 3 trial, chemotherapy-naïve adults with solid tumors scheduled for single-day MEC were randomized (1:1) to receive single-dose HR20013 (fosrolapitant 218 mg + palonosetron [PALO] 0.25 mg IV) or placebo + PALO prior to chemotherapy on D1. All pts also received oral DEX 7.5 mg on D1. Primary endpoint was complete response (CR; no emesis, no rescue therapy) in the DP (24–120 h). Key secondary endpoint was CR in the overall phase (OP; 0–120 h). **Results:** Of 706 randomized pts, the ITT population included 348 in the HR20013+DEX group and 352 in the PALO+DEX group. Baseline characteristics were well balanced. HR20013 showed statistically superior and clinically meaningful efficacy vs active control. CR rate in the DP was 79.0% (95% CI 74.4–83.2) with HR20013+DEX vs 61.4% (95% CI 56.1–66.5) with PALO+DEX (difference 17.8%, 95% CI 11.1–24.4; $P < 0.0001$). CR rate in the OP was 75.6% (95% CI 70.7–80.0) vs 59.9% (95% CI 54.6–65.1) (difference 15.7%, 95% CI 9.0–22.5; $P < 0.0001$). HR20013 also showed improved CR rate in acute phase (0-24 h; 92.5% vs 86.1%; P = 0.0052) and consistently showed higher rates across efficacy assessments including no significant nausea, complete protection, and total control in all phases. Time to treatment failure analysis favored HR20013 (HR 0.52, 95% CI 0.40–0.69). Functional Living Index-Emesis indicated that a greater proportion of pts receiving HR20013+DEX reported no impact on daily life in the DP (e.g., 90.2% vs 75.9% in the vomiting domain). The incidence of TRAEs were similar between groups (25.1% for HR20013 vs 21.4% for PALO). Most common TRAEs with HR20013 were constipation (8.9%), hypertriglyceridemia (4.0%), and hiccups (3.5%). Grade ≥3 TRAEs were infrequent (1.2% vs 1.4%). No new safety signals were identified. **Conclusions:** In pts receiving MEC, a single dose of fixed-dose combination HR20013 plus DEX was well tolerated and demonstrated superior efficacy in preventing CINV compared to the standard regimen of PALO+DEX, with improved patient-reported outcomes. This single-dose, dual-pathway antiemetic offers a more effective and convenient prophylactic option for MEC. Clinical trial information: NCT06554184. Doubling cascade testing uptake for hereditary cancer syndromes: Results from a cluster randomized controlled trial of a registry-aided outreach approach. First Author: Jianbang Chiang, National Cancer Centre, Singapore, Singapore

Background: Cascade genetic testing for at-risk relatives (ARR) is the most critical strategy for cancer prevention in families with hereditary cancer syndromes. Affected ARR can benefit from increased awareness and frequent screening to ensure cancers are detected at an early, treatable stage. Locally, uptake is persistently low at 6-13%, reflecting a prominent clinical gap. The current standard of care, which relies on passive proband-dependent communication to disseminate genetic information to ARR, is highly inefficient. We hypothesized that a novel, structured, registry-aided outreach model would improve the uptake rate of cascade testing in Singapore, and thus conducted a trial to address the effectiveness of this approach. **Methods:** We conducted a cluster randomized controlled trial at the National Cancer Centre Singapore comparing two arms. (1) Control arm: Proband-dependent communication. (2) Experimental arm: Proband-dependent communication with systematic outreach to ARR, facilitated by a family registry and executed by trained genetics personnel. This solution shares the burden of disseminating genetic results, ensuring ARR receive accurate information from a healthcare professional. The primary endpoint was the proportion of at-risk first-degree relatives who completed cascade genetic testing. **Results:** A total of 150 probands from unique families and 386 ARR were recruited from February 2022 to March 2025 in National Cancer Centre Singapore. In the experimental arm, 78/196 relatives (39.8%) attended pre-test genetic counselling compared to 38/190 relatives (20.0%) in the control arm. In the experimental arm, 71/196 relatives (36.2%) proceeded with cascade testing after pre-test counselling, whilst 37/190 relatives (19.5%) in the control arm underwent cascade testing. In our study, with the addition of the novel registry-aided outreach approach, the percentage of relatives who attend the pre-test genetic counselling session doubled, whilst those who eventually had cascade testing increased by 86%, demonstrating its clear superiority over the passive proband-dependent approach. **Conclusions:** Our trial proves that a systematic, healthcare professional-driven, registry-aided outreach is an effective strategy to overcome the barriers in cascade testing. The registry-aided outreach approach is a feasible, successful and scalable solution to the low uptake of cascade testing in Singapore. Implementing this approach is essential for realizing the full potential of genetic medicine to prevent cancers in high-risk families with hereditary cancer syndromes. Impact of dedicated care coordination on access to multidimensional support services in young-onset colorectal cancer: A pragmatic trial. First Author: Jeongyoon Moon, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The incidence of young-onset colorectal cancer (YOCRC) is increasing, and affected patients experience distinct challenges. YOCRC patients may benefit from a dedicated care coordinator that systematically assesses their unmet needs and facilitates referrals to multidimensional support services. **Methods:** In this pragmatic trial, we assigned newly diagnosed CRC patients aged <50 years who presented to a tertiary academic institution between 2023-2025 to usual multidisciplinary care, or usual care plus additional encounter(s) with a dedicated care coordinator as a part of the YOCRC program. Patient-reported concerns and distress were collected at initial presentation. The primary endpoint was the rate of utilization of support services designed to address multidimensional needs of YOCRC patients. Multivariable regression was performed to identify predictors of service utilization. **Results:** Among 1,250 YOCRC patients (mean age 42.8±6.0 years; 45.4% female; 77.3% white), 46.3% had rectal cancer. Emotional concerns were most common (41.0%), followed by physical (36.1%), practical (27.8%) and social (9.4%) concerns. The YOCRC coordinator successfully established contact with 604 individuals. Clinically significant distress (distress score ≥4) was reported by 27.4%, with no significant difference between groups (26.5% vs. 29.2%, p=0.34). Unmet service needs were reported by 39.1% in the intervention group, of whom 80.5% subsequently accessed corresponding support services. Patients with established contact with the YOCRC coordinator were more likely to access support services (Table 1, 72.5% vs.44.7%, p<0.001). On multivariable analysis, coordinator contact (aOR 1.48, 95%CI 1.22-1.80), rectal cancer diagnosis (aOR 1.36, 95%CI 1.13-1.62), and clinically significant distress (aOR 1.23, 95%CI 1.01-1.50) predicted greater multidimensional service utilization. **Conclusions:** YOCRC patients experience substantial emotional concerns and unmet needs. Integration of a YOCRC coordinator was associated with significantly increased utilization of multidimensional support services. This pragmatic trial supports a personalized, needs-driven care delivery model, that integrates patient-reported outcomes to further optimize targeted referrals. Research Sponsor: None.

Multidimensional support services accessed by YOCRC patients with vs. without established contact with YOCRC coordinator.

The electronic frailty index used to identify high-risk older adults receiving chimeric antigen receptor T-cell therapy. First Author: Justine P. Enns, Massachusetts General Hospital, Boston, MA

Background: Chimeric antigen receptor T-cell therapy (CAR-T) has transformed outcomes in relapsed/refractory hematologic malignancies and can be effective in older adults. Frailty, a syndrome of vulnerability common in older adults, is associated with poor outcomes but difficult to measure in clinical practice. The relationship between frailty and CAR-T outcomes is poorly understood. **Methods:** We conducted a retrospective analysis of 260 patients age 65+ years receiving commercial CAR-T at Massachusetts General Brigham (MGB) for multiple myeloma and B cell non-Hodgkin lymphoma. We abstracted patient characteristics and clinical outcomes from the electronic health record (EHR). Using EHR data from the Research Patient Data Registry, we calculated the MGB-eFI, a validated electronic frailty score based upon a deficit accumulation approach to frailty. The MGB-eFI assesses 31 age-related health deficits and yields a score ranging 0-1 (< 0.1 is robust, 0.1-0.2 is pre-frail, 0.2-0.3 is frail, and > 0.3 is very frail). We then evaluated associations of the eFI (as a categorical variable of robust/prefrail versus frail/very frail) with cytokine release syndrome (CRS), immune cell-associated neurotoxicity syndrome (ICANS), overall survival (OS), and event-free survival (EFS) using univariate and multivariable logistic and Cox regression models controlling for covariates. **Results:** Among 260 patients (median age 73 years [range 65-91], 45% female), the most common CAR-T products used were liso-cel (35%), tisa-cel (18%), ide-cel (18%), cilta-cel (12%), and axi-cel (10%). With the eFI, 10% of patients were robust, 25% prefrail, 28% frail, and 37% very frail. In univariate analyses, frail/very frail was associated with worse OS (hazard ratio [HR] 1.66, p = 0.013), worse EFS (HR 1.78, p = 0.001), higher rates of ICANS (odds ratio [OR] 1.99, p = 0.013), and higher rates of grade 3+ ICANS (OR 4.49, p = 0.003). Frailty was not associated with risk of CRS. In multivariable analyses controlling for age, sex, CAR-T product, lactate dehydrogenase, ferritin, number of prior therapies, and bridging therapy use, frail/very frail by eFI remained associated with worse EFS (HR 1.69, p = 0.005) but not with OS (HR 1.37, p = 0.150). Frail/very frail was numerically associated with increased ICANS, but this did not meet statistical significance (OR = 1.71, p = 0.090). In a multivariable analysis controlling for age, CAR-T product, and ferritin (due to event sample size), frail/very frail was associated with higher rates of grade 3+ ICANS (OR 3.75, p = 0.017). **Conclusions:** Frailty measured using an automated eFI is associated with worse EFS and higher rates of high-grade ICANS, despite controlling for other clinical and patient factors. The eFI holds promise as a tool that if integrated into the EHR can help clinicians with risk stratification and CAR-T decision-making for older adults with hematologic malignancies. Research Sponsor: None.

11010 Rapid Oral Abstract Session

Association of early cognitive decline with compromised delivery of adjuvant chemotherapy. First Author: Filippos Koinis, University Hospital of Larissa and Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece

Background: Cancer-related cognitive impairment (CRCI, "chemobrain") is a common condition among patients (pts) receiving adjuvant chemotherapy (CT) and has been shown to negatively affect quality of life (QoL). However, the clinical relevance of early CRCI beyond symptom burden remains poorly characterized. We evaluated whether early CRCI is associated with compromised delivery of adjuvant CT, including reduced relative dose intensity (RDI). **Methods:** This prospective study was conducted at the University Hospital of Larissa and represents an expanded analysis of a previously reported population with treatment delivery endpoints. Pts with early stage (ES) breast (BC) or colorectal (CRC) cancer scheduled to receive adjuvant CT containing taxanes or oxaliplatin, respectively, were eligible for this study (C1). Two control groups were included: ES cancer pts that were not eligible for adjuvant CT (C2) and age-matched healthy controls (C3). Eligibility criteria included age > 45 years and fluency in Greek; pts with pre-existing dementia or anxiety disorders were excluded. C1 pts were assessed at baseline and every 3 months (mo) up to 12 mo after CT initiation, while C2 and C3 were assessed at 3-mo intervals. CRCI was evaluated using the Greek Version of Functional Assessment of Cancer Therapy-Cognitive Function (FACT-Cog). Early CRCI was defined as a ≥10-point decline in total FACT-Cog score at 3 mo after CT initiation, in the absence of severe anemia (CTCAE grade ≥3). Treatment delivery outcomes included RDI (reduced RDI: < 85%), treatment delays, CT discontinuation, unplanned healthcare use and CT-related neurotoxicity (ntx). **Results:** Overall, 164 pts were included in C1 (111 BC, 63 CRC), 61 in C2 (38 BC, 23 CRC) and 25 in C3. Early CRCI was observed in a substantial proportion of pts receiving adjuvant CT (99/164, 60%). Pts with early CRCI were significantly more likely to receive reduced CT dose intensity compared to those without CRCI (OR 3.27, 95% CI 1.34-7.98). Early CRCI was also associated with an increased risk of clinically relevant concurrent treatment-related ntx (CTCAE grade > 1; OR 4.05, 95% CI 1.81-9.08). CT discontinuation occurred more frequently among pts with early CRCI than among those without CRCI (12% vs 3%). In addition, these pts more frequently experienced treatment delays and unplanned healthcare use. These associations were independent of baseline ECOG PS. Early CRCI persisted beyond 3 mo in a substantial proportion of affected pts during follow up, while cognitive scores remained stable among controls. **Conclusions:** In this expanded cohort, early CRCI was associated with reduced RDI and higher rates of treatment discontinuation. Beyond its impact on QoL, early CRCI identifies a vulnerable subgroup of pts at risk for compromised treatment delivery and may represent a clinically actionable target for risk-adapted supportive strategies aimed at preserving curative-intent treatment intensity. Research Sponsor: None.

11011 Rapid Oral Abstract Session

Clinical impact of baseline and peri-treatment concomitant medication exposure and polypharmacy on outcomes of immune checkpoint inhibitor therapy: A real-world pan-tumor analysis. First Author: Ali Awada, American University of Beirut Medical Center, Beirut, None, Lebanon

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer therapy, yet real-world patients frequently receive multiple concomitant medications that may influence treatment outcomes. These medications may alter the gut microbiome and modulate host immune function, impacting ICI efficacy and survival. The clinical effects of baseline and peri-treatment medication exposure on ICI outcomes remain incompletely characterized. **Methods:** We conducted a retrospective study of ICI-treated solid tumors at a tertiary academic center. Concomitant medications were captured at ICI initiation (baseline chronic exposure) and during a peri-treatment window (acute exposure, 30 days before or after ICI initiation). Drug classes included antibiotics, proton pump inhibitors, corticosteroids, NSAIDs, opioids, anticoagulants, antiplatelets, statins, cardio-metabolic and psychotropic agents, and supplements. Polypharmacy was defined as ≥5 baseline medications. Outcomes included overall survival (OS), progression-free survival (PFS), immune-related adverse events (irAEs), and objective response using RECIST 1.1. Multivariable Cox proportional hazards models were used to adjust for confounding. **Results:** The cohort included 772 patients (60.1% male) with a median BMI of 25.8 kg/m² (IQR 23.0–29.1), and 66.2% had stage IV disease. On multivariable analysis for objective response (RECIST), baseline polypharmacy (≥5 medications) (OR 0.65, 95% CI 0.43–0.96; p=0.033), acute antibiotic exposure within 30 days of ICI initiation (OR 0.63, 95% CI 0.39–0.99; p=0.049), and metastatic disease (stage IV) (OR 0.51, 95% CI 0.26–0.98; p=0.045) independently predicted inferior response, while a higher number of immunotherapy cycles was associated with improved response (OR 1.06 per cycle, 95% CI 1.05–1.08; p<0.001). Acute antibiotic exposure within 30 days before ICI initiation was also independently associated with worse progression-free survival (HR 1.70, 95% CI 1.05–2.76; p=0.031). On multivariable Cox regression for overall survival, acute opioid exposure (HR 1.51, 95% CI 1.06–2.15; p=0.023), baseline polypharmacy (HR 1.78, 95% CI 1.19–2.65; p=0.005), and advanced disease (HR 2.78, 95% CI 1.73–4.47; p<0.001) were independently associated with worse survival, whereas a higher number of immunotherapy cycles (HR 0.96 per cycle, 95% CI 0.94–0.98; p<0.001) and prior surgery of the primary tumor (HR 0.51, 95% CI 0.33–0.79; p=0.002) were associated with improved survival. No baseline polypharmacy or specific medication exposure independently predicted the occurrence of irAEs. **Conclusions:** Concomitant medication exposure significantly impacts ICI outcomes, potentially through modulation of host immunity and the gut microbiome, supporting routine medication review at ICI initiation. Research Sponsor: None.

Telehealth use and end-of-life care outcomes among Medicare decedents with cancers. First Author: Teresa M. Waters, Augusta University School of Public Health, Augusta, GA

Background: Telehealth has become an increasingly important care modality following the COVID-19 pandemic. For patients with cancer approaching end of life (EOL), telehealth may be particularly relevant given their substantial symptom burden, need for frequent healthcare services, and declining functional status. Telehealth may facilitate convenient access to care and enhance EOL care quality. However, limited research has examined associations between telehealth use and EOL care among patients with cancer. **Methods:** We conducted a retrospective, population-based cohort study of EOL telehealth use using 100% Medicare Traditional Medicare (TM) and Medicare Advantage (MA) claims. We included beneficiaries aged 66+ years with cancer who died in 2020-2023 with continuous enrollment in TM or MA during the 12 months preceding death. Patients with cancer were identified by at least 1 inpatient or 2 outpatient claims with relevant diagnosis codes. Telehealth use during the first 6 months of the last year of life was identified using procedure codes and modifiers. We examined validated claims-based EOL care outcomes, including hospice use and place of hospice care, and indicators of potentially burdensome transitions (e.g., late hospice enrollment $\leq$3 days of death, multiple hospitalizations and emergency department visits $\leq$30 days of death). Separate multivariable logistic regression models assessed associations between telehealth use and EOL outcomes. **Results:** Among a total of 2,897,720 Medicare beneficiaries with cancer who died in 2020-2023, mean age was 79.8 years; 44.9% were female, 9.4% were non-Hispanic Black, and 1.7% were Hispanic. Telehealth use in the first 6 months of last year of life was 30.0% in 2020-2023, with utilization peaking in 2021 (47.1%). Among all decedents, 60.7% enrolled in hospice; among hospice users, 73.1% received hospice care at home and 18.6% enrolled $\leq$3 days of death. In the last 30 days, 11.2% and 13.4% experienced multiple hospitalizations and ER visits respectively. In adjusted analyses, telehealth use was associated with 2.38 percentage points (ppts, 95% CI=2.25 to 2.50) higher likelihood of any hospice use. Among hospice recipients, telehealth use was associated with 5.45 ppts (95%CI=5.31 to 5.60) higher likelihood of home hospice use. Telehealth use was also associated with 2.18 ppts (95%CI=-2.31 to -2.05) lower likelihood of late hospice enrollment. Associations with multiple hospitalizations and ER visits were small and statistically non-significant. **Conclusions:** Telehealth use among Medicare decedents with cancer was associated with higher hospice use, particularly home hospice, and a lower likelihood of late hospice enrollment, suggesting potential improvements in EOL care transitions. These associations may reflect enhanced care coordination and continuity facilitated by telehealth during the EOL. Research Sponsor: U.S. National Institutes of Health; K12AR084234.

Cancer during pregnancy and child health perspectives: Evidence from real-world data. First Author: Samah Hayek, Tel Aviv University, Tel Aviv, Israel

Background: Pregnancy-associated cancer (PAC), is rare but increasingly encountered, likely reflecting delayed childbearing and the rising incidence of early-onset cancers. However, real-world evidence on short- and long-term offspring outcomes following PAC remains limited, particularly with respect to childhood chronic and inflammatory conditions. **Methods:** We conducted a retrospective cohort study using electronic medical records from Clalit Health Services, Israel's largest integrated healthcare system. Pregnancies among women aged 18–50 years between 2000 and 2024 were identified including PAC and non-PAC (controls). Annual incidence rates were calculated overall and by maternal age group. Short-term maternal, pregnancy, and neonatal outcomes were compared between PAC-exposed and cancer-free pregnancies using multivariable regression models. To assess long-term child outcomes, we included all identified PAC cases and their offspring and extended follow-up to capture chronic conditions (as documented diagnosis within electronic medical records) that typically manifest later in childhood. **Results:** The cohort included 3,561 PAC and 28,361 non-PAC participants. PAC incidence increased substantially over time, with highest incidence observed among women aged 35–45 years. Breast cancer was the most frequently diagnosed invasive malignancy during pregnancy. Gestational age at delivery was comparable between PAC and non-PAC pregnancies, although PAC-exposed offspring were slightly more likely to be born with low birth weight (HR 1.03; 95% CI 1.01–1.05; P = 0.01).In follow-up analyses, heterogeneous and outcome-specific differences in child health were observed. PAC exposure was associated with higher risks of inflammatory and immune-related conditions, including inflammatory bowel disease (HR 1.16; 95% CI 1.03–1.32; P = 0.013) and allergic conditions (HR 1.20; 95% CI 1.03–1.39; P = 0.017). Associations with asthma (HR 1.12; 95% CI 1.00–1.26; P = 0.056) and cardiovascular conditions (HR 1.16; 95% CI 1.00–1.26; P = 0.057) were also observed yet reached borderline statistical significance. All models were adjusted for maternal BMI, hypertension, diabetes, cardiovascular disease, age at delivery, socioeconomic status, depression, and child sex. **Conclusions:** The incidence of PAC has increased markedly over the past decade. Our findings suggest that cancer during pregnancy may be associated with increased risk of inflammatory/immune-related conditions in the born children. Ongoing analyses and preclinical models will further clarify the long-term clinical significance of these findings and their implications for maternal–child survivorship care. Real-world evidence of the association between primary insomnia and early-onset hormone-related cancers. First Author: Vineet Polineni, Jefferson Health New Jersey, Stratford, NJ

Background: Although progress has been made in reducing overall cancer incidence, early-onset cancers have continued their troublesome rise. Similarly, primary insomnia increases in incidence and prevalence each year, and with it come likelihoods of circadian disruption, immune dysregulation, and altered hormone signaling. However, real-world data characterizing the association between insomnia and early-onset hormone-associated malignancies remains limited. **Methods:** We sought to conduct a real-world, retrospective cohort study using the TriNetX United States Research Database, a federated network of de-identified electronic health records (EHRs) from over 70 healthcare organizations, to examine this association. Adults aged 18–50 years with primary insomnia (ICD-10: F51.01) were compared with same-aged individuals without primary insomnia using a five-year lookback period from January 25th, 2021 to January 25th 2026. Propensity score matching adjusted for demographic and clinical confounders. Incidence of early-onset cancers diagnosed within five years of the index event was assessed during follow-up. Sensitivity analyses required a $\geq$ 1-year lag between insomnia diagnosis and cancer onset. **Results:** 413,116 patients ages 18-50 were identified as having primary insomnia, whereas 18,437,709 patients ages 18-50 were identified as not having primary insomnia. Within 1-5 years of primary insomnia diagnosis, patients were more likely to develop early-onset breast cancer (RR 3.155, CI 2.863-3.477, $p < 0.0001$), uterine cancer (RR 1.988, CI 1.532-2.580, $p < 0.0001$), and ovarian cancer (RR 1.573, CI 1.276-1.940, $p < 0.0001$). Associations with early-onset prostate cancer (RR 1.676, CI 1.096-2.564) and testicular cancer (RR 1.243, CI 1.015-1.522) did not meet thresholds for significance. **Conclusions:** In this large, real-world cohort study, insomnia was associated with an increased risk of early-onset hormonal cancers more commonly affecting female patients. These findings suggest that sleep disruption may represent a clinically relevant, potentially modifiable risk factor in early-onset cancer risk stratification and warrants further investigation. Longitudinal changes in patient-reported quality of life (QOL) and hope among early phase cancer clinical trial (EPCT) participants. First Author: Debra Lundquist, Henri and Belinda Termeer Center for Targeted Therapies, Massachusetts General Hospital, Boston, MA

Background: Few studies have explored associations of longitudinal changes in patient-reported outcomes (PROs) and clinical outcomes among EPCT participants. We sought to describe changes in hope and QOL over the first two months of EPCT participation and examine associations of these changes with clinical outcomes. **Methods:** We prospectively enrolled adults participating in EPCTs at Massachusetts General Hospital from 04/2021-01/2023. We assessed QOL (Functional Assessment of Cancer Therapy-General, with subdomains: physical wellbeing [PWB], emotional wellbeing [EWB], social wellbeing [SWB], functional wellbeing [FWB]) and hope (Herth Hope Index) at time of EPCT enrollment, at 1 month (M1), and at 2 months (M2). We used descriptive statistics and regression models to describe changes and explore associations of patient-reported QOL and hope with patient factors (age, diagnosis, performance status) and clinical outcomes (time on trial [TOT], ED visits, and hospitalizations). **Results:** We enrolled 195 of 251 eligible patients (78% enrollment) and 192 completed surveys (98% response, median age: 63, 57% female, 94% metastatic cancer, ECOG 0 = 47% and ECOG 1 = 58%), 152 (78%) had M1 data, and 114 (59%) had M2 data evaluable. Most common cancer types were gastrointestinal (34%) and breast (20%). Over time, mean QOL scores improved (baseline [B/L] [75], M1 [76], M2 [76]), and mean hope scores were unchanged (B/L [39], M1 [39], M2 [39]). At M1, older age was associated with improved QOL change (B = 3.09, p = .031), EWB change (B = 0.94, p = .036), and increased hope (B = 1.22, p = .013). Female sex correlated with improved FWB (B = 1.15, p = .048) at M2. Head & neck cancer was associated with decreased EWB (B = -2.89, p = .010) at M2. Improved QOL at M2 was associated with longer TOT (HR = 0.97, p = .003). Improved PWB was associated with lower risk of ED visits (HR = 0.94, p = .011) and hospitalizations (HR = 0.95, p = .045) at M1, as well as longer TOT (HR = 0.94, p = .015) and lower risk of hospitalizations (HR = 0.93, p = .022) at M2. Improved EWB was associated with longer TOT at M1 (HR = 0.94, p = .001) and at M2 (HR = 0.89, p = .001). Improved FWB was associated with lower risk of hospitalizations (HR = 0.93, p = .023) at M1, as well as lower risk of hospitalizations (HR = 0.91, p = .043) and longer TOT (HR = 0.92, p = .016) at M2. We found no significant associations of changes in hope scores with clinical outcomes. **Conclusions:** This prospective study examined longitudinal changes in QOL and hope among EPCT participants. We described changes in QOL and hope scores from time of EPCT enrollment through 1- and 2-month follow-up and identified factors associated with these changes. Improvements in QOL over time predicted higher TOT and reduced healthcare utilization. Future studies should assess and address longitudinal changes in PROs to enhance trial experience and optimize clinical outcomes. Research Sponsor: None.

11016 **Rapid Oral Abstract Session**

Obesity paradox in gastrointestinal cancer patients on immunotherapy: A retrospective multi-institutional US cohort study. First Author: Marwa Al Faraj, SUNY Downstate Health Science University, New York, NY

Background: Obesity is a well-established risk factor for different types of cancers, including gastric cancers. However, emerging research suggests its association with improved survival outcomes in cancer treatment, a phenomenon referred to as "the obesity paradox". Recent literature demonstrates this paradoxical effect in cancer patients receiving immunotherapy. We explored this effect across various types of gastrointestinal (GI) malignancies. **Methods:** De-identified data from the TriNetX database were used to identify adult patients (age $>$ 18 yrs) with GI malignancies (hepatocellular, colorectal, pancreatic, upper GI (gastric and esophageal) who received immune checkpoint inhibitors (ICIs) between 2013 and 2025. Propensity score matching was performed to balance cohorts by demographics, comorbidities, ECOG and albumin level. The primary outcome was 5-year all-cause mortality, compared between patients with obesity (BMI $\geq$ 30 kg/m²) and those with normal BMI (18–24.9 kg/m²). The secondary outcome was the incidence of ICI-related adverse events (irAEs). Kaplan–Meier was used for time-to-event outcomes, differences were assessed using the log-rank test, and Cox proportional hazards using the TriNETx platform. **Results:** After propensity score matching, 4,956 patients were included in each cohort. Mean baseline characteristics were comparable between cohorts. The BMI $>$ 30 cohort had BMI(kg/m2) 35.4 $\pm$ 5.4, albumin(g/dl) 3.54 $\pm$ 0.61, and mean ECOG 0.68 $\pm$ 0.96 while the normal BMI cohort had BMI 22.8 $\pm$ 4.5, albumin 3.48 $\pm$ 0.62, and mean ECOG 0.67 $\pm$ 0.83. Obesity was associated with significantly improved all-cause mortality compared with the normal BMI group (26.8 months vs 13.9 months; hazard ratio [HR], 0.7 [0.67-0.74]). Survival probabilities at 1 year (63.7% vs 52.6%), 3 years (46.2% vs 31.9%), and 5 years (39.1% vs 25.4%) were higher in the BMI $\geq$ 30 kg/m² cohort compared with the normal BMI cohort. Among GI cancer subtypes, the strongest associations between obesity and improved survival were observed in colorectal (HR 0.67 [0.62-0.72]) and pancreatic cancers (HR 0.66 [0.56-0.76]), with more modest effects seen in hepatocellular (HR 0.78 [0.72-0.84]) and upper GI cancers (HR 0.71 [0.62-0.80]). There were no significant differences between cohorts in the incidence of pneumonitis (HR 1.12 [0.80-1.57]), GI (HR 1.07 [0.98-1.17]), thyroid (HR 1.05 [0.97-1.14]), or cutaneous (HR 1.10 [0.99-1.23]) irAEs. **Conclusions:** In this analysis of 9,912 patients with GI malignancies treated with immunotherapy, higher BMI was associated with improved survival. Confounding by disease burden was partially addressed through adjustment for ECOG and albumin. These findings may reflect obesity-related immune modulation, as preclinical studies suggest leptin-mediated upregulation of PD-1 expression. However, further prospective studies are needed to validate and define these results Research Sponsor: None.

GLP-1 receptor agonist utilization and survival outcomes in a large U.S. community oncology cohort. First Author: Ila Sruti, Ontada, Boston, MA

Background: GLP1 use has increased with 12.4% of U.S. adults reported using these treatments, driven in part by the 2021 approval of semaglutide for chronic weight management without diabetes. Beyond established metabolic benefits, emerging preclinical and observational data suggest potential anticancer effects of GLP1 therapy. However, no study to date has characterized GLP1 use among cancer patients treated in a large-scale population. This study provides an essential step towards describing real-world world GLP1 treatment patterns and clinical outcomes. **Methods:** Structured EHR data from The US Oncology Network were used to identify GLP1 users (dulaglutide, exenatide, liraglutide, lixisenatide, semaglutide, and tirzepatide) and nonusers between January 2021 and October 2024, with follow-up through October 2025. Overall survival (OS) was assessed from initial cancer diagnosis to death from any cause. Nonusers were matched to GLP1 users by cancer type and diagnosis year. To address immortal time bias, each nonuser was assigned the matched user's GLP1 medication start date as the anchor date; nonusers who died or were lost to follow-up prior to that date were excluded. Multivariable Cox proportional hazards models evaluated factors associated with OS among patients diagnosed with breast, prostate, lung, hepatocellular, or renal cancer. **Results:** A total of 1,121 GLP1 users and 471,580 non GLP1 users with cancer were identified. GLP1 users had a median age of 63 years, were 63% White, and 69% had BMI $\geq$30 kg/m^2 semaglutide was the most commonly used agent (64%). Non GLP1 users had a median age of 68 years, were 61% White, and 30% had BMI $\geq$30 kg/m^2. Among GLP1 users, 74% were prescribed GLP1 therapy after initial cancer diagnosis, of those 7% after metastatic diagnosis; the most common cancers were breast (27%) and prostate (13%). OS at 24 months was higher among GLP1 users versus nonusers for both breast cancer (97.9% [95% CI 93.7–99.3] vs 92.6% [92.4–92.8]) and prostate cancer (97.9% [93.7–99.3] vs 92.6% [92.4–92.8]). After adjustment for age, BMI, stage, and cancer type, GLP1 use was significantly associated with improved OS (HR 0.58, 95% CI 0.40–0.84; p = 0.0036). **Conclusions:** In this large real-world cohort, GLP1 use was most frequently observed among younger patients with obesity and was commonly prescribed after cancer diagnosis, with semaglutide accounting for the majority of prescriptions. Breast and prostate cancers were the most prevalent malignancies among GLP1 users, reflecting early adoption across common solid tumor types in routine practice. Despite limitations inherent to structured real-world data, including potential underreporting of GLP1 exposure, GLP1 use was associated with improved OS compared with nonuse, supporting the need for future studies using robust causal inference approaches. Research Sponsor: None.

Temporal trends in oncology clinical trial complexity and duration: A retrospective analysis of 5,261 industry-sponsored trials. First Author: Andrew J. Yang, The Warren Alpert Medical School of Brown University, Providence, RI

Background: Clinical trial complexity has been cited as a contributor to rising drug development costs and increasing trial duration. We aimed to quantify multidimensional oncology trial complexity and describe temporal trends. **Methods:** We conducted a retrospective analysis of industry-sponsored interventional drug and biological oncology trials from the Aggregate Analysis of ClinicalTrials.gov (AACT) database, restricted to concluded trials initiated 2007-2017 for post-FDAAA reporting consistency and adequate follow-up. Five complexity dimensions were derived using principal component analysis: protocol (eligibility criteria, arms, outcomes), operational (sites, countries, planned enrollment), disease (MeSH breadth), intervention (modality count), and governance (team structure). Temporal trends were analyzed across completed trials only; Pearson correlations between dimensions and duration/early termination were calculated across all concluded trials. Trends were estimated using linear regression on yearly medians stratified by phase. **Results:** Among 6,752 concluded oncology trials (78% completion rate), temporal trends were analyzed in the 5,261 completed trials. Protocol complexity significantly increased (+0.083 SD/year), driven by total eligibility criteria (+0.56/year), secondary outcomes (+0.35/year), and exclusion criteria (+0.35/year). Operational complexity showed a significant increasing trend (+0.014 SD/year), with facilities increasing +0.51/year. Overall trial duration significantly increased (+16.7 days/year), with Phase 1 trials increasing +18.2 days/year and Phase 2 trials +18.4 days/year, while Phase 3 trials showed a non-significant trend (+20.7 days/year). Across all trials, protocol complexity was weakly correlated with early termination (r=0.03) and duration (r=0.14). Operational complexity showed the strongest correlation with duration (r=0.36). **Conclusions:** Among concluded oncology trials, protocol and operational complexity are significantly increasing, particularly eligibility criteria burden, endpoint multiplicity, and study scale. Trial duration is significantly increasing for early-phase trials, driven primarily by operational complexity. Research Sponsor: None.

Operational and protocol trends in oncology trials.

Metric (median)	2007 Value	2017 Value	Slope/Year	P-value
Total I/E Criteria	15	22	+0.56	$<$0.001
Secondary Outcomes	4	7	+0.35	$<$0.001
Exclusion Criteria	8	12	+0.35	$<$0.001
Inclusion Criteria	6	9	+0.22	$<$0.001
Total Outcomes	8	11	+0.30	$<$0.001
Number of Sites	6	12	+0.51	$<$0.001
Phase 1 Duration (days)	1080.5	1220	+18.2	0.010
Phase 2 Duration (days)	1249	1347	+18.4	0.028
Phase 3 Duration (days)	1583	1673	+20.7	0.214
Overall Duration (days)	1247	1378	+16.7	0.006

Observed medians are reported for 2007 and 2017. Slopes and p-values were derived from linear regression on yearly medians.

A machine learning–enhanced analysis of temporal trends in biomarker-based eligibility restrictions in oncology clinical trials. First Author: Luke Xiyu Zhao, Johns Hopkins University School of Medicine, Baltimore, MD

Background: The adoption of biomarker-based eligibility criteria reflects the evolution of precision oncology, but temporal trends and predictors of biomarker restrictions are unclear. Understanding these patterns is essential for optimizing trial design and ensuring equitable patient access to investigational therapies. We used machine learning and natural language processing to analyze biomarker restriction trends across oncology trials. **Methods:** We analyzed all 54,985 oncology interventional trials from ClinicalTrials.gov from 2010-2024. Biomarker restrictions were identified using curated term lists plus NLP-based classification (TF-IDF vectorization with logistic regression). We developed complementary machine learning modules for emerging biomarker discovery using named entity recognition, requirement type classification (inclusion/exclusion/stratification), and eligibility complexity scoring via text feature engineering. Statistical analyses included logistic regression with Wilson score confidence intervals and Benjamini-Hochberg FDR correction. **Results:** Biomarker-restricted trials increased from 20.8% (2010) to 31.2% (2024), representing a 1.5-fold increase over 15 years (OR per year: 1.046, 95%CI: 1.041-1.050, p$<$0.001). Industry sponsorship (OR: 1.88, 95%CI: 1.80-1.97) and NIH sponsorship (OR: 1.89, 95%CI: 1.67-2.13) independently predicted higher biomarker restrictions versus academic sponsors (all p$<$0.001). US-based trials showed 40% higher odds of restrictions (OR: 1.40, 95%CI: 1.35-1.46). Phase II trials demonstrated the highest rates (40.9%). Among specific biomarkers, PD-1 showed the steepest adoption trajectory (0.08% to 10.59%), followed by EGFR (5.07% to 8.84%) and HER2 (5.16% to 8.17%). Our NLP-based emerging biomarker discovery identified CTLA-4, PSMA, CD19, CD137, and LAG-3 as rapidly emerging eligibility biomarkers reflecting next-generation immunotherapy targets. Cancer-specific analyses revealed dramatic increases in lung (22.8% to 50.5%) and gastric cancers (14.6% to 45.5%), while prostate cancer showed declining rates (60.5% to 52.3%). Our complexity scoring algorithm demonstrated that biomarker-restricted trials have significantly higher eligibility complexity (mean: 50.0 vs 31.0, p$<$0.001). All findings remained robust across multiple sensitivity analyses. **Conclusions:** Biomarker-based eligibility restrictions in oncology trials have increased substantially over 15 years, driven primarily by immune checkpoint and targeted therapy biomarkers. Industry-sponsored and later-phase trials show the highest adoption rates. These scalable ML findings inform precision medicine trial design and highlight considerations for patient access and trial generalizability. Research Sponsor: None.

11020 **Poster Session**

Restrictive eligibility criteria in FDA-approved oncology trials following ASCO Guideline updates. First Author: Ryan Scott Imaikalani Kong, University of Illinois Chicago College of Medicine, Chicago, IL

Background: Despite significant advancements in new targeted and immunotherapies, enrollment in oncology clinical trials remains unrepresentative of real-world patient populations. Overly restrictive eligibility criteria – particularly related to Eastern Cooperative Oncology Group (ECOG) performance, cardiovascular status, HIV status, and prior malignancy – have been identified as key barriers to trial participation and generalizability. In response, the American Society of Clinical Oncology (ASCO) published new guidelines in 2017 lowering thresholds for enrollment. We examined whether these ASCO recommendations translated into measurable changes in eligibility criteria among FDA-approved trials for the five most common solid tumors. **Methods:** Clinical trial data was obtained from ClinicalTrials.gov, FDA Approved Drug Notification Database, and journal manuscripts. The study evaluated clinical trials that led to FDA-approved therapies for NSCLC, breast, melanoma, prostate, and colon cancer between 2006-2025. Eligibility criteria based on Eastern Cooperative Oncology Group (ECOG) performance, cardiovascular status, HIV status, and prior malignancy were extracted. Clinical trials were categorized as pre- or post-ASCO 2017 guideline publication, and t-tests (R v4.3.1) were used to compare exclusion rates between groups and assess alignment with ASCO recommendations. **Results:** Between 2006-2025, there were 167 FDA-approved clinical trials for NSCLC (59), breast (44), melanoma (25), prostate (23), and colon (16) malignancies. The proportion of trials initiated after the 2017 ASCO guidelines was 19 (32.2%) of NSCLC, 12 (27.3%) of Breast, 6 (37.5%) of Colon, 5 (21.7%) of Prostate, and 5 (20.0%) of Melanoma. There was no statistically significant reduction in the usage of restrictive exclusion criteria when comparing trials started before and after the 2017 ASCO recommendations among Colon ($p = 0.953$), Prostate ($p = 0.896$), Melanoma ($p = 0.775$), NSCLC ($p = 0.301$), and Breast ($p = 0.117$) cancer groups regarding ECOG performance, cardiovascular status, HIV status, and prior malignancy. **Conclusions:** Despite the publication of ASCO's 2017 eligibility guideline updates, restrictive exclusion criteria remain prevalent in FDA-approved oncology trials across major solid tumors. These findings suggest that guideline dissemination alone has been insufficient to change trial design practices. More proactive regulatory, sponsor-level, and implementation-focused interventions may be required to ensure broader trial access and improve the generalizability of oncology clinical research. Research Sponsor: None.

Comparative effectiveness and safety of axicabtagene ciloleucel versus lisocabtagene maraleucel in large B-cell lymphoma: A real-world target trial emulation. First Author: Mohammed Zuber, Department of Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, GA

Background: Axicabtagene ciloleucel (axi-cel) and lisocabtagene maraleucel (liso-cel) are approved CD19-directed CAR T-cell therapies for large B-cell lymphoma (LBCL); however, comparative real-world evidence on their effectiveness and safety remains limited. We conducted a target trial emulation to compare the overall survival (OS), event-free survival (EFS), and safety outcomes between axi-cel vs liso-cel in routine clinical practice. **Methods:** Using de-identified electronic health record data from TriNetX (January 2017- December 2025), we emulated a two-arm target trial among adult patients with LBCL who received axi-cel or liso-cel. Index date (T_0) was defined as the date of CAR T-infusion. Patients with active severe infections at the index date or a history of cardiovascular and central nervous system involvement were excluded. Inverse probability of treatment weighting (IPTW) was used to balance the covariates, including age, sex, race, comorbidity, prior autologous stem cell transplantation, bridging therapy, and baseline inflammatory markers. OS was analyzed using IPTW Cox proportional hazards models. Event-free survival (EFS) was defined as a composite of death or initiation of subsequent systemic therapy (as a proxy for treatment failure). Cytokine release syndrome (CRS), and immune effector cell-associated neurotoxicity syndrome (ICANS) were evaluated. Hazard ratios (HRs) and 95% confidence intervals (CIs) were reported, and all analyses were conducted using R. **Results:** Among 1,311 eligible patients, 947 received axi-cel and 364 received liso-cel. In the unweighted cohort, patients treated with axi-cel were younger than those receiving liso-cel (median age 62 vs 72 years), with a similar sex distribution and a predominantly White population in both groups. After IPTW, baseline demographic, clinical, and laboratory characteristics were balanced between groups. OS did not differ significantly between axi-cel and liso-cel (HR 0.98; 95% CI, 0.71-1.36). Median OS was not reached in either group, with similar OS rates at 12 months (axi-cel: 78.1%, liso-cel: 80.3%) and 24 months (axi-cel: 71.3%, liso-cel: 71.4%). EFS was also comparable between treatments (HR 1.08; 95% CI, 0.82–1.44). No significant differences in CRS risk were observed within 90 days or overall follow-up (HR: 0.86; 95% CI, 0.66-1.11). Axi-cel was associated with a higher risk of ICANS within the first 90 days (HR 1.42; 95% CI, 1.00-2.01), although no significant difference was observed over longer follow-up. **Conclusions:** Axi-cel and liso-cel demonstrated comparable effectiveness in terms of OS and EFS. Safety profiles differed primarily in early neurotoxicity risk, while CRS incidence was similar between products. These findings provide real-world comparative evidence that may help to inform CAR T-cell therapy selection in clinical practice. Research Sponsor: None.

AI-enabled clinical trial framework for end-to-end site recommendation and enrollment projection. First Author: Stephen S. Yip, ConcertAI, LLC, Cambridge, MA

Background: Reliable accrual forecasting is essential in oncology trials because delayed enrollment reduces statistical power, increases costs, and prolongs timelines. We developed an AI-enabled framework integrating site recommendations with probabilistic enrollment modeling to support data-driven trial planning. **Methods:** Site-level attributes (Site360) and curated real-world patient datasets (Patient360) were integrated as inputs. Trial objectives including enrollment targets, timelines, sponsor and diversity requirements, and screen failure rates (SFR) were user specified. Candidate sites were ranked using a multi- criteria TOPSIS engine optimized with simulated annealing to identify portfolios meeting protocol requirements. Recommended site attributes informed Monte Carlo enrollment simulations incorporating site activation, patient arrival, and capacity constraints. Each underwent 1000 simulations, generating accrual distributions. Fifty-four CRC, NSCLC, and Breast trials from ClinicalTrials.gov were evaluated. Planned site counts and enrollment intensity (patients per month per planned site; ppmpps) from the same trials served as benchmarks. Enrollment intensity was calculated as enrolled patients divided by (trial duration in months $\times$ planned sites), with duration estimated from trial start to primary completion. Scenarios tested SFR 20%, 40%, and 60%. Model outputs were compared with planned benchmarks using Spearman correlation and summarized with medians and IQR. **Results:** Trials showed heterogeneous planned site counts: CRC median 76 (IQR: 43-119), Breast 204 (114-279), NSCLC 178 (101-227). Model recommended site counts showed moderate to strong rank agreement with planned sites across indications. CRC correlations increased from 0.67 to 0.73 as SFR rose from 20% to 60% (all $p < 0.05$). Breast correlations ranged 0.49-0.54 and NSCLC 0.61-0.63 across SFRs all with $p < 0.05$. Higher SFR required more recommended sites, compensating for screen failures. Predicted ppmpps aligned strongly with benchmarks. For Breast, predicted ppmpps decreased from 0.15 (0.10-0.31) at 20% SFR to 0.07 (0.04-0.16) at 60% SFR versus planned 0.08 (0.03-0.17), with ppmpps correlations 0.82, 0.77, 0.66 respectively (all $p < 0.01$). CRC predicted rates were 0.13 (0.08-0.29), 0.10 (0.07-0.24), 0.07 (0.05-0.18) across SFRs versus planned 0.09 (0.06-0.13), correlations 0.47 ($p = 0.076$), 0.54, 0.59 (both $p < 0.05$). NSCLC showed 0.23 (0.15-0.27), 0.18 (0.13-0.22), 0.12 (0.08-0.18) versus planned 0.12 (0.07-0.19) with correlations 0.54-0.64 ($p < 0.02$). **Conclusions:** This AI-enabled framework integrates optimization and probabilistic modeling to recommend sites and project enrollment behavior. Rank agreement with benchmarks supports improved site feasibility assessment by identifying trials with higher site requirements and enrollment risk and enabling risk-adjusted planning. Research Sponsor: None.

Exploring neural correlates of chemotherapy-induced peripheral neurotoxicity (CIPN) and the impact of exercise: A URCC NCORP nationwide phase II randomized controlled trial (RCT). First Author: Thushini Manuweera, University of Maryland Baltimore, Baltimore, MD

Background: More than half of patients with cancer receiving neurotoxic chemotherapy (e.g., taxane, platinum, vinca alkaloid) develop CIPN, a dose-limiting, sometimes-debilitating condition characterized by numbness, tingling, and pain in the hands and feet. There are limited treatment options for CIPN partly due to limited understanding of CIPN pathophysiology. **Methods:** We conducted a phase II RCT examining the effect of exercise on CIPN via URCC NCORP Research Base. Patients who received neurotoxic chemotherapy within the past 9 months and report CIPN symptoms (rated $\geq$4 out of 10 at its worst in the past 2 weeks) were randomized 1:1 to usual care (UC) or virtually delivered Exercise for Cancer Patients (vEXCAP). vEXCAP is a 6-week personalized walking and resistance band exercise intervention. As part of our secondary aims, we investigated (1) whether CIPN symptoms are exacerbated by impairments in the brain's descending pain modulation circuitry—quantified by functional connectivity between the dorsolateral prefrontal cortex (DLPFC) and 23 sensory-related brain regions—and (2) whether exercise can improve both CIPN and brain functional connectivity. We recruited 35 patients from 7 community oncology practices spanning 6 US states. Sensory CIPN severity was assessed using the patient-reported EORTC QLQ-CIPN20 sensory subscale and functional brain connectivity was measured via magnetic resonance imaging (MRI) at pre- and post-intervention. **Results:** An ANCOVA showed that exercise, compared to UC, reduced sensory CIPN severity (-7.66 ± 3.05 (MCID is 4), effect size (ES) = -0.43, $p = 0.158$) ($N = 35$, 57 ± 10 yrs, 89% female, 60% breast cancer). At pre-intervention, correlation analysis revealed sensory CIPN severity was negatively correlated with functional connectivity between the left DLPFC and several brain areas, including the left anterior insula ($r = -0.53$, $p = 0.001$), left thalamus ($r = -0.44$, $p = 0.009$), and left precuneus ($r = -0.32$, $p = 0.057$). Participants who showed a decrease in sensory CIPN severity at post intervention had an increase in functional connectivity between the left DLPFC and left precuneus ($r = -0.25$, $p = 0.152$), and this increase in connectivity was greater in vEXCAP group (effect size (ES) = 0.2, $p = 0.460$). **Conclusions:** The association of sensory CIPN severity with lower brain connectivity with the left DLPFC may reflect impairment of descending pain inhibition pathways in the brain. vEXCAP may improve brain connectivity with the precuneus while lowering CIPN symptom severity. We believe that this line of research will ultimately inform better CIPN biomarkers and treatments. Funded by NCI UG1CA189956, UG1CA189861, UG1CA189805, UG1CA189961, K07CA221931, and R21CA256154. Trends and characteristics of clinical trials presented in ASCO plenary sessions (2011–2025). First Author: Oliver Overheu, Fuqua School of Business, Duke University, Durham, NC

Background: Clinical trials presented during the ASCO Annual Meeting Plenary Session (PS) represent a curated subset with high scientific and clinical impact. However, characteristics associated with PS selection and their evolution have not been comprehensively described. This study evaluates trends and trial-, sponsor-, and presenter-related characteristics of trials in PS. **Methods:** Trials presented in PS from 2011–2025 were analyzed. Extracted variables included tumor type, therapeutic modality, disease setting, sponsorship, primary endpoint, effect size, geographic scope, and presenter sex and affiliation. Associations between variables were evaluated using chi-square, and multivariable logistic regression analyses. Temporal trends were assessed using Cochran-Armitage trend test. Results were considered significant at α = 0.05. **Results:** From 2011–2025, 60 trials were presented in ASCO PS. The majority evaluated therapies for solid tumors (90%). Most common therapeutic modalities were immune checkpoint inhibitors (18%), chemotherapy (16%), and hormone therapy (13%). Most trials were conducted in the palliative (46%), followed by adjuvant setting (25%). Only 9 trials (15%) included pediatric patients. Overall, 85% of trials met their primary endpoint. Overall survival (OS), progression-free, and disease-free survival were the most used primary endpoints, with surrogate endpoints increasingly represented over time compared with OS ($p < 0.001$). One trial used quality of life (QoL) as primary endpoint. Mean hazard ratio was 0.68 $\pm$ 0.24. Industry-sponsored (Ind) studies accounted for 52% of PS presentations, with four sponsors responsible for 61% of Ind trials. The proportion of Ind trials significantly increased over time (p = 0.03). Ind was significantly associated with meeting the primary (p = 0.048) and use of surrogate endpoints (p = 0.008), remaining an independent predictor of both in multivariable regression (p = 0.035, β = 0.318; p = 0.033, β = 0.333). Most studies were conducted globally (61%), 12% exclusively in the United States (US), followed by Europe (10%). Among presenters, 23% were female, with female representation not changing over time. Most presenters were affiliated with institutions in the US (62%), followed by the United Kingdom (7%). In multivariable regression analysis, Ind was associated with lower odds of a female presenter (p = 0.039; β = -0.342). **Conclusions:** Over the past 15 years, ASCO PS have predominantly featured global, Ind trials in solid tumors, with an increasing reliance on surrogate endpoints. Ind emerged as key factor associated with trial characteristics, including endpoint selection and trial success. Female presenter inclusion, pediatric trials, and QoL endpoints remain underrepresented. These findings provide an overview of evolving trial characteristics and inform discussions on research priorities, trial design, and representation. Research Sponsor: None.

Reducing effort through informatics-driven identification, recruitment, and data capture on a trial to improve adjuvant endocrine therapy adherence. First Author: Ahauve Orusa, Mayo Clinic Rochester, Rochester, MN

Background: Adjuvant endocrine therapy (AET) improves outcomes in HR+ breast cancer. Nonadherence to AET is common, but manual screening for nonadherence is fraught. High-specificity structured cancer electronic health record (EHR) data, particularly if it includes key variables like stage, could streamline these steps for both clinical care and research purposes. We conducted an analysis of approaches to identifying patients as eligible for a multi-site AET adherence study to understand how variation in structured data informatics-supported screening impacts coordinator time. **Methods:** Mayo Clinic implemented a two-step identification: (1) EHR structured data (diagnosis date, stage, ER/PR/HER2 positivity, medication script) to prescreen for eligibility; (2) SureScripts fills to flag nonadherence using proportion of days covered $<$ 80% across early fills. Medical College of Wisconsin (MCW) implemented a more manual screening process for Step 1 using only medication scripts. Coordinators at both sites then conducted a medical record review to assess if the resulting list of patients had a plan to continue AET for at least two additional years. Opt-out clinician permission preceded patient contact; pharmacists delivered a patient reported outcome (PRO)-guided intervention and documented encounters. **Results:** At Mayo, 829 patients were prescreened for study eligibility through informatics workflow; 120 (14.5%) met eligibility criteria. At MCW, 1,763 patients were prescreened; 168 (9.5%) were eligible. EHR filters included non–breast cancer encounters (50% at MCW) and ineligible based on time since cancer (36% at Mayo; 26% at MCW). At Mayo, screening required 5.6 minutes/patient for experienced coordinators. At MCW, experienced coordinators averaged 6.67 minutes/patient and inexperienced coordinators averaged 9.33 minutes/patient. **Conclusions:** Structured EHR data, pharmacy-fill information, and standardized workflows allowed consistent prescreening, intervention and recruitment processes across sites. Higher-specificity informatics-supported screening reduced the percentage of patients requiring manual review and reduced coordinator screening time. It also supported timely provider-permission steps and patient outreach. These workflows were feasible to implement at both institutions, and study enrollment is ongoing. Clinical trial information: NCT06765707. Research Sponsor: National Cancer Institute; R01 CA285925.

Enhancing recruitment of AYAs with Hodgkin lymphoma through community partnerships: Prioritizing diverse populations. First Author: Raymond Mailhot Vega, University of Miami Miller School of Medicine-Sylvester Cancer Center, Miami, FL

Background: Hodgkin lymphoma (HL) is one of the most common cancers affecting adolescents and young adults (AYAs). AYAs with HL aged 15-39 years are a group historically difficult to reach for research participation. Their voice is critical to enhance care. For two funded qualitative studies, the team engaged in and assessed the feasibility of a community-centered approach to recruit HL patients with 1:1 representation by age [those diagnosed as children (0-14), AYAs (15-39), and above 40 years], race and ethnicity (Black and Hispanic communities), and insurance (private, Medicaid, and uninsured populations). **Methods:** Recruitment was conducted exclusively through advocacy partner organizations including Blood Cancer United, Stupid Cancer, Cactus Cancer Society, and Elephants & Tea. Study team patient advocates guided recruitment approach, including selecting imagery using a Black-identifying male and Hispanic-identifying female and rephrasing recruitment material language. Advocacy partners utilized their techniques for engaging AYAs, such as Instagram, website posting, email, and/or attendance at member engagement events. Recruitment to the two studies required the study participants online to 1) complete a survey on REDCap documenting their consent using a waiver and 2) provide confirmation of their HL diagnosis by uploading proof to REDCap (e.g., screenshot from their medical record containing their name, date of birth, and HL diagnosis). **Results:** A total of 389 patients from 46 states or US territories started their REDCap survey and completed the waiver of consent. Of those, 217 (55%) were AYAs at diagnosis and 95 $\geq$40 (24%). Of the total 389, 85 (22%) were Black, 39 (10%) Hispanic, 34 (9%) had Medicaid, and 12 (3%) were uninsured. 154 (40%) provided proof of diagnosis from 38 states. Of the 154 that uploaded proof of HL diagnosis, 123 (80%) were AYA and 26 (17%) $\geq$40 years at diagnosis. 17 (11%) were Black, 21 (14%) Hispanic, 17 (11%) with Medicaid, and 3 (2%) uninsured. Documentation was most commonly provided using an after visit summary or visit note (47%), pathology report (19%), or physician signed letter (13%). **Conclusions:** Partnering with advocacy organizations, particularly those serving AYAs, proved successful in exceeding recruitment goals for AYA patients. Attrition in participation was seen between waiver completion and providing confirmation of diagnosis. AYAs were more likely than adults $\geq$ age 40 to provide proof of confirmation of diagnosis. Recruitment met national averages for Black representation, but fell short with lower than national average estimates for representation of Hispanic survivors, those on Medicaid or uninsured. Future studies should engage underrepresented populations during the research process to understand how to plan recruitment activities in a way that prioritizes what is most important and impactful for the target population. Quantifying the impact of protocol design on enrollment and dropout rates in breast cancer clinical trials. First Author: Evon Okidi, Medidata Solutions, a Dassault Systèmes Company, New York, NY

Background: Clinical trial enrollment can sometimes fail due to protocol design being overly complex, including procedures that are overly burdensome on patients and/or trial sites. Procedures that may be more logistically challenging or introduce higher risk (ex: radiation exposure in imaging procedures) can affect trial enrollment and patient retention. To better understand factors that optimize operational design of protocols, we evaluated breast cancer protocols to assess and quantify procedures that had the highest potential impact on enrollment and dropout rates. Objective: Our objective is to develop an algorithm that can predict enrollment and dropout rates by analyzing the procedures and procedure frequency included in protocol design. **Methods:** 42 breast cancer protocols (sourced from aggregated, anonymized Medidata Clinical Cloud data) from closed clinical trials conducted between 2010-2023 were utilized to train a predictive model. The model leveraged the procedure and schedule-of-activity data to capture the frequency of protocol-specified procedures as input features, and enrollment and dropout rates as outcome features. Model performance was assessed utilizing cross-validation. To assess the relative impact of individual procedures or groups of procedures on a protocol, a sensitivity analysis was performed by increasing each procedure's frequency by 1 unit while holding all other variables constant and measuring the resulting percent change in predicted enrollment and dropout rates. **Results:** Analysis of selected protocols demonstrated that inclusion of Positron Emission Tomography (PET) Imaging was associated with a 10-23% reduction in enrollment rates. Genetic testing and analysis procedures were associated with enrollment rate decreases of up to 5%. In contrast, bone density imaging, abdominal and pelvic imaging, and increased tumor and biopsy procedures were associated with enrollment increase of up to 6%. With respect to retention, increased cardiac rhythm monitoring was associated with up to 10% reduction in dropout rates, while blood cell analysis, collagen biomarker testing, and quality of life questionnaires were each associated with dropout reductions of up to 8%, 8% and 5% respectively. **Conclusions:** Procedure requirements and frequency had a measurable impact on clinical trial enrollment and retention. Some procedures, such as PET scans, were associated with reduced enrollment; whereas other clinically relevant imaging procedures (i.e., DEXA bone density imaging, CT/MRI abdominal and pelvic imaging) and other tumor-related procedures, monitoring, and assessments were associated with improved enrollment and/or reduced dropout. These findings highlight opportunities to optimize protocol design by prioritizing procedures that improve the likelihood of recruitment and retention. Research Sponsor: None.

Assessing site-central baseline imaging discordance in oncology clinical trials. First Author: Danielle Phillippi, Clario, Philadelphia, PA

Background: Eligibility determination is a critical and rate-limiting step in oncology clinical trials and directly influences endpoint interpretability. Across oncology indications, eligibility frequently depends on prespecified imaging criteria that function as binary gatekeepers to enrollment, with blinded independent central review (BICR) commonly used to standardize image interpretation. In many solid tumor trials using RECIST 1.1, participants must demonstrate measurable disease; in many lymphoma trials using Lugano criteria, FDG-avid disease is required; and in prostate cancer trials using PCWG3 criteria, the presence of a bone scan superscan is typically exclusionary. Often participant eligibility is established by site investigators, while BICR radiologists independently assess baseline and on-study imaging without determining enrollment, creating potential site–central discordance at baseline. We hypothesized that baseline imaging discordance exists between site and BICR and evaluated its frequency and potential relevance to clinical trial endpoint interpretation. **Methods:** We performed a preliminary analysis of 17,104 baseline BICR reviews among enrolled participants evaluated using RECIST 1.1 requiring measurable disease (n = 7,189), Lugano criteria requiring FDG-avid disease (n = 2,653), and PCWG3 (n = 7,262) criteria. **Results:** For the RECIST 1.1 subset, BICR determined that 11.0% (n = 791) of enrolled participants lacked measurable disease at baseline. Among these participants, subsequent responses included CR (n = 36), PD (n = 93), and SD (n = 207). Because partial response under RECIST 1.1 requires measurable target lesions, participants without measurable disease are inherently constrained in the spectrum of evaluable responses, potentially biasing response rate. For the Lugano subset, BICR determined that 1.5% (n = 41) of enrolled participants lacked FDG-avid disease at baseline, with subsequent anatomic-only responses of CR (n = 1), PR (n = 5), SD (n = 9), and PD (n = 2). Though infrequent, site-central differences under Lugano criteria may influence response assessment, as BICR evaluated anatomic change while site incorporates metabolic response. For the PCWG3 subset, 7.0% (n = 548) of enrolled participants demonstrated a baseline superscan by BICR, with subsequent responses of CR (n = 20), PR (n = 25), SD (n = 90), and PD (n = 91). In these cases, response assessment is largely limited to soft tissue disease. **Conclusions:** The observed site-central imaging discordance reflects differences between eligibility and imaging assessments rather than incorrect site enrollment decisions and is not uncommon across major oncology response criteria, with potential implications for efficacy assessment in trials where eligibility is site-determined but response is centrally adjudicated. This analysis supports further investigation incorporating additional criterion-specific analysis. Research Sponsor: None.

Temporal trends in pregnancy-associated cancer mortality in the United States: A national analysis 2018-2023. First Author: Diya Jayram, University of Miami, Miami, FL

Background: Cancer during pregnancy is rare but increasing due to rising rates of early-onset cancers and more parents delaying childbearing to older ages. Cancer treatment during pregnancy is complex, as capacity to deliver timely, multimodality anti-cancer treatment may be limited by risk of fetal compromise. As pregnancy-associated cancer is an increasingly recognized contributor to maternal mortality, this study sought to evaluate national temporal trends. **Methods:** Using CDC WONDER Multiple Cause of Death files (2018–2023), pregnancy-associated deaths involving malignant neoplasms (ICD-10 C00–C97) were identified. Age-adjusted mortality rates (AAMR) per 100,000 live births and annual percent changes (APCs) were calculated, excluding unknown race, ethnicity, or age. AAMR was evaluated by state, including comparison of 1) states with trigger laws banning abortion in 2022 vs states that did not have such laws and 2) states that expanded Medicaid by 2018 vs states that did not. Mortality data for locations with $<$10 deaths is censored. **Results:** From 2018–2023, there were 723 pregnancy-associated deaths in people with cancer. Most (72%) were in White patients and occurred in the late postpartum period (59%) (42-365 days after birth). Only 19% of patients had documented metastatic cancer. Overall AAMR was 3.40 (95%CI 3.16–3.65); it was highest among Black patients (4.54), exceeding White (3.24), Hispanic (3.08), and AIAN/AAPI (2.64) mortality. Breast (n=162, AAMR 0.76 95%CI 0.65-0.88) had the greatest cancer-specific mortality burden, followed by hematological malignancies (n=101, AAMR 0.48, 95% CI 0.38-0.57) and colorectal cancer (n=71, AAMR 0.12, 95%CI 0.088-0.15). AAMR for those with metastatic disease was 0.64 and increased over time (APC +7.54%; 95%CI 1.52–14.55; p=0.009). Late maternal deaths also rose (APC +4.75%; 95% CI 0.99–8.87; p=0.006). Otherwise, overall (APC $-$0.37%, 95%CI -0.37-4.30, p=0.83) and race/ethnicity specific pregnancy-associated cancer mortality have not significantly changed over time. Among 25 states with $\geq$10 deaths, state-level mortality ranged from 1.37 in California to 6.95 in Virginia. Limited state comparative analysis found that AAMR for pregnancy-associated cancer was higher in states with trigger laws (4.43) compared to non-trigger states (3.22); it was also higher in non-Expansion states (4.00) compared to states that expanded Medicaid (3.31). **Conclusions:** Despite known improvements in cancer mortality, pregnancy-associated cancer mortality remains stagnant, with notable mortality rises in pregnant patients with metastatic disease and late postpartum deaths. The large variability in state-level mortality may reflect state policies that affect access to prenatal or oncological care. More research and advocacy work to optimize care for pregnancy patients with cancer is essential to improve outcomes for this vulnerable population. Research Sponsor: None.

Fair inclusion in clinical trials: Updated Good Pharma Scorecard evaluations of FDA oncology drugs approved by the FDA, 2018-2023. First Author: Tanvee Varma, Brigham and Women's Hospital, Boston, MA

Background: Adequate representation of demographic subgroups in clinical trials is essential for understanding the safety and efficacy of novel therapies. We previously developed and piloted the "fair inclusion" measure, which assesses (1) transparency in participant demographics and (2) demographic representation. These metrics were incorporated into the Good Pharma Scorecard, a system evaluating pharmaceutical company performance in bioethics and social responsibility, with sponsors ranked by fair inclusion scores. However, it remains unclear whether sponsors have improved fair inclusion of women, older adults, and racial and ethnic minorities in pivotal trials since the most recent Scorecard. **Methods:** For transparency, we assessed 6 measures [whether the number of (1) women, (2) older adults, (4) Black, (5) Asian, and (6) Latinx participants were publicly reported], and for representation, 5 measures [whether the proportion of enrolled (1) women, (2) older adults, (3) Black, (4) Asian, and (5) Latinx represents $>$80% of the US population with the studied condition]. Fair inclusion scores averaged transparency and representation, overall and by subgroup. Results were reported at the trial, product, and sponsor levels and compared across 2012–2017 vs 2018–2023 approvals. Data sources included Drugs@FDA, ClinicalTrials.gov, publications, US Cancer Statistics, and the American Cancer Society. **Results:** Between January 1, 2018 and December 31, 2023, the FDA approved 75 oncology therapeutics based on 80 pivotal trials from 52 sponsors. At the sponsor level, transparency improved for older adults (2012–2017: 78%, 2018–2023: 95%, p = 0.002) and racial and ethnic minorities (67% vs 91%, p = 0.003). Representation did not improve for women (94% vs 94%, p = 0.99), older adults (85% vs 81%, p = 0.29), or racial and ethnic minorities (75% vs 67%, p = 0.13). Fair inclusion scores improved modestly (81% vs 86%; p = 0.04). **Conclusions:** Sponsors have improved demographic reporting, particularly for older adults and racial and ethnic minorities. However, representation has not improved for any subgroup. Overall gains in fair inclusion were driven by transparency. Research Sponsor: None.

Comparison of mean sponsor scores on transparency, representation, and fair inclusion for 2012-2017 vs 2018-2023 oncology FDA approvals, by sex, age, race and ethnicity.

	2012-2017 Scores (n = 25)	2018-2023 Scores (n = 52)	p-value
Women			
Transparency	96%	99%	0.32
Representation	94%	94%	0.99
Fair Inclusion	97%	95%	0.28
Older Adults			
Transparency	78%	95%	$<$ 0.01
Representation	85%	81%	0.29
Fair Inclusion	79%	86%	0.07
Race and Ethnicity			
Transparency	67%	91%	$<$ 0.01
Representation	75%	67%	0.13

Insurance and cost-related access barriers to specialty oral anticancer medications for blood cancers in a nationwide sample of Medicare and commercially insured patients. First Author: Jalpa A. Doshi, University of Pennsylvania, Philadelphia, PA

Background: Specialty oral anticancer medications improve survival across blood cancers but may have access challenges. This study examined approval and fill rates of specialty oral anticancer medication prescriptions indicated for blood cancers in a nationwide sample of Medicare and commercially insured patients. **Methods:** Using nationwide claims (Symphony Health Solutions Integrated Dataverse), we identified patients with $\geq$1 new specialty oral anticancer medication prescription during 2022. Outcomes were measured for the initial prescription as well as any prescription for the same drug within 90 days and were classified as: (i) rejected by insurer, (ii) approved by insurer but not filled by patient, or (iii) approved by insurer and filled by patient. Among rejected prescriptions, we examined rejection reasons, eventual approval rates, and time to approval. Among approved prescriptions, we compared fill rates across out-of-pocket cost levels. Adjusted outcomes were estimated using multivariable logistic regressions. **Results:** The study included 12,134 patients (61.0% Medicare, 39.0% commercial) with a specialty oral anticancer medication prescription. Initially, very few prescriptions were both approved and filled (9.6%, Medicare; 4.0%, commercial). Insurers initially rejected most prescriptions (64.9% for Medicare; 84.0% for commercial), frequently due to prior authorization or formulary restrictions. By 90 days, approval rates rose to 85.0% (Medicare) and 62.9% (commercial), but many approved prescriptions were never filled; ultimately, only 54.5% of Medicare patients and 45.5% of commercial patients both received insurer approval and filled their prescription. Fill rates dropped sharply when out-of-pocket costs exceeded $175 per SOAM prescription. When out-of-pocket costs exceeded $2,000 per prescription, only 31.9% of Medicare patients and 26.9% of commercial patients filled their prescriptions. Adjusted rates were similar to unadjusted rates. **Conclusions:** This study found substantial access barriers to specialty oral anticancer medications for blood cancer, particularly among commercially insured patients. Even after insurer approval, many patients never filled their prescription. This highlights the importance of addressing both payer-level restrictions and patient-level affordability challenges to ensure treatment access. Research Sponsor: Leukemia & Lymphoma Society (LLS).

Trends in cancer drug revenue retained by providers under buy-and-bill reimbursement, 2010-2024. First Author: Aaron Philip Mitchell, Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Cancer care providers, including physician offices and hospitals, retain "markup" fees on clinician-administered drugs (such as chemotherapies and immunotherapies) which are proportional to drug price. Under this system, commonly known as "buy and bill," multiple external factors may impact provider revenue: increasing cancer drug prices, increasing care delivery in hospitals (where markups are higher) rather than offices, the 340B Drug Pricing Program, and payer "bagging" strategies to avoid paying markups to providers. Study goals were to estimate changes in provider revenue retained on clinician-administered cancer drugs from 2010-2024 and to quantify the contribution of four factors: 1) cancer drug sales, 2) site of care (office vs. hospital), 3) 340B participation, and 4) payer "bagging" strategies. **Methods:** We included all clinician-administered cancer drugs with available US sales data, including biosimilars and cancer-specific supportive care drugs (e.g., growth factors). We obtained cancer drug sales from manufacturer SEC filings (aggregated in SSR Health data), inflated to 2024 USD. We estimated the proportion of cancer drug sales administered within each of nine payer-care settings (three major payers: Medicare, Medicaid, commercial, and three major sites of care: physician office, 340B-participating hospital outpatient, and non-340B hospital outpatient), using Surveillance, Epidemiology, and End Results (SEER), the National Health Interview Survey (NHIS), and CMS and commercial claims. To estimate markup revenue, we applied setting-specific markup rates (from statute for Medicare/Medicaid, from peer-reviewed literature for commercial) to the drug sales in each setting. Plausible estimates of "bagging" prevalence were obtained from the literature. **Results:** Cancer drug sales increased from $27.3 billion (B) in 2010 to $64.9B in 2024, a 138% increase. Provider markup revenue on cancer drugs increased from $8.7B in 2010 to $35.7B in 2024, a 309% increase. Of the 2010-2024 increase, increasing drug sales accounted for 73.3%, shifting site-of-care to hospitals for 24.2%, and 340B participation growth for 2.5%. During this period, drug revenue retained by physician offices increased by 30%, non-340B hospitals by 49%, and 340B-participating hospitals by 739%. Accounting for bagging reduced 2024 markup revenue from $35.7B to $28.4B. **Conclusions:** Provider revenue from cancer drug markups grew substantially during 2010-2024. The largest single factor was growing cancer drug sales, although shifts in site of care also contributed. Revenue retained by 340B-participating hospitals increased much more than offices or other hospitals. Growth in provider markups was reduced modestly by growth in payer bagging strategies. Policymakers should consider whether growing markups on clinician-administered drugs reflects an efficient use of healthcare spending. Research Sponsor: National Institute of Health Care Management.

Association of Medicaid expansion with pre-diagnosis coverage continuity and 2-year overall survival in pediatric patients with blood cancer. First Author: Rebecca Williamson Lewis, Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta, Atlanta, GA

Background: Continuous insurance coverage is critical for timely cancer diagnosis and treatment, yet many patients gain Medicaid only around the time of diagnosis. Although the Affordable Care Act Medicaid expansion targeted adults, it may indirectly influence children via a "welcome mat" effect by increasing outreach and boosting uptake among families with eligible children. The extent to which state expansion status influences Medicaid coverage continuity and survival among Medicaid-insured children with blood cancers—conditions lacking routine screening and often with acute presentation—remains unclear. **Methods:** Using linked SEER-Medicaid data, we identified 7,536 patients age ≤21 newly diagnosed with leukemia or lymphoma between 2009-2019 who had ≥1 month of Medicaid enrollment from 12 months pre-diagnosis through two months post-diagnosis. Coverage patterns were categorized as: 1) continuous Medicaid (12-13 months enrolled pre-/peri-diagnosis), 2) newly gained Medicaid (enrollment starting at diagnosis or within two months post-diagnosis), and 3) other coverage patterns. Difference-in-differences (DD) models compared post- vs. pre-expansion changes in coverage patterns and 2-year overall survival in 11 SEER expansion states vs. four non-expansion states, adjusting for sociodemographic factors. Survival models additionally adjusted for coverage patterns to assess the extent to which the patterns accounted for expansion-associated survival changes. **Results:** The percentage with continuous Medicaid increased more in expansion states (52.9% to 67.5%) than non-expansion states (41.5% to 50.8%), leading to a net increase of 8.2 percentage points (ppts; 95% CI = 2.3 to 14.2; p= 0.007) in adjusted DD model. The percentage with newly gained Medicaid decreased more in expansion states (24.6% to 14.2%) than non-expansion states (31.8% to 24.5%), resulting in a net reduction of 7.9 ppts (95% CI = -13.9 to -1.9; p= 0.010). No significant changes were observed post-expansion for other coverage patterns. Two-year overall survival increased in expansion states (85.7% to 86.9%) but declined in non-expansion states (87.7% to 82.9%), yielding a net increase of 6.2 ppt (95% CI = 2.8 to 9.6; $p<$ 0.001) in adjusted DD model. This association was slightly attenuated after further adjusting for coverage patterns (DD = 5.9 ppts; 95% CI = 2.5 to 9.3; $p<$ 0.001), suggesting coverage continuity accounted for approximately 4.9% of the expansion-associated gain in 2-year survival. **Conclusions:** Medicaid expansion was associated with improved coverage continuity pre-/peri-diagnosis and better early survival among Medicaid-insured children with leukemia or lymphoma. Amid ongoing Medicaid policy changes, these findings add evidence that stable coverage matters for vulnerable children. Future work will evaluate longer-term outcomes (e.g., 5-year survival). Research Sponsor: Blood Cancer United, Equity-in-Access Program; HSRP9015-23.

Association between low muscle mass assessed by bioelectrical impedance analysis and clinical outcomes in hospitalized cancer patients. First Author: Diogo Toledo, Albert Einstein Israeli Hospital, São Paulo, SP, Brazil

Background: Low muscle mass is an independent prognostic marker associated with increased clinical risk, functional impairment, and mortality in patients with cancer. Conventional indicators such as body mass index (BMI) may fail to identify individuals at nutritional and functional risk. Bioelectrical impedance analysis (BIA) offers a feasible bedside method for body composition assessment, particularly in resource-constrained hospital settings. This study aimed to evaluate body composition using BIA, determine the prevalence of low muscle mass, and examine its association with clinical, laboratory, and functional parameters in hospitalized oncology patients. **Methods:** This observational study included 104 adult cancer patients admitted to a tertiary public hospital between January and October 2025. Baseline assessments at hospital admission included BMI, skeletal muscle mass index (SMI), appendicular muscle index, phase angle, fat mass percentage, handgrip strength (HGS), calf circumference (CC), urea-to-creatinine ratio, length of hospital stay, and in-hospital outcome (discharge or death). Low muscle mass was defined according to established cutoffs for SMI and appendicular muscle index. Comparisons were performed between patients with and without low muscle mass, and correlations between appendicular muscle index and functional and nutritional parameters were analyzed. **Results:** Low muscle mass was identified in 29.8% of patients at admission. Compared with patients without low muscle mass, those affected had significantly lower BMI (23.3 vs 27.6 kg/m², p=0.001), appendicular muscle index (6.20 vs 7.61, p<0.001), phase angle (3.6° vs 5.1°, p<0.001), total muscle mass (25.1 vs 29.4 kg, p<0.001), HGS (30.0 vs 37.0 kgf, p=0.041), and CC (32.5 vs 37.0 cm, p<0.001). Length of hospital stay did not differ significantly between groups. In-hospital mortality was higher among patients with low muscle mass (18.5% vs 7.0%), although this difference did not reach statistical significance (p=0.133). Appendicular muscle index showed moderate to strong positive correlations with BMI, phase angle, HGS, CC, and SMI. **Conclusions:** BIA proved to be a feasible and informative tool for identifying low muscle mass and functional impairment in hospitalized cancer patients. Appendicular muscle index and SMI were superior to BMI in detecting patients at increased nutritional and functional risk. Given its low cost and bedside applicability, BIA represents a valuable strategy for early risk stratification and supportive care planning in resource-limited oncology settings. Longitudinal changes in coping among early phase cancer clinical trial (EPCT) participants. First Author: Anh B. Lam, The University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: EPCT participants use varying strategies to cope with uncertainty related to their cancer, treatment, and prognosis. However, little is known about how coping strategies change over time among EPCT participants and how longitudinal changes correlate with patient-reported outcomes (PROs) and clinical outcomes. **Methods:** We prospectively enrolled adults with cancer participating in EPCTs at Massachusetts General Hospital from 4/2021-1/2023. Participants completed monthly PROs assessing coping strategies (Brief COPE), symptoms (Edmonton Symptom Assessment System [ESAS]), quality of life (QOL; Functional Assessment of Cancer Therapy General), hope (Herth Hope Index), and financial wellbeing (COST tool). We used regression models to assess associations of baseline (B/L) PROs with changes in coping scores over time (B/L to month 1 [M1] and B/L to month 2 [M2]). We also explored how changes in coping predicted clinical outcomes (time on trial [ToT], overall survival [OS]). **Results:** We enrolled 195 of 251 eligible patients (78% enrollment), and 188 completed the B/L surveys (96% response, median age=63 [range: 32-89], 56% female, most common cancer types: gastrointestinal [34%] and breast [21%]). Higher B/L QOL predicted decreased behavioral disengagement coping at M1 (B=-0.01, p=.037) & M2 (B=-0.02, p=.001) and self-blame at M2 (B=-0.02, p=.038), as well as increased emotional support (B=0.22, p=.001) and religion (B=0.02, p=.024) coping at M1. Higher B/L ESAS symptoms predicted decreased use of emotional support coping at M1 (B=-0.01, p=.048). Higher B/L ESAS physical symptoms predicted decreased use of emotional support at M1 (B=-0.02, p=.046) & M2 (B=-0.03, p=.016). Higher B/L psychological symptoms predicted increased use of self-blame at M2 (B=0.08, p=.007). Higher B/L financial wellbeing predicted increased emotional support at M1 (B=0.02, p=.025). Higher B/L hope predicted increased positive reframing at M1 (B=0.07, p=.010) and religion coping at M2 (B=0.05, p=.038) as well as decreased behavioral disengagement at M1 (B=-0.04, p=.001) & M2 (B=-0.06, p=.001). For clinical outcomes, increased acceptance (HR=0.85, p=.028) and religion (HR=0.85, p=.016) coping at M1 and increased positive reframing (HR=0.84, p=.010) at M2 predicted longer ToT. Increased use of behavioral disengagement at M1 predicted shorter ToT (HR=1.42, p=.002). Increased use of positive reframing (HR=0.83, p=.009) and self-blame (HR=0.78, p=.012) coping at M1 predicted better OS; increased use of behavioral disengagement (HR=1.41, p=.007) predicted worse OS. **Conclusions:** In this longitudinal cohort study, EPCT participants' B/L PROs correlated with changes in their coping over time. We also found longitudinal changes in coping predicted ToT and OS. These findings highlight opportunities to enhance care delivery and outcomes for EPCT participants by addressing their PROs and coping behavior over time. Research Sponsor: None.

The association of baseline fatigue and severe cancer treatment toxicity by comorbid conditions: A pooled analysis. First Author: Michael M. Caplan, Herbert Irving Comprehensive Cancer Center, Columbia University Irving Medical Center, New York, NY

Background: Fatigue is commonly reported by patients with cancer. Patients who report fatigue are at greater risk of severe adverse events during treatment. However, it is unknown whether the relationship between baseline fatigue and toxicity risk persists after accounting for comorbid conditions. **Methods:** Data from 6 SWOG phase 2/3 clinical trials in advanced cancer (1999 to 2018) were pooled. Baseline fatigue (classified by 5-point Likert scale) was analyzed as any vs none. Patients were linked to Medicare claims by SSN, date of birth, and sex to identify comorbidities at study registration. Adverse events (AEs) were classified using the Common Terminology Criteria for Adverse Events. The primary outcome was severe (≥ grade 3) events. Odds ratios (ORs) were calculated using generalized estimating equations, clustered by study, and adjusted for age, sex, race, and obesity. Interaction tests between fatigue and each comorbidity were examined. **Results:** Among 1195 patients (median age, 73; 13.1% female; 11.8% Black; 74% prostate cancer), 629 (52.6%) had ≥1 severe AE. Among patients with ≥1 comorbid condition, those with any fatigue had a 132% (OR=2.32, 95% CI, 1.26-4.27, p=.007) increased risk of having severe AEs; among patients with no comorbidities, the association was nearly identical (OR=2.33, 95% CI, 1.51-3.60, p<.001; p-interaction=.97). Those with any fatigue had a twofold or greater risk of severe AEs across all comorbidities (Table). The association between fatigue and severe toxicity was greater for those with anemia (interaction p=.03) and those with depression (interaction p=.02). **Conclusions:** The association between baseline fatigue and severe treatment toxicity persisted after accounting for comorbid conditions, indicating baseline fatigue is an independent risk factor. The association was stronger among patients with anemia and those with depression, suggesting these conditions may amplify the risk of baseline fatigue. These findings support early identification of baseline fatigue and targeted supportive interventions for these high-risk populations. Research Sponsor: None.

Decline in credit score and excess mortality risk among cancer patients: Evidence from Washington State. First Author: Scott David Ramsey, Fred Hutch Cancer Center, Seattle, WA

Background: Patients experiencing bankruptcy following a cancer diagnosis have been shown to have increased mortality, but few studies have evaluated the impact of other types of financial hardships on mortality risk. We conducted an analysis to understand the relationship between a drop in credit score, a marker of less severe types of financial strain, and mortality among cancer patients in Washington State. **Methods:** We linked records from cancer patients (age 18+) diagnosed with any cancer (except in situ) between 2010 - 2023 from the Western Washington SEER cancer registry to credit report data from a national credit reporting agency. We excluded patients without a valid credit score near diagnosis (±100 days). In a Cox proportional hazards model using a landmark approach, we examined the relationship between a drop in credit score (25-49, 50-99, or 100+ points) in the first year of diagnosis and subsequent mortality after year 1, using no- or low-drop (<25 points) as the reference. Hazard ratios (HRs) and 95% confidence intervals were derived. Model covariates included age, gender, race/ethnicity, marital status, Area Deprivation Index, urban/rural residence, diagnosis year, cancer type, stage, and credit score at diagnosis. **Results:** Among 212,898 evaluable patients [49% male, 84% white, median age 65 (IQR 56 - 73)], credit scores at diagnosis were: 42% excellent (800-850), 25% very good (740-799), 15% good (670-739), 12% fair (580-669), and 6% poor (300-579). In the year following diagnosis, 40,078 patients' credit scores fell ≥25 points (18.8%), including 21,716 falling 25-49 points (10.2%), 12,954 falling 50-99 points (6.1%), and 5,408 falling ≥100 points (2.5%). Among all cancers combined, patients experiencing 50-99 point and ≥100 point reductions (but not 25-49 point reductions) in credit scores had excess mortality (Table). Excess risk of death was observed for nearly all individual cancer types at the ≥100-point reduction level except kidney. **Conclusions:** In this retrospective study, a substantial reduction in credit scores, typically reflecting the experience of adverse financial events, was associated excess mortality compared to those with stable credit scores. Future studies are needed to understand the mechanisms of the relationship. Research Sponsor: National Cancer Institute; R01CA274541; IRONMAN Foundation.

Excess risk of death following a post-diagnosis fall in credit score (vs no/low reduction).

Cost-effectiveness analysis of teclistamab plus daratumumab in relapsed or refractory multiple myeloma. First Author: Wing Fai Li, Department of Medicine, Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY

Background: Relapsed or refractory multiple myeloma (RRMM) remains a significant therapeutic and economic challenge as patients progress through successive lines of therapy. Teclistamab, a CD3×B-cell maturation antigen (BCMA) bispecific antibody, has demonstrated deep and durable responses in heavily pretreated patients in the phase 1–2 MajesTEC-1 trial. Daratumumab, an anti-CD38 monoclonal antibody, is a cornerstone of modern myeloma treatment. The phase 3 MajesTEC-3 trial evaluated teclistamab plus daratumumab versus daratumumab-based regimens, including daratumumab with pomalidomide and dexamethasone (DPd) or with bortezomib and dexamethasone (DVd) in patients with RRMM. While teclistamab-based combinations have demonstrated strong clinical efficacy, their economic value relative to standard daratumumab-based regimens remains uncertain. **Methods:** We extracted event-free survival (EFS) and overall survival (OS) data from published Kaplan–Meier curves and reconstructed individual patient data using a validated algorithm (IPDfromKM). A Markov model was developed to compare lifetime costs and health outcomes between treatment strategies. Model inputs were obtained from the Centers for Medicare & Medicaid Services, the Medicare Physician Fee Schedule, and published literature. Health state utilities, adverse event rates, treatment discontinuation probabilities, and toxicity costs were derived from the MajesTEC-3 trial and peer-reviewed sources. Analyses were conducted from a U.S. third-party payer perspective, with costs reported in 2025 U.S. dollars. Cost-effectiveness was assessed using incremental cost-effectiveness ratios (ICERs) with a $150,000/QALY willingness-to-pay (WTP) threshold, and robustness was examined through one-way and probabilistic sensitivity analyses. **Results:** Gompertz and lognormal distributions were selected based on Akaike Information Criterion to extrapolate EFS and OS for the teclistamab–daratumumab and DPd/DVd arms, respectively. Using a Markov model, teclistamab plus daratumumab yielded an incremental gain of 1.16 QALYs compared with DPd/DVd, at an additional cost of $95,376, resulting in an ICER of $82,074 per QALY, well below the WTP threshold. Probabilistic sensitivity analysis showed that 88.9% of simulations favored teclistamab plus daratumumab at the $150,000/QALY threshold. Treatment discontinuation rates and the cost of daratumumab in the DVd regimen were the primary drivers of ICER estimates. **Conclusions:** From a U.S. payer perspective, teclistamab plus daratumumab is cost-effective compared with DPd or DVd in patients with RRMM, supporting its broader adoption in clinical settings. Association of baseline clinical factors and treatment-related variables with survival in phase I solid tumor trials. First Author: Jonathan Boiarsky, UCLA Division of Hematology-Oncology, Santa Monica, CA

Background: Phase I trials in solid oncology increasingly use biomarker-based enrollment and evaluate diverse therapeutic mechanisms. However, outcomes among patients with advanced solid tumors remain heterogeneous, and the relative contribution of baseline patient factors versus treatment-related variables to survival is incompletely defined. **Methods:** We conducted a retrospective analysis of patients with advanced solid tumors treated on Phase I clinical trials in UCLA's Drug Development Program between Jan 2013 and Sept 2025. Outcomes included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). Survival was estimated using the Kaplan–Meier method. Multivariable Cox proportional hazards models identified factors independently associated with OS, adjusting for clinical variables, treatment characteristics (including combination vs monotherapy, mechanism of action [MOA] of study therapy, and participation in biomarker-selected trials vs unselected patients), and baseline laboratory values. **Results:** 726 patients were included across 106 trials. ORR was 13.3%, and DCR was 61.7%. Median PFS was 2.9 months (95% CI 2.66–3.39), and median OS was 10.4 months (95% CI 9.15–12.34). In univariable analysis, treatment-related characteristics, including combination therapy, were associated with OS, whereas participation in biomarker-selected trials and specific MOA was not consistently associated with survival. In multivariable analysis, OS was independently associated with baseline performance status (ECOG 1 vs 0: HR 1.35, 95% CI 1.12-1.63, p = 0.0015), combination therapy (HR 0.81, 95% CI 0.68-0.98, p = 0.0283) and female sex (HR 0.79, 95% CI 0.65-0.96, p = 0.0164). Baseline physiological parameters were strong predictors of OS, including higher hemoglobin (HR 0.90 per 1g/dL increase, 95% CI 0.85-0.96, p = 0.0018), higher albumin (HR 0.48 per 1g/dL increase, 95% CI 0.38-0.61, p < 0.0001), and higher lymphocyte count (HR 0.75 per 1.0K/μL increase, p = 0.0005). **Conclusions:** In this large retrospective cohort of patients treated on Phase I solid oncology trials, survival outcomes were primarily dictated by baseline physiological reserve and functional status rather than trial design features. While combination-based regimens were independently associated with OS, participation in biomarker-selected trials and MOA of study therapy did not retain prognostic significance after adjustment for clinical and laboratory factors. These findings suggest that baseline function and nutritional status remain the primary determinants of survival in early phase trials, highlighting the importance of rigorous clinical selection even in the era of increasingly diverse and novel therapeutic mechanisms. Ongoing analyses will further delineate prognostic factors associated with survival in this cohort. Research Sponsor: None.

Reduced treatment adherence and cancer mortality in patients with depression. First Author: Edmund Men Qiao, Department of Radiation Medicine and Applied Sciences, University of California, San Diego, La Jolla, CA

Background: Depression affects up to 20% of cancer patients and is associated with poorer cancer outcomes. The lack of mechanistic explanations for this interaction greatly limits clinical interventions. We hypothesize that patients with late-stage malignancies have lower treatment adherence that may increase risk of cancer-specific mortality (CSM). **Methods:** We selected patients age 66+ years diagnosed with breast, colon, rectal, prostate, or non-small cell lung cancer (NSCLC) from 2010-2017 using Surveillance, Epidemiology, and End Results (SEER)-Medicare. International Classification of Diseases (ICD)-9 or ICD-10 codes identified depression. Late-stage included locally advanced (Stage III+ or high-risk prostate) or metastatic. Locally advanced treatment adherence was defined as receiving curative therapy <1 year from diagnosis. In metastatic patients, this was defined as receiving systemic therapy along with number of cycles/months, <6 months from diagnosis. Multivariate Fine Gray regression with non-cancer death as a competing event evaluated CSM. Multivariate logistic regressions modeled the impact of depression on receiving therapy, and multivariate linear regression modeled its role on cycles/months of systemics received. **Results:** The cohort included 93,384 patients, with median age of 74 years and follow-up of 4.2 years. In total, 21,690 patients (23.2%) had depression, highest in NSCLC (27.1%) and lowest in prostate (13.4%). Depression was associated with 6-36% increased risk ($p<0.01$) of CSM (Table 1). Locally advanced patients with depression had 15-32% lower odds ($p<0.01$) of receiving curative treatment. Patients with metastatic disease and depression had significantly lower odds of receiving systemic therapy, reduced cycles/months of systemics, or both (Table 1). **Conclusions:** Depression was associated with increased risk of CSM across five tumor histologies. Patients with depression exhibited decreased treatment adherence for all subtypes, underscoring a possible mechanistic explanation for increased CSM in this population. Research Sponsor: None.

APS-TMA phenotypes as a failure-to-rescue signal during U.S. cancer hospitalizations: National Inpatient Sample, 2018–2022. First Author: Tarek Tabbah, Sunrise Health GME Consortium, Las Vegas, NV

Background: Failure-to-rescue (FTR), defined as mortality following major inpatient complications, reflects both patient disease pathology and hospital rescue capacity. Antiphospholipid syndrome (APS) and thrombotic microangiopathy (TMA) phenotypes are rare, high-acuity thrombotic syndromes observed during cancer hospitalizations, but whether excess mortality reflects independent risk factor versus complication-mediated risk is unclear. **Methods:** A serial cross-sectional, hospitalization-level analysis was performed using the 2018–2022 Healthcare Cost and Utilization Project National Inpatient Sample (NIS). Adult hospitalizations with a principal diagnosis of malignancy were identified using ICD-10-CM codes (C00–C97; D45–D47). APS and TMA phenotypes were defined using any-diagnosis ICD-10-CM proxies for APS and TMA, including TTP/HUS, and combined as an APS/TMA phenotype. Because laboratory and medication data are unavailable in the NIS, exposures were analyzed as inpatient phenotypes rather than presumed diagnoses. Major complications included mechanical ventilation and acute kidney injury requiring dialysis. Failure-to-rescue was defined as in-hospital mortality among admissions with ≥1 major complication. National estimates incorporated discharge weights, hospital clustering, and stratification; multivariable models adjusted for All Patient Refined Diagnosis Related Group (APR-DRG) severity. **Results:** Among an estimated 4.81 million principal malignancy hospitalizations nationally, APS/TMA phenotypes occurred in 0.48% of admissions. Compared with non-phenotype admissions, APS/TMA phenotype hospitalizations had higher mortality (9.43% vs 4.35%) and higher rates of major complications, including mechanical ventilation (5.85% vs 2.57%) and dialysis-requiring acute kidney injury (2.11% vs 0.61%). In severity-adjusted modeling incorporating APR-DRG severity, APS/TMA phenotype was not independently associated with mortality (adjusted OR 0.99, 95% CI 0.70–1.40), indicating that excess mortality was largely mediated by complications and underlying illness severity. **Conclusions:** APS/TMA phenotypes identify a rare but high-acuity subgroup of cancer hospitalizations characterized by disproportionate ICU-level support and dialysis utilization, functioning as a national failure-to-rescue signal rather than an independent driver of mortality after severity adjustment. These findings highlight the importance of early recognition and severity-directed rescue strategies for high-risk thrombotic phenotypes during cancer admissions. Research Sponsor: None.

Premature cancer mortality in the United States, 1999–2023: Analysis of CDC WONDER data. First Author: Kwame Adjei Sefah, Bridgeport Hospital/Yale New Haven Health System, Bridgeport, CT

Background: Premature cancer deaths (defined as mortality in adults aged 20-69 years) represent significant years of potential life lost (YPLL) and substantial disease burden, yet comprehensive national trends remain insufficiently characterized. **Methods:** CDC WONDER cancer mortality database (1999-2023) was queried for cancer-related deaths among individuals aged 20-69 years across USA. Age-standardized mortality rates (ASMR) per 100,000 person-years were calculated using 2000 U.S. Census standard population. Join point regression analysis identified temporal trend inflection points with annual percentage change (APC) and 95% confidence intervals (CI). Stratification included sex, race/ethnicity, geographic region, and 15 major cancer types. **Results:** From 1999–2023, 3,847,200 premature cancer deaths occurred in the U.S. (mean 153,888/year). Annual deaths increased 12.4% (152,100 in 1999 to 171,000 in 2023), while age-standardized mortality declined 18.6% (ASMR 87.3 to 71.1 per 100,000). Joinpoint analysis identified three phases: stability in 1999–2005 (APC −0.42%), accelerated decline in 2005–2015 (APC −2.18%), and slower improvement in 2015–2023 (APC −0.73%). Males had higher mortality than females in 1999 (ASMR 105.4 vs 69.2), with declines in both sexes (APC −1.89% males; −2.34% females), narrowing the male–female gap from 52.2% to 37.8% by 2023. Racial/ethnic disparities persisted: Black Americans had the highest ASMR in 2023 (84.3), 18.6% higher than Whites (71.1), with slower declines (APC −1.23% vs −2.07%); Hispanics/Latinos had the lowest ASMR (52.8) and fastest declines (APC −3.12%); American Indian/Alaska Native populations showed persistently high rates (89.2) with minimal change (APC −0.18%). In 2023, leading contributors were lung (38,200 deaths; ASMR 17.5; APC −3.78%), breast (23,100; 10.5; −2.45%), colorectal (11,800; 5.3; −3.12%), pancreatic (8,400; 3.8; −0.28%), and ovarian cancer (6,200; 2.8; −1.86%), together accounting for 58.2% of premature deaths. Cervical cancer declined sharply (APC −4.23%), while melanoma increased (APC +2.15%). **Conclusions:** Premature cancer mortality in the United States declined 18.6% from 1999-2023, yet significant and widening disparities persist by race/ethnicity, geography, and socioeconomic status. Alarming stagnation in declining rates post-2015, coupled with increasing absolute deaths among aging cohorts, signals necessity for intensified prevention efforts targeting modifiable risk factors. Research Sponsor: None.

Dose-response relationship of serum iron, ferritin, and transferrin saturation with cancer-related mortality: An analysis of population-based data. First Author: Saima Gill, Department of Medicine, King Edward Medical University, Lahore, Pakistan

Background: Altered iron homeostasis has been linked to cancer outcomes, with epidemiologic evidence suggesting that both reduced iron availability (low transferrin saturation or anemia) and elevated iron markers, particularly ferritin, may correspond to higher cancer mortality. However, population-level data quantifying dose–response relationships between continuous iron indices and cancer-related mortality remain limited. This study evaluates the dose–response association of serum iron, transferrin saturation (TSAT), and ferritin with cancer mortality using nationally representative NHANES data. **Methods:** NHANES laboratory data were linked to National Death Index mortality files (1999–2019). Survey-weighted Cox proportional hazards models and Fine–Gray competing-risk models were used to assess linear, quintile-based, and restricted cubic spline–modeled non-linear relationships between iron biomarkers and cancer mortality. Models were further adjusted to evaluate independent effects of each biomarker. **Results:** A total of 52,593 participants were included, with 6,875 recorded deaths. In survey-weighted $\log_2$ Cox models, serum iron (HR 1.41; 95% CI 0.17–11.68) and ferritin (HR 1.14; 95% CI 0.84–1.55) showed no significant linear association with cancer mortality, while TSAT suggested a nonsignificant inverse trend (HR 0.30; 95% CI 0.02–5.43). Quintile analyses revealed no consistent dose–response pattern for serum iron or TSAT; ferritin showed lower mortality in the second quintile (HR 0.33; 95% CI 0.12–0.92) without a graded pattern across higher quintiles. In mutually adjusted models including all three biomarkers, none demonstrated independent linear associations. Fine–Gray analyses identified a statistically significant but clinically small association for ferritin, whereas serum iron and TSAT remained nonsignificant. Restricted cubic spline models showed no clear non-linear dose–response for any biomarker. **Conclusions:** Among the iron indices evaluated, ferritin demonstrated the strongest and most consistent association with cancer-related mortality, although no clear linear or non-linear dose–response pattern emerged. Ferritin may serve as a more informative marker for risk stratification, but further mechanistic and longitudinal studies are warranted. Research Sponsor: None.

Predictors of mechanical ventilation in metastatic cancer hospitalizations: A National Inpatient Sample study. First Author: Davin Turku, The Brooklyn Hospital Center, Brooklyn, NY

Background: Invasive mechanical ventilation (MV) represents a major escalation of supportive care in metastatic cancer and is consistently associated with high short-term mortality in prior observational cohorts. We sought to identify patient and hospital factors associated with MV utilization in metastatic cancer hospitalizations using national inpatient data. **Methods:** We analyzed the National Inpatient Sample (2016–2020), including adult hospitalizations with metastatic cancer (ICD-10-CM C77–C79). MV was identified using ICD procedure codes. Survey-weighted multivariable logistic regression estimated adjusted odds ratios (aOR) for MV utilization, adjusting for age group, sex, race/ethnicity, payer, hospital bed size, hospital region, and comorbidity burden using vwcheck (van Walraven score derived from Elixhauser comorbidities). **Results:** In the complete-case regression cohort (weighted N=6,859,238), MV utilization varied across demographic and health-system factors. MV was less likely with older age (≥65 vs 18–44: aOR 0.80, 95% CI 0.75–0.87) and in females (aOR 0.96, 95% CI 0.93–0.99). Black race was associated with higher MV odds compared with White race (aOR 1.18, 95% CI 1.13–1.23). Compared with Medicare, Medicaid (aOR 1.08, 95% CI 1.01–1.14) and self-pay (aOR 1.17, 95% CI 1.05–1.30) had higher MV odds. MV was more likely in medium vs small hospitals (aOR 1.08, 95% CI 1.03–1.14) and large vs small hospitals (aOR 1.08, 95% CI 1.03–1.13). Regional variation persisted (South vs Northeast: aOR 1.11, 95% CI 1.06–1.17; West vs Northeast: aOR 1.07, 95% CI 1.01–1.13). Higher vwcheck was strongly associated with MV (aOR 1.07 per unit). **Conclusions:** Among hospitalized patients with metastatic cancer, the use of mechanical ventilation varied by patient demographics, payer status, hospital size, and region, even after adjustment for comorbidity burden. These differences suggest heterogeneity in illness severity and/or thresholds for escalation of care across health systems. Mechanical ventilation remains a marker of high-risk hospitalization in advanced cancer, and understanding the factors associated with its use may help inform inpatient supportive-care planning and quality improvement efforts. Research Sponsor: None.

Predictors of mechanical ventilation in metastatic cancer hospitalizations (NIS 2016–2020).

Predictor	Adjusted OR (95% CI)	p-value
Age ≥65 vs 18–44	0.80 (0.75–0.87)	<0.001
Female vs male	0.96 (0.93–0.99)	0.01
Black vs White	1.18 (1.13–1.23)	<0.001
Medicaid vs Medicare	1.08 (1.01–1.14)	0.02
Self-pay vs Medicare	1.17 (1.05–1.30)	0.004
Medium vs small hospital	1.08 (1.03–1.14)	0.002
Large vs small hospital	1.08 (1.03–1.13)	0.001
South vs Northeast	1.11 (1.06–1.17)	<0.001
West vs Northeast	1.07 (1.01–1.13)	0.01
van Walraven score (per unit)	1.07 (1.06–1.08)	<0.001

Addressing housing instability as a quality-of-care determinant in cancer: A meta-analysis across national and Veterans Affairs cohorts. First Author: Adarsh Vardhan Tangella, MedStar Washington Hospital Center, Washington, DC

Background: Housing instability is an under-recognized determinant of cancer outcomes that directly affects screening adherence, treatment delivery, and survival. Over 650,000 Americans experience homelessness nightly, yet its impact on oncologic quality-of-care metrics remains poorly quantified. We conducted a meta-analysis to evaluate disparities in cancer screening, treatment, and survival among persons experiencing homelessness (PEH) versus housed individuals, and to assess whether housing status functions as a system-level quality indicator. **Methods:** Real-world evidence from the Veterans Health Administration (VHA), National Inpatient Sample (NIS), and community cohorts (2011–2024) was pooled using random-effects DerSimonian–Laird models. Eligible studies reported odds ratios (ORs) or hazard ratios (HRs) comparing PEH with housed counterparts. Heterogeneity was summarized using I^2 statistics, and all analyses were performed in Stata. **Results:** Six cohorts contributed sixteen effect estimates encompassing >200,000 cancer cases. PEH were less likely to be up to date for colorectal cancer screening (pooled OR 0.56, 95% CI 0.23–1.31; I^2 = 93.9%). Homelessness was associated with markedly lower odds of surgery or other invasive procedures (pooled OR 0.42, 95% CI 0.26–0.66; I^2 = 98.4%) and substantially higher odds of discharge against medical advice (pooled OR 5.37, 95% CI 3.39–8.50; I^2 = 92.9%). In gastrointestinal cancer admissions, PEH also had longer hospital stays and higher costs. Within VHA datasets, homelessness independently predicted higher all-cause mortality after lung (HR 1.09–1.29) and colorectal cancer (HR 1.18–1.22). Veterans who gained housing after diagnosis achieved survival comparable to continuously housed peers (HR ≈ 1.0). **Conclusions:** Across diverse U.S. datasets, homelessness is consistently associated with lower screening uptake, reduced treatment receipt, and higher mortality—outcomes that represent measurable quality-of-care failures. Stable housing acts as a protective, modifiable factor influencing survival independent of access or insurance. Incorporating housing status screening into oncology intake workflows can close equity gaps, improve safety, and advance value-based cancer care. Housing stability should be recognized as a core quality metric in oncology. Research Sponsor: None.

Cohorts included in the meta-analysis of homelessness and cancer outcomes.

Study	Cancer Type(s)	Main Outcomes	Effect (95% CI)
Asgary 2014	Colorectal	Screening	OR 0.35 (0.23–0.53)
VA Cohort 2011–21	CRC, Breast	Screening / Colonoscopy	aIRR 0.84 (0.83–0.84); 0.88 (0.84–0.92)
Shah 2024	All cancers	Procedure / Therapy / AMA	AOR 0.53; 0.73; 4.29
Mevawalla 2019	GI	Surgery / AMA	OR 0.33; AOR 6.86
VA Mortality 2011–20	Lung	Mortality	HR 1.21 (0.93–1.57)
Health Affairs 2024	Lung, CRC, Breast	Mortality by housing	HR 1.09–1.29 (lung); 1.22 (CRC)

Impact of symptom burden, psychological distress, and treatment accessibility on quality of life in people with cancer in Syria. First Author: Mohamad Yousef Almawaz, Damascus University- Faculty of Medicine, Damascus, Syrian Arab Republic

Background: In low-resource and conflict-affected settings, barriers to cancer care may amplify symptom burden and psychological distress, leading to poor quality of life (QoL). This study aimed to evaluate the impact of symptom burden (fatigue), psychological distress (depression), sources of psychological support, and treatment accessibility on the quality of life (QoL) of people with cancer in Syria. **Methods:** A cross-sectional study was conducted between April and May 2025 at Albairwni Hospital, Syria'national cancer center. Adult outpatient oncology patients completed validated Arabic versions of the Patient Health Questionnaire-9 (PHQ-9), Brief Fatigue Inventory (BFI), and Functional Assessment of Cancer Therapy–General 7 (FACT-G7). Socio-demographic and clinical data included cancer type, stage, metastasis, relapse, complications, treatment accessibility, and sources of psychological support. Statistical analyses included group comparisons and Spearman correlation. **Results:** Among 225 participants (median age 53; 71.6% female; 65.8% rural). 41.8% reported difficult access to treatment, while only 18.7% reported easy access. Psychosocial support was primarily provided by family (87.1%), followed by religious sources (37.3%) and healthcare providers (18.2%). Breast cancer comprised 49.3% of cases. By PHQ-9, 77.3% had depressive symptoms (mild 26.7%, moderate 25.8%, moderately severe 17.8%, severe 7.1%). Mean BFI total score was 32.5 ± 23.6. Worse depression, greater fatigue and poorer QoL were associated with difficult treatment access (PHQ-9 P = 0.01; BFI P = 0.01; FACT-G7 P = 0.005), advanced stage (PHQ-9 & FACT-G7 P<0.001; BFI P=0.001), presence of metastases (PHQ-9 P = 0.001; BFI P = 0.01; FACT-G7 P < 0.001). Relapse was associated with higher depression and greater fatigue (PHQ-9 P = 0.04; BFI P = 0.03), while cancer-related complications were associated with worse scores across all scales (PHQ-9 P < 0.001; BFI P = 0.001; FACT-G7 P < 0.001). Health-provider support was associated with lower symptom severity and better QoL (BFI P = 0.01; FACT-G7 P = 0.003). Spearman correlations showed strong inverse relationships between fatigue measures and QoL (BFI total vs. FACT-G7 $\rho = -0.71$, P < 0.001), while QoL scores showed a graded decline as depression severity increased (P < 0.001). **Conclusions:** Depressive symptoms and fatigue are strongly associated with poorer QoL in cancer patients. Modifiable factors-notably treatment accessibility and health provider support- correlate with better outcomes and may be targets for interventions to improve patient wellbeing in low-resource oncology settings. Research Sponsor: None.

The AI paradox in precision oncology: Prospective blinded validation of large language models against molecular tumor board. First Author: Arun Seshachalam, Dr. GVN Cancer Institute, Tiruchirappalli, India

Background: Molecular tumor boards (MTBs) are central to precision oncology but remain limited in accessibility. Large language models (LLMs) are increasingly proposed as scalable clinical decision-support tools, yet prospective validation is sparse. We evaluated multiple LLMs against MTB consensus, focusing on molecular pathway interpretation, actionability, and evidence strength. **Methods:** This prospective, blinded, cross-sectional validation study included consecutive cases discussed at a Tamil Nadu Medical and Pediatric Oncologist Society–initiated national MTB (July 2025–January 2026). Anonymized clinical and genomic data were analyzed using a standardized prompt across 4 latest LLM versions [ChatGPT (5, 5.1, 5.2), Perplexity, Gemini (2.5 Flash, 3 Pro), and DeepSeek], each queried in 2 independent runs to assess reproducibility; AI systems were blinded to MTB decisions, and reviewers to AI identity. Concordance was classified as concordant, discordant, AI non-evaluable (extraction failure or non-reproducible), or MTB non-evaluable (no predominant molecular pathway). The primary endpoint was end-to-end concordance; conditional concordance excluding non-evaluable outputs was secondary. Predictors of concordance were evaluated using univariate and multivariate logistic regression. **Results:** Of 108 cases, 80 were evaluable for AI comparison. Mean age was 56 years; 65% were male; 90% had ECOG 0–2; 73% had metastatic disease; and 82% were treated with palliative intent. The cohort was heavily pretreated, with 48% receiving ≥3 prior lines. Common pathways included EGFR/RAS/RAF/MAPK (34%), PI3K/AKT/mTOR (23%), and HRD/DDR (18%). End-to-end concordance was 88%, 74%, 83%, and 55% across the four LLMs. AI non-evaluable outputs due to extraction failure or non-reproducibility across two independent runs occurred in 3.8% to 21.3% of cases across platforms, highlighting important limitations in reliability. Citation-level hallucination rates were high (41%, 36%, 49%, and 48%). On univariate analysis, higher evidence level predicted concordance across all models (all P ≤ 0.03). ESCAT tier was also significantly associated with concordance for LLM-2, LLM-3, and LLM-4. On multivariate analysis, evidence level remained the only consistent independent predictor for three LLMs, while ESCAT tier retained significance for one model. Inter-rater reliability was excellent (96.3%; κ = 0.93). **Conclusions:** LLM concordance is highest in guideline-supported, high-actionability settings but declines in low-evidence, poor-targetability scenarios—precisely where clinical support is most needed. This "AI paradox," combined with substantial hallucination risk, indicates that while LLMs may assist first-pass molecular interpretation, expert multidisciplinary MTBs remain essential for safe and reliable precision oncology. Research Sponsor: None.

Evolution of immune checkpoint inhibitor trials in oncology from 2011 to 2025: A cross-sectional study. First Author: Runzhe Chen, Sun Yat-sen University Cancer Center; UTHealth Houston School of Public Health, Guangzhou, China

Background: Immune checkpoint inhibitors (ICIs) have transformed the oncology therapeutic landscape since the first FDA approval in 2011. Over the past decade, ICIs have expanded rapidly across tumor types, disease settings, and therapeutic strategies. However, a comprehensive evaluation of the long-term evolution and key characteristics of global ICI clinical trials remains limited. We conducted a cross-sectional analysis to characterize temporal trends and fundamental features of ICI oncology trials registered on ClinicalTrials.gov from 2011 to 2025. **Methods:** All interventional oncology trials with a primary treatment purpose registered on ClinicalTrials.gov between January 1, 2011, and December 31, 2025, were included. ICI trials were defined as studies investigating agents targeting CTLA-4, PD-1, PD-L1, or next-generation immune checkpoints (e.g., LAG-3, TIGIT, TIM-3). Trials were categorized by phase, randomization, enrollment, funding source, geography, tumor type, treatment setting, and primary endpoints. Descriptive statistics summarized trial characteristics and temporal trends. **Results:** A total of 8,756 interventional treatment-purpose ICI trials were identified. Annual trial starts increased from 32 in 2011 to a peak of 955 in 2021, remaining consistently high thereafter (858 in 2022, 848 in 2023, and 817 in 2024), and reaching 940 in 2025. Most trials were Phase 2 (4,174/8,756; 47.7%), Phase 1 (1,756; 20.1%), or Phase 1/2 (1,374; 15.7%), while Phase 3 trials only accounted for 870 (9.9%) overall. The number of Phase 3 trials increased from 4 in 2011 to 100 in 2019, declined during 2020–2022, and subsequently rebounded to 101 in 2023, 110 in 2024, and a peak of 137 in 2025, reflecting ongoing maturation toward late-stage development. Funding was most frequently categorized as other (5,291; 60.4%), followed by industry (3,065; 35.0%) and US federal sources (400; 4.6%). The most common tumor groups were non–small cell lung cancer (NSCLC) (1,014; 11.6%), melanoma (579; 6.6%), breast cancer (498; 5.7%), and colorectal cancer (431; 4.9%). Among trials with available location data (n=8,152), the United States (4,173; 51.2%) and China (2,647; 32.5%) were the most frequent trial locations. **Conclusions:** Over the past 15 years, ICI clinical trials have expanded markedly in number and across tumor types; however, the majority remain early-phase, open-label, and small in scale, with Phase 3 studies comprising less than 10% of all trials. Encouragingly, the recent increase in late-phase trials suggests continued maturation of the immuno-oncology field and sustained progress toward regulatory approval. Persistent geographic concentration highlights the need to broaden global participation and strengthen the generation of confirmatory evidence to maximize the clinical impact of ICIs in cancer care. Baseline financial and credit status of participants enrolled in SWOG S1912CD. First Author: Veena Shankaran, Fred Hutch Cancer Center, Seattle, WA

Background: Financial hardship is associated with adverse outcomes in cancer patients. While there is a critical need for interventions to prevent financial hardship, their scale and impact depend on the baseline financial status of patients. CREDIT (SWOG S1912CD) is a national prospective, randomized pragmatic trial evaluating the impact of a financial navigation intervention versus usual care on financial, clinical, and psychosocial outcomes. We report baseline demographic and financial characteristics of trial enrollees, using a combination of self-reported and credit data. **Methods:** Enrollees were within 6 months of diagnosis of a metastatic/stage IV solid tumor or hematologic malignancy. A total of 329 patients were randomized between July 2021 and December 2024 (165 control, 164 intervention). We assessed baseline income, employment, debt, homeowner status, financial fragility (ability to come up with $2,000 in 30 days), mean Comprehensive Score for Financial Toxicity (COST), and financial coping strategies (e.g. loans, cost-related nonadherence). We also examined the proportion of patients with adverse credit indicators (bankruptcies, third-party collections, repossessions, tax liens, delinquent mortgage payments) in their baseline credit reports. We compared mean COST score for patients with versus without adverse credit indicators. **Results:** Most patients (median age 61.5) were White (78%), 51% had commercial insurance while 33% had Medicare. The most common cancer types were gastrointestinal (23%), lung (12%), and breast (11%). Median household income was $50,001-$75,000, 70% were homeowners, and 32% reported a change in employment following cancer diagnosis and prior to enrollment. 39% reported financial fragility, 71% reported debt (32% with debt greater than $25K), and 20% reported taking loans from friends or family in the prior 3 months. Mean COST score was 19.6, with 45% of patients reporting scores $\leq$ 17.5, consistent with significant financial toxicity. 18.5% of patients had utilized $\geq$ 75% of credit limit on credit cards. The proportion of patients with prior bankruptcy, third-party collection, repossession, or delinquent mortgage payment were 3.3%, 16%, 2.7%, and 2.5% respectively. Mean COST score was significantly lower in patients with an adverse credit indicator compared to those without (21.4 vs. 13.0, $p<0.0001$) suggesting good correlation between credit data and patient-reported outcome measure. **Conclusions:** A significant proportion of patients newly diagnosed with cancer reported debt, financial fragility, and significant financial toxicity. A smaller proportion had more severe financial challenges identifiable in their baseline credit reports. There is clearly a need for interventions to address and mitigate financial hardship in this population. Final primary analysis of the impact of CREDIT in this financially challenged population is forthcoming. Clinical trial information: NCT04960787. Research Sponsor: National Cancer Institute.

Palliative care for advanced cancer: Medicare Advantage and provider networks. First Author: Xin Hu, Emory University School of Medicine, Atlanta, GA

Background: Palliative care is a specialized medical approach to improve symptoms and quality of life for patients with serious illnesses, including cancer, yet its utilization remains low. While enrollment in Medicare Advantage (MA) has grown and surpassed Traditional Medicare (TM), less is known about differences in palliative care between MA and TM and the extent to which MA plan design, particularly provider networks, contributes to these differences. **Methods:** Using the 2025 SEER–Medicare linkage, we identified Medicare beneficiaries aged $\geq$66 years diagnosed with distant-stage breast, colorectal, lung, pancreatic, or prostate cancer between 2016 and 2021. We included patients who survived at least 2 months after diagnosis and had continuous enrollment in TM or MA from 1 year before diagnosis to death/end of follow-up. The primary outcome was the cumulative incidence of palliative care billing within 6 months of diagnosis. To assess the role of provider networks, we first assigned each patient a treating oncologist based on the plurality of visits with cancer diagnosis codes; we then conducted 1:1 matching of patients enrolled in a given MA plan to patients in TM treated by the same oncologists within the same county. Multivariable Cox proportional hazards models estimated differences in palliative care billing between TM and MA overall and by MA plan type, before and after matching, adjusting for sociodemographic and clinical characteristics. **Results:** Among 135,402 beneficiaries with advanced cancer, 67.7% were enrolled in TM and 32.3% in MA; over half were female, 7.3% Hispanic, and 9.5% non-Hispanic Black. The 6-month cumulative incidence of palliative care billing was 13.3% among MA beneficiaries and 9.3% among TM beneficiaries. In adjusted analyses, MA enrollment was associated with higher palliative care billing (hazard ratio [HR], 1.39; 95% CI, 1.34–1.44). When stratified by plan types, palliative care was particularly higher among patients in health maintenance organization (HMO) plans (HR=1.66, 95%CI=1.60-1.72) but not other plan types. After matching on treating oncologists, 23,033 TM and 23,033 MA patients were included. Matched MA beneficiaries were less likely to have HMO plans than those not matched (49.1% vs. 76.7%). Differences in palliative care were attenuated and statistically non-significant, with cumulative incidence of 11.0% and 10.4% among MA and TM, and an adjusted hazard ratio of 1.05 (95%CI=0.99, 1.11). Similar attenuation was observed in HMO plans (1.16, 95%CI=1.08, 1.24). **Conclusions:** Palliative care billing was significantly higher among MA than TM beneficiaries, but these differences were substantially reduced after accounting for provider networks. These findings suggest that between-provider variation accounts for the majority of the difference in palliative care receipt between TM and MA beneficiaries. Household costs of breast cancer and coping mechanisms in Kenya: A case of Kenyatta National Hospital. First Author: Lyndah Kemunto Manoti, University of Nairobi, Nairobi, Kenya

Background: In 2020, cancer was the third leading cause of mortality in Kenya, with breast cancer the most prevalent cancer and the second leading cause of cancer-related deaths. Patients and the health system faced a substantial economic burden due to breast cancer, which requires long-term medical attention as a chronic condition. Research has identified cost as a primary obstacle to accessing breast cancer healthcare services, particularly in low- and middle-income countries (LMICs). Objectives: The objective of this study was to examine the household costs of breast cancer among patients receiving treatment at Kenyatta National Hospital, Kenya's national referral hospital. Specifically focusing on cost incurred, drivers of cost and cost coping mechanisms. **Methods:** Cross-sectional descriptive research design was utilized to quantify the cost of breast cancer among 103 breast cancer patients at the Kenyatta National Hospital in 2024. Data were collected via a semi-structured questionnaire on the direct medical costs, direct non-medical costs, and indirect costs incurred, as well as cost coping mechanisms. To assess the drivers of cost, multivariable linear regression model was used to determine associations between the independent variables and cost outcomes. **Results:** The mean total costs of breast cancer were estimated to be USD 14,255 (KES 2,138,330). Direct medical costs (USD 8,916/KES 1,337,475) were the largest component, followed by direct non-medical costs (USD 1,917/KES 287,625) and indirect costs (USD 3,421/KES 513,229). Targeted therapy was the largest cost component within direct medical costs, representing 45.37% of direct medical costs. Luminal B and Stage IV breast cancer incurred the highest total costs. Patients primarily relied on public health insurance and personal income and savings to cater for the costs. Despite all participants using the National Health Insurance Fund (NHIF), now Social Health Authority (SHA), it only covered 25-50% of the direct medical costs. Out-of-pocket expenditures were significant, with 97% of respondents using personal income and savings, 29% liquidating assets, and 22% taking loans. **Conclusions:** Breast cancer patients and their households incur significant costs in Kenya. This underscores the need for urgent health financing reforms that ensure broadened insurance coverage, and social protection systems that ensure Kenyans have access to comprehensive cancer care and prevent cancer-related financial toxicity and impoverishment. Research Sponsor: Kenyatta National Hospital; KNH/R&P/23/24-25/10/5.

Disparities in race and insurance status among hospitalized patients with pancreatic cancer and protein–energy malnutrition: A nationwide analysis, 2016–2022. First Author: Alexandra Sueldo, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: Protein–energy malnutrition (PEM) is frequently encountered in patients with pancreatic cancer and is associated with worse clinical outcomes. Although sociodemographic differences in malnutrition risk have been described, it is unclear whether racial and insurance-based disparities persist after accounting for clinical complexity, socioeconomic factors, and hospital characteristics. We sought to identify independent predictors of PEM among hospitalized patients with pancreatic cancer using a nationally representative inpatient cohort with multivariable adjustment for relevant covariates. **Methods:** We conducted a retrospective cohort study using the National Inpatient Sample (NIS) from 2016 to 2022. Adult hospitalizations with pancreatic cancer were identified using ICD-10-CM code C25, and PEM was defined using ICD-10-CM codes E40–E46. Multivariable regression models evaluated independent predictors of PEM and its associations with in-hospital mortality, length of stay, discharge disposition, and hospital charges. Models adjusted for demographic factors, comorbidities, and hospital characteristics, with survey weights applied to generate national estimates. **Results:** Among an estimated 263,890 hospitalizations for pancreatic cancer, 37% were associated with PEM. After adjustment, Black patients (adjusted odds ratio [aOR] 1.39, 95% CI 1.31–1.48) and Asian/Pacific Islander patients (aOR 1.41, 95% CI 1.27–1.56) had higher odds of PEM compared with White patients. Medicaid insurance was associated with increased odds of PEM (aOR 1.12, 95% CI 1.03–1.22), whereas private insurance was associated with lower odds (aOR 0.85, 95% CI 0.80–0.91) relative to Medicare. Higher comorbidity burden (Charlson Comorbidity Index $\geq$3) was the strongest predictor of PEM (aOR 1.54, 95% CI 1.45–1.64). Median household income was not independently associated with PEM. PEM was more common in urban hospitals and those with larger bed size. **Conclusions:** In this national inpatient cohort, PEM was common among patients hospitalized with pancreatic cancer and demonstrated racial and insurance-based disparities that persisted after adjustment for income, comorbidities, and hospital characteristics. These findings highlight potential gaps in nutritional risk recognition and underscore the importance of standardized inpatient nutritional screening and targeted interventions for high-risk populations. Research Sponsor: None.

Malnutrition and cachexia as drivers of failure-to-rescue in gynecologic cancer hospitalizations, 2016–2023. First Author: Charles Abraham Joseph Larson, Trinity School of Medicine, Warner Robins, GA

Background: Malnutrition and cancer cachexia are underrecognized in administrative data yet may identify hospitalized oncology patients with limited physiologic reserve. Rather than acting solely as baseline comorbidities, these conditions may amplify the lethality of inpatient complications. The prevalence, temporal trends, and outcome-modifying role of malnutrition were evaluated among U.S. gynecologic oncology hospitalizations using a failure-to-rescue framework. **Methods:** A retrospective, survey-weighted analysis of the National Inpatient Sample (NIS), 2016–2023, was conducted. Adult hospitalizations with gynecologic malignancies (ICD-10-CM C51–C58) were included; palliative encounters (Z51.5) were excluded. Malnutrition was defined using a narrow phenotype (E43, E44.*, E46) and a broader definition including cachexia (R64). Outcomes included in-hospital mortality, ICU escalation (mechanical ventilation and/or shock), major complications (sepsis, bleeding/transfusion, venous thromboembolism, acute kidney injury, bowel injury/peritonitis, respiratory failure), length of stay (LOS), hospitalization cost, and failure-to-rescue (death following $\geq$1 complication among surgical admissions). Survey-weighted estimates with 95% confidence intervals (CI) were reported. **Results:** The cohort included 1,019,030 weighted hospitalizations. Malnutrition prevalence was 12.75% (95% CI, 12.53–12.98) using the narrow definition and increased from 9.61% in 2016 to 15.32% in 2023. In-hospital mortality was higher among malnourished admissions (4.36% [95% CI, 4.11–4.63] vs 1.55% [95% CI, 1.48–1.61]). Malnutrition was associated with greater ICU escalation (5.63% [95% CI, 5.35–5.92] vs 2.48% [95% CI, 2.41–2.56]), AKI (31.53% [95% CI, 30.93–32.13] vs 17.54% [95% CI, 17.33–17.76]), and any major complication (64.97% [95% CI, 64.35–65.60] vs 44.07% [95% CI, 43.74–44.40]). Resource utilization was higher with malnutrition (LOS 8.98 vs 4.71 days; cost $28,155 vs $18,740). Among admissions with complications, mortality was higher with malnutrition (6.27% [95% CI, 5.90–6.65] vs 3.16% [95% CI, 3.03–3.29]). In the surgical subcohort, failure-to-rescue mortality was 2.55% (95% CI, 1.98–3.28) with malnutrition versus 0.82% (95% CI, 0.70–0.95). **Conclusions:** In U.S. gynecologic oncology hospitalizations, malnutrition and cachexia identify a high-risk inpatient phenotype with disproportionate complication burden and post-complication mortality. These findings support malnutrition as a modifier of failure-to-rescue rather than an isolated baseline risk factor and highlight inpatient nutritional vulnerability as a target for early risk stratification and supportive intervention. Research Sponsor: None.

Comprehensive molecular profiling in advanced non–small cell lung cancer (NSCLC): Measurable survival and value impacts of implementation. First Author: Stanley Ifeanyi Ozogbo, Allegheny Health Network Cancer Institute, Pittsburgh, PA

Background: Comprehensive molecular profiling (CMP) is key to precision oncology in advanced non–small cell lung cancer (NSCLC), enabling identification of actionable driver alterations and delivery of matched targeted therapies that improve survival. CMP has been universally recommended by international guidelines for over a decade. Despite mature evidence and widespread availability, real-world adoption remains strikingly low. We evaluated the real-world impact of molecular profiling on survival, healthcare utilization, and cost in NSCLC, and quantified the magnitude of its ongoing underuse. **Methods:** We analyzed NSCLC patients aged $\geq$18 years treated between January 2019 and December 2025 using two independent real-world datasets: TriNetX and Highmark Health. Patients were categorized based on receipt of broad-panel molecular profiling consistent with guideline-directed indications. Outcomes included overall survival (OS), emergency department (ED) visits, inpatient admissions, and healthcare costs. Survival was assessed using Kaplan–Meier methods, with multivariable regression to adjust for clinical factors. **Results:** Among 33,977 NSCLC patients in TriNetX, only 2,354 (6.9%) underwent molecular profiling, despite the majority of NSCLC patients presenting with advanced disease. Molecularly profiled patients experienced a substantial survival advantage, with median OS of 1,784 days versus 1,074 days in untested patients (adjusted hazard ratio 0.61; $p<0.001$). Molecular profiling was also associated with significantly fewer inpatient admissions (0.651 vs 0.875; $p<0.001$) and ED visits (0.437 vs 0.583; p=0.047). Highmark Health data independently validated these findings, demonstrating significantly improved 4-year OS in molecularly tested patients (55% vs 43%; $p<0.001$). Importantly, these survival gains were achieved without a statistically significant increase in total cost per patient per month at follow-up (p=0.083). **Conclusions:** Across two large, independent real-world datasets, comprehensive molecular profiling in NSCLC was associated with meaningful improvements in survival and reductions in healthcare utilization, even when applied primarily in advanced disease. These benefits were achieved without a significant increase in overall costs, supporting the value-based impact of precision oncology. Yet fewer than 1 in 15 eligible NSCLC patients underwent molecular profiling between 2019 and 2025, revealing a profound and persistent failure to implement guideline-concordant care. This underuse directly translates into avoidable mortality and unnecessary healthcare utilization. System-level solutions, including standardized and reflexive molecular testing at diagnosis, are urgently needed to ensure precision medicine is delivered as standard care in advanced NSCLC patients. Overall survival of Black patients with newly diagnosed multiple myeloma in the era of triplet and quadruplet therapies. First Author: Hamlet Gasoyan, Cleveland Clinic, Cleveland, OH

Background: Black individuals have been shown to have a higher incidence of multiple myeloma, as well as worse survival, compared with White patients. A single VA-based study demonstrated that with equal access to myeloma therapy, Black patients have superior survival compared to White individuals. Nevertheless, it is unknown whether this finding holds in other settings. **Methods:** This retrospective cohort study included adult patients newly diagnosed with multiple myeloma between January 1, 2017, and December 31st, 2023, in one health system in Ohio and Florida. We captured receipt of triplet or quadruplet therapy within one year of diagnosis, as well as patients' overall survival (OS) through September 30, 2025, using the Cleveland Clinic electronic health record, including linked state and federal death records. A multivariable logistic regression model examined the association of race with the receipt of either triplet or quadruplet therapy within one year of diagnosis, and a multivariable Cox regression model examined the association of race with 5-year all-cause mortality. The Cox model was adjusted for receipt of either a triplet or quadruplet regimen within 1 year, age at diagnosis, sex, Charlson comorbidity index (CCI), ECOG performance status, baseline eGFR, urbanicity of patient's residence, area deprivation index based on Census Block Group, insurance type, and year of diagnosis. **Results:** We identified 1230 patients, 54.1% male, 74.1% White, 22.8% Black, 3.1% other races. Mean (SD) age at diagnosis of 67.2 (11.1); it was 67.7 (10.8) for White and 65.9 (11.7) for Black patients. Overall, 66.3% of the cohort had an ECOG performance score of 0-1, 59.9% had baseline eGFR $\geq$60, and 51.1% had a CCI of $\leq$2. Within one year of diagnosis, 707 patients (57.5% of the cohort) received either triplet or quadruplet therapy, including 56.6% (n=516) of White and 58.9% (n=165) of Black individuals. Both univariable and multivariable analyses did not indicate a significant association between race and receipt of either a triplet or quadruplet therapy (aOR for Black race vs. White, 0.91, 95% CI, 0.64-1.28). According to Kaplan-Meier estimate, the probability of 5-year OS in the overall cohort was 62.1% (95% CI, 59.0%-65.4%). In the multivariable Cox regression model for all-cause mortality at 5 years, aHR for death for Black patients vs. White was 0.76 (95% CI, 0.58-1.00). **Conclusions:** In this large and diverse cohort of patients who had equal access to triplet or quadruplet therapies for newly diagnosed multiple myeloma, Black patients did not have a higher risk of all-cause mortality at 5 years compared to White individuals. Our findings indicate that health equity initiatives aimed at improving access to multiple myeloma care among minority patients have the promise of addressing race-based disparities in survival. Impact of U.S. most-favored-nation (MFN) drug pricing on global oncology access. First Author: Ariel Hammerman, Medison Pharma, Petah Tikva, Israel

Background: U.S. cancer drug prices substantially exceed those in other OECD countries. In May 2025, a U.S. Presidential Executive Order mandated adoption of a Most-Favored-Nation (MFN) pricing policy, linking U.S. drug prices to those of economically comparable countries. In December 2025, the Centers for Medicare & Medicaid Services (CMS) proposed two MFN-based frameworks: the Global Benchmark for Efficient Drug Pricing (GLOBE) for Medicare Part B drugs and Guarding U.S. Medicare Against Rising Drug Costs (GUARD) for Part D drugs. Both require manufacturer rebates when U.S. prices exceed GDP-adjusted international benchmarks, creating potential incentives for manufacturers to alter global oncology pricing and launch strategies. This study assesses which international markets may face pricing pressure or delayed access to new oncology therapies following MFN implementation. **Methods:** The top 50 best-selling U.S. drugs in 2024 were reviewed, and 12 oncology drugs without generic or biosimilar competition were selected. List prices were collected from the 19 OECD reference countries included in GLOBE and GUARD. Prices were adjusted for GDP per capita using purchasing power parity (PPP). For each drug, the two lowest GDP-adjusted international prices were identified and compared with U.S. prices, using January 2026 Medicare Average Sales Price (ASP) data for Part B drugs and December 2025 Federal Supply Schedule (FSS) prices for Part D drugs. **Results:** Across all 12 drugs, GDP-adjusted benchmark prices were 48% to 90% lower than U.S. prices. Pembrolizumab, the top-selling oncology drug in 2024, had a U.S. Medicare price of $5,972 per 100 mg; the lowest adjusted prices were observed in South Korea ($2,116) and Japan ($2,271), representing reductions of 65% and 62%, respectively. Daratumumab, the second top-selling oncology drug, was priced at $2,831 per 400 mg in the U.S., compared with $1,467 in South Korea and $1,603 in the Netherlands (48% and 43% lower). The lowest benchmark prices most frequently originated from South Korea (n=5) and the Netherlands (n=4). Norway, Germany, and Japan each provided the lowest benchmark for one drug. Second-lowest benchmark prices were observed in Japan (n=4), South Korea (n=3), the Netherlands (n=2), Germany (n=2), and Norway (n=1). **Conclusions:** Countries serving as the lowest-price benchmarks- particularly South Korea, Japan, the Netherlands, Norway, and Germany- may face increased risk of upward pricing pressure or delayed access to innovative oncology therapies as manufacturers seek to limit U.S. MFN rebate exposure. Expanded use of confidential discounts, confidential rebates and other managed-entry agreements may help preserve access while reducing MFN benchmark risk. Research Sponsor: None.

When does time become a burden? Evaluating the association between time spent on cancer care and patient distress. First Author: Sarah Boyle, University of Minnesota, Minneapolis, MN

Background: While cancer care is time-intensive, the specific impact of various tasks on patient well-being is poorly understood. We evaluated how time spent on specific cancer-care tasks contributes to patient distress and identified patient populations most vulnerable to these time burdens. **Methods:** We enrolled individuals receiving treatment for advanced-stage ovarian or metastatic breast cancer at the University of Minnesota and the University of Alabama-Birmingham. Participants used a mobile app for 28 days to log time spent on out-of-home and at-home cancer-care related tasks. Daily distress was measured via the National Comprehensive Cancer Network (NCCN) Distress Thermometer (0-10; 0=no distress, 10=extreme distress). The primary outcome was clinically significant distress (NCCN distress score <4 vs. ≥ 4). Predictors included any time spent on each task type on a given day for both out-of-home healthcare tasks (lab, clinic, treatment, research, imaging, other) and at-home tasks (taking medications, scheduling appointments, managing medical bills/insurance claims, symptom management, monitoring health status, seeking information, and arranging help/transportation). A multi-level model with a random intercept for participants was used, adjusting for age, employment, education, dependent and partner status. Odds ratios and 95% confidence intervals are reported. **Results:** Analysis included 1,869 days from 60 participants (median age 59; 42% employed; 35% with dependents). Experience of significant distress was more likely on days including out-of-home treatment compared to days without treatment (OR: 2.54 [1.47, 4.39]). Participants were also more likely to experience significant distress on days including time spent on symptom management (OR: 2.59 [1.85, 3.64]), health monitoring (OR: 2.50 [1.56, 3.98]), and managing bills/claims (OR: 2.24 [1.22, 4.12]) compared to days without those tasks. Vulnerability varied: employed patients were more distressed by managing bills/claims and information seeking, while non-working patients experienced more distress on treatment days. Among those with dependents, scheduling was a unique stressor. **Conclusions:** Out-of-home treatment and at-home cancer-care tasks are significantly associated with patient distress. Findings suggest that interventions reducing at-home administrative and symptom burdens would reduce patient distress, and resources may need to be tailored based on employment and caregiving status. Clinical trial information: NCT05708703. Research Sponsor: U.S. National Institutes of Health; 1R01CA277714, P30 CA77598, P30 CA013148, UM1TR004405.

An AI-powered, human-in-the-loop, real-time registry platform to enable clinical trials, pragmatic studies, and prospective external control arms (ProECA) at scale in US community practices. First Author: Luis T. Campos, Oncology Consultants, Medical Center, Houston, TX

Background: Drug development is requiring novel approaches such as prospective external controls to reduce development timelines and de-risk phase transitions. The majority of oncology patients in the US are seen at community oncology centers, many of which have limited clinical research infrastructure. The Kaleido registry was initiated to address these challenges through a hybrid operational technology model combining on-site staff, clinical note preparation, pre-visit abstraction, and automated workflows to facilitate pre-screening, data capture and research operations. **Methods:** The Kaleido registry enrolls patients at US community oncology practices with variable research infrastructure and is actively enabling seven studies. Real-time abstraction is performed prior to each patient visit across an expanding set of indications, including non-small cell lung cancer (NSCLC), colorectal cancer (CRC), prostate cancer, and myeloproliferative neoplasms, enabling standardized data collection and systematic/unbiased trial pre-screening. An automated prescreening tool was developed and validated against manual chart review. Standardized draft notes are generated to reduce clinical documentation burden. A patient questionnaire captures social determinants of health (SDOH) and self-reported performance status. **Results:** As of 1/1 2026 more than 16,000 patients (60% female, median age 70 years, range 19-105) from 28 sites have been consented. Most common diagnoses are breast (29%), colorectal (9%), prostate (6%) and lung cancer (6%). 99% of approached patients filled out the patient questionnaire and missingness of race/ethnicity/education/marital status was $<4\%$. Comprehensive biomarker testing exceeded 85% for patients with metastatic NSCLC. Time from specimen collection to NGS results (median 18 days, range 5-45) or PD-L1 (median 21 days, range 4-45) was a key driver of delays in evaluating trial-eligibility. Patients were consistently identified prior to starting next line of therapy. The model identified additional trial-eligible patients beyond standard workflows even at high-performing sites. In 2025, more than 500 patients were included in trials, ProECAs and pragmatic studies with enhanced data depth within the registry. **Conclusions:** The Kaleido registry demonstrates a scalable, integrated infrastructure for real time patient identification and comprehensive prospective data collection in the community setting. By facilitating community trial enrollment, pragmatic studies and prospective external controls while reducing operational burden of clinical teams, Kaleido has the potential to significantly accelerate drug development. Association of drug industry payments to oncologists and use of guideline-preferred cancer treatments. First Author: Aaron Philip Mitchell, Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Payments from the drug industry to oncologists are common and influence physicians' prescribing decisions. However, whether payments affect the likelihood that patients receive optimal cancer treatment has not been assessed. **Methods:** This was a population-based cohort study. We used fee-for-service Medicare claims to identify patients with incident cancer diagnosis (new cancer diagnosis code after $>=$ 1 year with no cancer diagnosis codes) from 2014-2020. We used National Comprehensive Cancer Network (NCCN) Guidelines to identify treatment scenarios (e.g., metastatic melanoma, stage III colon adjuvant therapy) with variation in the clinical benefit among recommended treatment options. The patient cohort corresponding to each scenario was identified using claims. We used NCCN Guidelines to identify the "optimal" treatment for each scenario (defined as the designated "preferred" treatment, with NCCN Evidence Blocks scores used for tiebreaks) at each time point across the study period. The primary outcome was whether a patient received the treatment that was, as of their diagnosis date, the optimal treatment for their cancer (vs. any non-optimal treatment). The primary exposure[s] were whether a patient's medical oncologist received personal ("general") payments (source: linked Open Payments data) related to 1) optimal treatment or 2) any non-optimal treatment, during the year prior to the patient's cancer diagnosis. We fit Poisson-family generalized estimating equations, with physician-level clustering and adjustment for scenario, year, and patient characteristics, to estimate the relative risk (RR) of optimal treatment. **Results:** There were 14 clinical scenarios comprising 15,835 patients. There were 3,429 (21.7%) patients whose oncologist received payment for the optimal treatment, 4,891 (30.9%) for non-optimal payments, and 1,993 (12.6%) to both payment types. Oncologist receipt of payment for optimal treatment was associated with a greater likelihood (RR=1.07, 95%CI:1.01-1.13), and payment for non-optimal treatment was associated with lower likelihood (RR= 0.94, 95%CI:0.89-0.98) of patients receiving optimal treatment. Associations became stronger as payment dollar value increased; for optimal payments $\geq$\$10,000, RR=1.26 (95%CI:1.02-1.57), and for non-optimal payments $\geq$\$10,000, RR=0.70 (95%CI: 0.49-1.00). An estimated 41.6% of unexposed patients received optimal treatment; versus 52.6%, 29.3%, and 33.8% among patients exposed to $\geq$\$10,000 of payments for optimal treatment only, $\geq$\$10,000 non-optimal payments only, and $\geq$\$10,000 of both payment types, respectively. **Conclusions:** Industry payments related to the optimal cancer treatment were associated with increased use of the optimal treatment. However, payments related to non-optimal treatments were more common and were associated with decreased use of optimal treatment. Format matters: Digital vs print delivery of a job retention intervention during breast cancer therapy. First Author: Yashasvini Sampathkumar, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Talking to Employers and Medical Staff about Work (TEAMWork) is an English/Spanish intervention, delivered as a booklet or mobile app, which was developed to improve work outcomes among women undergoing (neo)adjuvant breast cancer therapy. TEAMWork provides education on work accommodations based on vocational rehabilitation principles, employer negotiation strategies, symptom self-management tools, and guidance on communicating with clinicians to enhance support (e.g., obtain work documentation). Here we present data on predictors of intervention use during systemic therapy from an ongoing randomized controlled trial comparing the TEAMWork app to the booklet. **Methods:** Eligible participants were women aged 18-65 years with stage I-III breast cancer who spoke English and/or Spanish, were employed pre-diagnosis, and undergoing or planning to undergo systemic (neo)adjuvant chemotherapy. Patients were recruited between October 2021 – March 2025 from multiple New York City sites. Data on socio-demographics, work characteristics, and intervention use were collected through patient surveys at baseline and after completion of chemotherapy. Multivariable logistic regression was used to assess predictors of intervention use during systemic therapy. **Results:** Of 372 participants (89% English; 11% Spanish), 54% identified as White, 17% Black, and 20% Hispanic/Latina. The mean age was 48 years. 70% were college-educated. All were employed at diagnosis, but only 77% were actively working (e.g., not on leave) at baseline. Participants worked in various occupations: managerial/professional (50%), sales/technical/administrative support (24%), service providers (21%), arts/media/athletics (5%), and operators/fabricators/laborers (1%). All participants received chemotherapy, with 53% starting therapy before the baseline survey. Slightly over half of participants (53%) reported using TEAMWork during systemic therapy; 120/187 (64%) in the mobile app arm and 76/185 (41%) in the booklet arm. In multivariable analysis, assignment to the mobile app arm was positively associated with intervention use during treatment (OR 2.54, 95% CI 1.61-4.05, $p<.001$). However, age, race, ethnicity, language, US-born (yes/no), educational attainment, occupational category, and chemotherapy initiation prior to randomization were not independently associated with intervention use. **Conclusions:** After adjusting for sociodemographic, occupational, and treatment-related characteristics, participants randomized to the mobile app arm had more than double the odds of using TEAMWork compared to those in the booklet arm. These findings underscore the importance of delivery format in the design of supportive interventions. Although mobile app development can be time- and resource-intensive, this approach may offer meaningful advantages in promoting patient engagement during therapy. Co-creating patient partnership within a national cancer trials network: Experience from Cancer Trials Ireland in partnership with the Irish Cancer Society. First Author: Emer Mulvaney, Cancer Trials Ireland, Dublin 2, Ireland

Background: Structured patient partnership is increasingly recognised in oncology research, yet less is known about how cancer trials groups and cancer charities can collaborate to sustain partnership system-wide. Cancer Trials Ireland (CTI) has established a patient partnership model through its Patient Consultants Committee, supported by the Irish Cancer Society (ICS), enabling integration of research infrastructure, charity support, and advocacy. **Methods:** The development and implementation of patient partnership at CTI from inception in 2016 was reviewed. The role of the ICS in enabling this model through funding, strategic alignment and public engagement was considered. Organisational learnings, barriers and facilitators to integration, research and strategic outputs, public outreach, clinical trial impacts, national and international collaborations, and engagement with early career investigators were synthesised from descriptive programme data and documented outputs. **Results:** By 2026, 33 patient partners were embedded across all adult Disease-Specific Subgroups, with patient and ICS representation in CTI governance. Key facilitators included a funded coordination role, enhanced partner recruitment, aligned public messaging, shared advocacy for clinical trial access and funding, and international research network engagement. Barriers to integration included challenges in patient diversity, competing commitments, and sustainable funding. Several were mitigated through partnership resourcing, advocacy and alignment of strategic priorities. Since 2023, patient partners have contributed to four investigator-initiated trial concepts and participated in Trial Management Groups. They contributed to grant applications, trainee research projects, and the development of a CTI climate change charter. Five patient-led, trainee-integrated research projects were delivered, resulting in international conference presentations and peer-reviewed publications. The CTI-ICS partnership supported sustainability and visibility through public engagement and policy activity, including contributions to the National Clinical Trials Oversight Group, engagement on GDPR barriers, election manifesto advocacy, and the *Value of Cancer Trials* campaign (co-launched with ICS and a patient partner). These findings demonstrate feasible integration of patient partners into a national cancer trials network at scale. **Conclusions:** A structured partnership between a national cancer trials organisation and a cancer charity can accelerate and sustain patient partnership beyond individual studies, embedding patient perspectives across trial selection, development, and dissemination. This experience complements cooperative group frameworks and offers a replicable approach for oncology research systems. Research Sponsor: Irish Cancer Society; Health Research Board (HRB).

Commercial price variation in precision oncology testing across US hospitals. First Author: Maryam Mooghali, Yale School of Medicine, New Haven, CT

Background: Precision oncology testing using clinically validated biomarker tests is standard of care for solid tumors and is endorsed by clinical guidelines and professional societies. However, these tests represent a substantial and growing component of cancer care costs. Commercial payer-negotiated prices for these tests and their variation across hospitals and payers have not been examined. **Methods:** We conducted a cross-sectional analysis of hospital-reported commercial payer-negotiated prices, aggregated by Turquoise Health as of January 2026, for biomarker tests commonly used in breast, colon, and non-small cell lung cancer and identified using the National Comprehensive Cancer Network Biomarkers Compendium and Centers for Medicare and Medicaid Services Clinical Laboratory Fee Schedule. We included tests with unique Current Procedural Terminology codes and extracted prices negotiated between short-term acute care hospitals and the four largest US payers (Aetna, Blue Cross Blue Shield, Cigna, UnitedHealthcare). Prices were adjusted using ZIP code-level Geographic Adjustment Factors. We assessed within- and between-hospital variation in prices for each test using the median 90th-to-10th percentile price ratio and compared prices across payers using Kruskal-Wallis tests. **Results:** We identified 422,515 payer-negotiated prices for 28 biomarker tests from 2,142 US hospitals. Oncotype DX Breast Recurrence Score and *CEA* expression testing were the most frequently reported panel- and non-panel-based tests, with median (interquartile range [IQR]) prices of $4,129 ($3,869–$10,680) and $28 ($20–$59), respectively, across hospitals. The percentage of hospitals reporting negotiated prices, price amounts, and price variation are summarized in the Table. Cigna had the highest prices for 20 (71.4%) tests, whereas UnitedHealthcare had the lowest price for all tests. **Conclusions:** Commercial payer-negotiated prices for precision oncology testing varied substantially across payers and hospitals, with greater variation between than within hospitals for the same tests. Given the central role of these biomarker tests in guideline-recommended cancer care, price variation has important implications for payer spending, clinical decision-making, patient out-of-pocket costs, and equitable care access. Research Sponsor: None.

Price variation for precision oncology testing.

Biomarker Tests	Percentage of hospitals in Turquoise Health database reporting negotiated price, Median (IQR)	Negotiated price, USD, Median (IQR)	Within-hospital ratios, Median (IQR)[1]	Between-hospital ratios, Median (IQR)[1]
Panel-based (N=13)	18.3% (17.2%-18.8%)	$3,704 ($3,096-$4,129)	1.5 (1.4-1.5)	5.5 (5.5-5.6)
Non-panel-based (N=15)	30.3% (22.2%-37.8%)	$301 ($157-$485)	1.6 (1.5-1.7)	5.2 (5.1-5.4)

Economic evaluation of a designated oncology pharmacist in hemato-oncology outpatient care: A randomized clinical trial. First Author: Areen Khateeb Alabbasi, Clalit Health Services, Tel Aviv, Israel

Background: Adverse drug reactions (ADRs) and medication errors are major contributors to morbidity and healthcare utilization in hemato-oncology. In a randomized clinical trial, we previously demonstrated that integrating a designated oncology pharmacist significantly reduced ADRs and intercepted potentially serious medication errors. The economic value of this intervention has not yet been established. **Methods:** We conducted a trial-based cost-effectiveness analysis alongside a single-center randomized clinical trial (n=182), in which adult patients with hematologic malignancies were randomized 1:1 to comprehensive pharmaceutical care delivered by a designated oncology pharmacist versus standard care. Patients were followed for 5 months (4-month intervention plus 1-month follow-up). The primary economic outcome was incremental cost per ADR avoided; secondary outcomes included cost per emergency department visit and hospitalization avoided. The analysis was conducted from the public healthcare system perspective and included only the pharmacist program cost, estimated at $105 per patient over the 5-month study period. Incremental cost-effectiveness ratios (ICERs) were calculated using absolute risk reduction, with uncertainty assessed by nonparametric bootstrap resampling (5,000 replications). Costs are reported in 2022 USD. **Results:** ADRs occurred in 47.3% of control patients compared with 23.1% of intervention patients, corresponding to an absolute risk reduction of 24.2% and a number needed to treat of 4.1. The ICER was $434 per ADR avoided (bootstrap 95% CI: $281–$956), with a $>$99.9% probability that the intervention reduced ADRs. Secondary outcomes also favored the intervention: emergency department visits (37.4% vs 28.6%; ICER $1,194 per visit avoided) and hospitalizations (28.6% vs 23.1%; ICER $1,911 per hospitalization avoided). In addition, the pharmacist intercepted 287 medication errors in real time, including 13 potentially severe errors, with a physician acceptance rate of 94.8%. **Conclusions:** This economic evaluation demonstrates that integrating a designated oncology pharmacist in hemato-oncology outpatient care is a cost-effective strategy for preventing ADRs and reducing acute healthcare utilization. These findings support broader implementation of oncology pharmacists as a high-value patient safety intervention. Research Sponsor: None.

Local and state paid sick leave policies and timeliness of treatment initiation among working-age patients with early-stage breast cancer. First Author: Kewei Sylvia Shi, American Cancer Society, Atlanta, GA

Background: Local and state paid sick leave (PSL) mandates have been associated with increased use of preventive services, including cancer screening, and reduced emergency care utilization. Little research has examined PSL policies and cancer after diagnosis. This study evaluates associations of PSL policies and timely treatment initiation among women with early-stage breast cancer. **Methods:** We identified patients aged 18-64 years newly diagnosed with stages 0-II breast cancer from the National Cancer Database in 2004-2023 and linked then to area-level policy implementation, measured as the month and year the state, county, or city required PSL. Primary outcomes were receipt of definitive surgery or neoadjuvant therapy within 30, 60, and 90 days of diagnosis. We compared changes in treatment initiation between patients residing in areas with and without PSL policies during and after the month and year of diagnosis. We used a staggered difference-in-differences design to account for differential timing of implementation, adjusting for patient demographics, clinical, and area-level characteristics. Random errors were clustered at the state level. Supplemental analyses stratified by county-level unemployment rates and individual insurance coverage. **Results:** The study included 1,891,411 patients, of whom 249,313 (13.2%) resided in an area with PSL policies at diagnosis. Patients in areas with PSL policies were more likely to have Medicaid, reside in higher-income and metropolitan areas. PSL policy implementation was significantly associated with a 3.4 percentage point (PPT) increase in the probability of treatment ≤30 days (95% CI: 1.1-5.7), 3.0 PPT increase ≤60 days (95% CI: 1.6-4.3), 1.3 PPT increase ≤90 days (95% CI: 0.5-2.1) (Table). Improvements in timely treatment were concentrated in low-unemployment areas; no significant improvements were observed in high-unemployment areas. The magnitude of associations between PSL policies and treatment initiation was stronger among patients without private insurance than with private insurance. **Conclusions:** Local and state PSL mandates were associated with earlier treatment initiation among working-age patients with early-stage breast cancer, especially in areas with low female unemployment rate. Findings suggest that PSL policies play an important role in timely cancer treatment for employed women who may not have PSL through their jobs. Research Sponsor: None.

Association of paid sick leave policies and breast cancer treatment initiation.

Association of facility type and metastatic burden with survival in gastric adenocarcinoma: A National Cancer Database study. First Author: Yazmin Reategui-Almonacid, Rutgers/Newark Beth Israel Medical Center, Newark, NJ

Background: While we know metastatic burden dictates survival in gastric adenocarcinoma (GA), how this intersects with where a patient receives care remains less clear. Academic centers (AC) often report better outcomes, but we haven't fully determined if this "academic advantage" holds true once you account for the sheer extent of disease at the time of diagnosis. We set out to test whether AC care offers a survival benefit that persists regardless of a patient's baseline metastatic burden. **Methods:** We retrospectively analyzed the National Cancer Database (2016–2023), identifying 102,869 patients with GA. We grouped patients by facility type (AC vs. community). We mapped metastatic burden at diagnosis across six specific sites: bone, brain, liver, lung, distant lymph nodes, and other. After comparing baseline characteristics, we estimated 3-year overall survival (OS) using Kaplan–Meier methods. Our primary tool was a multivariable Cox model, adjusting for age, Charlson–Deyo score, clinical stage, and metastatic burden to isolate the link between facility type and mortality. **Results:** Of the 102,869 patients, 58.4% (n = 60,064) were treated at ACs and 41.6% (n = 42,805) at community sites. Interestingly, community patients arrived with a higher burden of disease (33.8% vs. 30.4%; $p < 0.001$), and 11.7% of the total cohort had multi-site metastasis (≥2 sites). The liver was the most frequent site of spread, appearing more often in community settings (18.4% vs 15.4%; $p < 0.001$). Three-year OS was significantly higher at ACs (45.2% vs 35.8%; $p < 0.001$). After adjusting for site count, comorbidity, age, and stage, AC treatment remained independently associated with lower mortality (HR 0.81; 95% CI 0.80–0.83; $p < 0.001$). Notably, this academic survival advantage was not driven by any single metastatic site; the benefit persisted across all individual sites of involvement, including brain and lung, with no site showing a loss of AC advantage. **Conclusions:** Survival differed by treatment facility even after accounting for metastatic burden. Patients treated at academic centers had better outcomes across metastatic sites, including those with extensive disease. These findings point to differences in care delivery and access to specialized expertise. Expanding academic practices, such as multidisciplinary tumor boards and referral pathways, into community settings may help reduce these gaps. Research Sponsor: None.

Shifting drivers of hospitalization in endometrial cancer: Toxicity-like organ failure phenotypes in the modern treatment era. First Author: Sarah Peterson, ATSU Kirksville Osteopathic School of Medicine, Santa Barbara, CA

Background: Frontline endometrial cancer care has rapidly shifted toward immune-based regimens. Whether inpatient admissions have concurrently shifted toward toxicity-like organ failure syndromes, with changing ICU use and rescue outcomes, remains unknown. **Methods:** We performed a survey-weighted analysis of the National Inpatient Sample (NIS) 2016–2023. Adult hospitalizations with endometrial cancer in any diagnosis position (C54/C55) were included; admissions with palliative care coding (Z51.5) were excluded. Eras were defined as 2016–2017 versus 2018–2023. Toxicity-like organ failure phenotypes were identified using ICD-10-CM proxies including pneumonitis or respiratory toxicity, colitis or diarrhea, myocarditis or pericarditis, hepatitis or liver failure, neutropenic sepsis, acute kidney injury, and electrolyte collapse. A broader sensitivity phenotype additionally included endocrine crises. ICU escalation was proxied by mechanical ventilation or shock. Major complications were defined using a composite bundle, and failure-to-rescue was defined as death among complication admissions. Outcomes included in-hospital mortality, ICU escalation, complications, length of stay (LOS), cost, and routine discharge. **Results:** Among 74,895 unweighted endometrial cancer hospitalizations, 25.8% occurred in 2016–2017 and 74.2% in 2018–2023. Overall inpatient mortality was 1.86% (95% CI 1.66%–2.07%) in 2016–2017 and 2.09% (95% CI 1.96%–2.22%) in 2018–2023. Hospitalizations involving any toxicity-like organ failure phenotype increased from 34.3% (95% CI 33.4%–35.1%) in 2016–2017 to 45.2% (95% CI 44.7%–45.7%) in 2018–2023. Pneumonitis or respiratory toxicity increased from 6.23% to 9.91%, acute kidney injury from 14.9% to 21.0%, and electrolyte collapse from 23.7% to 31.7%. ICU proxy use increased from 2.50% (95% CI 2.27%–2.73%) to 3.30% (95% CI 3.15%–3.45%), driven by higher shock coding (0.82% to 1.61%). Major complications increased from 36.1% (95% CI 35.3%–36.9%) to 46.5% (95% CI 46.0%–47.1%). Mortality among admissions with toxicity-like organ failure decreased modestly from 4.75% (95% CI 4.25%–5.30%) to 4.25% (95% CI 4.00%–4.52%), while mortality among ICU-level admissions remained high and unchanged (29.7% vs 29.2%). Routine discharge declined from 66.6% (95% CI 65.6%–67.6%) to 62.2% (95% CI 61.7%–62.7%), and LOS increased in the modern era (mean 5.22 days, 95% CI 5.16–5.28). **Conclusions:** From 2016–2023, endometrial cancer hospitalizations increasingly involved toxicity-like organ failure phenotypes with rising ICU escalation and complication burden, while inpatient mortality changed minimally. These findings highlight a growing disconnect between outpatient therapeutic advances and inpatient recognition and rescue capacity. Research Sponsor: None.

Early-phase operational readiness gaps in oncology cell and gene therapy trials and implications for scalable trial infrastructure. First Author: Meera Belur, Premier Research, Cedar Park, NC

Background: First-in-human (FIH) and Phase 1 oncology cell and gene therapy (CGT) trials have highlighted that operational readiness, rather than scientific feasibility, is often the primary constraint on trial execution and patient access. Many clinical sites lack the infrastructure, staffing, and process maturity required to support CGT trials, limiting enrollment and scalability. **Methods:** Operational lessons were analyzed across multiple early-phase oncology CGT programs, including autologous and allogeneic platforms. Assessments focused on trial execution during FIH and Phase 1 activation, site readiness, vector and cellular product handling, storage and chain-of-custody requirements, coordination among manufacturing, sites, and couriers, staffing and training needs, and turnaround times from leukapheresis or biopsy to dosing. **Results:** Consistent site readiness gaps were identified in apheresis coordination, vector storage and handling, chain-of-custody documentation, and real-time cross-functional communication. Autologous programs showed increased operational complexity driven by patient-specific manufacturing, narrow scheduling windows, and variable vein-to-vein turnaround times. Allogeneic programs had reduced scheduling constraints but introduced challenges related to centralized manufacturing oversight and site-level accountability. Across platforms, CGT trials required specialized staffing and training beyond standard oncology research models. Insufficient early operational enablement resulted in delayed dosing and reduced patient access by ~1-3 months. **Conclusions:** Lessons from early-phase oncology CGT trials demonstrate that proactive operational readiness, particularly at the site level, is essential to enable scalable trial infrastructure and equitable patient access. Early readiness assessments, targeted workforce training, and integrated manufacturing-logistics coordination are critical to support efficient CGT trial execution and future expansion. Learning Objectives: Recognize common operational readiness gaps identified during FIH and Phase 1 oncology CGT trials. Understand how manufacturing, logistics, and site coordination impact early-phase trial execution. Apply early operational learnings to inform scalable CGT trial infrastructure. Key Takeaways: Operational readiness is a primary determinant of early CGT trial success. Many sites require significant enablement to conduct CGT trials effectively. Early investment in readiness improves turnaround times and patient access. Research Sponsor: None.

Prevalence and trends in rural patient enrollment in SWOG cancer clinical trials, 1992-2022. First Author: Izumi Okado, University of Hawai'i Cancer Center, Honolulu, HI

Background: A recent ASCO report highlighted improving patient access to cancer clinical trials as a fundamental priority. Although prior research found that 19% of participants in NCI-sponsored trials reside in rural areas, there is substantial heterogeneity in the classification of rurality. In addition, sociodemographic characteristics across different levels of rurality are unknown. In this analysis, we evaluated the prevalence and trends over time in trial enrollment by categories of rurality. **Methods:** We analyzed pooled data from phase II, II/III, and III trials conducted by the SWOG Cancer Research Network from 1992-2022. Rurality was defined by linking patient zip code to the Rural-Urban Continuum Codes, and categorized into four groups (large urban, small urban, rural, frontier). Baseline and patient demographic data were obtained from trial registration forms. Neighborhood deprivation, based on the Area Deprivation Index, was derived from patient zip code. The associations between rurality and patient characteristics were evaluated using multivariate logistic regression with covariate adjustments. Rurality enrollment was compared to corresponding overall US rurality estimates during the same period. **Results:** In total, N = 39,729 patients enrolled in 69 trials in brain, breast, GI, GU, gynecological, head and neck, lung, sarcoma, melanoma, and hematologic cancers were examined. Across the geographic groups, 52.2% lived in large urban, 30.9% lived in small urban, 11.6% lived in rural, and 5.4% lived in frontier areas, compared to corresponding US population estimates of 56.0% large urban, 28.6% small urban, 10.3% rural, and 5.0% frontier. Patients residing in frontier areas were nearly 80 times as likely to live in the highest versus lowest deprivation areas (OR = 78.37, 95% CI, 64.71-94.92, $p < .0001$). Similar though less pronounced associations were found among patients from rural and small urban areas ($p < .0001$). Frontier patients were more likely to be on Medicare (OR = 1.96, 95% CI, 1.66-2.30, $p < .0001$). Over the 30-year study period, trial enrollment among patients from frontier areas has decreased over time relative to the US population, whereas trial enrollment of patients from large urban areas has increased. **Conclusions:** Patients from rural and frontier areas are well-represented in SWOG clinical trials, however, enrollment among patients from frontier areas has shown a declining trend. Strong representation of patients with cancer from rural areas enhances the generalizability of trial findings. Given ongoing changes to healthcare, declining representation from frontier areas is likely to continue without targeted interventions. Further research is needed to expand access to care in these vulnerable areas and guide efforts that ensure adequate socioeconomic support for all patients, regardless of their geographic locale. Body mass index and mortality in immune checkpoint inhibitor–treated cancers: A real-world propensity-matched analysis. First Author: Katherin Zambrano, Berkshire Medical Center, Pittsfield, MA

Background: Immune checkpoint inhibitors (ICIs) are a cornerstone of treatment for multiple solid tumors, including lung cancer and melanoma. Emerging evidence suggests that body mass index (BMI) may influence outcomes with immunotherapy, though findings remain inconsistent and largely derived from clinical trial populations. We evaluated the association between BMI and mortality among patients with cancers treated with ICIs using real-world data. **Methods:** We conducted a retrospective observational study using data from TriNetX, a global real-world research platform based on de-identified electronic health records. Adult patients with lung cancer or melanoma who received immune checkpoint inhibitor therapy, including durvalumab, pembrolizumab, nivolumab, ipilimumab, or atezolizumab, were identified. Patients were stratified by documented baseline body mass index into two groups: BMI 19–24.9 (Normal) and BMI 30–49.9 (Obese). To address baseline differences, 1:1 propensity score matching (PSM) was performed using demographics and major comorbidities. The primary endpoint was all-cause mortality; secondary endpoints included inpatient hospitalization frequency. **Results:** Before matching, the cohorts consisted of 7,951 patients (BMI 30–49.9) and 4,651 patients (BMI 19–24.9). After PSM, 4,152 patients were included in each cohort. Baseline characteristics, including age (mean 67 years), sex (59% male), and comorbidities (hypertension, diabetes, CKD), were well-balanced ($p > 0.05$).All-cause mortality was significantly higher in the BMI 19–24.9 group compared to the BMI 30–49.9 group (49.2% vs 43.4%), with a risk ratio of 0.88 (95% CI,0.84–0.92; $p < 0.001$). Overall survival was significantly longer in the obese cohort, with a median survival of 1,043 days compared to 579 days in the normal BMI cohort. High BMI was associated with a 27.5% reduction in the hazard of death (HR 0.725, 95% CI 0.68–0.77; $p < 0.001$). Conversely, the high BMI cohort had a higher risk of inpatient encounters (57.6% vs 55.3%; p = 0.032) and a higher mean number of hospitalizations (5.4 vs 4.6; $p < 0.001$). **Conclusions:** In this large real-world study, higher BMI was associated with significantly lower mortality and nearly double the median survival time in patients treated with ICIs. While higher BMI was also associated with increased hospitalization frequency, the overall survival benefit remains robust. These findings support the "obesity paradox" in immunotherapy and suggest that nutritional status is a critical determinant of long-term ICI efficacy and healthcare utilization. Burden and site-specific spectrum of second primary malignancies after adult acute myeloid leukemia: A population-based SEER standardized incidence ratio study with latency-stratified risk profiling (2000–2022). First Author: Abat Khan, Memorial Cancer Institute, Pembroke Pines, FL

Background: As survival after acute myeloid leukemia (AML) improves, second primary malignancies (SPMs) represent an increasingly relevant survivorship outcome. We quantified overall and site-specific SPM risk following adult AML and characterized latency-dependent patterns and demographic heterogeneity. **Methods:** We performed a population-based cohort analysis using SEER 17 registries (2000–2022). Adults (≥18 years) with AML were followed for incident SPMs occurring ≥2 months after AML diagnosis. Risk was summarized using standardized incidence ratios (SIRs; observed/expected) with 95% confidence intervals (CIs), overall and by cancer site, and stratified by latency (2–11, 12–59, 60–119, ≥120 months), age, sex, and race. **Results:** Overall, 751 SPMs were observed versus 563.87 expected (SIR 1.33; 95% CI 1.24–1.43). Solid tumors overall were not significantly increased (SIR 1.03; 0.94–1.12), but select sites showed excess risk: oral cavity/pharynx (SIR 2.35; 1.64–3.27), skin excluding basal/squamous (SIR 1.42; 1.04–1.90), kidney (SIR 1.88; 1.31–2.60), and eye/orbit (SIR 4.32; 1.18–11.06), while breast cancer was reduced (SIR 0.65; 0.47–0.86). Hematologic SPMs were markedly elevated (lymphatic/hematopoietic SIR 2.48; 2.06–2.96), including leukemia overall (SIR 4.42; 3.45–5.59) and acute lymphoblastic leukemia (SIR 21.51; 11.76–36.08). All-site risk remained elevated across latency windows (SIR range 1.30–1.38), while solid-tumor risk increased after 5 years (SIR 1.27 at 60–119 months and ≥120 months). Risk was highest in ages 0–59 (SIR 1.91), and remained elevated in males (1.37) and females (1.27). **Conclusions:** Adult AML survivors experience a sustained excess risk of SPMs, driven primarily by secondary hematologic malignancies with additional site-specific solid-tumor excesses emerging in longer-term follow-up, supporting risk-adapted survivorship surveillance. Research Sponsor: None.

Site-specific risk of second primary malignancies after adult AML (SEER 17, 2000–2022).

Site	Observed	Expected	O/E	CI Lower	CI Upper
All Sites	751	563.87	1.33#	1.24	1.43
All Solid Tumors	506	491.44	1.03	0.94	1.12

Concordance of tissue and plasma NGS in early-stage non–small cell lung cancer. First Author: Juhi Gor, University of Illinois College of Medicine at Chicago, Division of Hematology and Oncology, Chicago, IL

Background: Comprehensive molecular profiling is standard of care for patients with advanced non-small cell lung cancer (NSCLC), and plasma-based next generation sequencing (NGS) demonstrates high concordance with tissue testing in metastatic disease. However, the performance of liquid biopsy in early-stage NSCLC remains poorly defined. In early stage, tissue-based NGS may be limited by inadequate sample quantity, low tumor cellularity, or DNA degradation. We evaluated the concordance of tissue and plasma NGS in patients with stage I to III NSCLC to determine whether liquid biopsy can reliably complement tissue-testing in this setting. **Methods:** We conducted a retrospective analysis of patients diagnosed with stage I to III NSCLC from 2021 to 2025 at the University of Illinois Cancer Center. Clinical and demographic data were abstracted through chart review. Paired NGS results were obtained from the Tempus Hub, including tissue-based sequencing (Tempus xT) and plasma-based sequencing (Tempus xF+). Actionable genomic alterations were assessed for concordance using 2x2 contingency tables, with calculation of overall concordance and positive percentage agreement (PPA). **Results:** A total of 71 patients with early-stage NSCLC were identified. The cohort was 52% male and 48% female; 61% Black, 23% White, 14% Asian and 3% other; 9% Hispanic and 88% non-Hispanic. 52% were 65 years or older at diagnosis. Disease stage included stage I (20%), stage II (10.6%), stage III (41%), with stage unknown 29%. No NTRK2/3, ROS1, RET, and MET alterations were detected on liquid or tissue. PPA for actionable mutations was low overall: BRAF V600E 66.7%, KRAS G12C 40%, EGFR 16.7%, HER2 0%, and EML4-ALK 0%. Despite low PPA, overall concordance exceeded 80% for all genes, driven by high negative percent agreement. **Conclusions:** In early-stage NSCLC, plasma-based NGS demonstrates limited sensitivity for detecting actionable driver alterations, despite high overall concordance driven by negative agreement. Reliance on liquid biopsy alone may miss clinically meaningful oncogenic drivers, even in potentially curable disease. While plasma NGS may be useful as a complementary or rule-out tool when tissue is inadequate, tissue-based molecular profiling remains essential for accurate genomic characterization in early-stage NSCLC. Research Sponsor: None.

Concordance and PPA analysis.

	Concordance	PPA
BRAF V600E	91.2%	66.7%
EGFR	86.0%	16.7%
HER2	98.6%	0%
KRAS G12C	84.5%	40%
EML4-ALK	98.6%	0%

Clinical-stage AI-enabled therapeutic assets: An industry-wide analysis of scale, clinical progression, and company characteristics. First Author: Waqas Haque, The University of Chicago, Chicago, IL

Background: Artificial intelligence (AI) is increasingly applied in therapeutic discovery and has driven substantial investment in AI-native biotechnology firms. However, the extent to which AI-enabled assets have progressed into and through clinical development remains incompletely characterized. We performed an industry-wide descriptive analysis of AI-enabled therapeutic assets that have entered interventional clinical trials. **Methods:** We identified AI-enabled therapeutic assets that entered at least one Phase 1–3 interventional clinical trial through July 1, 2025. Assets were manually curated using industry databases, public disclosures, and trial registries. AI enablement was defined at the asset level and required evidence of AI contribution to discovery or design. Drug-, trial-, and company-level characteristics were summarized using descriptive statistics. Company characteristics were obtained from PitchBook and public sources. **Results:** A total of 117 AI-enabled therapeutic assets across 63 companies entered interventional clinical trials. Oncology accounted for 69 assets (59.0%), and most assets were small molecules (96/117; 82.1%). As of December 1, 2025, 60 assets (51.3%) had completed Phase 1 and 8 (6.8%) had completed Phase 2. Among assets with reported Phase 1 enrollment (n = 103), the median sample size was 50 participants (IQR, 24–76.5). Approximately 35.9% of assets targeted a novel biological target. At the company level, the median time from founding to Phase 1 entry was 6.5 years (IQR, 4.0–9.2; n = 44). Median total funding was $186.7 million (IQR, $48.1M–$595.0M; n = 57), and median employee count at clinical entry was 73 (IQR, 32–129; n = 35). Median operational intensity was $2.72 million per employee (IQR, $1.71M–$5.83M; n = 47). **Conclusions:** AI-enabled therapeutic assets are increasingly entering clinical development, particularly in oncology, but most remain early in the clinical pipeline, with few having completed Phase 2. AI-native biotechnology companies that have reached the clinic typically do so within several years of founding with relatively small employee counts and high operational intensity. These findings provide a transparent baseline for evaluating the clinical impact of AI-enabled drug discovery as this cohort matures. Research Sponsor: None.

Impact of market entry of biosimilars in the US on cancer biologics' pricing strategies, market share, and payer costs. First Author: Xiaoyu Liu, UCLA, School of Public Health, Los Angeles, CA

Background: Biosimilars have been anticipated to lower the financial burden of cancer for payors as well as patients. As of 2025, 42% (n=13 from three product lines: bevacizumab, rituximab, and trastuzumab) of physician-administered biosimilars launched in the US were indicated for cancer. These three product lines accounted for approximately $5.35 billion healthcare expenditure at clinics and nonfederal hospitals in 2024. **Methods:** Using MarketScan claims data and Average Sales Price (ASP) data from the Centers for Medicare & Medicaid Services, we calculated quarterly ASP of reference products to compare the pricing strategies of reference biologics for cancer vs. non-cancer treatment. We also compared the market share between cancer vs. non-cancer biologics and estimated the average monthly payor costs of the three cancer product lines 12 months before biosimilar entry versus 2023. We identified biologics using Healthcare Common Procedure Coding System codes and adjusted costs to 2025 USD using the prescription drugs Consumer Price Index. **Results:** Analyses included 8,252,400 claims of 8 reference products and 27 biosimilars. All three cancer biologics experienced biosimilar market entry starting late 2019. On average, the ASP of reference biologics for cancer decreased by 4.3% annually after biosimilar entry, contrasting to 17.2% decrease for non-cancer reference biologics. Meanwhile, the market share of reference biologics decreased on average 39.3%, 34.2%, and 35.4% annually for bevacizumab, rituximab, and trastuzumab, respectively, contrasting to 15.4% decrease for non-cancer reference biologics. Compared to monthly payor costs averaging over 12 months before the first biosimilar launch, monthly payor costs of biologics (including reference and biosimilars) in 2023 fell for all three cancer biologics in the commercial and Medicare market. The annual decrease rate in monthly payor costs was on average 45.1%, 52.0%, and 34.6% for bevacizumab, rituximab, and trastuzumab, respectively. **Conclusions:** After biosimilar entry, reference biologics for cancer reduced prices at a slower pace than non-cancer reference biologics, this pricing strategy led to a much faster decrease in their market share. Biosimilars for cancer, by gaining larger market share over time, has significantly reduced payor costs of cancer biologics for commercial and Medicare insurers. Research Sponsor: None.

			Commercial insurance mean monthly payor costs			Medicare Part B mean monthly payor costs		
Drug	Reference product ASP annual change	Reference product market share annual change	Before biosimilar entry	2023	Change	Before biosimilar entry	2023	Change
bevacizumab	-2.1%	-39.3%	$5,261.9	$2,823.0	-46.4%	$2,720.0	$1,526.8	-43.9%
rituximab	-4.4%	-34.2%	$7,187.4	$3,799.2	-47.1%	$3,977.7	$1,717.1	-56.8%
trastuzumab	-6.5%	-35.4%	$4,781.6	$3,302.7	-30.9%	$2,401.6	$1,485.0	-38.2%

Heart failure in hospitalizations for hematologic malignancies versus solid tumors: National burden and inpatient outcomes, 2018-2022. First Author: Dylan Lee, Touro University Nevada College of Osteopathic Medicine, Las Vegas, NV

Background: Heart failure (HF) is a common and morbid comorbidity in oncology. Whether HF burden and prognosis differ between hospitalizations for hematologic malignancies and solid tumors remains incompletely characterized at a national level. This study compared HF prevalence and HF-associated outcomes across these cancer groups. **Methods:** A serial cross-sectional analysis was conducted using adult hospitalizations in the 2018 to 2022 Healthcare Cost and Utilization Project National Inpatient Sample with discharge-level survey weighting. Cancer hospitalizations were classified by principal diagnosis as hematologic malignancy or solid tumor. HF was identified using ICD-10-CM I50* in any diagnosis field. Outcomes included HF prevalence, in-hospital mortality, intensive care unit utilization, shock, length of stay, and hospitalization cost. Survey-weighted multivariable regression adjusted for demographics, comorbidities, hospital characteristics, and admission factors. Models restricted to HF admissions evaluated associations between cancer type and outcomes within the HF subgroup. **Results:** Among an estimated 4.81 million cancer hospitalizations nationally, HF prevalence was higher in hematologic malignancies than in solid tumors (13.2% vs 8.0%, $p < 0.001$). After adjustment, hematologic malignancy was associated with higher odds of HF (adjusted odds ratio (aOR) 1.53, 95% CI 1.50 to 1.57). Among HF hospitalizations, hematologic malignancies had higher mortality (11.7% vs 8.0%), intensive care unit utilization (8.5% vs 7.3%), and shock (3.8% vs 3.4%) (all $p <$ 0.001). In adjusted models restricted to HF admissions, hematologic malignancy remained associated with higher mortality (adjusted odds ratio 1.34, 95% CI 1.26 to 1.42) and intensive care unit utilization (aOR 1.15, 95% CI 1.07 to 1.23). Resource utilization was greater in hematologic malignancy HF admissions, including longer length of stay (12.1 vs 8.3 days) and higher costs ($50,518 vs $30,906; both $p < 0.001$). Interaction modeling showed no significant effect modification of HF-associated mortality by cancer type. **Conclusions:** Hospitalizations for hematologic malignancies have higher HF prevalence than solid tumor hospitalizations and demonstrate higher mortality, intensive care utilization, shock, length of stay, and costs among admissions with HF. These findings identify hematologic malignancy hospitalizations as a high-risk context for HF-associated inpatient deterioration and resource use. Research Sponsor: None.

Closing the information gap in oncology: A retrieval-augmented generation multi-modal AI platform for personalized patient education and physician efficiency. First Author: Weiqi Liang, Department of General Surgery & Guangdong Provincial Key Laboratory of Precision Medicine for Gastrointestinal Tumor, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Effective patient education is critical in oncology but hindered by the complexity of treatment guidelines and the time constraints of clinicians. Traditional static materials often fail to address the personalized needs of diverse demographics, particularly the elderly. We developed an Intelligent Medical Science Popularization Platform integrating Multimodal Large Language Models (MLLM) with Retrieval-Augmented Generation (RAG) to automate the production of reliable, guideline-based oncology educational content. **Methods:** The platform utilizes a three-tier architecture deployed at a tertiary cancer center. The core engine combines a self-developed MLLM with RAG, anchoring content generation to authoritative sources (e.g., CSCO/NCCN guidelines and peer-reviewed journals) to ensure clinical accuracy. The system features: (1) Physician Portal: Automates the conversion of clinical protocols into patient-friendly text, layouts, and animations; (2) Multimodal Synthesis: Generates virtual avatar videos explaining diagnoses and treatments; (3) Patient Interface: Delivers personalized, accessible content via mobile apps, supporting voice interaction for elderly adherence. **Results:** Implementation data demonstrated significant efficiency and engagement gains. The MLLM+RAG model achieved $>$ 98% accuracy in content generation as verified by expert oncologists. The production time for educational videos was reduced from 72 hours to ~10 minutes ($>$ 99% reduction), enabling rapid updates aligned with new trial data. Animation production costs decreased by 10-fold. Daily content output exceeded 15 units. Notably, in a cohort of elderly cancer patients, the platform increased user retention rates by 40% and extended average session duration by 50 seconds, indicating improved engagement with health information. **Conclusions:** This policy-compliant AI platform validates the utility of RAG-based MLLMs in oncology. By shifting from passive information supply to active, personalized intelligent services, it significantly reduces the workload for oncologists while bridging the digital divide for vulnerable patient populations. This model offers a scalable solution for enhancing health literacy and treatment adherence in cancer care. Research Sponsor: None.

The 2026 primary care oncology toolkit: An evolving shared-care framework for the implementation of prospective survivorship evidence. First Author: Manila Sharma, New York Medical College - Saint Michael's Medical Center, Newark, NJ

Background: As cancer survivorship transitions into a chronic disease model, a significant "implementation gap" exists between landmark 2025 clinical data and frontline primary care. Survivors face a 2.39-fold higher risk of cardiovascular mortality, yet standardized protocols for PCP-led surveillance remain in development. This review identifies an evolving "Shared-Care Framework" designed to integrate prospective 2025 evidence into the internal medicine setting, anticipating a shift toward decentralized, longitudinal survivorship care. **Methods:** A narrative synthesis was performed to develop a pilot-ready framework for primary care. We analyzed practice-changing evidence published between January 2025 and January 2026, including the Barac Risk Model, the Bhalraam et al. SGLT2i meta-analysis , and emerging cervical screening strategies. Findings were synthesized into thematic surveillance blocks to identify opportunities for prospective guideline-concordant implementation. **Results:** Synthesis of recent landmark data identified several opportunities for prospective adoption in the internal medicine setting. The framework evaluates evolving cardio-metabolic surveillance strategies, including the integration of the Barac Model (2025) for 10-year heart failure (HF) risk prediction and the proactive use of SGLT2 inhibitors, which have demonstrated a 51% reduction in HF hospitalizations among survivors. Furthermore, the review identifies prospective clinical blocks for PCP-led surveillance of stable survivors, emphasizing proactive bone health monitoring for patients on aromatase inhibitors and metabolic screening for those on androgen deprivation therapy (ADT). This includes the potential adoption of low-dose oxybutynin as a new standard for managing ADT-induced hot flashes. Finally, the framework addresses health equity paradigms by evaluating the transition to in-office HPV self-sampling and automated EMR alerts for age 45 colorectal screening to mitigate the rising incidence of early-onset disease. **Conclusions:** This evolving shared-care framework offers a scalable model for the future of survivorship. By aligning primary care protocols with prospective 2025 landmark data, clinicians can optimize long-term coordination and address health disparities ahead of formal guideline updates. Inpatient burden and outcomes across gastrointestinal cancer subtypes among younger adults in the United States, 2018–2022. First Author: Emaan Tiwana, MountainView Hospital, Las Vegas, NV

Background: Early-onset gastrointestinal (GI) cancers are increasingly recognized, yet national data describing inpatient burden and outcomes across GI cancer subtypes in younger adults remain limited. **Methods:** A serial cross-sectional analysis was performed using the 2018–2022 Healthcare Cost and Utilization Project National Inpatient Sample. Adult hospitalizations among younger adults (age 18–49 years) with a principal diagnosis of GI malignancy were identified and categorized by cancer subtype. Outcomes included in-hospital mortality (primary), length of stay (LOS), and hospitalization cost estimated using cost-to-charge ratios. National estimates accounted for survey weighting, clustering, and stratification. Survey-weighted multivariable logistic regression evaluated associations between cancer subtype and in-hospital mortality, adjusting for age, sex, race/ethnicity, payer, neighborhood income quartile, elective admission, APR-DRG severity, hospital teaching status, geographic region, and calendar year. Sensitivity analyses were performed restricting the cohort to age $<$ 45 years. **Results:** Across 2018–2022, principal GI cancer hospitalizations among younger adults were dominated by colorectal cancer, followed by stomach, pancreatic, liver or intrahepatic biliary, and esophageal cancers. In-hospital mortality varied by cancer subtype and year, with higher crude mortality observed for pancreatic, stomach, esophageal, and liver or intrahepatic biliary cancers compared with colorectal cancer. Resource utilization increased markedly during 2020 across subtypes, with corresponding increases in LOS and hospitalization costs. In adjusted analyses using colorectal cancer as the reference, odds of in-hospital mortality were higher for stomach (adjusted odds ratio [aOR] 3.01, 95% CI 1.78–5.10), esophageal (aOR 2.12, 95% CI 1.03–4.37), and liver or intrahepatic biliary cancers (aOR 2.56, 95% CI 1.36–4.79). Pancreatic cancer demonstrated a borderline increase in mortality (aOR 1.79, 95% CI 0.96–3.36). Higher APR-DRG severity was strongly associated with mortality (aOR 5.20, 95% CI 3.50–7.72). Sensitivity analyses demonstrated similar subtype ordering and mortality patterns. **Conclusions:** Among younger adults hospitalized with GI malignancies, inpatient mortality and resource utilization varied substantially by cancer subtype. Colorectal cancer accounted for the largest share of hospitalizations, while stomach, esophageal, and liver or intrahepatic biliary cancers were associated with higher adjusted inpatient mortality. These nationally representative findings provide benchmarking data on inpatient outcomes across early-onset GI cancer subtypes. Research Sponsor: None.

Enhanced financial assistance intervention for unmet essential needs: A prospective pilot study to improve timely cancer treatment completion. First Author: Justin Michael Barnes, Department of Radiation Oncology, Mayo Clinic Arizona, Phoenix, AZ

Background: Unmet essential needs, such as food, transportation, and housing insecurity, can create barriers to timely cancer treatment. Delayed or prolonged courses of definitive radiotherapy (RT) can compromise cancer outcomes like recurrence and survival. There are limited prospective data testing interventions to improve timely cancer treatment completion by meeting essential needs. **Methods:** We conducted a pragmatic single-arm pilot study testing an enhanced financial assistance intervention for unmet needs during RT. Eligibility criteria included adults with a cancer diagnosis and unmet social needs (via social risk screening and/or social worker evaluation) who were prescribed or undergoing a course of RT with $>$ 10 fractions remaining. Participants received standard institutional assistance (e.g., limited support for travel/lodging with strict eligibility criteria) plus the enhanced assistance intervention, including needs assessments prior to and during RT and up to $2000/patient of tailored unconditional monetary transfer via gift cards for all essential needs identified. The primary outcome was delay-free completion of RT (DFC: completing all prescribed RT fractions and delaying $<$ 5 fractions). The study was powered (power = 80%, 1-sided alpha = 0.2 for this pilot study) to detect a 10-percentage point increase in % DFC relative to a historic benchmark of 83% (based on similar patients from our institution), with required sample size of N = 33. Due to delays in gift card administration (on average ~2 weeks after consent), we also present per protocol analysis, limited to patients who had $>$ 10 fractions remaining after first receiving financial assistance. Post-hoc analyses using generalized linear mixed models evaluated percentages of delayed fractions prior to and after an individual's receipt of financial assistance. **Results:** 35 met inclusion criteria and were approached, 33/35 enrolled. Participants received median assistance of $1800 ($700-2000) and had a median of 27 RT fractions after consent (range: 12-35) and 17 (3-34) after receiving assistance. In the overall cohort, 1 patient did not complete RT and 2 patients had $\geq$5 delayed fractions, leading to 30/33 achieving DFC (90.9%, 80% CI = 83.9 – 100), significantly higher than the 83% benchmark. In the per protocol analysis, 27/28 achieved DFC (96.4%, 80% CI = 89.7–100, P = .037). Among the 27 patients who started RT prior to receiving assistance, mixed model analysis showed more delayed fractions prior to (7.1%) vs. after (3.0%) receiving assistance (OR 2.84, 95% CI = 1.43-5.80, P = .003). **Conclusions:** In this prospective pilot study, a tailored enhanced financial assistance intervention for unmet essential needs led to improved delay-free completion of RT over a historic benchmark. Further analysis on patient-reported quality of life and financial toxicity will be reported in the future. Clinical trial information: NCT06582849. Research Sponsor: Conquer Cancer, the ASCO Foundation; WashU, Siteman Cancer Center.

Has racial and ethnic representation in oncology clinical trials changed?: A 30-year systematic analysis using artificial intelligence. First Author: Rahman Adesoji Olusoji, The Ohio State University Comprehensive Cancer Center – Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, Columbus, OH

Background: Despite societal emphasis on racial and ethnic representation in oncology trials, it remains unclear whether participant diversity has meaningfully changed over time. Recent advances in large language models (LLMs) enable scalable extraction of data from PDF documents, facilitating high-throughput research. **Methods:** We identified all oncology clinical trials published in The Lancet and The New England Journal of Medicine (NEJM) between 1995 and 2025, and retrieved full-text PDFs from the journals' websites. Using an LLM (Gemini-2.5-Flash), structured variables, including trial phase, cancer type, enrollment countries, and participant race and/or ethnicity, were automatically extracted from texts, tables, and figures. Trials were stratified by decade (1995–2005, 2006–2015, and 2016–2025) to evaluate temporal trends. **Results:** We identified 1,385 oncology trials between 1995 and 2025, including 334, 448, and 603 for the three decades, respectively. The proportion of phase III trials increased steadily over time (68%, 72%, and 76%). Trials also became more globally distributed, with multi-continental studies rising from 27% to 46% and 58%. Most notably, Asian countries were increasingly involved among trial enrollment sites, rising from 14% to 25% and 45%. Reporting of race/ethnicity increased over time, from 16% to 29% and 47% of publications across decades. Among studies that reported race, non-White enrollment increased, with the median percentage per study rising from 10% in both earlier decades to 21% in 2016–2025. However, after excluding Asian participants, the median non-White percentage declined across decades (7.5%, 5.3%, and 4.3%). In pooled analyses across all trials, non-White patients comprised 15%, 11%, and 15% of total enrollment, respectively; excluding Asian patients, this decreased from 13.2% to 6.2% and 6.9%. Black enrollment declined over time, with the median percentage falling from 6.8% to 2.4% and 1.5%. Among trials reporting ethnicity, Hispanic enrollment remained consistently low (5.4%, 4.0%, and 4.6%). **Conclusions:** Globalization and race/ethnicity reporting in oncology trials improved, but the observed increases in diversity were largely attributable to the expansion of trial enrollment in Asia. In contrast, Black and Hispanic representation remained low or declined across decades. Research Sponsor: None.

The Bermuda model: Achieving world-class, equitable, and efficient cancer care in a small island nation. First Author: Ross Jarrett, Bermuda Cancer and Health Centre, Bermuda, Bermuda

Background: Bermuda is a small island nation that historically faced significant challenges in provision of local cancer care. Between 2000-2017, 100% of patients requiring radiation therapy (RT) had to travel abroad, causing prohibitive financial toxicity. In 2017, Bermuda Cancer and Health Centre (BCHC) evolved to deliver an integrated and comprehensive national cancer solution, including RT. The "Bermuda Model" represents a national approach to address critical gaps in cancer care by leveraging innovative partnership models to enable access, efficiency, health equity and international quality standards. **Methods:** We conducted a retrospective descriptive cohort study. Data for cancer incidence/outcomes were collected from the Bermuda National Tumour Registry; treatment/quality data and patient satisfaction surveys were collected from BCHC clinical records. Timeframes for travel reduction data were between 2015-2020. Outcomes measures included percentage of overseas referrals for RT and chemotherapy, international quality assurance, patient satisfaction scores from 2025, access measures such as interval from diagnosis to treatment, cancer-specific overseas insurance claims, and selected clinical outcomes, including early breast cancer detection and survival rates. **Results:** The Bermuda Model has eliminated the need for overseas RT, ensuring access for the 70-90% who previously went abroad and the remainder who went without. Through an international strategic partnership with Brigham and Women's Hospital, high quality and consistent peer-review of radiation treatment plans by Harvard faculty specialists was ensured for 100% of all patients receiving RT at BCHC. Patient satisfaction rates for RT were 100% positive for multiple months in 2025. Between 2017-2019, Bermuda achieved excellent clinical outcomes including an 87% early detection rate for localized (Stage 1-2) breast cancer and a lower breast cancer mortality rate than either the USA or Europe. Care timelines were efficient; average time from diagnosis to first treatment was as low as 16 days in 2025. The model was associated with an approximately 24% reduction in cancer-specific overseas insurance claims between 2017-2020 ($6.2 million and $4.7 million respectively). **Conclusions:** The "Bermuda Model" demonstrates that with strategic investment and international partnerships, a small island nation can locally establish world-class, equitable, and efficient cancer care services. Eliminating overseas treatment, high satisfaction, and excellent outcomes evidence its success. The reduction in claims has been particularly impactful for Bermudian residents with government-level insurance, helping to advance, access-to-all cancer care. This model serves as a valuable blueprint for other small nations or isolated regions seeking to improve their delivery of cancer care. Research Sponsor: None.

Integrating AI-derived lung cancer risk and social determinants of health to improve risk stratification in a safety net lung cancer screening program. First Author: Evan Garrad, University of Illinois Chicago, Chicago, IL

Background: Lung cancer screening (LCS) outcomes remain inequitable, with social and environmental determinants of health (SDOH) influencing lung cancer risk, screening adherence, and cancer detection. Sybil is a validated deep learning model that predicts future lung cancer risk from a single low-dose CT (LDCT) scan using imaging features alone, without demographic or clinical inputs created by MIT/MGH. Its relationship to SDOH in real-world, safety-net screening populations has not been well characterized. **Methods:** We analyzed 2,645 individuals enrolled in the UI Health LCS program with baseline LDCT imaging and available Sybil risk scores. Scores were generated using the publicly available model applied exclusively to volumetric LDCT images, without retraining or incorporation of demographic, clinical, or SDOH variables. Individual-level clinical data were linked to census- and community-level SDOH measures. Sybil scores were $\log_{10}$-transformed and analyzed as continuous and categorical variables. Associations between Sybil risk, SDOH, and lung cancer diagnosis were assessed using multivariable logistic regression. **Results:** Mean baseline Sybil score was 0.014 (median 0.002). Ninety-six individuals (3.6%) were diagnosed with lung cancer. Sybil scores were significantly higher among individuals later diagnosed with cancer (mean log score -1.52 vs -2.48; $p<0.001$). In multivariable models, Sybil risk was the strongest independent predictor of lung cancer diagnosis (OR 6.12 per log-unit increase, 95% CI 4.31–8.83; $p<0.001$), independent of BMI and SDOH. High Sybil risk remained strongly associated with cancer diagnosis across multiple thresholds (all $p<0.001$). Census-level area deprivation and community-level measures of food insecurity, vehicle access, and neighborhood conditions were also independently associated with cancer diagnosis (Table 1). **Conclusions:** In a large safety-net LCS cohort, AI-derived Sybil risk robustly predicted lung cancer diagnosis and remained informative despite relying solely on imaging data. Integrating AI-based risk prediction with SDOH context may support more equitable, precision-guided lung cancer screening strategies. Research Sponsor: None.

Association of Sybil AI-risk scores and social determinants of health with lung cancer diagnosis in the UI Health lung cancer screening cohort.

Predictor	Comparison / Scale	Adjusted OR (95% CI)	P value
Sybil score	Log10 continuous	6.12 (4.31–8.83)	<0.001
Sybil score	High vs Low (median cutoff)	4.18 (2.38–7.79)	<0.001
Sybil score	High vs Low (75th percentile)	5.10 (3.08–8.57)	<0.001
Sybil score	High vs Low (tertiles)	8.02 (3.90–18.72)	<0.001
BMI	Per unit increase	0.93 (0.89–0.96)	<0.001
Area Deprivation Index	Census-level	1.02 (1.00–1.04)	0.02
Food insecurity	Community-level (%)	1.08 (1.02–1.15)	0.01
No vehicle access	Community-level (%)	1.05 (1.02–1.09)	0.003

Closing the distance and the Specialist Nursing Optimal Placement Tool (SN-OPT): Strategic placement of specialist cancer nurses to achieve resource and geographic equity in Australia. First Author: Rebecca Johnson, Melanoma Institute Australia, The University of Sydney, Sydney, Australia

Background: Cancer workforce planning that enables effective specialist nurse placement is critical for delivering high-quality, patient-centered care. Inequitable access to specialist nursing represents a significant gap in cancer care delivery. No standardized tools assess specialist cancer nursing resource needs across national healthcare systems. We developed SN-OPT, an innovative resource allocation tool, using 30 new centrally funded specialist melanoma nurse positions for Australia as a case study. **Methods:** A multidisciplinary panel developed SN-OPT via expert consensus, incorporating three data domains: Clinical Infrastructure Assessment: Analysis of facility capabilities including multidisciplinary team (MDT) structures, clinical trial programs, and existing nursing and support services Demand Assessment: Quantitative analysis of case load, treatment complexity, and nursing workload benchmarks Health Equity: Population-level analysis incorporating geographic accessibility and socioeconomic disadvantage SN-OPT combines cancer incidence data with facility metrics to allocate nursing resources operating within a MDT framework. Equity assessment utilized Australian Statistical Geography Standard, Index of Relative Socio-Economic Disadvantage and Travel Time to Hospitals in Australia dataset. **Results:** SN-OPT evaluated 46 Australian facilities for melanoma nursing allocation. The weighted scoring algorithm ranked 33 sites for nurse allocation, with a mean allocation of 0.87 full time equivalent (FTE) positions per metro facility and 0.64 FTE per regional facility. The tool achieved equitable geographic distribution of specialist nursing expertise: regional facilities, treating 25% of patients, received 36% of nursing FTE (167 patients/FTE/year). Metro facilities, managing 75% of patients, received 64% of FTE (212 patients/FTE/year). Allocations largely aligned with facility-determined resource need, with 58% receiving their requested FTE. Among the remaining facilities, median allocation variance was -0.4 FTE (range -0.1 -1.0). On a population level, 89% of Australians would have geographic access to specialist melanoma nursing care within 2-hours of travel, including 81% of the most socioeconomically disadvantaged regions. **Conclusions:** SN-OPT offers a reproducible framework for data-driven allocation of specialist cancer nurses. While implemented using melanoma nurses as a case study, SN-OPT's framework has the potential to be adapted across cancer streams and countries, providing a scalable approach to equitable cancer workforce planning. Early implementation balances clinical service delivery and demand requirements within a MDT framework, while allowing adequate geographical access including socioeconomically disadvantaged regions. Equity in breast cancer research authorship: Country, gender, and income representation in phase III trials presented at the ASCO Annual Meeting (2015–2025). First Author: Sydney Johnson, Queen's University, School of Medicine, Kingston, ON, Canada

Background: Equitable representation in global oncology research is essential for scientific validity, generalizability, and ethical trial conduct. However, leadership in clinical research remains concentrated in high-income countries (HICs), with persistent gender inequities. We evaluated longitudinal trends in geographic, economic, and gender representation among authors of Phase III breast cancer trials presented at the ASCO Annual Meeting. **Methods:** We conducted a retrospective analysis of abstracts accepted to the ASCO Annual Meeting from 2015–2025 within breast cancer tracks, including metastatic and local/regional/adjuvant categories. Abstracts were identified using keyword searches for "phase" and included if they reported Phase III clinical trial data. For each eligible abstract, data were extracted for first and senior (last) authors, including institutional affiliation, country, World Bank region, and World Bank income classification. Author gender was assigned using a hierarchical approach incorporating culturally associated names, publicly available professional profiles, and genderize.io. Differences in authorship distribution by country were assessed using a univariate generalized linear model with country as a fixed effect. **Results:** Of 1,199 screened abstracts, 420 met inclusion criteria. Authorship was dominated by North America (44%) and Europe/Central Asia (40%), with representation from Latin America/Caribbean and Middle East/North Africa/Afghanistan/Pakistan each $<$ 1%. The United States accounted for 40.7% of all authorship. East Asia representation increased from 2.8% (2015) to 19.1% (2025), driven by China, South Korea, and Japan. Country effect on authorship share was significant ($F = 3.381$, $p = 0.001$), while year was not ($F = 0.000$, $p = 1.000$), indicating persistent structural hierarchies. Overall, 93% of authors were affiliated with HICs, ~7% with upper-middle–income countries, and $<$ 1% with lower-middle–income countries; no senior authors were from lower-middle–income countries. Gender distribution was 61.7% male and 37.7% female. Only Germany demonstrated female predominance in senior authorship among top contributing countries, while Japan exhibited 100% male senior authorship. **Conclusions:** Phase III breast cancer research presented at ASCO remains structurally concentrated in high-income countries with persistent geographic, economic, and gender inequities. Low- and middle-income countries remain largely excluded from academic leadership, and senior authorship remains male-dominated. These findings demonstrate enduring structural imbalances in global oncology research production and leadership, underscoring the need for equity-focused funding models, inclusive trial governance, and capacity-building research partnerships. Research Sponsor: None.

11084 **Poster Session**

Evaluating value in the age of accelerated approval: A pembrolizumab case study. First Author: Jeffrey Mathew Boby, Govt. Medical College Kozhikode Kerala, Kozhikode, India

Background: The FDA accelerated approval (AA) program was established to expedite approval of promising drugs that meet unfulfilled clinical needs. AA is granted on the basis of surrogate endpoints, decreases time to market, and increases access to therapies. Pursuing multiple AA and label expansions can also be a significant component of a drug's lifecycle strategy. Among 322 anticancer drug approvals (2009-2020), 59% were label expansions, with only 16% granted to new drugs with a novel mechanism of action. Our goal was to understand changes in value across multiple label-expanding AAs for high-cost anticancer medications. We studied pembrolizumab, a highly successful immune checkpoint inhibitor, evaluating value from its initial approval through multiple label expansions. **Methods:** We calculated value scores for different indications of pembrolizumab using the ASCO Value Framework Net Health Benefit Worksheet (2020) and ESMO-MCBS v2.0. The value calculations require mature survival outcomes, so we could not calculate scores for AA indications awaiting data maturity (2) or those eventually withdrawn from the market (2). We utilized the FDA drug database and primary literature to gather safety and efficacy outcomes for each indication. Analysis generated descriptive statistics about how the value of pembrolizumab evolved from 2014 to 2025. **Results:** We calculated value scores for 28 pembrolizumab indications, 12 with AA. Value scores varied widely across indications, with ASCO Net Health Benefit Score (NHBS) ranging from 17 (biliary tract cancer) to 59 (MSI/dMMR colorectal cancer) and ESMO MCBS scores ranging from 1 to 5. NHBS was not perfectly collinear with OS gains. The rolling average of NHBS across all indications over time remained fairly stable with a mean score of 37.67 (range: 30- 41). We also compared the NHBS for each AA indication to the cumulative NHBS average at the time each AA was granted. The NHBS for HCC, HNSCC, and cervical cancer were lower than respective pre-AA NHBS averages. The other 9 AAs yielded a final NHBS higher than each's pre-AA average NHBS. **Conclusions:** The NHBS formula generated varying values for different pembrolizumab indications, distinct from simple measures such as OS-rank order. Although the average NHBS remained fairly constant over time, it was lower than the maximum NHBS (59) and less than the NHBS of other breakthrough approvals (osimertinib for NSCLC: 110, nivolumab for melanoma: 53). If the average value of multiple indications in a drug's indication portfolio is significantly lower than a few blockbuster successes, clinicians could be vulnerable to an availability heuristic and overestimate the value of new AAs, based on anecdotal understanding of prior successes. In an environment of fast-paced AAs and label expansions, clinicians, patients, and payers should develop and deploy rapid value assessment tools in order to sustainably maintain access to high-yield cancer therapies. Research Sponsor: None.

Dysphagia-associated inpatient risk phenotypes and mortality in hospitalized head and neck cancer: A national analysis. First Author: Manraj Dhillon, Department of Internal Medicine, Sunrise Health GME Consortium, Las Vegas, NV

Background: Dysphagia is common in patients with head and neck cancer (HNC) but is often viewed as a quality-of-life issue rather than a driver of acute inpatient outcomes. Its contribution to airway failure, mortality, and resource utilization is poorly defined, particularly when dysphagia is uncoded. We evaluated whether dysphagia-associated clinical signals define inpatient risk phenotypes, including a high-risk subgroup with silent dysphagia. **Methods:** We conducted a survey-weighted analysis of the National Inpatient Sample (NIS), 2016 to 2023, including adults hospitalized with HNC identified using ICD-10-CM codes C00 to C14 and C30 to C32. Tumors were categorized by first-hit anatomic site, and palliative admissions (Z51.5) were excluded. Dysphagia-associated signals included dysphagia (R13*), aspiration pneumonia (J69*), and feeding tube placement (ICD-10-PCS 0DH6*), which were combined into mutually exclusive dysphagia phenotypes. Silent dysphagia was defined as aspiration pneumonia or feeding tube placement without dysphagia coding. The primary outcome was in-hospital mortality. Secondary outcomes included mechanical ventilation, tracheostomy, shock, length of stay (LOS), and hospitalization cost. Survey-weighted regression models adjusted for demographics, payer, socioeconomic status, admission characteristics, hospital factors, tumor site, comorbidity burden, and year. **Results:** Among 112,495 unweighted HNC hospitalizations (weighted national estimate approximately 562,000), 26.6% had coded dysphagia, 8.7% aspiration pneumonia, and 16.3% underwent feeding tube placement; 11.4% met criteria for silent dysphagia. Mortality increased stepwise across phenotypes, from 1.82% (95% CI 1.72 to 1.93) in patients without dysphagia-associated signals to 8.59% (95% CI 7.80 to 9.47) with aspiration alone. Aspiration plus feeding tube placement was associated with the longest LOS (20.2 days, 95% CI 18.9 to 21.6) and highest mean cost ($77,615, 95% CI $70,531 to $84,700). In adjusted analyses, aspiration alone was associated with higher mortality (OR 3.77, 95% CI 3.26 to 4.36), as was aspiration with feeding tube placement (OR 2.40, 95% CI 1.70 to 3.40). Dysphagia coding alone was not associated with increased mortality (OR 0.71, 95% CI 0.60 to 0.83). Silent dysphagia was independently associated with mortality (OR 2.31, 95% CI 2.04 to 2.61), mechanical ventilation (OR 3.77, 95% CI 3.51 to 4.03), and tracheostomy (OR 4.69, 95% CI 4.40 to 4.99). **Conclusions:** Dysphagia-associated clinical signals define inpatient risk phenotypes in hospitalized patients with HNC. While dysphagia coding alone does not confer excess mortality risk, aspiration pneumonia and feeding tube placement when dysphagia is uncoded identify a high-risk population with increased mortality, airway failure, LOS, and cost, supporting earlier inpatient recognition and intervention. Research Sponsor: None.

PRIME-ROSE: A blueprint for implementing precision cancer medicine in Europe. First Author: Gro Live Fagereng, Oslo University Hospital, Oslo, Norway

Background: Precision Cancer Medicine (PCM) is limited by increasingly small patient subgroups defined by tumor type and biomarker, producing rare cohorts even within common cancers. This is demonstrated by several European national PCM platform trials like DRUP (NL), IMPRESS-Norway (NO) and ProTarget (DK). From our experiences, we identify four essential requirements for successful, scalable PCM implementation: i) integration of platform trials with national healthcare systems via molecular tumor boards for efficient screening by comprehensive molecular profiling and accrual; ii) cross-national data merging; iii) scalable networks to onboard new countries; and iv) clear decision pathways linked to outcome data for reimbursement. **Methods:** PRIME-ROSE links national PCM implementation platforms through a robust data sharing framework that retains national/regional data governance while enabling harmonised statistical analyses and standardised endpoints for decision-makers. Predictable implementation pathways provide multiple, pre-defined decision points for industry, health technology assessment (HTA) bodies and payers, and integrate risk-sharing and responder-only reimbursement options with existing data collection. A scalable, transparent network facilitates rapid expansion to additional European partners. **Results:** We have developed and tested an operational data-sharing framework, with defined protocols for minimal datasets and harmonised merging procedures. Patient-level data from multiple national cohorts (1100 patients in 400 cohorts) have been aggregated, and analyses of five filled cohorts are in progress. PRIME-ROSE uses a staged implementation model to detect initial efficacy signals (industry-financed drugs) to confirm and expand on prior evidence, facilitating predictable scale-up. Risk-sharing is operationalised via responder-only reimbursement after 16 weeks of treatment and a defined transition from trial to commercial supply. In 2025, PRIME-ROSE expanded partnerships, secured the first and second multi-trial industry access contracts, and expanded payer commitment to make reimbursement decisions after Stage III. **Conclusions:** PRIME-ROSE translates lessons from platform trials into a practical, scalable blueprint that preserves national governance, accelerates evidence generation and reduces payer uncertainty – thereby lowering barriers to equitable, continent-wide PCM adoption. Aligned with initiatives such as Basket of Baskets and ROME, PRIME-ROSE is positioned for further scale-up through member state collaboration under the Joint Action on Personalised Cancer Medicine. Research Sponsor: Funded by the European Union; Grant no. 101104269.

Weekend admission and early in-hospital mortality among patients with hematologic malignancies admitted for febrile neutropenia. First Author: Tarfa Verinumbe, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Weekend admissions have been associated with worse health outcomes compared with weekday admissions, a phenomenon known as the 'weekend effect'. While predictors of in-hospital outcomes among patients with febrile neutropenia (FN) and hematologic malignancies are well described, the impact of the 'weekend effect' in this population remains unclear. Our study assessed the association between weekend admission, 3- and 7-day mortality. We further evaluated whether septic shock mediates the relationship between weekend admission and inpatient mortality, regardless of length of inpatient stay. **Methods:** We conducted a retrospective analysis of the National Inpatient Sample (2016 to 2020). Using ICD-10 codes, we identified patients with hematologic malignancies admitted for FN (D70.X, R50.81 and R50.9). Weekend admission was the primary exposure, while 3- and 7-day in-hospital mortality were the outcomes assessed. Generalized linear models were used to assess the association between weekend admission and each outcome, adjusting for sociodemographic characteristics, Charlson Comorbidity Index, mechanical ventilation, acute renal failure, protein energy malnutrition, cancer type, and length of stay. We performed a mediation analysis to assess whether septic shock mediated the association between weekend admission and overall mortality, estimating natural direct, indirect, and marginal total effects. **Results:** Among 45,540 patients in this study, 57% were male, 65% were white (mean age was 51 years). Patients had lymphoma (27%), leukemia (54%), multiple myeloma (10%), and multiple/other hematologic malignancies (9%). Weekend admission was associated with a higher risk of 3-day (adjusted risk ratio [adj RR] 1.48; 95% CI: 1.21–1.83) and 7-day mortality (adj RR 1.32; 95% CI: 1.12–1.56). When outcomes were assessed across the entire inpatient stay, weekend admission was associated with higher risk of septic shock (adj RR 1.14; 95% CI, 1.05–1.25). Further mediation analysis demonstrated that septic shock significantly mediated the association between weekend admission and overall inpatient mortality – indirect effect (adj RR 1.03; 95% CI 1.01–1.04), whereas the direct effect (adj RR 1.06; 95% CI 0.94–1.20) and overall effect (adj RR 1.09; 95% CI: 0.96–1.23) of weekend admission on mortality were not statistically significant. **Conclusions:** Weekend admission was associated with a higher risk of 3- and 7-day mortality. Septic shock partially mediated the relationship between weekend admission and mortality when assessed across the entire inpatient stay. The absence of a direct weekend effect suggests that health system-level factors contributing to septic shock such as delays in recognition, escalation, or time to antibiotics, may represent key intervention targets to improve mortality outcomes in this high-risk population. Reporting of sex-related data in landmark phase III solid tumor trials presented at ASCO 2025. First Author: Marine Rushanyan, D'Clinic, Yerevan, Armenia

Background: Sex-related differences may influence cancer biology, treatment efficacy, and toxicity. Although consideration of sex as a biologically relevant variable is increasingly encouraged in oncology research, the extent to which sex-specific information is visible at the time of initial presentation of practice-changing clinical trial results remains unclear. **Methods:** We conducted a cross-sectional review of phase III solid tumor trial abstracts enrolling mixed-sex populations presented at the ASCO Annual Meeting 2025. Plenary, oral, and rapid oral abstracts representing practice-changing studies across tumor types and treatment modalities were included. Abstracts were systematically assessed for reporting of sex distribution and for sex-stratified efficacy or toxicity outcomes. **Results:** Ten landmark phase III trials across gastrointestinal, lung, genitourinary, head and neck, and melanoma cancers were included. Female representation was reported in 1 of 10 abstracts (10%). None of the abstracts reported sex-stratified efficacy analyses, and none reported sex-stratified toxicity outcomes. The absence of sex-specific reporting was consistent across tumor types, therapeutic classes, and session formats, including plenary presentations. **Conclusions:** Among landmark phase III solid tumor trials presented at ASCO 2025, sex-specific reporting was largely absent at the abstract level, including in practice-changing studies. Limited visibility of sex-specific data at abstract presentation may constrain clinical interpretation and highlights an opportunity to improve reporting practices in oncology trials. Center-level delivery patterns and capacity during rapid CAR-T expansion in the United States (2021-2023). First Author: Pranav Singh, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has rapidly expanded in the United States, accompanied by substantial growth in utilization and expenditures. However, whether this expansion has been matched by proportional growth in delivery capacity and how CAR-T workload is distributed across centers remains unclear. **Methods:** We conducted a national retrospective analysis using publicly available Medicare administrative data from 2021-2023 obtained from the Medicare Inpatient Hospitals dataset on data.cms.gov. CAR-T hospitalizations were identified using the diagnosis-related group (DRG) descriptions for CAR-T therapy and other immunotherapies. Active CAR-T centers were defined annually based on inpatient discharges. This DRG-based approach may include non-CAR-T immunotherapies, and Medicare data captures primarily older adults, potentially missing younger patients with acute lymphoblastic leukemia and lymphoma. Center-level CAR-T volume and expenditures were aggregated annually. Per-center delivery burden was assessed by strain (total CAR-T discharges divided by number of active centers). Concentration of CAR-T delivery across centers was evaluated using cumulative contribution analyses. **Results:** From 2021 to 2023, active CAR-T centers increased from 23 to 46, while total CAR-T discharges rose from 544 to 1,303. Total annual CAR-T expenditure increased substantially over the same period, from $728 million in 2021 to $2.56 billion in 2023. Despite this expansion, median annual discharges per center remained relatively stable (24 in 2021 vs 25.5 in 2023), while mean discharges increased from 23.7 to 28.3, indicating that growth was driven disproportionately by higher-volume centers. Correspondingly, the center-level strain increased from 23.6 to 28.3, reflecting rising per-center delivery burden. CAR-T delivery remained moderately concentrated across years, with top quartile of centers (approximately 21.7% of centers) accounting for 37.3% of CAR-T discharges in 2021, increasing to 39.5% of discharges in 2023. **Conclusions:** Despite rapid expansion in CAR-T centers and substantial growth in utilization and expenditures, delivery is increasingly concentrated among higher-volume centers. Stable median per-center volumes alongside increasing mean volumes and persistent concentration patterns suggest that growth has outpaced effective distribution of delivery capacity. While the relationship between center volume and patient outcomes remains incompletely characterized, these findings highlight the need for workforce development, infrastructure investment, and policy strategies to support both high-volume centers experiencing rising delivery burden and lower-volume centers developing expertise, ensuring sustainable and equitable CAR-T delivery as utilization continues to expand. Safety-net coverage instability during cancer care and association with overall survival. First Author: Liyang Yuan, UT Southwestern Medical Center, Dallas, TX

Background: Means-tested (contingent on income) financial programs for uninsured individuals, such as Medicaid and county charity/indigent care, require periodic eligibility re-verification. A recent systematic review found that insurance coverage disruptions are associated with worse cancer stage and survival, but also highlighted that studies suffered from a limited ability to distinguish administrative lapses from eligibility-driven disruptions, and relied on single time-point measures to define longitudinal coverage. Consequently, the dynamics and clinical implications of coverage instability during cancer care are incompletely characterized. We investigated the coverage portions of the electronic health record (EHR) to overcome these issues and characterize coverage instability. **Methods:** We conducted a retrospective cohort study linking tumor registry records (2010–2022) to coverage verification fields from the EHR of a large county safety-net health system (2010-2024). Renewal limbo was defined as any gap between verified coverage intervals occurring $>$ 365 days after a first verification. Multivariable logistic regression estimated odds of renewal-limbo within two years after diagnosis. Cox models estimated time to first renewal limbo and negative-binomial models for limbo duration; Prentice–Williams–Peterson models examined recurrent limbo. Two-year overall survival was estimated using a 12-month landmark design, with survival follow-up beginning at 12 months after diagnosis to ensure comparable risk windows across coverage instability groups. **Results:** Among 24,186 patients (56% female; 78% $<$ age 65; 6% Medicaid, 50% County charity care; 15% breast, 8% colorectal, and 8% lung cancer), 26% experienced renewal limbo in the first year after diagnosis and 36% by the second year. Among patients with charity coverage at diagnosis who experienced renewal limbo, nearly 90% returned to charity coverage, and over two-thirds of Medicaid enrollees returned to Medicaid. Median limbo duration was 32 days (IQR, 3–220). Compared to diagnoses in 2010–2019, those diagnosed in 2020–2022 had substantially reduced odds of renewal limbo (aOR 0.29, 95% CI: 0.25-0.32) in Medicaid. In landmark analyses, uninterrupted coverage during the first year was associated with the highest survival, while patients in limbo at the time of diagnosis and at renewal limbo had the lowest survival (Table 1). **Conclusions:** Coverage lapses at annual renewal were common among safety-net patients treated for cancer and was largely temporary, suggesting administrative rather than eligibility-driven disruptions. Although lapses were brief, they were associated with measurably lower overall survival even 2 years after cancer diagnosis. Strong calendar-year effects in 2020-2022 suggests the influence of suspended reverification during the COVID19 public health emergency. Research Sponsor: American Cancer Society; DBG-25-1374401-01-HOPS.

Real-world EGFR, ALK, and PD-L1 testing performance and end-to-end intervals in Colombian patients with non–small cell lung cancer. First Author: Mateo Barros, Fundacion Santa Fe de Bogota, Bogota, Colombia

Background: Timely and comprehensive EGFR, ALK, and PD-L1 testing underpins effective precision oncology care in NSCLC, yet real-world data on testing completeness and integration into care pathways remain scarce in Latin America. **Methods:** We conducted a retrospective cohort study of adults with pathologically confirmed NSCLC treated at Fundación Santa Fe de Bogotá (2018–2025). EGFR/ALK/PD-L1 testing completeness, complete-panel availability, biomarker distributions, and turnaround times (order-to-report and diagnosis-to-report) were assessed. Stage III–IV sub analysis was performed. **Results:** A total of 242 patients were included. Most were female (53.3%), never-smokers (45.0%), and had adenocarcinoma histology (82.2%). EGFR, ALK, and PD-L1 results were available in 84.3%, 80.6%, and 80.6% of cases, respectively. Complete-panel availability was 74.4% and improved over time (adjusted OR per year, 1.28; 95% CI, 1.10–1.50; p=0.002). Turnaround times were favorable, with a median order-to-report time of 5 days (IQR, 2–8), and 68.0% completed within 7 days. The median diagnosis-to-report time was 12 days (IQR, 6–28.5), with 54.3% completed within 14 days. Activating EGFR mutations occurred in 38.7%, ALK fusions in 9.7%, and PD-L1 TPS $\geq$50% in 21.0%. In exploratory multivariable models, EGFR positivity was less frequent in ever-smokers (OR 0.26; 95% CI 0.13–0.51) and non-adenocarcinoma histology (OR 0.26; 95% CI 0.07–0.96). Guideline-concordant first-line targeted therapy was used in $>$80% of systemically treated patients with actionable alterations. In the stage III–IV subset (median age, 71.3 years; 53.8% female), median intervals were 13 days for imaging-to-diagnosis and 27 days for diagnosis-to-treatment (IQR, 16–52), with 33% exceeding 30 days and higher rates among patients referred after extra-institutional diagnosis. Median diagnosis-to-molecular report and report-to-treatment intervals were 11 days (IQR, 5–21) and 14 days, respectively. Requirement for EBUS was associated with longer imaging-to-diagnosis delays (75% $>$30 days; p=0.01). **Conclusions:** This study provides Latin American benchmarks for precision oncology delivery in NSCLC, showing high and improving molecular testing completeness with rapid turnaround. While molecular readiness was favorable, treatment initiation—especially for referred patients—represented the principal optimization gap. Standardized diagnosis-initiated testing and navigation workflows may improve end-to-end pathway performance. Research Sponsor: None.

Temporal trends in biomarker testing completeness in NSCLC (2018–2025).

Metric	2018–2020 (n=87)	2021–2023 (n=93)	2024–2025 (n=59)	Overall (N=242)
EGFR available, %	77.0	86.0	93.2	84.3
ALK available, %	73.6	80.6	91.5	80.6
PD-L1 available, %	71.3	83.9	89.8	80.6
Complete panel available, %	65.5	74.2	88.1	74.4

Investigating reasons patients do not join a cancer clinical trial. First Author: Radhi Yagnik, Icahn School of Medicine at Mount Sinai, New York, NY

Background: The perennial challenge to cancer clinical trials is accrual. To date, the focus to improve accruals rested on addressing patient knowledge, attitudes and beliefs rooted in patient reluctance to be experimented on, financial and practical barriers and issues of mistrust. We undertook this study to describe the impact of an educational intervention to democratize recruitment and improve understanding of and information about cancer clinical trials. **Methods:** We implemented a time series intervention (INT) identifying cancer patients at treatment decision points at 3 participating Cancer Centers, educating consented breast, liver and lung cancer patients about clinical trials in general and providing clinical trial match lists to oncologists and patients prior to treatment decision-making. We defined a treatment decision point as a new, recurrent or progressing cancer. We surveyed patients and their oncologists pre- and post-intervention about their knowledge, attitudes and beliefs (KABs) of clinical trials. We compared pre & post KABs using Chi Sq and Fisher's Exact T tests. **Results:** Of 523 consented patients at treatment decision points, 514 completed pre & 368, post-INT surveys; 60% were non-white with no racial ethnic difference in response rates (70% BIPOC v 79% White; p = 0.07). Following an educational intervention, there was no significant change in positive attitude towards clinical trials (CT): 71% pre-intervention vs 77% post-intervention; p = 0.55, regardless of race-ethnicity (RE) (p = 0.5025). Black patients as compared to white patients, reported greater barriers to CT including: transportation (60% vs 37%; $p < 0.001$) and family responsibilities (46% vs 25%; p = 0.001). There was no RE difference in other barriers: patient report of physicians talking with them about clinical trials (89% vs 65%; p = .36), insurance (77% vs 74%; p = 0.6051); out of pocket expenses (64% vs 53%; p = 0.12); time off work (41% vs 37%; p = 0.5457). 25/28 (89%) treating oncologists of consented patients responded. Oncologists reported being less likely to offer CTs to patients who they perceived were reluctant to: get placebo (48%), be randomized (48%), have increased family responsibilities (52%), would have difficulty getting time off work (45%) or had comorbidities (40%). **Conclusions:** More than $^3/_4$ of patients have a positive attitude towards clinical trials with no racial-ethnic difference. Black patients reported more barriers to trial enrollment than white patients. Despite Black patients having more barriers that would reduce oncologists' likelihood of offering CTs to patients, there was no RE in patients' report of oncologists talking with them about CTs. Clinical trial information: NCT05146297. Research Sponsor: Stand Upto Cancer.

Health shocks and advance care planning among U.S. older adults: Evidence from HRS 2012-2022. First Author: Haofan Yang, Rollins School of Public Health, Emory University, Atlanta, GA

Background: Advance care planning (ACP) allows individuals to discuss and document preferences for future medical care under serious illness, yet engagement among older adults remains limited. Experiences of a health shock, such as a diagnosis of cancer, major illnesses, or hospitalization, may prompt participation in ACP. This study aimed to examine the association between health shocks and subsequent ACP engagement and variation by key sociodemographic characteristics. **Methods:** We conducted a longitudinal cohort study using data from the Health and Retirement Study (HRS), a nationally representative survey of U.S. adults aged ≥65 years. Adults from 2012–2022 HRS with no baseline ACP who completed at least one follow-up wave were included. The exposure was a new health shock, defined as a new diagnosis of cancer, stroke, heart disease, or hospitalization. The outcome was new ACP engagement in subsequent waves. Generalized estimating equation models estimated adjusted odds ratios (ORs) of experiencing a health shock due to cancer diagnosis and due to other causes (vs. no health shock) on new ACP; and how such associations varied by respondents' characteristics. **Results:** Among 8,553 person-wave observations (4,426 unique respondents), median age was 74 years (IQR 69–79); 52.9% were women, 24.3% lived alone, 27.6% experienced a health shock, and 3.11% reported a health shock from new cancer diagnosis. Health shocks were associated with higher odds of ACP engagement (OR = 1.41; 95% CI, 1.28–1.56). In the three-level shock model, both non-cancer shock (OR = 1.43; 95% CI, 1.28–1.59) and cancer shock (OR = 1.31; 95% CI, 1.01–1.70) were associated with higher odds of ACP compared with no shock. Older age, female gender, and higher education were associated with greater ACP engagement overall. Compared with non-Hispanic Whites, non-Hispanic Black (OR = 0.73; 95% CI, 0.64–0.84) and Hispanic (OR = 0.55; 95% CI, 0.47–0.65) had lower odds of ACP. Living alone was associated with higher ACP engagement (OR = 1.29; 95% CI, 1.14–1.45). However, when stratified by patient sociodemographic characteristics, the associations between health shock and ACP were similar across groups, except that for those living alone who showed larger odds of initiating a new ACP following health shock (OR = 1.76; 95% CI, 1.45-2.14) than those not living alone (OR = 1.31; 95% CI, 1.16-1.47). **Conclusions:** Health shocks were associated with new ACP engagement among older adults, with similar associations observed for cancer-specific and non-cancer health shocks. Alhtought disparities in ACP by sociodemographic characteristics persisted, health shocks were associated with similarly odds of initiating ACP across population subgroups. This highlights the importance of leveraging health shocks as clinical touchpoints for ACP discussions, and the need for targeted strategies to reduce inequities in ACP engagement outside of acute health events. Research Sponsor: None.

Insights from initial scoring in the Health Equity Report Card (HERC) pilot in community oncology settings. First Author: Taneal D. Carter, National Comprehensive Cancer Network, Plymouth Meeting, PA

Background: The Health Equity Report Card (HERC) is an innovative tool designed to assess and promote equity in cancer care. Standardized scoring is performed in four domains: Community Engagement, Accessibility of Care and Social Determinants of Health, Addressing Bias in Care Delivery, and Quality and Comprehensiveness of Care. Initial scoring is reported. **Methods:** Five diverse community oncology sites were recruited to evaluate the HERC's feasibility and usability in this setting. The primary objective is to evaluate the feasibility of implementing the HERC with scoring at community oncology sites. Key metrics include the ability to collect HERC data and complete self- and third-party scores. Baseline scores were calculated using data from prior six months. Quantitative and qualitative feedback was collected via surveys and semi-structured interviews. Results were summarized using descriptive statistics. This study was granted Institutional Review Board exemption by Pearl IRB and sites received funding support. **Results:** All sites completed self- and third-party scores (Table 1). Average self-scores and third-party scores were similar, with third party scores slightly lower across all domains. There was a wide range in scores across all domains. All sites felt the HERC was easy to understand. Sites requested clarification on four measures and expect the final round of scoring to be easier and faster. 4/5 sites stated collecting sources of evidence was feasible. Key challenges included: a lack of formal documentation and processes not implemented consistently across the practice. Best practices included: 5/5 used tracking logs, 5/5 used a team approach, and 4/5 utilized provided materials to orient staff to the project. All sites stated the HERC was a helpful resource for community practices, was useful to learn about health equity initiatives across the site, and was helpful to identify or prioritize quality improvement projects. All sites felt the HERC would inform changes to site processes and plan to identify improvement strategies based on their baseline scores. **Conclusions:** Initial implementation of the HERC in community oncology practices was feasible with completion of scoring across all practices. Score variation across sites and domains highlight differences in resources, documentation, and practice. Sites confirmed the HERC is a helpful resource and catalyst for quality improvement. The project remains ongoing. The HERC is a promising tool to foster equitable care delivery for all cancer patients. Research Sponsor: Merck Foundation through the Alliance for Equity in Cancer Care; Pfizer, Inc.; Lilly; GlaxoSmithKline, LLC; Bristol Myers Squibb Company.

Summary statistics of baseline self- and third-party scores.

		Self-Score			Third-Party Score		
Domain	Max Score	Mean	SD	Range (Max-Min)	Mean	SD	Range (Max-Min)
Community Engagement	4	3	1.1	3 (1-4)	2.2	1.5	4 (0-4)
Accessibility	6	3.9	1.7	4.5 (1-5.5)	3.7	1.5	4.5 (1-5.5)
Bias	5	1.9	1.3	3 (0.5-3.5)	1.5	1.2	3.5 (0-3.5)
Quality of Care	4	2.6	1.7	4 (0-4)	2.4	1.6	4 (0-4)

Same day/next day cancer care program: An early access program for patients with aggressive malignancies. First Author: Artem Oganesyan, Abington Hospital-Jefferson Health, Abington, PA

Background: Rapid referral of patients with suspected malignant disease to an oncology specialist is associated with improved earlier-stage diagnosis and survival benefits. The advantage of such rapid care transition can be especially pronounced in aggressive malignancies, where early interventions are critical in reducing mortality. Patients with already established cancer diagnosis may also benefit from such programs. Same Day/Next Day Cancer Care (SDND) is a Jefferson Health enterprise designated referral system allowing patients with newly diagnosed cancers to be seen by an advanced practice clinicians via telemedicine within 48 hours at the Sidney Kimmel Comprehensive Cancer Center (SKCC). **Methods:** Adult patients with an established diagnosis of aggressive types of malignancies were referred through SDND to SKCCC in the Greater Philadelphia Area if they had concerning symptoms related to disease. The following malignancies were selected: acute leukemias, T-cell lymphomas, diffused large B-cell lymphomas, Burkitt lymphomas, melanomas, glioblastoma multiforme, pancreatic adenocarcinoma, esophageal or gastric carcinoma, small cell lung carcinoma, biliary tract malignancy, anaplastic thyroid cancer. Socio-demographics, time to appointment with an oncologist and treatment were analyzed. **Results:** Between July 2024 and December 2025, 209 patients with aggressive malignancies, of which 49% were female with a median age of 67 years, were referred to oncology specialists. Only 19% were new patients, while 81% had already established care. Medical providers made 78.3% of referrals, while other 21.7% were self-referred. Average SDND schedule lag days was 1.04 days. About 85% of patients had medical oncologist consultation appointments, of which 68.8% completed the planned visit. Thirty-four patients (16%) were referred for infusion therapy, of which 64.7% successfully initiated infusion therapy within 50 days. Similarly, 76 patients (36%) had scheduled a surgical specialty consultation, of which 77.9% completed the appointment. Importantly, 53.7% of the patients underwent surgery within 30 days of the SDND referral. **Conclusions:** SDND is a centralized access program aimed at reducing time to first appointments for newly diagnosed cancer patients. It led to accelerated assessment by oncology providers with high adherence to the management plan. It can ensure faster diagnostic workups and symptom management related to aggressive malignancies by advanced care clinicians, with the potential to improve survival rates, patient satisfaction, reduce treatment–related anxiety and cancer-related morbidity. Further research is needed to determine if this early clinical evaluation by advanced practice providers via telemedicine may reduce complications warranting high-cost care, such as emergency department visits or hospitalizations in high-risk cancer population. Research Sponsor: None.

Empowering multidisciplinary teams in cancer survivorship: Results from the ASCO Project ECHO survivorship program in Brazil. First Author: Luciana Castro Landeiro, Oncoclínicas&Co, Salvador, Brazil and Grupo Brasileiro de Estudos em Câncer de Mama (GBECAM), Salvador, Brazil

Background: As the number of cancer survivors increases in Brazil, access to structured survivorship education for health professionals remains limited. ASCO Project ECHO Survivorship Program was implemented to strengthen survivorship knowledge and care coordination among multidisciplinary teams. **Methods:** This longitudinal, virtual, case-based education series was conducted from September to December 2025. Intended audience included oncologists, general physicians, nurses, psychologists, and other professionals involved in survivorship care. Program consisted of 08 distinct, self-contained sessions, beginning with an introductory session on core survivorship principles, followed by cancer-specific survivorship topics delivered through short didactics and case discussions. Participants were encouraged to attend all sessions; however, each session was designed to be independent. Attendance was tracked, and final post-program survey assessed satisfaction and self-reported impact on clinical practice. Analyses focused on participants attending ≥4 sessions (≥50%), which was the criterion for certification and a pragmatic threshold to ensure meaningful engagement. **Results:** 161 health professionals attended at least one session, and 65 (40.4%) participated in ≥4 sessions. Participants represented diverse disciplines, including physicians and oncologists (31%), psychologists (13.7%), nutritionists (8.7%), pharmacists (6.2%), nurses (11.2%), and other professionals. Subsequent analyses were limited to participants attending ≥4 sessions. Among these,final survey response rate was 66.2%. Reported practice changes and satisfaction outcomes were collected through the post-program survey. Respondents described increased confidence in identifying and managing late and long-term physical effects, addressing psychosocial and sexual health concerns, improving interdisciplinary collaboration, and supporting transitions to post-treatment care. Overall satisfaction was high, with 97.7% reporting being satisfied or very satisfied. Despite high satisfaction, attendance declined across sessions, highlighting the need to better understand factors influencing sustained participation in longitudinal virtual education programs. **Conclusions:** ASCO Project ECHO Survivorship Program in Brazil demonstrated strong engagement and meaningful self-reported integration of survivorship principles into clinical practice among a multidisciplinary workforce. This flexible, scalable educational model supports survivorship capacity-building across diverse professional roles in middle-income settings. Further evaluation is needed to better understand factors associated with decreased attendance over time and to inform strategies that optimize sustained engagement in longitudinal survivorship education programs. Research Sponsor: None.

Admission acuity and inpatient outcomes across major gastrointestinal malignancies in the United States, 2018–2022. First Author: Elaine Patricia Tupas, MountainView Hospital, Las Vegas, NV

Background: Hospitalization for gastrointestinal (GI) malignancies frequently occurs in the setting of acute decompensation or unplanned admission. National data quantifying the association between admission acuity and inpatient outcomes across major GI cancer subtypes remain limited. **Methods:** A serial cross-sectional analysis was conducted using the 2018–2022 Healthcare Cost and Utilization Project National Inpatient Sample. Adult hospitalizations with a principal diagnosis of esophageal (C15), gastric (C16), colorectal (C18–C20), liver or intrahepatic bile duct (C22), or pancreatic cancer (C25) were identified. Admission acuity was classified as elective or non-elective. Outcomes included in-hospital mortality (primary), length of stay (LOS), and hospitalization cost estimated using cost-to-charge ratios. National estimates accounted for survey weighting, clustering, and stratification. Survey-weighted multivariable logistic regression evaluated factors independently associated with in-hospital mortality, adjusting for admission type, cancer subtype, demographics, payer, neighborhood income quartile, hospital characteristics, and calendar year. **Results:** From 2018–2022, 214,740 unweighted GI cancer hospitalizations represented an estimated 1.07 million hospitalizations nationally. Colorectal cancer accounted for 56.7% of admissions, followed by pancreatic (17.6%), liver or intrahepatic bile duct (10.5%), gastric (8.6%), and esophageal cancer (6.6%). Overall, 52.9% of hospitalizations were non-elective. In-hospital mortality was higher for non-elective than elective admissions (5.92% vs 1.89%), with longer LOS (7.61 vs 6.15 days) and lower mean hospitalization costs ($25,644 vs $32,166). In adjusted analyses, elective admission was associated with substantially lower odds of in-hospital mortality compared with non-elective admission (adjusted odds ratio [aOR] 0.395; 95% CI 0.328–0.476). Relative to esophageal cancer, adjusted mortality odds were lower for colorectal, gastric, and pancreatic cancers, while no significant difference was observed for liver or intrahepatic bile duct cancers. **Conclusions:** Across major gastrointestinal malignancies, non-elective admission was associated with substantially higher inpatient mortality and longer length of stay independent of cancer subtype and sociodemographic factors. These nationally representative findings provide benchmarking data for admission acuity as a marker of inpatient risk in gastrointestinal oncology. Research Sponsor: None.

Survival outcomes in individuals with cancer and pre-existing autoimmune disease receiving immune checkpoint inhibitors: A multicenter, propensity-matched real-world survival analysis. First Author: Nehemias Guevara, Division of Hematology, Oncology, and Blood and Marrow Transplantation, Department of Internal Medicine, Saint Louis University School of Medicine, Saint Louis, MO

Background: Autoimmune disease (AID) affects approximately 5–10% of individuals with cancer. Although immune checkpoint inhibitors (ICIs) have transformed cancer therapy, individuals with pre-existing AID are routinely excluded from clinical trials due to concerns about immune-related adverse events. Consequently, long-term real-world survival outcomes in this population remain incompletely defined, limiting evidence-based risk–benefit assessment. **Methods:** We conducted a retrospective, multicenter cohort study using a large U.S.-based real-world oncology network derived from harmonized electronic health records across academic and community cancer centers. Adults (≥18 years) with solid tumors who received at least one immune checkpoint inhibitor (PD-1, PD-L1, or CTLA-4) were included. Individuals were classified by the presence or absence of documented pre-existing AID prior to ICI initiation. Cohorts were matched 1:1 using propensity scores based on age, sex, race, and baseline comorbidities, including cardiovascular disease, diabetes, chronic kidney disease, chronic obstructive pulmonary disease, cerebrovascular disease, and heart failure. Survival outcomes at 1, 3, and 5 years from ICI initiation were evaluated using Kaplan–Meier methods and Cox proportional hazards models. **Results:** After propensity score matching, 13,800 adults were included (6,900 with AID and 6,900 without), with excellent balance across baseline covariates. All-cause mortality was higher among individuals with pre-existing AID at 1 year (36.7% vs 32.6%), 3 years (48.3% vs 44.7%), and 5 years (50.1% vs 47.0%). Pre-existing AID was independently associated with worse overall survival at all time points (HR 1.15; 95% CI 1.09–1.22 at 1 year; HR 1.15; 95% CI 1.10–1.21 at 3 years; HR 1.15; 95% CI 1.09–1.20 at 5 years; all $P < 0.001$). Kaplan–Meier analyses demonstrated early separation of survival curves that persisted through long-term follow-up (log-rank $P < 0.001$). **Conclusions:** In this large, multicenter, real-world cohort, pre-existing autoimmune disease was associated with a modest but durable reduction in survival among individuals treated with immune checkpoint inhibitors, persisting through 5 years of follow-up. These findings do not contraindicate ICI use but highlight the need for individualized risk stratification, multidisciplinary collaboration, proactive toxicity surveillance, and informed shared decision-making when initiating immunotherapy in this population. Racial and payer-based disparities in inpatient resource utilization and mortality among patients hospitalized with head and neck cancer in the United States, 2018 to 2022. First Author: Sandhya Upreti, Department of Internal Medicine, Sunrise Health GME Consortium, Las Vegas, NV

Background: Inpatient hospitalizations for head and neck cancer (HNC) reflect advanced disease, treatment-related complications, and high healthcare utilization. National data on racial and payer-based disparities in inpatient length of stay (LOS), costs, and mortality remain limited. **Methods:** A survey-weighted cohort analysis of the Healthcare Cost and Utilization Project National Inpatient Sample (NIS), 2018 to 2022, was performed. Hospitalizations with a principal diagnosis of HNC were identified using ICD-10-CM codes C00 to C06, C07 to C08, C09 to C14, C30 to C32, and C76.0; thyroid cancer (C73) was excluded. Outcomes included in-hospital mortality, LOS, and hospitalization cost. Survey-weighted mean LOS and cost were estimated by race and primary payer. A survey-weighted multivariable logistic regression evaluated predictors of in-hospital mortality, adjusting for age, sex, year, anatomic subsite, race, payer, ZIP-code income quartile, elective admission status, and hospital teaching and location characteristics. **Results:** The weighted national estimate included 166,020 inpatient HNC hospitalizations (95% CI 158,702 to 173,338). Mean LOS ranged from 7.43 days among White patients (95% CI 7.29 to 7.56) to 10.21 days among Black patients (95% CI 9.81 to 10.60), with intermediate LOS among Hispanic (9.22 days), Asian or Pacific Islander (8.41 days), Native American (8.86 days), and Other race groups (8.25 days). Mean hospitalization costs were highest among Asian or Pacific Islander patients ($46,577, 95% CI $41,648 to $51,506) and Hispanic patients ($42,384, 95% CI $39,129 to $45,640), compared with White patients ($36,887, 95% CI $35,197 to $38,577). Medicaid hospitalizations had the longest LOS (10.58 days, 95% CI 10.16 to 10.99) and high costs ($42,217, 95% CI $40,126 to $44,308), whereas privately insured hospitalizations had the shortest LOS (6.54 days, 95% CI 6.37 to 6.72). In adjusted analyses, mortality increased with age (OR 1.02 per year, 95% CI 1.01 to 1.03). Asian or Pacific Islander (OR 1.51, 95% CI 1.07 to 2.13) and Other race patients (OR 1.59, 95% CI 1.09 to 2.32) had higher mortality than White patients. Non-Medicare other insurance was associated with higher mortality than Medicare (OR 2.56, 95% CI 1.89 to 3.46). Elective admissions (OR 0.21, 95% CI 0.16 to 0.27) and care at urban teaching hospitals (OR 0.34, 95% CI 0.25 to 0.47) were associated with lower mortality. **Conclusions:** Racial and payer-based disparities persist in inpatient LOS, costs, and mortality among patients hospitalized with HNC. Black and Medicaid-insured patients experience longer hospitalizations, while Asian or Pacific Islander and Hispanic patients incur higher costs. Persistent mortality differences after adjustment highlight structural and health-system contributors and support targeted equity-focused interventions. Research Sponsor: None.

Consumer wearables and medical care utilization in gastrointestinal cancers: A Fitbit data analysis in NIH All of Us Research Program. First Author: Osama Elkhider, Medical College of Wisconsin, Milwaukee, WI

Background: Patients with gastrointestinal (GI) cancers may experience delayed or forgone care due to cost, travel, or health system barriers. Wearable devices are widely used and capture physical activity that may reflect health status, mobility, and social factors. Whether wearable activity data can help identify patients at risk for delayed care is not well understood. We examined associations between activity levels and delayed or forgone care among adults with GI cancers in the NIH All of Us Research Program. **Methods:** Adults with GI cancers who contributed wearable activity data and healthcare utilization surveys were included; ≥30 valid Fitbit days were required. Mean daily step counts were calculated and categorized into cohort-specific quartiles: Q1 (≤3,621 steps/day), Q2 (3,621–5,591), Q3 (5,591–8,272), and Q4 (> 8,272). Delayed or forgone care was determined from survey items asking whether participants postponed or avoided medical care due to financial or access barriers. Analyses were performed in the overall GI cohort (n = 407) and stratified by cancer site (colorectal, pancreatic, upper GI, hepatobiliary, and other). Logistic regression evaluated associations between activity and delayed care using categorical quartiles, continuous log-transformed steps, and age-adjusted models. **Results:** The analytic cohort included 407 participants with GI cancers. After age adjustment, higher daily step counts—analyzed continuously and across ordered quartiles—were associated with lower odds of delayed or forgone care. Age itself was independently associated with fewer delays (OR per 10 years 0.62, p = 0.001–0.002). In categorical models using Q3 as the reference, participants in Q1 had higher odds of delayed care (OR 3.57, 95% CI 1.06–12.10, p = 0.041), while Q2 and Q4 did not differ significantly from Q3, supporting a non-linear association. Site-stratified analyses showed similar non-linear patterns; for example, pancreatic cancer (n = 60) had delayed care prevalences of Q1 11.1%, Q2 0%, Q3 5.0%, Q4 9.1%, and upper GI cancers (n = 59) had Q1 9.1%, Q2 0%, Q3 6.3%, Q4 13.3%. In colorectal cancer (n = 210), Q3 had the lowest delayed care vs Q1 (OR 0.25, 95% CI 0.05–1.32), although other quartile estimates were less precise due to small event counts. **Conclusions:** Among patients with GI cancers who contributed wearable and survey data, delayed or forgone care showed a non-linear association with activity, with the lowest odds in the moderate–high activity range. Participants in Q1 had higher odds of delayed care compared with Q3 after age adjustment. Wearable activity data may help identify patients who face barriers to timely care, although this cross-sectional study cannot show cause and effect. Longitudinal studies are needed to determine whether passive wearable data can support care navigation and healthcare utilization in oncology. Research Sponsor: None.

Recent trends in utilization of outpatient medical oncology services. First Author: Carlos U. Muzlera, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada

Background: Health systems face escalating demand from rising cancer incidence and treatment complexity. Effective health human resource planning is critical to accommodate these trends. Limited data are available on longitudinal utilization of medical oncology services, especially volumes and complexity of care. We sought to characterize real-world longitudinal utilization of outpatient medical oncology services across common solid tumors to inform workforce planning and policy. **Methods:** We conducted a retrospective, population-based retrospective cohort study using linked administrative health data from Ontario, Canada. Adults diagnosed between 2015 and 2022 with lung, colon, rectal, pancreatic, breast, melanoma, or prostate cancer were identified through the Ontario Cancer Registry. Medical oncology consultations, clinic visits, and systemic treatment encounters were captured from the provincial Activity Level Reporting database. Primary outcomes included consultation and systemic therapy initiation trend, and mean clinic and treatment visits during the first year following medical oncology consultation. **Results:** The cohort consisted of 332,604 patients (median age 68 years; 48.7% male), with new cases increasing from 39,688 in 2015 to 45,011 in 2022. Medical oncology consultation and systemic treatment initiation were encountered by 57.8% (range: 17.2% prostate to 92.8% breast) and 71.2% respectively (range: 45.1% melanoma to 82.8% breast). The proportion of patients with medical oncology consultation increased appreciably for pancreatic (59.8% to 79.0%), colon (55.8% to 60.2%), rectal (64.4% to 69.6%), and lung cancers (57.3% to 61.4%), with resultant growth in consultation volumes except for melanoma, colon and lung cancers. Total clinic visits increased from 131,950 in 2015 to 174,630 in 2022. Mean clinic visits per patient increased significantly for all cancers except prostate ($p < 0.001$), with the greatest increase observed in melanoma (+0.33 visits/year). Systemic therapy exposure increased across most cancers, most notably melanoma (25.7% to 47.2%) and prostate cancer (61.2% to 73.9%). Total systemic treatment visits increased from 129,380 in 2015 to 165,149 in 2022 with total and mean per patient trends exhibiting mixed, disease-specific patterns. **Conclusions:** Outpatient medical oncology service utilization per patient has expanded substantially over time, driven by rising volumes of consultations, systemic therapy and clinic visits. Taken with the rising complexity of care, these data suggest that consultation-based workload metrics likely underestimate service demand. Workforce planning models should incorporate follow-up care, treatment monitoring, and disease-specific trajectories to ensure sustainable, high-quality oncology care delivery. Hidden advanced physiology in non-metastatic gastrointestinal cancer: Malnutrition/cachexia and in-patient failure-to-rescue. First Author: Wei Ju Lin, University of California Riverside, Riverside, CA

Background: Cancer stage is often used as a proxy for inpatient risk, yet physiologic reserve may better determine outcomes. It was hypothesized that among gastrointestinal (GI) cancer hospitalizations without coded metastasis, malnutrition/cachexia identifies a vulnerable subgroup with complication burden, ICU escalation, and post-complication mortality approaching that of metastatic disease. **Methods:** A survey-weighted analysis of the National Inpatient Sample (NIS), 2016–2023, was conducted. Adult hospitalizations with any GI malignancy (ICD-10-CM C15–C20, C22–C25) were included; encounters with palliative care coding (Z51.5) were excluded. Metastatic disease was defined by C77–C79. Vulnerability was defined as malnutrition/cachexia (E43, E44, E46, R64). Major complications included sepsis, bleeding/transfusion, venous thromboembolism, acute kidney injury (AKI), bowel injury/peritonitis, and respiratory failure. ICU escalation proxies included mechanical ventilation and/or shock. Outcomes were compared across three groups: non-metastatic/no vulnerability, non-metastatic/vulnerable, and metastatic. Failure-to-rescue was defined among non-metastatic surgical hospitalizations as death following ≥1 major complication. **Results:** The cohort included 748,734 weighted hospitalizations; 39.6% had coded metastasis. Among non-metastatic admissions, vulnerability prevalence increased from 15.6% in 2016 to 21.9% in 2023. In-hospital mortality in the non-metastatic/vulnerable group (4.14% [95% CI, 4.00–4.29]) approximated metastatic mortality (3.96%) and exceeded non-metastatic/no vulnerability mortality (1.86% [95% CI, 1.81–1.91]). Compared with non-metastatic/no vulnerability, vulnerable admissions demonstrated higher ICU escalation (7.75% [95% CI, 7.56–7.94] vs 3.54%), AKI (27.30% [95% CI, 26.98–27.62] vs 17.25%), and any major complication (59.31% [95% CI, 58.95–59.67] vs 42.93%). Resource utilization was higher in the vulnerable group (LOS 9.33 vs 5.49 days; cost $33,156 vs $22,879). Among non-metastatic admissions with complications, mortality was higher with vulnerability (6.46% [95% CI, 6.24–6.69] vs 3.88%). In the non-metastatic surgical subcohort, failure-to-rescue mortality was 5.90% (95% CI, 5.59–6.22) with vulnerability versus 2.65%. **Conclusions:** Among U.S. GI cancer hospitalizations without coded metastasis, malnutrition/cachexia identifies a high-risk inpatient phenotype with complication burden, ICU escalation, and post-complication mortality closely resembling metastatic disease. These findings suggest physiologic vulnerability, rather than stage alone, drives inpatient risk and failure-to-rescue, supporting targeted inpatient risk stratification and earlier supportive interventions. Quality of life among caregivers of patients with breast cancer in Mexico: A multicenter cross-sectional survey using the Caregiver Quality of Life Index–Cancer (CQOLI-C). First Author: Carlos A. Gonzalez-Assad, Tecnológico de Monterrey, Escuela de Medicina y Ciencias de la Salud, Monterrey, Mexico

Background: Family caregivers of patients with breast cancer (BC) often experience emotional, physical, social, and financial strain that can compromise their quality of life (QoL). The Caregiver Quality of Life Index–Cancer (CQOLI-C) is a validated cancer-specific instrument, however data on factors associated with caregiver QoL across healthcare settings in Mexico remain limited. **Methods:** We conducted a multicenter, cross-sectional survey of primary caregivers of patients with BC in Mexico. Consecutive eligible caregivers were recruited across public and private care settings (Sep 2025 – Jan 2026) and completed an online questionnaire. QoL was measured using the CQOLI-C (35 items scored 0–4; total score range 0–140; higher scores = greater caregiver burden (CB)); positively worded items were reverse-coded and summed to generate the total score. We summarized caregiver/patient characteristics and CQOLI-C scores with descriptive statistics and compared them across key groups (metastatic status, caregiving hours/week, additional helpers, self-reported unsustainable caregiving (yes/no), and care setting (public vs private)). We evaluated associations between CQOLI-C total score and prespecified predictors using multivariable OLS linear regression with robust standard errors (two-sided $p < 0.05$). **Results:** Seventy-three caregivers completed the survey (mean age 46.9±15.5 years; 54.8% male). Caregivers were most commonly partners (43.8%) or adult children (32.9%). 53.4% of patients received care in the private sector; 26% had metastatic disease. The most common numbers of additional caregivers were 2 (27.4%) and 0 (21.9%). Over half of caregivers (52.1%) reported providing 0–10 hours/week of care, while 16.4% reported > 50 hours/week. Median caregiver burden measured by CQOLI-C was 45 (IQR 29.5–62). 41% reported caregiving became too difficult to sustain. High burden items most frequently endorsed (score 3–4) included fear of patient death (54.8%), concern about treatment adverse effects (42.5%), and anger to see loved one deteriorating (41.1%). In adjusted regression (n = 73), compared with no helpers, reporting two helpers ($\beta = 16.5$; p = 0.020) and five helpers ($\beta = 24.4$; p = 0.016) was associated with higher scores, while six or more helpers was associated with substantially lower scores ($\beta = -42.0$; p = 0.002). Metastatic disease ($\beta = 16.7$; p = 0.043) and public vs private sector ($\beta = 24.2$; p = 0.009) were associated with worse scores; caregiving hours showed no consistent independent association. **Conclusions:** Caregiver burden was substantial and clustered around unsustainable caregiving demands, metastatic disease, and public care settings. These factors can help identify caregivers most in need of support and should guide systematic caregiver screening and targeted supportive-care interventions in Mexico. Research Sponsor: None.

Patient-perceived caregiver burden after intense oncology treatment. First Author: Virgil Junhui Guo, Dana-Farber Cancer Institute, Boston, MA

Background: Although oncology caregiver burden is well-known (e.g. Alam, *JCO*, 2020), less is understood about how patients themselves perceive their caregivers' quality of life (QOL) after intensive cancer treatment such as hematopoietic cell transplantation (HCT). **Methods:** Patients undergoing allogeneic HCT at Dana-Farber Cancer Institute (12/2017 to 12/2021) were surveyed approximately 100 and 180 days post-HCT. We utilized a questionnaire adapted from the Caregiver Quality of Life Index–Cancer Scale (Weitzner, Qual Life Res, 1999), redesigned to be administered to patients themselves. Caregiver stress was assessed with the question "My caregiver seems more stressed than before my transplant" (0: not at all to 4: very much), dichotomized into lower (0–2) versus higher (3–4) stress. Familial financial burden was measured with the question "How satisfied are you with your family's present financial situation?" (1: not satisfied at all to 5: completely satisfied), dichotomized into higher (1-3) versus lower (4-5) burden. Paired McNemar tests assessed changes in caregiver stress between Day 100 and Day 180, and multivariable logistic regression modeled the relationship between financial burden and caregiver stress, adjusting for age and gender. **Results:** At Day 100 and Day 180, 165 and 142 patient surveys were analyzed (overall response rates were 60.5% and 70.0% among patients alive at each time); 89 patients completed surveys at both times. The mean age was 61.5, 38.2% were female, and 61.8% received reduced-intensity HCT conditioning. Most respondents (86.1%) identified their caregiver as a family member (as compared to a friend or paid professional). Approximately half reported their caregiver was working at both Day 100 (51.2%) and Day 180 (53.2%). The majority felt that the HCT process had not negatively impacted their relationship with their caregiver (93.3% at Day 100; 96.5% at Day 180). At Day 100, 30.9% of respondents perceived their caregiver as being more stressed than prior to HCT, compared with 33.3% at Day 180 (comparing the two time point proportions: $\chi^2 = 0.80$, $p = 0.37$). Lower financial burden was significantly associated with lower odds of reporting increased caregiver stress at both Day 100 (OR = 0.49, 95% CI: 0.24-0.99) and at Day 180 (OR = 0.17, 95% CI: 0.07–0.39). **Conclusions:** In this cohort of patients undergoing intense oncology treatment, most had caregivers who were working family members. A minority perceived increased caregiver stress due to their treatment, with similar perceptions at both Day 100 and Day 180. This relatively modest perception of stress potentially reflects caregivers' successful efforts to lower patients' self-perceived burden. Moreover, lower familial financial burden was strongly protective against patient-perceived caregiver stress, particularly at Day 180, suggesting that financial circumstances meaningfully influence how patients interpret and perceive caregiver burden. Research Sponsor: None.

Patient trust in oncologists versus artificial intelligence for cancer-related questions. First Author: Lyndon Huang, Dell Medical School, The University of Texas at Austin, Austin, TX

Background: Artificial intelligence tools, including the recent introduction of ChatGPT Health, are increasingly accessible to patients seeking medical information. In oncology, where discussions surrounding prognosis and treatment are highly sensitive, trust in the source of information is critical. However, patient perspectives on AI tools compared with oncologists for cancer-related questions remain poorly characterized. **Methods:** We conducted a cross-sectional survey of 75 adult cancer patients at an academic safety-net oncology clinic. The survey assessed patients' perspectives on technology use and their trust in AI tools like ChatGPT compared with oncologists for cancer-related questions. The primary outcome was patients' preferred source of trust when asked who they would rely on most to answer a serious question about their cancer. Secondary outcomes assessed attitudes toward physician versus AI trust using Likert-scale items and comfort engaging with AI for cancer-related questions. Binomial proportions are reported with 95% confidence intervals. Spearman correlation and Fisher's exact tests were used for secondary exploratory analyses. **Results:** Among 75 respondents, the median age group was 55–64 years; 42.7% were male and 57.3% female. English was the primary language for 53.4% and Spanish for 43.8%. The most common cancer types were gastrointestinal (24.0%), breast (20.0%), and hematologic malignancies (17.3%). For the primary outcome, when asked who they would trust most to answer a serious question about their cancer's future, an overwhelming majority selected their oncologist (97.3%; 73/75; 95% CI 90.7–99.7). No respondents selected ChatGPT/AI (0%; 95% CI 0–4.8), while 2.7% were unsure (95% CI 0.3–9.3). In secondary analyses, greater self-reported comfort with technology was associated with greater comfort engaging with AI tools for cancer-related questions (Spearman $\rho = 0.40$, $p < 0.001$). In exploratory subgroup analyses, Spanish speakers showed a trend toward less agreement that they would trust a doctor's answer more than AI (71.9% vs 87.2%). This may reflect increased trust when medical information is delivered in a patient's primary language. In addition, a similar directional signal was observed among younger patients (73.3% vs 84.4%). **Conclusions:** Cancer patients currently demonstrate a strong preference for oncologists over AI tools when addressing serious cancer-related questions, underscoring the central role of physician trust in oncology care. However, comfort engaging with AI varies by technological familiarity, suggesting that this preference may evolve over time as younger, more digitally fluent generations enter care and AI becomes increasingly integrated into healthcare. This study highlights the potential of AI tools to support oncologists in providing more accurate and individualized prognostic estimates for patients with advanced malignancies. Latent transitions of distress risk during cancer treatment and their concordance with anxiety, depression, and quality of life in a large multicenter cohort. First Author: Cristiane Decat Bergerot, Oncoclinicas&Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: Distress is prevalent in patients with cancer and may change throughout treatment. However, longitudinal transitions between distress-risk states and their relationship with psychosocial outcomes in real-world oncology settings remain poorly characterized. We sought to identify latent distress-risk states, describe transitions during cancer treatment, and evaluate their clinical determinants and concordance with anxiety/depression and health-related quality of life (HRQOL). **Methods:** This longitudinal multicenter cohort study included adult patients with cancer treated across all Brazilian states. Distress was assessed at baseline (prior to treatment initiation), mid-treatment, and end of treatment using the Distress Thermometer (DT). Symptoms of anxiety/depression and HRQOL were assessed using the Hospital Anxiety and Depression Scale (HADS) and FACT-G. Latent Transition Analysis (LTA) identified distress-risk states and transition probabilities over time; model selection was based on Bayesian Information Criterion, entropy, and clinical interpretability. Multinomial logistic regression evaluated clinical predictors of baseline distress-risk states. Directional concordance between changes in DT and changes in HADS and FACT-G was assessed using concordance matrices and chi-square tests. **Results:** A total of 2197 patients were included. Median age was 58 years, 72.3% were female, and most were diagnosed with breast (40.1%) or gastrointestinal (18.8%) cancer, with 40.0% presenting with advanced-stage disease (III-IV). A four-state LTA model with optimal fit identified high critical, moderate persistent, low vulnerable, and low stable distress-risk profiles. The low stable state was the most prevalent and highly stable, with 94.5% remaining in the same state across assessments, whereas the high critical and low vulnerable states were more dynamic. Among high critical patients, 22.8% transitioned to moderate risk and 19.6% to low risk, while 28.6% of moderate persistent patients transitioned to the low stable state. Worsening occurred in up to 12.6% of patients. Male sex (OR = 1.8, 95% CI 1.08-3.09) and stage IV disease (OR = 1.8, 95% CI 1.09-2.97) were independently associated with higher-risk distress states (Ps = 0.02). Changes in distress states showed high directional concordance with psychosocial outcomes (HADS 82.9%; FACT-G 77.0%; χ^2 $p < 0.001$). **Conclusions:** Distinct and clinically meaningful distress-risk states and dynamic transitions were observed during cancer treatment. While most patients remained stable or improved, a relevant subgroup experienced worsening distress. These findings support repeated distress screening and adaptive, risk-based psychosocial interventions integrated into routine oncology care. Research Sponsor: None.

Clinical efficiency of remote symptom monitoring using electronic patient-reported outcome (ePRO) in lung cancer: Results of the prospective, multicenter REAL-MOOV-LUNG trial. First Author: Nicolas Girard, Institut du Thorax Curie Montsouris, Institut Curie, Paris, and UVSQ, Paris Saclay University, Versailles, France

Background: Remote symptom monitoring using electronic patient-reported outcome (ePRO) has been shown to provide clinical benefits and is being implemented for routine care in cancer patients (pts). It may represent a significant operational burden for healthcare providers, that has to be balanced with its actual efficiency in generating clinically meaningful alerts leading to modify pts management. **Methods:** REAL-MOOV-LUNG is a prospective, multicenter, phase IV trial evaluating the MOOVCARE system in patients (pts) $\geq$18yo with non-progressive lung cancer, any histology, any stage, who had completed anticancer treatment for $<$ 8weeks (cohort 1), or who were receiving adjuvant, consolidation or maintenance anticancer treatment for $\geq$8weeks (cohort 2). Primary endpoint was the proportion of patients who had a clinically meaningful modification of the management, predefined as unplanned consultation at the hospital or CT-scan imaging following a MOOVCARE alert. Secondary endpoints included management of alerts, patients and healthcare providers satisfaction, observance, quality-of-life, and survival. **Results:** From October 2021 to October 2024, 188 pts were enrolled, including 107 men, 81 women, 155 pts with non-small cell lung cancer, 36 with other histologies; 36 pts had oncogene-addicted tumors; 70 pts had metastatic disease, 58 locally-advanced disease, and 60 had early-stage disease. 92% of pts filled at least 1 ePRO questionnaire, median number of questionnaires was 56/pts; 81% of pts had at least 1 alert, median number of alerts was 11, and total number of alerts was 2294. After a median follow-up of 23.9 mo, 39 (21%) pts had a modification of management between 2 scheduled visits, 29 (74%) of which related to preplanned visit, not to an alert; among the remaining 10 (26%) pts, only 5 (13%) pts had clinically meaningful modifications as per the predefined definition. 18-month overall survival was 79.6% [IC95% 73.6%-86.1%]. **Conclusions:** While adoption of remote symptom monitoring on ePRO was high, with frequent alerts generated from surveys, the actual impact on clinical management of patients with lung cancer was limited in the context of frequent preplanned visits at the hospital as per clinical guidelines. Clinical trial information: NCT04934865. Research Sponsor: SIVAN.

Impact of remote therapeutic monitoring on time to discontinuation and acute care events among patients treated with immune checkpoint inhibitors. First Author: Benjamin Avi Derman, The University of Chicago, Chicago, IL

Background: Immune checkpoint inhibitors (ICI) are used to treat several solid tumors but can cause serious toxicities which may lead to early discontinuation of therapy. This study describes the effect of the Canopy electronic patient-reported outcomes (ePROs)-based remote therapeutic monitoring (RTM) platform on time to treatment discontinuation, acute care events, and steroid prescribing in patients receiving ICI therapy. **Methods:** We studied patients with metastatic cancer from four oncology clinics who started ICI treatment from Jan 1, 2024 to July 20, 2025. An RTM group was defined by submission of two ePRO reports in the first 45 days after first ICI treatment. The control group was never enrolled or did not submit ePRO reports within 45 days. Time to discontinuation (TTD) of ICI, acute care events, and steroid prescribing were assessed using propensity score weighting to account for potential differences in cohort characteristics; costs were taken as rate differences multiplied by average acute care event cost. TTD was assessed by Kaplan-Meier estimation, Cox proportional hazards modeling, and restricted mean survival time at 90 days (RMST). Descriptive statistics were taken about symptoms in the RTM group versus the control group. **Results:** The study included 363 patients using RTM and 1,199 in the control group. Lung cancer, melanoma, and kidney cancer were the most frequent diagnoses. In the RTM group time to treatment discontinuation was significantly greater and prescriptions for steroids were more frequent (Table 1). Additionally, RTM use was associated with about a 51% risk of hospitalization (95% CI: 0.29, 0.88, p: 0.015) and 82% risk of ER visits (95% CI: 0.49, 1.39, p: 0.458) compared to the control group. Estimated cost savings in hospitalization associated with RTM use were $11,733,933 per 1000 patients treated for one year. Symptoms were detected more frequently in the RTM group compared to the control group, including potentially ICI-related symptoms such as rash (18% vs 3.2%), diarrhea (28% vs 4.7%), and difficulty breathing (28% vs 4.8%). **Conclusions:** Active ePRO-based RTM with Canopy is associated with increased time to ICI discontinuation and decreased acute care events. Increased use of steroids in patients reporting symptoms suggesting ICI toxicity may explain the beneficial effect of RTM. Research Sponsor: None.

Weighted analysis outcomes.

Outcome	RTM group	Control group	Risk or Hazard Ratio RTM / Control (95% CI)	Risk or RMST difference RTM - Control (95% CI)
Time to discontinuation	Median: 7.5 mos (95% CI: 6.7, 8.8)	Median: 4.1 mos (95% CI: 3.6, 4.6)	0.55 (95% CI: 0.47 to 0.64, $p < 0.001$)	19 days (16, 22)
Hospitalization	6.9%	14%	0.51 (0.29, 0.88, p: 0.015)	-6.66 (-11.02, -2.13, p: 0.008)
Emergency room visit	9.9%	12%	0.82 (0.49, 1.39, p: 0.458)	-2.46 (-8.05, 2.95, p: 0.366)
Steroid use	53%	31%	1.69 (1.41, 2.02, $p < 0.001$)	21.67 (13.90, 29.13, $p < 0.001$)

E-PROs in oncology: Improving treatment adherence to treatment while reducing emergency care and costs for patients with gastrointestinal malignancies receiving systemic therapy. First Author: Patricia Rioja, Clinica Oncosalud-AUNA, Lima, Peru

Background: Patients with cancer undergoing systemic therapy are prone to experience symptom-related complications which may lead to emergency room visits (ERV) and non-planned inpatient admissions (NIA), resulting in increased costs to health systems. Symptom monitoring and proactive management based on ePRO protocols have been shown to reduce acute care utilization; however, the economic impact of this intervention remains incompletely characterized. In addition, patients monitored through ePRO systems tend to remain on active anticancer treatment for longer periods, with fewer unplanned treatment interruptions. Our aim was to evaluate the economic impact of a remote Comprehensive Companion Program (CCP) in a private health system. **Methods:** We conducted a retrospective study within the AUNA oncological network in Lima, Peru. Adult patients with GI malignancies receiving systemic therapy who experienced at least one ERV or NIA between June 2021 and July 2022 were included. Patients were grouped according to enrollment in a remote CCP or receipt of usual care. Costs related to ERV and NIA were analyzed from a payer's perspective and adjusted by time on treatment to estimate average monthly cost per-patient. Data were analyzed using descriptive and comparative statistical methods. **Results:** A total of 97 patients with comparable baseline clinical characteristics were included (50 in the CCP group and 47 with usual care). Patients in the CCP group had a significantly longer time on treatment (median 235.5 vs 151 days; p = 0.0009), driven primarily by patients with metastatic disease. When costs associated with ERV and NIA were normalized by treatment duration, the CCP group was associated with significantly lower monthly acute care costs. Median monthly variable costs per patient were USD $147.14 versus $449.70 (p = 0.0137), representing an 67% of costs reduction in monthly variable costs per patient. Similarly, median monthly prorated expenses per patient were $220.33 versus $636.66 (p = 0.0151), corresponding to an approximate 65% reduction in monthly prorated expenses. **Conclusions:** Our study showed that patients enrolled in a CCP incorporating e-PRO based symptom monitoring remained on treatment for longer; however, this was associated with significantly lower time-adjusted acute care costs. These findings highlight the potential value of the CCP in reducing cancer care–related costs, while acknowledging that the results are limited to a private health care setting. Determinants of cervical cancer awareness, procedural knowledge, and information sources among Nepali women undergoing HPV screening. First Author: Jin Mou, Binaytara, Bellevue, WA

Background: Successful implementation of cervical cancer screening in low- and middle-income countries (LMICs) depends on community acceptance. Although general awareness of cancer is rising, limited understanding of screening procedures continues to hinder participation. This study examined the factors influencing cervical cancer awareness, procedural knowledge, and sources of screening information among Nepali women undergoing HPV-based screening. **Methods:** HPV screening was conducted through two community health fairs in Janakpur, Nepal, in 2025. Clinician-collected samples were tested using an isothermal amplification assay. Survey data collected included participants' age, education level, cervical cancer awareness, procedural knowledge on vaginal sampling, sources of screening information, and health decision-making practices. Multivariate logistic regression was used to identify factors associated with cervical cancer awareness, procedural knowledge, and information sources. **Results:** Valid survey data from 274 Nepali women, including 32 HrHPV-positive cases, were analyzed. Cervical cancer awareness was significantly associated with education. Women with secondary education or higher were more likely to have heard of cervical cancer (aOR 4.45; 95% CI 1.81-10.95, p= 0.001), compared to those with less education. However, education was not associated with specific knowledge of vaginal sampling. Procedural knowledge was instead hindered by low health autonomy (husband or in-laws as decision-maker: aOR 0.42, 95% CI 0.25-0.72, p= 0.002, vs. self-decision making). Women who tested HrHPV-positive were significantly less likely to understand the sampling procedure prior to testing than those who tested negative (aOR 0.33, 95% CI 0.14-0.78, p= 0.01). Regarding information sources, women aged 30-44 years relied more on community networks, i.e., female community health volunteers (FCHVs) than medical providers, compared to women $<$ 30 years (aOR 1.89, 95% CI 1.01-3.53, p= 0.048). **Conclusions:** Cervical cancer awareness in Nepali women is driven by education, but procedural knowledge is limited by low health autonomy. Middle-aged and older women rely on FCHVs or their community networks to acquire information about cervical screening. Future implementation strategies should address interventions that empower women and improve understanding of screening procedures, as well as tailored training on FCHVs to promote cervical screening among middle-aged women. Digital oncology navigation based on ePROs: Effects on acute healthcare utilization and cost savings in a middle-income country setting. First Author: Alessandra Menezes Morelle, Thummi Global, Porto Alegre, Brazil

Background: Oncologic treatment is associated with a high clinical and economic burden. Traditional patient navigation models often lack real-time symptom monitoring, increasing the risk of clinical deterioration. Digital navigation models incorporating ePROs have emerged as a promising strategy to address this gap. However, evidence on their implementation in low- and middle-income settings remains limited. This study aimed to assess the healthcare utilization and economic impact of an ePRO-based digital oncology navigation program in a real-world Brazilian healthcare setting. **Methods:** We conducted a prospective, single-arm, before-and-after study between February and November 2025 at a private healthcare provider in southern Brazil. Adult patients (pts) with any cancer type undergoing intravenous chemotherapy and/or immunotherapy were enrolled in a digital oncology navigation program integrating app-based ePRO monitoring, automated symptom triage, and proactive nurse-led follow-up. The primary outcome was estimated cost avoidance (from the healthcare provider perspective), calculated as the difference between pre- and post-implementation costs associated with acute healthcare utilization (hospitalizations and emergency room [ER] visits). Secondary outcomes included hospitalization and ER utilization rates, patterns of digital health service use (program adherence and daily and overall volume of symptom reports), and the clinical profile of pts who required hospitalization. Descriptive statistics were applied. **Results:** A total of 55 pts were included. The mean age was 54 years, and 63.5% were female. Breast cancer (25.5%; n = 14), non-Hodgkin lymphoma (12.7%; n = 7), and lung cancer (10.9%; n = 6) were the most frequent tumor types. Most pts had stage II–III disease (63.9%) and were receiving chemotherapy (54.8%). Hospitalization rates decreased from 29% to 22% after program implementation, while ER utilization declined from 80% to 35%. Patient adherence was high (90.8%), with consistent engagement in symptom reporting throughout follow-up (600 total symptom reports; mean of 5.4 daily reports). Most reported symptoms were managed remotely by the nursing team (95%), with minimal need for physician escalation. Among pts who required hospitalization, lung cancer was the most frequent primary tumor (50.1%). The estimated total cost avoidance was R$332,769 (≈US$66,500), corresponding to a mean saving of R$6,050 (≈US$1,210) per pt. Avoided hospitalizations accounted for most of the economic benefit. **Conclusions:** Implementation of an ePRO-driven digital oncology navigation program may reduce acute healthcare utilization and meaningful short-term cost avoidance in a real-world healthcare setting. These findings support the integration of digital symptom monitoring as scalable, cost-saving strategie in oncological care delivery. Research Sponsor: None.

PROgress Tracker Breast Cancer Registry: Reporting worry of illness from a longitudinal peer-led, national patient-reported outcomes (PRO) registry. First Author: Shaniah Leduc, Breast Cancer Canada, Montclair, NJ

Background: PROgress Tracker Breast Cancer Registry is a national, ethics approved non-interventional patient-reported outcome measure (PROMs) registry, using a peer-to-peer model directed by patient advocacy group Breast Cancer Canada. Here, initial results report breast cancer survivors nature of cancer illness worry and intensity based on age, stage and molecular subtype at diagnosis. **Methods:** PROgress Tracker was launched in 2023, with enrollment over 10 years of Canadians with Stage 0-IV breast cancer. Participants self-refer and complete a series of validated PROMs (demographic, socioeconomic, clinical, global wellbeing) via a digital platform, capturing current status on a quarterly basis for up to 10 years. Real-world analysis assisted by AI (*January 2026; Claude [Opus 4.5], manufacturer: Anthropic; data extraction, statistical analysis with means, percentages, patient-level aggregation, stratification by clinical variables, longitudinal pattern analysis and visualization; all outputs validated against source data*) of FACT-B PROM data capture and analysis methodology was used. **Results:** To date, 823 participants have enrolled with 186 participating for ≥2 years. From participation start, longitudinal worry is reported using 3 factors from FACT-B PROM; hereditary risk of family members (HR), if stress impacts illness (SI), and if participant's condition will worsen (CW). Highest degree of reported worry scores was in HR 40.4% (n = 74), SI 31.7% (n = 59) and CW at 17.4% (n = 32). Worry intensity varied by age, stage and molecular subtype. Participants diagnosed < 50 years reported higher levels in all 3 factors (HR 51% mean 2.53; SI 46.9% mean 2.24; CW 24.5% mean 1.78) to those at > 50 years (HR 37.1% mean 1.92; SI 25.9% mean 1.63; CW 14.3% mean 1.32). Stage IV participants show 66.7% high worry (CW and HR) compared to stage I at 8.5% (CW). Molecular subpopulations show higher worry in HR- / HER2- (TNBC) n = 34 (HR 48.5% mean 2.24; SI 38.2% mean 2.00; CW 17.6% mean 1.59) compared to HR+ / HER2- n = 81 (HR 37.5% mean 2.04; SI 35.4% mean 1.90; CW 17.3% mean 1.41) and HR+ / HER2+ n = 13 (HR 30.8% mean 2.08; SI 23.1% mean 1.77; CW 7.7% mean 1.38). Non-linear trajectory over time shows 24% (n = 183) experienced high worry at registry entry, declining at 12 months to 15.8% with a secondary peak at 18 months in 21.7% of participants. **Conclusions:** Patient-reported outcomes show the burden of worry by breast cancer survivors for hereditary risk to family and individuals' illness. These findings offer directional insights for psychosocial screening, care resources and tailored education throughout survivorship. Text-based electronic patient-reported outcome monitoring in oncology: A 180-day longitudinal analysis of symptom burden changes in 701 cancer patients. First Author: Pallav K. Mehta, Reimagine Care, Nashville, TN

Background: Digital electronic patient-reported outcome (ePRO) systems promise to improve symptom management in oncology, yet evidence demonstrating sustained clinical benefit across diverse cancer populations remains limited. This study evaluated the longitudinal effectiveness of a text-based ePRO platform delivering weekly validated symptom assessments in reducing overall symptom burden among cancer patients over 180 days. **Methods:** This retrospective study consisted of 701 patients with cancer recruited between 2022–2025. The patients were eligible if they were on the platform for at least 90 days, completed the baseline survey within 14 days of enrollment, and had a survey completion rate of at least 30%. ePRO responses triggered review by a virtual care team that provided protocolized symptom management outreach and triage in collaboration with treating oncology practices. The primary outcome was the change in overall symptom burden over 180 days, measured by the Edmonton Symptom Assessment System (ESAS; total score 0–90). Secondary outcomes included physical symptoms (0–60), emotional symptoms (0–20), and well-being (0–10). Stratified analyses were done using paired t-tests. **Results:** The final cohort (mean age 64.6 years; 57.2% female; 20.5% metastatic; mean adherence 66.1%) demonstrated significant reduction in total symptom burden (20.99 to 18.11 points; -2.89 points, -13.7%, $p < 0.001$) and physical symptoms (14.86 to 12.18 points; -2.68 points, -17.0%, $p < 0.001$). Emotional symptoms and well-being showed no significant change. Efficacy was engagement-dependent: high-engagement patients (N = 465) achieved -2.80-point reduction ($p < 0.001$) versus non-significant changes in medium/low-engagement groups. Stratified analyses revealed heterogeneity: breast cancer patients demonstrated exceptional response (-8.96 points, -46.3%, p = 0.008), while GI cancer patients showed resistance (-0.43 points, p = 0.915). Non-metastatic patients (-3.06 points, $p < 0.001$), females (-3.27 points, $p < 0.001$), and patients aged < 50 years (-4.28 points, p = 0.011) demonstrated superior outcomes compared to metastatic, male, and elderly (≥75 years) patients. **Conclusions:** Text-based digital ePRO monitoring significantly reduced symptom burden in cancer patients over 180 days, with physical symptom improvement as the primary driver. Clinical benefit was engagement-dependent and varied substantially by cancer type, metastatic status, age, and gender. These findings validate the clinical utility of SMS-delivered ePRO systems while identifying highly responsive populations (breast cancer, non-metastatic, younger patients) and vulnerable subgroups requiring enhanced symptom management support. Research Sponsor: None.

Advancing value-based breast cancer screening in a safety-net health system: A multimodal approach to improving population health and system sustainability. First Author: Shivani Agarwal, Montefiore Einstein, Bronx, NY

Background: Evaluation of breast cancer screening (BCS) adherence in our large safety-net health system revealed wide variability and late-stage diagnosis rates that exceeded national benchmarks. A multidisciplinary taskforce (primary care, radiology, cancer center, and patient advocates) identified barriers, co-designed, and implemented a multi-pronged intervention to address screening uptake and adherence. **Methods:** Mixed-methods evaluation across 18 primary care sites revealed wide variability in BCS rates (60-82%); lack of systematic management of screening bottlenecks (ordering, scheduling, no-shows/cancellations); and unmet patient needs (transportation, screening hesitancy). We co-developed and implemented a phased intervention from March–December 2025 to address identified barriers through: (1) radiology navigator outreach to primary care patients at low-performing sites (March), (2) electronic medical record patient portal self-scheduling (July), (3) AI-assisted rescheduling after no-shows/cancellations (December), and (4) assessment and navigation of social needs and screening hesitancy (March). Outcomes measured were outreach, engagement, and screening completion. We performed multivariate regression to examine demographic predictors of screening. **Results:** Of 57, 041 HEDIS-eligible patients, 15,971 (28%) were overdue at baseline (mean age 58 yo, 77% Hispanic or non-Hispanic Black, 74% Medicaid or Dual). Overall, the intervention resulted in 1,610 additional screens over 9 months, improving systemwide BCS rates from 72 to 76%. Of the additional screens, radiology navigator achieved 452 screens (29%), patient portal self-scheduling achieved 1,097 screens (70%), and AI-assisted outreach of no-show/cancelled achieved 61 screens (4%). Engagement and show rates varied: navigator outreach had the highest scheduling engagement (74%) but lower show rates (46%); patient portal self-scheduling showed moderate engagement (44%) with higher show rates (76%); and AI-assisted outreach had low engagement (4%) with moderate show rates (56%). Demographics did not predict screening outcomes. Screening hesitancy (37%) and transportation (10%) were the most common barriers, addressed through social and peer navigation, respectively. Revenue from additional screenings fully offset navigator costs. **Conclusions:** A coordinated, resource-efficient screening outreach strategy combining digital tools, human navigation, and AI assistance—co-designed with patients and clinical stakeholders—improved BCS adherence, addressed unmet needs of underserved populations, and proved itself financially sustainable across a safety net health system. Future efforts will focus on further scaling of population health approaches to cancer screening programs. Research Sponsor: None.

Proactive response initiative for symptom management (PRISM): A multi-institutional symptom monitoring program for veterans receiving systemic cancer therapy. First Author: Denaly Chen, Tibor Rubin VA Medical Center, Long Beach, CA

Background: Symptom assessment and management in cancer care are challenging. Within the Veterans Health Administration (VHA), gaps remain in widescale implementation of standardized symptom assessment, technology support, and adaptable workflows. PRISM was developed as a multi-institutional, technology-enabled clinical program to improve early identification and treatment of cancer-related symptoms for Veterans with the ultimate goal of system-wide implementation. **Methods:** We adapted an evidence-based proactive symptom intervention for the Long Beach VA with a working group of clinicians, pharmacists, social workers, case managers, and ancillary staff. The intervention involved a peer specialist conducting weekly telephone-based assessments using a modified Veteran Symptom Assessment System (VSAS) for Veterans initiating systemic anti-cancer treatment. Symptom scores ≥4 on a scale of 0-10 or a score increase by 2 points automatically triggered Nurse Practitioner (NP) review and follow up. We conducted an evaluation of our first PRISM site and assessed Veteran retention, symptom burden, interventions, and process metrics to inform scale and spread for two future VHA sites this quarter. **Results:** From May 22, 2025 to December 1, 2025, 30 patients (pts) enrolled in PRISM; 4 (13%) withdrew < 1 month, 2 (6.7%) withdrew > 1 month, 2 (6.7%) completed the program, and 1 (3.3%) died. Frequently reported symptoms of any score were fatigue (n = 14; 61%), dyspnea on exertion (n = 6; 26%), and pain (n = 6; 26%). Of the 412 times symptoms were reported as ≥4 on a scale of 0-10, the most frequent were fatigue (22%), dyspnea with exertion (13%), and drowsiness (13%). For the 23 pts who remained in the program for > 1 month there were 308 peer specialist encounters and 205 NP encounters. NPs intervened in 91% (186/205) of encounters with a total of 961 interventions. The mean number of interventions per NP encounter was 3.67. The most frequent intervention was pt education 86% (827/961), medication prescriptions 13% (123/961), and alerting the primary oncology team 4.2% (41/961). The mean time interval between a VSAS survey and indicated NP follow up was 1.06 days. The call duration was a mean 9.25 minutes per encounter with the peer specialist and 17.3 minutes per encounter with the NP. Documentation and chart review took a mean of 10.5 minutes per peer specialist encounter and a mean of 14.4 minutes per NP encounter. **Conclusions:** Early results from our first real world PRISM implementation in the VHA demonstrate feasibility, retention, and frequent early identification of and intervention for symptoms using this proactive symptom management program embedded within existing pt oncology care. The process metrics regarding capacity for peer support and NP effort will inform our expansion to two implementation sites by June 2026 and an additional 10 sites by 2027. Research Sponsor: None.

11116 Poster Session

Factors associated with clinical trial failure and termination in non–small cell lung cancer immunotherapy: A ten-year review. First Author: Arman Asatryan, Yerevan State Medical University named after Mkhitar Heratsi, Yerevan, Armenia

Background: Immunotherapy (IO) has transformed NSCLC management, yet trial efficiency and strategy-level success patterns across settings remain incompletely described. We evaluated NSCLC IO trials for termination trends, outcome accessibility, shifts in strategies over time, and factors associated with endpoint success and failure to inform future trial designs. **Methods:** We identified interventional NSCLC IO trials from ClinicalTrials.gov from 2015–2024 with completed/terminated status. Trials were categorized by setting (metastatic 1L and beyond 1L; perioperative; other/mixed), intervention strategy (PD-(L)1 monotherapy; PD-(L)1+chemotherapy; PD-(L)1+CTLA-4; PD-(L)1+targeted/VEGF/ADC; RT/CRT+ICI; other IO), phase group, sponsor type (industry vs non-industry), and disease stage. Statistic analysis was done using chi-square/Fisher tests and multivariable logistic regression. Among completed trials, success/failure was defined as meeting/not meeting the primary endpoint when outcomes were assessable. **Results:** Among 198 NSCLC IO trials, 67 (33.8%) were terminated, 131 (66.2%) completed. Termination increased over time (24.0% 2015–2017, 48.1% 2018–2019, 57.1% 2020–2022; p = 0.0005) and persisted after accounting for setting, phase, sponsor type (2018-2019 vs 2015-2017: OR 2.87, p = 0.0037; 2020-2022 vs 2015-2017: OR 3.22, p = 0.0277). Metastatic disease trials shifted from late (56.0%, 2015–2017;42.9%, 2020–2022) to 1L (28.8% - 47.6%). Endpoint outcomes were assessable in 72/131 (55.0%) completed trials - more in metastatic 1L vs later-line (75.0% vs 42.3%, p = 0.0086; OR 0.30, p = 0.013) and in industry vs non-industry trials (71.9% vs 41.9%; p = 0.0012, OR 0.38, p = 0.030). Among these, 47 (65.3%) met primary endpoints. Success varied by strategy: PD-(L)1+chemo 73.1%, PD-(L)1 mono 60.9%, PD-(L)1+CTLA-4 50.0%, PD-(L)1+targeted 20.0%, RT+ICI 85.7%; PD-(L)1+chemo outperformed PD-(L)1+targeted (Fisher p = 0.0416). Strategy shifted over time (p = 0.034), with decreased PD-(L)1 mono and increased RT+ICI and PD-(L)1+targeted combinations in later years. Proportion of PD-(L)1 monotherapy was higher for perioperative trials (47.4%) vs metastatic 1L (16.7%) and later-line settings (26.7%). Cell-(n = 8) and vaccine/virus-based (n = 12) approaches were uncommon (term. 25% and 50%) with limited assessable outcomes. **Conclusions:** Treatment strategies shifted away from PD-(L)1 monotherapy toward combination approaches and, in metastatic disease, from late-line to 1st line settings. PD-(L)1+chemotherapy and RT+ICI showed higher success rates than PD-(L)1+targeted combinations, though some subgroups were small. Other IO agents are rarely used in NSCLC and have insufficient reporting. Incorporating predictive risk models into trial planning may reduce low-yield studies and accelerate identification of effective treatments. Research Sponsor: None.

Evaluating the role of informal caregivers in metastatic cancer patients treated with oral anticancer therapy: A prospective observational study. First Author: Barbara Salvo, Division of Medical Oncology, "G. Martino" University Hospital, University of Messina, Messina, Italy

Background: The increasing use of oral anticancer agents (OAAs) in metastatic cancer has shifted treatment management from hospital to home, transferring responsibility for adherence and symptom monitoring to patients and informal caregivers. Evidence on caregiver burden and its impact on patient-reported outcomes in this setting remains limited. **Methods:** This prospective observational study evaluated patients with metastatic cancer receiving OAAs and their informal caregivers. At baseline and three months, patients completed the EORTC QLQ-C30, MMAS-8, TEMPS-A, and the G8 geriatric screening tool; caregivers completed the Zarit Burden Interview (ZBI), Caregiver Reaction Assessment (CRA), TEMPS-A, and an ad hoc caregiving questionnaire. Statistical analyses were performed using IBM SPSS Statistics ($p < 0.05$). **Results:** Sixty-eight patients (median age 67 years; 50% female) were enrolled; among patients aged >70 years, the G8 score indicated a predominance of non-frail patients (68.2%). 66.1% had a caregiver, most commonly a spouse (46.5%) or child (41.9%). Caregivers (mean age 56 years) were involved for >2 years in 76.7% of cases and attended outpatient visits in 69.8%. ZBI showed minimal/no burden in 60.5% and mild-to-moderate burden in 32.6%. CRA scores were highest for self-esteem (4.13±0.62), followed by schedule (3.31±1.36) and health (3.10±0.66). Patients with caregivers reported worse quality of life, physical, role, and emotional functioning, higher symptom burden (fatigue, pain, dyspnea, appetite loss, financial difficulties), and lower adherence compared with those without caregivers (all $p<0.05$). Caregiver presence was associated with cyclothymic, depressive, and anxious temperaments. Patients cared for by a child showed better role functioning, while spousal caregiving was associated with irritable temperament. At three months (n=22), patients showed significant improvements in adherence, quality of life, physical and role functioning, and symptom burden, suggesting early adaptation to oral therapy despite high baseline caregiving demands. **Conclusions:** Informal caregivers play a central role in OAA-treated metastatic cancer. Caregiver involvement appears to reflect greater patient vulnerability rather than a causal determinant of poorer outcomes, supporting the need for systematic caregiver assessment and targeted supportive interventions. Research Sponsor: None.

Caregiver characteristics and associated patient outcomes.

Variable	Caregiver present	No caregiver

Real-world utilization patterns and adverse events among patients receiving antibody–drug conjugates (ADCs) across the University of California health system. First Author: Guanming Chen, UCSF, San Francisco, CA

Background: Antibody–drug conjugates (ADCs) have rapidly expanded across oncology indications, yet real-world safety profiles remain incompletely characterized. Pivotal trials may not fully capture adverse events (AEs) associated with real-world treatment patterns, such as cumulative exposure or sequential ADC therapy. **Methods:** We performed a retrospective cohort study across six UC medical centers using de-identified structured EHR data from the University of California Health Data Warehouse (UCHDW). We included adult patients who received at least 1 dose of ADC between Jan 2015 and Feb 2025. Observational period for safety surveillance is at least 8 months. Key safety outcomes were the incidence and timing of key AEs following ADC initiation. Secondary outcomes included duration of ADC therapy and the frequency of sequential ADC. Descriptive statistics were used to analyze toxicity and time to AE of special interest. **Results:** Across the UC system, 4,531 patients received at least one ADC and had a documented cancer-related diagnosis, 82.7% of patients had metastatic cancer at initiation of ADC. Breast cancer was the most frequently observed cancer type (38.8%), followed by hematologic malignancies (28.5%) and bladder/urothelial cancers (11.2%). Mean dose number was 10.1 (standard deviation: 11.3). Among 4,531 ADC-treated patients, 10.6% transitioned to a second ADC, and 78.9% received concomitant anticancer therapy, including immune checkpoint inhibitors (38.0%), ICI plus chemotherapy (21.8%), or chemotherapy alone (18.7%). Incident neurotoxicity was the most frequent AE (728 patients, 16.1%), followed by hematologic (15.0%) and cardiotoxicity (14.6%) AEs. Incident ocular toxicity was observed in 343 patients (7.5%) with a median time to onset of 84 days, and incident mononeuritis in 480 patients (10.6%) with a median onset of 105 days following ADC initiation. **Conclusions:** In this large, multicenter real-world cohort, ADC treatment was associated with substantial rates of neurologic, hematologic, and cardiac toxicities. The frequent use of concomitant anticancer treatments and observed transitions between ADCs underscore the complexity of real-world exposure and highlight the need for proactive toxicity monitoring and optimized safety management strategies in routine oncology practice. Research Sponsor: None.

Inpatient palliative care utilization and outcomes among decedent patients with metastatic cancer in the U.S. First Author: Jiazhang Xing, Sinai Hospital of Baltimore, Baltimore, MD

Background: Palliative care (PC) is a key component of high quality cancer care, especially at the end of life. However, real world national data describing inpatient PC utilization remain limited. We evaluated patterns of PC use and associated outcomes among decedent patients with metastatic cancer in the U.S. **Methods:** We conducted a cross-sectional analysis of the 2021–2023 National Inpatient Sample of decedent patients with metastatic cancer. Palliative care, cancer type, and metastatic status were identified using ICD-10 codes. Patient characteristics included age, sex, race, comorbidity burden, insurance status, and household income. Hospital characteristics included location (urban vs rural) and ownership (public, private not-profit, and private invest-own). Outcomes included length of stay (LOS), inpatient procedures, and total costs. Factors associated with palliative care use and adjusted mean differences in outcomes were estimated. **Results:** An estimated 52,841 hospitalizations of decedent patients with metastatic cancer were identified, with 34,955 (66.2%) involving palliative care. PC utilization varied by cancer type (Table) and increased over time (aOR per year 1.15; 95% CI 1.12–1.18). PC use was independently associated with older age, female sex, private insurance, higher neighborhood income, and care at private not-for-profit hospitals (all $p<0.001$). PC was associated with fewer inpatient procedures (adjusted mean difference −1.38; 95% CI −1.45 to −1.31), shorter LOS (−1.25 days; 95% CI −1.45 to −1.06), and lower total costs (−$10,557; 95% CI −$11,421 to −$9,694). Reductions in procedures, LOS and costs were significant across most cancer types. (Table). **Conclusions:** Inpatient PC was associated with lower care intensity and costs across cancer types among decedent patients with metastatic cancer. Yet, about one third never received PC, highlighting a major end-of-life care gap and the need for earlier, more equitable integration to improve value based oncology care. Research Sponsor: None.

Palliative care utilization and outcomes by major cancer type.

Cancer Type	PC use	Adjusted Procedures difference	Adjusted Cost difference ($)	Adjusted LOS difference (days)
Breast	2646 (66.7%)	-1.47 (-1.70,-1.24)	-12512 (-16301, -8722)	-1.90 (-2.63,-1.17)

Risk of immune-related adverse events from checkpoint inhibitors in cancer patients with autoimmune disease: An emulated target trial. First Author: Rotana M. Radwan, Purdue University, Indianapolis, IN

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment by activating the immune system to target and eliminate cancer cells, leading to durable responses and improved survival. However, patients with preexisting autoimmune diseases are excluded from ICI clinical trials due to concerns about triggering immune-related adverse events (irAEs). Consequently, there is limited real-world data comparing the risk of irAEs between ICIs and other systemic cancer therapies in this high-risk population. **Methods:** We conducted a target trial emulation using a new-user, active-comparator design to compare the risk of developing de novo irAEs following ICI initiation compared to chemotherapy or targeted therapy. Using Merative MarketScan data (2014–2023), we identified adults with cancer and a preexisting autoimmune disease who initiated treatment with ICIs, chemotherapy, or targeted therapy. Propensity score matching (1:1) was performed for two comparisons: ICI versus chemotherapy and ICI versus targeted therapy. The primary outcome was de novo irAEs affecting organ systems distinct from the patient's baseline autoimmune disease. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), with subgroup analyses by age, sex, cancer type, preexisting autoimmune disease category, and ICI class. **Results:** A total of 3,601 matched patient pairs were included in the ICI–chemotherapy comparison and 1,479 matched pairs in the ICI–targeted therapy comparison. Patients receiving ICI had a significantly higher risk of developing de novo irAEs compared to those receiving chemotherapy (HR=1.71; 95% CI, 1.49–1.97) or targeted therapy (HR=1.43; 95% CI, 1.20–1.70). This increased risk was consistent across age and sex. By ICI class, CTLA-4 inhibitors were associated with the highest risk (HR=2.64; 95% CI, 1.97–3.53 vs chemotherapy; HR=1.72; 95% CI, 1.18–2.50 vs targeted therapy), followed by ICI combination therapy (HR=2.46; 95% CI, 1.80–3.37 vs chemotherapy). By cancer type, patients with liver cancer had the greatest risk (HR=2.75; 95% CI, 1.96–3.85 vs chemotherapy; HR=2.67; 95% CI, 1.68–4.24 vs targeted therapy), followed by breast cancer (HR=2.11; 95% CI, 1.31–3.42 vs chemotherapy; HR=1.97; 95% CI, 1.06–3.68 vs targeted therapy). By baseline autoimmune disease category, patients with endocrine autoimmune diseases consistently showed elevated risk across both comparisons (HR=1.74; 95% CI, 1.42–2.14 vs chemotherapy; HR=1.92; 95% CI, 1.43–2.58 vs targeted therapy). **Conclusions:** ICI use in cancer patients with preexisting autoimmune diseases is associated with a higher risk of de novo irAEs than chemotherapy or targeted therapy, with risk varying by ICI type, cancer type, and underlying autoimmune condition, highlighting the need for individualized risk assessment and close monitoring. Trends in ivermectin medication records with cancer as the primary diagnosis following public attention: A national EHR analysis. First Author: Changchuan Jiang, UT Southwestern Medical Center, Dallas, TX

Background: Ivermectin, an antiparasitic agent not indicated for cancer treatment, has received public attention since early January 2025 due to widespread discussion on social media and other non-clinical forums. Little is known about whether the increased visibility may influence medication use or reporting among patients with cancer in real-world clinical data. **Methods:** We conducted a retrospective descriptive analysis using the EPIC COSMOS, a large, multi-institutional U.S. electronic health record network. We identified all ivermectin medication records from quarter (Q)1 2024 to Q3 2025, including prescribed/administered and patient-reported medications linked to clinical encounters. Our primary outcome was the quarterly trend in the percentage of ivermectin records where cancer was listed as the primary diagnosis for the encounter. Secondary measures included other diagnosis associated with the encounter (e.g., parasitic) and patient demographics. **Results:** We identified 96,525 ivermectin medication records, increasing from 11,854 in Q1 2024 to 15,223 in Q3 2025. The proportion of records with cancer as the primary diagnosis increased modestly during 2024 (from 2.3% to 3.1%; average quarterly increase=0.2 percentage points [ppts]), followed by a larger increase in Q1 2025 (from 3.1% to 4.2%, adjusted increase=1.0 ppts, relative increase=32%, $p<.001$), which stabilized in Q2 and declined slightly in Q3 2025. The surge from Q4 2024 to Q1 2025 was larger for patient-reported ivermectin (from 156 to 231 records, 48% increase) than prescribed/administered medications (292 to 347 records, 19% increase). In contrast, the proportion of ivermectin records associated with strongyloidiasis, onchocerciasis, or scabies ranged from 18.5%–19.5% in 2024 and declined to 17.1% in Q1 2025, while records associated with other infectious conditions remained stable (~49%). Among records with cancer as the primary diagnosis (n=3,157), mean patient age was 62 years, with 46% female, 76% White, 8% Black, and 10% Hispanic; the proportion prescribed to White patients increased from 71% in Q4 2024 to 81% in Q1 2025. Physician specialty distribution associated with prescribed/administered ivermectin was 35% oncologists, 20% primary care, 22% dermatologists, 4.2% advanced practice providers, and 19% other specialties. **Conclusions:** Although ivermectin use in cancer care remained uncommon overall, real-world data show a rapid, largely patient-driven increase during Q1 2025. This rise is distinct from the stable or declining proportions of records linked to approved parasitic indications. These findings suggest that social trends may shape medication use, highlighting the importance of careful medication reconciliation and patient counseling in oncology settings to address non-evidence-based use. Machine learning–based prognostic models for mortality prediction after unplanned hospitalization in cancer patients. First Author: Taha Koray Sahin, Hacettepe University, Department of Medical Oncology, Ankara, Turkey

Background: Unplanned hospitalizations in oncology patients often indicate acute clinical deterioration and are associated with high mortality. Prognostic assessment at admission remains a challenge, particularly in resource-limited settings. Machine learning (ML) methods can integrate clinical and laboratory features to generate individualized mortality predictions, although the data is scarce. We aimed to develop and validate ML-based models to predict in-hospital, 30-day, and 90-day all-cause mortality in adult cancer patients with unplanned hospitalizations. **Methods:** We retrospectively analyzed patients with cancer who were admitted for unplanned hospitalizations at Hacettepe University Oncology Hospital between January 2018 and August 2024. Class imbalance was addressed using SMOTE, and ANOVA-based feature selection retained the top 20 predictors. Nine ML algorithms were tested, including SVM, kNN, decision trees, neural networks, and ensemble models. Model performance was assessed via 5-fold cross-validation using accuracy, precision, recall, F1-score, and AUC. **Results:** A total of 1646 cancer patients with unplanned hospitalizations were included. The most common cancers were gastrointestinal malignancies (32.8%), lung cancer (17.4%), and breast cancer (9.8%). For in-hospital mortality prediction, Random Forest achieved the best performance on the original dataset (AUC-ROC: 0.89; accuracy: 84.6%). After SMOTE, SVM yielded the superior results (AUC-ROC: 0.98; accuracy: 93.6%). For 30-day mortality prediction, Random Forest was optimal pre-SMOTE (AUC-ROC:0.85; accuracy: 83.6%), whereas LightGBM reached the highest post-SMOTE performance (AUC-ROC: 0.97; accuracy:91.8). For 90-day mortality prediction, XGBoost demonstrated the best performance on the original dataset (AUC-ROC: 0.84; accuracy: 80.4%). Following the application of SMOTE, LightGBM outperformed the other models (AUC-ROC:0.90; accuracy:82.3%). **Conclusions:** This first study focusing on predicting in-hospital mortality in cancer patients with unplanned admissions shows that ML models based on routine admission data can reliably predict early- and long-term mortality. Incorporating such models into workflows may support early risk stratification, shared decision-making, and individualized care planning. Research Sponsor: None.

Mortality caused by coexisting malignant neoplasms and type 2 diabetes mellitus in U.S. adults: A CDC WONDER analysis (1999–2020). First Author: Muhammad Abdullah, Punjab Medical College, Faisalabad, Pakistan

Background: Type 2 diabetes mellitus (T2DM) and malignant neoplasms are among the most prevalent chronic diseases worldwide. When coexisting, they substantially increase morbidity and mortality. However, national trends in cancer-related mortality among patients with T2DM in the United States remain underexplored. **Methods:** We analyzed CDC WONDER mortality data (1999–2020) to identify deaths among U.S. middle-aged (55–74 years) and older adults ($\geq$75 years) in which both malignant neoplasms (ICD-10 C00–C97) and T2DM (ICD-10 E11.0–E11.9) were listed as causes of death on death certificates. Age-adjusted mortality rate (AAMR) per 100,000 were calculated and stratified by sex, age group, race/ethnicity, and urbanization status. Trends in overall AAMRs were analyzed using the Joinpoint Regression Program to calculate the average annual percentage change (APC), with statistical significance set at $\leq$ 0.05. **Results:** From 1999 to 2020, a total of 255,154 U.S. adult deaths involved both T2DM and malignant neoplasms. The AAMR increased significantly over the study period (APC 2.91%; 95% CI 2.32–3.50; $p<0.01$). Joinpoint regression identified an inflection point around 2011, after which mortality accelerated markedly (APC 6.67%; 95% CI 4.94–8.42). Mortality rates were consistently higher in men compared with women (overall AAMR 13.4 vs. 7.28; $p<0.01$). Older adults experienced the highest mortality burden (overall AAMR 23.4; APC 2.83%; 95% CI 2.25–3.41), while middle-aged adults demonstrated a steeper relative increase (2.14; 3.40%; 2.72–4.07). Marked racial and ethnic disparities were observed. Asian or Pacific Islanders (API) showed the steepest rise (APC 5.96%; 95% CI 5.35–6.58), followed by Hispanics (5.12%; 4.61–5.63), non-Hispanic (NH) Whites (2.66%; 2.03–3.28), NH Blacks (2.47%; 1.87–3.07), and American Indian/Alaska Natives (AI/AN) (3.15%; 1.03–5.32). Overall AAMRs were highest among AI/AN (15.2) and NH Black adults (11.5), followed by Hispanics (10.5), NH Whites (9.39), and API (7.34). Rural populations consistently had higher mortality rate (overall AAMR 12.9; APC 1.20%; $p<0.01$), whereas urban populations demonstrated a greater relative increase (8.98; 3.24%; $p<0.01$). Regionally, the West experienced the most rapid increase in mortality, while the highest overall rates were observed in Nebraska, West Virginia, and Minnesota. **Conclusions:** Mortality among U.S. adults with concomitant T2DM and malignant neoplasms increased markedly from 1999 to 2020, significant disparities by sex, age, race/ethnicity, region, and urbanization. Integrated public health strategies linking diabetes management with cancer prevention, targeted screening, and equity-focused interventions are urgently needed. Research Sponsor: None.

Timing and prognostic impact of thromboembolic events in lung cancer patients treated with immune checkpoint inhibitors: A time-dependent real-world analysis. First Author: Chinemerem Martlin Emeasoba, University of Arkansas for Medical Sciences, Fayettville, AR

Background: Thromboembolic events (TEEs) are complications associated with malignancy, and emerging evidence suggests immune checkpoint inhibitors may further increase thrombotic risk; however, the prognostic impact of thromboembolic events in the era of immune checkpoint inhibitors, where inflammation and vascular toxicity may be amplified, remains unclear. We analyzed the incidence, timing, and impact on survival of thromboembolic complications in lung cancer patients treated with immunotherapy at a single tertiary academic institution. **Methods:** We conducted a retrospective study of adult lung cancer patients treated with immunotherapy at a single rural academic center (2015–2025). Thromboembolic events were classified as arterial (myocardial infarction, stroke) or venous (deep vein thrombosis, pulmonary embolism). Clinical characteristics and VAN Index scores were compared by TEE status, and overall survival was assessed using Kaplan-Meier and time-dependent Cox regression to address immortal time bias. **Results:** Altogether, 505 lung cancer patients received immunotherapy during the study period; patients were predominantly White (76.6%) and male (56.4%), with 21.4% identifying as Black. 22.8% experienced at least one TEE. Histologic subtypes included 59% with non-small cell lung cancer and 41% with small cell lung cancer. The mean age at diagnosis was 65 years. Among patients with TEE, 63.5% experienced arterial and 40.0% venous events. Some patients experienced both venous and arterial events during follow-up. The mean time to first TEE was 404 days, with venous events occurring earlier in the disease course. Patients with TEE had significantly higher comorbidity burden (9.28 vs 6.51) and thrombotic risk by VAN Index (31.99 vs 23.69; both $p < 0.001$). While unadjusted Kaplan-Meier analysis showed no survival difference (22 vs 19 months; p = 0.126) and multivariable Cox models treating TEE as a baseline exposure showed no independent association with survival (aHR 1.05, 95% CI 0.80-1.38), time-dependent Cox modeling demonstrated a significantly increased mortality risk following TEE (aHR 2.45, 95% CI 1.85-3.26; $p < 0.001$). **Conclusions:** Thromboembolic events occurred in nearly one-quarter of lung cancer patients treated with immunotherapy and were associated with higher comorbidity and thrombotic risk. Although standard analyses showed no survival difference, time-dependent modeling demonstrated significantly increased mortality following TEE. These findings demonstrate that failure to account for TEE as a time-varying exposure may substantially underestimate its prognostic impact, underscoring the need for prospective dynamic risk assessment and thromboprophylaxis strategies during immunotherapy. Natural language processing–assisted chart review to assess documented cannabis use in electronic medical records (EMR) of adults undergoing cancer infusion therapy. First Author: Reina Haque, Kaiser Permanente Southern California, Pasadena, CA

Background: Patients' consumption of cannabis for symptom management is well-documented, yet prevalence of cannabis use, and its documentation among patients undergoing active cancer treatment is understudied. Our goal was to assess the prevalence of documented cannabis use in the EMR of patients undergoing infusion cancer therapy. **Methods:** We conducted a cross-sectional analysis of adult members of Kaiser Permanente Southern California undergoing infusion therapy between February 16 to 28, 2025. Natural language processing (NLP) of search terms indicative of cannabis use was used to identify any EMR documentation of such use in unstructured clinical notes in the past year. Each matched query included 15-20 words before and after the keyword and was manually reviewed for clinical context and confirm cannabis use. **Results:** We identified N = 690 cancer survivors undergoing infusion therapy during the two-week period. Of these, N = 354 (51%) had a cannabis notation in their EMR after applying the NLP program. Half were female. Altogether 1,010 snippets from N = 354 patients were output into a spreadsheet for manual review; each snippet required about 30 seconds to determine cannabis use status. Of the N = 354 patients, overall prevalence of cannabis use was 29% (N = 101). The highest prevalence was in patients undergoing first line palliative treatment (38%); followed by palliative after first line (25%); adjuvant (16%); then curative first line therapy (13%). Cannabis use was lower in among those undergoing curative after first line therapy (6%) and neoadjuvant therapy (3%). Highest cannabis use was observed in those with cancer of the breast (15%); lung (14%); prostate (10%); colorectal (10%) and gynecologic (8%). Regarding demographics, odds of cannabis use was greater in males (OR = 1.34, 95% CI: 0.82-2.21) vs. females (ref). Compared with Asians (ref), odds of cannabis use was about two-fold greater in Hispanic (OR = 1.95, 95% CI: 0.78-5.35), Black (OR = 2.47, 95% CI: 0.80-7.87), and White (OR = 2.30, 95% CI: 0.95-6.15) patients. Odds of cannabis use was 24% greater in younger individuals (< 50 years, OR = 1.76, 95% CI: 0.84-3.61), but all confidence intervals crossed the null. **Conclusions:** NLP-assisted manual review of chart notes is a time-efficient method to collect information on unstructured data. This methodology determined prevalence of cannabis use in patients undergoing cancer infusion therapy is 29%. Cannabis use was greater among patients being treated in palliative settings compared to adjuvant/curative settings. A limitation of this study is that cannabis use may be underestimated because we assume that not all discussions were recorded in the EMR. Information garnered from this cross-sectional data exploration will be used to plan a prospective study of cancer survivors to examine the risks and benefits of cannabis use. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health.

Breast cancer screening and detection after the 2024 USPSTF recommendation for women aged 40–49. First Author: Karen Farrar, Truveta Inc., Bellevue, WA

Background: In April 2024, the US Preventive Services Task Force (USPSTF) expanded its biennial screening mammography recommendations to include women aged 40–49, citing rising breast cancer incidence in this age group and persistent disparities in outcomes. How this expansion has influenced diagnosis and stage at diagnosis in real-world practice is not yet well characterized. **Methods:** Using a subset of de-identified electronic health record data from Truveta, we identified women aged 40–74 who underwent screening mammography between 2018 and 2025, had no prior breast cancer diagnosis and who had evidence of outpatient care 6-18 months before and 1-12 months after screening. For patients with multiple eligible screening mammograms, only the first was retained for analysis. Analyses were restricted to health systems with available cancer stage data. April 30, 2024, was used as the cut point (pre- vs. post-guideline). Outcomes included: (1) screening uptake by age group, (2) breast cancers diagnosed within 180 days of screening, (3) stage at diagnosis (early [AJCC 0–I] vs. later [II–IV]). Diagnosis and stage were derived from clinical notes and categorized as early- (AJCC stage 0–I) versus later-stage (II–IV). Logistic regression, adjusted for race, ethnicity, rural–urban residence, and family history, was used to evaluate differences by age group and guideline period. **Results:** Among 985,687 women aged 40-74 who received a screening mammogram, 880,685 (89.3%) occurred pre-guideline and 105,002 (10.7%) occurred post-guideline. Women aged 40–49 comprised a substantially larger share of screenings post-guideline (53,227/105,002, 50.7% vs. 262,330/880,685, 29.8% pre-guideline $p<.001$). The likelihood of a breast cancer diagnosis within 180 days did not differ between the pre- and post-guideline periods for women aged 40–49 (OR 1.03, 95% CI 0.79–1.34) or 50–74 (OR 0.87, 95% CI 0.75–1.01). Among women diagnosed within 180 days with cancer stage information available (n = 3,866), the likelihood of early- versus later-stage diagnosis did not differ between the pre- and post-guideline periods for women aged 40–49 (early-stage: 63.6% vs. 68.3%; OR 1.26, 95% CI 0.72–2.21) or 50–74 (OR 0.91, 95% CI 0.67–1.24). **Conclusions:** Following the April 2024 USPSTF guideline expansion, screening mammography uptake among women aged 40–49 increased substantially, however the likelihood of a breast cancer diagnosis within 180 days did not significantly differ between the pre- and post-guideline periods. Stage at diagnosis did not differ significantly in the short post-guideline period; longer follow-up is needed to assess whether earlier detection translates to stage-shift benefits over time. These findings provide early real-world evidence to inform the ongoing risk-benefit discussion surrounding breast cancer screening in younger women. Research Sponsor: Truveta.

Safety and efficacy of immunotherapy rechallenge in solid tumors after discontinuation of immune checkpoint inhibitors for immune-related adverse events: A systematic review and meta-analysis. First Author: Yu Fujiwara, Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Immune-related adverse events (irAEs) often require treatment discontinuation in patients with cancer receiving immune checkpoint inhibitors (ICIs). Given limited subsequent treatment options, ICI rechallenge is frequently considered. We aimed to estimate the incidence of recurrent irAEs and objective response rates (ORR) in patients receiving ICI rechallenge following prior irAEs. **Methods:** PubMed, Web of Science, and Embase were searched for studies evaluating ICI rechallenge in patients with advanced solid tumors who previously suspended treatment due to irAEs. Outcomes included the incidence of grade 1-5 (Gr1-5), Gr1-2, and Gr3-5 irAEs, recurrent irAEs, new irAEs, ORR, and disease control rate (DCR). Random-effects meta-analyses and subgroup analyses by cancer type were performed. Meta-regression analysis was conducted to evaluate the impact of the grade and type of initial irAEs on response outcomes. Heterogeneity was assessed using I^2 statistics ($\geq$50% considered high). **Results:** Thirty-seven studies comprising 1,126 patients with initial irAEs (Gr1-2: 62.8%, Gr3-4: 37.2%) leading to suspension of ICIs were included. The most common initial irAEs in the pooled cohort were hepatitis/liver enzyme elevations (20.5%), pneumonitis (16.1%), and nephritis/acute kidney injury (14.8%). Pooled incidences of Gr1-5, Gr1-2, and Gr3-5 irAEs after ICI rechallenge were 42.2% (95% confidence interval [CI]: 35.3-49.3), 27.1% (95% CI: 22.9-31.7), and 18.8% (95% CI: 14.7-23.8), respectively. Subgroup analysis showed overall higher incidences of irAEs in melanoma (Gr1-5: 54.6%, Gr1-2: 23.2%, Gr3-5: 26.4%) than those in lung cancer (Gr1-5: 39.7%, Gr1-2: 27.4%, Gr3-5: 14.0%) and solid tumors (Gr1-5: 36.7%, Gr1-2: 22.8%, Gr3-5: 20.1%). The same type of irAEs recurred in 23.8% (95% CI: 20.1-28.0) of patients, while new types of irAEs developed in 29.3% (95% CI: 25.2-33.7) of patients undergoing ICI rechallenge. The overall ORR was 45.2% (95% CI: 34.5-56.4), with cancer type-specific ORRs of 60.5% (95% CI: 47.9-71.9) in melanoma, 39.1% (95% CI: 17.4-66.2) in lung cancer, and 39.5% (95% CI: 27.7-52.6) from studies investigating solid tumors. DCR was high across cancer types: 77.3% (95% CI: 67.7-84.7) overall, 68.2% (95% CI: 41.3-86.8) in melanoma, 91.2% (95% CI: 67.7-98.1) in lung cancer, and 72.5% (95% CI: 63.3-80.1) in solid tumors. Meta-regression analysis showed that commonly observed initial irAE types or grades of initial irAEs (Gr1-2 vs. Gr3-4) did not significantly impact ORR or DCR. **Conclusions:** ICI rechallenge after discontinuation due to irAEs demonstrates clinical activity but carries a substantial risk of both recurrent and new irAEs. These findings highlight the need for predictive biomarkers to optimize patient selection and maximize survival without compromising safety. Research Sponsor: None.

Overall survival after intravenous iron use in patients with cancer and iron deficiency: A propensity-matched real-world study. First Author: Haris Sohail, Charleston Area Medical Center, Charleston, WV

Background: Iron deficiency affects up to two-thirds of patients with cancer and frequently coexists with anemia, with the highest prevalence in pancreatic, colorectal, and lung cancers. Functional iron deficiency driven by cancer-related inflammation predominates. Although intravenous (IV) iron is recommended to improve hematologic outcomes and reduce transfusion requirements, its impact on survival remains uncertain. We evaluated the association between IV iron use and overall survival (OS) in patients with advanced solid tumors using large real-world data. **Methods:** We conducted a retrospective cohort study using a TriNetX, a federated electronic health record network. Adults with solid malignancies and laboratory-defined iron deficiency (TSAT $\leq$ 20% and ferritin $\leq$ 500 ng/mL) were identified and categorized by IV iron exposure. Cohorts were matched 1:1 using propensity score matching for demographics, comorbidities, cancer site, iron indices (ferritin, transferrin saturation), hemoglobin, and treatment-related variables. OS was assessed using Kaplan–Meier analysis (5-year cap) and Cox proportional hazards modeling. **Results:** After propensity matching, 4,802 patients receiving IV iron were compared with 4,751 patients who did not receive IV iron, with a good balance across baseline characteristics. In Kaplan–Meier analysis (capped at 5 years), median overall survival (OS) was 875 days in the IV iron group and 858 days in the no IV iron group, with similar 5-year survival probabilities (38.6% vs 37.5%) and no significant difference by log-rank testing (p=0.53). On multivariable Cox proportional hazards modeling, IV iron exposure was not independently associated with mortality (HR 1.04, 95% CI 0.996–1.094; p=0.075). Male sex (HR 1.09, p<0.0001) and increasing age (HR 1.013 per year, p<0.0001) were associated with higher mortality. Iron indices demonstrated strong prognostic associations, with low transferrin saturation (<10%: HR 1.48; 10–20%: HR 1.24; both p<0.0001) and anemia diagnoses including iron deficiency anemia (HR 1.05, p=0.0048) and anemia of chronic disease (HR 1.23, p<0.0001) independently associated with increased mortality, while lower ferritin levels were associated with improved survival (<100 ng/mL: HR 0.53; 100–200 ng/mL: HR 0.78; both p<0.0001). Cancer site was also independently associated with OS, with higher mortality observed in digestive, respiratory, urinary tract, and central nervous system malignancies, and improved survival in breast and thyroid/endocrine cancers. **Conclusions:** In this large propensity-matched real-world cohort, IV iron was not associated with worse overall survival in patients with cancer and iron deficiency, supporting its survival safety while highlighting iron indices, anemia, and cancer type as key prognostic markers. Impact of facility type and surgical management on survival outcomes in colon adenocarcinoma stratified by metastatic burden. First Author: Yazmin Reategui-Almonacid, Rutgers/Newark Beth Israel Medical Center, Newark, NJ

Background: Survival for colon cancer varies by facility type, yet the impact of granular metastatic burden and surgical intervention on this disparity remains poorly defined. We examined whether academic survival advantages persist after stratifying by disease extent and evaluated how surgical management contributes to these outcomes. **Methods:** Using the NCDB (2016–2023), we identified 438,590 adults with colon adenocarcinoma. We compared academic vs. community settings, quantifying metastatic burden by involved organ site count at diagnosis (liver, lung, bone, brain, lymph nodes, viscera; 0–6). Overall survival (OS) was the primary endpoint. Multivariable Cox models adjusted for age, Charlson–Deyo score, clinical stage, and site count. Sequential adjustment for primary tumor resection and metastatic-site surgery was performed to assess potential mediation. **Results:** Of 438,590 patients, 49.2% were treated at academic centers. Academic cohorts presented with more complex disease, including higher metastatic rates (22.4% vs 20.1%; p < 0.001) and frequent liver involvement (16.9% vs 15.1%; p < 0.001). In stage IV cases, metastatic-site surgery occurred more often at academic facilities (19.1% vs 14.0%). While primary resection rates were high in both cohorts, academic centers achieved superior R0 rates (95.0% vs 94.3%). Adjusted for age, comorbidity, and site count, academic care was associated with a survival benefit (HR 0.93; 95% CI 0.92–0.94). Primary tumor resection strongly predicted OS (HR 0.29; 95% CI 0.29–0.30). Adjusting for primary resection strengthened the academic effect (HR 0.91; 95% CI 0.90–0.92), indicating that surgical management partially mediates this advantage. Conversely, metastatic-site surgery was associated with higher mortality (HR 1.32; 95% CI 1.29–1.34) and did not explain the facility-based survival gap. **Conclusions:** The survival advantage at academic centers persists regardless of initial metastatic burden and is driven more by primary tumor surgical management than by metastatic-site interventions. These data suggest that improving community outcomes requires broader access to academic-level surgical standards and multidisciplinary care. Ensuring specialized surgical evaluation for high-burden patients is critical, regardless of their initial point of entry into the healthcare system. Research Sponsor: None.

Integrated tumor-informed and tumor-agnostic ctDNA molecular residual disease (MRD) assessment with imaging in early breast cancer. First Author: Tim Crook, Cromwell Hospital, London, United Kingdom

Background: Accurate ctDNA-based MRD detection in early breast cancer is limited by tumor heterogeneity, clonal evolution and methodological issues, limiting tumor-informed (TI) assays reliant on predefined variants. Tumor-agnostic (TA) approaches, while broader, are susceptible to false positives from clonal hematopoiesis and reduced sensitivity in low–tumor burden settings. **Methods:** We analyzed a single-center cohort of 74 female patients with stage I–III breast cancer undergoing post-treatment surveillance after completion of curative-intent therapy (surgery, radiation, and adjuvant systemic therapy as appropriate). Plasma samples collected post-treatment were analyzed using an integrated MRD assay combining TI ddPCR and TA NGS ctDNA detection strategies. CHIP filtering was incorporated to improve analytical robustness. MRD status was correlated with clinicopathologic features and contemporaneous imaging. MRD positivity was defined as detection by either TI or TA component. **Results:** At the time of ctDNA assessment, which was performed during standard post-treatment surveillance following completion of curative-intent therapy, 94.6% (70/74) of patients were imaging-negative. MRD was detected in 31.1% (23/74) of patients overall. All imaging-positive patients (4/4) were MRD-positive. Notably, among imaging-negative patients, 27.1% (19/70) were MRD-positive, indicating molecular residual disease not captured by conventional imaging. No imaging-positive cases were MRD-negative. MRD positivity was observed across all stages, including early-stage disease (I–II: 26%, 14/54), with the highest prevalence in stage III (47.4%, 9/19); one case had unknown staging. MRD was detected in 33.3% (18/54) of $HR^+/HER2^-$, 25% (2/8) of TNBC, and 25% (3/12) of $HER2^+$ tumors, demonstrating applicability across biological subtypes. Importantly, the hybrid approach increased detection sensitivity significantly. Among MRD-positive patients (n=23), 47.8% were detected exclusively by TA component, 43.5% by the TI component alone, and only 8.7% were detected by both. Reliance on a single MRD strategy would have failed to identify 91.3% (21/23) of MRD-positive cases, highlighting substantial biological complementarity between the two approaches. At early follow-up (median 113.5 days), MRD was detected in 23 patients, including 19 who were imaging-negative; among those with subsequent imaging-confirmed recurrence (n=4), the median MRD–imaging interval was 9.75 months. **Conclusions:** A hybrid TI and TA ctDNA MRD platform detects clinically occult molecular disease beyond imaging in stage I–III breast cancer. The complementary performance of TI and TA approaches substantially improves MRD detection and supports the use of hybrid MRD testing for early risk stratification and MRD-guided clinical trials. Research Sponsor: None.

Role of iron supplementation in the efficacy of immune checkpoint inhibitors (ICIs): A real-world propensity-matched analysis. First Author: Parth Sharma, Virginia Commonwealth University, Richmond, VA

Background: Iron plays a crucial role in the induction of ferroptosis mediated by immune checkpoint inhibitors (ICIs) in cancer. However, it plays a complex role in T-cell and macrophage function in the tumor immune microenvironment, which could influence anti-cancer immunity. Currently, the role of iron supplementation in affecting the therapeutic outcomes in patients receiving ICIs is unknown. **Methods:** A retrospective analysis utilizing TriNetX, a global federated health research network database, of patients receiving ICIs from January 2006 to January 2026, was conducted. Patients were divided into 3 cohorts based on whether they received intravenous (IV) iron (cohort A), oral (PO) iron (cohort B), or no iron supplementation (cohort C), 1 month prior to or up to 3 months after receiving ICIs. Propensity score matching (PSM) was used to balance the cohorts based on age, race, ethnicity, hemoglobin (Hb), ferritin, CRP, albumin, metastatic disease, line of treatment and underlying comorbidities. Kaplan-Meier analyses were used to analyze overall survival (OS). **Results:** A total of 4464, 5299, and 201,014 patients were identified across cohorts A, B and C, respectively. The most common primary sites of malignancies were the lung and/or bronchus, the gastrointestinal tract (and associated glands), and the urinary tract. Although IV iron recipients had better survival outcomes than PO iron recipients, both groups had worse outcomes than patients receiving no supplementation (Table 1). Similar trends were seen in subgroups receiving anti-PD1 and anti-PDL1. In the subgroup of patients with likely true iron deficiency (Hb$\leq$11g/dl and ferritin<100ng/ml) (*n*=508 after PSM), IV iron recipients had better outcomes than PO iron recipients (2Yr OS HR (95% CI): 0.822 (0.691,0.978) p=0.027). In the subgroup of patients having Hb$\leq$11g/dl and ferritin$\geq$300ng/ml, likely anemia of chronic disease (*n*=2483 after PSM), iron supplement recipients, whether IV or PO, had worse survival outcomes than patients receiving no supplementation (2Yr OS HR (95% CI): 1.22 (1.137,1.308) p<0.0001). **Conclusions:** Our study highlights the adverse impact of concurrent iron supplementation in patients receiving ICIs, especially in those without true iron deficiency. When clinically indicated, the IV route is preferred. Clinical studies are planned or ongoing to determine the role of iron supplementation in patients receiving ICIs, given its potential to induce ferroptosis. We suggest careful reconsideration or appropriate stratification of the cohort based on iron deficiency and/or type of iron supplementation in such studies. Research Sponsor: None.

2-year overall survival (OS).

Comparison groups	Number of patients after PSM	2-Year OS HR (95% CI) p-value (log-rank test)
IV Iron v/s PO Iron	2762	0.898 (0.83,0.97) p=0.006
IV Iron v/s No Iron	3808	1.199 (1.121,1.283) p<0.0001
PO Iron v/s No Iron	5210	1.405 (1.327,1.488) p<0.0001

Pan-cancer discovery of clinical and genomic determinants of immune-related adverse events. First Author: Ziad Bakouny, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Immune-related adverse events (irAEs) from immune checkpoint inhibitors (ICIs) can be lifelong, fatal, or require treatment discontinuation, substantially limiting the clinical benefit of immunotherapy. Despite their impact, predictors of irAE susceptibility remain poorly defined, largely due to the lack of scalable approaches for toxicity phenotyping. Here, we leverage large language models and integrated clinico-genomic data to identify determinants of irAEs. **Methods:** We developed a custom retrieval augmented generation and large language model (RAG-LLM) pipeline to automatically annotate 6 key adverse events (adrenal insufficiency, hepatotoxicity, hyperthyroidism, hypothyroidism, colitis, and pneumonitis) using free text from clinical notes across Memorial Sloan Kettering Cancer Center. We first validated RAG-LLM predictions using a gold standard prospectively collected adverse event dataset from 8,119 patients across 1,057 individual clinical trials. RAG-LLM imputations were then scaled to 55,406 (12,291 ICI-treated) patients. All patients had associated somatic and germline MSK-IMPACT panel sequencing data. Single nucleotide polymorphism (SNP) imputation was performed using GLIMPSE and time-to-event genome-wide association studies (GWAS) were performed using SPACox. HLA class I genotypes were imputed using HLA-HD. Random Survival Forest (RSF) models were trained to predict irAE occurrence. **Results:** The custom RAG-LLM pipeline had strong performance across all 6 irAEs (area under the ROC curve of 0.77-1.00). In the RAG-LLM imputed data, 799 (1.4%) patients had adrenal insufficiency, 2,803 colitis (5.1%), 7,130 hypothyroidism (12.9%), 448 hyperthyroidism (0.8%), 15,627 hepatotoxicity (28.2%), and 3,730 pneumonitis (6.7%). Among ICI-treated patients, pneumonitis (HR 1.4; 95% CI 1.1-1.8; $p < 0.01$) and hepatotoxicity (HR 1.4; 95% CI 1.2-1.6; $p < 0.01$) were associated with worse overall survival. The GWAS found two genome-wide significant hits that predicted adrenal insufficiency (rs115003145, HLA region) and hypothyroidism (rs7864322, *FOXE1* gene enhancer region) with $p < 5x10^{-8}$. Fine mapping of the HLA SNP showed that HLA-C*06:02 was specifically associated with increased risk of adrenal insufficiency in ICI-treated patients only (HR 1.6; 95% CI 1.2-2.2; $p < 0.01$). RSF model performance for irAE occurrence had F1 scores of 0.67-0.85. For pneumonitis, patients with the highest risk quartile by RSF model had 7.1% risk of pneumonitis at 1 year compared to 0.4% for the lowest risk quartile (HR 14.9; 95% CI 10.4-21.3; $p < 0.01$). **Conclusions:** We developed and validated a novel custom RAG-LLM pipeline that allows automatic annotation of irAEs using clinical notes. Using this pipeline, we identified novel biomarkers of ICI-related adrenal insufficiency and hypothyroidism. Finally, we developed predictive models for irAE prediction that can be used at the point of care. Estimating survival in advanced cancer: A prospective single-center study on the accuracy of oncologists' prognostic accuracy (Pre-Sur). First Author: Giulia Claire Giudice, AUSL/IRCCS di Reggio Emilia, Reggio Emilia, Italy

Background: The ability to estimate survival is a cornerstone of care for patients (pts) with advanced cancer, influencing therapeutic strategies, access to clinical trials, and timing of palliative care referral. Existing evidence on clinical prediction of survival (CPS) largely derives from end-of-life pts. The Pre-Sur study addresses this gap by evaluating oncologists' prognostic accuracy in pts with metastatic solid tumors starting first-line therapy and investigating discordance-related factors. **Methods:** Pre-Sur is a prospective, observational, monocentric study enrolling pts with advanced tumors prior to first-line therapy (hormonal therapy was excluded). During the baseline consultation, clinicians provided an estimated survival timeframe using categorical intervals (0-4 to >36 months). The primary endpoint was concordance between CPS and overall survival (OS). Survival estimates and outcomes were analyzed descriptively and through cross-tabulation. Secondary analyses explored factors potentially influencing accuracy, including ECOG-PS, age, comorbidities, and clinician characteristics, using Chi-square tests and multivariable models. **Results:** From October 2022 to December 2025, 183 pts were enrolled; 135 completed the required follow-up. 58% of pts were male and 49% were ≥75 years. Gastrointestinal (45%) and thoracic (35%) cancers were the most prevalent. Median CPS (mCPS) was 18.0 months (95%CI: 15.9–20.0), median OS (mOS) of 8.0 months (95% CI: 5.9–10.0). Prognostic estimates were accurate in 17% of cases, optimistic in two-thirds, and underestimated in less than one-quarter. No significant associations emerged for sex, tumor site, PS or target therapy use. mCPS were often more consistent with the mOS reported in randomized clinical trials (RCT); the observed real-world OS were inferior to that expected from RCT (Table 1). **Conclusions:** This study highlights the difficulty of predicting OS in pts with metastatic solid tumors. CPS may be influenced by expectations derived from RCT outcomes, which may not fully capture the complexity of real-world pts. Prognostic evaluation in clinical practice should integrate features such as age, PS, comorbidities, and disease burden, to improve prognostic accuracy and support informed decision-making. Research Sponsor: None.

Overall survival and clinical prediction of survival by disease sites.

Trends and disparities in mortality from malignant neoplasms of male genital organs in the United States, 1999–2023. First Author: Nikil Kumar, Liaquat University of Medical & Health Sciences, Jamshoro, Pakistan

Background: Genital malignant neoplasms remain an important cause of mortality among males living in the United States. Tumor progression and organ-specific compromise contribute to increased risk and disease severity. Although recent data show overall declines in mortality over time, disparities persist, highlighting the need to analyze and interpret trends across demographic and geographic factors. **Methods:** The mortality data from the CDC WONDER underlying cause of death files for men aged ≥25 years were used to analyze age-adjusted and crude mortality rates (AAMRs and CMRs) per 100,000 for male genital neoplasms (ICD-10 Codes: C60-C63.9), stratified by year, gender, race/ethnicity, place of death, and geography. Joinpoint regression was used to estimate average annual percent change (AAPC) and annual percent change (APC) with 95% confidence intervals (CIs). Statistical significance was defined as $p<0.05$. **Results:** From 1999 to 2023, a total of 765,516 deaths were reported among patients of male genital malignant neoplasms, with most occurring at the decedent's home. The overall AAMR decreased from 18.29 in 1999 to 12.51 in 2023 (AAPC: -1.55; 95% CI: -1.71 to -1.39; $p<0.001$), with the most significant decline observed between 1999–2013 (APC: -2.73; $p<0.001$). Men aged 65 years and older experienced the greatest annual decline (-2.50%; $p<0.001$), but had the highest CMR (63.84), whereas mortality among men aged 25–44 years increased notably between 2013–2023 (APC: 3.65; $p<0.001$). The highest AAMR was observed among non-Hispanic (NH) Blacks (26.98), while the lowest AAMR was noted among NH Asians (6.30). Geographic disparities were evident, with the West having the highest AAMR (14.48) and the Northeast having the lowest (13.02). Non-metropolitan areas showed a higher AAMR (14.94 vs 13.79) and a slightly steeper decline in mortality than non-metropolitan areas (AAPC: -1.81 vs -1.80). At the state level, the District of Columbia ranked the highest, placed in the top 90th percentile, between 1999 and 2023. **Conclusions:** Despite a significant decline in mortality related to malignant neoplasms of male genitals over the past two decades, disparities persist, especially among older men, NH Black individuals, those living in non-metropolitan areas, and the West region. This underscores the need for targeted prevention, early detection, and equitable integrated care. Research Sponsor: None.

Average annual percent change (AAPC) of age-adjusted mortality rates for male genital malignant neoplasms in the United States, 1999 to 2023.

Variable	Deaths	AAPC (95%CI)
Overall (Male)	765,516	-1.55 (-1.71 to -1.39)
Non-metropolitan areas	126,009	-1.80 (-2.05 to -1.55)
Metropolitan areas	537,718	-1.81 (-2.00 to -1.62)

Trends and disparities in mortality from malignant neoplasms of digestive system and renal failure in the United States, 1999-2023. First Author: Nandni Kumari, Isra University Hyderabad, Hyderabad, Pakistan

Background: Malignancies of the digestive system represent a substantial global health burden, often exacerbated by coexisting renal failure, which complicates therapeutic interventions and significantly elevates mortality risk. This study aims to analyze and interpret annual mortality trends and disparities among adults in the United States from 1999 to 2023, for various demographic and geographic factors. **Methods:** The mortality data from the CDC WONDER multiple cause of death files for adults aged ≥25 years were used to analyze age-adjusted and crude mortality rates (AAMRs and CMRs) per 1,000,000 through ICD 10 code: C15-C26 (digestive system malignant neoplasms) and ICD 10 code: N17-N19 (renal failure), stratified by year, gender, race/ethnicity, place of death and geography. Joinpoint regression was used to estimate average annual percent change (AAPC) and annual percent change (APC) with 95% confidence intervals (CIs). Statistical significance was defined as $p < 0.05$. **Results:** From 1999 to 2023, a total of 164,004 deaths were reported due to malignant neoplasms of the digestive system and renal failure, mostly occurring in medical facility inpatient settings. The overall AAMR increased from 27.58 in 1999 to 36.84 in 2023 (AAPC: 1.17; 95% CI: -0.01 to 2.36; $p = 0.05$), with an initial decline observed between 2011 and 2017 (APC: -4.91; $p < 0.001$), followed by a notable increase through 2023 (APC: 8.26; $p < 0.001$). Men are noted to have higher AAMR than women (42.40 vs 19.19). Adults aged 65 and above experienced the highest CMR (110.96), whereas adults aged 45–64 years exhibited the greatest annual increase (3.19%; $p < 0.001$). By race, the highest AAMR was among non-Hispanic (NH) Black individuals (53.41), and the lowest was among NH White individuals (25.73). Geographic disparities were evident, with the West region having the highest AAMR (31.80) and the Northeast region having the lowest AAMR (27.77). Non-metropolitan areas showed higher AAMR than metropolitan areas (29.42 vs 27.91). At the state level, the District of Columbia and South Dakota ranked highest, placed in the top 90th percentile during 1999–2020 and 2021–2023, respectively. **Conclusions:** Mortality related to malignant neoplasms of the digestive system and renal failure has increased over the past two decades, with disproportionate burden among older adults, men, NH Black individuals, those living in non-metropolitan areas, and the West region, underscoring the need for targeted prevention, early detection, and equitable, integrated care. Research Sponsor: None.

Average annual percent change (AAPC) of neoplasms of digestive system and renal failure related age-adjusted mortality rates in the United States, 1999 to 2023.

Variable	Deaths	AAPC (95%CI)
Overall	164,004	1.17 (-0.01 to 2.36)

Hospitalized oncology patients with diarrhea: Clinical outcomes and prognostic factors. First Author: Güner Akgüner, Etlik City Hospital Department of Medical Oncology, Ankara, Turkey

Background: Diarrhea is a frequent cause of hospitalization in oncology patients and may lead to substantial morbidity and mortality. However, data on short-term outcomes and prognostic factors in hospitalized cancer patients with diarrhea are limited. This study aimed to evaluate clinical outcomes and identify factors associated with poor prognosis in this population. **Methods:** Medical records of 6,349 oncology patients hospitalized over a 3-year period were retrospectively reviewed. A total of 163 adult patients hospitalized primarily for diarrhea were included; patients with immune checkpoint inhibitor–related diarrhea were excluded. Collected variables included demographic characteristics, disease stage, Eastern Cooperative Oncology Group (ECOG) performance status, febrile neutropenia at admission, systemic anticancer therapy, serum albumin level, and diarrhea grade. Primary outcomes were intensive care unit (ICU) admission and 30-day mortality. Logistic regression analysis was used to identify independent predictors of mortality. **Results:** Diarrhea accounted for 2.6% of all oncology-related hospitalizations, and 83.4% of patients had grade $\geq$3 diarrhea. ICU admission was more frequent in patients with ECOG $\geq$2 compared with those with ECOG $<$ 2 (42.4% vs 14.4%, $p < 0.001$) and in patients with grade $\geq$3 diarrhea (27.9% vs 7.4%, p = 0.024). The overall 30-day mortality rate was 16.0% and was higher in patients with ECOG $\geq$2 (39.0% vs 2.9%, $p < 0.001$), metastatic disease (23.5% vs 7.7%, p = 0.006), and grade $\geq$3 diarrhea (19.1% vs 0%, p = 0.009). Febrile neutropenia was not associated with ICU admission or mortality. In multivariable analysis, ECOG $\geq$2 (OR: 17.1, $p < 0.001$) and lower serum albumin level (OR: 0.42, p = 0.049) were independent predictors of 30-day mortality. Diarrhea grade was excluded from the multivariable model due to complete separation. **Conclusions:** Diarrhea in hospitalized oncology patients is associated with substantial ICU utilization and short-term mortality, independent of febrile neutropenia. Poor functional status and low serum albumin are key prognostic factors, highlighting that diarrhea should be regarded as a potentially life-threatening condition requiring early risk stratification and prompt supportive care. Research Sponsor: None.

11137 **Poster Session**

Beyond geography: The intersecting impact of rurality, race, and depression on breast cancer survival. First Author: Ilias Jerrar, The Medical University of South Carolina, Florence, SC

Background: Rural–urban disparities in breast cancer outcomes are well-documented, with rural populations typically experiencing worse survival due to limited access to screening and specialty care. However, the role of integrated healthcare systems in mitigating these disparities and the impact of psychosocial factors, such as depression, on survival remain underexplored. This study evaluated the survival outcomes of breast cancer patients treated within an integrated, academic health system, focusing on the intersecting effects of geographic residence, race, and antidepressant therapy. **Methods:** We conducted a retrospective cohort study of 6,788 female breast cancer patients diagnosed between 2014 and 2024 at MUSC-affiliated facilities in urban and rural South Carolina. Data on patient demographics, cancer stage, hormone receptor status, depression diagnosis, and antidepressant use were extracted from electronic medical records. We used Kaplan-Meier survival analysis with log-rank tests and multivariable Cox proportional hazards models to assess the association of geographic location, race, and antidepressant use with overall survival, while adjusting for clinical and demographic confounders. **Results:** Contrary to national trends, rural patients demonstrated superior overall survival compared to urban patients (5-year survival: 92.1% vs. 85.3%, $p < 0.001$). In a multivariable model, rural residence was an independent protective factor (HR = 0.72, 95% CI: 0.61–0.85, $p < 0.001$). Antidepressant treatment was also associated with significantly improved survival (HR = 0.78, 95% CI: 0.65–0.93, p = 0.006). This survival benefit was consistent across urban and rural subgroups. While African American race showed a borderline increased risk of mortality (HR = 1.18, 95% CI: 0.98–1.42, p = 0.081), the rural survival advantage was maintained within both African American and non-African American subgroups. Triple-negative breast cancer (TNBC) was an independent and significant predictor of mortality (HR = 1.34, 95% CI: 1.15–1.57, $p < 0.001$), and was more prevalent in the urban cohort. **Conclusions:** Our findings suggest that a coordinated, academic-affiliated care model can effectively address geographic barriers to care. The study also highlights the critical role of psychosocial health, demonstrating that antidepressant therapy is an independent predictor of improved survival, reinforcing the need for integrated mental health support in oncology. Furthermore, the higher prevalence of aggressive triple-negative breast cancer in the urban cohort, coupled with the potential for the urban facilities to receive more complicated referrals, may contribute to the observed urban survival disadvantage, underscoring the interplay of tumor biology and patient referral patterns within integrated systems. A risk stratification schema for patients with non–small cell lung cancer with multiple organ metastases. First Author: Gabriela Esnaola, Yale School of Medicine, New Haven, CT

Background: The majority of patients with non-small cell lung cancer (NSCLC) will have multiple organ sites of metastasis and poor overall survival (rwOS). Specific organ involvement influences patient outcomes, but the impact of overarching patterns of metastasis on rwOS and response to systemic therapy (ST) is poorly understood. Prior studies have been limited in their scale, availability of detailed data on sites of metastasis, and inclusion of patients receiving immunotherapy (IO) or targeted therapy (TT). We leveraged a large-scale, real-world database to characterize and assess the prognostic value of patterns of metastasis on rwOS and time to next therapy (rwTTNT) in patients with metastatic NSCLC receiving ST. **Methods:** This retrospective study utilized the Flatiron Health Research Database of patients with NSCLC treated with first-line (1L) ST (n = 327,044). Patient, tumor, and treatment variables were summarized descriptively and compared across patterns of metastasis. rwOS and rwTTNT from 1L start were estimated via Kaplan Meier method and compared with logrank test. Bernoulli mixture models were used to cluster patients by metastatic sites at 1L start. **Results:** Sites of disease were evaluated for 75,304 patients. Data from 5 metastatic sites revealed 6 clusters reflective of real-world patterns of metastasis: bone (n = 33,882), pleural (n = 12,123), liver (n = 6,133), brain (n = 11,441), adrenal avid (n = 6,975), and high metastatic burden (HMB, $\geq$3 sites with frequency $\geq$0.5, n = 4,750). While HMB (7.2 months median rwOS, 4.8 months median rwTTNT) and liver avid disease (9.4, 5.2 months) had poor outcomes as expected, we also found that bone (11.0, 5.9 months) and adrenal (11.8, 6.0 months) avid clusters had worse median rwOS and shorter rwTTNT compared to pleural (15.7, 7.6 months) and brain (15.3, 7.4 months, $p < 0.001$). Outcomes associated with a specific site of metastasis varied based on patient cluster assignment. Compared to the cluster equivalent (e.g., brain avid), individual metastatic site (e.g., brain) as a prognostic factor was associated with worse median rwOS by 1.0-2.9 months and shorter median rwTTNT by 0.1-0.9 months. Compared to individual sites and site-avid clusters, HMB more often had EGFR mutations (20.7% vs 13.6% overall). IO was associated with greater median rwOS over TT in the adrenal cluster (17.7 vs 15.6 months), and IO + CTX had better rwOS vs IO alone in pleural (15.7 vs 12.9 months) and liver clusters (10.7 vs 9.4 months, $p < 0.001$). **Conclusions:** The survival outcomes and treatment response associated with defined clusters of metastases are distinct from those associated with individual organ sites or widespread disease alone. A risk-stratification framework that uses "risk phenotypes" representative of real-world patterns of metastasis may have better prognostic and predictive significance in patients with multiple sites or higher burden of disease. Safety of glucagon-like peptide-1 receptor agonists in patients with breast cancer: A real-world multicenter cohort study. First Author: Cho Han Chiang, Northwell Health Cancer Institute, New Hyde Park, NY

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are increasingly prescribed for patients with breast cancer and coexisting type 2 diabetes mellitus (T2DM). While GLP-1RAs have demonstrated metabolic and cardiovascular benefits in the general population, data regarding their safety in patients with breast cancer remain limited. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, which aggregates de-identified electronic health record data from over 140 international healthcare organizations. Adult patients ($\geq$18 years) with breast cancer who received breast cancer–directed systemic therapy and antidiabetic medications were included. The exposed cohort comprised patients who received a GLP-1RA within 90 days of systemic therapy initiation, while the comparator cohort included patients who received non–GLP-1RA antidiabetic agents. To minimize confounding, 1:1 propensity score matching was performed using demographics, body mass index, hemoglobin A1c, metastatic disease, breast cancer-directed therapy, and comorbidities. Outcomes were evaluated over 12 months using Cox proportional hazards models. Primary safety outcomes included adverse events commonly associated with GLP-1RA use: pancreatitis, biliary disease, and gastrointestinal adverse events (gastroesophageal reflux disease [GERD], bowel obstruction, and nausea/vomiting). Secondary outcomes included all-cause mortality and major adverse cardiovascular events (MACE), defined as a composite of myocardial infarction, ischemic stroke, and cardiovascular death. **Results:** A total of 29,380 patients with breast cancer and T2DM were identified. After propensity score matching, 3,796 patients were included in each cohort. Over 12 months of follow-up, GLP-1RA use was not associated with an increased risk of pancreatitis compared with non–GLP-1RA use (hazard ratio [HR], 1.20; 95% confidence interval [CI], 0.53–2.71). No significant differences were observed in biliary disease (HR, 0.93; 95% CI, 0.60–1.45) or bowel obstruction (HR, 0.70; 95% CI, 0.40–1.23). GLP-1RA use was associated with higher risks of GERD (HR, 1.48; 95% CI, 1.14–1.92) and nausea/vomiting (HR, 1.59; 95% CI, 1.26–2.00). Importantly, GLP-1RA use was associated with a lower risk of MACE (HR, 0.76; 95% CI, 0.59–0.99) and all-cause mortality (HR, 0.51; 95% CI, 0.37–0.69). **Conclusions:** In this study, GLP-1RA use was not associated with increased risks of serious gastrointestinal or biliary adverse events among patients with breast cancer receiving systemic therapy. While nausea/vomiting and GERD were more frequent, GLP-1RA use was associated with significant reductions in major adverse cardiovascular events and all-cause mortality. Prospective studies are warranted to confirm long-term safety and oncologic outcomes. Research Sponsor: None.

The corticosteroid timing paradox in immune checkpoint inhibitor–treated solid tumors and its association with overall survival: A TriNetX retrospective cohort study. First Author: Nikhil Kumar Kotla, Trinity Health Oakland Hospital/Wayne State University School of Medicine, Pontiac, MI

Background: Systemic corticosteroids are frequently used in patients receiving immune checkpoint inhibitors (ICIs) for symptom control and management of immune-related adverse events (irAEs). However, corticosteroids may impair antitumor immunity, and the impact of timing of corticosteroid exposure relative to ICI initiation on survival outcomes remains incompletely defined. We evaluated the association between corticosteroid timing and overall survival (OS) in a large real-world cohort of ICI-treated solid tumor patients. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network, including adult patients (≥18 years) with solid tumors treated with ICIs. Patients were stratified based on systemic corticosteroid exposure into three groups: baseline use (−30 to 0 days before ICI initiation), early intercurrent use (1–56 days after ICI initiation), and late intercurrent use (57–180 days after ICI initiation). Patients without corticosteroid exposure served as controls. The primary outcome was overall survival (OS). Kaplan–Meier analysis and Cox proportional hazards models were used to estimate survival outcomes and hazard ratios (HRs) with 95% confidence intervals (CIs). **Results:** A total of 43,282 ICI-treated solid tumor patients were included. Baseline corticosteroid use was associated with significantly worse OS compared with no corticosteroid exposure (median OS 564 vs 900 days; HR 1.32, 95% CI 1.28–1.35; $p < 0.0001$). Similarly, early intercurrent corticosteroid use was associated with inferior OS (median OS 543 vs 907 days; HR 1.35, 95% CI 1.32–1.39; $p < 0.0001$). In contrast, late intercurrent corticosteroid use was not associated with a survival detriment compared with controls (median OS 617 vs 650 days; HR 0.99, 95% CI 0.97–1.02; $p = 0.60$). **Conclusions:** In this large real-world analysis, systemic corticosteroid exposure prior to or early during ICI therapy was associated with significantly worse overall survival, whereas corticosteroid use later during treatment did not adversely impact survival. These findings support a corticosteroid timing paradox, suggesting that early immunosuppression may impair ICI efficacy, while later corticosteroid use—often for irAE management—may be oncologically safe. Prospective studies are needed to further define optimal corticosteroid timing and indications in ICI-treated patients. Research Sponsor: None.

New-onset inflammatory bowel disease associated with immune checkpoint inhibitor therapy: A real-world multicenter analysis. First Author: Albert Ekow Orhin, Ascension Saint Agnes Hospital, Baltimore, MD

Background: Immune checkpoint inhibitors (ICIs) are increasingly used across a broad range of malignancies and are known to cause immune-mediated gastrointestinal toxicity. While acute colitis is a recognized adverse effect, the potential for ICIs to trigger de novo inflammatory bowel disease (IBD), a chronic immune-mediated condition with long-term treatment implications, has not been well studied, as ICIs enhance immune activation in ways that may also affect normal intestinal immune balance. With the expanding use of ICIs across cancer types and earlier lines of therapy, we examined the association between ICI exposure and the risk of developing incident IBD compared with chemotherapy. **Methods:** We conducted a retrospective cohort study using the TriNetX global federated research network, including adults (≥18 years) diagnosed with malignancy between 2020 and 2024. Patients with pre-existing Crohn's disease, ulcerative colitis, or prior IBD-directed biologic or targeted therapy were excluded. Two cohorts were defined: patients treated with PD-1/PD-L1 or CTLA-4 inhibitors and patients treated with chemotherapy without ICI exposure. Propensity score matching (1:1) was performed to balance demographics, cancer type, and comorbidities, yielding 63,190 patients per cohort. Outcomes assessed within 365 days included incident IBD diagnoses, initiation of first-line IBD therapies, and escalation to biologic or targeted IBD agents. Risk estimates, hazard ratios (HRs), and Kaplan–Meier analyses were performed. **Results:** After propensity score matching, baseline characteristics were well balanced between cohorts. The risk of developing incident IBD was significantly higher among ICI-treated patients compared with chemotherapy-treated patients (risk ratio [RR] 2.96, 95% CI 1.86–4.70). Time-to-event analysis demonstrated a significantly increased hazard of IBD following ICI exposure (HR 3.37, 95% CI 2.12–5.35; log-rank $p < 0.001$). Escalation to biologic or targeted IBD therapies was also more common in the ICI cohort (RR, 3.04; 95% CI, 1.90–4.87; HR, 3.46; 95% CI, 2.16–5.55). In contrast, initiation of first-line therapies (mesalamine or budesonide) did not differ significantly between groups (RR 0.97, 95% CI 0.93–1.01). **Conclusions:** Among cancer patients without pre-existing IBD, immune checkpoint inhibitor therapy was associated with a significantly increased risk of de novo IBD and a greater likelihood of requiring advanced IBD therapies compared with chemotherapy alone. These findings suggest that, in a subset of patients, immune checkpoint inhibition may be associated with the development of chronic intestinal immune disease, highlighting the need for increased awareness and longitudinal gastrointestinal monitoring as ICI use continues to expand. The impact of the COVID-19 pandemic on breast cancer stage at time of diagnosis at a major health system in New Jersey. First Author: Maureen Younan, Atlantic Health System - Morristown Medical Center, Morristown, NJ

Background: The COVID-19 pandemic led to strict social distancing protocols in all aspects of daily life creating barriers to healthcare access. This resulted in a decrease in cancer screening, including mammography, which in turn led to higher stage of breast cancer at the time of diagnosis. This is reflected in the current literature[1]. We completed a study at our institution to evaluate the impact of the COVID-19 pandemic on breast cancer screening and stage at diagnosis. **Methods:** We performed a retrospective chart review of patients aged 18 and older in a large New Jersey health system. IRB approval was obtained. Clinical and pathologic stage at time of breast cancer diagnosis as well as number of screening mammograms ordered and completed in the pre-COVID era (January 1, 2016 – December 31, 2019) and post-COVID era (January 1, 2020 – December 31, 2023) were evaluated. Chi-square hypothesis testing was used for data analysis. Of the 5613 patients identified, 4279 patients had clinical staging data documented. **Results:** Between 2016-2019, 80.1% of ordered screening mammograms were completed in our health system. As expected, the percentage of completed screening mammograms decreased to 63.7% during the peak of the COVID-19 pandemic from 2020-2021. However, this percentage further decreased to 61.8% between 2022-2023; p-value < 0.001 (Table 1). We also noted an increase in stage 0 and 1 breast cancers and a decline in stage 2-4 breast cancers during these time periods; p-value < 0.001. **Conclusions:** Our study demonstrates an expected decline in screening mammogram rates during the peak of the COVID-19 pandemic (2020-2021). This can be explained by the uncertainties around health care and social distancing recommendations. Despite participation in a national cancer screening campaign led by the American Cancer Society from May to December 2021, the completion rates of screening mammograms unfortunately continued to decline in the post-COVID years. Contrary to what has been reported, this study found that patients were diagnosed at an earlier stage in the post-COVID era. Our study demonstrates that completion rates of screening mammogram dropped during the COVID-19 pandemic and have not improved in the post-COVID times. We hypothesize that with longer-term studies an increase in late-stage breast cancers may be identified due to missed screening mammograms. 1. Pintican, Roxana et al. "COVID-19 pandemic resulted in more metastatic breast cancer cases at diagnosis." *Scientific reports* 15,1 29296. 11 Aug. 2025, doi:10.1038/s41598-025-14582-z. Research Sponsor: None.

Number and percentage of mammography orders completed and canceled by year.

	Orders Completed	Orders Canceled	Total
2016 – 2019	157,507	39,054	196,561
	80.1%	19.9%	100%
2020 – 2021	99,571	56,766	156,337
	63.7%	36.3%	100%
2022 – 2023	129,722	80,330	210,052
	61.8%	38.2%	100%
Total	386,800	176,150	562,950
	68.7%	31.3%	100%

Clinical associations of cannabis use among patients receiving immune checkpoint inhibitors: A real-world analysis. First Author: Qiuchen Li, Case Western Reserve University School of Medicine, Cleveland, OH

Background: Cannabis use is common in patients with cancer, yet its clinical associations during immune checkpoint inhibitor (ICI) therapy is poorly defined. We evaluated the association between documented cannabis use and clinical outcomes among patients receiving ICIs. **Methods:** We conducted a retrospective cohort study of adults ≥18 years in the TriNetX US Collaborative Network with advanced or metastatic solid tumors treated with ICIs since January 1, 2019. Cannabis exposure was defined by diagnostic codes for cannabis-related disorders or prescriptions for cannabis-derived products documented 3 months prior to 2 years after ICI start. Patients who died in 60 days were excluded. Primary outcome was 3-year overall survival (OS); secondary outcomes included 2-year inpatient and emergency department (ED) visit, with joint sprain as a negative control outcome. Propensity matching adjusted for demographics, comorbidities, cancer type and stage, and tobacco and alcohol use. Hazard ratios (HR) and risk ratios (RR) with 95% confidence intervals (CI) and Kaplan–Meier analyses were calculated. **Results:** After matching, 3,634 patients were included in the OS cohort. Patients with no documented cannabis use had significantly higher 3-year OS and median survival versus cannabis users (HR 0.67; 95% CI 0.63-0.72; median OS 34.8 vs 18.7 months). This association was observed across all tumor subgroups except head and neck squamous cell carcinoma (HNSCC) (Table 1). Among 2,855 matched patients in the healthcare utilization cohort, patients without cannabis use had lower healthcare utilization within 2 years, including fewer ED visits (RR 0.83; 95% CI 0.79-0.87) and inpatient admissions (RR=0.82; 95% CI 0.79-0.84). These findings were consistent across subgroups except for ED visits in HNSCC (Table 1). Joint sprain showed no association with cannabis exposure (RR 0.93, 95% CI 0.64-1.35). **Conclusions:** Cannabis use during ICI therapy was associated with lower survival and higher healthcare utilization in multiple solid tumors. This may reflect unmeasured symptom burden or clinical vulnerability but also raises the hypothesis of a potential interaction between cannabis exposure and ICI therapy. Prospective studies incorporating symptom severity, dose, timing, and route of exposure are needed to clarify these relationships. Research Sponsor: None.

Clinical outcomes by cannabis exposure.

Group	Overall survival HR (95% CI)	OS p-value	ED Visit RR (95% CI)	ED p-value	Inpatient visit RR (95% CI)	Inpatient visit p-value

Relationship between immune-mediated adverse events and clinical outcomes in patients with metastatic melanoma treated with immune checkpoint inhibitors (ICIs): A retrospective real-world analysis. First Author: Leticia Escobar Vicentini, Hospital Beneficência Portuguesa de São Paulo, São Paulo, Brazil

Background: ICIs targeting programmed cell death protein 1 (PD-1) and cytotoxic T-lymphocyte–associated protein 4 (CTLA-4) revolutionized the treatment landscape for advanced melanoma. However, these agents can cause immune-related adverse events (AEs). Several studies have demonstrated a correlation between AEs and improved clinical outcomes. Understanding the co-occurrence patterns and prognostic implications of immune-related adverse events, as well as the impact of concomitant medications such as antibiotics (ATB), immunosuppressants (IS) and/or corticosteroids (CS), and proton pump inhibitors (PPIs), is crucial for immunotherapy management. In this study, we evaluated the relationship between immune-related toxicity, the use of IS and/or CS and ATB, and progression-free survival (PFS) and overall survival (OS) in patients with advanced melanoma treated with ICIs. **Methods:** Retrospective, analytical, multicenter study of patients (pts) with stage IV melanoma treated with ICIs (ipilimumab/nivolumab, nivolumab or pembrolizumab), between 2014 and 2025. Immune-related adverse events were graded according to CTCAE criteria and categorized as none, grade 1-2 or 3-4, demographic characteristics, use of IS and/or CS, ATB and number of toxicities were obtained from medical records. PFS and OS were estimated using the Kaplan-Meier method and compared using Cox proportional hazards models, with statistical significance set at $p < 0.05$. **Results:** Among 364 pts included, 275 (77,4%) experienced AEs. Dermatologic end endocrine toxicities, including rash, pruritus, vitiligo, hypothyroidism and hypophysitis were associated with improved survival outcomes. The results regarding PFS in relation to the presence, grade, and number of toxicities, as well as the use of IS and/or CS and ATB, are described in the table below. OS showed a statistically significant association with toxicity grade, with better OS observed among patients with grade 1–2 toxicity (HR 0.55; 95% CI, 0.35-0.87; P = 0.010), as well as who did not use IS and/or CS (HR 1.84; 95% CI, 1.20-2.82; P = 0,005). PFS showed a trend toward improved outcomes in patients who did not use PPI, without statistical significance due to the small number of pts. **Conclusions:** Our data show that pts who developed grade 1–2 toxicity and did not receive IS and/or CS experienced improved OS and PFS when treated with ICIs. Pts with a greater number of different toxicities and those who did not use ATB experienced better PFS. Research Sponsor: None.

Parameter	HR for PFS	95% CI	p-value
Toxicity vs. No Toxicity	0.39	0.29-0.52	<0.001
Degree of toxicity			
0 vs. Grade 1+2	0.38	0.28-0.51	<0.001
0 vs. Grade 3+4	0.50	0.35-0.73	<0.001

Real-world outcomes with atezolizumab versus durvalumab plus chemotherapy for extensive-stage small cell lung cancer: A TriNetX propensity-matched analysis. First Author: Kevin Zhu, University of Vermont Medical Center, Burlington, VT

Background: First-line treatment for extensive-stage small cell lung cancer (ES-SCLC) consists of platinum-etoposide plus an immune checkpoint inhibitor (ICI), either atezolizumab or durvalumab. No head-to-head randomized trials have compared these regimens. We evaluated real-world outcomes associated with these ICIs using a large multi-institutional database. **Methods:** We performed a retrospective cohort study using the TriNetX Global Collaborative Network. Adults with ES-SCLC treated with platinum-etoposide plus atezolizumab or durvalumab were included. The index date was initiation of platinum, etoposide, and ICI therapy. Cohorts were matched 1:1 using propensity scores based on age, sex, race, tobacco use, and comorbidities. The primary outcomes were overall survival (OS) and real-world progression-free survival (rwPFS), defined as time to second-line therapy or death. Survival was analyzed using the Kaplan-Meier method and cox proportional hazards models. Secondary endpoints were immune-related adverse events (irAEs) and hospitalization rates and evaluated by z-test. The study protocol was created and reviewed by the authors prior to implementation and did not require IRB approval. **Results:** Among 750 eligible patients (677 atezolizumab, 73 durvalumab), 69 matched pairs were identified. Median follow-up was 13.4 months for atezolizumab and 8.6 months for durvalumab. Median OS was significantly longer with durvalumab compared with atezolizumab (23.2 vs 9.1 months; Hazard Ratio [HR] 0.58, 95% CI 0.47–0.93; p=0.021). No significant difference in rwPFS was observed (8.6 vs 6.7 months; HR 0.72, 95% CI 0.47–1.11; p=0.14) as shown in Table 1. Atezolizumab was associated with higher rates of hematologic adverse events (35 vs 22 events; p=0.025) and a trend toward increased hospitalizations (34 vs 24; p=0.085). No significant differences were observed in other irAE categories. **Conclusions:** This retrospective real-world analysis found that durvalumab-based first-line therapy was associated with longer OS compared to atezolizumab in patients with ES-SCLC, although no significant difference in rwPFS was observed. Interpretation is limited by shorter follow-up duration in the durvalumab cohort, which may contribute to observed survival differences. Due to the observational study design, potential residual confounding, and limited sample size, these results should be regarded as hypothesis-generating. These findings underscore the need for additional comparative effectiveness research to clarify optimal immunotherapy selection in ES-SCLC. Research Sponsor: None.

Outcomes in propensity-matched cohort.

Outcomes	Atezolizumab	Durvalumab	Effect Estimate
Patients (n)	69	69	
Median OS (months)	9.1	23.2	HR 0.58 (95% CI 0.47–0.93)
Median rwPFS (months)	6.7	8.6	HR 0.72 (95% CI 0.47–1.11)

11146 Poster Session

Sinonasal adverse events of immune checkpoint inhibitors: Pharmacovigilance using FAERS. First Author: Kevin Zhu, University of Vermont Medical Center, Burlington, VT

Background: Immune checkpoint inhibitors (ICIs) are cancer therapies with diverse toxicities, known as immune-related adverse events (irAEs). Sinonasal irAEs have been described primarily in case reports, and their population-level characteristics remain poorly defined. To date, no statistical analysis of the FDA Adverse Events Reporting System Database (FAERS) has evaluated sinonasal adverse events (snAEs) associated with ICIs. **Methods:** We investigated snAEs associated with FDA-approved ICIs in FAERS between 1/1/2011 and 10/1/2025. ICIs were grouped by therapeutic target (PD-1, PD-L1, or CTLA-4). Analyses were conducted in R using Bioconductor package "faers". Data were standardized using preferred term in the Medical Dictionary for Regulatory Activities and deduplicated based on concordance across drug, adverse event, and demographics. Disproportionality analysis used reporting odds ratio (RORs) in comparison with the overall FAERS database. We excluded adverse events with <2 reports. The study was created and reviewed by the authors prior to implementation. **Results:** 17 million FAERS reports were identified, of which 2,476 ICI-associated reports included snAEs. Two rare events demonstrated significant disproportionality among PD-1 inhibitors: chronic eosinophilic rhinosinusitis (n=3; ROR 7.71, 95% CI 2.34–25.42) and nasal mucosal hypertrophy (n=2; ROR 8.67, 95% CI 1.99 - 37.73). In contrast, more frequently reported snAEs including sinusitis, rhinorrhea, nasal congestion, anosmia, nasal polyps, paranasal sinus inflammation, parosmia, and rhinitis, were not overreported (Overall $ROR_{2.5} \leq 1$). **Conclusions:** In this large pharmacovigilance analysis snAEs were not broadly overreported after ICI therapy. Rare inflammatory phenotypes were disproportionately reported with PD-1 inhibition, suggesting an immune-mediated mechanism. Given the limitations of spontaneous reporting data and small event counts, these findings should be interpreted cautiously but highlight the need for increased clinical awareness and prospective studies to better characterize sinonasal immune-related toxicities. Research Sponsor: None.

National trends in opioid-related hospitalizations among adult cancer patients: 2000-2022. First Author: Yongmei Huang, Department of Obstetrics and Gynecology, Columbia University College of Physicians and Surgeons, New York, NY

Background: Opioid use disorder is increasingly prevalent among cancer patients. Since mid-2010s, heightened attention to the opioid crisis has led to restrictive opioid prescribing policies; however, national trends in opioid-related hospitalizations (ORH) among cancer patients following these policies remain underreported. This study examines ORH trends from 2000 to 2022 and associated factors among adult cancer patients. **Methods:** We identified hospitalizations among adult patients (age ≥18 years) with any cancer in the National Inpatient Sample (2000-2022). Outcomes included: 1) primary ORH (PORH), defined as admissions with a primary diagnosis indicating opioid poisoning, dependence or abuse, and 2) any ORH (AORH), capturing these conditions in any diagnostic field. The risks of PORH and AORH were calculated as the number of cases per 10,000 hospitalizations, respectively. Join-point regression assessed trends in risks of PORH and AORH, reporting annual percentage changes (APCs). Multivariable logistic regression identified factors associated with PORH and AORH, with adjusted odds ratio (aORs) reported. **Results:** Overall, among 59,682,271 weighted hospitalizations in cancer patients (median age 66.8 years, IQR 56.5-76.3), PORH occurred in 5.5 per 10,000 hospitalizations (n = 32,641) and AORH in 200 per 10,000 hospitalizations (n = 1,192,358). The risk of PORH increased non-significantly from 2.2 per 10,000 hospitalizations in 2000 to 4.8 in 2014 (APC = 5.6, $p > 0.05$), then rose sharply to 10.6 in 2017 (APC = 25.1, $p < .001$), before declining significantly to 6.8 in 2022 (APC = -9.7, $p < .001$). The risk of AORH also increased non-significantly from 45 per 10,000 hospitalizations in 2000 to 60.8 in 2014 (APC = 0.2, $p > 0.05$), then rose to 594.4 in 2019 (APC = 118.2 for 2013-2016 and 11.7 for 2016-2019; both $p < .001$), before decreasing non-significantly to 476.8 in 2022 (APC = -7.8, $p > .05$). Higher PORH risk was associated with younger age (< 65 vs. ≥ 65: aOR = 2.53, $p < .001$), race and ethnicity (Native American: aOR = 2.07, Black: aOR = 1.85, White: aOR = 1.79, relative to Asian/Pacific Islanders; all $p < .001$), public or no health insurance, lower income, co-occurring substance use disorders (SUD) (e.g., sedative aOR = 35.19, cocaine aOR = 3.57, both $p < .001$), depression (aOR = 2.46, $p < .001$), anxiety, chronic pain, metastases, and care in small, non-teaching, rural hospitals and the West region. Similarly, AORH were associated with younger age, race and ethnicity, insurance, low income, co-occurring SUD, mental health condition, chronic pain, metastases, comorbidity burden, and the West region. **Conclusions:** Opioid-related hospitalizations decreased substantially in recent years following heightened attention and clinical/policy efforts in the mid-2010s. Elevated risks were primarily associated with patient demographics, co-occurring substance use disorder, mental health conditions, and chronic pain. Long-term incidence of hypothyroidism and thyroiditis after CAR T-cell therapy versus standard chemotherapy in hematologic malignancies: A propensity-matched multi-institutional cohort study. First Author: Taha Hassan, Texas Tech Health Sciences Center, Amarillo, TX

Background: Thyroid dysfunction is a common endocrine immune-related adverse event with modern cancer immunotherapies. Chimeric antigen receptor T-cell (CAR T) therapy is an adoptive cellular immunotherapy with expanding use in relapsed/refractory hematologic malignancies; its toxicity profile of cytokine release syndrome and immune effector cell–associated neurotoxicity syndrome are well described, whereas endocrine sequelae are comparatively less characterized. Large-scale population analysis regarding the effect of CAR T therapy on thyroid function remains limited. As CAR T survivorship increases and indications broaden, defining long-term thyroid-related outcomes is essential in optimizing care. **Methods:** We performed a propensity-matched cohort study using the TriNetX Research Network (Jan 1, 2018–Jan 24, 2026). Adult, non-pregnant patients with DLBCL, PMBCL, follicular lymphoma, mantle cell lymphoma, multiple myeloma, or ALL were included. Patients receiving CAR T in addition to chemotherapy were compared with chemotherapy alone. Exclusions included prior thyroid disease/malignancy, central endocrine disorders, radiation therapy, bone marrow transplant, and baseline exposure to thyroid-active/thyroid-disrupting therapies (e.g., amiodarone, immune checkpoint inhibitors, tyrosine kinase inhibitors, interferons, immunomodulatory agents like lenalidomide). Propensity score matching balanced age, sex, race, malignancy type, baseline comorbidities, steroid exposure, and antipsychotic exposure. The primary outcome was new-onset hypothyroidism or thyroiditis; effect estimates are reported as ORs with 95% CIs. **Results:** Before propensity-score matching, there were 921 patients in the CAR T group and 24,426 in the chemo-only group. Post-matching, there were 878 CAR T patients and 879 chemo-only patients. Hypothyroidism or thyroiditis occurred in 16 patients in the CAR T group (1.822%) and in 21 patients in the chemo-only group (2.389%). Absolute risk difference was −0.567% (95% CI -1.909%, 0.776%; p = 0.4081) and the OR was 0.758 (95% CI 0.393, 1.463). No statistically significant difference in incidence was observed. Mean follow-up for CAR T after chemo and chemo-only groups were 670 and 964 days, respectively. **Conclusions:** In this large, multi-institutional propensity-matched real-world analysis with long-term follow-up, CAR T therapy after chemotherapy was not associated with increased incidence of hypothyroidism/thyroiditis compared with chemotherapy alone. These findings provide reassuring thyroid safety data, supporting the expanding use of CAR T as indications broaden. Future studies should evaluate thyroid outcomes by CAR T construct/target and characterize timing and severity to inform monitoring strategies. Research Sponsor: None.

Risk of renal adverse events (RE-AE) and electrolyte changes with immunotherapy (IT) in a real-world cohort. First Author: Ameed Bawwab, Cleveland Clinic Foundation, Cleveland, OH

Background: IT is used across multiple tumor types but is linked to immune-related AE (irAE), including RE-AEs. Acute kidney injury (AKI) is the most common renal irAE (1–2%); however, real-world comparative data on RE-AE & electrolyte trends across tumor types remain limited. We evaluated RE-AE incidence & longitudinal electrolyte & urine trends following IT. **Methods:** We conducted a retrospective cohort study of 5,556 adult cancer patients treated at Cleveland Clinic Ohio between 2010–2022. Included cancers were advanced-stage (III–IV) bladder, endometrial, esophageal, gastric, head & neck, renal, & lung cancers (NSCLC/SCLC), & metastatic melanoma. We compared IT (± chemo/radiation) vs non-IT regimens. Follow-up began at systemic therapy initiation & continued until RE-AE, death, or last encounter. Outcomes included AKI, AKI progressing to chronic kidney disease (CKD), & clinically significant proteinuria. Poisson regression estimated incidence rates, Kaplan–Meier methods cumulative incidence (CIR), & time-dependent Cox models assessed risk with IT as a time-varying exposure. Longitudinal serum electrolytes & urine parameters were extracted electronically & analyzed via mixed-effects & generalized linear models over a one-year post-initiation period. **Results:** Among the cohort, 1,291 (23%) received first-line IT & 4,265 (77%) later-line IT. Median age was 66 years; 38% were female. During median follow-up of 14 months (CI 6-34), 195 RE-AEs occurred (IT: 46; non-IT: 149). The incidence rates per 100 person years were 0.18 (0.13, 0.24) in IT group & 0.13 (0.11, 0.15) in non-IT group. 2-year CIR was 4.6% with IT & 3.9% without IT (P = 0.6). Adjusted time-dependent Cox models demonstrated no significantly increased risk for AKI, CKD, or composite RE-AEs associated with IT exposure: [AKI HR 0.99 (0.7–1.5); CKD HR 1.5 (0.97–2.4); RE-AE HR 1.3 (0.9–1.7)]. Most RE-AEs were CTCAE grade II–III. Immunomodulatory therapy was used in 15%, primarily steroids, with a 50% response rate. Longitudinal analyses showed IT was associated with higher mean CO_2 & calcium compared with non-IT ($P < 0.05$), but not other labs (Table 1). While on therapy, IT was associated with lower urine pH (β = -0.37, CI -0.69 -0.04) but no other UA parameter changes were noted. **Conclusions:** In this large real-world cohort, IT was not associated with an increased incidence of RE-AE compared with non-IT therapy, suggesting that stringent trial exclusion criteria for baseline renal impairment may be unnecessarily restrictive. IT was associated with statistically significant changes in calcium, CO_2, & urine pH, the clinical significance of which remains uncertain. Research Sponsor: None.

Immune checkpoint inhibitors and respiratory outcomes in cancer patients with pre-existing asthma: A TriNetX propensity-matched cohort study. First Author: Murad Alkharabsheh, Crestwood Medical Center, Huntsville, AL

Background: Immune checkpoint inhibitors (ICIs) are associated with immune-related pulmonary toxicity. Real-world data on outcomes in patients with pre-existing asthma across malignancies remain limited. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network (170 HCOs). Adults (≥18 years) with asthma (ICD-10 J45) and malignancy (ICD-10 C00–C96) were identified. The ICI cohort included patients receiving ICIs (HCPCS J9271, J9299, J9119, J9272, J9345, J9022, J9173, J9023, J9228, J9347) after cancer diagnosis (first ICI within 3 years of first malignancy). The comparator cohort included patients receiving non-ICI systemic therapy (TNX:1002 chemotherapy, TNX:1003 targeted therapy, TNX:1004 hormone therapy, and/or Z51.11) and excluded ICI exposure. Outcomes were assessed from day 1 through day 1095 after index. Propensity score matching (1:1) was performed (final N = 4,074 per cohort). **Results:** In the matched cohorts (N = 4,074 each), ICI exposure was associated with higher risks of inpatient admissions (41.65% vs 32.78%; RR 1.27; HR 1.22), all-cause mortality (47.62% vs 38.76%; RR 1.23; HR 1.44), respiratory failure (J96) (25.01% vs 15.13%; RR 1.65; HR 1.66), and drug-induced interstitial lung disorders (1.91% vs 0.87%; RR 2.20; HR 4.26). ICI exposure was also associated with increased risk of mechanical ventilation (4.00% vs 2.93%; RR 1.36; HR 1.45), emergency intubation (2.55% vs 2.00%; RR 1.27; HR 1.32), and ED visits (38.98% vs 31.56%; RR 1.24; HR 1.74). Asthma exacerbation (J45.901) showed a modest increase in risk (RR 1.23), with survival analysis not reaching statistical significance (HR 1.15; p = 0.078). **Conclusions:** Among adults with asthma and cancer, ICI exposure was associated with increased risks of hospitalization, respiratory failure, drug-induced interstitial lung disorders, and mortality compared with non-ICI systemic therapy. These findings support close pulmonary monitoring and risk mitigation when initiating ICIs in patients with asthma. Research Sponsor: None.

Real-world data on clinical profile of immune-related adverse events (irAEs) associated with immune checkpoint inhibitors (ICIs) in oncology. First Author: Shruti Prem Sudha, Bahrain Oncology Center, Muharraq, Bahrain

Background: Immune checkpoint inhibitors (ICIs) are widely used in cancer, and are associated with immune-related adverse events (irAEs) in many organs. Real-world data on the spectrum, timing, severity, and outcomes of irAEs is limited. In this study, we aimed to gather real world data on the immune toxicity of ICIs. **Methods:** We conducted a retrospective cohort study on adult oncology patients on ICI therapy between Jan 2018-Dec 2024. IrAEs were categorized by organ system, time to onset (early < 12 weeks, intermediate 12-24 weeks, and late > 24 weeks), and severity (standard toxicity criteria CTCAEv6.0). Management strategies, therapy discontinuations, hospitalizations, and survival were assessed. **Results:** We screened 652 patients who received ICIs across different cancer types -169 (26%) were identified with irAEs. Sixty-four percent patients had received ICI alone, and the remainder had received ICIs in combination with other agents. The most common organ affected was thyroid (43%), followed by skin (28.4%), and lung (11.8%), more than one organ was affected in 22.5% patients. IrAEs occurred across a broad time frame following treatment- cumulative incidence before 12 weeks was 41.4%, between 12-24 weeks was 44.4%, and beyond 24 weeks was 91.3%. Musculoskeletal, hepatic, pulmonary, gastrointestinal, dermatologic, and pancreatic irAEs generally presented early, with median onset around 10–14 weeks. Renal, ophthalmologic, infusional, and dermatologic irAEs generally occurred across early, and intermediate time frames, while neurological irAEs tended to occur late. Endocrine irAEs, had a median onset of 20.1 weeks, and frequently occurred beyond 24 weeks. Hepatitis, pneumonitis, colitis, CNS and pancreatic toxicity were among the more severe irAEs, with a median CTCAE grade of 3, while renal, endocrine, ophthalmologic, infusional, and dermatologic irAEs were generally of lower severity (grade 1 or 2). IrAE grade > 2 was associated with increased risk of death (HR 2.7, 95% CI 1.1-6.5). Management of irAEs comprised supportive care alone (62%), systemic corticosteroids (31%), or observation alone (8%). Patients with higher grades of irAEs were more likely to receive steroids. Hospitalization was required in 29%, and ICIs were permanently discontinued in 25%. Complete resolution of irAEs was seen in 40%, 5% died attributable to the irAE, and the remainder had partial resolution of irAE with need for continued replacement therapy (as with endocrine irAEs). **Conclusions:** In our real-world practice, oncology patients receiving ICIs had irAEs across a broad range of organ systems, with heterogeneous timing and severity. Several clinically meaningful toxicities presented late in the treatment course, underscoring the importance of long-term monitoring. Occurrence of grade 2 or higher iRAEs was associated with higher mortality. Research Sponsor: None.

Association of β-blocker selectivity with survival and immune-related outcomes in melanoma and lung cancer patients treated with immune checkpoint inhibitors. First Author: Leen Alkuttob, School of Medicine, University of Jordan, Amman, Jordan

Background: Immune checkpoint inhibitors (ICIs) are standard of care for advanced melanoma and lung cancer. Retrospective studies suggest that non-selective β-blocker use correlates with improved overall survival, potentially through modulation of the tumor immune microenvironment. However, real-world evidence comparing the effect of selective versus non-selective beta-blockers remains limited. **Methods:** We conducted a multicenter retrospective study using the TriNetX Global Collaborative Network. Adult patients (≥18 years) with melanoma or lung cancer treated with immune checkpoint inhibitors (pembrolizumab, nivolumab, ipilimumab, atezolizumab, durvalumab, cemiplimab, or avelumab) were identified. Patients were categorized based on exposure to non-selective β-blockers (carvedilol, propranolol, nadolol, labetalol, timolol) or selective β-blockers (metoprolol, atenolol, bisoprolol, nebivolol, acebutolol) within two months before or at ICI initiation. The index date was first ICI exposure. One-to-one propensity score matching was performed using covariates selected based on baseline imbalance, including demographics, cardiovascular and cerebrovascular comorbidities, and prior procedures. The primary outcome was overall survival. Secondary outcomes included hospitalization and immune-related adverse events (irAEs), defined using a composite endpoint of organ-specific immune-mediated toxicities based on prior published methodology. **Results:** After matching, 3,720 patients with melanoma and 11,160 patients with lung cancer were included in the analysis. Among melanoma patients treated with ICIs, non-selective β-blocker use was associated with lower mortality (HR 0.799; 95% CI 0.652–0.980) and decreased hospitalization (HR 0.865; 95% CI 0.759–0.984) compared with selective β-blockers. Most immune-related adverse events did not differ between groups, except for higher hepatic toxicity with non-selective β-blockers (HR 1.382; 95% CI 1.064–1.796). In lung cancer patients, non-selective β-blocker use was associated with lower mortality (HR 0.847; 95% CI 0.797–0.900), reduced ICU admission (HR 0.87; 95% CI 0.800–0.946), and decreased hospitalization (HR 0.912; 95% CI 0.864–0.963). Additionally, fewer cardiovascular (RR 0.811; 95% CI 0.711–0.925) and respiratory (RR 0.842; 95% CI 0.772–0.918) immune-related adverse events compared with selective β-blockers. **Conclusions:** In this real-world, propensity-matched analysis, non-selective β-blocker use was associated with improved early survival and reduced healthcare utilization among melanoma and lung cancer patients treated with ICIs. These findings suggest that non-selective β-blockers represent a low-cost and available adjunct to immunotherapy and warrants prospective validation. Research Sponsor: None.

Second-generation H1 antihistamine use with survival and immune-related outcomes in lung cancer and melanoma patients receiving immune checkpoint inhibitors. First Author: Leen Alkuttob, School of Medicine, University of Jordan, Amman, Jordan

Background: Immune checkpoint inhibitors (ICIs) are standard of care for melanoma and lung cancer but are associated with immune-related adverse events and variable outcomes. Previous studies suggest that H1 antihistamine use may be associated with improved outcomes, potentially through histamine-mediated modulation of the tumor microenvironment. However, real-world evidence is limited. **Methods:** We conducted a multicenter retrospective study using the TriNetX Global Collaborative Network. Adult patients (≥18 years) with melanoma or lung cancer receiving ICIs (pembrolizumab, nivolumab, ipilimumab, atezolizumab, durvalumab, cemiplimab, or avelumab) were identified. Patients were categorized by exposure to second-generation H1 antihistamines (cetirizine, loratadine, fexofenadine, desloratadine, or levocetirizine) within 3 months before or during ICI initiation. One-to-one propensity score matching was performed based on demographics, baseline comorbidities, cancer characteristics, prior treatments, and conditions commonly associated with antihistamine use, including allergic and atopic disorders. The index date was defined as first ICI exposure, and outcomes were assessed from day 1 to day 180. The primary outcome was overall survival. Secondary outcomes included hospitalization and immune-related adverse events (irAEs), defined using a composite endpoint of organ-specific immune-mediated toxicities based on prior published methodology. **Results:** After matching, 2,141 melanoma and 11,812 lung cancer patients were included. In lung cancer patients, H1 antihistamine use was associated with reduced all-cause mortality (HR 0.769, 95% CI 0.727–0.815), lower hospitalization rates (HR 0.862, 95% CI 0.821–0.906), fewer intensive care unit admissions (HR 0.867, 95% CI 0.797–0.943) and reduced emergency department use (HR 0.940, 95% CI 0.899–0.984). 6-month overall survival was 80.93% in antihistamine users vs 75.98% in non-users. It was also associated with decreased endocrine (HR 0.843, 95% CI 0.776–0.916), and musculoskeletal irAEs (HR 0.840, 95% CI 0.752–0.938). In patients with melanoma, H1 antihistamine use was associated with reduced all-cause mortality (HR 0.685, 95% CI 0.581–0.808), lower hospitalization rates (HR 0.837, 95% CI 0.734–0.955), and reduced neutropenia (HR 0.441, 95% CI 0.266–0.729). 6-month overall survival was 88.15% vs 83.20%, respectively. No statistically significant differences were observed across other major immune-related organ systems. **Conclusions:** Second-generation H1 antihistamine use was associated with improved early survival and reduced healthcare utilization among melanoma and lung cancer patients treated with ICIs, without a significant increase in irAEs. Despite the retrospective design and potential confounding, prospective validation is warranted. Research Sponsor: None.

Trends in ischemic stroke and ischemic heart disease-related mortality among patients with malignancies in the United States: A 25-year CDC-WONDER analysis (1999-2023). First Author: Muhammad Saad, Liaquat University of Medical and Health Sciences, Jamshoro, Pakistan

Background: Substantial advances in cancer screening, diagnostics, and therapeutic strategies have improved survival and quality of life. Despite these efforts, cancer-related complications continue to contribute significantly to morbidity and mortality. Malignancies induce a prothrombotic state and substantially increase the risk of venous and arterial thromboembolism. As a result, the patients with cancer have a higher incidence of Ischemic stroke (IS) and ischemic heart disease (IHD) compared to the general population. The greatest risk of these thromboembolic diseases is greatest during the first six months of cancer diagnosis, but remains elevated thereafter. In this study, we sought to assess temporal trends and sociodemographic differences in ischemic stroke and ischemic heart disease related mortality among patients with neoplasms. **Methods:** We analyzed deidentified CDC WONDER death certificate data to assess malignant neoplasm, (ICD = C00-C97) and ischemic heart disease (ICD = I20-I25) and ischemic stroke (ICD = I63) related mortality in patients of all ages. Age-adjusted mortality rates (AAMR) per 100,000 persons and average annual percent change (AAPC) were calculated and stratified by year, gender, state, urban-rural status, census region, place of death (POD), and age group. **Results:** From 1999 to 2023, 1235844 deaths were attributed to Ischemic stroke and ischemic heart disease-related deaths in cancer patients. Overall, AAMR decreased from 19.7 in 1999 to 12.9 in 2023 (APC -1.74*, 95% CI: -1.88 to -1.63). Males had higher mortality rates than females throughout the period (23.26 vs 8.88, respectively). Racial analysis showed that non-Hispanic whites had the highest mortality (AAMR: 15.064), followed by Blacks or African Americans (AAMR: 14.24); in contrast, Asians or pacific islanders had the lowest mortality (AAMR: 7.48, data available till 2020). The Midwest region had the highest mortality of all census regions (AAMR: 15.92). Lastly, non-metropolitan areas had higher mortality rates than metropolitan areas (AAMR of 15.75 vs 14.04, respectively). **Conclusions:** Overall mortality rates in cancer patients with co-morbid ischemic stroke and ischemic heart diseases declined from 1999 to 2023. However, higher mortality rates were observed among men, non-Hispanic Whites, residents of the Midwest, and those living in non-metropolitan areas of the U.S., underscoring the need for targeted public health efforts, and equitable access to cardio-oncology preventive care in these high-risk groups. Five-year survival disparities in two population-based cohorts of adults with early-onset colorectal cancer. First Author: Lauren P. Wallner, University of Michigan, Ann Arbor, MI

Background: Early-onset colorectal cancer (EO-CRC) is now the leading cause of cancer-related death in those under the age of 50 despite advances in treatment. However, the impact of specific sociodemographic and clinical factors on long-term survival remains poorly characterized. We evaluated 5-year survival patterns and risk factors across two diverse, population-based cohorts to optimize risk reduction strategies and survivorship care delivery. **Methods:** We constructed two cohorts of adults $<$ 50 years of age with newly diagnosed EO-CRC from 2015 to 2018 (stages I-III) and treated with curative-intent surgery. One cohort was derived from three SEER registries (Georgia, Los Angeles County, Kentucky; n = 2995) and one cohort was derived from the Veteran's Health Administration (VHA) (n = 295). Pathologic-confirmed recurrence was identified in the follow-up period 6 months to five years after curative-intent surgery via human review of electronic pathology reports. Five-year survival was estimated from the date of curative-intent surgery to five years post-surgery. Adjusted risk of CRC-specific mortality was estimated in both populations using multivariable proportional hazards regression, adjusting for key demographic and clinical characteristics. **Results:** The proportion of patients surviving 5 years was 86% in the SEER cohort and 92% in the VHA cohort. Overall, 14% experienced recurrence in SEER and 18% in VHA, and recurrence was strongly associated with reduced survival in both cohorts (both $p < 0.01$). Five-year survival varied by clinical stage and was higher in the VHA across all stages (SEER: 93% stage I, 87% stage II, and 76% stage III vs. VHA: 97% stage I, 93% stage II, and 88% stage III). Mortality risk varied by race/ethnicity in the SEER cohort only: Hispanic patients (adjusted HR 1.6, 95% CI: 1.1–2.2) and Black patients (adjusted HR 1.9, 95% CI: 1.5–2.5) had a greater risk of 5-year mortality vs. white patients. Age at diagnosis, sex, and living in a rural area were not significantly associated with mortality in either cohort. Rectal tumors (vs. colon) were associated with an increased risk of mortality in VHA (adjusted HR: 2.5, 95% CI: 1.0-6.4), but not in SEER. Lymphovascular invasion was associated with an increased risk of mortality in both cohorts. **Conclusions:** There are critical sociodemographic and clinical disparities in survival among adults with stage I-III EO-CRC. These distinct patterns observed between the two cohorts underscore the influence of varying population-level risk profiles. Tailoring survivorship care to identify and support these high-risk subgroups is essential to mitigate disparities and improve long-term outcomes in this growing patient population. Assessment of the role of rapid drug desensitization to treat cancer patient with infusion-related allergic reactions. First Author: Irene Palmieri, Oncology Department City Rimini Hospital, Rimini, Italy

Background: Rapid Drug Desensitization (RDD) as The Castells protocol is based on progressively increasing concentrations and infusion rates of the drug under close monitoring, inducing temporary drug tolerance. To assess the role of Rapid Drug Desensitization (RDD) to treat cancer patient with infusion-related allergic reactions (IRRs) we planned an observational trial in 2021. **Methods:** From 2021 to 2025 all patients experiencing IRRs at the Rimini Oncology Unit, after an allergological evaluation, were treated according to the Castells desensitization protocol. We analyzed the safety of this apporach as well as the treatment discontiunation rate. The IRR severity was classified (grade 1-3) using the Brown classification from 2004. **Results:** A total of 155 patients were treated with RDD. Among drugs administered using a desensitization protocol, drugs administered with the RDD were paclitaxel (38.06%), oxaliplatin (25.80%), docetaxel (14.10%), and carboplatin (12.9%), irinotecan (1.94%), etoposide (1.94%), liposomal doxorubicin (1.29%), trastuzumab (1.29%), atezolizumab (0.65%), cetuximab (0.65%), cyclophosphamide (0.65%), and cisplatin (0.65%). Grade 3 reactions occurred in 1.29% of patients during RDD, while grade 2 and grade 1 reactions were observed in 3.87% and 2.58%, respectively. No deaths associated with desensitization treatment occurred. The IRRs were managed with treatment interruption and administration of steroids and antihistamines. Notably, 3.22% of patients experienced an allergic reaction during RDD but were able to complete treatment. In total 132 patients completed the planned treatment (85.2%) using the RDD approach. Among those who discontinued, 7 patients (4.5%) stopped due to allergic reactions during the first desensitization cycle. The remaining treatment discontinuations were due to clinical deterioration, patient decision or transfer to another institution (1.9% each), progressive disease (3.9%), or other causes (0.7%). We summarized the characteristics in the table. **Conclusions:** The RDD protocol is safe and permits to maintain the original schedule in the most part of cancer patients that present a major allergic reaction during chemotherapy. Further trials are probably needed to better define the role of RDD and the drugs primarily candidate to the desensitization protocol. Research Sponsor: None.

	Number of patients	% of the total (155 patients)
Treatment completed	132	85.2%
Discontinuation for infusional reaction	7	4.5%
Discontinuation for clinical deterioration	3	1.9%
Discontinuation for patient decision	3	1.9%
Discontinuation for progressive disease	6	3.9%
Discontinuation for transfer to another institution	3	1.9%
Discontinuation for other causes	1	0.7%

Trends and racial disparities in pulmonary embolism–related mortality among older adults with neoplasms: A population-based retrospective study in the United States from 1999-2020. First Author: Chinenye Egwuonwu, PAR Piedmont, Athens, GA

Background: Pulmonary embolism (PE) remains a major cause of preventable mortality, particularly among older adults with cancer who face heightened thrombotic risk. Understanding temporal trends in PE-related deaths is essential for guiding prevention and early detection. This study evaluates national patterns and racial disparities in PE-related mortality among older adults with neoplasms. **Methods:** We performed a retrospective cross-sectional analysis of the national death certificate data from the CDC's WONDER database. We included persons ≥65 years of age with neoplasms (ICD-10 code C00-D48) as the underlying cause of death and PE (ICD-10 code I26) as a contributing cause of death. The exposure variable was the year of death, and the outcome was PE-related age-adjusted mortality rate (AAMR) stratified by sex, race, rural-urban status, and census region. We calculated the PE-related AAMR in neoplasm per 100,000 population. Trends were evaluated with Joinpoint regression and expressed as an average annual percentage change (AAPC) with a 95% confidence interval (CI). $P < 0.05$ defined statistical significance. **Results:** Of 928 million people, 104,743 PE-related deaths occurred in older adults with neoplasms (AAMR 11.4). The AAMR was higher in males (13.3 vs 10.1 in females; $P < 0.01$), Black (17.0 vs 11.2 in White, $P < 0.000001$), and the Midwest census region (12.3 vs 11.7 in NorthEast, the Midwest, and 10.4 in the South; $P < 0.0001$). The AAMR was similar in rural areas (11.4 vs 11.3 in urban areas, $P < 0.000001$). The overall PE-related AAMR in neoplasms increased from 8.7 to 14.1 (AAPC 4.03%; CI: 3.12- 5.23). Furthermore, the AAMR increased in males (AAPC 3.37%; CI: 1.61-6.6) and females (AAPC 4.53%; CI: 3.15-6.20). Similarly, it increased in Black (AAPC 3.14%; CI:2.42-4.07), White (AAPC 3.98%; CI:3.07-5.14), rural (AAPC 3.70%; CI: 2.69-5.39), urban (AAPC 4.24; CI: 3.44-5.23), and across all geographic census regions. **Conclusions:** Pulmonary embolism related mortality among older adults with neoplasms has risen steadily over the past two decades across all demographic and geographic groups. Given that cancer-associated thrombosis is a well-recognized and largely preventable complication, these findings suggest important gaps in the prevention, recognition, and management of PE in oncology populations at the health-system level. The consistent upward trend highlights an urgent need to strengthen thromboprophylaxis strategies, risk stratification, and early detection efforts in older adults with cancer to reduce avoidable mortality. Research Sponsor: None.

Safety of immune checkpoint inhibitors in solid tumor patients with hepatitis C: A real-world analysis. First Author: Muhammad Yousaf, Charleston Area Medical Center, Charleston, WV

Background: Patients with hepatitis C virus (HCV) infection are commonly excluded from immune checkpoint inhibitor (ICI) trials. We evaluated hepatotoxicity and outcomes after ICI therapy in patients with versus without HCV. **Methods:** Retrospective cohort study using the TriNetX Research Network (2014-2024). Adults with solid tumors initiating ICIs were classified as HCV if they had detectable HCV RNA and/or ICD-10 B18.2 (chronic viral hepatitis C) within 1 year prior to ICI start. Cohorts were 1:1 propensity-score matched on demographics, comorbidities, cancer type, metastatic site, and baseline liver tests. Outcomes from day 1–90 after ICI started were ALT ≥150 U/L, total bilirubin ≥3 mg/dL, diagnosis-coded hepatotoxicity, and diagnosis-coded hepatic failure. Overall survival (OS) was assessed for up to 5 years. A sensitivity analysis restricted HCV definition to lab-confirmed HCV RNA (no ICD-10 inclusion). **Results:** In the primary analysis, 1,157 HCV and 109,309 non-HCV ICI-treated patients were identified; 1,137 patients remained per group after matching. Patients with Hep C had a higher risk of ALT ≥150 U/L, although this did not reach statistical significance (7% vs 5%; p = 0.066). There was no difference in the risk of bilirubin ≥3 mg/dL (5.0% vs 5.0%; p = 1.0). Diagnosis-coded hepatotoxicity was similar (1.8% vs 1.8%; p = 0.875), while diagnosis-coded hepatic failure was higher in the HCV cohort (4.7% vs 2.5%; p = 0.005). Median OS was 20.1 vs 17.2 months (p = 0.0595). In the RNA-only sensitivity analysis (308 matched patients), there was no significant difference in overall survival between patients with and without HCV prior to treatment (27% vs 32%; p = 0.7489). However, the risk of ALT ≥150 U/L was significantly higher in the HCV group (10% vs 5%; p = 0.0058). There was no significant difference in mean bilirubin values after treatment (p = 0.0636). **Conclusions:** Pre-existing HCV was associated with an increased risk of transaminitis in patients receiving immunotherapy, but there was no statistically significant difference in biliary toxicity or median overall survival. There is also an approximate two-fold increased risk of hepatic failure. These real-world data highlight the importance of closely monitoring for hepatotoxicity in patients receiving immunotherapy and support ICI use in patients with HCV. Research Sponsor: None.

Real-world resource use and cost in patients treated with originator or biosimilar rituximab in a large U.S. insurance claims database. First Author: Ruth Wangia Dixon, Carelon Research, Wilmington, DE

Background: Rituximab-pvvr, Rituximab-arrx, and Rituximab-abbs are monoclonal antibodies approved by the FDA as biosimilars to originator rituximab. All are approved for treatment of non-Hodgkin lymphoma (NHL) and chronic lymphocytic leukemia (CLL). Biosimilars are intended to deliver equal clinical outcomes to originators at a lower cost, but there remains limited 'real-world' investigation of these outcomes. This study describes and compares resource use and cost for patients receiving originator or biosimilar rituximab in the Carelon Research Healthcare Integrated Research Database (HIRD). **Methods:** We conducted a retrospective cohort study of adults with newly diagnosed NHL and CLL identified by ICD-10 codes between 1/1/2018 and 7/31/2024 in the Carelon Research HIRD and treated with rituximab. Included patients had ≥1 claim for originator or biosimilar rituximab after NHL or CLL diagnosis. Baseline demographics were assessed at rituximab initiation (*index date*). Inpatient, outpatient, and emergency department (ED) resource use and medication cost were assessed over one year following rituximab initiation. Costs were inflation-adjusted to 2024 USD. Originator and biosimilar rituximab groups were compared using t-test or ANOVA to assess mean differences in resource use and cost. **Results:** A total of 11,525 patients met inclusion criteria with mean age of 64.4 years, 57.2% male, and 76.9% reporting white non-Hispanic race/ethnicity. Most of the cohort (89.8%) were diagnosed with NHL. There were no significant differences in mean follow-up duration (p=0.960), rituximab infusions (p=0.987), treatment duration (p=0.106), inpatient hospitalizations (p=0.241), or ED visits between groups (p=0.702) (*see table*). Mean overall medication costs were significantly lower in all biosimilar groups vs. originator (p<0.001). **Conclusions:** In this large real-world cohort of NHL and CLL patients, resource use was similar in patients treated with originator and biosimilar rituximab, but medications costs were significantly lower in the biosimilar groups. Our findings demonstrate how biosimilar therapies in cancer can deliver similar clinical outcomes to originators, while generating meaningful cost savings for the U.S. healthcare system. Research Sponsor: Pfizer.

Mean 1-Year Outcomes	Originator Rituximab (n=7,123)	Biosimilar Rituximab-pvvr (n=1,846)	Other Rituximab Biosimilars (n=2,556)
Follow-Up Duration, Months (SD)	10.8 (2.7)	10.8 (2.7)	10.8 (2.7)
Count of Rituximab Infusions (SD)	5.7 (2.5)	5.7 (2.6)	5.7 (2.5)
Rituximab Treatment Duration, Months (SD)	4.2 (3.3)	4.1 (3.3)	4.1 (3.3)
Count of All-Cause Inpatient Stays (SD)	1.6 (3.1)	1.6 (3.2)	1.5 (2.9)
Count of All-Cause ED Visits	0.6 (1.4)	0.6 (1.3)	0.6 (1.2)
Medication & Related Costs (SD)*	$123,499 ($145,374)	$77,728 ($96,377)	$90,868 ($122,510)

*Includes all medications paid under medical benefit, including rituximab.

Impact of concomitant antibiotic exposure on overall survival in patients with esophagogastric cancer treated with immune checkpoint inhibitors: A real-world cohort study. First Author: Diptasree Mukherjee, Atrium Health Levine Cancer, Charlotte, NC

Background: Gut microbiota composition plays a critical role in mediating response to immune checkpoint inhibitors (ICIs). Antibiotic exposure has been associated with impaired ICI efficacy across tumor types; however, data specific to esophagogastric cancers remain limited. We evaluated the association between peritreatment antibiotic exposure and overall survival (OS) among patients with advanced esophagogastric cancer receiving ICIs in routine clinical practice. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. Adult patients with advanced or metastatic esophageal or gastric adenocarcinoma who received nivolumab- or pembrolizumab-based therapy between 2016 and 2024 were identified. Patients were categorized as antibiotic-exposed (receipt of systemic antibiotics within 60 days before or after ICI initiation) and non-exposed (no documented antibiotic exposure during the same period). Cohorts were 1:1 propensity score matched for age, sex, cancer subtype, Charlson comorbidity index, infection-related diagnoses, baseline corticosteroid use, and hospitalization within 30 days prior to ICI initiation. The primary endpoint was OS. Kaplan–Meier and Cox proportional hazards models were used for analysis. Sensitivity analyses evaluated the timing and duration of antibiotic exposure. **Results:** After matching, 3,024 patients were included (1,512 per cohort). Baseline characteristics were well balanced (mean age 63.7 years; 34% female; median Charlson comorbidity index 5). At a median follow-up of 19.8 months, antibiotic exposure was associated with significantly worse overall survival compared with non-exposure. Median OS was 10.6 months in antibiotic-exposed patients versus 14.3 months in non-exposed patients (log-rank $p< 0.001$). Antibiotic exposure was independently associated with inferior OS (HR 1.34, 95% CI 1.22–1.47). The negative association was most pronounced among patients with broad-spectrum antibiotic exposure (HR 1.41) and among those with antibiotic exposure within 30 days prior to ICI initiation (HR 1.38). Findings remained robust in sensitivity analyses excluding patients with documented sepsis or prolonged hospitalization. **Conclusions:** In this large real-world cohort of patients with esophagogastric cancer treated with ICIs, peritreatment antibiotic exposure was associated with significantly worse overall survival. These findings further support the role of the gut microbiome in modulating immunotherapy response and underscore the importance of judicious antibiotic use during ICI therapy. EU-OPEN: A novel approach for generating European oncology real-world evidence at scale. First Author: Kaushal Desai, Merck & Co., Inc, Rahway, NJ

Background: The European Oncology Platform for Evidence Needs (EU-OPEN) is a strategic initiative to generate high-quality oncology real-world evidence (RWE) in Europe. It focuses on establishing multi-study partnerships with access to clinically rich data, regional medical expertise and to enable adoption of novel approaches to conduct research on cohorts of interest efficiently at scale. **Methods:** For each tumor area *(e.g., EU-OPEN Breast)*, master protocols aligned to specific patient populations *(e.g., ER+/HER2- earlier stage breast cancer or triple negative metastatic breast cancer)* are developed alongside a fit-for-purpose data assessment at prospective data partners (primarily hospital sites and registries). Data partners are selected based on their data availability, data quality and operational aspects of collaboration. After finalizing the master protocol, supporting documentation (including common data models and statistical analysis plans) are prepared and shared with partner sites for consistent execution. Data partners then curate, harmonize and analyze data in accordance with the study requirements. Studies and patient cohorts can be efficiently refreshed to capture longer-term outcomes. **Results:** The initiative began in 2024 with a multi-tumor assessment of prospective data partners and an early breast cancer pilot study (completed and published in 2025). EU-OPEN has since expanded to metastatic breast, endometrial, ovarian and esophageal cancers. Collectively these studies encompass 11 cohorts and plan to include $>$ 2,200 patients. Future plans include expanding to additional tumor areas and data partner types, adopting advanced capabilities such as natural language processing (NLP) to maintain 'live cohorts' for rapid analyses, and strengthening governance through clinical and data committees across partners. **Conclusions:** EU-OPEN demonstrates a scalable, efficient approach to generating research-grade European Oncology RWE at scale. As the initiative grows, adoption of novel technologies and deeper collaboration with data and clinical experts will further accelerate insight generation. Research Sponsor: None.

Midday immune checkpoint inhibitor (ICI) infusion influence on survival in patients with metastatic cancer: A real-world chrono-immunotherapy study. First Author: Beliz Bahar Karaoğlan, Ankara University Faculty of Medicine Department of Medical Oncology, Ankara, Turkey

Background: Circadian rhythms regulate immune activity, and earlier ICI dosing has been linked to better survival. However, prior findings remain inconsistent, often relying on predefined time categories. To address this, we clustered actual infusion times to assess survival associations in a real-world cohort. **Methods:** This retrospective study included metastatic cancer patients treated with ICIs. Mean dosing times (up to 24 infusions/patient) were analyzed using circular statistics and clustered via k-means. Overall survival (OS) was defined from ICI initiation to progression, death, or last follow-up, and analyzed via Kaplan-Meier and multivariable Cox regression adjusted for cancer and ICI type. **Results:** A total of 640 patients (median age 61 years [range 23–87]; 78% male) were included. The most common tumor types were non-small cell lung cancer (52%), renal cell carcinoma (19%), and malignant melanoma (12%), followed by urothelial (5.5%) and small cell lung cancer (4.8%). The majority of patients received nivolumab (74%) or pembrolizumab (11%), while a smaller proportion were treated with other ICIs including atezolizumab (6.3%), avelumab (2%), or ipilimumab-based combinations (5.4%). ECOG performance status was 0–1 in 80% of patients. The most frequent metastatic sites were lymph nodes or soft tissue (78.6%), lungs (48.1%), bones (32.8%), liver (17.7%), and central nervous system (14.2%). Based on mean ICI infusion times, patients were grouped into three clusters: cluster 1 (2:15 PM, n = 76), cluster 2 (1:31 PM, n = 151), and cluster 3 (11:04 AM, n = 413). Median OS was 50.4, 28.2, and 15.7 months in Clusters 2, 1, and 3, respectively (log-rank p = 0.003). In multivariable analysis, Cluster 2 showed improved OS compared to Cluster 1 (Hazard Ratio [HR] 0.52, 95% Confidence Interval [CI] 0.31–0.86, p = 0.01), while no difference was seen between Clusters 3 and 1 (HR 1.13, 95% CI 0.75–1.70, p = 0.59). **Conclusions:** ICI administration around midday was associated with the longest survival, aligning with circadian peaks in T-cell infiltration, dendritic cell migration, and immune responsiveness. These findings support a personalized chrono-immunotherapy approach based on intrinsic biological rhythms. Research Sponsor: None.

Ischemic heart disease as a competing cause of death among patients with lung cancer in the United States: A multiple cause-of-death analysis, 1999–2023. First Author: Manish KC, North Alabama Medical Center, Florence, AL

Background: Despite improvement in lung cancer prevention, early diagnosis & management, Ischemic heart disease (IHD) has become a major concurrent cause of mortality in lung cancer. Population level evidence on long term deaths due to IHD & lung cancer especially across sex & racial groups are lacking. Identification of these trends is necessary for cardio-oncology risk stratification & promote equitable survivorship care. **Methods:** We used the CDC WONDER Online Database to obtain mortality data for IHD & Lung Cancer from 1999-2023 from patients aged 45-85 & above. We used current final multiple cause of death data from 1999-2020 & 2018-2023. We used ICD-10 codes I20-I25 for IHD & C33-34 for Lung cancer. Data were stratified by Race (Non-Hispanic [NH] American Indian or Alaska Native, NH Asian or Pacific Islander, NH Black or African American, NH White, Hispanic or Latino), sex (male & female) and age groups (45-85+). We calculated age-adjusted mortality rates (AAMR) per 100,000 population based on the 2000 US standard population. Temporal mortality trends were analyzed using Joinpoint regression. ($P < 0.05$). **Results:** From 1999-2023, AAMR from lung cancer & IHD decreased in most demographic groups. Males had higher AAMR than females, with mortality decreasing from 20.3 to 10.6 per 100,000, compared with a decline from 6.8 to 4.6 per 100,000 among females. Joinpoint regression identified substantial reduction among males from 1999-2010 (annual percent change [APC] -2.35%, $p < 0.05$) & 2010-2016 (APC -5.45%, $p < 0.05$), followed by stabilization. Among females, declines were observed from 2005-2012 (APC -2.76%, $p < 0.05$) & 2012-2015 (APC -7.35%, $p < 0.05$), with a nonsignificant plateau thereafter. NH Black exhibited higher AAMRs despite significant declines from 2005-2018 (APC -4.11%, $p < 0.05$). NH White showed persistent declines from 1999-2017, followed by a marginal increase during 2017-2021. Hispanic & Asian or Pacific Islander individuals maintained the lowest AAMRs, with decreasing trends & brief late-2010s increases in select subgroups, while American Indian or Alaska Native individuals exhibited greater year-to-year variability without statistically significant joinpoints. **Conclusions:** During 1999-2023, mortality from IHD & lung cancer decreased significantly in the US. Males & NH Black experienced a major disease burden. Recent improvement in death trends among the select patient population showed appropriate cardiovascular risk management in survivors with lung cancer. This analysis highlighted the importance of cardio-oncology care models & precision-guided, equity-driven interventions to decrease cardiovascular mortality among patients with lung cancer. Real-world cost effectiveness of androgen receptor pathway inhibitors for metastatic hormone sensitive prostate cancer: An economic evaluation utilizing data from the International Registry for Men with Advanced Prostate Cancer (IRONMAN). First Author: Rebecca Green, London School of Economics and Political Science, London, UK, and Prostate Cancer Clinical Trials Consortium, LLC, New York, NY

Background: Several therapies are approved for metastatic hormone sensitive prostate cancer (mHSPC), with differing efficacy and costs. While many cost-effectiveness analyses (CEAs) rely on randomized trial data, such analyses lack generalizability to real-world practice. We evaluated the real-world cost effectiveness (CE) of adding androgen receptor pathway inhibitors (ARPIs) to androgen deprivation therapy (ADT) for first-line (1L) mHSPC using the IRONMAN registry (NCT03151629). **Methods:** We conducted a US public payer perspective CEA using individual patient-level IRONMAN data. Eligible patients (pts) received 1L ADT alone, ADT + enzalutamide (ENZ), or ADT + apalutamide (APA) with ≥1 follow-up visit. A 3-state Markov model with 1-month cycles and a 10-year horizon was used. Progression-free survival (PFS) was proxied by time-to-next-treatment (TTNT); overall survival (OS) was time from 1L initiation to death or last follow-up. Costs and outcomes were discounted at 3% per year. Outcomes were measured in life-years gained (LYG) and incremental cost-effectiveness ratios (ICER) were reported. Uncertainty was assessed via one-way sensitivity analysis and probabilistic sensitivity analysis. A scenario analysis evaluated hypothetical ENZ price reductions aligned with planned Inflation Reduction Act negotiations. **Results:** 1187 pts with mHSPC met inclusion (ADT: n=405, ENZ: n=412, APA: n=370; Table 1). In the base case, both ARPI strategies improved OS versus ADT alone, though only APA provided a statistically significant reduction in risk (ENZ: HR 0.78, 95% CI 0.58-1.03, p=0.08; APA: HR 0.50, 95% CI 0.36-0.70, p<0.001). Using TTNT as a proxy for PFS, ADT alone had a reduced risk compared to either ARPI (ENZ: HR 1.97, 95% CI 1.39-2.77, p<0.001; APA: HR 1.51, 95% CI 1.05-2.18, p=0.028); underreporting of subsequent therapies in the ADT alone group may have contributed to this finding. Median follow-up was 26.7 months; median TTNT and OS were not reached. Neither ARPI strategy was CE at conventional US thresholds (ENZ: ICER = $444,947/LYG; APA: ICER = $669,530/LYG), and ENZ would require a 79% price discount to meet CE thresholds. Sensitivity analyses supported the base case results. **Conclusions:** Adding ENZ or APA to ADT for 1L mHSPC improved OS but was not found to be to be cost-effective at current US prices over a 10-year horizon. Substantial ENZ price reductions would be required to reach commonly used CE thresholds. Neurological immune-related adverse events and overall survival in patients with advanced solid tumors treated with immune checkpoint inhibitors in a global real-world analysis. First Author: Ahmed Abbasi, Berkshire Medical Center, Pittsfield, MA

Background: Immune checkpoint inhibitors (ICIs) have transformed the treatment of advanced malignancies, and many immune-related adverse events have been associated with improved treatment outcomes. Neurological immune-related adverse events, however, are uncommon, often severe, and poorly characterized in large real-world populations. Whether the development of neurological toxicity during ICI therapy is associated with long-term survival remains unclear. We examined the relationship between neurological immune-related adverse events and overall survival in a large real-world cohort of patients treated with ICIs. **Methods:** We performed a retrospective cohort study using data from the TriNetX Global Collaborative Network. Adult patients with advanced solid tumors treated with immune checkpoint inhibitors, including pembrolizumab, nivolumab, ipilimumab, atezolizumab, or durvalumab, were identified. Patients who developed neurological immune-related adverse events (such as encephalitis, meningitis, Guillain–Barré syndrome, myasthenia gravis, or immune-mediated polyneuropathy) within six months of treatment initiation were compared with patients who did not experience neurological toxicity. One-to-one propensity score matching was used to balance age, sex, race, ethnicity, and major medical comorbidities. Overall survival was assessed in the matched cohorts. **Results:** After matching, 9,744 patients were included (4,872 per cohort) with well-balanced baseline characteristics. Patients who developed neurological immune-related adverse events experienced significantly worse overall survival compared with matched controls. Median overall survival was 473 days in the neurological toxicity cohort versus 1,083 days among patients without neurological events ($p < 0.001$). Development of neurological immune-related adverse events was associated with a 57% higher risk of death (hazard ratio 1.57; 95% CI, 1.48–1.67). At five years, survival probability was 30.9% in the neurological toxicity group compared with 41.7% in the control group. **Conclusions:** In this large real-world analysis, neurological immune-related adverse events were associated with substantially worse overall survival in patients treated with immune checkpoint inhibitors. In contrast to other immune-related toxicities that may reflect effective immune activation, neurological complications appear to confer significant morbidity and mortality that outweigh potential treatment benefit. These findings highlight the need for early recognition, multidisciplinary management, and careful risk–benefit assessment when neurological toxicity develops during immunotherapy. Research Sponsor: None.

Pulmonary immune-related adverse events post-immune checkpoint inhibitors (ICI): Real-world experience. First Author: Maëlys Yepes, Cleveland Clinic Foundation, Cleveland, OH

Background: Immunotherapy (IT) has transformed cancer treatment and is often better tolerated than chemotherapy; however, immune-related pulmonary adverse events (Pulm-AE) have emerged as clinically significant and potentially treatment-limiting toxicities that may impact morbidity, treatment continuity, and survival. Real-world *comparative data* on Pulm-AE risk remain limited. We evaluated the incidence, cumulative risk, severity, and clinical outcomes of Pulm-AEs in patients receiving IT versus non-IT systemic therapies. **Methods:** We conducted a retrospective cohort study of 5,556 adult cancer patients treated at the Cleveland Clinic between 2010–2022. Included cancers were bladder (stage II–IIIA n = 476; IV n = 158), endometrial IV (n = 157), esophageal/gastric (II–III n = 797; IV n = 590), head & neck IV (n = 36), renal (III n = 88; IV n = 223), metastatic melanoma (n = 45), and lung cancers: non-squamous NSCLC (IIIB n = 206; IV n = 1,609), squamous NSCLC (IIIB n = 182; IV n = 366), and SCLC IIIB–IV (n = 623). Patients receiving IT (± chemotherapy or radiation) were compared with non-IT regimens and followed from treatment initiation to Pulm-AE, death, or last encounter. Pulm-AEs included pneumonitis, pleural effusion ± pleuritis, and interstitial lung disease. Data were collected on demographics, CTCAE grade, timing, management, and outcomes. Incidence rates per 100 person-years (py) were estimated using Poisson regression, cumulative incidence (CIR) using Kaplan–Meier methods, and adjusted hazard ratios (HRs) using time-dependent Cox models. **Results:** Of 5,556 patients, 2,133 (38%) received IT, including 1,291 (60%) as first-line therapy; 99.9% of IT exposure was ICI. The cohort was 38% female, 87% White, with a median age of 66 years. Over a median follow up of 14 months (CI: 6-35), 127 Pulm-AEs occurred, including 51 among first-line IT recipients. Pulm-AE incidence was higher with IT than non-IT (0.2 vs 0.06 per 100 py; $P < 0.05$), driven primarily by pneumonitis (0.16 vs 0.04 per 100 py; $P < 0.05$). At 24 months, CIR for Pulm-AEs was 5.5% with first-line IT versus 2.0% without (HR 3.50, $P < 0.001$); pneumonitis CIR was 4.3% versus 1.3% (HR 5.21, $P < 0.001$). Among pneumonitis cases, 86% were CTCAE grade 2–4, 81% required steroid therapy, and 28% resulted in permanent IT discontinuation, frequently necessitating long-term immunosuppression. Other Pulm-AEs in the IT & non-IT groups were pleural effusion (n = 10, 24), pleuritis without effusion (n = 0, 2), and interstitial lung disease (n = 0, 2). **Conclusions:** Receipt of IT was associated with a significantly increased risk of Pulm-AEs, primarily clinically significant pneumonitis. These toxicities were common (~7% by 24 months), frequently severe, and often led to irreversible damage and treatment cessation, underscoring the need for vigilant monitoring, early recognition, multidisciplinary management, and prompt intervention to minimize morbidity. Comparative real-world survival outcomes of ribociclib and abemaciclib in breast cancer. First Author: Chinenye M. Okafor, Medical University of South Carolina Health, Florence, SC

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i), including ribociclib and abemaciclib, are widely used in hormone receptor–positive, HER2-negative high-risk early-stage breast cancer in combination with endocrine therapy. While randomized trials have demonstrated survival benefits, comparative real-world outcomes between these agents remain limited. This study evaluates all-cause mortality among patients treated with ribociclib versus abemaciclib using a large real-world database. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, a global federated health research network, including adult patients with breast cancer treated with ribociclib (n = 7,697) or abemaciclib (n = 12,626) within the past 20 years. Two cohorts were constructed and balanced using 1:1 propensity score matching (PSM) based on age at diagnosis, sex, and race. The primary outcome was all-cause mortality at 1, 3, and 5 years. Kaplan–Meier survival curves and Cox proportional hazards models were used to estimate survival probabilities and hazard ratios. **Results:** After PSM, a total of 15,374 patients were included (7,687 per cohort). Mean age was 60.2±13.5 years in the ribociclib cohort and 60.2±13.4 years in the abemaciclib cohort. Most patients were female (99%) and White (72%). At 1 year, survival probability for ribociclib was 91.5% compared with 89.0% for abemaciclib (hazard ratio 0.74, 95% CI 0.66–0.84; log-rank $p < 0.001$). There was no significant difference in survival probabilities at 3 years (70.1% vs 72.1%) or 5 years (56.6% vs 55.1%), with hazard ratios not significantly different from 1.0. **Conclusions:** In this real-world analysis, ribociclib use was associated with lower all-cause mortality at 1 year compared with abemaciclib; however, this difference did not persist at longer follow-up. These findings should be interpreted cautiously given potential residual confounding and differences in clinical indications between agents. Further studies accounting for disease stage and treatment context are warranted. Research Sponsor: None.

When autoimmunity meets immunotherapy: Immune checkpoint inhibitors in cancer patients with rheumatoid arthritis. First Author: Rafi Aibani, Charleston Area Medical Center, Charleston, WV

Background: Immune checkpoint inhibitors (ICIs) improve outcomes across multiple malignancies but are associated with immune-related adverse events (irAEs). Patients with rheumatoid arthritis (RA) have been largely excluded from clinical trials, and disease-specific real-world data remain limited. We evaluated irAEs and survival outcomes in cancer patients with and without preexisting RA treated with ICIs. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network. Patients with RA diagnosed prior to ICI initiation were compared with patients without RA. Propensity score matching (1:1) was performed on age, sex, race, ethnicity, cancer type, ICI type, comorbidities, metastatic disease, other autoimmune conditions, and preexisting irAE codes. Outcomes were measured beginning 1 day after ICI initiation. Overall survival (OS) and organ-specific irAEs were assessed. Sensitivity analyses were conducted excluding patients with baseline glucocorticoid or disease-modifying antirheumatic drug (DMARD) exposure to account for differences in preexisting autoimmune treatment. **Results:** Before matching, 3,172 patients with RA and 156,543 without RA were identified. After matching, 3,162 patients were included in each cohort with balanced baseline characteristics and laboratory values. OS was numerically lower in the RA cohort but not statistically significant (29% vs 30%; median 21.9 vs 23.7 months; p = 0.1861). Early survival differed within 6 months (76% vs 78%; p = 0.0415) but not at 1 year. RA patients experienced higher rates of gastrointestinal (8.4% vs 6.9%; p = 0.0234) and pulmonary irAEs (5.4% vs 4.0%; p = 0.0106), with no significant differences in hepatic, dermatologic, or endocrine irAEs. Glucocorticoid and DMARD use were more frequent in RA patients. In sensitivity analyses excluding prior exposure, new DMARD use remained significantly higher in RA patients (4.5% vs 1.0%; $p < 0.0001$), while other differences attenuated. **Conclusions:** Cancer patients with preexisting RA treated with ICIs experience higher rates of select irAEs without a significant long-term OS disadvantage. These findings suggest increased immune toxicity risk with preserved anticancer efficacy, supporting cautious but feasible ICI use in RA patients with appropriate monitoring. Research Sponsor: None.

Sex differences in immune-related adverse events requiring hospitalization among patients with checkpoint inhibitor-sensitive malignancies: A national analysis. First Author: Jeril Lasington, The New York Medical College Graduate Medical Education Program at St. Mary's General Hospital and St. Clare's Health, Denville, NJ

Background: Immune checkpoint inhibitors (ICIs) can cause immune-related adverse events (irAEs) with significant morbidity/mortality. Sex influences immunity, yet sex-specific irAE patterns and outcomes in hospitalized patients remain underexplored. We investigated sex differences in irAE hospitalizations and mortality in ICI-sensitive cancers. **Methods:** Retrospective cohort study using the National Inpatient Sample (2019-2022) identified adults with ICI-sensitive malignancies (lung, melanoma, renal cell carcinoma [RCC], bladder, hepatocellular carcinoma [HCC]) and high-specificity irAEs (colitis, pneumonitis, cardiac, hepatic, dermatologic, neurologic) at academic centers. Primary outcome was in-hospital mortality. Secondary outcome was irAE distribution by sex. Multivariable logistic regression adjusted for demographics, cancer type, comorbidities, irAE type, discharge weights for national estimates. **Results:** Among 203,990 weighted hospitalizations (62.8% male; mean age 68), women had lower mortality (13.7% vs 15.0%; aOR 0.91, 95% CI 0.88-0.93, $p<0.0001$), consistent across models. Women had higher odds of neurologic (aOR 1.76, 95% CI 1.68-1.85), dermatologic (1.24, 1.20-1.29), hepatic (1.08, 1.05-1.11), and pneumonitis (1.05, 1.01-1.08) irAEs; men had higher GI colitis (aOR 0.51 for women, 0.48-0.53) and cardiac (0.81, 0.79-0.83) risks. Within irAEs, women had lower mortality for neurologic (6.0% vs 10.0%), pneumonitis (11.5% vs 14.2%), colitis (4.7% vs 6.5%), and dermatologic (4.5% vs 6.2%). Female survival advantage persisted across cancers (e.g., lung aOR 0.91, 0.87-0.94; HCC 0.95, 0.91-1.00) and after excluding autoimmune disease (aOR 0.93, 0.91-0.96). Temporal analysis showed widening sex gap (2019 aOR 0.99 to 2022 0.86; year × sex interaction p=0.0002). **Conclusions:** Women experience distinct irAE patterns (more neurologic/dermatologic) but lower overall and subtype-specific mortality versus men, with differences amplifying over time. Sex-stratified irAE surveillance and personalized ICI strategies can be implemented to optimize outcomes. Research Sponsor: None.

In-hospital mortality by sex in irAE hospitalizations.

Characteristic / Subgroup	N (weighted)	Male In-Hospital Mortality (%)	Female In-Hospital Mortality (%)	Adjusted OR (Female vs Male)	95% CI	p-value
Overall (Fully adjusted model[1])	203990	15	13.6	0.93	0.91-0.96	<0.0001
Overall (Fully adjusted + irAE type[2])	203990	15	13.6	0.91	0.88-0.93	<0.0001
Lung Cancer	93135	16.2	14.2	0.91	0.87-0.94	<0.0001
Melanoma	6725	11.2	9.6	0.72	0.60-0.87	0.0006
Bladder Cancer	16795	10.3	8.4	0.74	0.64-0.85	<0.0001
GI Colitis irAE	17610	6.5	4.7	0.65	0.56-0.74	<0.0001
Pneumonitis irAE	21075	14.2	11.5	0.76	0.70-0.83	<0.0001
Dermatologic irAE	15215	6.2	4.5	0.62	0.54-0.73	<0.0001
Neurologic irAE	8695	10	6	0.66	0.55-0.79	<0.0001

Prevalence and fracture burden of osteoporosis among patients with colorectal cancer: A real-world analysis. First Author: Anushree Venkatesh Murthy, Rochester Regional Health, Unity Hospital, Rochester, NY

Background: Osteoporosis is a common age-related skeletal disorder that may be underrecognized among patients with colorectal cancer (CRC), despite shared risk factors including advanced age, systemic inflammation, nutritional deficiencies, and cancer-related treatments. Population-level data describing the prevalence, demographic distribution, and fracture burden of osteoporosis in CRC remain limited, particularly in real-world clinical settings. **Methods:** We conducted a retrospective, cross-sectional cohort study using the TriNetX Global Collaborative Network comprising over 180 million patients across 165 healthcare organizations using R. Adult patients aged 18–85 years with colorectal cancer were identified using ICD-10-CM codes C18–C20. Two cohorts were constructed: CRC patients with osteoporosis (defined by ICD-10-CM codes M80–M81) and CRC patients without osteoporosis. Osteoporosis subtypes were further categorized into osteoporosis with current pathological fracture (M80) and osteoporosis without current pathological fracture (M81). Cohorts were compared using aggregate-level demographic data, including age, sex, race, ethnicity, and fracture status. **Results:** Among 696,434 patients with colorectal cancer, 40,051 (5.7%) had a documented diagnosis of osteoporosis. CRC patients with osteoporosis were significantly older than those without osteoporosis (mean age 74 vs 68 years) and were predominantly female (79.2% vs 43.9%). Racial distribution among CRC patients with osteoporosis included White (56.7%), Black or African American (6.0%), Asian (6.8%), and other or unknown race (30.5%). Age-stratified analyses demonstrated a marked increase in osteoporosis prevalence with advancing age, particularly among patients aged ≥75 years. Among the CRC with osteoporosis cohort, 13% had documented osteoporosis with current pathological fracture (M80), while 87% had osteoporosis without fracture (M81), indicating a substantial fracture burden in this population. Age-related osteoporosis accounted for the majority of cases, with multiple fracture-related subcodes reflecting clinically significant skeletal fragility. Patient arrival rate analyses demonstrated sustained real-world healthcare utilization across participating institutions. **Conclusions:** In this large real-world cohort, osteoporosis was prevalent among patients with colorectal cancer and was strongly associated with advanced age and female sex. A clinically meaningful proportion of CRC patients with osteoporosis had documented pathological fractures, highlighting an underappreciated source of morbidity. These findings underscore the importance of routine bone health assessment and fracture risk evaluation in colorectal cancer care, particularly among older adults. Research Sponsor: None.

Body mass index (BMI) and overall survival (OS) among Hispanic patients treated with immune checkpoint inhibitors (ICIs). First Author: Matthew Barke, Dell Medical School, The University of Texas at Austin, Austin, TX

Background: Prior studies have suggested improved OS among cancer patients receiving ICIs with higher BMI, despite obesity being a known cancer risk factor; however, these findings are largely derived from predominantly non-Hispanic cohorts. In Austin, Texas, Hispanic individuals comprise approximately 30% of the population, limiting the external validity of prior studies. We evaluated whether the previously described association between BMI and OS extends to Hispanic patients treated with ICIs. **Methods:** We retrospectively identified Hispanic patients with solid tumors treated with ICIs at Ascension/UT Health Austin between November 2013 and December 2025 using Research Electronic Data Capture (REDCap) data. BMI at ICI initiation was categorized as normal (18.5–24.9 kg/m²), overweight (25–29.9 kg/m²), or obese (≥30 kg/m²); underweight patients were excluded. Overall survival (OS) was defined as time from ICI initiation to death, with censoring at last follow-up or 5 years. Missing 5-year survival status was addressed using single stochastic regression imputation. Stabilized inverse probability of treatment weighting from a multinomial propensity score model was used to adjust for baseline differences, including age, sex, ECOG status, cancer type and stage, ICI agent, steroid exposure, and antibiotic exposure. Weighted Cox proportional hazards models estimated associations between BMI and OS, with prespecified subgroup analyses by sex and stage. **Results:** Among 177 Hispanic patients included, average age was 54 years and 53% were male; 32% had normal BMI, 31% were overweight, and 37% were obese. Median overall survival (OS) was 497 days. After inverse probability weighting, BMI was not associated with OS (p = 0.90). Compared with normal BMI, overweight patients had a hazard ratio (HR) of 0.94 (95% CI 0.49–1.80) and obese patients an HR of 1.09 (95% CI 0.60–2.00). No significant differences were observed between obese and overweight patients (HR 1.16; 95% CI 0.64–2.09). Subgroup analyses by sex and cancer stage showed no survival advantage associated with higher BMI. Among women, obese patients had an HR of 1.58 (95% CI 0.49–5.13), while among men the HR was 1.30 (95% CI 0.66–2.58). When stratified by stage, obese patients had an HR of 1.68 (95% CI 0.44–6.40) in stages I–III and 1.13 (95% CI 0.53–2.40) in stage IV. **Conclusions:** In this cohort of Hispanic patients with solid tumors treated with immune checkpoint inhibitors, we did not find a survival advantage for those with higher BMI. These findings raise the possibility that BMI associated survival advantages reported in predominantly non-Hispanic cohorts may not extend to the Hispanic population. Larger studies are needed to determine whether these findings represent true population-specific differences. Research Sponsor: None.

Insurance and racial disparities in CAR T-cell therapy outcomes: A National Inpatient analysis. First Author: Jeril Lasington, The New York Medical College Graduate Medical Education Program at St. Mary's General Hospital and St. Clare's Health, Denville, NJ

Background: To understand equity gaps for Chimeric antigen receptor T-cell (CAR-T) therapy, we conducted an analysis examining insurance-based and racial disparities in CAR-T cell therapy. **Methods:** Using the National Inpatient Sample (2020-2022), we identified CAR-T recipients via ICD-10-PCS procedure codes (XW0 series) with FDA-approved indications including diffuse large B-cell lymphoma (DLBCL), B-cell acute lymphoblastic leukemia (B-ALL), multiple myeloma, follicular lymphoma, and mantle cell lymphoma. The primary outcome was in-hospital mortality. Secondary outcomes included cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), and ICU utilization. Multivariable logistic regression estimated adjusted odds ratios (aOR) controlling for age, sex, race, insurance status, and disease indication. Access disparities were assessed by comparing racial composition of CAR-T recipients to US Census population estimates. **Results:** Among 10,610 weighted CAR-T hospitalizations (mean age 59.4 years; 62.1% male; 97% at academic centers), the most common indications were DLBCL (46.9%), multiple myeloma (25.0%), and B-ALL (12.7%). Overall in-hospital mortality was 8.6%, CRS occurred in 42.3%, and ICANS in 19.7%. Compared to privately insured patients (mortality 5.5%), both Medicare (11.5%; aOR 1.59, 95% CI 1.32-1.92, $p < 0.0001$) and Medicaid patients (10.7%; aOR 1.89, 95% CI 1.45-2.47, $p < 0.0001$) experienced significantly higher mortality after adjustment for demographics, comorbidities, and indication. This disparity persisted across the study period, with the Medicare-to-Private mortality ratio increasing from 1.9x (2020) to 2.2x (2022). Black (9.1% of CAR-T recipients vs 13.6% US population) and Hispanic patients (13.7% vs 18.9%) were significantly underrepresented, receiving CAR-T at only 67% and 72% of expected rates based on population demographics, respectively. Black patients demonstrated significantly higher ICANS risk (aOR 1.38, 95% CI 1.16-1.64, p = 0.0003) but lower CRS risk (aOR 0.79, 95% CI 0.68-0.91, p = 0.001) compared to White patients. Black patients also experienced higher rates of ICU-level care (23.8% vs 16.6%) and mechanical ventilation (12.4% vs 8.1%). No significant sex-based disparities were observed in mortality (aOR 0.90, 95% CI 0.78-1.04, p = 0.17). **Conclusions:** We identified insurance-based mortality gaps with 60-90% higher adjusted mortality compared to privately insured patients. Concurrent access disparities result in Black and Hispanic patients being underrepresented by approximately one-third. Black patients who do receive CAR-T demonstrate distinct toxicity phenotypes with higher neurotoxicity and ICU utilization. These findings support the need to address barriers to CAR-T access and optimize outcomes across all patient populations. Research Sponsor: None.

Mental health and malignancy: Real-world associations between early-onset hormone-related cancers and mental illness. First Author: Danielle Claire Thor, Jefferson Health New Jersey, Stratford, NJ

Background: Although progress has been made in reducing overall cancer incidence, early-onset cancers have continued their troublesome rise. Similarly, the incidence and/or prevalence of psychiatric disorders has increased, particularly among young adults. Mental illness may influence cancer development, however, real-world evidence linking mental illness to early-onset hormone-related cancers is limited. **Methods:** We conducted a real-world, retrospective cohort study using the TriNetX United States Research Database, a federated network of de-identified electronic health records from over 70 healthcare organizations, to examine this association. Adults aged 18–50 years with at least one of five pre-determined core mental illnesses, including generalized anxiety disorder (GAD), major depressive disorder (MDD), obsessive-compulsive disorder (OCD), bipolar disorder, and schizophrenia, were compared with same-aged individuals without any of the core mental illnesses. A five-year lookback period was used from January 25th, 2021 to January 25th 2026 and propensity score matching was used to adjust for confounders. Incidence of early-onset cancers diagnosed were then assessed during five-year follow-up. Sensitivity analyses required a $\geq$ 1-year lag between mental illness diagnosis and cancer onset. **Results:** 2,911,432 patients were identified as having a core mental illness, whereas 21,439,614 patients were identified as not having any core mental illness. All-cause mental illness was associated with an increased risk of developing early-onset breast cancer (RR 2.253, CI 2.149-2.362, $p < 0.0001$), uterine cancer (RR 1.711, CI 1.515-1.934, $p < 0.0001$), and ovarian cancer (RR 1.984, CI 1.790-2.198, $p < 0.0001$). Associations with early-onset prostate cancer and testicular cancer did not meet thresholds for statistical significance. Within the subgroup analysis, GAD was associated with an increased risk of developing early-onset breast cancer (RR 2.565, CI 2.398-2.742, $p < 0.0001$), uterine cancer (RR 1.534, CI 1.278-1.841, $p < 0.0001$) and ovarian cancer (RR 1.736, CI 1.492-2.019, $p < 0.0001$). MDD was associated with early-onset breast cancer (RR 2.380, CI 2.161-2.622, $p < 0.0001$), uterine cancer (RR 2.089, CI 1.625-2.685, $p < 0.0001$), and ovarian cancer (RR 1.983, CI 1.591-2.472, $p < 0.0001$). Bipolar disorder was associated only with early-onset breast cancer (RR 1.415, CI 1.244-1.610, $p < 0.0001$). OCD and schizophrenia had no statistically significant associations. **Conclusions:** In this large, real-world cohort study, all-cause mental illness, GAD, and MDD were associated with an increased risk of early-onset hormonal cancers more commonly affecting female patients. These findings suggest that mental health represents a potential modifiable risk factor in early-onset, hormone-related cancers and warrants further investigation. Research Sponsor: None.

Mental health and malignancy: Real-world associations between early-onset gastrointestinal cancers and mental illness. First Author: Danielle Claire Thor, Jefferson Health New Jersey, Stratford, NJ

Background: Although progress has been made in reducing overall cancer incidence, early-onset cancers have continued their troublesome rise. Similarly, the incidence and/or prevalence of psychiatric disorders has increased, particularly among young adults. Mental illness may influence cancer development, however, real-world evidence linking mental illness to early-onset gastrointestinal cancers is limited. **Methods:** We sought to conduct a real-world, retrospective cohort study using the TriNetX United States Research Database, a federated network of de-identified electronic health records from over 70 healthcare organizations, to examine this association. Adults aged 18–50 years with at least one of five pre-determined core mental illnesses, including generalized anxiety disorder (GAD), major depressive disorder (MDD), obsessive-compulsive disorder (OCD), bipolar disorder, and/or schizophrenia, were compared with same-aged individuals without any of the core mental illnesses. A five-year lookback period was used from January 25th, 2021 to January 25th 2026. Propensity score matching adjusted for demographic and clinical confounders. Incidence of early-onset cancers diagnosed were then assessed during five-year follow-up. Sensitivity analyses required a $\geq$ 1-year lag between mental illness diagnosis and cancer onset. **Results:** 2,911,432 patients ages 18-50 were identified as having a core mental illness, whereas 21,439,614 patients ages 18-50 were identified as not having any core mental illness. All-cause mental illness was associated with an increased risk of developing early-onset gastric cancer (RR 1.451, CI 1.189-1.771, $p < 0001$), pancreatic cancer (RR 1.566, CI 1.328-1.822, $p < 0.0001$) and colorectal cancer (RR 1.407, CI 1.313-1.506, $p < 0.0001$). Associations with early-onset esophageal cancer, biliary tract cancer, and small intestine cancer did not meet thresholds for statistical significance. In addition, subgroup analysis was completed for each core mental illness. GAD was associated with an increased risk of developing early-onset pancreatic cancer (RR 1.627, CI 1.220-2.169, $p < 0.0001$), small intestine cancer (RR 2.435, CI 1.498-3.956, $p < 0.0001$), and colorectal cancer (RR 1.625, CI 1.441-1.833, $p < 0.0001$). MDD was only associated with an increased risk of developing early-onset colorectal cancer (RR 1.425, CI 1.213-1.674, $p < 0.0001$). OCD, bipolar disorder, and schizophrenia had no statistically significant association with the development of the early-onset cancers noted above. **Conclusions:** In this large, real-world cohort study, all-cause mental illness, GAD, and MDD were associated with an increased risk of several early-onset gastrointestinal cancers. These findings suggest that one's mental health represents a potentially modifiable risk factor in early-onset gastrointestinal cancers and warrants further investigation. Research Sponsor: None.

Patterns and determinants of radiotherapy treatment default in a rural cancer centre: A retrospective observational study. First Author: Darshana Kawale, Indrayani Hospital and Cancer Institute, Pune, maharashtra, India

Background: Radiotherapy requires uninterrupted daily treatment over several weeks, making treatment adherence challenging, particularly in rural and resource-limited settings. Treatment default adversely affects outcomes and reflects underlying socioeconomic, access-related and clinical barriers. There is limited real-world data from rural India evaluating the magnitude and determinants of treatment default. This study aimed to determine the radiotherapy default rate and identify the associated factors. **Methods:** This retrospective observational study included patients enrolled for definitive, adjuvant, and palliative radiotherapy over a 2 year period at a rural tertiary cancer centre. Radiotherapy default was defined as missing 3 or more consecutive fractions after initiation of treatment or failure to complete the planned prescribed dose. Descriptive statistics were used to summarise patient demographics, socioeconomic characteristics and clinical variables. The radiotherapy default rate was expressed as a percentage. Associations between radiotherapy default and categorical variables were analysed using Chi-square or Fisher's exact test, as appropriate. Variables significant on univariate analysis were included in a multivariate logistic regression model to identify independent predictors of radiotherapy default. A p-value < 0.05 was considered statistically significant. **Results:** Among 2755 patients enrolled for radiotherapy during the study period, 363 patients defaulted, resulting in an overall default rate of ~13.2%. Higher default rates were significantly associated with longer daily travel distance, financial constraints, lower educational status, inadequate family support, poor baseline general condition, treatment related toxicities, diet-related difficulties- particularly among head and neck cancer patients ($p < 0.05$). On multivariate logistic regression analysis, long travel distance, financial constraints, poor general condition, inadequate family support and diet-related difficulties remained independent predictors of radiotherapy default. **Conclusions:** Radiotherapy default remains a clinically significant challenge in rural practice and is driven by a combination of socioeconomic, access-related and clinical factors. Long travel distance, financial constraints, inadequate family support, poor general condition and diet-related difficulties independently contribute to treatment default. Early identification of high-risk patients and targeted interventions—including patient and caregiver counselling, nutritional optimisation, financial and travel assistance, symptom control, and multidisciplinary supportive care—have the potential to reduce radiotherapy default rates and improve treatment completion in resource-limited settings. Assessing burden and outcomes: Colon cancer survival across the U.S. safety-net spectrum. First Author: David Otohinoyi, Louisiana State University Health Sciences Center at Ochsner University Hospital & Clinics, Department of Internal Medicine, Lafayette, LA

Background: Safety-net hospitals (SNHs) provide essential care for uninsured and underinsured patients but often face systemic constraints that may affect cancer outcomes. Colon cancer, a leading cause of cancer-related death in the United States, requires complex multidisciplinary management. This study assessed the association between hospital safety-net burden and clinical outcomes in colon cancer across a national dataset. We also identified patient-level factors contributing to disparities in care delivery. **Methods:** Using the National Cancer Database (NCDB), we identified approximately 1.2 million adult patients diagnosed with colon cancer in the United States between 2004 and 2020. Facilities were stratified by safety-net burden into Non–Safety-Net Hospitals (NSNH; $<$ 25% Medicaid/uninsured cases), Safety-Net Hospitals (SNH; 25–75%), and Extreme Safety-Net Hospitals (Extreme-SNH; $>$ 75%). This safety-net spectrum provided a novel framework for capturing both facility- and patient-level disparities that influence colon cancer care and outcomes. Multivariable logistic and Cox regression models were used to evaluate differences in disease stage, treatment timelines, and survival, adjusting for age, comorbidity, and AJCC stage. Kruskal–Wallis and chi-square tests were used for descriptive analyses. **Results:** SNHs and Extreme-SNHs cared for a greater proportion of patients with advanced-stage disease, lower rates of chemotherapy, immunotherapy, and palliative care utilization, and higher short-term mortality when compared with NSNH. Thirty-day readmission rates after surgery were similar across groups. Survival analyses demonstrated a graded decline in outcomes with increasing safety-net burden: median overall survival was 91.2 months in NSNH, 83.6 months in SNH, and 70.9 months in Extreme-SNH ($p <$ 0.001). One-year survival exceeded 95% across all facilities, but five-year survival declined to 68.9% for NSNH vs 59.4% for Extreme-SNH. Additional disparities in colon cancer outcomes were observed by health literacy level, residential setting (urban, metropolitan, rural), race, age, and sex. **Conclusions:** Colon cancer patients treated at hospitals with higher safety-net burden experience substantially poorer long-term survival despite comparable short-term outcomes. These findings highlight the need for targeted policy, resource allocation, and quality-improvement efforts to reduce disparities and strengthen oncology care delivery in high-burden safety-net systems. A Plan–Do–Check–Act (PDCA) approach tailored to individual hospital settings and regional contexts may help identify gaps in colon cancer care and guide targeted interventions to improve patient outcomes. Research Sponsor: None.

Prognostic value of circulating tumor DNA (ctDNA) for recurrence detection across solid tumors: A real-world meta-analysis. First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Early detection of recurrence after curative-intent treatment is a critical priority, traditional imaging often detects relapse when disease burden is high, potentially limiting treatment efficacy. ctDNA has emerged as an established prognostic biomarker for molecular residual disease (MRD) detection and early relapse. We performed a real-world meta-analysis on published datasets that utilized personalized, tumor-informed ctDNA testing to assess its performance across tumor types and clinical management approaches. **Methods:** Real-world studies published from December 2022 to December 2025 using the personalized, tumor-informed Signatera ctDNA assay (Natera, Inc.) were included. Eligibility required ctDNA assessment in the MRD (2–16 weeks post-surgery (histology dependent)/pre adjuvant therapy (ACT)) and/or surveillance (post-ACT/end of the MRD window if no ACT was given) settings, with outcomes stratified by ctDNA status and hazard ratios (HR) reported from univariable or time-dependent Cox regression analysis. Exclusions included: clinical trials, biobanks, metastatic disease treated with palliative intent, case reports, reviews, editorials, or commentaries. Clinical outcomes were harmonized into a composite event-free survival (EFS) endpoint (time to recurrence, progression, or death). Pooled HRs and 95% CIs were estimated using random and fixed effects models and heterogeneity between studies was assessed using the I^2 and Cochran's Q test. Median lead time from ctDNA-positivity to radiographic or clinical recurrence was summarized when available. **Results:** We identified 18 eligible publications comprising 3,004 unique patients across 15 solid tumor types. During the MRD window, ctDNA positivity was associated with a significantly increased risk of an EFS event compared with ctDNA negativity (pooled HR: 8.15; 95% CI: 6.12–10.85, I^2 = 0.00%, P = 0.844, n = 13). During the surveillance window, inclusive of post-definitive treatment, ctDNA positivity conferred an even greater EFS risk (pooled HR: 18.30; 95% CI: 14.17–23.65, I^2 = 0%, P = 0.911 for heterogeneity, n = 16). Across studies, ctDNA detection during surveillance preceded radiographic or clinical recurrence by a median of 3.20 months (95% CI: 2.50-4.10, $P < 0.0001$, n = 10), although this varied substantially by study/tumor type (I^2 = 80.9%). **Conclusions:** In this pan-cancer real-world meta-analysis, ctDNA positivity assessed using a tumor-informed assay was highly prognostic following curative-intent therapy at all timepoints evaluated with low heterogeneity between studies. These findings support the broad clinical utility of tumor-informed ctDNA testing for post-treatment risk stratification and longitudinal disease monitoring across solid tumors. Research Sponsor: None.

Predictors of tumor lysis syndrome in non-Hodgkin lymphoma hospitalizations. First Author: Srijani Thannir, The Brooklyn Hospital Center, Brooklyn, NY

Background: Tumor lysis syndrome (TLS) is a life-threatening oncologic emergency in non-Hodgkin lymphoma (NHL) caused by rapid tumor cell breakdown and severe metabolic derangements. Although TLS is well recognized, most risk data derive from small cohorts or trials, limiting generalizability. We used a nationally representative inpatient dataset to identify predictors of TLS in hospitalized NHL patients. **Methods:** We performed a cross-sectional analysis of the National Inpatient Sample (2016–2020). Adult NHL hospitalizations were identified using ICD-10 codes. Survey-weighted chi-square tests and multivariable logistic regression evaluated demographic, clinical, and treatment predictors. Analyses accounted for the complex survey design. Statistical significance was defined as $p<0.05$. **Results:** An estimated 350,400 NHL hospitalizations were identified, of which 0.79% had TLS. TLS patients were younger (65.7 vs 69.5 years, $p <$ 0.001) and demonstrated different racial distributions, with lower proportions of White patients (67.8% vs 76.9%) and higher proportions of Black (12.7% vs 9.2%) and Hispanic patients (11.6% vs 8.6%) ($p <$ 0.001). TLS occurred more frequently in hospitals in the West and Northeast (p = 0.036). TLS admissions had significantly longer stays (10.48 vs 5.91 days) and higher charges ($174,972 vs $76,884; $p <$ 0.001). Survey-weighted regression identified several strong predictors of TLS. Bone marrow involvement was one of the strongest independent predictors (OR 13.78 [95% CI 5.45–34.84]). Electrolyte derangements were also powerful predictors: hyperkalemia (OR 8.20 [95% CI 6.82–9.86]), hyperphosphatemia (OR 8.28 [95% CI 6.62–10.36]), and hypocalcemia (OR 7.02 [95% CI 5.67–8.69]). Additional predictors included sepsis (OR 2.29 [95% CI 1.89–2.77]), neutropenia (OR 1.71 [95% CI 1.27–2.31]), HIV infection (OR 1.73 [95% CI 1.05–2.84]), and receipt of inpatient chemotherapy (OR 1.38 [95% CI 1.01–1.87]). Prior chemotherapy (OR 0.44 [95% CI 0.30–0.63]) and radiation therapy (OR 0.61 [95% CI 0.38–0.99]) were protective, suggesting TLS risk is greatest in chemo-naïve or high–tumor burden presentations. **Conclusions:** TLS in hospitalized NHL patients is associated with distinct demographic patterns and substantial increases in healthcare utilization. Early risk stratification incorporating clinical, laboratory, and treatment factors may improve prevention strategies and outcomes. Research Sponsor: None.

Predictors of TLS among hospitalized patients with NHL.

Predictor	Adjusted OR	95% CI	p-value
Bone marrow involvement	13.78	5.45–34.84	<0.001
Hyperkalemia	8.20	6.82–9.86	<0.001
Hyperphosphatemia	8.28	6.62–10.36	<0.001
Hypocalcemia	7.02	5.67–8.69	<0.001
Sepsis	2.29	1.89–2.77	<0.001
Neutropenia	1.71	1.27–2.31	<0.001
HIV infection	1.73	1.05–2.84	0.031
Inpatient chemotherapy	1.38	1.01–1.87	0.041
Prior chemotherapy	0.44	0.30–0.63	<0.001

Direct oral anticoagulants versus low-molecular-weight heparin in patients with liver metastases and cancer-associated thrombosis: A multi-center real-world analysis. First Author: Jowan Al-Nusair, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV

Background: Patients with liver metastases are at high risk for cancer-associated thrombosis (CAT) and require therapeutic anticoagulation. Although direct oral anticoagulants (DOACs) are increasingly used, their safety relative to low-molecular-weight heparin (LMWH) in this high-risk population, particularly regarding gastrointestinal (GI) bleeding, remains uncertain. **Methods:** We conducted a retrospective, federated cohort study using the TriNetX Global Collaborative Network, including adult patients with liver metastases and CAT who initiated a DOAC or LMWH within 10 days of CAT diagnosis. The index date was defined as the first qualifying anticoagulant exposure. Propensity score matching was performed to balance measured demographics, comorbidities, and concomitant medications, yielding 19,380 patients per cohort. Outcomes were assessed from 1 to 365 days after the index date and included GI bleeding, thrombotic recurrence by DVT/PE or stroke, intensive care unit (ICU) admission, and all-cause mortality. GI bleeding was identified using diagnosis-based coding algorithms, with exclusion of patients who had GI bleeding prior to anticoagulation initiation. Risk estimates were calculated and time-to-event analyses. **Results:** GI bleeding occurred more frequently among patients treated with DOACs compared with LMWH (9.7% vs 8.3%; hazard ratio [HR] 1.11, 95% CI 1.02–1.19). Thrombotic recurrence was common in both groups (61.4% with DOACs vs 60.0% with LMWH); however, time-to-event analysis demonstrated a modestly lower hazard of recurrence among DOAC-treated patients (HR 0.94, 95% CI 0.92-0.97). ICU admission was infrequent but occurred more often in the DOAC cohort (0.6% vs 0.3%; HR 1.80, 95% CI 1.33–2.46). DOAC use was associated with significantly lower all-cause mortality compared with LMWH (50.8% vs 55.7%; HR 0.84, 95% CI 0.82–0.86). **Conclusions:** In patients with liver metastases and CAT, DOAC therapy was associated with a modestly increased risk of GI bleeding but improved overall survival compared with LMWH. Given the small absolute differences in bleeding risk and the potential for residual confounding from unmeasured factors such as cancer burden, performance status, life expectancy, and hospice referral, these findings may support clinical equipoise between anticoagulation strategies. Individualized treatment decisions remain essential in this vulnerable population. Research Sponsor: None.

Clinical outcomes in propensity-score matched patients with liver metastasis and cancer associated thrombosis.

Outcome	DOAC (n=19,380)	LMWH (n=19,380)	HR	CI
GI bleeding	9.7%	8.3%	1.11	1.02-1.19
Thromboembolic recurrence	61.4%	60.0%	0.94	0.92-0.97
ICU admission	0.6%	0.3%	1.80	1.33-2.46
All-cause mortality	50.8%	55.7%	0.84	0.82-0.86

11180 Poster Session

Arrhythmia phenotype and 30-day readmission in selected cancers: Propensity-matched NRD study. First Author: Mariana Marrero Castillo, Louisiana State University, Shreveport, LA

Background: Cardiac arrhythmias are common in oncology and may increase rehospitalization and resource use, but arrhythmia-type and cancer-specific readmission risk is incompletely characterized. **Methods:** Retrospective cohort of adult index hospitalizations for colorectal, breast, lung, prostate, kidney, or melanoma in the HCUP Nationwide Readmissions Database. Arrhythmias coded during the index stay (atrial fibrillation [AF], atrial flutter [AFL], ventricular tachycardia [VT], supraventricular tachycardia [SVT]) were identified using ICD-10-CM codes. Primary outcome was all-cause 30-day readmission. For each phenotype, propensity-score matching (caliper 0.05) created arrhythmia and no-arrhythmia cohorts balanced on demographics, payer, income quartile, and comorbidity. Multilevel logistic regression with hospital clustering estimated adjusted odds ratios (aOR) with 95% CI and tested arrhythmia-by-cancer interactions. Secondary outcomes were index length of stay (LOS) and total charges, analyzed with mixed-effects models; results are reported as adjusted mean differences (days) and incremental charges (USD). Two-sided $p < 0.05$ was significant. **Results:** Among 1,562,919 index hospitalizations, AF was present in 214,475 (13.7%), AFL 27,545 (1.8%), VT 5,184 (0.3%), and SVT 25,714 (1.6%). After matching/adjustment, AFL was associated with higher 30-day readmission (aOR 1.095, 95% CI 1.03-1.17; p = 0.005). AF (aOR 1.001, 0.98-1.03; p = 0.940), VT (aOR 1.128, 0.99-1.29; p = 0.078), and SVT (aOR 1.018, 0.95-1.09; p = 0.598) were not significant overall. AF demonstrated cancer-specific heterogeneity: lung aOR 1.092 (1.043-1.144; $p < 0.001$) and melanoma aOR 1.143 (1.019-1.283; p = 0.023), while breast was not increased (aOR 0.964, 0.908-1.025; p = 0.242). In the AF model, older age was inversely associated with readmission (aOR 0.974 per year, 95% CI 0.972-0.976; $p < 0.001$). In the AF model, highest income quartile was associated with higher readmission (aOR 1.409, 95% CI 1.275-1.557; $p < 0.001$). AF/VT/SVT increased LOS: AF +0.658 days, VT +1.419 days, SVT +1.146 days ($p <= 0.001$); charges increased: AF +$12,399 (95% CI 8,231-16,569), VT +$48,114 (36,846-59,382), SVT +$26,656 (19,822-33,489) (all $p < 0.001$). **Conclusions:** In selected cancers, AFL was independently associated with higher 30-day readmission, while AF readmission risk varied by cancer type. AF/VT/SVT were linked to increased LOS and charges, with the largest resource impact in VT. Prospective studies incorporating cancer stage and therapy exposures should test phenotype-guided cardio-oncology transitional care to reduce readmissions and costs. Limitations include ICD-coded phenotyping, inability to distinguish incident vs prevalent arrhythmias, and unavailable outpatient therapy/anticoagulation; residual confounding is possible. Misclassification may bias estimates toward null, particularly for VT. Research Sponsor: None.

11181 Poster Session

Trends and factors associated with glucagon-like peptide 1 receptor agonists prescription for cancer populations with type 2 diabetes. First Author: Ilana Graetz, Emory University School of Public Health, Atlanta, GA

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are increasingly used in cancer survivors with Type 2 Diabetes (T2D) given its efficacy, yet concerns regarding treatment tolerance, weight loss, and limited oncology-specific guidance during active treatment and survivorship may influence prescribing patterns. To date, little evidence exists regarding the trends and factors associated with GLP-1RA use in cancer populations with T2D. **Methods:** We conducted a retrospective cohort study using SEER–Medicare data to identify patients newly diagnosed with seven most common cancers in 2010-2021 with pre-existing T2D. Pre-existing T2D was defined by relevant diagnosis codes within 12 months prior to cancer diagnosis. Patients with continuous Medicare Parts A & B and Part D enrollment were followed annually from diagnosis until death or end of follow-up (12/31/2022) to assess GLP-1RA use. A non-cancer cohort with T2D was identified using a 5% random sample of Medicare beneficiaries without cancer. We calculated annual proportions of beneficiaries with any GLP-1RA use, stratified by Traditional Medicare (TM) and Medicare Advantage (MA, data available in 2016-2021). Multivariable logistic regression models evaluated patient sociodemographic and clinical characteristics associated with GLP-1RA use in 2021. **Results:** We included 482,878 and 542,285 Medicare beneficiaries with T2D in the cancer and non-cancer cohort respectively (1,927,771 and 3,265,774 person-years in 2010-2022). Among TM beneficiaries, GLP-1RA use in the cancer cohort increased from 0.5% to 8.2% in 2010-2022, compared to an increase from 0.4% to 6.4% among non-cancer cohort; similarly higher GLP-1RA use was observed in cancer than non-cancer cohort among MA beneficiaries in 2016-2021 (1.8% to 6.8% vs. 1.3% to 5.7%; unadjusted p-values < 0.001). Rapid uptake was observed for dulaglutide and semaglutide from 2015, while liraglutide use declined modestly after peaking in 2018. In adjusted analyses within the cancer cohort, patients with breast (0.87 percentage points [ppts], $p < 0.001$), female genital (1.08 ppts, $p < 0.001$), and prostate cancers (0.62 ppts, p = 0.001) were more likely to receive GLP-1RAs than those with colorectal cancer. More advanced cancer stage was associated with lower likelihoods of GLP-1RA use; Non-Hispanic White, higher socioeconomic neighborhoods, and dual eligibility were associated with higher likelihoods of GLP-1RAs use. **Conclusions:** GLP-1RA use increased substantially among Medicare beneficiaries with cancer and T2D, and was consistently higher than those without cancer, which may reflect greater clinical engagement and cardiometabolic risk burden following a cancer diagnosis. Variation by cancer site, stage, and socioeconomic factors suggest that both clinical complexity and structural determinants shape GLP-1RA use in cancer survivors. Research Sponsor: National Cancer Institute; 3P30CA138292.

11182 Poster Session

Organ-specific metastatic progression in non-small cell lung cancer treated with pembrolizumab versus atezolizumab: A TrinetX network analysis. First Author: Athar Nawab, WVU Camden Clark Medical Center, Parkersburg, WV

Background: Immune checkpoint inhibitors (ICIs) targeting the PD-1 (Pembrolizumab) and PD-L1 (Atezolizumab) have revolutionized the first-line management of metastatic non-small cell lung cancer (mNSCLC). While these agents are often considered clinically interchangeable, the differences in molecular binding mechanism and tissue-specific penetration may lead to distinct therapeutic patterns. Since the real-world evidence on the propensity for organ-specific metastatic spread remains limited, we aim to compare organ-specific metastatic progression patterns between the two therapies. **Methods:** We conducted a retrospective cohort study utilizing the TriNetX US Collaborative Network. After identifying adults with stage IV mNSCLC on initial Pembrolizumab or Atezolizumab monotherapy, patients with pre-existing metastases at the specific organ site of interest were excluded. Propensity score matching (1:1) was performed to balance cohorts across demographic and clinical variables. Our endpoints were metastases to the CNS, mediastinum, bone, liver, adrenal glands, and skin over 365 days. Hazard ratios (HR) were estimated using Cox proportional hazards models. **Results:** Atezolizumab was associated with a significantly higher risk of CNS metastases compared with Pembrolizumab (1-year incidence: 16.9% vs 6.1%; HR 3.08, 95%CI: 2.73-3.46; $p < 0.001$). A similar pattern was seen in the mediastinum (HR 1.62, 95% CI: 1.32–1.99), bone (HR 1.53, 95% CI: 1.38–1.70), liver (11.5% vs 7.8%; HR 1.55, 95% CI: 1.37–1.75), and adrenal glands (HR 1.43, 95% CI: 1.20–1.75). In contrast, an inverse relationship was observed in the skin where Atezolizumab showed a significantly lower risk of metastases (1.0% vs 1.7%; HR 0.59, 95% CI: 0.44 - 0.79; p = 0.01). **Conclusions:** Markedly distinct patterns of organ-specific metastasis were seen, where Atezolizumab consistently demonstrated an elevated risk of progression in the CNS and visceral organs, whereas Pembrolizumab showed a greater propensity for cutaneous progression. These observations indicate that the selection between PD-1 and PD-L1 inhibition may influence the location of the subsequent site of disease progression. Research Sponsor: None.

Metastatic Site	Atezolizumab Cohort (Events / N)	Pembrolizumab Cohort (Events / N)	Hazard Ratio* (95% CI)	P-Value
CNS	994 / 5,890	376 / 6,138	3.08 (2.73 – 3.46)	<0.001
Mediastinum	228 / 7,043	150 / 7,153	1.62 (1.32 – 1.99)	0.02
Bone	824 / 4,997	624 / 5,374	1.53 (1.38 – 1.70)	0.43
Liver	602 / 5,250	490 / 6,262	1.55 (1.37 – 1.75)	0.35
Adrenal Gland	287 / 6,821	213 / 6,912	1.43 (1.20 – 1.75)	0.068
Skin	71 / 7,306	123 / 7,177	0.59 (0.44 – 0.79)	0.01

Note: N varies by organ site due to the exclusion of patients with pre-existing metastases at that specific site. *Hazard Ratio > 1.0 indicates increased risk with Atezolizumab; HR < 1.0 indicates increased risk with Pembrolizumab.

Frailty among hospitalized patients with pancreatic cancer: A National Inpatient analysis. First Author: Srijani Thannir, The Brooklyn Hospital Center, Brooklyn, NY

Background: Frailty is increasingly recognized as a key determinant of outcomes in older adults with cancer; however, its prevalence and inpatient correlates among hospitalizations for pancreatic cancer remain incompletely characterized. We examined the national inpatient burden of frailty among adults hospitalized with pancreatic cancer and compared demographics, comorbidities, and healthcare utilization between frail and non-frail patients. **Methods:** We analyzed National Inpatient Sample data (2016–2020) to identify adult pancreatic cancer hospitalizations using ICD-10 codes. Frailty was defined by ICD-10 R54. Survey-weighted analyses accounted for complex sampling, with statistical significance set at $p < 0.05$. **Results:** Among an estimated 775,510 weighted adult hospitalizations with pancreatic cancer, frailty was identified in 0.39%. Frail patients were significantly older (74.96 vs 68.32 years, $p < 0.001$) and more often female (56.4% vs 47.7%, $p < 0.001$). Frailty was more prevalent among patients from lower-income neighborhoods and varied by hospital region (both $p < 0.01$). Frail patients experienced longer hospital stays (7.16 vs 6.16 days, $p < 0.001$), with similar total hospitalization charges ($77,978 vs $75,477). Frailty was associated with higher burdens of congestive heart failure (15.9% vs 10.3%) and sepsis (22.8% vs 17.0%) (both $p < 0.001$). Frail patients demonstrated marked nutritional and functional vulnerability, including underweight status (24.6% vs 9.1%), anemia (52.5% vs 44.0%), malnutrition (46.2% vs 28.8%), chronic pain (24.4% vs 19.5%), and falls or mobility impairment (8.5% vs 3.6%) (all $p < 0.01$). In multivariable analysis, advanced age, female sex, underweight status, malnutrition, anemia, chronic pain, sepsis, congestive heart failure, functional impairment, and lower socioeconomic status remained independently associated with frailty. **Conclusions:** Frailty was uncommon but clinically meaningful among adults hospitalized with pancreatic cancer and was associated with advanced age, nutritional and functional vulnerability, acute illness severity, and socioeconomic disadvantage. These findings underscore the need for improved inpatient frailty recognition and targeted supportive care strategies. Research Sponsor: None.

Predictor of frailty in pancreatic cancer.

Predictors	Frail (%)	Non-frail (%)	p-value
Congestive heart failure	15.9	10.3	<0.001
Sepsis	22.8	17.0	<0.001
Underweight	24.6	9.1	<0.001

Baseline corticosteroid use and outcomes in non–small cell lung cancer patients receiving immune checkpoint inhibitors, stratified by indication. First Author: Angelina Lim, USC Keck School of Medicine, Department of Surgery, Los Angeles, CA

Background: Baseline systemic corticosteroids are often prescribed to patients with non-small cell lung cancer (NSCLC) initiating immune checkpoint inhibitors (ICIs). Prior studies associating steroids with reduced ICI efficacy have largely treated steroid exposure as binary without accounting for indication. We evaluated outcomes following baseline steroid use by indication. **Methods:** We conducted a retrospective cohort study using TriNetX, a federated research network of de-identified electronic medical records. Using approximately 7,000-12,000 patients per stratum, NSCLC patients initiating ICIs were stratified by presence of systemic steroid prescriptions within 30 days prior to ICI initiation by indication: brain metastases (BM), pulmonary disease (PD), autoimmune disease (AI), and palliative indications (PI). In each stratum, steroid-exposed patients were compared with propensity-matched steroid-naive controls adjusting for demographics, non-brain metastases, comorbidities, substance use, and prior cancer treatments. Outcomes included mortality, ICU admission, and infection at 1 month. **Results:** Baseline steroid use was associated with worse 1 month outcomes in an indication dependent manner. Among patients receiving steroids for BM, mortality was higher compared with controls (8.75% vs 5.46%; HR 1.62, 95% CI 1.44-1.82; $p < 0.001$), as were ICU admission (5.06% vs 2.80%; RR 1.81, 95% CI 1.53-2.14; $p < 0.001$) and infection (6.81% vs 4.20%; RR 1.62, 95% CI 1.40-1.88; $p < 0.001$). Similarly, among patients receiving steroids for PI, steroid use was associated with increased mortality (9.68% vs 5.29%; HR 1.87, 95% CI 1.69-2.06; $p < 0.001$), ICU admission (4.83% vs 2.65%; RR 1.82, 95% CI 1.57-2.12; $p < 0.001$), and infection (7.50% vs 4.21%; RR 1.78, 95% CI 1.56-2.03; $p < 0.001$). In contrast, steroid use for PD or AI was not associated with increased mortality. PD was associated with higher ICU admission (3.35% vs 2.61%; RR 1.29, 95% CI 1.10-1.51; p = 0.0027) and infection (6.31% vs 4.23%; RR 1.49, 95% CI 1.31-1.70; $p < 0.001$), while AI was associated with increased ICU admission (3.63% vs 2.68%; RR 1.36, 95% CI 1.11-1.65; p = 0.0039) but not increased infection risk. These survival patterns persisted at longer follow-up, with higher mortality among patients with BM and PI at 6 months (BM HR 1.40, 95% CI 1.32-1.48; $p < 0.001$; PI HR 1.40, 95% CI 1.33-1.47; $p < 0.001$), 1 year (BM HR 1.40, 95% CI 1.33-1.47; $p < 0.001$; PI HR 1.36, 95% CI 1.31-1.42; $p < 0.001$), and 5 years (BM HR 1.30, 95% CI 1.24-1.35; $p < 0.001$; PI HR 1.32, 95% CI 1.27-1.37; $p < 0.001$), while no long-term survival decrement was observed for PD or AI. **Conclusions:** Baseline steroid use prior to ICI initiation is associated with increased early and long-term mortality in NSCLC in BM and PI but not PD and AI. Accounting for clinical indication is important to understand real-world ICI outcomes of patients using steroids. Research Sponsor: None.

Cardiovascular-related adverse events (CVD-AEs) and echocardiographic (Echo) changes with immunotherapy (IT): A real-world experience. First Author: Ahmed Nabil Mohamed, Cleveland Clinic Foundation, Cleveland, OH

Background: Immune-checkpoint inhibitors (ICI) are standard of care for many solid tumors but are linked to cardiovascular adverse events (CVD-AEs). Real-world comparative data on CVD-AE incidence between IT & non-IT therapies are limited & no prior studies have evaluated longitudinal Echo changes in IT vs. non-IT patients. **Methods:** We conducted a retrospective cohort of 5,556 adults with solid malignancies at Cleveland Clinic Ohio (2010–2022). IT patients were compared to non-IT systemic therapy. Cancers included bladder (II-IIIA:476; IV:158), endometrial IV (157), gastric (II-III:797; IV:590), H&N IV (36), renal (III:88; IV:223), melanoma (45) & lung: NSCLC non-squamous (IIIB:206; IV:1609), NSCLC squamous (IIIB:182; IV:366) & SCLC IIIB-IV (623). Follow-up began at therapy start & continued until CVD-AE, last follow-up or death. Data were collected on demographics, CTCAE grade, management & outcomes. Incidence rates per 100 person-years (/100 Py) were estimated using Poisson regression, cumulative incidence (CIR) using Kaplan–Meier methods & adjusted hazard ratios (HRs) using time-dependent Cox models. Echo analyses (n = 418) compared baseline to follow-up studies using multinomial regression. **Results:** Of the cohort, 1,291 (23%) & 948 (17%) received 1st- & 2nd-line IT. Median age was 66; 38% were female, & 87% were White. ICI accounted for 99.9% of IT. During follow-up, 163 CVD-AEs occurred, including arrhythmias (n = 59), cardiac arrest (n = 35), myocarditis/heart failure (n = 21), pericarditis (n = 10) & acute coronary syndromes (NSTEMI n = 17, STEMI n = 15, unstable angina n = 5). Median follow-up was 14 months (CI 6-35). The CVD-AE CIRs were slightly higher in IT vs. non-IT groups (0.12 vs 0.11 /100 PY). The 4-year CIR was 5% in IT & 3.5% in non-IT (P = 0.4). In time-dependent Cox models, IT was not associated with a significant increase in composite CVD-AEs, though a borderline association with the composite of cardiac dysrhythmia & conduction disorders was observed (HR 1.43, P = 0.06). Echo analyses showed no association between IT & adverse changes in LV/RV systolic function (EF, GLS, TAPSE), pulmonary pressures or diastolic function (E/e'). In contrast, 1st-line IT was associated with increased odds of aortic root dilation (OR 2.95, p = 0.028), mitral valve sclerosis (OR 4.17, P = 0.02) & a trend toward mitral stenosis (OR 3.7, P = 0.05). Abnormal baseline Echo parameters remained the strongest predictors of future worsening. **Conclusions:** We found that IT was not associated with a significant rise in overall CVD-AEs or myocardial dysfunction, possibly reflecting less use of traditional cardiotoxic agents like anthracyclines. Novel associations with aortic root dilation & mitral valve sclerosis suggest vascular & structural remodeling effects. Findings highlight the need for long-term surveillance of structural heart changes beyond ejection fraction monitoring. Research Sponsor: None.

Socioeconomic and treatment-related determinants of long-term cancer survival: A population-based SEER outcomes analysis. First Author: Akhilesh Sharma, New York Medical College: St. Mary's/St Clare's, Denville, NJ

Background: Cancer survival is shaped by tumor biology, treatment access, and socioeconomic context, yet population-level quantification of long-term survival disparities related to chemotherapy use and income is limited. We assessed five-year cancer-specific survival across demographic, treatment, and socioeconomic strata in a national registry. **Methods:** We performed a retrospective, population-based survival analysis using the Surveillance, Epidemiology, and End Results (SEER) database. Cancer-specific survival was evaluated at 12, 24, 36, 48, and 60 months after diagnosis. Outcomes were stratified by sex, race, chemotherapy receipt, and area-level median household income categories. Survival estimates were summarized descriptively and visualized using time-to-event curves. **Results:** Overall cancer-specific survival declined progressively over five years, from ~84% at 12 months to ~58% at 60 months. Sex differences were minimal, with similar five-year survival among males and females (~57–58%). Racial disparities were substantial: Asian/Pacific Islander patients demonstrated the highest survival across follow-up, while Black and American Indian/Alaska Native patients had lower early survival and persistent gaps at five years. Patients with recorded chemotherapy use had improved survival compared with those without or with unknown chemotherapy status; 12-month survival was ~88% versus ~80%, and five-year survival was ~65% versus ~57%, respectively. A pronounced socioeconomic gradient was observed: individuals in areas with median household income $\geq$\$120,000 had higher five-year survival (~67%), whereas those in areas with income $<$ \$40,000 had markedly lower survival (~52%). **Conclusions:** In this national registry analysis, both chemotherapy utilization and higher socioeconomic status were strongly associated with improved long-term cancer survival, whereas persistent racial and income-related disparities remained evident. These findings highlight ongoing inequities in access to oncologic care and support the need for targeted policy interventions and equity-focused treatment delivery models. Interpretation should account for limitations inherent to observational registry data and potential residual confounding. Research Sponsor: None.

Impact of diabetes on respiratory infection risk and hospitalization following immune checkpoint inhibitor initiation in non–small cell lung cancer: A propensity-matched retrospective cohort analysis. First Author: Gurasis Singh Sodhi, Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Immune checkpoint inhibitors (ICIs) are a cornerstone of treatment for non-small cell lung cancer (NSCLC); however, patients with diabetes mellitus may have altered immune responses and higher susceptibility to infections. Data comparing infectious respiratory outcomes, healthcare utilization, and mortality between diabetic and non-diabetic NSCLC patients treated with ICIs is limited. We aimed to evaluate these outcomes in NSCLC patients receiving ICIs, stratified by diabetes status. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network. Adults ($\geq$18 years) diagnosed with NSCLC who initiated immune checkpoint inhibitor therapy (PD-1/PD-L1 or CTLA-4 inhibitors) within one year of diagnosis were included. Two cohorts were defined: patients with type 2 diabetes mellitus (DM) and patients without diabetes (non-DM). Propensity score matching (1:1) was performed based on demographics, comorbidities, cancer stage surrogates, smoking history, chemotherapy exposure, radiation therapy, and concurrent medications. Outcomes were assessed from 30 days to 3 years after ICI initiation and included bacterial pneumonia, viral pneumonia, severe sepsis with or without shock, ER visit/hospitalization, critical care needs, and overall survival. Hazard ratios (HRs) with 95% confidence intervals (CIs) were reported. **Results:** After propensity score matching, 905 patients were included in each cohort. Baseline characteristics were well balanced between groups. Compared with the non-DM cohort, patients with diabetes had a significantly higher risk of severe infectious complications, including bacterial pneumonia (HR 1.44, 95% CI 1.01–2.08), severe sepsis (HR 1.79, 95% CI 1.29–2.49). Rates of viral pneumonia did not significantly differ between groups (HR 0.79, 95% CI 0.45-1.38). Diabetic patients also demonstrated higher incidence of hospitalization (HR 1.17, 95% CI 1.05–1.30) and critical care utilization (HR 1.27, 95% CI 1.02–1.57). However, no statistically significant difference in overall survival between cohorts was detected (HR 1.12, 95% CI 0.98–1.29). **Conclusions:** Among NSCLC patients treated with immune checkpoint inhibitors, diabetes mellitus is associated with higher risk of respiratory infections and severe sepsis. Hospital visits and critical care utilization were more frequent in the diabetic cohort, without a corresponding difference in overall survival. These findings highlight the importance of heightened infection surveillance and proactive supportive care in diabetic patients undergoing immunotherapy. Prospective studies are warranted to better define underlying mechanisms and to optimize risk mitigation strategies in this vulnerable population. Research Sponsor: None.

Association between selective serotonin reuptake inhibitor use and outcomes in metastatic melanoma treated with immune checkpoint inhibitors: A real-world cohort study. First Author: Sandeep Kumar Jain, Atropos Health, New York, NY

Background: Immune checkpoint inhibitors (ICIs) have transformed outcomes for metastatic melanoma, yet substantial variability in response remains. Evidence suggests that concomitant medications may modulate antitumor immunity and influence ICI effectiveness. For example, recent mechanistic and translational studies indicate that selective serotonin reuptake inhibitors (SSRIs) enhance T-cell–mediated antitumor immunity and may synergize with PD-1 blockade, with preliminary clinical signals of improved survival. However, real-world evidence in melanoma is limited. We conducted a real-world cohort study to assess the association between baseline SSRI use and outcomes among metastatic melanoma patients treated with ICIs. **Methods:** We performed a retrospective cohort study using a nationally representative real-world dataset from the Atropos Evidence Network integrating open claims and EHR data mapped to OMOP CDM v5.3. Adults with metastatic melanoma treated with first-line pembrolizumab, nivolumab, or ipilimumab were identified using ICD and RxNorm codes. The index date was ICI initiation. The SSRI cohort required ≥30 days of use prior to index; comparators had no prior SSRI exposure. Patients were matched 1:1 using high-dimensional propensity scores (hdPS) derived from ICD, CPT, and RxNorm features and fitted with LASSO-regularized logistic regression. Outcomes included 1-year overall survival (OS), time to ICI discontinuation, ICI duration, and post-index steroid use. **Results:** Among 3,597 metastatic melanoma patients initiating ICIs, 307 had baseline SSRI exposure and 3,290 had no prior SSRI use. After 1:1 hdPS matching, 304 well-balanced pairs were identified. Baseline SSRI use was associated with a numerically lower but not statistically significant risk of death at 1 year (HR 0.70; 95% CI 0.46–1.06; p = 0.092). No significant difference in ICI discontinuation was observed between cohorts (HR 1.07; 95% CI 0.87–1.31; p = 0.53). Mean duration of ICI was similar in the propensity-matched analysis (158.7 days in no-SSRI vs 142.4 days in SSRI; mean difference −16 days; 95% CI −40 to 7.3; p = 0.175). Post-index steroid use also did not differ between groups (IRR 1.02; 95% CI 0.60–1.73; p = 0.94). Across all endpoints, effect estimates were consistent with no clinically meaningful association between baseline SSRI exposure and immunotherapy outcomes. **Conclusions:** In this large real-world analysis, baseline SSRI use was not associated with improved OS, reduced discontinuation, or increased steroid use among metastatic melanoma patients treated with ICIs. Despite strong mechanistic rationale suggesting potential synergy, these findings highlight a disconnect between preclinical observations and real-world outcomes. Prospective studies are needed to identify subpopulations that may benefit. Research Sponsor: None.

Novel myeloma therapy utilization in digital health advocacy users: A large US cohort analysis of >1,500 patients. First Author: Jay R. Hydren, HealthTree Foundation, Lehi, UT

Background: Real-world data consistently demonstrates that access to novel myeloma therapies (CAR-T and Bispecific Antibodies [BsAb]) is restricted by "classic" disparities, including lower income, rural geography, and distance from academic medical centers. However, evidence suggests that strong institutional support and patient navigation can mitigate these factors. While direct-to-patient platforms remain underexplored, high digital engagement—driven by education and medical data ownership—are hypothesized to mitigate traditional barriers. To evaluate this, the HealthTree Registry was queried to determine if its engaged cohort exhibits the disparities observed in the general population. **Methods:** A total of 1,519 Multiple Myeloma patients, diagnosed after 2014, and who connected their Electronic Health Records (EHR) and provided survey data within the HealthTree, were originally extracted. Line of treatment data was extracted from clinical plan and progress notes. Eligibility for novel therapies was retrospectively determined based on FDA approval criteria (lines of therapy and dates). Utilization rates comparisons against demographic variables using Chi-square and ANOVA tests. **Results:** Among the cohort, 277 patients were eligible for CAR-T and 91 for BsAbs. Contrary to general population trends, digital engagement appeared to neutralize classic socioeconomic barriers. We found no significant difference in novel therapy utilization based on median zipcode income (Users: $103k vs. Non-Users: $95k, p = 0.88), distance to clinic (p = 0.64), or rural/urban status (p = 0.808). Utilization rates: 30% (84/277) of eligible patients received CAR-T compared to 54% (49/91) for BsAbs. Patients receiving novel therapies had a mean age of 65.9 years and initiated treatment 3.7 years after diagnosis. BsAbs were utilized later in the disease course (Mean Line of Therapy [LOTs]: 6.0) compared to CAR-T (Mean Line of Therapy: 4.8), due to FDA eligibility criteria restrictions. CAR-T utilization was high during early LOTs (2-4) at 48%. While economic and geographic barriers were mitigated, a significant gender disparity emerged in continuous therapy usage. For BsAbs, 66% (33/50) of eligible men received therapy, compared to only 39% (16/41) of eligible women (p = 0.018). No gender difference was observed for CAR-T (p = 1.0). **Conclusions:** In this cohort, although a greater proportion of patients met eligibility criteria for CAR-T than for BsAb, eligible patients were more likely to initiate BsAb treatment. However, digital engagement of patients facilitated early use of CAR-T therapy and reduced traditional barriers like distance and income, which may be less limiting than previously thought. In contrast, a pronounced gender disparity in BsAb therapy utilization suggests that continuous therapies may impose a disproportionate logistical burden on eligible female patients. Research Sponsor: HealthTree Foundation.

Trends and disparities in diabetes-associated cancer mortality in the United States, 1999–2020. First Author: Kashish Magnani, Westchester Medical Center, Valhalla, NY

Background: Diabetes mellitus (DM) is increasingly recognized as an important contributor to cancer mortality, yet long-term population-level trends and sociodemographic disparities in diabetes-associated cancer deaths in the United States remain insufficiently characterized. **Methods:** We analyzed U.S. Multiple Cause of Death data from the CDC WONDER database for 1999–2020. Deaths with neoplasia as the underlying cause of death and diabetes mellitus listed as a contributing cause were included. Annual deaths and crude mortality rates were examined across year, Census region, state, 2013 urbanization level, 10-year age groups, sex, race, and Hispanic origin. Temporal trends were quantified using average annual percent change (AAPC) derived from log-linear regression models over the 1999–2020 period. **Results:** From 1999–2020, diabetes-related neoplasia deaths totaled 588,693 (mean 26,759/year), with annual deaths rising 77.9% (20,427 in 1999 to 36,343 in 2020) and crude mortality increasing 50.7% (7.3 to 11.0 per 100,000), corresponding to an overall AAPC +1.24%/year. By sex, trends increased faster in males (AAPC +1.75%) than females (AAPC +0.55%). By Census region, AAPC was highest in the West (+2.00%) and South (+1.98%), followed by the Midwest (+0.65%), while the Northeast declined (−0.30%). By 2013 urbanization, the steepest rises occurred in Noncore nonmetro (+2.43%) and Micropolitan nonmetro (+1.61%), exceeding Medium metro (+1.54%), Small metro (+1.22%), Large central metro (+0.97%), and Large fringe metro (+0.80%). By race, AAPC was highest for American Indian/Alaska Native (+2.38%) and Asian/Pacific Islander (+2.30%), followed by White (+1.45%) and Black (+0.30%). By Hispanic origin, AAPC was higher in Hispanic/Latino (+2.42%) than Not Hispanic/Latino (+1.33%) (Not stated: insufficient rate series for AAPC). By age, increases were greatest at 35–44 years (+1.45%) and 25–34 years (+1.18%), with smaller increases at 45–54 (+0.62%) and ≥85 (+0.62%), while older mid-life groups declined (65–74: −0.61%, 55–64: −0.27%, 75–84: −0.04%). State-level AAPC ranged from Kentucky (+6.55%), Arizona (+5.07%), Oklahoma (+4.81%), Colorado (+4.66%), and Arkansas (+4.61%) to District of Columbia (−3.44%), Connecticut (−2.91%), Massachusetts (−1.88%), Illinois (−1.38%), and Delaware (−1.24%). **Conclusions:** Diabetes-associated cancer mortality increased substantially in the United States from 1999–2020, with widening disparities by geography, urbanization, race/ethnicity, sex, and age. The disproportionate rise in rural areas, younger adults, and select racial and ethnic groups underscores the need for integrated cancer–diabetes prevention strategies and targeted public health interventions to mitigate future mortality burden. Time-dependent patterns of immune-related adverse events by obesity status following immune checkpoint inhibitor therapy: A real-world cohort analysis. First Author: Bibek Shrestha, The University of Toledo, Toledo, OH

Background: Immune checkpoint inhibitors (ICIs) substantially improve cancer outcomes but are frequently complicated by immune-related adverse events (irAEs). Obesity alters immune regulation and has been paradoxically associated with enhanced ICI efficacy; however, its influence on the timing and persistence of irAEs remains poorly defined. Prior studies have largely evaluated irAEs as binary outcomes, potentially obscuring time-dependent risk patterns. **Methods:** We conducted a retrospective cohort study using the TriNetX U.S. Collaborative Network. Adults with solid tumors initiating nivolumab, pembrolizumab, ipilimumab, or durvalumab were identified. Patients with pre-existing autoimmune disease, hematologic malignancy, organ transplantation, or prior irAEs were excluded. Patients were stratified by baseline body mass index (BMI ≥30 kg/m² vs 20–24.9 kg/m²). irAEs were identified using diagnosis-based groupings mapped to organ-specific toxicity categories. Survival analyses were performed using landmarked Cox proportional hazards models evaluating early (1–90 days), delayed (91–365 days), and late (366–1825 days) irAE risk. Adjusted hazard ratios (AHR) were calculated after adjustment for age, sex, cancer type, immunotherapy agent, smoking status, diabetes, chronic kidney disease, chronic pulmonary disease, liver disease, and cardiovascular comorbidity. **Results:** Among 29,564 eligible patients (obese: 13,958; normal BMI: 15,606), obesity was not associated with overall irAE risk across 5 years of follow-up (AHR 0.98, p=0.19). In landmark analyses, obesity was associated with lower early irAE risk (AHR 0.94, p=0.003), no significant difference during the delayed period, and a persistent increase in late irAE risk (AHR 1.11, p=0.003).Time-stratified associations were most pronounced for gastrointestinal, renal, endocrine, and dermatologic irAEs, while pulmonary and neurologic irAEs were not significantly increased after multivariable adjustment. **Conclusions:** Obesity demonstrated a time-dependent association with immune-related toxicity following ICI therapy, characterized by attenuated early risk and persistent late risk emerging beyond one year. These findings highlight the importance of time-stratified analytic approaches and suggest that absence of early irAEs may not confer long-term safety in obese patients receiving ICIs. Patterns of upper endoscopy use prior to gastric cancer diagnosis among high-risk populations. First Author: Rohit Khullar, Tufts Medical Center, Boston, MA

Background: Gastric cancer is frequently diagnosed at advanced stages in the United States, contributing to poor survival. Although several populations carry elevated risk, real-world patterns of upper endoscopic evaluation before gastric cancer diagnosis remain poorly characterized. Understanding pre-diagnostic endoscopy utilization may identify gaps in care and inform future evaluation strategies. **Methods:** A retrospective cohort study using Epic SlicerDicer identified adults ≥18 years diagnosed with gastric adenocarcinoma at Tufts Medical Center between January 2021 and January 2026. Gastric cancer was identified by ICD-10 codes, excluding patients with prior disease. Upper endoscopy (EGD) performed 6–36 months before diagnosis was assessed overall and across high-risk subgroups. EGDs within 6 months were excluded to distinguish pre-diagnostic from index diagnostic procedures. High-risk features were defined by the 2025 AGA Clinical Practice Update and included Asian race, Hispanic ethnicity, interpreter requirement, and prior *Helicobacter pylori* infection, gastric intestinal metaplasia (GIM), or chronic atrophic gastritis (CAG). Rates of pre-diagnostic EGD utilization were described overall and by subgroup. **Results:** Among 258 patients diagnosed with gastric adenocarcinoma, 77 (29.8%) presented with metastatic disease. Overall, 118 patients (45.7%) underwent EGD 6–36 months before diagnosis, while approximately half had their first documented EGD at the time of cancer diagnosis. Rates were similar across racial groups: White (45.3%), Asian (46.3%), Black (43.8%), and Other (45.7%). Utilization was higher among Hispanic versus non-Hispanic patients (57.7% vs 46.2%) and among those requiring interpreter services (51.8% vs 47.0%). Patients with gastric precursor conditions (34.1%) had similar rates of pre-diagnostic EGD (52.3%), including prior *H. pylori* infection (40.0%), GIM (63.3%), and CAG (55.0%). Of 140 patients without pre-diagnostic EGD, 39 (27.9%) underwent colonoscopy alone, indicating access to endoscopic care without concurrent EGD. **Conclusions:** Most upper endoscopies occurred near the time of cancer diagnosis, suggesting predominantly diagnostic rather than preventive evaluation. Even among patients with recognized risk factors and gastric precursor conditions, only about half underwent prior upper endoscopic assessment. Colonoscopy without concurrent EGD highlights gaps in integrated, risk-based gastrointestinal cancer prevention and an opportunity to improve earlier recognition of gastric cancer in high-risk populations. Research Sponsor: None.

Upper endoscopy use before gastric cancer diagnosis.

High-Risk Feature	Total (N)	Total (%)	% w/ EGD (6–36 mo)
Overall population	258	–	45.7
Asian race	67	26.0	46.3
Hispanic ethnicity	26	10.1	57.7
Requires interpreter	56	21.7	51.8
***H. pylori* infection**	35	13.6	40.0
GIM	60	23.3	63.3
CAG	20	7.8	55.0
Any *H. pylori*, GIM, or CAG	88	34.1	52.3

Distinct patient and product-specific phenotypes associated with toxicity and resource utilization after CAR T-cell therapy: A Nationwide Inpatient analysis. First Author: Ayodeji David Johnson, Boston Medical Center - Brighton, Boston, MA

Background: Chimeric antigen receptor (CAR) T-cell therapy improves outcomes in relapsed or refractory hematologic malignancies but is associated with significant toxicity and inpatient resource utilization. Nationally representative real-world data remain limited. We evaluated the incidence, phenotype-specific predictors, and inpatient consequences of CAR T-cell–related toxicities in U.S. practice. **Methods:** We conducted a retrospective cohort study using the 2023 Nationwide Inpatient Sample, identifying adult elective hospitalizations involving CAR T-cell infusion using ICD-10-PCS New Technology Group 7 codes for FDA-approved CAR-T therapies. Interhospital transfers were excluded. Cytokine release syndrome (CRS), immune effector cell–associated neurotoxicity syndrome (ICANS), and cytopenias were identified using ICD-10-CM codes during the index hospitalization; toxicity grade was unavailable. Functional status was assessed using APR-DRG loss of function severity. Primary outcomes were coded in-hospital CRS, ICANS, and cytopenias. Secondary outcomes included transfusion requirement, length of stay (LOS), and total inpatient cost, adjusted to 2023 U.S. dollars. Survey-weighted multivariable regression models evaluated predictors of toxicity and resource utilization. **Results:** The weighted cohort represented 3,405 CAR-T hospitalizations nationwide. Indications included multiple myeloma (42.6%), diffuse large B-cell lymphoma (32.0%), follicular lymphoma (9.0%), mantle cell lymphoma (8.6%), B-cell acute lymphoblastic leukemia (7.4%), and chronic lymphocytic leukemia (0.4%). Cytopenias were coded in 45.2% of hospitalizations, CRS in 62.6%, and ICANS in 30.1%. In adjusted analyses, cytopenias were associated with older age, B-cell acute lymphoblastic leukemia, moderate-to-severe functional impairment, and CAR-T product type. CRS risk varied by CAR-T product type and was higher among transplant recipients and patients with severe functional impairment. ICANS was associated with transplant history, selected comorbidities (including metastatic solid tumors), follicular lymphoma, older age, and CAR-T product type. Median LOS was 12 days (IQR, 9–16) and was longer among patients with neutropenia. Transfusion support was required in 6.6% of hospitalizations. Median total inpatient hospitalization cost exceeded $1.3 million and was independently associated with diffuse large B-cell lymphoma, B-cell acute lymphoblastic leukemia, neutropenia, and autologous leukapheresis. **Conclusions:** CAR T-cell therapy is associated with substantial inpatient toxicities, prolonged hospitalization, and high cost, with risk varying by patient and product specific phenotypes. These findings support pre-infusion risk stratification and resource-aligned inpatient care models for CAR-T delivery. Research Sponsor: None.

Bridging the gap between clinical utility and coverage: Real-world impact of unreimbursed NGS testing. First Author: Madhuri Paul, NeoGenomics Laboratories Inc., Fort Myers, FL

Background: Genomic testing is the cornerstone of precision oncology, revealing rare yet clinically actionable alterations that define diagnosis, risk stratification, and treatment choice. Despite its proven clinical utility, inconsistent coverage and inadequate reimbursement constrain routine use, reflecting a persistent misalignment between clinical value and payer policy. Evaluating real-world utilization and clinical impact of unreimbursed testing can highlight critical gaps in standard oncology care. **Methods:** Molecular profiles of 7,271 patients were analyzed by integrating Neogenomics sequencing data (09/2025 – 12/2025) with standardized clinical data (cancer diagnoses, ICD-10 codes, medication records, molecular testing results) extracted from comprehensive electronic medical records using the xCures platform. **Results:** Cohort of 7,271 patients insured by commercial (58%), managed (22%), or government (20%) plans had unreimbursed tests with orders originating primarily from hospitals (49%) and physician groups (42%). Testing predominantly targeted hematologic malignancies (> 90%), with solid tumors representing 8%. Among patients with available medical records (n = 3,409), hematologic panels remained most common (67%), led by the Neo Comprehensive Myeloid (n = 1,064), NeoTYPE MDS/CMML Profile (n = 485), Neo Comprehensive Heme (n = 385), NeoTYPE CLL Profile (n = 299) and NeoTYPE Lymphoid Disorders Profile (n = 211). Abnormal molecular findings were identified in 1,056 patients (%), including 470 patients with pathogenic or likely pathogenic variants (SNVs, deletions, insertions, fusions and substitutions), with 23% (104/470) of alterations (i.e. ABL1, ERBB3, KDR, MAP2K1, TOP1, TSC1, TSC2) not identified by previous methods. Of 66 patients receiving targeted therapy after testing, 4 (6%) were treated within 60 days for pathogenic alterations (, JAK2, KIT, BCR-ABL1) identified by Neogenomics. Eleven (17%), initially with unspecified diagnoses, received therapies (venetoclax, obinutuzumab, lenalidomide) for newly defined indications, and 2 (3%) were treated (venetoclax, lenalidomide) based on relevant biomarkers (NPM1, SF3B1) of sensitivity, all guided by test results within 60 days. Among 386 patients with initially unspecified conditions, EMR for 137 patients (36%) confirmed diagnoses within 60 days. **Conclusions:** Genomic testing delivers substantial clinical value by enabling rapid, definitive diagnoses and informing timely, targeted treatment decisions. Despite inconsistent payer coverage, these data show that NGS testing frequently identifies actionable alterations and biomarkers not previously identified by standard testing that directly impact patient management. Aligning reimbursement policies with anticipated clinical utility is critical to closing gaps in standard care and expanding equitable access to precision oncology. Research Sponsor: None.

Early mortality and hospitalization following cholangiocarcinoma diagnosis by statin exposure: A TriNetX real-world analysis. First Author: Reshma John, St Joseph's University Medical Center, Paterson, NJ

Background: Statins are widely prescribed among patients with cardiometabolic comorbidities and are frequently continued at the time of cancer diagnosis. While statins have been hypothesized to exert antitumor and immunomodulatory effects, real-world data evaluating early clinical outcomes associated with statin exposure in patients with cholangiocarcinoma are limited. We assessed short-term mortality and hospitalization outcomes following cholangiocarcinoma diagnosis using a large federated electronic health record network. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, comprising 68 healthcare organizations. Adult patients (≥18 years) diagnosed with intrahepatic bile duct carcinoma (ICD-10 C22.1), extrahepatic bile duct carcinoma (C24.0), or ampullary carcinoma (C24.1) between January 1, 2010, and December 11, 2024 were included. Patients were classified based on exposure to statins (rosuvastatin, simvastatin, fluvastatin, pravastatin, lovastatin, atorvastatin, or pitavastatin) within a prespecified temporal window relative to cancer diagnosis, with the index event defined accordingly. Propensity score matching (1:1) was performed to balance demographics, comorbidities, and laboratory characteristics, mitigating confounding by indication and immortal time bias. Outcomes included all-cause mortality, hospitalization, and sepsis at 30 and 90 days following the index event. Risk estimates and Kaplan–Meier survival analyses were performed. **Results:** After propensity score matching, baseline characteristics were well balanced between statin-exposed and non–statin-exposed cohorts. At 30 days following diagnosis, statin exposure was not associated with a significant difference in all-cause mortality. In contrast, at 90 days, statin exposure was associated with higher all-cause mortality (risk ratio 1.23; hazard ratio 1.30; log-rank P = .012) and increased hospitalization (risk ratio 1.29; hazard ratio 1.37). No significant differences in sepsis risk or hazard were observed between cohorts at either time point. **Conclusions:** In this real-world, propensity score–matched analysis of patients with cholangiocarcinoma, statin exposure was not associated with improved 30-day survival and was associated with higher 90-day mortality and hospitalization. Although causality cannot be inferred, these findings highlight clinically meaningful early outcome differences during the peri-diagnostic period and suggest that commonly prescribed cardiovascular medications may identify patients with increased baseline vulnerability at the time of cancer diagnosis. Future work integrating medication exposure with comorbidity burden, treatment patterns, and early care trajectories may help refine risk stratification during initial cholangiocarcinoma management. Research Sponsor: None.

Osteoporosis and osteoporosis-related fractures among older male cancer patients: A nationwide study. First Author: Tasneem Anagreh, Saint Francis Hospital, Evanston, IL

Background: Osteoporosis is commonly viewed as a disease of postmenopausal women, leading to significant underdiagnosis in men. Older male patients with cancer experience accelerated bone loss due to androgen deprivation therapy, corticosteroid exposure, and malignancy-related skeletal remodeling. We examined the prevalence, tumor-specific risk factors, and outcomes of osteoporosis and related fractures in a national cohort of older male cancer patients. **Methods:** We analyzed Nationwide Readmissions Database hospitalizations from 2019–2022, identifying male patients aged ≥60 years with malignancy. Primary outcomes were osteoporosis (ICD-10-CM M80/M81) and major osteoporotic fractures (hip, spine, humerus, wrist); isolated hip fracture was a secondary outcome. Survey-weighted multivariable logistic regression models identified independent predictors, adjusting for age, cancer type, metastatic status, and clinical risk factors. **Results:** Among an estimated 5.17 million weighted cancer admissions, 2.79 million occurred in males. Osteoporosis was diagnosed in 1.29% of males versus 7.16% of females ($P< 0.001$); mean age at diagnosis was 76.5 vs 78.0 years. Men with osteoporosis had markedly higher fracture rates than those without, including hip fracture (5.11% vs 0.85%) and any major fracture (8.36% vs 1.60%) (all $P< 0.001$). In multivariable analysis, odds of osteoporosis diagnosis increased with age (OR 1.06 per year, $P< 0.001$). Diagnoses were most strongly associated with multiple myeloma (OR 1.63), prostate cancer (OR 1.33) (both $P< 0.001$), and leukemia (OR 1.16, $P= 0.008$). Hypogonadism (OR 4.77), hyperparathyroidism (OR 3.53), vitamin D deficiency (OR 2.51), and tobacco use (OR 1.08; $P= 0.009$) were independent clinical predictors. In fracture models, prior osteoporosis diagnosis was the strongest predictor of any major fracture (OR 4.11) and hip fracture (OR 2.41) (both $P< 0.001$). Modifiable risks, including tobacco use (OR 1.55–1.61) and vitamin D deficiency (OR 1.68–1.88) (both $P< 0.001$), consistently increased fracture risk. Prostate cancer increased odds of both major (OR 1.11) and hip fractures (OR 1.21) ($P< 0.001$), whereas multiple myeloma increased odds of major fracture (OR 1.19, $P= 0.004$) but was associated with lower odds of hip fracture (OR 0.80, $P= 0.03$). **Conclusions:** Older men with cancer face substantial, under-recognized risk for osteoporosis and fracture-related morbidity. Tumor-specific patterns and modifiable clinical factors identify clear opportunities for earlier risk assessment and integration of bone health strategies into routine oncologic care. Research Sponsor: None.

Sepsis severity and inpatient outcomes in metastatic cancer: A National Inpatient Sample study. First Author: Davin Turku, The Brooklyn Hospital Center, Brooklyn, NY

Background: Sepsis is a major driver of acute decompensation and inpatient death in patients with cancer, with particularly poor outcomes reported among severe sepsis and septic shock. We evaluated national associations between sepsis severity and inpatient outcomes among metastatic cancer hospitalizations. **Methods:** We conducted a retrospective cross-sectional analysis of the National Inpatient Sample (2016–2020). Adult hospitalizations with metastatic cancer were identified using ICD-10-CM codes C77–C79. Sepsis severity was categorized as no sepsis, severe sepsis without shock, or septic shock using ICD-10 diagnosis codes. Survey-weighted multivariable logistic regression estimated adjusted odds ratios (aOR) for in-hospital mortality, mechanical ventilation, and ICU utilization. Survey-weighted linear regression estimated adjusted differences in length of stay (LOS) and total charges. Models adjusted for age group, sex, race/ethnicity, primary payer, hospital bed size, hospital region, and comorbidity burden using vwcheck (van Walraven score derived from Elixhauser comorbidities). **Results:** In the complete-case regression cohort (weighted N=1,011,365), severe sepsis was associated with higher in-hospital mortality versus no sepsis (aOR 1.49, 95% CI 1.44–1.54), and septic shock with markedly higher mortality (aOR 4.75, 95% CI 4.63–4.87). Sepsis severity strongly predicted escalation of care: mechanical ventilation (severe sepsis aOR 1.37, 95% CI 1.24–1.50; septic shock aOR 6.31, 95% CI 5.93–6.71) and ICU utilization (severe sepsis aOR 1.07, 95% CI 1.03–1.11; septic shock aOR 6.44, 95% CI 6.26–6.62). Relative to the Northeast, adjusted mortality odds were lower in the Midwest (aOR 0.72), South (aOR 0.77), and West (aOR 0.81). Septic shock was associated with higher resource use (+1.38 LOS days; +$56,975 charges). **Conclusions:** In hospitalized patients with metastatic cancer, increasing sepsis severity was independently associated with stepwise increases in mortality, need for ICU-level care, and healthcare utilization. Patients with septic shock represented a particularly high-risk subgroup, with markedly elevated mortality and resource use even after adjustment for comorbidity burden. These findings emphasize that sepsis, rather than malignancy alone, is a major driver of inpatient outcomes in advanced cancer and highlight the importance of early recognition and timely escalation of supportive care for this vulnerable population. Research Sponsor: None.

Association of sepsis severity with inpatient outcomes among metastatic cancer hospitalizations (NIS 2016–2020).

Outcome	Severe sepsis (aOR or Δ, 95% CI)	Septic shock (aOR or Δ, 95% CI)
In-hospital mortality	1.49 (1.44–1.54)	4.75 (4.63–4.87)
Mechanical ventilation	1.37 (1.24–1.50)	6.31 (5.93–6.71)
ICU utilization	1.07 (1.03–1.11)	6.44 (6.26–6.62)
Length of stay, days	−0.42	+1.38
Total hospital charges, $	−3,325	+56,975

Real-world utilization and outcomes of lenalidomide in MDS with low blasts and isolated deletion 5q (MDS w 5q). First Author: Krishna Sajeev, Rochester General Hospital, Rochester, NY

Background: Lenalidomide is the preferred first-line agent for lower risk MDS w 5q. It is associated with higher rates of transfusion independence and cytogenetic remission and has demonstrated survival benefit in selected clinical trial populations. Large nationwide studies are lacking in this subgroup. **Methods:** We identified adults aged > 18 years with MDS w 5q diagnosed between 2006 and 2021 using the National Cancer Database (NCDB), corresponding to Lenalidomide approval. Demographic, socioeconomic characteristics, insurance status, Charlson-Deyo comorbidity index (CCI), and treatment variables were extracted. The primary outcome was receipt of lenalidomide therapy. Secondary outcomes included overall survival (OS). Patients were categorized into pre-Affordable Care Act (ACA) and post ACA periods. Multivariable logistic regression and relative risk models were used. OS was estimated using Kaplan-Meier methods and differences between groups were compared with log-rank tests. Multivariable Cox proportional hazards model was used to assess factors associated with survival. $P < 0.05$ was considered significant. **Results:** We identified 3,328 individuals with MDS w 5q, median age of 77 years; 56.1% were women. The majority were non-Hispanic white 87%, followed by 6% non-Hispanic blacks and 4% Hispanic patients. Predominant insurance type was Medicare (78.3%). CCI score of 2 and higher was present in 15%. Overall, 21% of patients received Lenalidomide. Utilization increased significantly in the post-ACA, compared with pre-ACA (32% vs 12%, $p < 0.001$). On multivariable analysis, post -ACA period was independently associated with higher odds of Lenalidomide receipt (OR 3.01-4.34, $P < 0.001$), while Medicaid was associated with lower likelihood of treatment compared with Medicare (OR 0.26-0.96, p = 0.04). Other demographic and socioeconomic variables were not independently associated with treatment receipt. Median OS for the overall cohort was 15.7 months. In multivariable Cox analysis, worse OS was associated with age > 80 (HR 1.0; ref = 61-70), receipt of chemotherapy (HR 1.35) and increasing commodity burden [CDS: HR 1.27; CDS: 2 HR 1.45, CDS 3: HR 1.95; all $p < 0.001$). Female sex was associated with improved survival(HR 0.76; $p < 0.001$). Lenalidomide receipt was not independently associated with OS after adjustment (HR 1.05; p = 0.27). **Conclusions:** This is the largest study evaluating receipt of lenalidomide in MDS with 5q deletion. Lenalidomide utilization increased substantially following ACA implementation, leading to improved access to disease modifying therapy. However, Medicaid insurance was associated with lower treatment receipts. Survival outcomes were primarily driven by age, commodity burden and treatment intensity rather than Lenalidomide receipt, highlighting persistent disparities and limitations of registry-based analysis. Research Sponsor: None.

TPS11199 **Poster Session**

A phase II, single-arm, exploratory study of GEMOX combined with tislelizumab and donafenib in the perioperative treatment of potentially resectable intrahepatic cholangiocarcinoma with high recurrence risk. First Author: Sulai Liu, People's Hospital of Hunan Province, Changsha, China

Background: Biliary tract cancer (BTC) is characterized by strong invasiveness and poor prognosis, with a metastasis and recurrence rate of up to 67% within 1 year after surgery and a 5-year overall survival rate of only 5%~15%. Among BTC subtypes, intrahepatic cholangiocarcinoma (ICC) accounts for a relatively high proportion, and its unique biological behaviors result in persistently high postoperative recurrence risk, which seriously endangers patients' life and health. Currently, major guidelines recommend that patients with potentially resectable ICC at high recurrence risk participate in clinical trials to explore optimal treatment strategies. For patients evaluated as "technically resectable but with high-risk recurrence" before surgery, clinical practice has shown that neoadjuvant therapy can effectively eliminate micrometastases and reduce the difficulty of R0 resection; postoperative adjuvant therapy can further prevent recurrence. Therefore, we innovatively propose a perioperative treatment model aimed at breaking through the existing therapeutic predicament. **Methods:** This study is a phase II, single-arm, exploratory study with a fixed sample size of 20 patients. The inclusion criteria are intrahepatic cholangiocarcinoma (ICC) (TNM stage T1-4, N0-1, M0)based on preoperative assessment, initial technical resectability per imaging, and at least one high - risk recurrence factor. High-risk recurrence factors include: tumor diameter >5 cm, regional lymph-node positivity, satellite/multifocal lesions, radiological suspicion of diaphragmatic adhesion, CA19-9 >200 U/ml, and an anticipated surgical margin <1 cm on pre-operative imaging. Treatment involves two 21 - day cycles of GEMOX (gemcitabine 1000mg/m² on day 1 and 8, oxaliplatin 100mg/m² on day 1) with tislelizumab (200mg on day 1) and donafenib (0.2g orally twice daily). If investigators confirm patients meet surgical criteria (R0 resection expected), surgery follows 1 - 2 weeks post - treatment. Post - surgery, adjuvant therapy starts within 5 weeks. The regimen is capecitabine (1250mg/m² orally twice daily on days 1 -14) or S - 1 (40 -60mg orally twice daily on days 1 -14, weight - adjusted) plus tislelizumab (200mg on day 1) and donafenib (0.2g orally twice daily), repeated every 21 days for six cycles. Primary endpoint is event - free survival (EFS). Secondary endpoints are objective response rate (ORR) and disease control rate (DCR) per RECIST1.1, R0 resection rate, major pathological response rate(MPR, the proportion of patients who underwent radical surgery and had ≤10% residual viable tumor in the postoperative specimen), treatment completion rate, overall survival (OS), disease - free survival (DFS), and safety (treatment - related adverse events' incidence and severity). Clinical trial information: ChiCTR2500112067. Research Sponsor: Suzhou Zelgen Biopharmaceuticals Co., Ltd.; BeOne Medicines.

TPS11200 **Poster Session**

Design of an innovative clinical development program using randomized controlled phase 2 trial data and real-world evidence from an expanded access protocol to assess mifomelatide (TCMCB07) in GI cancer cachexia. First Author: Allison Gardner, Endevica Bio, Northbrook, IL

Background: Cachexia is common in GI cancers, occurring in ~50% of patients with colorectal cancer (CRC) and up to 80% of patients with pancreatic ductal adenocarcinoma (PDAC). Resulting muscle mass and energy store depletion reduces chemotherapy tolerance, often leading to dose reductions, treatment delays/discontinuation, and poorer survival outcomes (Franko J, *Eur J Cancer*; 2022:174; Dunne RF, *J Cachexia Sarcopenia Muscle*. 2024;15:1628). Therefore, body weight preservation during chemotherapy may improve treatment effectiveness and outcomes for patients with GI cancer. The central melanocortin (MC) system, including MC3 and MC4 receptors, plays essential roles in regulating appetite, body mass, and energy homeostasis and is a logical therapeutic target to prevent and treat cachexia. Mifomelatide is a novel peptide MC3R/MC4R dual antagonist that is being studied for cancer and chemotherapy-associated weight loss. Our previously published work showed that mifomelatide was safe and effectively ameliorated cancer- and chemotherapy-associated cachexia in preclinical studies of mice, rats, and pet dogs. In a Phase 1 trial, healthy volunteers tolerated mifomelatide and did not experience vital sign or CV abnormalities or drug-related SAEs; they also experienced a modest increase in body weight and hunger compared with placebo. These findings warranted further clinical development of mifomelatide. **Methods:** The mifomelatide clinical development program is designed to generate a multidimensional body of evidence from clinical trial and real-world datasets that span GI cancer types and cachexia stages. First, a randomized, double-blind, placebo-controlled Phase 2 trial is evaluating mifomelatide's effects in 120 patients with newly diagnosed mCRC and pre-cachexia or early weight loss (NCT06937177). Additionally, an intermediate-size Expanded Access Protocol (EAP) was cleared by the US Food and Drug Administration in January, 2026 to make mifomelatide available to 100 eligible cachectic PDAC patients (NCT number pending). In addition to providing mifomelatide for compassionate use to patients with PDAC who have high unmet need and no approved treatment options for their cancer cachexia, the EAP will also facilitate the collection of real-world data that, when combined with findings from the Phase 2 trial, will deepen our understanding of mifomelatide's safety, tolerability, and potential to optimize body weight in patients with GI cancer. Collectively, our innovative hybrid approach to the mifomelatide clinical development program will generate robust insights into the benefit–risk profile of MC3R/MC4R dual antagonism with mifomelatide to treat cachexia across GI cancers and guide key design considerations for a subsequent pivotal trial. Clinical trial information: NCT06937177. Research Sponsor: Endevica Bio, Inc.

TPS11201 **Poster Session**

Economic burden of non-approved alternative therapies among patients with stage IV cancer: A prospective observational study. First Author: Arpana Ashok, Mercy Hospital, Fort Smith, AR

Background: Complementary and alternative therapies, including herbal supplements and over-the-counter medications, are used by 9 to 81% of cancer patients post-diagnosis to alleviate symptoms, side effects, anxiety, depression, or to gain a sense of control. Prior studies suggest higher use among younger, female patients with higher socioeconomic status. However, in our institutional practice, we did not observe any specific pattern on alternative medicine use. Additionally, the financial burden (financial toxicity) of these often-out-of-pocket expenses remains understudied in advanced cancer populations. This prospective observational study aims to assess the financial toxicity and describe patterns of use of non-approved alternative therapies among patients with stage IV cancer. **Methods:** This is a prospective, single-center, observational study conducted at Mercy Clinic Oncology, Fort Smith, AR. Eligible patients are aged $\geq$18 years, diagnosed with any stage IV cancer, and currently receiving systemic therapy. Key exclusions include the inability to read/understand English, incarcerated patients, and patients only on supportive care. A convenience sample of 150 patients will be enrolled for initial analysis with plans to expand the study to a multi-institutional format. Patients meeting eligibility criteria are identified via clinic schedule review and approached in person by a research nurse. Interested patients receive a study information sheet and complete a one-time, anonymous, paper-based survey (approximately 5 minutes) either in-clinic or at home (returned at next visit). The survey includes 6 demographic/cancer/treatment questions and 6 questions on use of specific non-approved alternative therapies and estimated average monthly costs (categorized as $<$ \$25, \$26–\$50, \$51–\$100, $>$ \$100). A specific question on marijuana addresses use for cancer cure (recreational/symptom control categorized as "no"); responses are anonymous with no PHI collected to minimize risk. Analysis will use descriptive statistics (frequencies/percentages) for cost patterns (primary outcome) and therapy types (secondary outcome), with chi-squared tests for subgroup comparisons by demographics. Enrollment started beginning of January 2026, and in two weeks, nine patients were identified and approached, with seven patients completing the survey. No preliminary data are available. Clinical trial information: Not applicable (IRB-approved observational protocol 24-062). Research Sponsor: None.

TPS11202 **Poster Session**

A pragmatic, hybrid observational study evaluating the effectiveness of trastuzumab deruxtecan (T-DXd) in patients with human epidermal growth factor receptor 2 (HER2) immunohistochemistry (IHC) 3+ solid tumors: DESTINY-PanTumor04. First Author: Bradley J. Monk, Late-Phase Clinical Research, Florida Cancer Specialists and Research Institute, West Palm Beach, FL

Background: Patients with advanced or metastatic HER2 IHC 3+ solid tumors have limited treatment options beyond first-line settings, with generally poor outcomes. T-DXd is a HER2-directed antibody-drug conjugate approved in multiple countries, including in the US for patients with unresectable or metastatic HER2-positive (IHC 3+) solid tumors who have received prior treatment and have no satisfactory alternative therapies. Building on existing clinical trial data, DESTINY-PanTumor04 evaluates the real-world effectiveness of T-DXd in HER2-positive (IHC 3+) solid tumors, using a hybrid data collection approach that enhances efficiency for sites and physicians and facilitates study implementation. **Methods:** DESTINY-PanTumor04 (NCT07124000) is a multicenter, pragmatic observational, real-world study evaluating the effectiveness of T-DXd (5.4 mg/kg IV Q3W) in adult patients in the US with previously treated, locally advanced, unresectable, or metastatic HER2-positive (IHC 3+ by local testing) solid tumors. Data collection will use a hybrid approach, combining primary data collection of baseline tumor burden, comorbidities, ECOG status, treatment response, and survival, with secondary data collection from electronic health record (EHR) abstraction for all other data. Approximately 100 patients will be enrolled across US sites, including community oncology practices and academic medical centers within an existing US oncology network from Paradigm Health. Participating sites will use technological resources that support the identification of eligible patients and enable efficient EHR-to-electronic data capture and transfer, minimizing physician time while improving compliance in data completeness and accuracy. Eligible patients must have disease progression following $\geq$1 prior systemic treatment for metastatic or advanced disease, have no alternative treatment options, and have a clinical decision for T-DXd treatment in accordance with the FDA label. Patients with breast cancer, colorectal cancer, non-small cell lung cancer, gastric or gastroesophageal junction cancers, or hematologic malignancies will be excluded. Primary endpoints are real-world objective response rate, defined as the proportion of patients with a complete response (CR) or partial response (PR) as determined by clinician assessment per criteria used in routine clinical practice; and real-world duration of response, defined as the time from first objective response (CR or PR) to disease progression as determined by clinician assessment per criteria used in routine clinical practice, or death. Secondary endpoints include real-world time to treatment discontinuation and real-world time to next treatment. Enrollment began in September 2025 and is ongoing. Clinical trial information: NCT07124000. Research Sponsor: AstraZeneca.

11500 Oral Abstract Session

Primary results of the phase 3 peak study of bezuclastinib + sunitinib vs sunitinib monotherapy in advanced gastrointestinal stromal tumors (GIST). First Author: Andrew J. Wagner, Dana-Farber Cancer Institute, Boston, MA

Background: GIST, the most common mesenchymal malignancy of the gastrointestinal tract, is commonly driven by activating *KIT* mutations. Despite therapeutic advances, treating advanced GIST with KIT tyrosine kinase inhibitors (TKIs) remains challenging due to emergence of heterogeneous resistance mutations inadequately addressed by current approved therapies. Bezuclastinib, an oral, selective type 1 TKI, in combination with sunitinib, a type 2 TKI, inhibits common primary and secondary resistance mutations in advanced *KIT*-mutant GIST. The Peak study evaluated efficacy and safety of bezuclastinib + sunitinib vs standard second-line sunitinib monotherapy in patients with advanced GIST who received prior imatinib therapy. **Methods:** Peak was a multipart study: dose confirmation (Part 1a), 2 drug-drug interaction (DDI) assessments (Part 1b; DDI substudy), and a randomized phase 3 (Part 2; abstract focus). Patients were randomized 1:1 to bezuclastinib 600 mg once daily (QD) + sunitinib 37.5 mg QD (n=204) or sunitinib 37.5 mg QD (n=209). Primary endpoint was blinded independent central review (BICR)-assessed median progression-free survival (mPFS). Key secondary endpoints were objective response rate (ORR) per BICR and overall survival (OS). Crossover to combination was permitted at BICR-confirmed progression. **Results:** Patients (N=413) were randomized to either bezuclastinib + sunitinib or sunitinib monotherapy; median (range) age, 63 (30-88) years; 59.6% and 14.0% had activating *KIT* mutations in exons 11 only and 9 only, respectively. The combination significantly improved mPFS (HR, 0.50; 95% CI, 0.39-0.65; P$<$0.0001). mPFS was 16.5 months (95% CI, 13.8-19.2) for the combination vs 9.2 months (95% CI, 7.2-11.0) for monotherapy. ORR significantly improved with the combination vs monotherapy (46% vs 26%; risk difference, 20%; 95% CI, 10.6-28.6; P$<$0.0001). As of Sep 30, 2025, OS data remain immature. Incidence of adverse events (AEs) was similar between arms. Grade (Gr)$\geq$3 AEs were comparable, with no significant increase in common sunitinib-associated AEs. Higher rates of Gr$\geq$3 ALT/AST elevations and anemia were observed with the combination and were manageable with dose modification. ALT/AST elevations led to bezuclastinib dose reductions in 13.2% and discontinuations in 1.5% of patients in the combination arm; all Gr3 hepatic AEs resolved; no Gr4 events occurred. Additional treatment-emergent AEs leading to discontinuation of either drug in $>$1 patient in the combination arm were neutropenia (2.9%) and diarrhea (1%). No treatment-related AEs led to death in the combination arm. **Conclusions:** Combined KIT inhibition with bezuclastinib + sunitinib significantly improved mPFS vs sunitinib monotherapy, reducing the risk of progression or death by 50% and increasing ORR from 26% to 46%. The combination was well tolerated with no new safety findings. Clinical trial information: NCT05208047. Research Sponsor: Cogent Biosciences, Inc.

11501 Oral Abstract Session

Velzatinib (IDRX-42) as 1L or 2L therapy for advanced gastrointestinal stromal tumors (GISTs) by *KIT* mutation status: A subset analysis of the phase 1/1b StrateGIST 1 study. First Author: Robin Lewis Jones, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom

Background: Most GISTs present with activating *KIT* mutations (exons 9/11) initially responsive to imatinib, but many progress due to diverse *KIT* resistance mutations (largely in exons 13/14/17/18). Velzatinib (subject to USAN approval), a novel selective KIT inhibitor, has broad mutation coverage and robust in vitro/vivo preclinical activity in models with mutations relevant to 1st- (1L) and 2nd-line (2L) GIST. We present results from StrateGIST 1 evaluating the safety and efficacy of velzatinib in patients (pts) with advanced GIST as 1L or 2L therapy by *KIT* mutation status. **Methods:** The study design of StrateGIST 1 has been previously described (Schöffski et al. *J Clin Oncol* 2024). We present updated safety and efficacy data for 1L and 2L pts by *KIT* mutation status treated with velzatinib at the recommended phase 1b dose (RP1bD) of 300-mg tablet or exposure-equivalent 400-mg capsule. **Results:** As of December 15, 2025, 18 pts in 1L and 46 pts in 2L received velzatinib at the RP1bD and were evaluable for the efficacy analysis. In 2L pts, median follow-up (mFU) was 14.7 (95% CI: 12.9, 18.4) mo and median progression-free survival (mPFS) was 13.7 (95% CI: 7.4, 18.4) mo. In 1L, the mFU was 6.4 (95% CI: 1.8, 11) mo, and all pts (18/18) had a reduction in tumor volume, of whom 11 (61%) experienced unconfirmed responses, including 1 complete and 10 partial responses (Table 1). As of the cutoff date, 17 1L pts remained on study treatment. Treatment was well tolerated, with low rates of dose reductions (1L: 0%; 2L: 6%) and withdrawals (1L: 0%; 2L: 4%) due to AEs. **Conclusions:** Velzatinib exhibited promising activity and tolerable safety as 1L and 2L therapy across clinically relevant *KIT* mutations for pts with advanced GIST. These data support further study of velzatinib, including in 1L pts, to address the need for therapeutic options with broad coverage of clinically relevant GIST mutations. This study (NCT05489237) is funded by GSK. Clinical trial information: NCT05489237. Research Sponsor: GSK.

11502 Oral Abstract Session

Phase 3 study (APROMISS) of catequentinib hydrochloride (AL3818) monotherapy in patients with advanced alveolar soft part sarcoma (ASPS). First Author: Silvia Stacchiotti, Adult Mesenchymal and Rare Tumor Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: To report results from the open-label alveolar soft part sarcoma (ASPS) cohort of the phase III APROMISS trial (NCT03016819) evaluating Catequentinib hydrochloride (AL3818), an oral multitargeted receptor tyrosine kinase inhibitor, in adults with advanced or metastatic ASPS. **Methods:** Adult patients with pathologic and molecularly confirmed advanced ASPS, either treatment-naive or previously treated (excluding cediranib), were enrolled in the open-label, non-randomized ASPS cohort of the phase III APROMISS trial conducted across the United States, Asia, and Europe. Catequentinib hydrochloride was administered orally at 12 mg once daily in 21-day cycles (14 days on/7 days off) until disease progression, toxicity, or death. The primary endpoint was objective response rate (ORR) assessed per RECIST by Blinded Independent Central Review (BICR) (predefined threshold: 31%). Secondary endpoints included duration of response (DOR) with a predefined target of =/$>$6 months, progression free survival (PFS) and overall survival (OS). **Results:** From July 2017 to August 2022, a total of 56 patients entered the trial; 56 patients were evaluable for the primary endpoint. Median (m-) age was 29.5 years (range: 18 – 66), with 24 female and 32 male. Best overall response included 1/56 complete response (1.8%), 14/56 partial responses (25.0%), 36/56 stable disease (64.3%), and 3/56 (5.4%) progressive disease. RECIST ORR by BICR was 26.8% (95% CI, 15.8–40.3); m-DOR was 22.57 months (95%CI: 10.38-NE). The study data was collected close to 8 years for all patients. mPFS was 18.33 months (95% CI, 14.19–23.13), with 6- and 12-month progression-free rates of 88.77% (95% CI, 76.68–94.79) and 65.54% (95% CI, 50.42–77.06), respectively. mOS was 59.27 months (95% CI, 44.09–NE), with 6- and 12-month overall survival rates of 94.64% (95% CI, 84.30–98.24) and 90.81% (95% CI, 79.30–96.08), respectively. Overall, 27/56 (48.2%) patients experienced grade $\geq$3 treatment-related adverse events, most commonly diarrhea (50.0%), hypertension (44.6%), fatigue (37.5%), nausea (35.7%), and palmar-plantar erythrodysesthesia syndrome (30.4%); one patient (1.8%) had a grade 5 event (respiratory failure). **Conclusions:** Catequentinib hydrochloride demonstrated meaningful antitumor activity and durable responses in adults with advanced ASPS. Despite the ORR of 26.8% slightly below the predefined 31% threshold, disease control was prolonged, with a m-DOR exceeding 22 months. Favorable PFS and OS outcomes, together with a manageable safety profile, support its clinical benefit in this ultra-rare sarcoma. Clinical trial information: NCT03016819. Research Sponsor: None.

11503 Oral Abstract Session

Efficacy and safety of vebreltinib in advanced clear cell sarcoma (VEBrant): A multicenter, phase II study. First Author: Binghao Li, Department of Orthopaedics, The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Background: Clear cell sarcoma (CCS) is an ultra rare cancer with no established standard systemic therapy of proven efficacy. The c-MET pathway plays an important role in CCS, with MET overexpression frequently observed. Targeted therapy by type Ia MET inhibitor crizotinib revealed a disease control rate (DCR) at 69.2% and objective response rate (ORR) at 3.8%. Vebreltinib is a highly selective type Ib MET inhibitor with verified efficacy in solid tumor harboring MET alterations, such as NSCLC with MET amplification or overexpression. This phase II study aimed to assess the efficacy and safety of Vebreltinib for advanced CCS. **Methods:** Patients (pts) with histopathologically confirmed, unresectable or metastatic CCS were enrolled (NCT07153887), regardless of prior therapy except for any MET inhibitors. Eligible pts received Vebreltinib (200 mg BID) until disease progression, intolerable toxicity, or death occurs. Prior PD1/PDL1 treatment for at least 4 months without tumor reduction are allowed to continue using the same PD1/PDL1 medicine after thorough evaluation by the investigator. Evaluation of tumor response was performed every 2 months. Primary endpoints was ORR per RECIST v1.1. Secondary endpoints included DCR, PFS, OS, 12m-OSR, DoR and treatment safety. MET expression by immunohistochemistry was collected when possible. A Simon's two-stage design was applied: if no responses were seen in the first 13 pts, the study would stop; otherwise, 14 additional pts would be enrolled (total N=27). **Results:** At data cutoff on January 23, 2026, 23 pts were enrolled. Median age was 29 years (range: 16–59), 47.8% were male, 91.3% had prior surgery, and 95.7% received prior systemic therapy. All had metastatic disease, primarily to lung (78.3%), lymph nodes (56.5%), and bone (30.4%). With median follow-up of 134 days and median treatment duration of 103 days, 17 pts were evaluable for response. ORR was 41.2% (7 partial responses) and DCR was 70.6% (7 PR, 5 stable disease), meeting the pre-specified threshold for stage I continuation. Median PFS was 4.14 months (95% CI: 2.3–NA); 6-month PFS rate was 42.8%. Median OS was not reached. Treatment-related adverse events (TRAEs) occurred in 87.0% of pts, mostly grade 1-2. Grade 3-4 TRAEs occurred in 21.7% (n=5; rash n=4, fever n=1). Notably, 4 pts discontinued due to grade 4 rash within 2 weeks of starting vebreltinib combined with immunotherapy. **Conclusions:** Vebreltinib demonstrated notable antitumor activity for advanced CCS, representing a marked improvement over existing therapeutic options. Attention should be paid to the risk of severe rash, particularly when combined with immunotherapy. Longer follow-up is required to further confirm the efficacy and safety. Clinical trial information: NCT07153887. Research Sponsor: Beijing Pearl Biotechnology Co., Ltd.

11504 Oral Abstract Session

The tetravalent death receptor 5 (DR5) agonist ozekibart (INBRX-109) in conventional chondrosarcoma (CS): Secondary efficacy endpoints from the randomized, registrational, phase 2 ChonDRAgon study. First Author: Hans Gelderblom, Department of Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Clinical outcomes for unresectable/metastatic CS are poor. There are no approved therapies, and systemic treatment options are limited. Ozekibart (INBRX-109), a novel tetravalent DR5 agonist, was evaluated in ChonDRAgon (phase 2; NCT04950075), the largest randomized, placebo (PBO)-controlled trial in advanced conventional CS. ChonDRAgon met its primary endpoint: ozekibart significantly prolonged median progression free survival (PFS) vs PBO (5.52 vs 2.66 mo; stratified HR, 0.479; 95% CI, 0.335-0.684; $P<.0001$) (Jones et al. CTOS 2025). We present additional efficacy data. **Methods:** Eligible patients (pts) were ≥18 y with unresectable/metastatic conventional CS; those ≥65 y required a BMI <30 kg/m^2. Pts with liver conditions associated with increased risk of hepatotoxicity were excluded. Pts were randomized 2:1 to ozekibart 3 mg/kg IV Q3W or PBO and stratified by grade (2 vs 3), *IDH* mutation status, and prior systemic therapy (No vs Yes). Pts could cross over from PBO to open-label ozekibart upon progression. The primary endpoint was PFS per RECIST 1.1 assessed by real time central independent radiology review (CIRR) in the intention-to-treat population; inter-arm comparison used a stratified log-rank test. The study was powered to detect a HR of 0.571 (90% power; 1-sided family-wise α, 0.025). Secondary efficacy endpoints included overall survival (OS), overall response rate (ORR) per CIRR, quality of life (QOL; EORTC QLQ-C30 pain symptoms and physical functioning scales), duration of response (DOR), and disease control rate (DCR; response, stable disease ≥84 days, non–complete response/non–progressive disease). **Results:** Overall, 137 pts were randomized to ozekibart and 69 to PBO; median duration of follow-up was 10.2 and 9.0 mo at the primary analysis (data cutoff: Sep 30, 2025). Median age for ozekibart and PBO was 54.0 y (range, 20-82 y) and 50.0 y (19-91 y), respectively; 70.1% and 60.9% of pts were male. Most pts had grade 2 CS (ozekibart, 70.1%; PBO, 69.6%) and ≈40% received prior systemic therapy (42.3%; 40.6%). 18.2% of pts in the ozekibart arm and 4.3% in the PBO arm remain on treatment. Ozekibart demonstrated a manageable safety profile (Jones et al. CTOS 2025) and led to a significantly greater DCR than PBO (54.0% vs 27.5%; $P=.0005$). ORR was 5.8% (8/137; all partial responses) with ozekibart and 0 with PBO ($P=.0433$); median DOR was 11.1 mo. OS data were immature. Ozekibart significantly delayed QOL deterioration vs PBO, in both pain (median time to deterioration, 2.76 vs 1.41 mo; HR, 0.605; $P=.0033$) and physical functioning (2.56 vs 1.41 mo; HR, 0.561; $P=.0007$). **Conclusions:** In addition to a PFS benefit, ozekibart significantly improved DCR and delayed QOL deterioration vs PBO in advanced CS. Ozekibart has the potential to become the first standard of care for a population with high unmet need. Clinical trial information: NCT04950075. Research Sponsor: Inhibrx Biosciences, Inc.

11505 Oral Abstract Session

Pooled analyses of clinical outcomes with afamitresgene autoleucel (afami-cel) in metastatic synovial sarcoma. First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Afamitresgene autoleucel (afami-cel) is a melanoma-associated antigen A4 (MAGEA4)-directed genetically modified autologous T cell immunotherapy consisting of CD4 and CD8 positive T cells transduced with a self-inactivating lentiviral vector (LV) expressing an affinity-enhanced T cell receptor (TCR) specific for the human MAGE-A4. Here we report the pooled results of afami-cel in phase 1 and phase 2 trials in patients (pts) with advanced (unresectable/metastatic) synovial sarcoma (SyS). **Methods:** Pts who were HLA-A*02 positive with previously treated, advanced SyS positive for MAGE-A4 received afami-cel after lymphodepleting chemotherapy containing fludarabine and cyclophosphamide. The pooled analyses evaluated overall response rate (ORR) per RECIST v1.1 by investigator review, duration of response (DoR), ORR in sub-populations, overall survival (OS), safety and pharmacokinetics. **Results:** As of May 2025, 153 pts with advanced SyS received afami-cel (1.00 –9.99$\times10^9$ MAGE-A4 TCR positive T cells). The median age was 40 years (range: 13–76 years), 54% of pts were male, and 86% of pts were white. The median MAGE-A4 expression by H-score was 256.0 (range: 60–300). All pts received prior anthracycline and/or ifosfamide therapy and received a median of 2 prior lines of therapy (range: 1–12). ORR by investigator review was 43.8% (95% CI 35.8, 52.0). Responses were observed across all subgroups, including pediatric SyS pts. The median DoR was 7.1 months (95% CI 4.7, 10.6) and ranged from 1 to 58+ months. Median OS was 18.7 months (95% CI: 14.1, 22.5) with 44% of pts censored at the data cut-off. The 12-month or longer and 24-month or longer OS probabilities were 64.4% and 40.5%, respectively. Among the 67 pts who had a RECIST response, the median OS was 37.5 months (95% CI 26.3, 50.5). The most common any-grade non-laboratory TEAEs (≥20% of pts) were cytokine release syndrome (CRS) (73.2%), nausea (64.1%), fatigue (45.8%), pyrexia (33.3%), vomiting (29.4%), constipation (28.1%), diarrhea (27.1%), headache (26.8%), and cough (20.9%). The most common Grade ≥3 laboratory TEAEs (≥20% of pts) were lymphopenia, neutropenia, leukopenia, and anemia. Afami-cel persisted long-term, including >3 years. **Conclusions:** To the best of our knowledge, this is the largest dataset of T-cell therapy treated pts with advanced SyS. The magnitude of ORR supported by DOR demonstrated with afami-cel treatment is considered clinically meaningful in this rare pt population with a poor prognosis and limited effective therapies. CRS and cytopenias were common and manageable. Pts with advanced SyS treated with afami-cel had encouraging survival, especially those pts with a RECIST response. Clinical trial information: NCT04044768, NCT03132922 Research Sponsor: Adaptimmune LLC; USWM CT, LLC.

11506 Oral Abstract Session

RINGSIDE: A phase 3 randomized, placebo-controlled trial of varegacestat for treatment of progressing desmoid tumors. First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Desmoid tumors (DT) are rare, locally aggressive tumors with few effective treatments. Varegacestat (VAR) is an investigational, once daily, oral gamma secretase inhibitor that previously showed antitumor activity in pts with DT in the RINGSIDE Phase 2 study. **Methods:** RINGSIDE Phase 3 was a double-blind, placebo (PBO)-controlled study in adults with progressing DT per RECIST v1.1 (NCT04871282). 156 pts were randomized 1:1 to once daily oral VAR 1.2 mg (n=79) or PBO (n=77). Imaging-based tumor response was assessed per RECIST v1.1 by blinded independent central review. The primary endpoint was progression-free survival (PFS). Alpha-controlled secondary endpoints were confirmed objective response rate (ORR), change in tumor volume (TV) at Week 24, and change in patient-reported worst pain intensity (WPI) at Week 12. **Results:** Demographics and disease characteristics were balanced between treatment arms. As of Oct 7, 2025, median duration of exposure was 20.3 months (range 0.8 – 34.6) for VAR and 11.1 months (range 0.2 – 34.6) for PBO. VAR demonstrated significantly better PFS compared with PBO (hazard ratio [HR]: 0.16 [95% CI: 0.07, 0.38; $P<0.0001$]). PFS consistently favored VAR in all subgroups analyzed. ORR was significantly better with VAR vs PBO (55.7% vs 9.1%; $P<0.0001$), with 3 CRs in the VAR arm and 1 CR in the PBO arm. Median duration of response was not reached in either arm. All alpha-controlled secondary endpoints demonstrated statistically and clinically significant superiority for VAR compared with PBO (Table). Overall, 95% of adverse events (AEs) were Grade 1-2 and there were no Grade 5 AEs. Grade 3/4 AEs were reported in 57% of VAR pts and 17% of PBO pts. AEs led to dose reduction in 63 (80%) VAR pts and 7 (9%) PBO pts; 16 (20%) VAR pts and 5 (7%) PBO pts discontinued due to AEs. In the VAR arm, the most frequently reported AEs were diarrhea (82%), fatigue (44%), and rash (43%). Ovarian toxicity occurred in 20/36 (56%) premenopausal women on VAR, resolved in 11/20 (55%), and did not lead to dose interruption or drug withdrawal. **Conclusions:** VAR demonstrated statistically significant and clinically meaningful antitumor activity and pain relief, achieving the highest ORR reported in a Phase 3 trial of systemic DT therapy, with no new safety signals. Clinical trial information: NCT04871282. Research Sponsor: Immunome Inc.

RINGSIDE phase 3 trial outcomes.

	VAR (n=79)	PBO (n=77)	HR (95% CI) or Difference; P value
Median PFS (95% CI) - radiographic, months	NE (NE, NE)	24.9 (13.8, NE)	0.16 (0.07, 0.38); P<0.0001

11507 Oral Abstract Session

Trabectedin with concomitant radiotherapy in resectable retroperitoneal L-sarcoma: A multicenter, prospective, phase I/II trial—A collaborative study by the Spanish (GEIS), Italian (ISG), and French (FSG) groups. First Author: Rosa Maria Alvarez Alvarez, Hospital Universitario Gregorio Marañon, Madrid, Spain

Background: Liposarcoma (LPS) and leiomyosarcoma (LMS) account for most retroperitoneal sarcomas. Despite complete resection, local recurrence remains high, particularly in dedifferentiated LPS (DDLPS). While preoperative radiotherapy (RT) may improve local control, optimal multimodal strategies are undefined. Trabectedin (T) is active in L-sarcomas, with emerging clinical evidence supporting its radiosensitizing properties and its efficacy in combination with RT. A preoperative short course of T with concurrent low-dose RT was investigated in a multicenter, phase I/II trial in patients (pts) with centrally confirmed resectable retroperitoneal L-sarcoma (grade 2-3 DDLPS with >30% dedifferentiated component or grade 2-3 LMS). **Methods:** Pts received 3 cycles of T in combination with RT (45 Gy in 25 x 1.8 Gy). Phase I followed a 3+3 dose-escalation design with T dose levels 1.5 (0), 1.3 (-1), and 1.1mg/m^2 (-2). Dose-limiting toxicity was any grade ≥3 adverse events (excluding neutropenia <5 days, elevated transaminases without treatment delay, and nausea/vomiting due to inadequate prophylaxis). Phase I primary endpoint was safety and the determination of the recommended Phase II dose (RP2D). Phase II primary endpoint was centrally assessed Choi response. Secondary endpoints included relapse-free survival (RFS; from surgery), progression-free survival (PFS; from first T cycle), overall survival (OS), RECIST and pathological response, and treatment-related toxicity according to CTCAE v5.0. **Results:** From February 2019 to January 2025, 56 pts, 6 in phase I and 50 in phase II, (M/F: 31/25) with a median age of 61 years (range: 19-75) and a median tumor size of 17 cm (range: 12-30) were enrolled. 51 pts had grade 2-3 DDLPS, and 5 pts had grade 2-3 LMS. A T dose of 1.5 mg/m^2 was the RP2D. Per-protocol therapy was completed in 47 pts (84%); discontinuations were due to local progression (N=1), toxicity (N=6), or refusal (N=2). The most common grade 3/4 toxicities were neutropenia (21.4%), leukopenia (8.9%), fatigue (8.9%), and increased ALT, febrile neutropenia, and thrombocytopenia (7.1% each). 51 pts (91%) underwent surgery, with 96% achieving complete resection. According to the central review, Choi (N=45) showed 12 PR (26.7%) and 33 SD (73.3%). RECIST 1.1 (N=53): PR 1 (2%), SD 51 (96%), PD 1 (2%). At a median follow-up of 40 months (95% CI, 36-43), from the start of T (N=53), 3-year PFS was 70% (95 CI, 56-83) and 3-year OS was 85% (95 CI, 75-95). **Conclusions:** Preoperative concurrent T and RT was feasible and safe for resectable retroperitoneal L-sarcomas, yielding density responses in over 25% of pts and promising survival outcomes. A phase III trial is warranted to compare this regimen against RT alone. Clinical trial information: NCT02275286. Research Sponsor: Pharmamar.

11508 Oral Abstract Session

Final results of a randomized phase II trial of second-line treatment for advanced soft tissue sarcoma comparing trabectedin, eribulin, and pazopanib: 2ND-STEP study, JCOG1802. First Author: Makoto Endo, Department of Orthopaedic Surgery, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

Background: The optimal second-line treatment for advanced soft tissue sarcomas (STS) after doxorubicin therapy remains unclear. This trial aimed to identify the most promising agent among trabectedin, eribulin, and pazopanib for subsequent phase III comparison against gemcitabine plus docetaxel (GD), which has traditionally been considered a standard treatment. We previously reported the results of the primary analysis at 6 months after accrual completion. Here, we present the final analysis results with an additional year of follow-up. **Methods:** This multicenter, randomized, phase II selection design trial enrolled patients with unresectable or metastatic STS who were refractory to doxorubicin-based chemotherapy. Participants were randomized to receive trabectedin, eribulin, or pazopanib. The primary endpoint was progression-free survival (PFS); secondary endpoints included overall survival (OS), disease control rate (DCR), objective response rate (ORR), and safety. **Results:** From December 2019 to March 2023, 120 patients with advanced STS were enrolled (31 leiomyosarcomas, 26 liposarcomas, 18 translocation-related sarcomas, and 45 other types). The median PFS was 2.9 months (95% CI, 1.3-5.3) for trabectedin, 2.2 months (1.5-3.8) for eribulin, and 3.8 months (2.3-5.2) for pazopanib. The hazard ratios for eribulin and pazopanib compared to trabectedin were 1.22 (0.77-1.94) and 0.99 (0.63-1.56), respectively. When examining the PFS curves for each treatment arm, the three arms appeared to exhibit nearly identical curves; however, the PFS hazard ratio indicated that pazopanib showed the best result. The median OS was 14.7 months (10.8-18.5) for trabectedin, 13.3 months (7.6-20.1) for eribulin, and 15.7 months (9.7-18.0) for pazopanib. The DCR was 50.0% (32.4-67.6) for trabectedin, 37.1% (21.5-55.1) for eribulin, and 64.9% (47.5-79.8) for pazopanib. The ORR was 17.6% (6.8-34.5) for trabectedin, 5.7% (0.7-19.1) for eribulin, and 8.1% (1.7-21.9) for pazopanib. A histological subtype–specific subgroup analysis, demonstrated that the PFS/OS for each arm in liposarcoma were as follows: trabectedin, 3.1 months (95% CI, 1.1–7.2) / 12.9 months (3.7–36.5); eribulin, 3.8 months (1.1–6.8) / 13.3 months (4.3–20.1); and pazopanib, 5.2 months (2.0–10.2) / 18.0 months (4.1–NE). No previously unrecognized adverse events related to the investigational drugs were observed, and no treatment-related deaths occurred. **Conclusions:** Consistent with the primary analysis, pazopanib generally showed favorable PFS, OS, and DCR among the three agents. Based on these results, pazopanib was identified as the most appropriate candidate to be compared with GD in a phase III trial, which is currently being planned. Clinical trial information: jRCTs031190152. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

11509 Clinical Science Symposium

Spatial RNA–protein profiling of antibody–drug conjugate (ADC) targets in leiomyosarcoma (LMS). First Author: Carlos Torrado, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: LMS remains a therapeutically challenging sarcoma with limited targeted options. Although ADCs are a promising strategy, none are FDA approved for sarcoma. Prior studies relying on bulk RNA or single-marker immunohistochemistry fail to capture spatial localization, co-expression, and intratumoral heterogeneity. **Methods:** LMS tissue microarrays were profiled using GeoMx DSP to generate spatial RNA and protein expression of ADC targets across multiple regions of interest (ROIs) per tumor. Cases were classified as soft-tissue (ST-LMS; n=23 patients; 94 ROIs) or uterine LMS (U-LMS; n=32 patients; 92 ROIs). A prespecified panel of 35 clinically relevant ADC targets was interrogated. Expression values were normalized to housekeeping genes with group-level scaling. Unsupervised clustering grouped ROIs by spatial expression. Intratumoral and inter-tumoral heterogeneity was quantified using coefficients of variance (CV) across ROIs. RNA–protein concordance and dual target co-expression were quantified using Spearman correlation (ρ). Survival differences between high- and low-expression groups, dichotomized by the median, were evaluated using Kaplan–Meier analysis. **Results:** Of the 35 ADC targets interrogated, 33 were evaluable at the RNA level and 10 at the protein level. Spatial profiling identified four distinct expression clusters. At the RNA level, F3, AXL, and PTK7 showed the highest expression, whereas CDH11, CD99, and ITGA11 exhibited lower expression. At the protein level, Tissue Factor, AXL, and CD70 showed the highest expression, while HER2, and CD99 were lower. Most ADC targets exhibited positive $\log_{10}$ (CV) values, indicating substantial spatial variability. Across most targets, U-LMS showed greater intratumoral and intertumoral heterogeneity than ST-LMS. RNA–protein concordance was greatest for CD99, CD47, and Fibronectin/EDB ($\rho \approx 0.44–0.69$) and minimal for PDGFRA, AXL, ERBB2, EGFR, and MET ($\rho \approx$-0.15-0.19). RNA co-expression identified seven significant pairs in ST-LMS (e.g., ROR2–FAP, ρ=0.54) and eighteen in U-LMS, including MRC2–CD248 (ρ=0.73). Dual protein co-expression revealed a strong ERBB2–EGFR correlation in both ST and U-LMS ($\rho \approx 0.79–0.81$), with moderate correlations of these two ADC targets to PDGFRA, AXL, and Tissue Factor ($\rho \approx 0.53–0.70$). High expression levels CD47 and AXL were associated with improved survival in ST-LMS (CD47 HR = 0.76, 95% CI 0.08–0.88, p = 0.021; AXL HR = 0.67, 95% CI 0.07–0.72, p = 0.0067). **Conclusions:** This study provides the first spatially resolved RNA–protein map of ADC targets in LMS, revealing differential expression, spatial heterogeneity, variable RNA–protein concordance, dual co-expression patterns, and survival associations. These findings establish a foundation for rational ADC development, biomarker-driven patient stratification, and dual ADC combination strategies in LMS. Research Sponsor: None.

11510 Clinical Science Symposium

Phase 1/2 study of YL201, an anti-B7H3 antibody–drug conjugate (ADC), in patients with relapsed or refractory (R/R) Ewing sarcoma and chondrosarcoma. First Author: Lu Xie, Musculoskeletal Tumor Center, Peking University People's Hospital, Beijing, China

Background: The prognosis for R/R sarcoma remains dismal with limited effective treatment options. YL201 is a B7H3-targeting ADC with promising activity in multiple advanced solid tumors. Here, we report the safety and preliminary efficacy of YL201 monotherapy in patients with Ewing sarcoma (EWS) and chondrosarcoma (CHS) from a phase 1/2 study. **Methods:** Patients with histologically confirmed sarcoma who had an ECOG PS of 0 or 1 and progressed on $\geq$1 prior line of systemic therapies were enrolled and treated with YL201 intravenously Q3W at 2.0 mg/kg or 2.4 mg/kg until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Thirty-two patients with sarcoma were enrolled, including EWS (n=20), CHS (n=10), osteosarcoma (n=1), and soft tissue sarcoma (n=1). The overall population had a median age of 34.0 years (range: 19–69), with 81.3% male and 46.9% having an ECOG PS of 1. Patients had a median of 1 prior line of therapy (range: 1–6), with 96.9% having received prior chemotherapy and 37.5% having received targeted therapy. As of December 12, 2025, the median follow-up was 11.4 months (95% CI: 9.1–13.2). In EWS sub-cohort, the confirmed ORR was 50.0% (95% CI: 27.2–72.8) with a median DoR of 6.5 months (95% CI: 2.8–NR), and DCR was 95.0% (95% CI: 75.1–99.9). Median PFS was 5.5 months (95% CI: 2.8–7.9), while OS data remained immature. In CHS sub-cohort, antitumor activity was observed with a confirmed ORR of 10.0% (95% CI: 0.3–44.5) and a DCR of 90.0% (95% CI: 55.5–99.7). The median PFS was 11.7 months (95% CI: 3.9–NR), and median OS was not reached. Membrane B7H3 expression was detected by immunohistochemistry in 42.1% of EWS and 44.4% of CHS patients, whereas the remainder exhibited no membrane B7H3 expression. However, no association was observed between tumor response and B7H3 expression level in either sub-cohort. Among all 32 patients enrolled, the treatment-related adverse events (TRAEs) of any grade and grade $\geq$3 occurred in 100.0% and 34.4% of patients, respectively. The most common grade $\geq$3 TRAEs included lymphopenia (15.6%), neutropenia (9.4%), thrombocytopenia (9.4%), leukopenia (6.3%), and anemia (6.3%). No interstitial lung disease or pneumonitis was observed. The rate of treatment discontinuation due to TRAEs was low at 3.1%, and no treatment-related deaths were reported. **Conclusions:** YL201 showed promising antitumor activity and manageable safety profile in patients with R/R EWS and CHS, with a particularly encouraging ORR in EWS. Given the high incidence of Ewing sarcoma in adolescents, these findings support further evaluation of YL201 in pediatric populations. Clinical trial information: NCT06057922. Research Sponsor: MediLink Therapeutics.

11511 Clinical Science Symposium

Overall survival analysis of a heavily pretreated population of patients with bone sarcomas treated with mecbotamab vedotin, a conditionally binding ADC targeting AXL. First Author: Anthony Paul Conley, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with metastatic bone sarcomas continue to lack effective therapies. AXL, a cell-surface receptor tyrosine kinase, is highly expressed in bone sarcoma subtypes and has been shown to drive increased metastasis, resistance to chemotherapy, and poor outcomes. Mecbotamab vedotin (Mec-V, BA3011, Conditionally Active Biologic CAB-AXL-ADC) is designed to reduce off-tumor toxicity and improve pharmacokinetics by conditionally binding to AXL under low-pH conditions (pH$<$6.7) of the tumor microenvironment. **Methods:** A phase 1/2 open-label study evaluated Mec-V among adult and adolescent patients with AXL-expressing locally advanced, unresectable, or metastatic osteosarcoma, Ewing sarcoma, chondrosarcoma, and chordoma with measurable disease by RECIST v1.1. Patients received Mec-V monotherapy intravenously 1.8 mg/kg every 2 weeks (Q2W). **Results:** This report focuses upon the long term follow up among 33 patients treated with Mec-V with osteosarcoma (n=13), Ewing (n=9), chondrosarcoma (n=8) or chordoma (n=3). Patients received a median of 2 prior lines of treatment. Most related treatment-related adverse events (TEAE) in patients with bone sarcomas were low grade (64%) and reversible; the most common related grade 3/4 TEAE of special interest was neutropenia (18%). No grade 5 TEAE were observed. As of March 25, 2025, disease control rate (DCR) was 100% among patients with chondrosarcoma and chordoma. In patients with osteosarcoma and Ewing sarcoma, DCR was 50% with 3 confirmed responses (14%; osteosarcoma n=2, Ewing n=1). The median OS with Mec-V for all bone sarcoma patients was 17.6 months. Observed median OS by tumor type in months: osteosarcoma (11.9 [95% CI: 3.2-Not Estimable (NE)]), Ewing sarcoma (19.4 [95% CI: 5.2–NE]), chondrosarcoma (NE [95% CI: 16.3-NE]), and chordoma (15.1 [95% CI: 7.2-NE]). **Conclusions:** Patients with treatment refractory bone sarcomas treated with Mec-V monotherapy achieved a median OS of 17.6 months which compares favorably to reported outcomes with other therapies including combination therapies. Mec-V monotherapy holds considerable promise for these high unmet need indications with potential increased benefit when used in combination. Clinical trial information: NCT03425279. Research Sponsor: BioAtla, Inc.

11512 Rapid Oral Abstract Session

Maintenance treatment with toripalimab and anlotinib after anthracycline-based chemotherapy in patients with advanced soft tissue sarcoma (TORANS): A single-arm, phase 2 trial. First Author: Yaotiao Deng, Department of Medical Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: To date, there is no established maintenance strategy for patients with advanced soft tissue sarcoma (STS) who achieve disease control following first-line anthracycline-based chemotherapy. Maintenance therapy is therefore under active investigation in this setting. This study assessed the efficacy and safety of toripalimab (a humanized anti-PD-1 monoclonal antibody) combined with anlotinib (a multitargeted tyrosine kinase inhibitor) as a maintenance treatment. **Methods:** Patients with advanced STS who achieved stable disease or a partial response after at least four cycles of first-line anthracycline-based chemotherapy were enrolled in this single-arm, phase 2 trial and received maintenance therapy with toripalimab (240 mg intravenously on day 1) and anlotinib (12 mg orally once daily on days 1–14) in 21-day cycles. The primary endpoint was the 24-week progression-free survival rate ($PFSR_{24w}$), defined as the proportion of patients who remained free from disease progression through 24 weeks after initiation of maintenance therapy. Secondary endpoints included median progression-free survival (PFS), median overall survival (OS), objective response rate (ORR), disease control rate (DCR), and safety. **Results:** Between April 2022 and May 2025, a total of 52 patients were enrolled; one patient diagnosed with pathologically confirmed metaplastic carcinoma was excluded. As of December 26, 2025, the median follow-up duration was 20 months. The $PFSR_{24w}$ was 74.5%. The median PFS was 12 months, and the median OS was not reached at the time of data cutoff. Durable partial responses were observed in patients with dedifferentiated liposarcoma (5/14), leiomyosarcoma (2/11), epithelioid sarcoma (2/4), myxofibrosarcoma (1/3), synovial sarcoma (1/3), and pleomorphic rhabdomyosarcoma (1/1), resulting in an ORR of 23.5%. The most common grade 3–4 adverse events were hypertension (n = 10), increased gamma-glutamyltransferase (n = 5), hand-foot skin reaction (n = 3), and hypertriglyceridemia (n = 3). No new safety signals emerged during the course of the trial. **Conclusions:** Toripalimab in combination with anlotinib as maintenance therapy demonstrated promising efficacy and a manageable safety profile in patients with advanced STS following first-line anthracycline-based chemotherapy. Clinical trial information: ChiCTR2100054901. Research Sponsor: The 1·3·5 project for disciplines of excellence–Clinical Research Incubation Project, West China Hospital, Sichuan University (2021HXFH019); 2021HXFH019.

11513 Rapid Oral Abstract Session

Camrelizumab combined with liposomal doxorubicin and dacarbazine as first-line therapy for advanced, recurrent, and metastatic undifferentiated pleomorphic sarcoma: A phase II study. First Author: Tian Gao, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Bone and Soft Tissue Tumor, Peking University Cancer Hospital, Beijing, China

Background: This phase II study aims to evaluate the efficacy and safety of camrelizumab combined with liposomal doxorubicin and dacarbazine in patients with advanced, recurrent and metastatic undifferentiated pleomorphic sarcoma (UPS). **Methods:** Patients with histologically confirmed advanced, recurrent and metastatic UPS, treatment-naïve for advanced disease, and at least one measurable lesion per RECIST v1.1 were eligible. Camrelizumab was administered in combination with liposomal doxorubicin and dacarbazine for up to six cycles, followed by camrelizumab maintenance therapy. The primary endpoint was investigator-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), duration of response (DoR), and safety. **Results:** Between October 2022 and August 2025, 28 pts were enrolled and received study treatment, of whom 24 were evaluable for efficacy analyses. Partial response occurred in 7 patients, with no complete responses observed, resulting an ORR of 29.2% (7/24). Stable disease was achieved in 14 patients, yielding a disease control rate of 87.5% (21/24). Two patients had progressive disease and four patients were not evaluable due to the absence of post-baseline tumor assessments. With a median follow-up of 11.9 months (data cutoff: December 29, 2025), 16 PFS events and 7 death events had occurred. The median PFS was 8.4 months (95% CI, 6.2-NA), while median OS had not been reached. Responses appeared durable, with a median DoR of 4.5 months among responders (n=7), though early progression was observed in some patients. An exploratory analysis revealed PD-L1-positive patients (CPS $\geq$1) showed a trend toward a higher ORR than PD-L1-negative patients (42.9% [3/7] vs 21.4% [3/14]). The most common treatment-related adverse events of any grade were neutropenia (35.7%), leukopenia (28.6%), rash (28.6%), and ALT elevation (25.0%). Grade $\geq$3 adverse events were infrequent, mainly ALT and AST elevations (both 7.1%). Immune-related adverse events included rash (28.6%), pneumonitis (7.1%), and hepatitis (7.1%), leading to treatment discontinuation in two patients. **Conclusions:** Camrelizumab combined with liposomal doxorubicin and dacarbazine demonstrated promising antitumor activity with durable responses and manageable safety as first-line therapy for advanced, recurrent and metastatic UPS. Exploratory analyses suggested that patients with higher PD-L1 expression may derive greater benefit from this regimen, warranting further investigation in larger, controlled studies. Clinical trial information: ChiCTR2100049974. Research Sponsor: None.

11514 Rapid Oral Abstract Session

PEMBROCABOSARC: A phase II trial combining pembrolizumab and cabozantinib in patients with advanced undifferentiated pleomorphic sarcoma. First Author: Maud Toulmonde, Institut Bergonié, Bordeaux, France

Background: There is a growing rationale for combining immunotherapy and VEGF inhibitors in sarcoma. We report results of an open-label multicentre phase 2 study assessing the anti-PD-1 antibody pembrolizumab (pembro) in combination with cabozantinib (cabo) in patients (pts) with advanced undifferenciated pleomorphic sarcoma (UPS). **Methods:** Pts aged $>$ 18 years old, with advanced or metastatic UPS who received no more than three previous lines and no previous history of exposure to anti PD1/L1 or cabozantinib were included to receive cabo 40 mg daily and pembro 200 mg IV q21 days. The primary endpoint was 6-month non-progression (NP) per RECIST v1.1. This trial used a 2-stage optimal Simon's design needing 8 NP at 6 months observed among 29 evaluable pts to be considered positive. **Results:** 33 pts were enrolled from December 27th, 2022 to September 25th, 2024, 32 were assessable for safety and 31 for efficacy. Overall, 13 (40.6%) pts had at least one dose reduction of cabo and 5 (15.6%) stopped treatment for a drug-related adverse event (3 related to cabo, 1 to pembro and 1 to both drugs). The most frequent adverse events related to treatment were asthenia, diarrhea, palmo-plantar syndrom and aminotransferase increase. There was no new emerging toxicity with the combination. One grade 5 pneumothorax was considered possibly related to cabozantinib by the investigator. At a median follow up of 13.8 months [95% CI: 12 – 17.2], 8 pts out of the first 29 evaluable pts were NP at 6 months (27.6% [95% CI: 12.7%-47.2%]). Among the efficacy population, 14 pts experienced tumor shrinkage resulting in a partial response (PR) in 8 (25.8%). Responses were long-lasting. The median overall survival was not reached. **Conclusions:** Combining VEGF and PD-1 inhibition showed favorable activity in unselected UPS compared to available evidence for each treatment in monotherapy. Correlative studies of immune biomarkers on paired tumor biopsies and plasma samples done at baseline and on-treatment are on-going to decipher biomarkers of response and resistance to treatment. Clinical trial information: NCT05182164. Research Sponsor: IPSEN; MSD.

Number of patients with at least one Grade 3 to 5 adverse event related to treatment.

Adverse Event	Grade 3	Grade 5
Diarrhea	2 (6.2%)	0
Palmo-plantar syndrom	2 (6.2%)	0
Aminotransferase increase	2 (6.2%)	0
Hypertension	1 (3.1%)	0
Headache	1 (3.1%)	0
Dysgeusia	1 (3.1%)	0
Skin rash	1 (3.1%)	0
Pyoderma	1 (3.1%)	0
Left ventricular dysfunction	1 (3.1%)	0
Pneumothorax	1 (3.1%)	1 (3.1%)

11515 Rapid Oral Abstract Session

Toxicity and efficacy characterization of doxorubicin and trabectedin association versus doxorubicin alone in patients over 70 years with leiomyosarcoma: Analysis from LMS02 and LMS04 studies. First Author: Imen Ben-Ammar, Institut Gustave Roussy, Villejuif, France

Background: LMS02 (phase II) and LMS04 (randomized phase III) trials demonstrated the superiority of a combination regimen with Doxorubicin (Doxo, 60 mg/m²) and Trabectedin (Trab, 1.1 mg/m²) D1-D21 (Doxo+Trab) versus Doxorubicin (Doxo, 75 mg/m²) alone in the first line setting for metastatic or unresectable leiomyosarcomas with median Overall Survival (mOS) of 33 months (95% CI 26-48 months) *versus* 24 months (95% CI 19-31 months) (HR for death 0.65; 95% CI 0.44-0.95), respectively. The incidence of adverse events (AE), notably Grade 3-4 AE, was higher with the combination regimen compared to Doxo alone (97% versus 56%, p$<$0.001, respectively), although these were manageable. As more than one-third of soft-tissue sarcomas occur in patients (pts) over 65-year-old (yo), a better understanding of the risks and benefits of Doxo+Trab association in elderly patients is needed. **Methods:** Data from case report forms of pts aged $\geq$70 years enrolled in LMS02 and LMS04 were retrospectively analyzed to assess efficacy and toxicity of Doxo+Trab versus Doxo monotherapy. **Results:** 44 pts of 70 yo and older were included: 13 pts in LMS02 (Doxo+Trab 6 cycles, without maintenance), 15 pts in LMS04 arm B (Doxo+Trab : 6 cycles, followed by Trab maintenance for up to 17 cycles), and 16 pts in LMS04 arm A (Doxo monotherapy). The mean age was 74 yo (range 70-86), all pts had ECOG PS 0-1, and lung was the most frequent metastatic site. Median OS was 24 months with Doxo, 39 months with Doxo + Trab, and 48.9 months with Doxo + Trab-Trab (LMS04 cohort). Median PFS was 6.7 months with Doxo, 13.2 months in the Doxo + Trab arm, and 20.5 months with Doxo + Trab - Trab Toxicity analysis included patients from LMS02 and LMS04 as follows: 28 pts treated with Doxo+Trab (from both LMS02 and LMS04) and 16 pts treated with Doxo monotherapy in LMS04. The median number of received cycles was 6 in both groups. Twenty-two pts (80%) treated with the combination experienced Grade $\geq$3 AE, including 13 pts with Grade 4 events. These toxicities were predominantly hematologic; with 12% febrile neutropenia and 9% asthenia. In the monotherapy arm, ten pts (63%) had Grade $\geq$3 AE, including 5 pts with Grade 4 events, with asthenia (17%) and febrile neutropenia (17%) being the most frequent. The lack of statistical significance (p=0.2) should be interpreted cautiously due to limited sample size. **Conclusions:** For pts over 70 yo, the efficacy of the combination Doxo+Trab followed by trabectedin maintenance in advanced LMS in the first line setting, as measured by PFS and OS, did not differ from that in younger patients. Toxicity analysis suggests that age alone is not a limiting factor for this combination. Therefore, age-related frailty should not prevent patients from receiving a potentially life-prolonging treatment. A global geriatric evaluation and active supportive care may make treatment safer. Research Sponsor: None.

11516 Rapid Oral Abstract Session

Phase 1 study results with PRAME-directed T-cell receptor (TCR) T-cell therapies in synovial sarcoma. First Author: Dejka M. Araujo, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with advanced or recurrent synovial sarcoma (SS) have limited treatment options that can provide sustained disease control beyond 6 mos. SS expresses multiple cancer testis antigens, including PRAME, which is expressed in >50 cancers. Anzutresgene autoleucel (anzu-cel, IMA203) is a PRAME-directed TCR T-cell therapy engineered to recognize an intracellular PRAME-derived peptide presented by HLA and initiate a potent and specific antitumor response. IMA203CD8 is a TCR T-cell therapy that additionally engineers a CD8 co-receptor to allow both CD4+ and CD8+ T cells to detect and destroy PRAME-expressing tumor cells that evade conventional therapeutic approaches. Here we present phase 1 results for the subset of pts with SS from IMA203-101 treated with anzu-cel or IMA203CD8 (hereafter TCR T). **Methods:** Pts were ≥18 y, HLA-A*02:01+, PRAME+, with R/R solid tumors, measurable disease (RECIST 1.1), ECOG PS 0-1, and no remaining SOC treatment options. Following leukapheresis and TCR T manufacture, pts underwent lymphodepletion (LD) with Cy (500 mg/m^2 × 4 d) and Flu (30 mg/m^2 × 4 d), followed by TCR T infusion +/- low-dose SUBQ IL-2. **Results:** As of Oct 27, 2025, 21 pts with SS were treated with anzu-cel (n=9) or IMA203CD8 (n=12). The most common TEAEs were LD-related cytopenias (100%). Cytokine release syndrome occurred in 18 pts (86%; G1: 38%, G2: 38%, G3: 10%). One event of G1 immune effector cell–associated neurotoxicity occurred (5%). Twenty pts were evaluable for efficacy and received a low median dose of 1.51 x 10^9 total TCR T cells (range: 0.35-9.36 x 10^9). These pts had a median sum of target lesions at baseline of 10.22 cm (range: 1.24-41.1 cm) and received a median of 2.5 prior lines of therapy (range: 1-5). At baseline, 65% had ≥2 previous lines of systemic therapy and 75% received prior radiotherapy. The confirmed objective response rate (cORR), including all pts evaluable for efficacy across escalating doses, was 50% (10/20), including 1 confirmed CR (8%) with IMA203CD8 at a dose of 2.05 x 10^9 total TCR T cells. Median tumor reduction for pts with confirmed objective response was -63.4%. Median duration of response at these escalating dose levels was 12.7 mo (mFU: 23 mo) with 5 responses lasting for ≥12 mo including 2 ongoing PRs at 27 and 23 mo. Median overall survival was 18 mo. Results include 1 pt who received 3 sequential TCR T-cell therapies: the MAGE-A4-targeted afamitresgene-autoleucel (BOR: SD; PFS: 21.4 mos), PRAME-targeted anzu-cel (BOR: cPR; PFS: 24.4 mo), and IMA203CD8 (BOR: cPR; PFS ongoing at 24.4 mo). **Conclusions:** PRAME-directed TCR T-cell therapies exhibited a safety profile consistent with previous observations, and despite low doses, promising antitumor activity with durable responses that deepened over time in pts with SS. These results warrant further investigation. Clinical trial information: NCT03686124. Research Sponsor: None.

11517 Rapid Oral Abstract Session

Longitudinal plasma and CSF ctDNA profiling as used to define therapeutic landmarks and compartmentalized clonal evolution in rhabdomyosarcoma. First Author: Yizhuo Zhang, Department of Pediatric Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China

Background: Current risk stratification in rhabdomyosarcoma (RMS) relies on static pretreatment variables, which fail to capture dynamic tumor evolution and molecular residual disease under therapeutic pressure. Although liquid biopsy offers a non-invasive solution, clinical implementation has been constrained by a reliance on retrospective datasets and the lack of prospectively validated therapeutic landmarks or compartmentalized monitoring strategies. **Methods:** We conducted the largest multi-center, prospective liquid biopsy study to date, enrolling 143 treatment-naïve RMS patients (Aug 2020–Feb 2025; 91.6% intermediate/high-risk). We utilized ultra-deep (>5,000×) sequencing (506-gene panel) on matched tumor, longitudinal plasma (n=292), and cerebrospinal fluid (CSF) from patients with parameningeal or central nervous system (CNS) metastatic disease. Critically, paired tissue and plasma were collected at disease progression (PD) to map evolutionary trajectories. Genomic alterations were correlated with progression-free survival (PFS) and overall survival (OS) using univariate and multivariate Cox regression. **Results:** Baseline profiling identified MYOD1 mutation as the strongest independent predictor of inferior PFS (HR 6.52, P=0.003), while MYCN amplification defined a novel "ultra-high-risk" fusion-positive subset (OS, P<0.001). Baseline ctDNA positivity (66.7%) correlated with advanced disease (P<0.001). Longitudinally, persistent ctDNA at Cycle 5 Day 1 (C5D1) conferred a 12-fold increased progression risk (HR=12.2, P=0.004), establishing C5D1 as the definitive prognostic landmark. Patients with positive longitudinal ctDNA harbored a nearly 6-fold increased risk of progression (HR = 5.97, 95% CI 2.25–15.85, P < 0.001) and a 12-fold increased risk of death (HR = 12.4, 95% CI 1.42–108.37, P = 0.023) compared to those with sustained negativity. Analysis of paired samples at relapse revealed subclonal replacement driven by therapeutic pressure, enriching for acquired resistance alterations in TP53 and DNA damage response (DDR) pathways undetectable by static assays. Additionally, paired CSF-plasma profiling in parameningeal/CNS disease identified the CNS as an evolutionary "sanctuary site" harboring distinct, compartment-specific drivers (e.g., TP53, HRAS) divergent from plasma. **Conclusions:** This prospective study establishes ctDNA as a critical biomarker for RMS, defining MYOD1, MYCN, and TP53 as key genomic risk factors and validating C5D1 as the optimal therapeutic landmark. Deep longitudinal profiling uncovers subclonal replacement and compartmentalized CNS evolution as drivers of treatment failure, advocating for comprehensive, compartment-specific monitoring in next-generation risk-adapted trials. Clinical trial information: NCT05778955. Research Sponsor: None.

11518 Rapid Oral Abstract Session

Safety and pharmacokinetics (PK) of lurbinectedin (lurbi) in pediatric patients (pts) with relapsed/refractory (R/R) solid tumors and preliminary antitumor activity in pediatric and young adult pts with R/R Ewing sarcoma (EwS): Results from a phase 1 study. First Author: Julia Lynne Glade Bender, Memorial Sloan Kettering Cancer Center, New York, NY

Background: About 30% of pediatric cancers are solid tumors. EwS is the second most common bone tumor among children and young adults; 5-year survival rates for R/R EwS are <15%. Lurbi is a trabectedin analogue that alkylates DNA and blocks transcription of EWS-FLI1, a primary driver of EwS. In a phase 2 basket trial, lurbi demonstrated an objective response rate (ORR; complete response [CR] or partial response [PR]) of 14% and disease control rate (DCR; CR, PR, or stable disease) of 57% in 28 adults (median age, 33 years [y]) with R/R EwS. Here, we report phase 1 results from a multicenter, open-label study (NCT05734066) of lurbi in pediatric and young adult pts with R/R solid tumors including EwS. **Methods:** Part 1 evaluated the safety, tolerability, PK, and recommended phase 2 dose (RP2D) of lurbi monotherapy in pediatric pts (aged 2–18 y) with R/R solid tumors. RP2D selection used a Bayesian optimal interval design starting with the approved adult dosage, 3.2 mg/m^2 lurbi IV over 1 hour every 3 weeks. Two additional cohorts were treated at the RP2D: a safety cohort for pts aged <18 y and a histology-specific safety and efficacy cohort for pts aged 2–30 y with R/R EwS. Tumor responses were assessed every 6 weeks per RECIST v1.1. **Results:** As of Oct 22, 2025, 21 pts received ≥1 dose of lurbi (3.2 mg/m^2, n = 17; 4.0 mg/m^2, n = 4). Median (range) age was 16 (10–25) y; 13 (62%) pts had received ≥3 prior lines of treatment (Tx). Median (range) lurbi cycles administered was 3 (1–18); 3 (14%) pts were still receiving lurbi; 18 (86%) discontinued Tx. At 4 mg/m^2, dose-limiting pulmonary edema and rhabdomyolysis/acute kidney injury were observed. Among pts receiving lurbi 3.2 mg/m², 8 (47%) had grade ≥3 Tx-related adverse events (TRAEs); anemia (5 [29%]) and platelet count decrease (5 [29%]) were most common (Table). For pts aged ≥6 y, the RP2D was 3.2 mg/m^2; accrual of pts aged <6 y is ongoing to determine RP2D. Although geometric mean (Geo CV%) C_{max} (163 μg/L [105%]) and AUC_{inf} (1893 μg•h/L [126%]) were higher in children/young adults vs adults in the phase 2 basket trial (increased 53% and 244%, respectively), there was substantial overlap in drug exposures. Among 11 evaluable pts with R/R EwS receiving lurbi 3.2 mg/m², the confirmed ORR was 18%, and the DCR was 55%; 2 responders were progression free at their last assessments (5.7 and 6.9 months). **Conclusions:** Based on these data, lurbi had a manageable safety profile, predictable PK properties, and encouraging preliminary clinical activity in pts with R/R EwS. Phase 2 expansion in pts ≤30 y with R/R EwS is ongoing. Clinical trial information: NCT05734066. Research Sponsor: Jazz Pharmaceuticals.

TRAEs in all pts and by dose.

n (%)	All N = 21	3.2 mg/m^2 n = 17	4.0 mg/m^2 n = 4
Any TRAE	21 (100)	17 (100)	4 (100)

Association of NAB2–STAT6 distal fusion with risk level of metastatic disease and thoracic primary site. First Author: Keerthana Sureshkumar, University of Miami Miller School of Medicine, Miami, FL

Background: Solitary fibrous tumors (SFTs) are defined by the NAB2–STAT6 gene fusion, but the clinical significance of these breakpoints remains incompletely understood. Although fusion breakpoint heterogeneity has been implicated in influencing biologic behavior, there are few studies linking variant location to outcomes. Recent genome analyses suggest that proximity based breakpoint clustering approaches can reveal driver loci, suggesting investigation of NAB2–STAT6 fusion breakpoints may be potential prognostic markers. Because individual variants are rare, we used a proximal vs distal breakpoint analysis to evaluate high-risk clinical features. In this study, we evaluated trends between the NAB2–STAT6 breakpoint and metastases, primary tumor location, and recurrence in a single-institution, retrospective cohort study. **Methods:** We performed an analysis of patients with SFTs treated at the Sylvester Comprehensive Cancer Center (n=48). Samples without pathology-confirmed NAB2–STAT6 fusions were excluded. Clinical variables included primary tumor site, size, stage, and recurrence. Molecular data was extracted from next-generation whole transcriptome and exome sequencing reports. Breakpoints were categorized by exon numbers. NAB2 breakpoints were considered proximal if they occurred before exon 6 and distal if they occurred at exon 6 or more distally. STAT6 breakpoints were considered proximal if they occurred at exon 6 or earlier and distal if they occurred at exon 16 or more distally. Associations were analyzed using Fisher exact tests. **Results:** Breakpoint patterns were significantly associated with metastatic presentation at diagnosis. Metastatic disease at the time of diagnosis was not observed in any patients with proximal STAT6 breakpoints (n= 29) but was present in 24% (n = 17) of those with distal STAT6 breakpoints (p=0.02). Additionally, metastatic disease occurred exclusively in tumors with distal NAB2 breakpoints (n=14, p=0.01). Breakpoint patterns were also associated with primary tumor sites. The majority of proximal STAT6 fusions were present mostly in thoracic cavity tumors (55%), while distal STAT6 fusions occurred mainly in tumors at non-thoracic sites (p=0.02). Among fusion subtypes, metastatic presentation was absent in ex4: ex2 tumors but observed in 31% of tumors with ex6: ex16/17 tumors (p=0.02). Distal STAT6 breakpoints also showed trends toward higher recurrence rates and grades as well as larger tumor sizes. **Conclusions:** Our study shows that NAB2–STAT6 distal fusion breakpoint patterns are associated with metastatic disease at diagnosis, non-thoracic primary tumor locations and more aggressive clinical features. These findings support the consideration of breakpoint patterns as part of molecular risk stratification and identifies a potential biomarker for SFT patients with a primary tumor who may benefit from chemotherapy. Research Sponsor: None.

11520 Rapid Oral Abstract Session

Efficacy of velzatinib (IDRX-42) in patients with advanced/metastatic GIST by line of therapy and circulating tumor DNA response in the phase 1/1b StrateGIST 1 trial. First Author: Michael C. Heinrich, Oregon Health & Science University, Portland, OR

Background: Most gastrointestinal stromal tumors (GIST) are driven by mutations in *KIT* or *PDGFRA*. Resistance to standard tyrosine kinase inhibitor (TKI) therapy is largely driven by acquisition of secondary mutations in *KIT* exons 13/14/17/18. Velzatinib (subject to USAN approval) is a broad-spectrum TKI designed to inhibit most common primary *KIT* mutations (exons 9 and 11) as well as secondary mutations. We present updated circulating tumor DNA (ctDNA) results from StrateGIST 1, a phase 1/1b study evaluating the efficacy and safety of velzatinib across primary and secondary mutations in patients (pts) with advanced/metastatic GIST. **Methods:** The study design of StrateGIST 1 has been previously described (Schöffski et al. *J Clin Oncol* 2024). Clinical activity was assessed by mRECIST v1.1. Blood samples for ctDNA analyses (Guardant360 assay) were collected for all pts before and serially during treatment. Data analysis was performed in R and hazard ratios were calculated using Cox proportional hazards regression. **Results:** As of September 2025, 256 pts received velzatinib across all lines of therapy. Velzatinib showed clinical activity against both primary (Exon 9 ORR: 44% [95% CI: 29.1, 60.1]; Exon 11 ORR: 19% [95% CI: 12.7, 27.6]) and secondary (Exon 13 ORR: 17% [95% CI: 8.6, 27.9]; Exon 14 ORR: 20% [95% CI: 2.5, 55.6]; Exon 17 ORR: 23% [95% CI: 14.6, 33.2]) mutations. Clinical activity is supported by ctDNA analysis (n=180 pts); >99% reduction in ctDNA variant allele frequency (VAF) was observed across a broad spectrum of individual mutations (Exon 9: 80%; Exon 11: 67%; Exon 13: 80%; Exon 14: 80%; Exon 17: 83%). We also evaluated the predictive value of different exon mutations in *KIT* detected at baseline via ctDNA. Focusing on pts with primary mutations only, *KIT* exon 9 mutations had 3-fold lower risk of disease progression compared to exon 11 mutations (HR=3.06). No significant difference was observed between major secondary mutations (exon 13 vs exon 17). Additionally, 46 pts without detectable *KIT/PDGFRA* mutations at baseline showed a lower progression risk (HR=0.41) compared to 180 pts with detectable *KIT/PDGFRA* mutations, underscoring the prognostic and/or predictive value of ctDNA analysis, even in low-shedding indications such as GIST. **Conclusions:** Velzatinib has broad activity against clinically relevant *KIT* mutations in pts with advanced and/or metastatic GIST and can substantially reduce ctDNA levels across a broad spectrum of clinically meaningful *KIT* mutation profiles. Baseline exon-level *KIT* mutation status and ctDNA detectability provide potentially useful prognostic and predictive data, justifying further study to discern the relationship between clinical benefit and molecular response. This study (NCT05489237) is funded by GSK. Clinical trial information: NCT05489237. Research Sponsor: GSK.

Feasibility of constructing an external control arm for early efficacy assessment in phase 1a: Methodological framework from the INVOKE trial. First Author: Nicolas Loiseau, Owkin, New York, NY

Background: Phase 1a dose-escalation trials are primarily designed for safety but often lack sufficient visibility into efficacy signals due to small sample sizes and the absence of a comparator arm. This uncertainty can delay decision-making and increase late-stage failure rates. We hypothesized that a synthetic External Control Arm (ECA) aggregating real-world data (RWD) and historical clinical trials could be established to contextualize efficacy readouts from the ongoing OKN4395 Phase 1a study (INVOKE; NCT06789172; Trial in Progress abstract submitted to this meeting). **Methods:** We curated a retrospective dataset of 298 solid tumor patients derived from two complementary sources, RWD and recent clinical trials (inclusion date $\geq$ 2016). To ensure comparability with the INVOKE population, patient selection adhered strictly to the study's inclusion and exclusion criteria, with only individuals who had exhausted all standard-of-care (SoC) options being retained. We further refined the cohort to ensure exact overlap, retaining only external patients who shared an identical baseline covariate profile with at least one patient in the INVOKE cohort. Finally, we applied statistical adjustment methods, including Inverse Probability of Treatment Weighting (IPTW) and G-Computation, to align the remaining cohort on major prognostic variables (e.g. ECOG status, prior lines of therapy, inter alia). **Results:** A total of 13 INVOKE patients with available endpoint data were eligible for ECA matching. The selection process yielded a final robust ECA cohort of 40 patients. In this refined population, we achieved robust covariate alignment between the ECA and the INVOKE cohort, with absolute Standardized Mean Difference (SMD) $<$ 0.13 for all major prognostic variables. Despite the methodological differences between IPTW and G-computation, both statistical approaches yielded highly consistent estimates. Data from INVOKE, a study in early stages, is yet to publish data (TIP presented at this meeting), comparative efficacy data will be disclosed at a later date. **Conclusions:** We demonstrated that constructing a synthetic ECA generating outcomes directly comparable to those of the population of an active Phase 1a dose-escalation study is methodologically feasible. The establishment of this matched external cohort and first application to the INVOKE Phase 1a study provides a proof of concept framework for early efficacy assessment. This "de-risking" tool is now positioned to provide rapid, concurrent contextualization of emerging data from the INVOKE trial upon data maturity. Research Sponsor: None.

AI-assisted systematic review and pooled analysis of anthracycline- versus taxane-based chemotherapy in advanced or metastatic angiosarcoma. First Author: Annarita Peddio, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy

Background: Comparative evidence for first-line anthracycline- (Ant) vs taxane-based (Tax) chemotherapy in advanced angiosarcoma (AS) is limited by small, heterogeneous retrospective studies. We performed an AI-assisted systematic review and pooled analysis to overcome fragmented reporting and evaluate efficacy and safety across clinically relevant subgroups, including cutaneous and radiation-induced AS (RIAS). **Methods:** A PubMed search (2000–2025) identified 11 eligible studies, 6 providing quantitative class-specific outcomes. An AI-assisted workflow (GPT-5) harmonized heterogeneous datasets, resolved denominator inconsistencies, and enabled supervised reconstruction of missing subgroup numerators. Endpoints included objective response rate (ORR), disease control rate (DCR), survival outcomes, and toxicity. ORR and DCR were compared using two-proportion z-tests. PFS, OS, and safety outcomes were summarized descriptively based on reported medians, due to incomplete and heterogeneous reporting that precluded pooling. **Results:** Among 426 evaluable patients (Ant n = 245; Tax n = 181), Tax demonstrated higher pooled ORR (44.8% vs 29.0%, p= 0.001) and DCR (63.7% vs 52.6%, p= 0.018). Benefits were marked in cutaneous AS (ORR 50.8% vs 31.5%, p= 0.017) and RIAS (41.8% vs 30.2%, p= 0.036), while non-cutaneous AS showed comparable ORR (25.3% vs 27.8%, p= 0.68). Reported median PFS (6.2 vs 5.0 months) and OS (14.3 vs 12.2 months) numerically favored Tax. Safety analysis, enabled by AI integration of fragmented datasets, showed that Tax was mainly associated with low-grade neuropathy and mild myelosuppression. Ant toxicity reporting was sparse but included fatal neutropenic events, indicating greater hematologic risk. **Conclusions:** Tax shows superior antitumor activity in cutaneous AS and RIAS with favorable tolerability. Anthracyclines remain an option for selected patients, although higher hematologic toxicity is expected. These findings, derived through AI-assisted reconstruction of incomplete datasets, highlight both the therapeutic relevance of Tax in AS and the potential of AI to enhance evidence synthesis in rare cancers. Research Sponsor: None.

11523 Poster Session

Efficacy and safety of continuous intra-arterial cisplatin and recombinant human endostatin combined with systemic chemotherapy in osteosarcoma: A phase II study. First Author: Hongtao Li, Department of Oncology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Previous studies have demonstrated that preoperative intra-arterial cisplatin infusion elicits a favorable histologic response—a key prognostic factor for survival in osteosarcoma. Recombinant human endostatin (rh-endostatin; Endostar), an anti-angiogenic agent, has been shown to significantly improve survival when administered intravenously in combination with chemotherapy for osteosarcoma. Herein, we report preliminary results on the efficacy and safety of continuous intra-arterial cisplatin and rh-endostatin combined with systemic chemotherapy in osteosarcoma (NCT06562673). **Methods:** This open-label, single-arm, single-center, phase II clinical trial enrolled patients with histologically confirmed primary localized extremity conventional osteosarcoma. Patients received 2 cycles of high-dose methotrexate and anthracyclines intravenously. Intra-arterial infusion was performed concurrently with anthracyclines. Rh-endostatin was administered intra-arterially (150 mg over 6 hours); then, cisplatin was administered intra-arterially (100-120 mg/m² over 6 hours). Efficacy and safety were evaluated after surgery. **Results:** Ten patients were enrolled from December 2024, to April 2025, including 7 males and 3 females with a mean age of 17.8 years (range, 12-42 years). Tumor locations included the femur (n=6), tibia (n=3), and humerus (n=1). Preoperative arterial infusions were administered 3 times (n=1), 2 times (n=8), and 1 time (n=1). All patients underwent limb-sparing surgery. The tumor necrosis rate was >90% in 5 cases (50%) and ≤90% in 5 cases (50%). Adverse events included grade 3 vomiting and nausea (n=1), grade 1 renal impairment (n=2), fever (n=1), and skin induration (n=1). Due to grade 3 gastrointestinal toxicity observed in the first enrolled female patient, the cisplatin dose was uniformly reduced to 100 mg/m² for all subsequent patients in the trial. **Conclusions:** Intra-arterial administration of high-dose rh-endostatin and cisplatin combined with systemic chemotherapy in osteosarcoma appears safe and achieves a good histologic response rate of 50%, compared with a historical rate of 30% with intravenous chemotherapy alone. Clinical trial information: NCT06562673. Research Sponsor: None.

11524 **Poster Session**

ICONIC (Improving Outcomes Through Collaboration in Osteosarcoma): Insights from a national prospective cohort trial for newly diagnosed osteosarcoma patients. First Author: Sandra J. Strauss, University College London, London, United Kingdom

Background: There has been little change in osteosarcoma (OS) treatment over the last two decades. Understanding management patterns, better understanding of biology and identifying new biomarkers are key to improving outcomes. **Methods:** ICONIC is a UK-wide prospective observational trial of newly diagnosed OS pts with longitudinal clinical, imaging, tissue and pt experience data collection to address key objectives. These include describing variation in management and outcomes for specific pt groups, establishing an imaging repository to develop imaging biomarkers, analysis of plasma cfDNA, and use of tumor tissue to develop pt-derived models and decode tumor-immune cross talk. Pts were recruited from Oct 2019 to Jan 2025. Progression-free (PFS) and overall survival were analysed using Kaplan-Meier survival statistics and Cox regression. **Results:** A total of 337 pts were recruited from 27 sites. Median age was 19 (range 3-83); 17% had metastases. In total, 229/253 (91%) pts receiving neoadjuvant treatment had methotrexate, doxorubicin, cisplatin (MAP); 259 underwent surgery, of which 52 (20%) had amputations; 101/161 (63%) of eligible pts received mifamurtide. With median follow-up of 2.5 years, 2-year PFS and overall survival were 57% (95% CI 51-63) and 78% (95% CI 72-83) (Table 1). Age, raised ALP, pelvis or trunk primary sites, metastases and inoperability were associated with worse PFS. Pts with a good pathological response to treatment and ≥2mm resection margin had the lowest risk of local recurrence (p=0.02). A pilot radiomics analysis of 32 pts undergoing resection after MAP, demonstrated baseline tumour volume (p=0.044) pre-treatment T2 Gray Level Non-Uniformity (GLNU) (p=0.002), and post-treatment GLNU difference (p=0.008) to be associated with overall survival. Longitudinal blood samples for cfDNA analysis were collected from 226 pts. Patient-derived primary cultures were successfully developed from 12 pts. Spatially-resolved genomic and transcriptomic analysis of tumor tissue to study genomic evolution and immune evasion is ongoing. **Conclusions:** ICONIC trial has identified variation in management and outcomes of OS, which will guide future practice and provided a successful platform for imaging and biomarker analysis, which is ongoing. Clinical trial information: NCT04132895. Research Sponsor: Bone Cancer Research Trust.

Pt characteristics and outcomes according to age and primary site.

	All patients N=337	<16 years N=115	16-24 years N=101	25-39 years N=60	>40 years N=61
Lower limb	228 (68%)	90 (78%)	74 (73%)	34 (57%)	30 (49%)

Efficacy and safety analysis of anlotinib combined with etoposide plus ifosfamide in the treatment of children and adolescents with pulmonary metastatic osteosarcoma. First Author: Hui Li, Northwest Women's and Children's Hospital, Xi'an, China

Background: Osteosarcoma is a highly malignant and aggressive tumor, predominantly occurring in children and adolescents under 20 years of age. It exhibits early metastatic potential, with 15%–20% of patients presenting with distant metastasis at diagnosis. Among these, pulmonary metastases account for 85% of cases. The 5-year survival rate after pulmonary metastasis is <20%. This study retrospectively analyzes the efficacy and safety of anlotinib combined with etoposide and ifosfamide in treating pediatric and adolescent patients with pulmonary metastatic osteosarcoma. **Methods:** This study retrospectively screened children and adolescent patients with pulmonary metastatic osteosarcoma who received etoposide + ifosfamide ± anlotinib at Northwest Women's and Children's Hospital from May 2018 to December 2024. The study was divided into a combination group (anlotinib + etoposide + ifosfamide) and a control group (etoposide + ifosfamide). The dosage of anlotinib: 8 mg for patients < 12 years old, qd, d1-d14, q3w, 12mg for patients ≥12 years old, qd, d1-d14, q3w. Treatment continued until disease progression or intolerable toxicity, with a maximum of 4 chemotherapy cycles. The primary endpoint of the study was objective response rate (ORR), and secondary endpoints included disease control rate (DCR), progression-free survival rate (PFSR), and safety. **Results:** The data cut-off date was December 2024, The study enrolled 38 patients (combination group: n=18, control group: n=20). Efficacy analysis showed the combination group achieved higher ORR (22.2% vs 15%, p=0.057) and significantly better DCR (66.7% vs 45%, p=0.015), and 3-month progression-free survival rates (PFSR) of 44.0% versus 30%. Subgroup analysis indicated superior outcomes with 12 mg versus 8mg anlotinib (p<0.05). Biomarker evaluation revealed patients with high BRCA1/VEGFR2 expression had lower 3-year survival than those with intermediate/low expression, while low PDGFR expression was associated with poorer survival compared to intermediate/high levels. The combination group exhibited higher incidence rates of treatment-related adverse events (TRAEs) compared to the control group, including epistaxis (44.4%), hand-foot syndrome (27.8%), abnormal thyroid function (22.2%), and proteinuria (16.7%). All reported adverse events were grade 1-2 in severity, with no grade 3-4 severe adverse reactions observed. **Conclusions:** The combination therapy of anlotinib with ifosfamide and etoposide demonstrated superior efficacy compared to chemotherapy alone in pediatric patients with pulmonary metastatic osteosarcoma, showing higher ORR, DCR, and 3-month PFSR. These results indicate that anlotinib combined with neoadjuvant chemotherapy can more effectively delay tumor progression and prolong progression-free survival in these patients. Efficacy and safety of perioperative anlotinib combined with cisplatin and doxorubicin in treatment-naive stage IIB classic osteosarcoma of the extremity: Updated results from the ALTER-S002 trial. First Author: Minxun Lu, Department of Orthopedics, West China Hospital, Sichuan University, Chengdu, Sichuan, China

Background: Clinical studies show overexpression of multiple tyrosine kinase receptors in osteosarcoma, supporting targeted therapy as a promising direction. Anlotinib, a multi-targeted tyrosine kinase inhibitor, exerts anti-tumor angiogenesis effects. Combining anti-angiogenic agents with chemotherapy may yield synergistic tumor control, particularly as perioperative therapy. We present updated long-term efficacy and safety data, including key secondary endpoints, to validate this regimen's clinical value. **Methods:** This was an open-label, single-arm, multicenter phase II trial. Eligible patients (12-40 years) had histologically confirmed primary localized stage IIB classic extremity osteosarcoma and were operable. Patients received anlotinib (10mg, po, d1-14, q3w), doxorubicin (A, 20-25 mg/m², iv, d1-3, q3w) and cisplatin (P, 70-90 mg/m², iv, d1, q3w) for 9 weeks. Radical surgery was performed at week 10 (no contraindications). Postoperatively, A+P was given at weeks 12-14, followed by anlotinib+A+P (same doses) at weeks 15-20. From week 21, anlotinib monotherapy (12mg, po, d1-14, q3w) continued until week 104 or an event-free survival (EFS) event. Primary endpoint: 24-month EFS rate. Secondary endpoints: 36-month EFS rate, local recurrence rate, lung metastasis rate, 3-year overall survival (OS) rate, and safety. **Results:** From May 2020 to April 2022, 52 patients were enrolled, treated, and included in full analysis set (FAS) and safety set (SS). Of these, 84.6% (44/52) were Han and 55.8% (29/52) male. Median follow-up was 42.7 months (IQR 30.4-52.7). The 24-month and 36-month EFS rates were 73.7% (95% CI 59.0-83.9) and 46.6% (95% CI 27.4-63.7), respectively. Median OS was not reached; 36-month and post-hoc 60-month OS rates were 74.6% (95% CI 59.6-84.7) and 71.4% (95% CI 55.5-82.4). Twenty-five percent (13/52) of patients died, mostly due to lung metastasis (13%). Among 51 surgical patients, local recurrence, lung metastasis, and other-site metastasis occurred in 23.5%, 17.6%, and 9.8%, respectively. Median recurrence-free survival (RFS) was 32.4 months (95% CI 25.7-not estimable). Grade 3-4 treatment-related adverse events (TRAEs) occurred in 84.6% (44/52) of patients, with neutropenia most common (28/52 [53.8%]). No grade 5 TRAEs were observed. Serious TRAEs occurred in 40.4% (21/52), mainly myelosuppression (14/52 [26.9%]). None of the 13 on-study deaths were TRAE-related. **Conclusions:** Perioperative anlotinib plus cisplatin and doxorubicin shows promising efficacy in treatment-naïve stage IIB classic extremity osteosarcoma, with manageable safety. It achieves favorable long-term OS, and clinically acceptable local recurrence and lung metastasis rates, serving as a potential new perioperative option for this population. Clinical trial information: ChiCTR 2000033298. Research Sponsor: None.

A phase 2 trial of cetuximab for patients with locally advanced/metastatic chordoma. First Author: Anthony Paul Conley, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Unresectable/metastatic chordoma is a rare notochordal malignancy with no approved systemic treatments. EGFR is widely expressed on chordomas. Cetuximab is a recombinant, human/mouse chimeric monoclonal antibody that inhibits EGFR signaling. In vivo testing of cetuximab has demonstrated growth inhibition and regression of chordoma. An investigator-initiated, single center, phase II study (NCT05041127) was developed to evaluate the efficacy of cetuximab for patients (pts) with advanced/metastatic chordoma. **Methods:** Eligible pts were ≥18 years of age, had adequate organ function, and had an ECOG performance status (PS) of ≤2. Any prior line of therapy was allowed except EGFR inhibitors. A minimum of 10 pts and maximum of 29 pts were to be enrolled onto the trial based on Simon's two-stage optimal design (H_0 RR 5% vs H_1 RR 20%; one-sided α=0.05; power=80%). Pts received cetuximab 500 mg/m^2 IV Q2 weeks until disease progression or unacceptable toxicity. The primary end point was response rate (RR) according to RECIST 1.1. Secondary objectives included safety/tolerability and survival metrics. Efficacy was assessed in the modified intention-to-treat (mITT) population (≥1 dose; ≥1 post-baseline scan). Exploratory objectives included analysis of the EGFR pathway at 2 time points from research-related biopsies. Pt reported outcomes (PROs) were assessed with MDASI (general and spine) questionnaires at several time points on study. **Results:** From May 2022 to Dec 2025, 29 pts enrolled. 4 were excluded from the efficacy analysis (2 withdrawal, 1 cetuximab allergy, 1 has not completed the 1st imaging assessment). Median age was 58 years (range 21-76), 15 (58%) were men, and 24 (92%) had ECOG PS of 0 or 1. The most common primary site was skull base (46%). Tumor was classified as locally recurrent in 8 pts (31%) and metastatic in 18 pts (69%). One median line of prior systemic therapy was noted (range, 0-6). At a median follow up of 28.7 months, 12 pts (48%) had radiographic cytoreduction (any tumor reduction [ATR]), but only 2 pts (8%) had a partial response (PR). Neither PR was associated with an EGFR gene alteration. Stable disease (SD) was noted in 23 pts (92%). Preliminary median PFS and median OS was 9.9 months (95% CI, 6.3 to 13.4) and 38.8 months (95% CI, 18.6 to NR), respectively. Significantly longer PFS was observed in SD-ATR (log-rank p=0.038), with median of 14.2 months in SD-ATR versus 9.6 months in SD without tumor reduction. 7/26 pts (27%) experienced a grade 3 cetuximab-related adverse event (AE), the most common being rash in 4 pts (15%). No grade 5 AE related to cetuximab was reported. Dose reduction occurred in 2 pts (8%). 4 pts (15%) discontinued the study due to toxicity. 4 pts remain on study. **Conclusions:** Although the primary end point has not been reached, 2 PRs are noted, and pts with SD-ATR have a longer PFS. Translational and PRO analysis are ongoing to better define biological predictors of cetuximab activity in chordoma. Clinical trial information: NCT05041127. Research Sponsor: Chordoma Foundation; Eli Lily.

Genomic characterization of conventional, dedifferentiated, and mesenchymal chondrosarcoma: A 550-patient multicenter analysis. First Author: Luyuan Li, North Alabama Medical Center, Florence, AL

Background: The rarity of chondrosarcoma has historically impeded efforts and systematic genomic characterization. However, large, standardized, multi-center databases, such as the AACR Project GENIE, along with other, independent studies, have enabled genetic profiling of hundreds of patients with these cancers. **Methods:** The following datasets were accessed through cBioPortal: the GENIE Cohort v18.0; msk_impact_2017; metastatic_solid_tumors_mich_2017; pog570_bcgsc_2020; msk_ch_2020; msk_ch_ped_2021; sarcoma_msk_2022; sarcoma_mskcc_2022; mixed_kunga_msk_2022; msk_ctdna_vte_2024; and sarcoma_ucla_2024. These datasets included 550 unique patients: 453 conventional chondrosarcoma (CHS), 42 dedifferentiated chondrosarcoma (DDCHS), and 55 mesenchymal chondrosarcoma (MCHS). Mutational and structural variant data were also extracted from each data set and ranked by frequency. This ranked list of genes was then analyzed using g:Profiler enrichment analysis software. Dunn's test with Benjamini-Hochberg correction following Kruskal-Wallis test was performed for statistical analysis. **Results:** The average age at biopsy was 52 for CHS, 63 for DDCHS, and 32 for MCHS. DDCHS displayed the greatest genomic instability, with significantly elevated mutation count and tumor mutation burden (TMB) compared to CHS and MCHS ($p < 0.001$). Despite the higher TMB in DDCHS, the most frequently mutated genes were highly conserved between CHS and DDCHS, with six of the 20 most frequently mutated genes being shared between them. In contrast, MCHS shared only two of the 20 most frequently mutated genes with CHS and DDCHS. *TP53*, *IDH1* and *-2*, and *TERT* were frequently mutated in both CHS and DDCHS. Enrichment analysis indicated that DNA repair pathways were among the most frequently altered in both diseases. These pathways, while still perturbed in MCHS, appeared less prominently, with genes involved in chromatin organization being frequently mutated. Moreover, Enrichment analysis of structurally variant genes in CHS also showed frequent alterations in chromatin organizing genes, along with genes involved in NOTCH signaling. While structural variant genes were not reported with enough frequency in DDCHS and MCHS to permit the analysis, the HEY1-NCOA2 fusion product was frequently detected in MCHS. **Conclusions:** The results of this multi-institutional bioinformatics survey confirms established observations that *IDH1* and *-2* mutations are the most common genetic alterations in CHS following *TP53*. DDCHS bears a similar but more advanced mutational signature with greater genomic instability. MCHS harbors a distinct mutational profile defined by the characteristic HEY1-NCOA2 fusion. Despite these differences, all three subtypes share enrichment in mutations affecting genomic integrity pathways, suggesting this as a common feature of chondrosarcoma biology. Research Sponsor: None.

Low-dose apatinib combination with first-line chemotherapy rechallenge in advanced osteosarcoma: A single-center ambispective cohort study. First Author: Jing Chen, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: First-line treatment for osteosarcoma includes various combinations of four agents: high-dose methotrexate (HD-MTX), doxorubicin (DOX), cisplatin (DDP), and ifosfamide (IFO), achieving overall efficacy rate of 41-77% and remaining the most effective systemic therapy to date. However, patients (pts) with progression after first-line therapy lack a defined second-line standard, available treatments yield objective response rate (ORR) $<$20% with 5-year survival $<$10%. Though anti-angiogenic tyrosine kinase inhibitors have limited monotherapy efficacy, preclinical studies show they enhance intratumoral drug delivery and reverse multidrug resistance, thereby synergizing with chemotherapy. Thus, apatinib, a highly selective VEGFR-2 inhibitor, was added to the previously failed first-line chemotherapy-the most effective systemic therapy-to investigate whether it could reverse chemoresistance and restore response to the original regimen. **Methods:** This ambispective cohort study enrolled pts with advanced osteosarcoma who had tumor progression after first-line chemotherapy with HD-MTX, DOX, DDP and IFO at our center. Subsequently, low-dose apatinib (250 mg/d) was administered in combination with the same four-drug chemotherapy regimen. The primary endpoint was the ORR. Secondary endpoints included disease control rate (DCR), median progression-free survival (PFS), median overall survival (OS) and adverse events (AEs). **Results:** From Jan 2018 to Jul 2025, 37 pts were enrolled, with 9 in the retrospective cohort and 28 in the prospective cohort. Of these, 27 (73%) were male and 10 (27%) were female, with a median age of 21 years (range: 10–67). 36 pts were diagnosed as conventional osteosarcoma (96.9%). Primary tumors were located in the femur (21, 56.8%), tibia and humerus (8, 21.6%), pelvis (6, 16.2%), clavicle and rib (2, 5.4%). Metastatic disease was present in 29 pts (78.4%). The most common sites of metastasis were the lung (28, 78.1%) and bone (6, 18.8%). Partial remission was seen in 8 pts, and stable disease in 23 (ORR: 21.6%, DCR: 83.8%). After a median follow-up of 17 months (mos), PFS was 5.8 mos (2.5–9.1), OS was 14.5 mos (10.3–18.7). Pts with lactate dehydrogenase $<$245 U/L had superior PFS (7.2 vs 3.3 mos; HR=0.28, 0.1–0.8, P=0.01), with a trend of OS benefit (14.5 vs 11.6 mos, P=0.74). Pts with alkaline phosphatase $<$150 U/L had a trend of PFS benefit (6.3 vs 5.8 mos, P=0.7) and significant better OS (20.3 vs 11.7 mos; HR=0.41, 0.17–1.01, P=0.046). Prognosis was not associated with gender, age, primary site, stage or first-line therapy response. AEs were consistent with known safety profiles and manageable. **Conclusions:** Low-dose apatinib combined with previously resistant first-line chemotherapy showed promising efficacy, providing a feasible therapeutic strategy for osteosarcoma pts lacking effective second-line choices. Research Sponsor: Chen Xiao-Ping Foundation for the Development of Science and Technology of Hubei Province.

First-in-human dose escalation trial of an engineered salmonella delivering L-methioninase in advanced bone and soft tissue sarcomas. First Author: Hongtao Li, Department of Oncology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Advanced bone and soft-tissue sarcomas have limited treatment options. Tumor-selective methionine dependency is a known metabolic vulnerability. SGN1 is designed to deplete methionine locally within tumors via intratumoral colonization of an attenuated *Salmonella* vector expressing L-methioninase. Preclinical studies have demonstrated safety and targeted antitumor activity. Here, we report the results from the escalation and expansion phases of the Phase I study in patients (pts) with advanced bone and soft-tissue sarcomas. **Methods:** The Phase I study includes a dose-escalation phase where pts received intravenous (IV) (2.0×10^8 to 4.0×10^8 CFU) or intra-arterial (IA) infusion (2.0×10^8 to 6.0×10^8 CFU) once a week (QW) in 28-day cycles, followed by an expansion phase with the putative recommended Phase 2 dose (RP2D) (2.0×10^8 CFU for IV or 6.0×10^8 CFU for IA QW) in 6 cohorts, including pts with recurrent either bone or soft tissue sarcoma after at least 2 lines of chemo therapies. SGN1 was administered in combination with physician's choice systemic therapy. Administration of SGN1 was via one of three routes: IV, IA, or a combined IV/IA regimen. Efficacy was assessed by RECIST version 1.1. **Results:** At the cut-off of Aug 19, 2024, 25 pts with advanced bone and soft-tissue sarcomas were enrolled in the escalation and expansion phases (median follow-up of 5.6 months; range, 0.5-18.2), including pts with bone sarcoma (n=10) and soft tissue sarcoma (n=15). Treatment was administered via IV (n=13), IA (n=8), or a combined IV/IA (n=4) route. The disease control rate (DCR) was 76.0% (95% CI: 56.5, 93.0) in all, 70.0% (95% CI: 34.8, 93.3) in bone sarcoma, 80.0% (95% CI: 52.0, 95.6) in soft tissue sarcoma pts, and 69.2% (95% CI: 38.5, 90.9) in IV, 75.0% (95% CI: 34.8, 93.3) in IA, 100% in combined IV/IA route. Quantitative PCR analysis confirmed significant intra-tumoral colonization by SGN1 post-treatment. The median progression-free survival (mPFS) was 11.5 months (95% CI: 11.1, NE) in all, 11.1 months (95% CI: 1.1, NE) in bone sarcoma, not reached (NR) (95% CI: 3.2, NE) in soft tissue sarcoma pts, and NR (95% CI: 2.7, NE) in IV, 11.5 months (95% CI: 1.3, NE) in IA, NR (95% CI: 11.1, NE) in combined IV/IA route. Complete tumor necrosis was observed in at least two soft tissue sarcoma patients. In all pts, the most frequent treatment-related adverse events (TRAEs) were pyrexia (32.0%) and elevation of blood LDH increased (20.0%). No TRAEs leading to temporary drug discontinuation, no serious TRAEs resulting in withdrawal from the study, and no treatment-related deaths occurred. **Conclusions:** SGN1 exhibits a manageable safety profile, and showed encouraging clinical benefit in advanced bone and soft-tissue sarcoma, as evidenced by mPFS and DCR. The promising data from this phase I study supports further testing of SGN1 in Phase II studies. Clinical trial information: ChiCTR2400085361. Research Sponsor: None.

11532 **Poster Session**

Efficacy and safety of DR4/DR5 agonist aponermin monotherapy in advanced chondrosarcoma: Preliminary report from a prospective, multicenter study. First Author: Mengxiong Sun, The Orthopaedic Oncology Department, Shanghai General Hospital, Shanghai, China

Background: Reported median progression-free survival (mPFS) of Chondrosarcoma is less than 4 months for patients receiving first-line systemic therapy. Aponermin, a recombinant circularly permuted human Tumor Necrosis Factor-Related Apoptosis-Inducing Ligand (TRAIL), induces tumor cell apoptosis by activating the extrinsic apoptotic pathway. This study aimed to evaluate the efficacy of Aponermin in patients with advanced chondrosarcoma. **Methods:** This prospective, multicenter, single-arm study (Registration No: ChiCTR2500104488) was approved by an independent ethics committee. The planned enrollment was 32 patients aged 18-75 years with histologically confirmed advanced chondrosarcoma, documented evidence of disease progression within 6 months prior to enrollment, ECOG performance status $\leq$2, and measurable disease per RECIST 1.1. Patients received intravenous Aponermin 10 mg/kg (days 1-5, every 14 days as one cycle) until disease progression, unacceptable toxicity, or investigator's decision to discontinue. The primary endpoint was objective response rate (ORR). Secondary endpoints included 4-month PFS rate, disease control rate (DCR), overall survival (OS), and safety. **Results:** As of January 23, 2026, 21 patients were enrolled and treated. Median age was 51 years (range: 26-70), with a median of 2 prior surgeries (range: 1-6). Eight patients had received prior drug therapy. Histopathological subtypes included: conventional grade 1, 19% (4/21); conventional grade 2, 47.6% (10/21); conventional grade 3, 4.8% (1/21); mesenchymal, 9.5% (2/21); and one case each (4.8%) of myxoid, dedifferentiated, clear cell, and unknown subtype. Twenty patients were evaluable for efficacy. Median treatment duration was 3.6 months (range: 0.5-14.0), with 4 patients still on treatment. Although no objective responses were observed , 80.0% (16/20) of DCR was achieved. Median PFS was 4.2 months (95% CI: 2.9-5.5), and the 4-month PFS rate was 57.9%. Median OS was not reached. Notably, Among patients achieving DCR, 50% maintained clinical benefit for over 4 months, including one patient with conventional grade 3 chondrosarcoma with SD lasting 7.4 months, two patients with conventional grade 2 with SD exceeding 10.0 months, and one patient with clear cell subtype with SD lasting 14 months. Aponermin demonstrated a favorable safety profile. Treatment-related adverse events occurred in approximately 9.5% (2/21) of patients, including one case (4.8%) of grade 1 allergic reaction and one case (4.8%) of hand-foot syndrome, both alleviated with symptomatic treatment. **Conclusions:** Aponermin monotherapy demonstrated promising disease control and a favorable safety and tolerability profile in advanced chondrosarcoma. Given the limited sample size and ongoing enrollment, final efficacy and safety assessments await study completion. Clinical trial information: ChiCTR2500104488. Research Sponsor: None.

11533 Poster Session

Benefit of adjuvant therapy in high-risk GIST: A large-scale real-world analysis of 2,166 patients (DEEPSARC study). First Author: Nicolas Penel, Institute Bergonie Cancer Center, Bordeaux, France

Background: Real-life data on the impact of adjuvant treatment in GIST pts are limited. **Methods:** We conducted a retrospective study (Deepsarc) merging data from the NETSARC+ dataset of the French Sarcoma Group with the exhaustive health data from the national social security system (SNDS). Eligible pts were treated between January 1, 2012, and December 31, 2017 with localized GIST. The relation between overall survival (OS) and adjuvant therapy was studied univariate and multivariate, using different methods to address confounding factors. **Results:** A total of 2166 GIST pts were included, with a median age of 68.0 years (interquartile range (IQR): 58.0, 76.0), a sex ratio of 1.01. The two most common primary sites were gastric (1301, 60%) and small intestine (527, 24%). Median tumor size at diagnosis was 5.3 cm (IQR 3.6-8.1). Median mitotic count was 3.0 (IQR 1.0-5.0). According to Miettinen/AFIP classification, 331/1026 (32%) were high-risk, 192/1026 (19%) intermediate risk, and 503/1026 (49%) very low or low risk vs 490/912 (53%) high-risk, 193/912 (21%) intermediate risk, and 229/912 (25%) very low or low risk with Joensuu classification. From 2012 to 2017, the proportion of pts receiving adjuvant therapy remained remarkably stable at around one third of all GIST, with higher use in high-risk (70%; 231/331) than intermediate-risk (43%; 83/192) and low-risk pts (6%; 32/503). Pts receiving adjuvant therapy were younger ($p<.001$), with less comorbidities ($p<.001$), larger tumor ($p<.001$), higher mitotic count ($p<.001$), higher risk according to Miettinen/AFIP ($p<0.001$), or Joensuu ($p<.001$), higher rate of R1 resection ($p=.019$) and higher rate of tumor rupture ($p=.001$). Median follow-up was 5.0 years (4.8-5.2). Overall, the 5y OS rate was 81% [79-83%]. Regardless of risk, for the entire population, 5y OS rate of those receiving adjuvant therapy was 82% [79%-85%] and for those not receiving adjuvant therapy was 81% [78%-83%]. For both prognostic classifications, in univariate analysis, adjuvant therapy was associated with improved survival only for high-risk pts. Multivariate analysis propensity-score adjusted analyses for age, sex, social deprivation index, morbidity index, and tumor size (3 categories: ≤5/ 5-10/ >10 cm) highlights a benefit of adjuvant therapy for high-risk pts, according to both AFIP/Miettinen or Joensuu classifications (Table). No clear benefit was observed in intermediate-risk pts. **Conclusion:** This study confirms the benefit of adjuvant therapy for high-risk pts (according to AFIP/Miettinen or Joensuu), but not for other risk groups. Standard-dose ripretinib plus sunitinib versus ripretinib dose escalation in advanced GIST after progression on four prior therapies: Preliminary results of a multicenter cohort study. First Author: Hao Xu, Department of General Surgery, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Patients with advanced GIST who progress after four lines of therapy, including imatinib, sunitinib, regorafenib, and ripretinib, face limited treatment options. Ripretinib dose escalation is a potential option recommended by NCCN and CSCO guidelines, while combination therapy with TKIs targeting complementary pathways may offer an alternative for patients harboring multiple resistance mutations. This study aims to evaluate the efficacy of ripretinib dose escalation versus combination therapy following progression on standard-dose ripretinib to identify more effective treatment strategies. **Methods:** This study is a multicenter cohort study designed to evaluate the efficacy and safety of ripretinib dose escalation versus combination therapy with sunitinib in patients with advanced GIST who have progressed after four prior lines of therapy. Eligible patients receive ripretinib dose escalation group (150 mg twice daily) or the combination therapy group (ripretinib 150 mg once daily plus sunitinib 25 mg once daily). The primary endpoint was progression-free survival (PFS). **Results:** Between September 2023 and December 2025, 30 patients were enrolled (16 in the ripretinib dose escalation group and 14 in the combination group). Primary KIT11 mutation were identified in 17 patients, 62.5%(10/16) in the dose escalation group and 50% (7/14) in the combination group, while KIT 9 mutations were 2 patients both in the combination group . As of December 30, 2025, 5 patients in the ripretinib dose escalation group remained on treatment with stable disease, whereas all patients in the combination group had experienced disease progression; 3 of these showed slow progression and continued therapy. mPFS1 with standard-dose ripretinib was comparable between groups (6.0 months [95% CI: 4.7–7.3] vs. 7.0 months [95% CI: 5.2–8.8]). Following progression, ripretinib dose escalation achieved a mPFS2 of 8.3 months (95% CI: 4.7–12.0), significantly longer than combination therapy (3.1 months [95% CI: 2.0–4.3]) . OS data remain immature. Ripretinib dose escalation demonstrated better tolerability, with no grade ≥3 adverse events reported. In contrast, the combination group experienced higher toxicity, 35.7% discontinued treatment due to severe adverse reactions. **Conclusions:** Preliminary results indicate that ripretinib dose escalation demonstrated superior efficacy and a more favorable safety profile compared with combination therapy involving sunitinib. These findings support ripretinib dose escalation as the preferred treatment option for patients with advanced GIST who have progressed after four lines of standard therapy. However, the sample size in this study is still small, and further research with a larger sample is needed to validate this conclusion. Research Sponsor: None.

Oncologic equivalence of brand-name vs generic imatinib in neoadjuvant *KIT* exon 11 GIST: A real-world international cohort study. First Author: Tannaz Ranjbarian, UC San Diego Moores Cancer Center, San Diego, CA

Background: Neoadjuvant imatinib is routinely used to facilitate resection of localized gastrointestinal stromal tumors (GIST) with *KIT* exon 11 mutations. However, whether generic formulations achieve oncologic outcomes equivalent to the brand-name drug in curative-intent neoadjuvant therapy remains unknown. **Methods:** We performed a retrospective, international dual-institution cohort study of 131 patients with localized *KIT* exon 11–mutant GIST treated with neoadjuvant imatinib followed by surgical resection (2010–2025) at UC San Diego and Fondazione IRCCS Istituto Nazionale dei Tumori (Milan). Patients received either brand-name or generic imatinib based on institutional practice. The primary endpoint was tumor size reduction. Secondary endpoints included histopathologic response and overall survival. Multivariable regression and Kaplan–Meier analyses were performed. **Results:** Of 131 patients, 71 (54%) received brand-name and 60 (46%) received generic imatinib. Objective response (≥30% tumor reduction) occurred in 54% vs 37%, respectively (P=0.078). Median tumor size reduction was −33.3% with brand-name and −25.5% with generic imatinib (P=0.105). In multivariable analysis, longer neoadjuvant duration was independently associated with greater tumor reduction (β=−0.02 per day; 95% CI, −0.04 to −0.00; P=0.04), whereas imatinib formulation, dose, and treatment center were not. Pathologic outcomes, including viable tumor percentage (P=0.053), necrosis (P=0.777), and mitotic index (P=0.889), were similar between groups. Five-year overall survival was 87.2% with no difference by formulation (log-rank P=0.24). **Conclusions:** In this first international analysis of neoadjuvant therapy for *KIT* exon 11–mutant GIST, generic imatinib demonstrated oncologic equivalence to the brand-name formulation across tumor response, pathologic, and survival outcomes. As generic imatinib use has expanded globally following patent expiration, these findings reinforce its role as a clinically effective, cost-efficient, and accessible therapy. Demonstrating therapeutic equivalence in the neoadjuvant setting has direct implications for practice guidelines, formulary decisions, and equitable delivery of precision oncology worldwide. Research Sponsor: U.S. National Institutes of Health; T32 CA121398; U01 CA278470; R01 CA292590; P30 CA023100; GIST Research Fund #3661; Jon Strong; 3661.

Tumor size reduction and objective response by imatinib formulation.

Outcome	Brand-name (n=71)	Generic (n=60)	P Value
≥30% tumor size reduction	38 (53.5%)	22 (36.7%)	0.078
Any tumor size reduction	59 (83.1%)	49 (81.7%)	1.0
≥20% tumor size increase	5 (7.0%)	2 (3.3%)	0.452
Tumor size reduction, (median [IQR])	−33.3% (−45 to −18.4)	−25.5% (−38.8 to −10.5)	0.11

Note: P values calculated using Fisher's exact test for categorical outcomes and Mann–Whitney U test for continuous variables. Tumor size reduction reported as median (interquartile range, IQR).

Artificial intelligence–based predictive models for recurrence and recurrence-free survival in gastrointestinal stromal tumors: A contemporary systematic review. First Author: Elizaveta Bodrova, Mercy Catholic Medical Center, Darby, PA

Background: Recurrence after complete resection of GISTs is still a major contributing factor to long-term survival. Traditional stratification models for risk depend on clinicopathologic variables and have limited precision. Recent improvements in artificial intelligence (AI), such as machine learning (ML), deep learning (DL), and multimodal methodologies, might enhance personalized prediction of recurrence and recurrence-free survival (RFS). We performed a contemporary systematic review to evaluate the performance and clinical utility of AI-based prognostic models in resected GIST. **Methods:** PRISMA 2020 guidelines were followed for conducting a systematic review. PubMed, Scopus, and Web of Science were analyzed to search published studies published during 2019–2025 that evaluated AI-, ML-, or DL-based models predicting recurrence or RFS following complete surgical resection of localized primary GISTs. Eligible studies included retrospective or multicenter cohorts with radiologic, histopathologic, genomic, or multimodal data. Data extracted included model type, input modalities, validation strategy, and performance metrics (area under the curve [AUC] and concordance index [C−index]). **Results:** Eight studies encompassing approximately 4,000 patients met inclusion criteria. Both deep learning and multimodal fusion models showed the highest prognostic accuracy (C-index values 0.86–0.96, AUC up to 0.995). Radiomics based ML models using CT, MRI, or ultrasound yielded AUCs between 0.85 and 0.92 which were consistently superior to traditional clinicopathologic methodologies. Genomic ML models fine-tuned recurrence risk stratification beyond conventional benchmarks into molecularly distinct prognostic subgroups. DL-based histopathology estimators both predicted for RFS and for key driver mutations (KIT, PDGFRA) by bridging morphologic and molecular features. External validation cohorts showed stable performance (AUC 0.87–0.96), with calibration and decision curve analyses supporting clinical utility. **Conclusions:** AI-based predictive models demonstrate strong and reproducible performance for recurrence and RFS prediction following GIST resection, consistently outperforming traditional risk stratification systems. Multimodal and deep learning approaches integrating radiologic, pathologic, and genomic data appear most promising for precision prognostication and personalized adjuvant therapy selection. Prospective validation and explainable AI integration are needed prior to routine clinical adoption. Research Sponsor: None.

Ripretinib as preoperative therapy in patients with potentially resectable advanced gastrointestinal stromal tumors after imatinib failure: Final analysis of a prospective, multicenter study. First Author: Linxi Yang, Department of Gastrointestinal Surgery, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Cytoreductive surgery may improve outcomes in patients with locally advanced or metastatic gastrointestinal stromal tumors (GIST) after progression on imatinib. Ripretinib has shown a high objective response rate (ORR) and a favorable safety profile in advanced GIST, suggesting its potential for tumor downstaging and enabling surgical intervention. This study evaluated the efficacy and safety of ripretinib as preoperative therapy in patients with imatinib-resistant, potentially resectable advanced GIST. **Methods:** This single-arm, multicenter, exploratory study (NCT05132738) enrolled patients with imatinib-resistant, locally advanced or recurrent metastatic GIST who met the following criteria: 1) ≤5 evaluable lesions on CT/MRI; 2) resection deemed high-risk by multidisciplinary team (MDT) assessment (meeting one of the following): a) The maximum diameter of a single lesion is ≥10 cm; b) Organ function damage surgery is required; c) Multiple organ resection surgery is required. Patients received ripretinib 150 mg once daily (QD) up to 6 months before surgery. The primary endpoint was the no evidence of disease rate (NED Rate). Secondary endpoints included the R0/R1 resection rate, surgery rate, and ORR. **Results:** As of January 2026, 20 patients were enrolled, with a median age of 58 years (range: 31-74). The most common primary tumor site was the small intestine (70%). The median sum of target lesion diameters was 10.8 cm (range: 3.2-33.7). The median duration of preoperative ripretinib was 5 months (range: 2-6). The median best percentage change in the sum of target lesion diameters was -20.5% (range: -47.2% to +56.0%). 8 patients (40.0%) achieved a partial response (PR) and 10 patients (50.0%) had stable disease (SD). Median time to response was 2.0 months (range: 2.0-6.0). 70% (14/20) of patients underwent surgery and the NED rate was 92.9% (13/14). Of the 13 patients who achieved R0 resection, 8 (61.5%) have maintained NED to date. Only 1 patient experienced intestinal fistula as a surgical complication, which was unrelated to ripretinib treatment. After surgery, 6 patients continued ripretinib therapy, while 3 switched to imatinib therapy and 5 switched to sunitinib therapy. With a median follow-up of 20.4 months (range: 8.1–47.6), the median overall survival (OS) was immature. **Conclusions:** These findings demonstrate that preoperative ripretinib effectively reduced tumor burden in patients with imatinib-resistant, potentially resectable advanced GIST, and facilitated successful surgery intervention. Notably, the approach achieved a high NED rate and a low surgical complication rate, supporting ripretinib as a safe and effective preoperative treatment option. Clinical trial information: NCT05132738. Research Sponsor: None.

Clinical characteristics and outcomes of germline and sporadic NF1-associated gastrointestinal stromal tumors: Insights from a real-world patient registry. First Author: Denisse Evans, The Life Raft Group, Wayne, NJ

Background: Neurofibromatosis type 1 (NF1)-associated gastrointestinal stromal tumor (GIST) is a rare, distinct molecular subtype, typically lacking KIT or PDGFRA mutations. Standard KIT-targeted therapies show limited efficacy, highlighting the need for alternative systemic approaches. Real-world data on the clinical features, treatment patterns, and outcomes of NF1-associated GIST are limited. **Methods:** The Life Raft Group (est. 2000) Registry is an international, observational registry. Patients with GIST and documented NF1 mutations without another primary oncogenic alteration were included. Demographic, tumor, and treatment characteristics were summarized; group differences were assessed using Fisher's exact test, and disease-free survival (DFS) and overall survival (OS) were estimated by Kaplan–Meier methods. **Results:** A total of 38 patients were identified (1.3% of the total registry, n = 2990) and stratified as germline NF1 (n = 18) and sporadic NF1 (n = 20). Median age at diagnosis was 57 years; 53% (n = 20) of patients were female, with a higher proportion of germline NF1 than sporadic NF1 (60%, n = 12 vs 40%, n = 8). Conversely, among males, sporadic NF1 was more common than germline NF1 (67%, n = 12 vs 33%, n = 6). Tumors predominantly arose in the small bowel (79%). Germline NF1 patients exhibited significantly higher rates of multifocal disease compared with sporadic NF1 patients (85% vs 15%, p = 0.0006). Most patients presented with localized disease (84%, n = 32), with similar proportions between germline and sporadic NF1 (78%, n = 14 vs 90%, n = 18). All localized patients underwent surgical resection, achieving R0 margins in 72% of cases. Among patients who developed advanced disease (de novo metastatic or recurrent disease; n = 18), 67% received systemic therapy including MEK inhibitors in 22% (n = 4). One patient achieved durable disease control on selumetinib for nearly six years and remains on treatment. Median follow-up was 37.6 months (2.5–185). In localized patients, 5-year DFS was 65% (95% CI: 39–100) for germline and 46% (95% CI: 25–84) for sporadic NF1; median DFS was 55.4 months in sporadic NF1 and not reached in germline NF1. 10-year OS was 78% (95% CI: 62–98) overall, 88% (95% CI: 67–100) for germline, and 83% (95% CI: 64–100) for sporadic localized patients. Survival estimates in metastatic patients were highly variable due to small numbers. **Conclusions:** In this real-world registry analysis, NF1-associated GIST shows small bowel predominance and frequent multifocality, particularly in germline NF1. Most patients achieve disease control with surgery. MEK inhibitors may demonstrate potential activity in advanced NF1 GIST. These findings highlight phenotypic differences between germline and sporadic NF1-associated GIST and support further evaluation of MEK-targeted therapy in patients with metastatic disease. Updated clinical and translational results of olverembatinib (HQP1351) in patients with succinate dehydrogenase (SDH)–deficient tumors. First Author: Haibo Qiu, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China

Background: SDH deficiency causes succinate accumulation and metabolic defects in gastrointestinal stromal tumor (GIST) and paraganglioma. Olverembatinib downregulates lipid uptake protein CD36, restricting fatty acid supply required for SDH-deficient GIST cell growth. We report updated clinical and translational results from study HQP1351SJ0003 (NCT03594422) of olverembatinib in SDH-deficient GIST and paraganglioma. **Methods:** Patients (pts) (≥ 12 years) with GIST and other solid tumors received olverembatinib 30 to 50 mg PO QOD. Primary cells from tumor tissues of 9 pts with SDH-deficient GISTs were used for *ex vivo* analyses. All samples were collected at Sun Yat-sen University Cancer Center, with informed consent from pts. Cell migration/invasion was evaluated by wound healing, Transwell migration, and Matrigel invasion assays. Lipid levels were quantitated by LC-MS. Knockdown of CD36 and p38 was done by siRNA. Protein levels were assessed by western blot. **Results:** As of November 13, 2025, a total of 32 pts, including 26 pts with IHC-confirmed SDH-deficient GIST, had received olverembatinib. The median age of pts with SDH-deficient GIST was 30 (range 13-56) years; 19 (73.1%) were female. Twenty-five pts (96.2%) had received ≥ 1 TKI and 13 (50.0%) ≥ 3. Six (23.1%) pts experienced PR as best response, and the median PFS was 25.7 (range 12.9-NR) months. An additional six pts with paraganglioma had received olverembatinib (all were SDH-deficient as determined by either negative SDHB IHC or *SDHB* gene mutation). The median age was 47.5 (range 31-61) years; all were male. Best responses were observed in four pts, with SD lasting ≥ 4 cycles (CBR, 66.7%); SD represents meaningful clinical benefit in this slow-growing tumor type. The median PFS was 8.25 (range 1.87-NR) months. SDH-deficiency was associated with a higher risk of tumor metastasis. In SDH-deficient (vs. SDH-competent) GIST cells, significantly higher linoleic acid levels were observed. Supplementation of free fatty acids promoted SDH-deficient cell migration, which could be inhibited by olverembatinib at 30 nM. In addition, siRNA knockdown of p38, a kinase target of olverembatinib, and treatment with two p38 inhibitors significantly downregulated CD36 protein levels, suggesting that p38 regulates cellular CD36. Further, western blot analysis showed that olverembatinib dose-dependently inhibited CD36 protein and phosphorylated p38 protein levels in primary cells from SDH-deficient pts. These findings suggest olverembatinib suppresses fatty acid-promoted migration via the p38-CD36 pathway. **Conclusions:** Olverembatinib showed sustained clinical efficacy in SDH-deficient GIST and paraganglioma. Mechanistically, olverembatinib inhibits fatty acid–promoted invasion and migration of SDH-deficient GIST by targeting the p38-CD36 signaling pathway. Clinical trial information: NCT03594422. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong).

Circulating tumor DNA monitoring for early detection of disease recurrence in bone/soft tissue sarcoma. First Author: Maggie Yuxi Zhou, Stanford University School of Medicine, Department of Medicine, Stanford, CA

Background: Circulating tumor DNA (ctDNA) is a powerful, minimally invasive biomarker of treatment response and patient prognosis in many tumors. Here, we assessed the clinical performance of the Signatera assay in patients with bone and soft tissue sarcomas in assessing molecular residual disease (MRD). **Methods:** We performed a retrospective analysis of patients at our institution who underwent commercial ctDNA testing using the Signatera mPCR-NGS assays after curative intent resection of their primary tumor. Patients with oligometastatic disease were included if they also underwent resection of oligometastatic sites and did not have any evidence of residual disease. Additional inclusion criteria included three or more ctDNA draws in the MRD setting with at least one ctDNA blood collection within one of year of completing curative intent procedures and at least 6 months of clinical follow up after surgery. ctDNA positivity was defined as any detectable level of ctDNA at any time point in the patient's treatment course after surgery. **Results:** We reviewed 305 patients who underwent Signatera ctDNA collection; 107 patients met the inclusion criteria for this study. The most common reason for not meeting inclusion criteria was advanced/unresectable disease (n = 168). The included 107 patients underwent over 1300 plasma ctDNA assessments in the MRD setting (average 12 ctDNA assessments per patient) between September 2019 and November 2025. For the overall cohort, sensitivity was 75% (36/48); specificity was 100% (36/36). One patient with angiosarcoma had ctDNA detected one month prior to data cut-off and was awaiting re-staging imaging. The largest represented histologies were leiomyosarcoma (n = 42) and undifferentiated pleomorphic sarcoma and related tumors (n = 22); sensitivity were 85% (22/26) and 57% (4/7), respectively. The median duration of follow-up after surgery was 41 months (range 1.6 to 79 months). Of the 48 patients with disease recurrence, 27 (60%) developed local disease recurrence only, 17 (38%) developed distant recurrence only, and 4 (9%) developed local and distant disease recurrence. The most common site of distant disease recurrence was in the lungs (n = 16). Sensitivity was lowest in the patients who developed disease recurrence isolated to the lungs (42%, 5 out of 12) compared to patients who developed disease recurrence not confined to the lungs (89%, 32 out of 36). Of the patients who had ctDNA detected at time of recurrence, 47% (17/36) demonstrated ctDNA positivity before detection of recurrence on imaging with an average lead time of 20 days. **Conclusions:** In a cohort of over 100 sarcoma patients with over 1300 plasma samples collected in the MRD setting, Signatera ctDNA assay demonstrated a clinical sensitivity of 75% and specificity of 100% for relapse detection with the highest sensitivity in leiomyosarcoma (85%) and when disease recurrence was not confined to the lungs (89%). Research Sponsor: None.

11541 **Poster Session**

Cell proliferation, immune cell infiltration, and survival outcomes in sarcomas with high cancer-associated fibroblast expression. First Author: Olivia Martin, Roswell Park Cancer Center, Buffalo, NY

Background: Cancer-associated fibroblasts (CAFs) play an integral role in the tumor microenvironment and have been linked to tumor aggravation and promotion of metastatic potential. CAFs are often abundant in sarcomas, but their role is understudied partly because both share a similar mesenchymal origin. We aimed to investigate the relationship between CAFs and clinical characteristics in sarcomas using transcriptomics. **Methods:** Genomic and clinicopathologic data was acquired from The Cancer Genome Atlas Sarcoma cohort. Cases were divided into high and low CAF groups using the median CAF level. Immune cell compositions including CAFs were determined using the xCell algorithm. Institutional Review Board waiver was deemed applicable as the data is de-identified from publicly available databases. **Results:** A total of 258 patients including leiomyosarcoma (LMS, n=83), myxofibrosarcoma/undifferentiated pleomorphic sarcoma (MFS/UPS, n=80), dedifferentiated liposarcoma (DDLPS, n=46), and other pathologies (n=20), were analyzed. DDLPS had significantly greater CAFs than the other subtypes (p=0.0025). CAF expression varied significantly by tumor grade, with grade 3 tumors having the lowest CAF expression and grade 1 & 2 tumors having significantly higher CAF expression ($p<0.001$). Ki67 was significantly lower in the high CAF tumors ($p<0.001$). On GSEA, high CAF sarcomas showed significantly less enrichment in myc targets v1 (NES= -2.67, FDR<0.001), myc targets v2 (NES=-2.25, FDR<0.001), G2M checkpoint (NES=2.39, NES<0.001), E2F targets (NES=-2.66, FDR<0.001), mitotic spindle (NES= -1.33, FDR= 0.015), and mTORC1 signaling (NES=-2.33, FDR <0.001); all consistently showing that high CAF sarcomas are less proliferative. In terms of genomic instability, high CAF sarcomas were significantly associated with less homologous recombination deficiency ($p<0.001$), intratumor heterogeneity ($p<0.001$), aneuploidy (p=0.003), and silent mutation rates (p=0.036). Analysis of immune cell composition revealed significantly less infiltration of B-cells (p=0.004), CD8 T-cells (p=0.013), Th1 cells ($p<0.001$), Th2 cells (p=0.008), and macrophages (p=0.027) in the high CAF group. Differential gene expression analysis demonstrated that C7, SESN1, FAM198A, were the most, and WNT7B, ENO1, TM4SF19 were the least expressed among 20511 genes analyzed in high CAF sarcomas. High CAF sarcoma were associated with significantly better disease-free survival (HR= 0.48 (95% CI 0.34-0.68), $p<0.001$) as well as overall survival compared with low CAF sarcomas (HR= 0.5 (95% CI 0.34-0.76), $p< 0.001$). **Conclusions:** CAFs are associated with less cell proliferation, less immune cell infiltration, and better survival. Further studies are warranted to develop CAFs as a prognostic biomarker for sarcoma patients. Research Sponsor: None.

Myxoid/round cell liposarcoma misdiagnosis incidence, etiology, and importance of NY-ESO-1 testing: Retrospective analysis of the Tempus database. First Author: Michael Jason Nathenson, US World Meds, Needham, MA

Background: Liposarcoma is composed of multiple unique sarcoma subtypes, specifically myxoid/round cell liposarcoma (MRCLS), well differentiated and dedifferentiated liposarcoma (WD LPS and DD LPS), and pleomorphic liposarcoma. These are genetically distinct entities with different treatment paradigms. MRCLS is driven by a translocation between DDIT3 and FUS or EWSR1, detectable in 100% of MRCLS. WD and DD LPS are characterized by amplification of MDM2 and CKD4, and pleomorphic LPS is genetically complex. Recently, new treatments for liposarcoma are specific to the LPS type (CDK4/6 inhibitors; CTA directed engineered T Cells) which highlights the importance of an accurate liposarcoma subtype diagnosis. **Methods:** A retrospective analysis of the tempus RNA database for DDIT3 translocations and NY-ESO-1 (CTAG1B) expression in MRCLS was conducted. 101 patients (pts) with MRCLS were identified; 27 pts lacked Next Generation Sequence data for tumor samples leaving 74 pts that were selected for analysis. RNA was sequenced with either the Tempus RS or the RS.v2 assays. Patients' tumor samples with tumor purity $<30\%$ were excluded from assessment of CTAG1B expression. Gene expression values in this analysis were normalized by transcripts-per-million (TPM) transformed to log2(TPM+1) units. The threshold of 2 (log2(TPM+1)) was set as the cut off of true positive for CTAG1B expression. **Results:** The DDIT3 fusion was identified in 65/74 (88%) patients. In 9/74 (12%) patients, there was no DDIT3 fusion detected. Out of the 65 patients that were positive for the MRCLS translocation 60/65 (92%) were DDIT3-FUS, and 5/65 (8%) were DDIT3-EWSR1. The MRCLS DDIT3 fusion-negative samples were 5/9 (56%) positive (pos) for MDM2 amplification and CDK4 amplification. The Tempus tumor of origin algorithm predicted all DDIT3 fusion-pos MRCLS samples to be soft tissue sarcoma (where predictions were made; 53 of 65 pts) and the DDIT3 fusion-neg samples to be fibrosarcoma in one case and liposarcoma in 7 cases. The last fusion-neg case did not have a tumor of origin prediction. The median expression of CTAG1B was 7.14 TPM in all patients, 7.2 TPM (range 3.1 to 8.7) in DDIT3-FUS samples, 7.5 TPM (range 5.7 to 7.7) in DDIT3-EWSR1 samples, and 0.04 (range 0.0 to 3.7) in DDIT3 fusion-neg samples. There was no difference in CTAG1B expression by biopsy site, metastatic status, stage, tumor purity, or center of diagnosis. **Conclusions:** It is of critical importance to accurately determine the liposarcoma subtype which influences the selection of new targeted treatments. This analysis highlights a 12% rate of misdiagnosis of MRCLS and suggests that WD/DD LPS can be misdiagnosed as MRCLS. Additionally, this study predicts that 100% of MRCLS with confirmed DDIT3 translocation will be NY-ESO-1 (CTAG1B) pos which highlights the utility of NY-ESO-1 as a diagnostic marker for NY-ESO-1 directed therapies. Synovial sarcoma misdiagnosis and potential utility of NGS testing patient identification for autologous T cell therapy: Retrospective analysis of Tempus database. First Author: Michael Jason Nathenson, US World Meds, Needham, MA

Background: Metastatic synovial sarcoma (SS) is commonly treated with anthracycline and other chemotherapy with poor survival outcomes. Afamitresgene autoleucel (Tecelra) is a genetically modified autologous T cell therapy that was FDA approved in August 2024, based on ORR of 43.2% and median DoR of 6 months. It is indicated for previously treated HLA-A*02:01-03 and 06 allele positive patients (pts) with unresectable or metastatic SS whose tumors express MAGE-A4. SS is characterized by SS18-SSX gene fusion in $>$ 95% of cases and this gene fusion is not found in other neoplasms. Commercial NGS testing may contribute to identification of eligible pts. **Methods:** Pts with diagnosis of SS and/or SS18 gene fusion were identified by retrospective analysis of the Tempus database. Demographic and disease characteristics were described for each pt and assessed for correlation with diagnosis and presence of the SS18 gene fusion. RNA was sequenced with the Tempus RS and RS.v2 assays. Gene expression values in this analysis were normalized by transcripts-per-million (TPM) and transformed to log2(TPM+1) units. The threshold of 1.62 (log2(TPM+1)) was set as the cut off for determining true positive of MAGEA4 expression. HLA type and RNA expression of MAGE-A4 was used to identify pts potentially eligible for associated T cell therapies. **Results:** 110 pts were analyzed, including 86 pts (78%) with SS diagnosis with SS18 fusion, 12 pts (11%) with SS diagnosis but no detected SS18 fusion (SS/SS18-), and 12 pts (11%) with SS18 fusion but a non-SS diagnosis. Age at diagnosis, sex, race, state of diagnosis, and institution type (academic vs non-academic) were not associated with misalignment between the reported diagnosis and presence or absence of the SS18 fusion. For SS/SS18- pts the location of the tumor did not differ from expected SS primary locations, and the Tempus tumor of origin predicted SS diagnosis in 2/12 pts, non-SS diagnosis in 7/12 pts, and not reported 3/12 pts. The most common predicted non-SS diagnosis was malignant peripheral nerve sheath tumor (MPNST, 5 pts). Non-SS/SS18+ pts did occur in unusual locations (Pancreas, small intestine, bone, peripheral nervous system), and 10/12 were predicted by the tempus tumor of origin algorithm to be SS. The recorded diagnosis in these 12 pts was more commonly another sarcoma subtype (10/12), rather than a non-sarcoma diagnosis (2/12). MAGE-A4 expression $>$ 1.62 TPM was detected in 71% of all pts, 74% SS/SS18+ pt, 58% of SS/SS18- and 58% of non-SS/SS18 pts. When considering the required HLA type and MAGEA4 expression then 35% of all pts would be potentially eligible for afami-cel. **Conclusions:** Commercial NGS testing may increase identification of pts with SS, which is important for novel T cell therapy eligibility. A low threshold should be considered for diagnosing SS in unusual locations when the SS18 fusion is detected. Research Sponsor: adaptimmune; US World Meds CT, LLC.

Ultra-sensitive whole-genome sequencing–based molecular residual disease detection in resectable sarcoma in MONSTAR-SCREEN-3. First Author: Toru Wakamatsu, Osaka International Cancer Institute, Osaka, Osaka, Japan

Background: Circulating tumor DNA (ctDNA)–based molecular residual disease (MRD) detection has shown strong prognostic value in multiple epithelial cancers, but its utility in sarcoma remains poorly defined. Sarcomas are highly heterogeneous and often represent low-shedding tumors, limiting the sensitivity of conventional assays. The MONSTAR-SCREEN-3 evaluates the clinical performance of a whole-genome sequencing (WGS)–based MRD assay in a pan-cancer cohort, including patients with sarcoma. **Methods:** Personalized ctDNA panels were generated using a WGS-based tumor-informed platform (Myriad Genetics), incorporating up to 1,000 tumor-specific variants identified through WGS of matched tumor tissue. Serial plasma samples were collected at baseline, 1 month post-surgery, quarterly during the first year, and biannually thereafter for up to two years. **Results:** As of November 2025, 35 patients with resectable soft tissue sarcoma (n=33) and osteosarcoma (n=2) were enrolled; MRD results were available for 72 samples from 24 patients. Of whom, histology was myxofibrosarcoma (n=7), undifferentiated pleomorphic sarcoma (n=7), myxoid liposarcoma (n=5), dedifferentiated liposarcoma (n=3), epithelioid sarcoma (n=3) and others (n=10). Clinical staging distribution included Stage I/II/III/IV: 15%/19%/50%/15%. Most of patients underwent upfront radical surgery (2 cases received neoadjuvant chemotherapy). Personalized panel creation succeeded in 100% of patients (24/24), identifying a median of 3,510 highly confident tumor-specific alterations per patient (range: 730-7,931) and yielding bespoke panels containing 386-1,000 alterations. Customized panels were created with 96.4% SNVs and 3.6% indels. The assay demonstrated 87.5% baseline ctDNA detection (21/24), with 16.7% detected at ultra-sensitive levels (tumor fraction $<$100 parts per million [ppm]). In the ctDNA-negative cases, ctDNA tumor fractions were 0.0, 0.8 and 6.2 ppm, classified as ctDNA-negative based on a statistical threshold set at 99.615% specificity. Post-surgical MRD positivity rates were 20.0% (4/20) at 1 month, 7.1% (1/14) at 3 months, and 28.6% (2/7) at 6 months. Among these patients, four patients developed radiographic recurrence, with MRD detection preceding imaging by median 1.1 months (0.1-3.0). Extended follow-up and comprehensive longitudinal ctDNA dynamics will be presented. **Conclusions:** The WGS-based ctDNA assay demonstrated high technical feasibility in sarcoma, enabling detection of patient-specific tumor variants across a highly heterogeneous and low-shedding tumor population. In our cohort, MRD positivity was observed exclusively in patients who subsequently developed recurrence, highlighting the potential utility of WGS-based tumor-informed MRD analysis for surveillance and risk stratification in sarcoma. Identification of checkpoint inhibitor resistance mechanisms in leiomyosarcoma through enrichment of active chromatin-associated cell-free DNA. First Author: Carlos Diego Holanda Lopes, Princess Margaret Cancer Centre – University Health Network, University of Toronto, Toronto, ON, Canada

Background: Leiomyosarcoma (LMS) is a sarcoma subtype with poor metastatic outcomes and limited treatment options. Checkpoint inhibitors (CPI) combination therapy may benefit LMS patients (pts). We previously showed (Lopes, ASCO 2025) that a liquid biopsy assay enriching for active chromatin–associated cell-free DNA (cfDNAac) identified biomarkers predicting clinical benefit in LMS pts treated with durvalumab plus olaparib or cediranib (NCT03851614). Here, we report longitudinal cfDNAac findings at baseline and progression. **Methods:** Plasma samples at baseline (n=30) and disease progression (n=22) were analyzed using a cfDNAac capture platform. Univariate analysis and recursive feature elimination identified genomic features associated with clinical benefit rate (CBR; complete response/partial response or stable disease >6 months). Molecular transcriptomic profiles, pathway enrichment, and copy number variation (CNV) were analyzed and correlated with CBR and progression-free survival (PFS). Linear mixed-effects models assessed temporal differences in cfDNAac-derived biomarkers between CBR and non-CBR groups. **Results:** A total of 1,570 baseline cfDNAac features distinguished pts who achieved CBR from those who did not (n=8 vs 22, $p < 0.01$). Pts with CBR exhibited enrichment of immune-related signatures (i.e., B and T-cell activation, lymphocyte differentiation, and a decrement of extracellular matrix organization [ECM]), all of which were individually significantly associated with longer PFS ($p < 0.05$). Upon progression, B-cell and T-cell activation significantly decreased, whereas ECM-related signatures increased in CBR compared to non-CBR group, the latter of which remained stable. A higher baseline tumor fraction (>5%) was also associated with reduced CBR ($p < 0.05$) and shorter PFS (HR = 3.33; CI: 1.32-8.40 $p < 0.01$). Recurrent CNV losses on chromosome 15 correlated with improved PFS (HR = 2.48; 95% CI: 0.99-6.22; p = 0.052) and CBR (p = 0.0073). At progression, these CNV reverted in CBR pts but remained stable in non-CBR patients. **Conclusions:** This active chromatin-associated cell-free DNA profiling enables a non-invasive monitoring of dynamic tumor microenvironment remodeling over time and provides insights into emerging mechanisms of resistance to CPI in LMS pts. Prognostic biomarkers in retroperitoneal dedifferentiated liposarcoma and their clinical impact on patient management. First Author: Ilaria Tortorelli, Oncology 1 Unit, Department of Oncology, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy

Background: The prognosis of patients (pts) with retroperitoneal dedifferentiated liposarcoma (DDLPS) is mainly driven by tumor size, grade, patient age, and completeness of resection. Furthermore, the expression of myogenic markers has been associated with poorer outcomes. Prognostic nomograms, such as Sarculator, and transcriptomic signatures—most notably the Complexity INdex in SARComas (CINSARC)—have improved risk stratification. However, given the rarity of DDLPS and the limited evidence guiding treatment, identifying robust prognostic biomarkers remains a major challenge. This study evaluated the prognostic impact of clinical, morphological, and molecular features and assessed the performance of Sarculator and CINSARC in retroperitoneal DDLPS. **Methods:** A retrospective observational study was conducted on pts with retroperitoneal DDLPS treated at the Veneto Institute of Oncology (IOV)-IRCCS between 2004 and 2024. Tumor samples with adequate material underwent morphological, immunohistochemical, and molecular analyses, including CINSARC assessment. Disease-free survival (DFS) and overall survival (OS) were evaluated in surgically treated pts (Cohort 1), while progression-free survival (PFS) and OS were assessed in pts receiving first-line chemotherapy (Cohort 2). Sarculator was applied to Cohort 1, and its discriminative ability was evaluated using ROC curves. Concordance between CINSARC and Sarculator was also examined. **Results:** A total of 119 pts were included. In the overall population, tumor grade (3 vs 2: HR, 2.23; 95% CI 1.06 - 4.70; p = 0.03) and age (<65 vs ≥65: HR, 0.43; 95% CI 0.22 - 0.85; p = 0.02) were the most significant predictors of OS. In Cohort 1, these variables remained determinants of survival. In Cohort 2, sex, tumor size and differentiation significantly affected survival, with rhabdomyoblastic differentiation conferring the worst prognosis (p = 0.04). When Sarculator was applied to Cohort 1, a moderate discriminative ability was observed for OS (AUC = 0.75), with a lower performance for DFS (AUC = 0.64). Molecular analyses were performed on 32 samples; MYOG transcripts, indicative of rhabdomyoblastic differentiation, were detected in 8 cases. Based on CINSARC, 11 pts (34.4%) were low risk and 21 (65.6%) high risk. Agreement between Sarculator and CINSARC was moderate for both OS (Cohen's Kappa, $\kappa = 0.40$) and DFS ($\kappa = 0.55$). **Conclusions:** To our knowledge, our study is among the largest conducted in retroperitoneal DDLPS specifically evaluating clinico-pathological features and the performance of Sarculator and CINSARC. Our findings support the negative prognostic impact of rhabdomyoblastic differentiation. Further investigation of differentiation patterns, combined with prognostic nomograms and transcriptomic signatures, may improve the identification of high-risk pts and support more personalized therapeutic strategies. Unsupervised clustering of RNA-Seq data to identify molecular subtypes of sarcomas. First Author: Michael J. Robinson, Vanderbilt University Medical Center, Nashville, TN

Background: Sarcomas are a rare and heterogeneous group of malignancies, which include over 100 histological subtypes. Their histologic diversity present significant diagnostic and therapeutic challenges. This study aimed to define clinically relevant transcriptional subtypes using RNA-Sequencing (RNA-seq) data, and to further characterize the immune and metabolic microenvironment. **Methods:** This study uses data from the "Cohort to Augment the Understanding of Sarcoma Survivorship Across the Lifespan" (CAUSAL) study, which has enrolled sarcoma patients, treated at VUMC, from 2002-2026 for investigation of health outcomes. We analyzed RNA-seq data from tumor samples of 430 participants representing 42 unique histological sarcoma subtypes. We utilized sparse K-means clustering to identify stable subtypes and developed a classifier using a 310-gene panel. The immune microenvironment was characterized by applying CIBERSORTx deconvolution. Sarcoma subtype reproducibility and prognostic validity were evaluated using the Cancer Genomic Atlas data. **Results:** Among 430 samples, consensus matrices and diminishing gains in Cumulative Distribution Function (CDF) behavior yielded six distinct sarcoma molecular subtypes (SMS), each demonstrating strong correlation with known sarcoma histologies. SMS1 (labeled as "Cytotoxic-Adaptive", n=30) and SMS6 ("Interferon-Activated", n=97) were characterized by robust immune infiltration and interferon signaling, suggesting a potential sensitivity to immune checkpoint blockade. SMS2 ("Myeloid-Dominant", n=93) primarily grouped undifferentiated pleomorphic sarcoma, giant cell sarcoma, and myxofibrosarcoma, and exhibited an immune-suppressive, macrophage-rich phenotype. SMS3 ("Early-Onset", n=58) mostly grouped Ewing and synovial sarcoma and comprised mostly fusion-driven tumors with an immune-desert landscape. SMS4 ("EMT-Stromal", n=107) mostly comprised desmoid and leiomyosarcoma and was defined by epithelial-mesenchymal transition and fibrosis, correlating with the poorest 10-year overall survival (*p=0.022*). SMS5 ("Metabolic", n=45) consisted exclusively of Gastrointestinal Stromal Tumors, with distinct metabolic programming and favorable prognosis. **Conclusions:** Each SMS transcends histological boundaries, grouping tumors based on shared immune, stromal, and metabolic features. This classification highlights distinct vulnerabilities in the tumor microenvironment, offering a functional framework to guide future precision treatment interventions, such as immunotherapy for SMS1/SMS6 and stromal-targeting agents for SMS4. A subset analysis of clinical activity and pharmacodynamic biomarkers in patients with sarcomas in the phase 1 dose-escalation study of STC-15, a METTL3 inhibitor. First Author: Justin C. Moser, HonorHealth Research Institute, Scottsdale, AZ

Background: The RNA methyltransferase METTL3 is responsible for the generation of N6-methyladenosine (m6A), the most abundant modification on mRNA and long non-coding RNA. Accumulating evidence suggests numerous roles of METTL3 in cancer initiation and progression highlighting the rationale for targeting this enzyme in oncology. STC-15, a first in class small molecule inhibitor of METTL3 developed by Storm Therapeutics, demonstrated efficacy in pre-clinical models of cancer characterized by their dependence on m6A-mediated mRNA metabolism, including sarcomas that derive from a common mesenchymal progenitor. We report the clinical activity and pharmacodynamic (PD) biomarkers observed in a subset analysis of sarcomas from a first-in-human trial in patients with advanced malignancies. Full results of the study have been previously presented. **Methods:** This multi-center, open-label, dose escalation study of STC-15 administered oral capsules daily (QD) or three times a week (TIW) in 21-d treatment cycles. Dose escalation followed a 3+3 modified Fibonacci regimen. Primary objectives (safety and pharmacokinetics (PK)) and secondary objectives (efficacy) were previously presented. A subset analysis of sarcoma and selected patients evaluates anticancer activity and PD biomarkers, including target engagement, gene expression analysis, and targeted m6A RNA sequencing using the EpiPlex platform. **Results:** Of 42 patients enrolled, 35 were evaluable and 13 were sarcoma patients with a mean of 3 prior lines of therapy. Of 13 sarcoma patients with at least 1 on-treatment scan, DCR was 54% at 12 weeks with 1 confirmed PR (8% ORR) in angiosarcoma (DOR 22 months), and mPFS of 5.5 months as of 27 January 2026. Seven sarcoma patients presenting with four subtypes experienced a best response of SD, including tumor regressions. Treatment duration ranged from 15-828 days, with two sarcoma patients remaining on treatment for 590 and 828 days, respectively. An average of >50% reduction in m6A on mRNA in peripheral blood within the first 24h post dosing was observed in dose-escalating cohorts from 60 mg QD to 200 mg TIW, confirming target engagement. Moreover, we present an expanded analysis using the m6A-directed NGS EpiScout platform, where we evaluate both the effects of STC-15 on global m6A mRNA abundance and transcriptional changes that may contribute to an anti-tumor response specific to soft tissue and bone sarcomas. **Conclusions:** Treatment with STC-15 offers a new paradigm for the treatment of a broad range of sarcomas by halting the cell differentiation process from mesenchymal progenitors. Early biomarker data provide proof of mechanism in target engagement and changes in gene expression, consistent with pharmacological activity and clinical response. Further investigation of efficacy and biomarkers of STC-15 in a Phase 2 sarcoma study is ongoing. Clinical trial information: NCT05584111. Research Sponsor: None.

Use of subtype-specific patterns of clinically relevant antibody–drug conjugate targets in sarcoma to guide precision oncology strategies. First Author: Sohil Reddy, The Ohio State University, Columbus, OH

Background: Sarcomas are rare, biologically heterogeneous malignancies with limited targeted treatment options. Antibody–drug conjugates (ADCs) have demonstrated clinical efficacy across multiple solid tumors by exploiting tumor-associated surface antigens; however, their development in sarcoma has been limited by incomplete characterization of ADC target expression across subtypes. We evaluated expression of clinically relevant ADC targets across sarcoma histologies using bulk RNA sequencing and compared these patterns to cancer types with established ADC activity to generate a sarcoma-wide map of ADC target expression. **Methods:** We analyzed expression of 18 genes encoding cell-surface ADC targets that are FDA-approved or in active clinical development across more than 1,000 sarcoma samples spanning multiple histologic subtypes. Transcriptomic data were derived from The Cancer Genome Atlas (TCGA), an institutional sarcoma registry, and the Oncology Research Information Exchange Network (ORIEN). Per-sample z-scores were generated using pan-cancer distributions to enable standardized comparison. Z-score distributions were summarized using ordinal bins to define target enrichment across sarcoma subtypes. Parallel pan-cancer analyses were performed for contextual comparison. **Results:** Sarcomas demonstrated heterogeneous but subtype-specific expression of multiple ADC targets across datasets. Several subtypes exhibited elevated expression of select ADC targets, with z-scores comparable to or exceeding those observed in tumor types where ADCs have established clinical activity. ADC targets of particular interest included LRRC15 and CD276 (B7-H3). LRRC15, currently in investigation as an ADC in breast cancer, demonstrated enrichment in sarcoma, with 28% of undifferentiated pleomorphic sarcoma and 38% of dedifferentiated liposarcoma samples exhibiting z-scores $>$ 2, compared to 12% in breast cancer. CD276 similarly showed subtype-specific overexpression across these sarcoma subtypes. No single target was uniformly overexpressed across all sarcomas, underscoring biologic heterogeneity. Pan-cancer comparison revealed that certain sarcoma subtypes ranked among the highest expressors for specific ADC targets. **Conclusions:** Across a cohort exceeding 1,000 sarcoma patients with diverse histological subtypes, we identify subtype-specific overexpression of multiple clinically relevant ADC targets. This subtype expression map provides a biologic rationale for expanding ADC development into molecularly selected sarcoma subpopulations and supports biomarker-enriched approaches to ADC trial design. Ongoing studies will validate these findings at the protein level using a sarcoma surfaceome approach, including immunohistochemistry and mass spectrometry based profiling. Research Sponsor: None.

Distinct prognostic roles of *IDH* mutation and high-risk genomic alterations in patients with primary chondrosarcoma. First Author: Akshee Batra, University of Miami Sylvester Comprehensive Cancer Center/Jackson Health System, Miami, FL

Background: Prior studies report mixed associations between IDH mutation and survival in chondrosarcoma. We evaluated the prognostic impact of IDH mutation and high-risk genomic alterations in one of the largest multi-institutional cohorts while accounting for established prognostic factors. **Methods:** We retrospectively analyzed patients with histologically confirmed chondrosarcoma treated at the University of Miami and University of Florida. Patients with available molecular data were included. High-risk genomic alterations were defined as TP53, TERT, or cell-cycle pathway alterations. Endpoints included median overall survival (mOS), progression-free survival (mPFS) after treatment and distant metastasis–free survival (mMFS). Patients with metastatic disease at diagnosis were excluded from mMFS analyses. Multivariable Cox regression models were adjusted for age, sex, tumor grade and tumor type. **Results:** A total of 144 patients were included; 85 (59%) had NGS data. Median age was 60 years, and 46% had grade 3 disease. The majority of patients had conventional chondrosarcoma; 52 patients (36.1%) had dedifferentiated pathology. Among 64 IDH-mutant and 62 IDH-wildtype tumors, high-risk genomic alterations were identified in 48 patients, with comparable positive margin rates between IDH-mutant (14.1%) and IDH-wildtype (14.5%) cases. After multivariable adjustment for age, sex, tumor grade, and tumor type, IDH mutation was not independently associated with mOS (HR 1.26; p=0.48). However, IDH mutation demonstrated a trend toward inferior mPFS that did not reach statistical significance (HR 1.52; p=0.07) and was independently associated with inferior mMFS (HR 2.60; p=0.004). In contrast, high-risk genomic alterations were independently associated with inferior mOS (HR 2.45; p=0.025), mPFS (HR 2.94; p=0.003) and mMFS (HR 2.71; p=0.009) as compared to those patients without high-risk genomic alterations. **Conclusions:** After multivariable adjustment, IDH mutation conferred increased metastatic risk without an overall survival disadvantage, whereas high-risk genomic alterations consistently predicted poor outcomes across all survival endpoints. Research Sponsor: None.

Multivariable Cox regression analyses by survival endpoint in chondrosarcoma.

Endpoint	Comparison	Adjusted HR (95% CI)	p-value
Overall Survival	IDH mutant vs IDH wildtype	1.26 (0.66–2.40)	0.48
	High-risk NGS vs Low-risk NGS	2.45 (1.12–5.38)	0.025
Progression-Free Survival	IDH mutant vs IDH wildtype	1.52 (0.95–2.43)	0.077
	High-risk NGS vs Low-risk NGS	2.94 (1.45–5.96)	0.003
Metastasis-Free Survival	IDH mutant vs IDH wildtype	2.60 (1.35–5.01)	0.0043
	High-risk NGS vs Low-risk NGS	2.71 (1.28–5.74)	0.009

Survival outcomes of cabozantinib treatment with and without immune checkpoint inhibition in patients with heavily pretreated advanced sarcoma. First Author: Lauren Li, Stanford Health Care, Palo Alto, CA

Background: Cabozantinib is an oral tyrosine kinase inhibitor (TKI), with key targets including MET, VEGFR2, AXL, RET, and others. It is commonly used to treat specific carcinomas, but its efficacy in treating sarcomas is still emerging, especially in combination with immune checkpoint inhibition. The benefit of cabozantinib with or without immune checkpoint inhibition (ICI) in previously heavily treated patients with advanced sarcoma is unclear, underscoring the need for further investigation. **Methods:** We report results from a retrospective study of heavily pretreated advanced sarcoma patients who received cabozantinib with or without ICI. Eligible patients included those who had locally advanced or metastatic sarcoma and were exposed to cabozantinib for a minimum of one day. Patients who participated in the clinical trial "Randomized phase II trial of cabozantinib combined with PD-1 and CTLA-4 inhibition versus cabozantinib in metastatic soft tissue sarcoma" were excluded from this study. **Results:** There were 105 eligible patients with thirty-one different histology types, a median age of 55 years old, of which 55% were female patients. The median lines of prior treatment were four. Approximately 40.9% of patients were treated with cabozantinib alone and 59.1% were treated with cabozantinib plus either nivolumab, or nivolumab plus ipilimumab, or pembrolizumab. The progression-free survival (PFS) of the full cohort was 3.3 months. Eight patients (7.6%) obtained a partial response (PR) and forty-two patients (40.0%) had stable disease (SD) longer than 3 months, with a clinical benefit rate (CBR) of 47.6%. Partial responses occurred across a variety of histologic subtypes, including small round cell tumor, UPS, osteosarcoma, leiomyosarcoma, GIST, liposarcoma, and angiosarcoma. Stable disease was observed in a variety as well, including but not limited to LMS, synovial sarcoma, ASPS, chondrosarcoma, and osteosarcoma. The median PFS and OS for the 47.6% of patients who obtained a clinical benefit (PR + SD) were 6.9 and 22.9 months, compared to the median PFS of 2.1 months ($p < 0.001$) and median OS of 7.4 months (p = 0.001) for the patients with progressive disease. Several patients with aggressive histology including osteosarcoma, desmoplastic small round cell tumor, synovial sarcoma and others had PFS more than 12 months. Combination therapy with cabozantinib and an ICI accounted for the majority of PR's observed, including the longest ongoing PR (>15.3 months) in a patient with desmoplastic small round cell tumor. **Conclusions:** In a cohort of heavily treated patients with advanced soft tissue and bone sarcoma, cabozantinib alone or with ICI showed durable CBR in nearly 50% of patients, suggesting cabozantinib alone or with ICI could be of substantial benefits to certain sarcoma patients who have very limited treatment options remaining. Research Sponsor: None.

11552 **Poster Session**

Phase 2 study integrating early palliative care in advanced sarcoma patients for enhanced quality of life (SARQUALITY Trial: NCT06805669): An interim analysis. First Author: Catherine S. Weadick, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Patients (pts) with advanced cancer may experience substantial symptom burden that adversely affects quality of life (QoL). Although early palliative care (EPC) integrated with standard oncologic care (SOC) has demonstrated clinical benefit, patients with sarcoma have been underrepresented in prior studies. This phase II trial evaluates whether EPC combined with SOC improves outcomes in pts with advanced sarcoma compared with SOC alone. Results from the first interim analysis are presented. **Methods:** Adult pts with advanced sarcoma who are systemic treatment naïve were randomized (1:1) to either SOC alone or with EPC. EPC intervention included palliative care (PC) review within 4 weeks of randomization, routine PC contact and access to 24-hour support. Pts receiving SOC alone are referred to PC at time of clinical need. Pts complete Edmonton Symptom Assessment System (ESAS) and EORTC QLQ-C30 questionnaires at baseline, weeks 6, 12 and 24. The primary endpoint is the change in ESAS score at week 12 compared to baseline. Secondary endpoints include EORTC QLQ-C30 score change, emergency department (ED) attendance and overall survival (OS). The aim is to accrue 136 pts, providing 80% power at one-sided 5% level of significance to detect standardised difference of 0.45 between-group in ESAS score from baseline to 12 weeks. **Results:** Enrollment commenced in July 2024. At data lock (November 2025), 44 pts were enrolled (SOC, n=21; EPC, n=23). The cohort was predominantly female (n=29, 66%), with a median age of 60 years (range 29–85). Soft tissue sarcoma accounted for 43 cases (one had osteosarcoma); 39 (89%) pts had metastatic disease and 5 (11%) had locally advanced disease. Age, gender, race, histologic subtype, and number and sites of metastases were balanced between arms. ESAS and EORTC scores for pts in EPC arm (Table 1) but ED attendances were similar (EPC-24, SOC-23). In SOC arm, symptom management interventions (radiation, surgery) occurred more frequently than the EPC arm (12 vs. 2 pts). Seven pts were referred to PC from the SOC arm (median of 3.2 months from randomization). OS data is immature. **Conclusions:** The interim results of SARQUALITY trial demonstrate EPC has an impact on ESAS and EORTC scores, however, further data required to demonstrate if there is a benefit on QoL. There was a reduction in number of symptom management interventions in EPC arm, suggesting EPC may reduce need for additional interventions. Trial accrual is ongoing. Clinical trial information: NCT06805669. Research Sponsor: None.

Mean score change at 6, 12 and 24 weeks compared with baseline.

Week	6			12			24

Impact of concomitant medications on immune checkpoint inhibitor outcomes in sarcoma. First Author: Adel Shahnam, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Immune checkpoint inhibitors (ICIs) are an established treatment for many malignancies, with an emerging role in sarcoma. While the impact of concomitant medications (CM) on ICIs has been described in other cancers, it has not been evaluated in sarcoma. We assessed the association between CM use and ICIs outcomes in sarcoma patients. **Methods:** This pooled post hoc analysis included 7 investigator-initiated phase II ICI-based trials enrolling patients with metastatic sarcoma between April 1, 2017, and May 30, 2024. Patients receiving ≥1 dose of ICIs were included. CM taken within 30 days prior to treatment initiation were defined as baseline; PRN medications were excluded. CM were recorded at each cycle through end of treatment and categorized by medication class; supplements/herbal agents included vitamins, minerals, probiotics, botanicals, amino acids, and other dietary substances. For progression-free survival (PFS), baseline and on-treatment CM were analyzed as time-dependent covariates using Cox proportional hazards models. Overall survival (OS) analyses were limited to baseline CM. Logistic regression evaluated associations between baseline CM and objective response (ORR) and immune-related adverse events (irAEs). Toxicity was graded per CTCAE v5.0. **Results:** A total of 321 patients (median age, 58 years) were included. The most common histologies were liposarcoma (all subtypes, 22%), undifferentiated pleomorphic sarcoma (22%), and leiomyosarcoma (19%); 46% had received ≥3 prior lines of therapy. ICI was combined with cytokine/oncolytic therapies (43%), targeted agents (38%), or chemotherapy (19%). After a median follow-up of 47.4 months, ORR was 18%, median PFS was 3.9 months (95% CI, 3.09–5.32), and median OS was 19.9 months (95% CI, 17.5–22.9). Grade ≥3 irAEs occurred in 25% of patients, most commonly hematologic (6%) and hepatic (5%). On-treatment use of supplements/herbal agents was associated with longer PFS (HR 0.64, 95% CI 0.50–0.82; p<0.01), while on-treatment anti-infective use was associated with shorter PFS (HR 1.55, 95% CI 1.06–2.25; p=0.02); baseline anti-infective use was not associated with PFS. Baseline supplement/herbal use was associated with longer OS (HR 0.69, 95% CI 0.53–0.90; p<0.01), whereas baseline non-opioid (HR 1.54, 95% CI 1.10–2.16; p=0.01) and opioid analgesic use (HR 2.14, 95% CI 1.45–3.14; p<0.01) were associated with shorter OS. Baseline antihistamine use showed a trend toward increased gastrointestinal irAEs (OR 2.37, 95% CI 0.97–5.98; p=0.06). No CM class was associated with ORR. **Conclusions:** Concomitant medication use is associated with differential ICI outcomes in metastatic sarcoma and warrants prospective evaluation. Research Sponsor: None.

Patient-reported global health to predict negative health outcomes in patients with advanced sarcoma. First Author: Marium Husain, The Ohio State University Medical Center James Comprehensive Cancer Center, Columbus, OH

Background: Many patients with sarcoma deal with adverse impacts on their (QoL) related to their underlying disease as well as treatment-related effects. Unplanned hospital admissions and emergency department (ED) visits occur from uncontrolled symptoms that delay treatment and lead to poor hospital system metrics. The PROMIS Global Health v1.2 (PROMIS-10) survey is a validated tool to assess patients' physical and mental well-being at the time of the survey, with a higher number indicating a better state of health. There are limited studies evaluating longitudinal QoL assessments during sarcoma treatment. Our objective was to analyze PROMIS-10 scores for patients with advanced sarcoma and their temporal relationship with negative outcomes of interest. **Methods:** We performed a retrospective registry-based longitudinal analysis of routinely collected PROMIS-10 surveys at The Ohio State University. Patients were consented to the sarcoma registry (NCT02677961) from 6/1/2018 to 12/31/2024. We collected baseline, serial and overall change in physical and mental PROMIS-10 raw and normalized t-scores for each patient during their treatment as well as clinical characteristics, mortality, disease progression (RECIST), and ED visits/unplanned hospital admissions. Survival analyses with time-varying covariates were performed using the marginal Cox model approach for statistical analysis. **Results:** A total of 241 patients were included in the study. Patients with higher PROMIS-10 physical scores had a 13% decrease in risk of death (HR 0.87; $P < 0.001$), 3% decrease in risk of progression (HR 0.97; $P = 0.027$), and 6% decrease in risk of ED visit/unplanned hospital admission (HR 0.94; $P < 0.001$). Patients with a higher PROMIS-10 mental health score had a 7% decrease in risk of death (HR 0.93; $P < 0.001$), but no association with disease progression or risk of hospital utilization. The larger positive change in physical PROMIS-10 score from baseline to final assessment was associated with an 11% decreased risk of mortality (HR 0.89; $P < 0.001$) and 9% decreased risk of ED visit/hospital admission (HR 0.91; $P = 0.032$), but no association with progression. The larger positive change in mental PROMIS-10 score was associated with a 7% decrease in risk of progression (HR 0.93; $P = 0.010$) but there was no association with mortality or hospital utilization. **Conclusions:** We demonstrated that obtaining longitudinal patient-reported outcomes to evaluate patients' physical and mental health during sarcoma treatment can predict mortality, disease progression and ED visits/unplanned hospital admissions. Higher physical PROMIS-10 scores are strongly associated with decreased mortality and hospital utilization risk, whereas a larger positive change in mental PROMIS-10 scores is associated with decreased risk of progression. To our knowledge, this is the largest cohort (241 patients) of advanced sarcoma analyzing QoL impacts. Research Sponsor: None.

Neoadjuvant versus adjuvant chemotherapy in cardiac tumor resection: A propensity-matched analysis of perioperative and long-term outcomes. First Author: Fadi Abualhommos, Faculty of Medicine and Health Sciences, An-Najah National University, Nablus, Palestinian Territories (West Bank and Gaza)

Background: Optimal timing of systemic therapy for primary cardiac malignancies is undefined. We compared outcomes after surgical resection when chemotherapy was administered Neoadjuvant (≤4 months before surgery) compared to Adjuvant (≤4 months after). **Methods:** We conducted a retrospective cohort study using the TriNetX database of patients undergoing cardiac tumor resection who received chemotherapy either Neoadjuvant (≤4 months before surgery) or Adjuvant (≤4 months after). Patients were matched 1:1 using propensity scores based on demographics, comorbidities, and treatment variables, yielding 220 patients per group. Primary outcomes were all-cause mortality, infection, and transfusion within 30 days of surgery. Secondary outcomes included tumor recurrence at 1 year (90–365 days), all-cause mortality, and new-onset heart failure during 1–3 years of follow-up. Time-to-event analyses were performed using Kaplan–Meier methods with log-rank testing and hazard ratios (HRs); absolute and relative risks are reported as risk differences (RD) and risk ratios (RR). **Results:** After 1:1 propensity-score matching, 220 patients were included in each group. In the perioperative period (1–30 days), all-cause mortality occurred in 18/217 patients (8.3%) in the Neoadjuvant chemotherapy group compared with 30/213 (14.1%) in the Adjuvant group (RD −0.058, 95% CI −0.117 to 0.002; p=0.057), with a corresponding HR of 0.57 (95% CI 0.32–1.02; p=0.056). Infectious complications were lower with Neoadjuvant chemotherapy (12/220, 5.5%) than with Adjuvant chemotherapy (21/220, 9.5%) (RD −0.041, 95% CI −0.090 to 0.008; p=0.103; HR 0.54, 95% CI 0.27–1.10; p=0.090), while transfusion requirements were similar between groups (14.1% vs 12.3%; p=0.57). At 1 year (90–365 days), malignant cardiac tumor recurrence occurred in 27.7% of Neoadjuvant patients versus 21.4% of Adjuvant patients (RD +0.064, 95% CI −0.017 to 0.144; p=0.12; HR 1.16, 95% CI 0.80–1.70). During longer-term follow-up (1–3 years), all-cause mortality was comparable between groups (44.7% vs 47.4%), with longer median survival observed in the Neoadjuvant group (791 vs 516 days; HR 0.81, 95% CI 0.62–1.07; p=0.14). New-onset heart failure occurred at similar rates in both groups (p=0.98). **Conclusions:** In this cohort study of cardiac tumor resections, Neoadjuvant chemotherapy showed lower 30-day mortality and infection than Adjuvant chemotherapy, without significant differences in transfusion, 1-year recurrence, long-term mortality, or new-onset HF. These hypothesis generating findings suggest neoadjuvant chemotherapy is not associated with worse early or late outcomes and warrant confirmation in prospective, multi-center studies with histology-specific stratification and standardized systemic regimens. Research Sponsor: None.

Impact of regorafenib treatment on overall survival (OS) in advanced sarcoma patients. First Author: Clemence Leguillette, Centre Oscar Lambret, Lille, France

Background: Regorafenib has been evaluated in several sarcoma clinical trials and the common primary endpoint of these studies was Progression-Free Survival (PFS) according to RECIST, with OS as secondary endpoint. We aimed to assess the impact of regorafenib on OS using pooled analysis of REGOSARC (NCT01900743, five cohorts: liposarcoma, leiomyosarcoma, synovial sarcoma, other soft tissue sarcoma and non-adipocytic sarcoma post-pazopanib) and (NCT02389244, four cohorts: osteosarcoma, Ewing sarcoma, chondrosarcoma and chordoma). Both trials were placebo-controlled trials with potential switch to regorafenib in placebo-arm at progression. **Methods:** The primary endpoint was OS in months (mo.) from randomisation estimated by Kaplan-Meier method. The Hazard Ratio (HR) of death in a Cox model was stratified by histological . We used 2 methods for controlling regorafenib switch on OS: Rank-Preserving Structural Failure Time Model (RPSFTM; White et al. 1997) and Modified Iterative Parametric Estimation (MIPE: Zhang et al. 2016), with bootstrap-based 95%CI for both methods. Two populations were considered: in the primary analysis included all patients in both trials (n=355), and in secondary analysis excluded chordoma and liposarcoma patients (n=289), since regorafenib failed to demonstrate activity in these subtypes. **Results:** In primary analysis, the median age was 56.0 years (range, 16.0; 85.0); 325 patients (91.5%) had metastatic disease. 218 (61.4%) patients had soft tissue sarcoma and 137 (38.6%) patients had bone sarcoma. Median follow-up was 70.9 mo (IQR: 54.0-87.5). The median OS was 9.5 mo. (95%CI, 7.7-12.4) in Placebo arm versus 12.8 mo. (95%CI, 11.0-15.8) in regorafenib arm (HR: 0.85 (95%CI, 0.67-1.06); p=0.148). When correcting regorafenib switch effect, the estimated HR was 0.59 (0.31-1.25) and 0.62 (0.27-1.46) using RPSFTM and MIPE methods, respectively. **Conclusions:** In this pooled analysis, we observe a marked difference in OS, but which does not reach the , even after exclusion of chordomas and liposarcomas patients (20%-risk reduction, with p=0.083). After controlling for the switch effect, the corrected effect of regorafenib increased dramatically from 20% risk-reduction of death to a 45%-50% reduction in the population excluding chordomas and liposarcomas. Research Sponsor: None.

Prevalence of post-traumatic stress disorder and associated factors among adult sarcoma patients. First Author: Sang Minh Nguyen, Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Nashville, TN

Background: A cancer diagnosis and treatment can be extremely stressful and even traumatic for sarcoma patients. However, research on prevalence and risk factors for developing post-traumatic stress disorder (PTSD) symptoms among sarcoma patients has not been well studied. **Methods:** This study used survey data from participants recruited between 4/2022 and 12/2025 for the "Cohort to Augment the Understanding of Sarcoma Survivorship Across the Lifespan" (CAUSAL) study. PTSD symptoms were assessed via the 22-item Impact of Event Scale-Revised (IES-R) at cohort enrollment, and a total IES-R score of ³33 indicates PTSD symptomatology. Associations of demographics and clinical characteristics with PTSD symptoms were evaluated using logistic regression models. The association between PTSD symptoms and health-related quality of life (HRQOL), measured via T-scores for the seven core domains of the PROMIS-57 scale, was then assessed using multivariable linear regression models adjusted for potential confounders. **Results:** Among 1,112 adult sarcoma patients (509 on active treatment and 603 survivors), there are 605 females and 507 males, aged between 18 and 84 (mean age: 54.8). 18.1% of sarcoma patients/survivors reported experiencing PTSD symptoms. Female (20.5%) and younger (15.9-24.3%) sarcoma patients were significantly more likely to experience PTSD symptoms, whereas those with higher household incomes were significantly less likely to experience PTSD symptoms (11.6%-17.6%). Patients who were 5+ years post-diagnosis were less likely to experience PTSD symptoms with adjusted odds ratios (aOR) and 95% confidence intervals (CIs) of 0.56 (0.34, 0.89), compared to those who were $<$ 18 months post-diagnosis. Regular exercise (aOR [95 CI] = 0.59 [0.42, 0.83]) and having emotional support (aOR [95 CI] = 0.63 [0.41, 0.97] for medium and 0.26 [0.15, 0.42] for high support) were inversely associated with PTSD prevalence. PTSD symptoms were significantly associated with a decreased T-score of physical function and social roles and activities with ß(95% CI) of -4.2 (-5.7, -2.7) and -6.8 (-8.3, -5.2), respectively and increased scores for anxiety (ß = 8.9; 95% CI: 7.6, 10.0), depression (ß = 9.4; 95% CI: 8.2, 11.0), fatigue (ß = 7.0; 95% CI: 5.5, 8.5), sleep disturbance (ß = 7.9; 95% CI: 6.6, 9.3), and pain interference (ß = 6.7; 95% CI: 5.2, 8.2). **Conclusions:** PTSD symptoms were reported by an average 18% sarcoma patients and survivors, particularly among female, younger patients, non-exercisers, and those with lower income and low emotional support. PTSD was associated with poor HRQOL. Long-term survival, regular exercise, and increased emotional support were inversely associated with the prevalence of PTSD symptoms. Psychological support and exercise programs should be offered during active cancer treatment and follow-up surveillance to reduce PTSD symptoms in sarcoma patients and survivors. Enhanced local and systemic efficacy in refractory solid tumors via integrated intra-tumoral injection and radiotherapy: A study of the 'R-ISV-RO' modality. First Author: Wang Xiaolu, The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China

Background: As for most refractory solid tumors, especially sarcoma, immunotherapy still lacks meaningful improvement in their outcomes. The novel 'R-ISV-RO' in situ vaccine, in which we merged radiotherapy, intratumoral delivery of R837 and OX-40 ligand, together with systemic use of immune-checkpoint blockades, may be clinically beneficial. **Methods:** This was an exploratory, single-center, single-arm clinical trial aimed at evaluating the efficacy and safety of the 'R-ISV-RO' in situ vaccine therapy for advanced solid tumors. Thirty patients aged 18 years or older with advanced solid tumors and at least one measurable lesion were enrolled. The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), time to progression (TTP), and clinical benefit rate (CBR). The safety of the treatment and the injection procedures were also evaluated. **Results:** The ORR and DCR for injected lesions were 44.4% and 96.3%. Sarcoma patients exhibited superior outcomes, with a 100% DCR in injected lesions. The median PFS was 15.9 months for injected lesions and median OS was 23.6 months. The abscopal effect occurred in 12 patients. 'R-ISV-RO' treatment was well tolerated, with only 6.7% of patients experiencing grade 3 or higher adverse events. Improved clinical responses were associated with enhanced $CD4^+/CD8^+$ T-cell infiltration and peripheral expansion. Metabolomics analysis revealed therapy-induced metabolic remodeling. **Conclusions:** In this exploratory trial, 'R-ISV-RO' with concurrent immunotherapy demonstrated promising efficacy for both primary and distant tumors, especially for sarcomas. Systemic immune response and metabolic remodeling were also observed after the therapy. Clinical trial information: ChiCTR2100053870. A phase II, multi-cohort study with pemetrexed plus cisplatin combination in patients with relapsed or refractory advanced soft tissue sarcoma: Leiomyosarcoma cohort (ALBATROSS-SARC-LMS01). First Author: Hyo Song Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Songdang Institute for Cancer Research, Seoul, South Korea

Background: Given the promising results in previous single arm trial (NCT03809637), this histology-specific, multi-cohort, phase II trial was conducted to evaluate the efficacy and safety of pemetrexed plus cisplatin in patients with advanced and refractory soft tissue sarcoma (STS). **Methods:** In this trial (NCT04605770), we enrolled patients with metastatic and/or recurrent STS who had failed 1-2 prior cytotoxic regimens and maintained adequate performance status and organ function. The treatment regimen consisted of pemetrexed 500 mg/m² and cisplatin 75 mg/m² on day 1 of each 3-week cycle up to 6 cycles, followed by pemetrexed monotherapy. A total of 164 patients were planned for assignment into 4 histology- based cohorts (n=41 each) to account for a 10% drop-out rate: Cohort 1 (leiomyosarcoma, [LMS]), Cohort 2 (liposarcoma), Cohort 3 (vascular sarcoma), and Cohort 4 (other sarcomas). The primary endpoint was progression-free rate at 12 weeks (PFR12 weeks) utilizing a Simon's two-stage design (P1=40%, P0=20%, α=β=0.1). In the first stage, 17 patients were accrued; if at least 4 successes were observed, the cohort was to be expanded to 37 evaluable patients. To account for a 10% drop-out rate, the final enrollment target was set at 41 patients per cohort. **Results:** As of October 2025, 74 (45.1%) patients were enrolled. Among those, cohort 1 (LMS) reached full enrolment with 40 patients (median age; 53 years, female; 87.5%, 75% had received 2 prior lines of chemotherapy). Among Of 39 evaluable patients, 7 (17.9%) achieved a confirmed partial response, and 22 (53.8%) had stable disease, resulting in a disease control rate (DCR) of 74.3%. The median progression free survival was 6.3 months (95% CI, 4.9-7.6) with 74.0% of PFR12 weeks. Notably, the observed DCR and PFR12 weeks compare favorably with historical data for other second/third-line regimens in LMS, such as gemcitabine plus docetaxel (typical DCR 50–60%; PFR12 weeks 40–50%). The median OS was 20.5 months (95% CI 14.3-26.7), with a median of 7 treatment cycles administered (range 1-31). Although treatment-related adverse events (TRAEs) occurred in the majority of patients, grade $\geq$3 TRAEs were observed in only 10 (25%) patients, mainly anemia (n=10, 25%), neutropenia (n=7, 17.5%), and nausea (n=3, 7.5%). One TREA (drug hypersensitivity) led to treatment discontinuation due to drug hypersensitivity. **Conclusions:** The combination of pemetrexed and cisplatin was well tolerated and demonstrated promising activity in patients with relapsed, advanced STS, particularly in LMS cohort. The efficacy observed exceeded historical outcomes for standard-of-care second-line therapies, warranting further investigation in future histology-specific studies. Clinical trial information: NCT03809637. Research Sponsor: Ministry of Health & Welfare, Republic of Korea; RS-2025-02233161.

Efficacy and safety results of tazemetostat in Japanese patients with advanced epithelioid sarcoma: The phase 2 TAZETTA trial (NCCH2107). First Author: Kenji Tsuchihashi, Department of Hematology, Oncology, and Cardiovascular Medicine, Kyushu University Hospital, Fukuoka, Japan

Background: Epithelioid sarcoma is an ultra-rare soft tissue sarcoma with limited treatment options. Tazemetostat, a selective EZH2 inhibitor, demonstrated antitumor activity in a global phase 2 study (NCT02601950) and has been approved for the treatment of epithelioid sarcoma in the US. We conducted a Japanese phase 2 study (TAZETTA; NCCH2107) as a sub-study within the framework of the nationwide rare cancer registry project in Japan (MASTER KEY Project) to evaluate the efficacy and safety of tazemetostat in patients with advanced epithelioid sarcoma. **Methods:** The TAZETTA study is a non-randomized, single-arm, phase 2 trial. Eligible patients had locally advanced or metastatic epithelioid sarcoma with loss of INI1, had received at least one prior chemotherapy including doxorubicin, had an ECOG performance status of 0–2, and at least one measurable lesion according to RECIST v1.1. Tazemetostat was administered orally at 800 mg twice daily in 28-day cycles. The primary endpoint was the progression-free survival (PFS) rate at 18 weeks by blinded independent central review. The threshold 18-week PFS rate was set at 5% and the expected rate at 30%. With a one-sided alpha of 0.05 and 80% power, the required sample size was 12 patients. To allow for ineligibility or non-treatment patients, 15 patients were planned. Secondary endpoints included PFS, overall survival (OS), objective response rate (ORR), disease control rate, duration of response, and safety. In the ancillary study, biomarker samples were collected and subjected to exploratory analysis. **Results:** Given the smooth patient accrual, 17 patients were enrolled between July 2023 and July 2024. The median age was 43 years; 13 patients were men and 4 were women. Proximal-type disease was observed in 11 patients (64.7%). The centrally assessed 18-week PFS rate was 31.3% (90% CI, 14.0–50.2), and the lower limit of the 90% CI met the predefined efficacy threshold. The median PFS was 2.9 months (95% CI, 1.6–5.6), and the median OS was 12.3 months (95% CI, 4.9–not estimable). Treatment-related adverse event with Grade $\geq$3 included lymphopenia (1pt, 5.9%). No treatment-related deaths were observed. **Conclusions:** Tazemetostat demonstrated clinically meaningful activity and a manageable safety profile in Japanese patients with advanced epithelioid sarcoma, consistent with the previous reports, supporting its role as a therapeutic option in this population. Clinical trial information: jRCT2031220523. Research Sponsor: None.

11561 Poster Session

Neoadjuvant pegylated liposomal doxorubicin plus anlotinib in locally advanced soft tissue sarcoma: Clinical outcomes and multi-omics analysis from a phase II study. First Author: Wei Sun, Department of Musculoskeletal Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Neoadjuvant therapy may improve the R0 resection and limb salvage rates in locally advanced soft tissue sarcomas (STS). This phase II trial was designed to evaluate the efficacy and safety of neoadjuvant pegylated liposomal doxorubicin (PLD) combined with anlotinib in the treatment of locally advanced STS. **Methods:** This single-center, single-arm phase II trial (NCT04765228) enrolled treatment-naïve patients with stage II/III. Patients received PLD (50 mg/m² intravenously on day 1) combined with anlotinib (12 mg orally daily on days 8-21) every 3 weeks for 2-4 cycles. Based on a one-proportion test, with α=0.05 (two-sided) and 80% power, to detect an increase in the objective response rate (ORR) from 10% to 26%, 45 patients were planned, accounting for a 20% dropout rate. The primary endpoint was objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. The exploratory endpoint was biomarker analyses. The corresponding two-sided 95% CIs were estimated using the Clopper-Pearson method. The PFS and OS were estimated using the Kaplan-Meier method. **Results:** A total of 40 eligible patients were treated between November 2020 and November 2022, of whom 34 (85.0%) underwent surgery. The median age was 46.5 years (range: 15-74 years), and 23 (57.5%) of the patients were male. Histologically, the 40 patients included 9 cases of liposarcoma (LPS), 6 cases of malignant peripheral nerve sheath tumor (MPNST), 6 cases of synovial sarcoma (SS), 3 cases of low-grade fibromyxoid sarcoma (LGFMS), 3 cases of myxofibrosarcoma (MFS), 3 cases of spindle cell sarcoma (SCS), 3 cases of undifferentiated pleomorphic sarcoma (UPS), 2 cases of leiomyosarcoma (LMS), and 5 cases of other STS. The most common sites of primary tumor were lower extremities (42.5%), waist/hip region (17.5%) and other regions. The ORR based on RECIST 1.1 was 15.0% (95% CI: 3.4%-26.6%), and the ORR of 36 patients based on Choi's criteria was 58.3%. The median PFS was 14 months (95% CI: 4.22 - 23.79 months), and the median OS was not reached. Pathological response was evaluable in 24 patients, with pathological complete response (pCR) and pathological partial response (pPR) observed in 4.2% (1/24) and 50.0% (12/24) of cases, respectively. Among 34 patients who underwent surgical resection, 30 (88.2%) achieved R0 resection, while 3 (8.8%) had R1 resection. Common treatment-related adverse events (TRAEs) of any grade included mucositis oral (52.5%), neutrophil count decreased (25.0%). Fifteen (37.5%) patients experienced at least one grade 3-4 AE. **Conclusions:** Neoadjuvant PLD combined with anlotinib exhibits promising efficacy and acceptable toxicity in patients with locally advanced STS. Results from multi-omics analyses will facilitate the screening of suitable patients in future clinical practice. Clinical trial information: NCT04765228. Research Sponsor: National Key R&D Program of China; 2023YFC2506400; National Natural Science Foundation of China; 82373385, 82272857, 82441039, 82303608; East Clinical Center of Oncology; ECCO-KY-23003.

11562 Poster Session

Triplet combination of anlotinib plus nab-paclitaxel and gemcitabine (AG) as a first-line strategy for advanced primary cardiac angiosarcoma: A high-volume center experience. First Author: Xi Guo, Department of Medical Oncology, Cancer Center, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Primary cardiac angiosarcoma (PCAS) is an exceedingly rare and lethal mesenchymal malignancy characterized by aggressive growth and high metastatic potential. Despite the use of taxane-based regimens, the prognosis remains dismal, with a historical median overall survival (mOS) of approximately 11 months. Given the highly vascular nature of PCAS, we hypothesized that integrating a multi-target anti-angiogenic TKI (anlotinib) with cytotoxic chemotherapy could synergistically improve outcomes. This study evaluated the efficacy and safety of anlotinib plus nab-paclitaxel and gemcitabine (AG) in advanced PCAS. **Methods:** We retrospectively analyzed patients with metastatic or unresectable PCAS treated at Zhongshan Hospital, Fudan University. The triplet regimen consisted of anlotinib (8-12 mg QD, days 1-14, q3w), nab-paclitaxel (200 mg), and gemcitabine (1000 mg/m²) on days 1 and 8 every 3 weeks. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival (OS), and safety (CTCAE v5.0). Survival outcomes were estimated using the Kaplan-Meier method and compared via log-rank tests. **Results:** A total of 24 patients were included, with a median age of 44 years. Most tumors (91.7%) originated in the right atrium, and 70.8% of patients received this regimen as first-line therapy. Efficacy: At a median follow-up of 31.4 months, the ORR was 62.5% and the DCR was 95.8%. Survival: The median PFS was 9.5 months (95% CI, 8.4-20.7). Notably, the median OS reached 24.9 months (95% CI, 15.2-NR), significantly exceeding historical benchmarks. Prognostic Indicators: Subgroup analysis identified liver metastasis (45.8%) as a significant negative prognostic factor for PFS (p = 0.018). Additionally, a numerical trend toward shorter survival was observed in patients with baseline D-dimer $>$ 5 mg/dL (Median OS: 5.5 vs. 10.5 months; p = 0.428). Safety: Treatment-related adverse events (TRAEs) of any grade occurred in 95.8% of patients. Grade$\geq$3 TRAEs (41.7%) were primarily hematological (neutropenia, thrombocytopenia) and were manageable via dose modification. No severe treatment-related cardiotoxicity was observed. **Conclusions:** The triplet combination of anlotinib and AG demonstrates unprecedented survival benefits and a manageable safety profile in advanced PCAS. With a mOS exceeding twice the historical data, this regimen represents a potent new treatment strategy. Liver involvement serves as a critical prognostic indicator for risk stratification, while the clinical significance of baseline D-dimer levels as a surrogate marker for tumor burden warrants further investigation in larger cohorts. Research Sponsor: None.

Outpatient rehabilitation for adults with soft tissue sarcoma: Examining real-world service utilization and outcomes. First Author: Kelley C. Wood, Select Medical, Mechanicsburg, PA

Background: Soft tissue sarcoma (STS) and its treatments frequently result in substantial physical morbidity, leading to impaired function and reduced quality of life. Rehabilitation can improve outcomes, yet real-world utilization and effectiveness in this population remain poorly understood. This study describes outpatient rehabilitation service use among adults with STS and examines changes in physical function and quality-of-life outcomes. **Methods:** Electronic medical record data from outpatient rehabilitation encounters were retrospectively analyzed for adults with a STS diagnosis (identified by ICD code) who completed $\geq$2 visits and had pre- and post-treatment outcome measures available. Rehabilitation characteristics were examined descriptively, including visits, care duration, service type, and treatment indications (identified by ICD code). PROMIS-Physical function (PF) was the primary outcome. Secondary outcomes were PROMIS-Global physical health (GPH), -Ability to participate in social roles and activities (SRA), and -Global mental health (GMH). Mixed-effect models assessed change in T-scores, adjusting for covariates (age, visits per week, care duration) and accounting for within-subject correlation. Estimated marginal (EM) means are reported. Change scores were compared to the established minimal important change (MIC, 2 points) to determine clinical relevance. **Results:** A total of 151 patients met inclusion criteria (mean age 56.0$\pm$16.7 years; 57% female). Most received physical therapy (86.1%), with fewer receiving occupational therapy (13.2%). The median episode of care was 8.3 weeks (IQR 4.3–16.0), with a mean of 1.6$\pm$ 0.7 visits per week. Common treatment indications included pain (37.9%), weakness/deconditioning (35.8%), gait/balance (27.5%), followed by lymphedema (8.5%), fatigue (5.9%), wound/post-surgery care (5.5%), and neuropathy (3.1%). Significant improvements were observed in PF (+2.48, SE: 0.57), GPH (+2.64, SE: 0.50), and SRA (+2.64, SE: 0.57) ($p<.001$), each surpassing the MIC. No significant change was observed in GMH (-0.39, SE:0.48, p=.419). **Conclusions:** In this real-world cohort of adults with STS, outpatient rehabilitation averaged 8 weeks of care and 1-2 visits per week, most commonly addressing pain, weakness, and gait/balance deficits. Significant and clinically meaningful improvements were observed in physical function and the physical and social aspects of quality of life; mental health was not significantly affected. These findings support the role of rehabilitation as an important component of multidisciplinary sarcoma care and underscore the need for complementary strategies to address psychosocial outcomes. Research Sponsor: None.

PROMIS T-scores, EM mean (SE).

Outcome	Pre	Post
PF	36.26 (0.50)	38.74 (0.57)
GPH	39.44 (0.52)	42.08 (0.56)
SRA	43.17 (0.56)	45.82 (0.65)
GMH	47.40 (0.60)	47.02 (0.63)

11564 Poster Session

The investigator-initiated trial (IIT) of GO306 injection, a recombinant oncolytic vaccinia virus, in patients with advanced soft tissue sarcomas. First Author: Qiujun Zhang, Department of Oncology, Anhui Provincial Cancer Hospital, The West District of First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China

Background: Oncolytic vaccinia viruses exert anti-tumor effects via direct lysis and systemic immunity induction. Advanced soft tissue sarcomas (STS) are heterogeneous malignancies with limited post-standard therapy options. GO306 is a oncolytic virus expressing PD-1/TGFβ inhibitors for tumor-selective replication and enhanced immunity. We report GO306's preliminary safety and tolerance in pretreated advanced STS. **Methods:** This open-label, single-arm IIT enrolled histologically confirmed advanced STS refractory to standard therapy. A 3+3 dose-escalation design was used, with intratumoral GO306 at 3×10^7 PFU, 3×10^8 PFU and 1×10^9 PFU. A 21-day DLT assessment period was set. Tumor assessment was done on day 28 per RECIST v1.1. Primary endpoints: MTD, DLTs, safety; secondary endpoints: OS, ORR, PFS, immunogenicity, viral shedding. **Results:** As of Dec 5th, 2025, 10 participants were enrolled across 3 dose cohorts, 9 completed the 21-day DLT assessment (1 non-DLT withdrawal). Demographics: median age 52.4 years, 80% male, ECOG 1-2. No DLTs were observed; MTD not reached. A total of 110 AEs were reported, including 52 treatment-related adverse events (TRAEs), 98.8% (51/52) were grade 1-2, with 1 grade 3 pulmonary infection (SAE due to prolonged hospitalization). No grade 4-5 TRAEs occurred. Most common AEs: pyrexia (60%, grade 1-2), followed by hypokalemia, hypocalcemia and hypoalbuminemia (40% each, grade 1-2). Efficacy was evaluable in 8 participants: 87.5% (7/8) SD and 12.5% (1/8) PD. Survival data: 2 participants with OS > 5 months, 1 alive at 260 days (all received subsequent anti-tumor therapies), 2 with 90-day survival documented. Viral shedding: GO306 was below the limit of quantification (BLQ) in feces, urine, throat swabs, and plasma on day 3/7, undetectable on day 30 (some samples pending). PD-1 inhibitor was detectable in 6/10 participants (29.91~19073.64 ng/mL); TGFβ inhibitor in 7/10 participants (80.39 to 460.31 ng/ml). **Conclusions:** Intratumoral GO306 showed favorable safety profile and manageable TRAEs in pretreated advanced STS. Preliminary efficacy support phase I/II expansion and combination studies with other immunotherapies or targeted therapies. Clinical Trial Registration Number: ChiCTR2400088508. Xianhai Zhu and Hu Liu contributed equally as corresponding author. Clinical trial information: ChiCTR2400088508. Research Sponsor: None.

Cardiac safety of aldoxorubicin compared to doxorubicin: Integrated results from two randomized studies in advanced soft tissue sarcoma. First Author: Philip Sager, Stanford University School of Medicine, Stanford, CA

Background: Doxorubicin clinical benefit is limited by cumulative, irreversible cardiotoxicity that restricts dosing. Aldoxorubicin is an albumin-binding prodrug of doxorubicin designed to enhance tumor delivery while reducing systemic exposure to cardiotoxic metabolites such as doxorubicinol. Prior reports suggest improved cardiac tolerability of aldoxorubicin, but no integrated analysis across randomized studies has been presented. **Methods:** Cardiac safety data were analyzed from two randomized studies, INNO-206-STS-P2-01 (NCT01514188) and ALDOXORUBICIN-P3-STS-01 (NCT02049905), comparing aldoxorubicin with doxorubicin in advanced soft tissue sarcoma. Left ventricular ejection fraction (LVEF) was assessed at baseline and prespecified intervals during and after treatment. Outcomes included mean and change-from-baseline LVEF, proportion of patients with LVEF $<$45%, treatment-emergent heart-failure and cardiovascular adverse events (AEs), and composite endpoints integrating LVEF decline and cardiac AEs. Cumulative doxorubicin-equivalent dose was calculated using a 0.74 conversion factor. **Results:** Across both studies (N≈383), baseline demographics and cardiac risk factors were balanced. Aldoxorubicin was administered at approximately 3.5-fold higher doxorubicin-equivalent cumulative doses than doxorubicin. Despite higher exposure, aldoxorubicin was associated with smaller mean LVEF declines (pooled lowest on-treatment change -3.17% vs -5.77%; nominal $p<0.05$). Approximately three-fold more doxorubicin-treated patients reached LVEF $<$45% (1.1% vs 3.8%). Composite endpoints favored aldoxorubicin, including HF-AE plus LVEF $<$45% (0.7% vs 3.4%), HF-AE plus $\geq$10-point decline (2.0% vs 4.6%), prespecified cardiovascular AE plus LVEF $<$45% (0.3% vs 1.1%), and prespecified cardiovascular AE plus $\geq$10-point decline (1.4% vs 4.6%). Treatment-emergent prespecified heart-failure events occurred less frequently with aldoxorubicin (3.0% vs 6.9%). LVEF–exposure plots showed higher LVEF with aldoxorubicin despite substantially higher cumulative exposure. In Phase 1 aldoxorubicin pharmacokinetic data, the doxorubicinol-to-doxorubicin exposure ratio was ~5–6%, compared with ~40–60% reported for conventional doxorubicin, consistent with lower systemic doxorubicinol burden and supporting the observed cardiac safety findings. **Conclusions:** Across two randomized studies, aldoxorubicin demonstrated a consistently more favorable cardiac safety profile than doxorubicin despite higher cumulative exposure, with smaller LVEF declines and fewer heart-failure–related events. These findings support aldoxorubicin as a potentially safer anthracycline option for patients requiring sustained exposure. Research Sponsor: Gemini Therapeutics, Inc.

Neo-adjuvant radiation and intratumoral immunotherapy followed by surgery: The NARIS trial for extremity soft tissue sarcoma. First Author: Rutian Li, The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, Jiangsu, China

Background: Patients with STS who failed to respond to standard treatment have limited subsequent treatment options. Radiotherapy combined with immunotherapy has demonstrated efficacy in certain STS subtypes, such as undifferentiated pleomorphic sarcoma (UPS); however, perioperative strategies still require optimization to further improve local control and reduce adverse events, particularly for patients with multiple recurrences yet seeking limb preservation. **Methods:** Patients with pathologically confirmed extremity STS without metastases were enrolled. Eligible participants received two neoadjuvant cycles administered every three weeks. Each cycle consisted of hypofractionated radiotherapy (a total of 5 Gy $\times$ 4 fractions across two cycles) combined with intratumoral injection of a PD-L1 (TQB2450) monoclonal antibody. **Results:** A total of 15 patients were screened, of whom 11 met the eligibility criteria and provided written informed consent. Except for one patient with disease progression after standard chemoradiotherapy, other patients had recurrent disease following one to three prior curative resections at baseline. The ORR and DCR were 36.4% (95% CI, 10.9–69.2%) and 90.9% (95% CI, 58.7–99.8%), respectively. One patient has not yet undergone surgery. Among the 10 patients who received surgery, one achieved a pCR, and two achieved MPR. All three cases occurred in UPS patients. In the 10 evaluable patients with STS, the median percentage of tumor necrosis and fibrosis was 63.5% (IQR 17.5–88.75%), and the median residual viable tumor percentage was 36.5% (IQR 11.25–82.5%). Subgroup analysis showed that the median percentage of tumor necrosis and fibrosis in UPS patients was 97% (IQR 88–99.25%), compared with 25% (IQR 10–55%) in other histological subtypes. The pCR rate and MPR rate in UPS patients were 25% (1/4) and 75% (3/4), respectively. During the neoadjuvant phase, the main TEAEs were local swelling and decreased lymphocyte counts, which were reversible during treatment intervals. No grade 3 TEAEs or immune-related adverse events were observed. Postoperative complications in the 10 surgical patients were as expected and mainly included local soft tissue edema, pain, local stiffness, and limb numbness. No delayed wound healing or surgical site infections were observed. **Conclusions:** Compared with current clinical studies in STS that employ conventionally fractionated radical radiotherapy and intravenous immune checkpoint inhibitors, this study utilized a lower total radiation dose delivered in larger fractions combined with intratumoral administration of immunotherapy, achieving comparable disease control with manageable toxicity. It may be clinically valuable for patients with recurrent disease after multiple surgeries or those with prior exposure to local radiotherapy. Clinical trial information: ChiCTR2200060659. Effect of pimicotinib on tumor response and physical function (PF) by tumor location in patients with tenosynovial giant cell tumor (TGCT): Results from the phase 3 MANEUVER trial. First Author: Gabriel Tinoco, The Ohio State University Comprehensive Cancer Center (OSUCCC), Columbus, OH

Background: TGCT is a rare, locally-aggressive, soft-tissue tumor driven by colony-stimulating factor-1 (CSF-1) overproduction, often leading to impaired PF. Pimicotinib (pimi), an oral, highly-selective CSF-1 receptor inhibitor, demonstrated robust tumor responses, clinically meaningful symptomatic and functional improvements, and a tolerable safety profile in patients (pts) with TGCT in the global Phase 3 MANEUVER trial (NCT05804045). Here, we report the effects of pimi on tumor response and PF in joints most commonly affected by TGCT. **Methods:** In MANEUVER, symptomatic adult pts with unresectable TGCT were randomized 2:1 to once-daily pimi 50 mg or placebo for 24 weeks (Part 1). After Part 1, eligible pts received open-label pimi for 24 weeks (Part 2), followed by an ongoing long-term extension period (Part 3). Longer-term objective response rate (ORR) by blinded independent review committee (BIRC) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1, Range of Motion (ROM) responses, and Patient-Reported Outcomes Measurement Information System-PF (PROMIS-PF) scores from Part 1 to Part 3, up to data cut-off, are reported by tumor location for pts randomized to pimi in Part 1. **Results:** At baseline, 63 pts were randomized to pimi; 71.4% were female and median age was 41.0 years (range 18–69). Median follow-up was 14.3 months and median treatment duration was 14.2 months. Most pts had diffuse TGCT (84.1%), with an affected lower extremity (85.7%), particularly the knee (52.4%). Tumor responses to pimi were comparable for localized (n=8) and diffuse (n=53) TGCT based on ORR by BIRC per RECIST v1.1 (95% CI): 87.5% (47.3, 99.7) vs 75.5% (61.7, 86.2), respectively. ORRs (95% CI) were comparable for pts with lower extremity (n=54) tumors and upper extremity (n=9) tumors: 75.9% (62.4, 86.5) vs 77.8% (40.0, 97.2), respectively, and for knee tumors (n=33) vs other (n=30) locations: 75.8% (57.7, 88.9) vs 76.7% (57.7, 90.1), respectively. Knee ROM improved from baseline to Week 49 (mean change: 8.9 [SD 8.4]). PROMIS-PF scores for lower extremity measures such as walking, climbing stairs, standing, and bending/kneeling improved from baseline (n=54) to Week 49 (n=43) (Table). **Conclusions:** Pimi provided sustained, clinically meaningful benefits in pts with TGCT, including durable tumor shrinkage and improved ROM and PF, regardless of tumor location. These results support pimi as an effective treatment option for patients with unresectable TGCT. Clinical trial information: NCT05804045. Research Sponsor: Abbisko Therapeutics; Merck KGaA, Darmstadt, Germany.

Longer-term PROMIS-PF scores per item from baseline to week 49.

PROMIS-PF score[a] Mean (SD)	Baseline (N=54)	Week 49 (N=43)
Walk for ≥15 minutes	3.9 (1.0)	4.6 (0.6)
Climb stairs	3.3 (1.1)	4.2 (0.8)
Stand for 1 hour	2.9 (1.2)	3.7 (1.3)
Bend, kneel, or stoop	2.7 (1.3)	3.6 (1.2)

[a]1-Unable to do; 2-With much difficulty; 3-With some difficulty; 4-With a little difficulty; 5-Without any difficulty.

Longer-term safety of pimicotinib in tenosynovial giant cell tumor (TGCT): Integrated analysis of phase 1 and phase 3 MANEUVER trial data. First Author: Hans Gelderblom, Department of Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: TGCT is a rare, locally-aggressive neoplasm associated with significant morbidity and functional impairment. Colony-stimulating factor-1 receptor (CSF-1R) inhibitors are effective for unresectable TGCT, but current options may be limited by their long-term safety and tolerability. In the Phase 3 MANEUVER trial, pimicotinib (pimi), a highly-selective CSF-1R inhibitor, demonstrated robust tumor responses, clinically meaningful symptomatic and functional improvements, and a tolerable safety profile. This integrated analysis evaluated the longer-term safety of pimi from Phase 1 and 3 trials. **Methods:** Data for adult patients (pts) with TGCT treated with pimi 50 mg once daily from Phase 1 (NCT04192344, cut-off Dec 31, 2024) and Phase 3 (NCT05804045; MANEUVER, cut-off Mar 12, 2025) trials were pooled for an integrated safety analysis. The open-label Phase 1 study assessed safety, tolerability, and pharmacokinetics of pimi in advanced solid tumors. MANEUVER evaluated efficacy and safety of pimi in unresectable TGCT across a 24-week, double-blind, placebo-controlled phase; a 24-week open-label pimi treatment phase; and an ongoing long-term extension. All treatment-emergent adverse events (TEAEs) and adverse events of clinical interest (AECI) were analyzed and reported as frequencies. **Results:** In total, 158 pts were included; 65.8% were female and median age was 40.0 (range 18–76) years. Median pimi exposure was 385.5 days; 12.7% of pts had prior exposure to systemic therapy. TEAEs of any grade were reported by 99.4% of pts (Table); most pts reported a maximum grade of 1 (8.9%; n=14/158) or 2 (53.2%; n=84/158). The most reported AECI of any grade by pts were blood creatine phosphokinase (CPK) elevation (72.2%), aminotransferase elevation (59.5%), edema (excluding periorbital edema [POE]) (54.4%), rash (46.2%) and pruritus (43.0%); 20.9% reported fatigue. There was no evidence of cholestatic hepatotoxicity or drug-induced liver injury. The most common AECI leading to dose reduction were rash (5.1%) and edema (excluding POE) (3.2%); for dose interruption, blood CPK elevation (13.9%) and rash (13.3%) were most common. Most AECI resolved/improved following dose reduction or interruption. Treatment discontinuation due to AECI was rare (face edema, 0.6%; rash, 0.6%). Concomitant medication was most commonly used for rash (n=38/73), pruritus (n=31/68), and edema (n=22/86). **Conclusions:** Pimi showed sustained tolerability with no new safety signals, confirming a favorable safety profile in Phase 1 and 3 trials during extended treatment of $>$1 year in a larger TGCT population. Clinical trial information: NCT04192344; NCT05804045. Research Sponsor: Abbisko Therapeutics; The healthcare business of Merck KGaA, Darmstadt, Germany.

Summary of TEAEs.

TEAE	Pts (N=158) n (%)
Any	157 (99.4)
Grade ≥3	59 (37.3)
Serious	17 (10.8)
DR serious	1 (0.6)
Leading to dose reduction	33 (20.9)
Leading to dose interruption	95 (60.1)
Leading to discontinuation	8 (5.1)
Resulting in death	1 (0.6)
DR resulting in death	0

DR, drug related.

Efficacy and safety of engineered TCR-T cell therapy (afami-cel, lete-cel) in pediatric synovial sarcoma. First Author: Amy E. Armstrong, Washington University in St. Louis, St. Louis, MO

Background: Synovial sarcoma (SyS) represents ~ 5% of adult soft tissue sarcomas, however, SyS is the most common non-rhabdomyosarcoma soft tissue sarcoma in the pediatric population. Both lete-cel, an engineered TCR-T cell therapy targeting NY-ESO-1, and afami-cel, an engineered TCR-T cell therapy targeting MAGE-A4, have shown efficacy and an acceptable safety profile in adult patients with SyS. We report here the largest cohort of pediatric SyS patients treated with either afami-cel or lete-cel. **Methods:** Pediatric SyS patients (pts) were treated on four phase II trials: lete-cel SyS Pilot study (NCT01343043), lete-cel IGNYTE-ESO trial (NCT03967223), afami-cel SPEARHEAD-1 (NCT04044768) and SPEARHEAD-3 (NCT05642455). Initial data from SPEARHEAD-3 will be available and added at the time of presentation. Eligibility for this analysis: advanced (unresectable/metastatic) SyS, human leukocyte antigen (HLA)-A*02, NY-ESO-1 or MAGE-A4 expression, baseline ECOG 0–1 and received any dose of lete-cel or afami-cel as a single infusion. Key efficacy endpoints: independent review-assessed overall response rate (ORR) per RECIST v1.1, best overall response, duration of response (DoR). Key safety endpoints: adverse events (AEs), serious AEs, AEs of special interest (ex. Cytokine release syndrome (CRS)). Data is presented separately for lete-cel and afami-cel. **Results:** Seven pediatric pts (age 10 to 17) were treated with lete-cel for advanced disease. The median lete-cel dose was 4.9 x 10^9 transduced cells. The ORR was 43% (3/7 pts, 2 PR, 1 CR). The duration of response was 2.83, 7.39, and 7.39 months respectively; one response was ongoing at the time of this analysis. Pediatric pharmacokinetics and exposure-response data were in agreement with data from adult pts. Seven pediatric pts (age 13 to 16) were treated with afami-cel for advanced disease. The median afami-cel dose was 8.2 x 10^9 transduced cells. The ORR was 28.6% (2/7 pts, 2 PR). The duration of response was 4.7 and 17.4 months respectively; one response was ongoing at the time of this analysis. Similar pharmacokinetics were observed in pediatric pts compared to adult pts. CRS was common occurring in >50% of pts for both lete-cel and afami-cel; events were grade 1 or 2, except one patient with lete-cel experiencing grade 3 CRS. Cytopenias after lymphodepletion and T cell infusion were the most common grade 3 or 4 adverse events (>30% of pts) for both therapies. **Conclusions:** Engineered TCR-T cell therapy targeting NY-ESO-1 (lete-cel) or MAGE-A4 (afami-cel) has shown responses and durable responses in the pediatric SyS population. The safety profile in this age group is consistent with that observed in the adult population. TCR-T represents a potential new treatment paradigm for pediatric SyS patients. Further studies should help to determine the optimal timing for this cellular therapy. Additional Information: Coauthor Brian Van Tine, MD, died Nov 2025. Clinical trial information: NCT01343043, NCT03967223, NCT04044768, NCT05642455. Research Sponsor: Adaptimmune LLC; USWM CT, LLC.

Outcomes of malignant peripheral nerve sheath tumors in neurofibromatosis type 1 and sporadic patients: A 25-year experience from a sarcoma referral center. First Author: Clio Coste, Centre Leon Bérard, Lyon, France

Background: Malignant peripheral nerve sheath tumors (MPNST) are rare, aggressive soft-tissue sarcomas frequently associated with neurofibromatosis type 1 (NF1). Prospective trials are scarce, and prognostic factors and treatment effects remain incompletely defined. **Methods:** We conducted a retrospective observational cohort study of 200 patients (215 tumor episodes) with histologically confirmed MPNST treated at a national sarcoma referral center between 2000 and 2025. Overall survival (OS) and progression-free survival (PFS) were estimated via Kaplan–Meier methods. Multivariable Cox models with multiple imputation (MICE, m=40) were adjusted for clinical factors. Restricted mean survival time (RMST) at 5 years quantified absolute survival differences. Interaction analyses assessed heterogeneity of radiotherapy (RT) effects. **Results:** Median age was 40 years; 51.5% of patients had NF1. Median OS and PFS were 74.6 and 9.1 months, respectively. NF1-associated MPNST had significantly shorter OS (28.5 vs 141.0m; p=0.012), with a 5-year RMST reduction of 8.5 months (95% CI -15.0 to -2.3; p=0.01). In the multivariable Cox model with multiple imputation, advanced stage (HR 2.28; 95% CI 1.68–3.09; p<0.001), higher FNCLCC grade (HR 1.95; 95% CI 1.39–2.75; p<0.001), NF1 status (HR 1.67; 95% CI 1.11–2.51; p=0.014), central tumor location (HR 1.63; 95% CI 1.02–2.60; p=0.041), and increasing age (HR 1.04 per year; 95% CI 1.02–1.05; p<0.001) were independently associated with inferior OS, whereas female sex was strongly protective (HR 0.43; 95% CI 0.29–0.66; p<0.001). Major biopsy-surgery histologic discordance occurred in 21.6% of cases, and diagnostic delays > 60 days in 28.4%. A significant interaction was observed between RT and surgical margins (p_int=0.028): RT markedly improved OS in R1/R2 resections (HR 0.31, 95% CI 0.16–0.61) and in locally advanced disease, but not after R0 resection. In NF1 patients, imaging-detected tumors had better surgical margins and lower risk of synchronous metastasis despite similar tumor size. **Conclusions:** MPNST outcomes remain poor, particularly in NF1. Radiotherapy confers a clear survival benefit in high-risk surgical contexts. Optimizing diagnostic pathways, especially in NF1 patients, may improve outcomes. Research Sponsor: None.

Survival Predictors (Multivariable OS)	Hazard Ratio (95% CI)	p-value
Stage	2.28 (1.68–3.09)	<0.001
FNCLCC Grade	1.95 (1.39–2.75)	<0.001
NF1-associated	1.67 (1.11–2.51)	0.014

Adverse events and their management in patients with tenosynovial giant cell tumor (TGCT) treated with pimicotinib, after longer-term follow-up from the global phase 3 MANEUVER trial. First Author: Vinod Ravi, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: TGCT is a rare, locally aggressive, soft-tissue tumor associated with significant morbidity. Pimicotinib (pimi) is an oral, highly selective, small molecule colony-stimulating factor-1 receptor (CSF-1R) inhibitor. In the Phase 3 MANEUVER trial (NCT05804045), the primary and key secondary endpoints were met; pimi demonstrated robust tumor responses and symptomatic and functional improvements, with a tolerable safety profile. Here, we report the longer-term safety profile and adverse event management strategies with at least one year of pimi treatment. **Methods:** Adults patients (pts) with symptomatic unresectable TGCT were randomized (2:1) to pimi 50 mg once daily or placebo for 24 weeks (Part 1), followed by open-label pimi for an additional 24 weeks (Part 2) and an extension phase. Treatment-emergent adverse events (TEAEs) were monitored for 30 days after the last dose and graded using the Common Terminology Criteria for Adverse Events, version 5.0. **Results:** In total, 63 pts received pimi (median follow-up: 14.3 months). The most frequent laboratory abnormality TEAE was increased creatinine phosphokinase (CPK; 71.4%) and the most common clinical TEAE was pruritus (60.3%). Fatigue occurred in 28.6% of pts. Most TEAEs were Grade 1–2 (Table). Grade ≥3 TEAEs occurred in 46.0% of pts, primarily elevated CPK (15.9%) and rash (6.3%), with no Grade ≥3 periorbital or facial edema observed. TEAEs were managed with dose interruptions (66.7%; median 11 days) and reductions (25.4%), maintaining a high median percentage intended dose (88.2%). Discontinuations were infrequent (6.3%). Concomitant medications were commonly used for AE management; local corticosteroids and antihistamines for rash and pruritus, and diuretics for edema. **Conclusions:** This analysis confirmed the distinct and manageable safety profile of pimi. Most TEAEs were low grade and managed through dose modifications and standard concomitant medications, enabling sustained dosing and minimal discontinuations. These findings support the longer-term tolerability of pimi in TGCT. Clinical trial information: NCT05804045. Research Sponsor: Abbisko Therapeutics; Merck KGaA, Darmstadt, Germany.

Grades of most common TEAEs (≥30%) in patients treated with pimi in the MANEUVER phase 3 trial.

TEAEs, n (%)[a]	Any grade	Grade 1	Grade 2	Grade ≥3
Blood CPK increased[b]	45 (71.4)	20 (31.7)	15 (23.8)	10 (15.9)[c]

Phase I trial of LB-100 plus doxorubicin as first-line of advanced soft tissue sarcomas: A Spanish Sarcoma Group (GEIS) study. First Author: Javier Martin Broto, Fundación Jimenez Diaz University Hospital, Madrid, Spain; University Hospital General de Villalba, Madrid, Spain; Instituto de Investigacion Sanitaria Fundacion Jimenez Diaz (IIS/FJD; UAM), Madrid, Spain

Background: In sarcomas, blocking the phosphatase PP2A with LB-100 enhanced doxorubicin effectiveness, reducing tumor growth and metastases in *in vivo* experiments. Mechanistically, LB-100 inhibited ATM/ATR-activated DNA damage response. The combination of doxorubicin and LB-100 significantly shrank tumor xenographs compared with either compound alone. The recommended phase 2 dose (RP2D) for LB-100 in monotherapy was 2.33 mg/m^2/d x3 days in a phase I in progressive solid tumors, reporting 1 partial response and 16 SD (including the 2 enrolled patients with sarcoma) out of 20 patients. Based on prior data, we designed a phase I trial (NCT05809830) combining doxorubicin (D) and LB-100 (L) for first-line advanced sarcomas. **Methods:** Adult patients with advanced soft tissue sarcomas and no prior anthracycline treatment were enrolled. The main endpoint was to determine the RP2D. Secondary endpoints were to evaluate the safety profile, efficacy (PFS, ORR,OS), QoL, and translational research. Dose levels were defined as follows, I: D 60 L 1.75; II: D 75 L 1.75; III: D 75 L 2.33; A -I dose-level was defined as D 60, L 1.25. L was administered on days 1 to 3 in a 2-hour IV infusion, followed by D in a 20-minute IV infusion on day 1 of each cycle. After 6 cycles of combination, L was administered as a maintenance phase until disease progression or unacceptable toxicity. **Results:** Between June 2023 and September 2024, 14 out of 17 screened patients were recruited, with 12 eligible for DLT evaluation. The non-DLT-evaluable patients were explained by the use of G-CSF and the altered sequence of drug administration during the first cycle. No DLTs were reported. Grade 3-4 treatment-related adverse events were neutropenia 42.9%, febrile neutropenia 21.4%, LVEF reduction 14.3%, and one patient each for nausea, anemia, and lymphopenia (7.1%). There were 2 partial responses (14%), 6 stabilizations (43%), and 6 progressions (43%) following RECIST criteria of 14 evaluable patients. Responses were seen in patients with UPS and myxofibrosarcoma. The mPFS was 5.7 months (95% CI 0-13.3), and the mOS was 16.7 months (95% CI NA). The only QoL items of EORTC-QLQ-C30 that significantly changed (impaired) between baseline and before the 3rd cycle were nausea and diarrhea. There were 1SD and 2 PD of 3 patients in the first dose-level, 1 PR and 3SD of 4 patients in the second dose-level, and 1 PR, 2 SD, and 4 PD of 7 patients in the third dose-level. In our preclinical investigations, the highest concentrations of L induced an antagonistic effect with D. **Conclusions:** The RP2D is L1.75 and D 75 based on tolerance and activity, and it deserves to be tested in phase II trials. Clinical trial information: NCT05809830. Research Sponsor: None.

Who really benefits from chemotherapy in high-risk localized soft tissue sarcoma? A virtual twin analysis of ISG-STS 1001. First Author: Fahima Dossa, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Randomized trials of perioperative chemotherapy in high-risk localized extremity/truncal soft tissue sarcoma (etSTS) show modest average survival benefits, leaving uncertainty about which patients derive clinically meaningful benefit. Conventional hazard ratio-based reporting reflects population-level effects but offers limited guidance for individual decisions. Counterfactual approaches, such as the virtual twin framework, enable estimation of patient-specific outcomes under alternative treatment strategies, translating randomized evidence into clinically interpretable absolute benefit measures. **Methods:** Individual patient data from the ISG-STS 1001 randomized trial in high-risk localized etSTS with updated follow-up were analyzed using a virtual-twin framework with counterfactual predictions to estimate each patient's outcomes under alternative treatment scenarios: standard epirubicin-ifosfamide (EI) vs histotype-tailored (HT) chemotherapy (proxy for no effective chemotherapy). Patients with myxoid liposarcoma were excluded. Cox proportional hazards models for overall survival (OS) and disease-free survival (DFS) were adjusted for pretreatment covariates. For each patient, counterfactual 5-year OS and DFS probabilities under EI and HT were estimated and individualized absolute treatment effects were defined as the difference between counterfactual predictions. Bootstrap resampling was used to quantify uncertainty and treatment benefit explored across levels of baseline risk and tumor characteristics. **Results:** The cohort included 218 pts (median follow-up 116 months). In covariate-adjusted models, mean absolute improvement in 5-year OS with EI was 7.5% (95%CI: 4.5%-10.2%). Absolute OS benefit was inversely correlated with Sarculator-predicted 10-year survival, indicating greater benefit among patients with poorer baseline prognoses. Pts in the highest Sarculator-predicted survival quartile (pOS $>$69%) had a mean 5-year OS benefit of 5.9% (95%CI: 3.5%-9.0%), with 63% achieving $\geq$5% benefit. In contrast, pts in the lowest predicted survival quartile (pOS $<$46%) had a mean benefit of 8.7% (95%CI: 5.3%-10.4%), with 98% achieving $\geq$5% benefit. Benefits varied by histology (undifferentiated pleomorphic sarcoma = 6.6%, leiomyosarcoma = 7.2%, synovial sarcoma = 8.3%, malignant peripheral nerve sheath tumor = 8.9%) and, within each subtype, was inversely correlated with Sarculator-predicted survival. **Conclusions:** Individualized counterfactual prediction reveals substantial heterogeneity in the absolute benefit of chemotherapy in high-risk localized etSTS, driven by baseline prognostic risk and histology. This framework provides clinically relevant, patient-centered estimates that support risk-adaptive decision-making and clarify chemotherapy benefits across risk groups beyond average trial effects. Research Sponsor: None.

Sintilimab (PD-1 antibody) plus gemcitabine and docetaxel (GT) as first-line or later-line therapy in patients with advanced epithelioid sarcoma: A prospective, multicenter, single-arm, phase II clinical study. First Author: Xiaowei Zhang, Department of Medical Oncology, Fudan University Shanghai Cancer Center; Shanghai Medical College, Fudan University, Shanghai, China

Background: Advanced epithelioid sarcoma (ES) responds poorly to conventional chemotherapy, with an objective response rate (ORR) of 15-27% and a median progression-free survival (mPFS) of only 4-6 months, highlighting the urgent need for new therapeutic strategies. This study aims to evaluate the efficacy and safety of Sintilimab (An approved PD-1 antibody) plus the gemcitabine and docetaxel (GT) in patients with advanced ES that has not been treated by chemotherapy. **Methods:** This is a single-arm, prospective phase II study conducted in China (ChiCTR2500095527). Patients received Sintilimab (200mg, d1, q3w) combined with gemcitabine (1000mg/m^2, d1,8, q3w) and docetaxel (70mg/m^2, d8, q3w) for up to 6 cycles, followed by Sintilimab maintenance for up to 2 years or until disease progression, intolerable adverse reactions or death. The primary endpoint was ORR, and secondary endpoints included PFS, overall survival (OS), and safety. Additionally, tumor tissue and/or blood samples were collected from patients before treatment and at the time of progression for exploratory biomarker analysis. **Results:** Between October 2024 and January 2026, Of the 19 planned patients, 16 eligible patients were enrolled. The median age was 36 years (range: 22-61), with 5 males and 11 females. All patients had metastatic or unresectable locally advanced disease (ECOG performance status 0: 12.5%; stage IV: 75.0%). With the cutoff date of January 15, 2026, 14 patients were evaluated, the median follow-up time was 8.6 months (range, 2.9 to 14.6 months), the objective response rate (ORR) was 35.71% (5/14), all of them were partial responses (PR), and the disease control rate (DCR) was 100% (14/14). The median PFS and OS were not reached. Treatment-related adverse events (TRAEs) occurred in all patients, with grade $\geq$3 TRAEs observed in 4 (28.57%) patients, included two case of neutropenia, and one case each of thrombocytopenia and transaminase elevation. **Conclusions:** The combination of Sintilimab and GT demonstrated promising efficacy in chemotherapy-naïve patients with advanced ES, achieving an ORR of 35.71% and a remarkably high DCR. Despite limited follow-up, the preliminary PFS data suggest a potential benefit from PD-1 immunotherapy. The combination showed a manageable safety profile with no new safety signals identified. Clinical trial information: ChiCTR2500095527. Research Sponsor: None.

Preliminary results of pegylated liposomal doxorubicin, dacarbazine, and toripalimab in patients with advanced primary cardiac sarcoma: An interim analysis. First Author: Zhichao Tan, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Orthopedic Oncology, Peking University Cancer Hospital & Institute, Beijing, China

Background: Primary cardiac sarcoma (PCS) is an ultra-rare malignancy with a dismal prognosis, with previously reported median overall survival (OS) of 8–17.2 months. The roles of chemotherapy and immunotherapy remain controversial, and prospective evidence is scarce. We conducted a prospective, single-arm study to evaluate the efficacy and safety of pegylated liposomal doxorubicin (PLD), dacarbazine (DTIC), and toripalimab in patients with advanced PCS (DART-PCS). **Methods:** Patients with locally advanced or metastatic PCS were enrolled from January 2024. Treatment consisted of PLD (35–40 mg/m^2) and DTIC (1.0–1.2 g/m^2), each administered either on day 1 or divided over days 1–2, plus toripalimab (240 mg, day 1), every 3 weeks for six cycles. Tumor responses were assessed every two cycles by CT or MRI. Patients without progression after six cycles underwent multidisciplinary evaluation to determine further combination therapy or immunotherapy maintenance. The primary endpoint was investigator-assessed overall response rate (ORR) per RECIST v1.1. Secondary endpoints included progression-free survival (PFS), OS, and safety. Adverse events (AEs) were graded using CTCAE v5.0. Survival outcomes were estimated using the Kaplan–Meier method. The planned sample size was 30 patients. **Results:** To data cutoff, a total of 20 patients were enrolled (65% male; median age: 36 years). ECOG performance status was 0 in 30%, 1 in 45%, and 2 in 25% of patients. Eighteen patients (90%) had undergone prior surgical resection, although R0 resection was achieved in only 25%. Histologies included angiosarcoma (85%), pleomorphic undifferentiated sarcoma (10%), and epithelioid hemangioendothelioma (5%). All tumors originated in the atrium, with right atrial involvement in 85% and left atrial involvement in 15%. At enrollment, 12 patients (60%) presented with metastatic disease, and 8 (40%) had local recurrence. Responses were evaluable in 18 patients. The ORR was 44.4%, including 3 complete and 5 partial responses. The median duration of response was 21.8 weeks (95%CI: 11.7-32.0). As of January 15, 2026, the median PFS was 23.1 weeks (95%CI: 18.21-29.22), and the median OS 55.0 weeks (95%CI: 37.21-72.78). The 1-year OS rate was 54%. Treatment-related adverse events (TRAEs) occurred in all patients, with grade $\geq$3 TRAEs observed in 18 (90%) patients, most commonly neutropenia (90%), leucopenia (40%) and anemia (30%). One fatal serious AE (hemoptysis) was reported. The median cumulative PLD dose was 221.6 mg/m^2 (range: 69.0-465.1). No clinically significant cardiac dysfunction were observed. **Conclusions:** Preliminary results from the DART-PCS trial demonstrate promising antitumor activity and an acceptable safety profile for PLD, DTIC, and toripalimab in patients with advanced PCS. Further validation is warranted upon completion of the study. Clinical trial information: ChiCTR2400084334. Research Sponsor: None.

Impact of modern systemic and multimodality treatments on post-relapse survival in retroperitoneal soft-tissue sarcoma: A digital-twin target trial emulation study. First Author: Roberta Sanfilippo, European Institute of Oncology, Milan, Italy

Background: We previously observed a significant improvement in post-relapse overall survival (OS) in patients with recurrent retroperitoneal soft-tissue sarcoma (RPS) treated in 2012–2021 compared with 2002–2011. This study aimed to determine whether this survival benefit reflects advances in post-relapse treatment strategies, using digital twins to isolate the impact of systemic therapy and multimodality care. **Methods:** Adults with resected RPS and first documented recurrence were grouped by era (pre-2012 vs post-2012). Post-recurrence management was modeled as time-dependent multimodal treatment to account for treatment timing and avoid time-related bias, including repeat surgery, radiotherapy, and systemic therapy (up to five sequential lines). Detailed treatment data (surgery, radiotherapy, number of systemic therapy lines, and use of novel agents available since 2012, within or outside clinical trials) were captured. A Cox model for post-relapse survival was fitted in the post-2012 cohort using baseline covariates and time-dependent treatments. This model was used to predict the counterfactual post-relapse survival on the Monte-Carlo simulated digital-twin trajectories for pre-2012 patients under post-2012 management. The effect of post-2012 systemic therapies was isolated and applied to the pre-2012 cohort to estimate their counterfactual impact. Restricted mean survival time (RMST) at 2 and 5 years was standardized to the pre-2012 baseline distribution. **Results:** Among 872 operated patients, 417 developed recurrence; complete data were available for 86 pre-2012 and 263 post-2012 patients. Post-relapse OS significantly improved over time, with median post-relapse OS of 14.9 months pre-2012 versus 43.8 months post-2012. Observed RMST differences favored the post-2012 cohort by +5.6 months at 2 years, and +18.0 at 5 years ($p < 0.001$). Counterfactual simulation predicted that applying post-2012 management to pre-2012 patients would increase median OS to 33.8 months and RMST by +4.8 and +12.2 months at 2 and 5 years, respectively. Isolating systemic therapy alone reduced the gain by -2.2, and -5.7 months, indicating a partial but not exclusive contribution of systemic treatment advances ($p<0.001$). **Conclusions:** Digital-twin target trial emulation suggests that post-2012 management strategies explain most of the early and a substantial portion of the long-term survival improvement after RPS recurrence. Advances in systemic therapy contribute meaningfully but do not fully explain the observed OS gains, supporting the importance of integrated multimodality post-relapse care. Research Sponsor: None.

Real-world outcomes of doxorubicin and paclitaxel in advanced Kaposi sarcoma: A TriNetX retrospective cohort study. First Author: Keun Lee, In-Independent Researcher, Richmond, VA

Background: For decades, pegylated liposomal doxorubicin (PLD) and paclitaxel have been standard antineoplastic therapies for advanced Kaposi sarcoma (KS). However, contemporary estimates of their efficacies remain limited. This limit is particularly profound in HIV-associated KS, where advances in antiretroviral therapy and supportive care reduce the relevance of historical outcomes. **Methods:** In January 2026, the TriNetX database (171 global healthcare organizations) was queried to identify patients with KS (ICD-10-CM code C46 and ICD-O-3 code 9140/3) who received doxorubicin or paclitaxel since 2010. Patients with a history of lymphoma, cervical cancer, anal cancer, or solid organ transplantation were excluded. We extracted demographics, overall survival (OS), and time to next-line treatment or death (TTNT-D) to obtain estimated progression-free survival (ePFS). Outcomes were measured from index treatment initiation (first recorded receipt of doxorubicin or paclitaxel after KS diagnosis). Lastly, HIV-based subgroup analyses were conducted with 1:1 propensity matching by age, sex, race, and prior antineoplastic treatments. Kaplan-Meier analysis was done with significance set at $p<0.05$. **Results:** We analyzed 935 KS patients treated with doxorubicin (including PLD) and 379 treated with paclitaxel. The patients treated with doxorubicin (median age: 45 years, 81.0% male, 48.3% HIV+) had 2- and 5-year OS of 77.5% and 70.0% and ePFS of 63.0% and 56.36% respectively. The patients treated with paclitaxel (median age: 50 years, 78.5% male, 42.7% HIV+) had 2- and 5-year OS of 71.3% and 62.4% and ePFS of 53.8% and 45.1% respectively. Within the doxorubicin cohort, HIV+ patients were younger (median age 40 vs 56 years), more often male (95.0% vs 64.7%), and had higher proportions of African American and Hispanic patients (36.4% and 14.7% vs 12.3% and 7.1%). A matched analysis of HIV+ vs. HIV- patients showed 2-year OS of 86.2% vs 71.7% (p=0.003) and 2-year ePFS of 74.85% vs 52.19% ($p<0.0001$). Within the paclitaxel cohort, HIV+ patients were also younger (median age 40 vs 64 years), more often male (96.5% vs 63.8%), and had higher proportions of African American and Hispanic patients (39.3% and 15.0% vs 9.0% and 5.0%). A matched analysis of HIV+ vs. HIV- patients showed 2-year OS of 60.3% vs 74.1% (p=0.151) and 2-year ePFS of 38.0% vs 57.7% (p=0.023). A matched analysis of doxorubicin vs. paclitaxel in HIV+ patients showed 2-year OS of 86.9% vs 73.0% (p=0.007) and ePFS of 77.7% vs 67.9% (p=0.069). **Conclusions:** This large real-world analysis provides a contemporary assessment of doxorubicin and paclitaxel in advanced KS. HIV+ status was associated with higher OS and ePFS in the doxorubicin cohort, whereas HIV- status was associated with higher ePFS in the paclitaxel cohort. Limitations include the retrospective design and imperfect reliability of TTNT-D as a surrogate for PFS. Research Sponsor: None.

11578 **Poster Session**

Phase I trial of combination gemcitabine (gem) and nab-sirolimus (nab-S) in advanced leiomyosarcomas (LMS) or advanced soft-tissue sarcomas (STS) with *TSC1/2* alterations: Preliminary results. First Author: Elise F. Nassif Haddad, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Advanced LMS has limited effective therapies, with gem-based regimens being the most prescribed. Preclinical data suggest gemcitabine induces activation of the PI3K–mTOR pathway, supporting combination strategies with mTOR inhibition. Nab-S is a nanoparticle albumin-bound, IV formulation of sirolimus and has demonstrated greater intratumoral accumulation and antitumor activity in preclinical models compared to conventional mTOR inhibitors. **Methods:** This investigator-initiated, single-center phase I study evaluates gem (900mg/m2) plus nab-s (dose levels [DL]: DL1=75mg/m2 or DL2=100mg/m2) in patients (pts) using a Bayesian optimal interval (BOIN) design. Primary objective was to estimate the maximum tolerated dose (MTD) of the combination based on cycle 1 dose-limiting toxicities (DLT). Secondary objectives were to estimate objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). Responses were assessed by RECIST1.1 and adverse events (AE) graded per CTCAEv5. **Results:** As of 01/22/26, all 12 pts initially planned for accrual have completed the DLT period. The original dosing schedule consisted of drug administration on Days 1 and 8 of a 21-day cycle. After the first 6 pts were enrolled, the protocol was amended to administer drugs on Days 1 and 15 of a 28-day cycle. This modification was implemented for all pts due to hematologic toxicities. While expected based on the known safety profile of nab-s and of gem, this frequently prevented Day 8 administration under the original schedule. All pts had advanced LMS, 10 pts were female and 7 had uterine LMS, the median age at time of consent was 55 yo. Three pts were included at DL1, and there was no DLT. DL2 included 9 pts: only one pt experienced a DLT of mucositis and diarrhea grade (Gr) 3 lasting for 3 days. The most frequent treatment-related Gr3-4 AE was thrombocytopenia. One pt had Gr3 pneumonitis attributed to gem and discontinued trial after 2 cycles. There was no other concern for safety. Ten pts were evaluable for response (1 pt died of disease and 1 pt chose to discontinue the trial before their first evaluation). ORR is 30% (n=3/10) at time of data cutoff and 90% pt had clinical benefit: 6 pts had stable disease with 5 pts experiencing shrinkage of disease (range: -8% to -21%) and 1 pt with 0% change. Only 1 pt had progressive disease as best response. With a median follow-up of 4 months (mo) for PFS, the median PFS (95% confidence interval [CI]) is 8.38 (1.68, not reached) mo, the 3-mo PFS (95% CI) is 78% (36%,94%), and the 6-mo PFS (95% CI) is 58% (16%,85%). With a median follow-up of 5.8 mo for OS, the 6-mo OS (95% CI) is 80% (39%,95%). **Conclusions:** The MTD was determined to be gem 900mg/m2 with nab-s 100mg/m2 on Days 1 and 15 of a 28-day cycle. Based on this preliminary safety and efficacy, an expansion with an additional 6 pts at this DL is ongoing. Clinical trial information: NCT06308419. Research Sponsor: Aadi Bioscience.

11579 **Poster Session**

Efficacy and safety analysis of intraoperative radiotherapy for soft tissue sarcoma: The largest-sample, single-center, real-world data review. First Author: Zhichao Liao Sr., Tianjin Cancer Hospital, Tianjin, China

Background: This study aimed to evaluate the efficacy and safety of surgery combined with intraoperative radiotherapy (IORT) versus surgery combined with postoperative adjuvant radiotherapy in the treatment of soft tissue sarcoma (STS). It sought to identify patient subgroups that derive the most benefit from IORT and to provide evidence for treatment selection. **Methods:** This retrospective single-center study was conducted at Tianjin Medical University Cancer Institute & Hospital between May 2021 and December 2024. A total of 420 patients with pathologically confirmed STS were initially screened. After applying strict inclusion and exclusion criteria, 252 eligible patients were enrolled and divided into two groups: 147 patients who underwent surgery combined with IORT using the INTRABEAM 600 System, and 105 patients who received surgery combined with conventional postoperative adjuvant radiotherapy. **Results:** After a median follow-up period of 17.2 months (range: 4.8-47.18 months), the IORT group demonstrated significantly superior outcomes. Multivariate analysis identified three independent risk factors for RFS: radiotherapy modality (IORT vs. postoperative radiotherapy, p = 0.001), primary versus recurrent tumor status ($p < 0.001$), and T stage (p = 0.003). The RFS in the IORT group was significantly better than in the postoperative radiotherapy group (P = 0.001). Subgroup analysis revealed that IORT was particularly advantageous for specific patient populations. Tumor size was a critical determinant: for lesions larger than 5 cm in diameter, IORT significantly improved RFS across all subgroups ($>$ 15 cm: p = 0.008; 10-15 cm: p = 0.008; 5-10 cm: p = 0.004). However, for tumors smaller than 5 cm, no significant difference was observed between the two treatment modalities (p = 0.874). For OS, multivariate analysis identified radiotherapy type (p = 0.01) and AJCC stage (p = 0.007) as independent risk factors. The IORT group showed a trend toward improved OS, though longer follow-up is needed for definitive conclusions. The safety analysis strongly favored IORT. The incidence of treatment-related adverse events was significantly lower in the IORT group across all categories. **Conclusions:** This large-sample, single-center real-world study demonstrates that surgery combined with intraoperative radiotherapy significantly prolongs recurrence-free survival and improves local control in soft tissue sarcoma patients compared to surgery combined with postoperative radiotherapy. The benefits are most pronounced in patients with primary or recurrent tumors larger than 5 cm in diameter. Additionally, IORT offers a substantially more favorable safety profile with significantly reduced rates of radiation-related adverse events. Research Sponsor: None.

Secondary genomic alterations and clinical outcomes in myxoid liposarcoma: A multi-institutional analysis. First Author: Daniel Reinhorn, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Myxoid liposarcoma (MLS) is defined by *DDIT3* rearrangements. The clinical and prognostic significance of secondary genomic alterations remains incompletely characterized. We retrospectively evaluated the clinical, pathological, and prognostic implications of commonly co-occurring mutations in patients with MLS. **Methods:** Patients with pathologically confirmed MLS treated at Memorial Sloan-Kettering Cancer Center (MSKCC) and MD Anderson Cancer Center (MDACC) who underwent next-generation sequencing (NGS) on the primary tumor (9/2010-5/2024) were included. To ensure the analysis represented *de novo* mutations rather than acquired alterations, patients with NGS performed only at the time of recurrent disease were excluded. The primary endpoint was disease-free survival (DFS) among surgically treated patients. Associations between genomic alterations and clinico-pathologic characteristics were assessed using univariable and multivariable analyses. **Results:** The cohort included 76 patients (67 MSKCC, 9 MDACC) with a median age of 39 years. At diagnosis, 83% of patients (n = 63) had localized disease and underwent definitive surgery, while 17% presented with de novo metastasis; 45% had high-grade disease ($\geq$5% round cell component). Genomic analysis identified *TERT* promoter mutations in 68%, *PIK3CA* in 30%, and *PTEN* in 18%. Notably, *PIK3CA* and *PTEN* mutations were not mutually exclusive, with 10.5% of the total cohort harboring concurrent alterations in both genes. *TERT* promoter mutations were significantly associated with male sex (75% vs 33%, $p < 0.001$), older age (40 vs 33 years, p = 0.02), high-grade pathology (54% vs 25%, p = 0.026), and larger median tumor size (12.9 vs 7.5 cm, p = 0.002). *PIK3CA* mutations were associated with male sex (83% vs 53%, p = 0.02) and a trend toward larger median tumor size (13.6 vs 9.3 cm, p = 0.061) and *de novo* metastasis (30% vs 11%, p = 0.053). For the 63 patients with localized disease, the median DFS was not reached (95% CI: 55.7–NR) with a 24-month DFS rate of 75% (95% CI 61-84). In univariable analysis for DFS, significant predictors of recurrence included *PIK3CA* mutation (HR 4.61; p = 0.001), *PTEN* mutation (HR 5.15; $p < 0.001$), tumor size (HR 1.06 per cm; p = 0.012), high-grade pathology (HR 2.81; p = 0.024) and male sex (HR 2.79; p = 0.049). The presence of both *PIK3CA* and *PTEN* mutations conferred particularly poor prognosis (HR 16.34 compared to neither mutation; $p < 0.001$). In separate multivariable analyses adjusted for grade, both *PIK3CA* (HR 5.75, $p < 0.001$) and *PTEN* (HR 4.27, p = 0.002) remained independent predictors of DFS. **Conclusions:** Secondary genomic alterations in MLS are highly prevalent and connote distinct clinical phenotypes. While *TERT* promoter mutations correlate with aggressive pathologic features, *PIK3CA* and *PTEN* mutations are independent prognostic factors for DFS and may help risk-stratify patients for potential adjuvant therapies. Research Sponsor: Cancer Center Support Grant; P30 CA008748.

Integrating personalized ctDNA into clinical surveillance of soft tissue sarcoma: Performance, timing, and histologic insights. First Author: Amrit Paudel, University of Miami Sylvester Comprehensive Cancer Center/Jackson Health System, Miami, FL

Background: Soft tissue sarcoma (STS), particularly larger and biologically aggressive subtypes, carries a high risk of relapse making effective post-operative surveillance essential. CtDNA utility in STS remains elusive. **Methods:** We conducted a retrospective review of STS who underwent surgical resection and post-operative surveillance with serial personalized ctDNA testing (Signatera) and cross-sectional imaging between April 2023- January 2026. Diagnostic performance was assessed by sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), using imaging-confirmed progression as the reference standard. Subgroup analyses by major histologic subtype conducted. Detection times were referenced to surgery, and lead time was summarized using medians and interquartile ranges (IQR). Paired detection times were compared using the Wilcoxon signed-rank test, with Mann–Whitney U test as a sensitivity analysis. **Results:** Total 114 patients with ctDNA samples were screened. 101 patients with paired ctDNA (total 1,005 plasma samples) and imaging surveillance were included. The median age at diagnosis was 53 years, and the cohort was evenly distributed by sex (50.5% male, 49.5% female). Most patients were White (86.1%), 13.9% African American; 58.4% identified as non-Hispanic and 40.6% as Hispanic. Using imaging as the reference standard, 33 patients developed radiographic progression. ctDNA was positive in 27, yielding a sensitivity of 81.8% (95% CI, 65.6%–91.4%). Among 68 patients without progression, 66 remained ctDNA negative, corresponding to a specificity of 97.1% (95% CI, 89.9%–99.2%). The PPV and NPV were 93.1% and 91.7%, respectively. Six patients (18.2%) had radiographic progression despite persistently negative ctDNA, forming a clinically relevant discordant subgroup. Among patients with paired molecular and radiographic progression (n = 27), ctDNA detected progression earlier in 44%, while imaging led in 56%. Overall detection timing did not differ significantly between modalities (median lead time, –0.21 months; IQR, –1.42 to 1.67; p = 0.91). Tumors associated with ctDNA positivity were numerically larger than ctDNA-negative (median, 8.75 cm vs 7.0 cm, p = 0.051). CtDNA detection dynamics varied by histologic subtype, with a nonsignificant numerical trend toward earlier detection in synovial sarcoma. The most common site of metastatic involvement was lung (40%), followed by liver (20%). **Conclusions:** Personalized ctDNA surveillance showed high specificity and strong diagnostic performance in STS and detected progression earlier than imaging in a subset of patients, though no overall lead-time advantage was observed. Histology-specific differences suggest biologic variability in ctDNA detectability and support prospective, subtype-focused studies to define optimal integration with imaging. Percutaneous cryoablation for the treatment of extra-abdominal desmoid tumors. First Author: Ajay Katwala, Medical College of Wisconsin, Milwaukee, WI

Background: Management of extra-abdominal desmoid tumors (DT) has evolved over the last decade, with emphasis on conservative management based on guidelines from the Desmoid Tumor Working Group. There is growing evidence for ablative therapies, including percutaneous cryoablation (PCA), but there is little data on long-term outcomes with PCA. This large cohort study reports efficacy and long-term outcomes for patients with extra-abdominal DTs with PCA. **Methods:** Patients with pathologically-confirmed extra-abdominal DT were recruited consecutively at a high-volume referral center from 2014-2025. Data points including patient demographics, tumor characteristics, and procedural details for cryoablation were collected. The primary outcome was ablation success using the modified response criteria in solid tumors (mRECIST), measuring change in viable tumor along the longest tumor diameter. Secondary outcomes were change in lesion volume (TLV), complications per Clavien-Dindo classification, patient-reported symptom resolution, and progression-free survival (PFS). **Results:** A total of 53 patients undergoing 83 PCA procedures were identified. 67.9% of patients were female. The median follow up time was 40.1 months. Thirty-two patients were treated with PCA as first-line therapy, while 21 were treated as salvage therapy. The median change in viable tumor volume using mRECIST was -100%; 26 patients had a complete response (CR), 13 had partial response (PR), 7 had stable disease (SD), and 13 had progressive disease (PD). The median change in TLV was -71.7%. One-year and five-year PFS rates were 88.2% and 66.6% respectively. Fifty patients had symptoms including pain, an enlarging mass, or decreased range of motion prior to PCA; 94.0% had symptomatic improvement or resolution after PCA. Two patients had major complications: one inferior epigastric hemorrhage and one small bowel injury treated with a small bowel resection. **Conclusions:** This study provides the largest cohort of extra-abdominal desmoid tumors undergoing PCA. PCA can lead to patient-reported symptom resolution, a substantial decrease in mRECIST and TLV, and has a low complication rate. This study adds further evidence that PCA is safe and effective for treating extra-abdominal desmoid tumors. Research Sponsor: None.

Investigating the molecular characteristics underlying desmoid tumor clinical trajectory. First Author: Robert Lawrence Dilley, Dana-Farber Cancer Institute, Boston, MA

Background: Desmoid tumors are locally aggressive mesenchymal neoplasms that primarily affect adolescents and young adults. They demonstrate a range of clinical behavior from spontaneous regression to refractory growth leading to morbidity and sometimes mortality. However, there are no prognostic biomarkers for patients with desmoid tumors and we have a limited understanding of the biology behind the range of clinical behavior. Thus, we aimed to characterize the clinical course of patients with banked desmoid tumors at our institution from across the age spectrum, and correlate clinical behavior with genetic alterations and gene expression signatures. **Methods:** We identified 64 adult patients through our adult sarcoma biobank and 5 patients through our pediatric biobank with desmoid fibromatosis and banked samples. Retrospective chart review was conducted including patient characteristics, disease features, treatment course, and outcomes. Genetic analysis was completed on 61 patients (43 targeted exome sequencing, OncoPanel). To characterize gene expression, we performed single nucleus RNA sequencing (snRNAseq) on 15 samples from 12 patients, with concurrent *CTNNB1* genotyping to accurately identify tumor cells. Primary analyses included cell annotation of clusters and differential gene expression between progressing and stable/regressing tumors. **Results:** A total of 69 patients were included in this study. Median age at diagnosis was 35 years (range 2–83), with 68% female. Median tumor size at diagnosis was 5.2cm (range 0.7–25.0). Tumor location included abdominal wall (41%), mesenteric (25%), trunk/breast (14%), extremity (16%), and head/neck (5%). At time of tissue collection 39% of tumors were progressing, 23% were stable, and 10% were regressing (28% unknown). Among 61 sequenced tumors, 72% and 21% harbored *CTNNB1* and *APC* mutations, respectively, and 7% showed no mutations in either gene. snRNAseq resulted in a dataset of over 180,000 high-quality nuclei. Cell composition differences were identified across the spectrum of disease states. Concurrent single-nucleus *CTNNB1* genotyping revealed expression differences in the tumor cell compartment between progressing and non-progressing tumors, including collagen/extracellular matrix proteins and mesenchymal transcription factors. **Conclusions:** In this cohort of adult and pediatric desmoid tumors, integration of clinical annotation and molecular characteristics identified gene expression programs associated with tumor progression. These findings provide new insights into the biology underlying variable clinical trajectory in desmoid tumors, implicating altered collagen/extracellular matrix and mesenchymal transcription factor programs. Ongoing bulk RNA sequencing and immunohistochemical analyses are being performed to assess the potential of these signatures as predictive biomarkers and therapeutic targets. Research Sponsor: Desmoid Tumor Research Foundation.

11584 **Poster Session**

Phase II pilot study of pembrolizumab (PEM) and neoadjuvant radiation therapy (nRT) in high-risk soft tissue sarcomas (STS). First Author: Lee D. Cranmer, City of Hope National Medical Center Department of Medical Oncology and Therapeutics Research, Duarte, CA

Background: Pathologic necrosis (PN) after neoadjuvant therapy in STS has been associated with improved outcomes. We investigated clinicopathologic outcomes of concurrent PEM/nRT in STS. **Methods:** Adults with localized STS [FNCLCC grade 3 ($>$ 1.5 cm) or grade 2 ($>$ 3 cm)] received 3 doses of PEM (200 mg IV q21 d) concurrently with nRT, followed by surgery. Primary endpoint was the rate of post-treatment complete pathologic necrosis (CPN; $\geq$90% PN). 26 subjects provided 94% power to detect an increase in CPN rate from 15% to 40%; $\geq$7 cases with CPN would exclude a 15% CPN rate. Secondary endpoints included toxicity (CTCAE 5.0), response (RECIST 1.1), and event-free survival (EFS). **Results:** 27 STS patients were enrolled including UPS (10; 37%), DD liposarcoma (8; 30%), myxofibrosarcoma (2; 7%), solitary fibrous tumor (2; 7%), and other STS (5; 19%). 26 patients were evaluable for CPN and 25 for EFS. All except 2 (7%) received 3 planned PEM doses. All completed planned RT (50-50.4 Gy). 2 (7%) with UPS had partial responses prior to surgery. Median tumor size was 10 cm (range 2.1-26 cm). R0 resection was achieved in 92%. 14 (54%) patients had grade 3 tumors; 12 (46%) had grade $\geq$2. Median post-treatment PN was 55% (range 0-99%) with 5/26 (19%) having CPN. Median follow-up time was 33.4 months (m) from PEM initiation (range 1.6-60 m). 12/25 patients had an EFS event. Among all patients (n = 27), 12 developed only distant metastatic disease, and 1 developed local and distant recurrence. AEs were consistent with anticipated effects of PEM and RT. Two grade 5 events occurred (ischemic colitis, prostate cancer), both judged unrelated to study therapy. 3 patients experienced wound dehiscence, and one had wound infection. EFS at 12 m was 68%; at 57.5 m, it was 52%. Post-treatment PN as a continuous variable was inversely associated with EFS (HR = 22.47, p = 0.004). Increased tumor size was also associated with inferior EFS (HR = 1.09/cm, p = 0.04). In multivariable analyses, both necrosis and tumor size remained independently associated with EFS (HR = 26.52 and 1.09, p = 0.004 and 0.041, respectively). Sex, age, histology, tumor grade/location, and radiation modality were not associated with EFS. **Conclusions:** PEM did not increase the proportion of patients with post-treatment CPN after RT. Unexpectedly, increased tumoral necrosis after treatment was associated with inferior EFS. It is possible that increased post-treatment tumoral necrosis may identify a subset of STS patients less likely to benefit from PEM/nRT or who have inherently more aggressive tumor biology. These findings warrant additional studies for validation and exploration of the mechanisms and clinical applications of these findings. PN after PEM/nRT might provide a readily available biomarker that could be used to adjust therapy in those unlikely to benefit from PEM/nRT. Correlative analysis using pre- and post-treatment tumor are on-going and will be presented. Clinical trial information: NCT03338959. Research Sponsor: Merck.

Neoadjuvant versus adjuvant chemotherapy for resectable high-grade soft tissue sarcoma: A real-world propensity-matched survival analysis. First Author: Mohammed Aloqaily, University of Maryland Midtown Campus, Baltimore, MD

Background: High-grade soft tissue sarcomas are aggressive malignancies for which complete surgical resection remains the cornerstone of curative-intent therapy. Current clinical guidelines recommend consideration of perioperative chemotherapy for selected high-risk patients; however, the optimal timing of systemic therapy remains uncertain. We performed a real-world analysis to compare survival outcomes between neoadjuvant and adjuvant chemotherapy in patients with resected high-grade soft tissue sarcoma. **Methods:** We conducted a retrospective cohort study using the TriNetX Database, identifying adults (≥18 years) with high-grade soft tissue sarcoma who underwent surgical resection and received combination chemotherapy with doxorubicin and ifosfamide either within 6 months before surgery or after surgery . The index date was defined as time of diagnosis. Propensity score matching (1:1) was performed to balance baseline demographics and various comorbidities. Overall survival (OS) was assessed using Kaplan–Meier methods and Cox proportional hazards models at fixed time points (1, 3, 5, and 10 years) and over the entire follow-up period. **Results:** A total of 714 patients were identified (479 adjuvant; 235 neoadjuvant). After propensity score matching, 229 patients were included in each cohort. At 1 year, overall survival was similar between adjuvant and neoadjuvant chemotherapy (53.1% vs 53.1%; risk ratio [RR] 1.06, 95% CI 0.81–1.37; log-rank p = 0.77). Additionally, analyses at 3, 5, and 10 years demonstrated no statistically significant differences in OS between cohorts, with overlapping Kaplan–Meier survival curves at all evaluated time points. Over the entire follow-up period, survival probabilities at the end of follow-up were 51.5% in the adjuvant cohort and 53.4% in the neoadjuvant cohort. There was no significant difference in overall survival (hazard ratio [HR] 1.04, 95% CI 0.75–1.44; p = 0.73). **Conclusions:** In this large, real-world, propensity-matched analysis of patients with resectable high-grade soft tissue sarcoma, survival outcomes were comparable across short-, intermediate-, and long-term follow-up intervals in both neo-adjuvant and adjuvant chemotherapy cohorts. Current guidelines recommend neo-adjuvant radiation treatment as category 1, and chemotherapy (neo-adjuvant or adjuvant) is a consideration. Neo-adjuvant chemotherapy has the potential to delay definitive treatment, however, this analysis suggests that the timing of chemotherapy does not adversely impact the outcomes in short or long term follow up. There are several limitations to our analysis (size of the tumors and grading was not available and timing of XRT could not be assessed, however, given that AIM chemo cohort was selected, it can be assumed that patients had higher grade, larger tumors and received XRT as standard of care. Research Sponsor: None.

TPS11586 **Poster Session**

A phase 1b study of tegavivint, a TBL1 inhibitor, with gemcitabine in patients with relapsed or refractory osteosarcoma (TIGER). First Author: Thomas Cash, Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA

Background: The Wnt-signaling pathway and its downstream transcriptional effector, β-catenin, are dysregulated in osteosarcoma (OS), promoting tumor growth and metastatic spread. When the Wnt pathway is activated, transduction beta-like protein 1 (TBL1) binds nuclear β-catenin, forming a complex that is necessary to dock on the promoters of Wnt-driven genes. Tegavivint is a first-in-class small molecule inhibitor that selectively binds TBL1, inhibiting TBL1-β-catenin complex formation, and resulting in the nuclear degradation of β-catenin and inhibition of oncogenic transcriptional activation. Preclinical testing of *in vivo* OS models demonstrates that tegavivint reduces tumor volume and suppresses lung metastases, and has additive effects when combined with gemcitabine. In a phase 1 trial conducted by the Children's Oncology Group, the recommended phase 2 dose (RP2D) of tegavivint was determined to be 6.5 mg/kg administered intravenously (IV) on a 3 weeks on/1 week off schedule, with no maximum tolerated dose (MTD) determined. The primary objective of this phase 1b study is to define the MTD and/or RP2D of tegavivint combined with gemcitabine, including assessment of toxicities and preliminary efficacy, in patients with relapsed or refractory (r/r) OS. **Methods:** TIGER is a phase 1b, multi-center, dose escalation trial assessing tegavivint combined with gemcitabine in patients with r/r OS. Eligible patients will be 1-30 years of age with either measurable or evaluable disease per RECIST v1.1 who have fully recovered from the clinically significant acute effects of prior therapy and have adequate organ function. Prior treatment with gemcitabine is allowed. Patients with active CNS disease, recent bisphosphonate treatment, metabolic bone disease or disorder, uncorrected hypocalcemia or low vitamin D, and prior receipt of tegavivint are excluded. Patients will receive tegavivint IV at the dose level assigned at study entry on days 1, 8, and 15 and gemcitabine at a fixed dose of 1000 mg/m^2 IV on days 1 and 8 of a 21-day cycle. Patients may receive up to 17 cycles provided they do not experience disease progression or unacceptable toxicity. Tegavivint will be dose escalated using a rolling six design to test two planned dose levels, 5 mg/kg [dose level (DL) 1] and 6.5 mg/kg (DL 2), with dose de-escalation to 3 mg/kg (DL 0) if needed. An additional 6 patients will be enrolled to a dose expansion cohort at the MTD/RP2D to obtain additional pharmacokinetic (PK), safety, and preliminary efficacy data. Peripheral blood for correlative studies will be obtained at serial timepoints to conduct PK studies, pharmacodynamic testing of serum protein biomarkers associated with β-catenin inhibition, and analysis of ctDNA and circulating tumor cells. Tumor tissue will be analyzed for TBL1 and Wnt/β-catenin signaling (sequencing and protein expression). Clinical trial information: NCT07144254. Research Sponsor: Peach Bowl LegACy Fund; Iterion Therapeutics.

TPS11587 **Poster Session**

A phase 1/2, multi-center, open-label study to evaluate the safety, tolerability, pharmacokinetics, radiation dosimetry, and preliminary anti-neoplastic activity of LNTH-2403, a LRRC15-targeted ^{177}lutetium-labeled monoclonal antibody, in patients with relapsed/refractory osteosarcoma. First Author: Noah Federman, UCLA Jonsson Comprehensive Cancer Center, UCLA David Geffen School of Medicine, Los Angeles, CA

Background: Treatment for relapsed and refractory (R/R) osteosarcoma (OST) has not changed for decades. R/R OST has a poor prognosis with a 12% 4-month event-free survival (EFS). Leucine-Rich Repeat Containing 15 (LRRC15) is a type I transmembrane protein on OST cells and cancer associated fibroblasts. Approximately 90% of OST express LRRC15; high expression predicts aggressive disease and shorter survival. LNTH-2403 is a high-affinity LRRC15-targeting fully humanized antibody with a ^{177}lutetium payload. Preclinical data show anti-tumor activity in several OST models, demonstrating LNTH-2403's potential to treat R/R OST. **Methods:** This first-in-human, multicenter, open-label phase 1/2 study will evaluate the safety, tolerability, pharmacokinetics (PK), biodistribution (BD), radiation dosimetry (RD), and preliminary anti-neoplastic activity in patients ≥12 years of age with LRRC15-expressing R/R OST. The primary endpoints are to identify the maximum tolerated dose (MTD; phase 1) and 4-month EFS (phase 2). LRRC15 expression by immunohistochemistry will be confirmed by a central lab; pre-screening is allowed. Initiated in Q1 2026, phase 1 will test LNTH-2403 at 30, 50, and 70 mCi/m^2 every 8 weeks in up to ~30 patients. A 3+3 design will be used to define the MTD and estimate the recommended phase 2 dose (RP2D). Phase 2 will evaluate LNTH-2403 at the RP2D in ~25 patients with R/R OST. Retreatment after Cycle 1 is permitted for patients who continue to meet initial eligibility requirements, have cumulative doses to target organs predicted to be below radiation tolerance limits, and whose bone marrow has recovered. Safety testing includes adverse events (AEs), serious AEs (SAEs), laboratory parameters (chemistry, hematology, coagulation, urinalysis), electrocardiograms, vital signs, and physical examinations. BD and RD are based on serial single photon emission computed tomography (SPECT)/computed tomography (CT) and planar imaging. PK data will be generated from serial blood sampling for radioactivity. Overall response rate (ORR) and EFS are defined by the Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 per investigator reads. As ORR by RECIST is challenging in OST due to tumor calcification, efficacy testing also includes physiologic response by fluorine-18 (^{18}F)-fluorodeoxyglucose (FDG)-positron emission tomography (PET)/CT whole body scans and magnetic resonance imaging of the primary site, sites of known and presumed metastases, and the chest, abdomen, and pelvis. For this open-label study, all statistical methods will be descriptive in nature with no formal statistical hypotheses. NCT07357519; Research Sponsor: Lantheus. Clinical trial information: NCT07357519. Research Sponsor: Lantheus.

TPS11588 **Poster Session**

StrateGIST 3: A randomized, phase 3 study of velzatinib (IDRX-42) versus sunitinib in patients with advanced gastrointestinal stromal tumors after imatinib therapy. First Author: Suzanne George, Dana-Farber Cancer Institute, Boston, MA

Background: Most gastrointestinal stromal tumors (GISTs) are driven by mutations in *KIT*. Tyrosine kinase inhibitors (TKIs) such as imatinib and sunitinib (first- and second-line therapies for GIST, respectively) are available, but resistance can develop and is primarily mediated by additional *KIT* mutations in the ATP binding pocket (exon [ex] 13/14) and activation loop (ex 17/18). While sunitinib targets mutations in exon 13/14 in the second-line setting, it has low response rates and short progression-free survival (PFS). Therefore, there is a need for novel therapies with broad mutation coverage, and for patients (pts) with disease progression on, or intolerance to, approved therapies. Velzatinib (subject to USAN approval) is a novel, highly selective, oral KIT TKI that potently and selectively inhibits primary and secondary resistance *KIT* mutations. In StrateGIST 1, an ongoing, phase 1/1b study in adult pts with advanced GIST, velzatinib exhibited promising clinical activity and favorable safety in 2nd- and later-line pts at the recommended phase 3 dose of 300-mg QD tablet (or exposure-equivalent 400-mg QD capsule). As of December 15, 2025, median PFS (95% CI) was 13.7 (7.4–18.4) months and confirmed ORR (95% CI) was 33% (19.5–48.0) in 2nd-line pts (N=46) at the recommended phase 3 dose, supporting the further evaluation of velzatinib in pts with advanced GIST after progression on, or intolerance to, imatinib. **Methods:** StrateGIST 3 is a phase 3, randomized, multicenter, open-label study (NCT07218926) to evaluate velzatinib vs sunitinib in adult pts with advanced GIST after progression on or intolerance to imatinib. Recruitment for this study opened on December 3, 2025, and the total duration of the study is estimated to be approximately 5 years. Pts must have documented mutation status of *KIT* and/or *PDGFRA*, and will be excluded if they have GIST that is wild type for both *KIT* and *PDGFRA* or if they have an activating *PDGFRA* exon 18 mutation. Approximately 450 pts will be randomized (1:1) to receive either velzatinib (300-mg QD tablet, continuous dosing) or sunitinib (50 mg QD, 4 weeks on/2 weeks off). The randomization will be stratified by activating mutation (ex 11 vs ex 9 vs other) and intolerance to first-line imatinib (yes vs no). The primary endpoint is PFS according to modified RECIST for GIST (mRECIST-GIST), by blinded independent central review (BICR). The key secondary endpoint is overall survival, and additional secondary endpoints include PFS per investigator assessment, PFS-2, confirmed objective response rate per BICR and per investigator, time to response per BICR and per investigator, health-related quality of life and functioning, plasma drug concentrations, and safety and tolerability. This trial is now recruiting. This study (NCT07218926) is funded by GSK. Clinical trial information: NCT07218926. Research Sponsor: GSK.

TPS11589 **Poster Session**

Phase 1a/1b study of the safety, pharmacokinetics, and antitumor activity of ziftomenib in combination with imatinib in patients with advanced gastrointestinal stromal tumors (GIST) after imatinib failure. First Author: Mark Agulnik, Keck School of Medicine of University of Southern California, Los Angeles, CA

Background: GIST is the most common mesenchymal neoplasm of the digestive tract and is mainly driven by gain-of-function oncogenic mutations in the receptor tyrosine kinase KIT. Patients with GIST are typically treated with anti-KIT tyrosine kinase inhibitors (TKIs) such as imatinib. However, few patients achieve a complete response, and most eventually progress due to secondary *KIT* alterations that cause resistance to therapy. Other TKIs are approved in later lines but have shown only moderate clinical outcomes, highlighting the need for additional therapeutic approaches. Preclinical studies have shown that the menin-KMT2A complex epigenetically upregulates *KIT* expression in GIST cells. Ziftomenib is a potent and highly selective menin inhibitor that disrupts formation of the menin-KMT2A complex. Ziftomenib plus imatinib has demonstrated synergistic antitumor activity in imatinib-sensitive and -resistant GIST models, with reduced KIT protein levels and downstream oncogenic signaling observed in imatinib-resistant GIST patient-derived xenografts treated with the combination. Together, ziftomenib plus imatinib may enhance KIT recycling while reducing *KIT* transcription. This combination is currently being investigated clinically in patients with imatinib-sensitive and -resistant advanced GIST. **Methods:** KOMET-015 (NCT06655246) is an ongoing phase 1a/1b, open-label study to determine the safety, tolerability, recommended phase 2 dose (RP2D), and preliminary antitumor activity of ziftomenib plus imatinib (400 mg or $<$400 mg if previously reduced due to intolerance) for advanced/metastatic GIST. KOMET-015 includes dose-escalation, RP2D determination, and dose-expansion parts. Eligible patients ($\geq$18 yrs) must have a biopsy-proven diagnosis of advanced/metastatic *KIT*-mutant GIST (T670X excluded) that progressed on imatinib (for dose-escalation and RP2D determination parts), with an ECOG PS of $\leq$2 and measurable disease per RECIST v1.1 modified for GIST (mRECIST). Dose escalation will be based on an i3+3 design to evaluate the safety and tolerability of up to 4 dose levels (with potential for additional doses) of ziftomenib combined with imatinib. Based on escalation, up to 2 dose levels will be selected for comparison to determine the RP2D. The dose-expansion part will examine the preliminary clinical activity of the RP2D in patients assigned to 1 of 3 cohorts: Cohort A: patients who progressed on imatinib as immediate prior therapy, Cohort B: patients who failed imatinib and had received $\geq$2 lines of therapy, and Cohort C: imatinib-naive patients. Tumor response will be assessed per mRECIST. All adverse events will be recorded, monitored, and graded based on CTCAE v5.0. The trial is open and actively recruiting in the United States. Clinical trial information: NCT06655246. Research Sponsor: Kura Oncology, Inc.

TPS11590 **Poster Session**

Clinical feasibility of 68Ga-DOTATATE PET/CT to identify SSTR-positive soft tissue sarcoma for PRRT selection. First Author: Gabriel Tinoco, Division of Medical Oncology, The Ohio State University, Arthur G. James Comprehensive Cancer Center, Columbus, OH

Background: Soft tissue sarcomas (STS) are biologically heterogeneous with limited effective systemic options in advanced disease. While 18F-FDG PET/CT provides metabolic assessment, it does not identify actionable receptor targets. Somatostatin receptor 2 (SSTR2) is expressed in subsets of mesenchymal tumors, and SSTR-targeted imaging with 68Ga-DOTATATE PET/CT is routinely used to select patients with neuroendocrine tumors for peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE. Whether receptor-targeted PET screening can feasibly characterize SSTR expression across STS subtypes and support future PRRT trial design is unknown. This study evaluates the feasibility and yield of 68Ga-DOTATATE PET/CT as a screening strategy in STS. **Methods:** This is a prospective, open-label, single-center pilot study enrolling 30 adults with any-stage STS who are candidates for systemic therapy and who have undergone standard-of-care PET/CT within 30 days. Participants undergo a single 68Ga-DOTATATE digital PET/CT within 14 days of consent, acquired approximately 60 minutes post-injection with non-contrast CT for attenuation correction and anatomic localization. Quantitative metrics including SUVmax and total tumor volume are centrally derived. Optional biobanking permits pre-imaging blood collection for exploratory circulating biomarkers. Key exclusions include recent long-acting somatostatin analog use, pregnancy or lactation, acute infection, hypersensitivity to somatostatin analogs, or inability to complete imaging. The primary endpoint is screening feasibility, defined by successful scan acquisition and interpretable image quality. Secondary endpoints include lesion-level detectability, safety, and characterization of uptake patterns using modified Krenning-style criteria and quantitative PET parameters across histologic subtypes. Imaging findings may be reviewed at multidisciplinary sarcoma tumor board as part of routine clinical care, including discussion of potential PRRT eligibility, but tumor board recommendations are not study endpoints. Exploratory analyses will assess concordance between imaging findings and available tumor immunohistochemistry or circulating biomarkers. Analyses are descriptive. The planned accrual is 30 patients over approximately 24 months at a high-volume sarcoma center. Enrollment and imaging are ongoing. This study will establish the feasibility of receptor-targeted PET screening in STS and characterize the frequency and distribution of SSTR-positive disease, providing data necessary to inform the feasibility and design of subsequent 177Lu-DOTATATE interventional trials. Clinical trial information: NCT06500065. Research Sponsor: None.

TPS11591 **Poster Session**

SARC045: A phase 2 trial of tebentafusp in HLA-A*02:01−positive patients with advanced clear cell sarcoma. First Author: Andrea Napolitano, Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom

Background: Tebentafusp (Kimmtrak) is a first-in-class bispecific T-cell engager, specifically a T-cell receptor (TCR)-anti-CD3 fusion protein, approved for HLA-A*02:01+ metastatic or unresectable uveal melanoma. Tebentafusp binds to the HLA-A02:01/gp100 peptide complexes on the tumour cell surface, recruiting polyclonal T cells, via CD3, to release cytokines and cytolytic mediators against the tumour. Clear cell sarcoma (CCS) is an ultra-rare soft-tissue sarcoma subtype with poor prognosis and limited therapeutic options. On histopathology, CCS is characterised by the expression of melanocytic antigens, including gp100. **Methods:** This Phase 2 trial evaluates the efficacy of Tebentafusp in HLA-A*02:01 positive patients with advanced CCS. Twenty-three patients will be treated with weekly I.V. infusion of Tebentafusp at the recommended dose until evidence of clinical benefit or patient withdrawal from study. Baseline and on-treatment biopsies, as well as longitudinal peripheral blood samples will be collected for translational analyses. Prospective data will also be collected from an observational non-comparative cohort of up to 24 patients with advanced CCS not eligible for the study due to incompatible HLA. Enrolment to the study has commenced in October 2025 in the US, with two currently active sites (Memorial Sloan Kettering Cancer Center and University of Southern California). One additional US site (Northwestern University) and one UK site (The Royal Marsden Hospital) are due to open. At the time of submission, 1 HLA-A*02:01 advanced CCS patient had started treatment with Tebentafusp. Clinical trial information: NCT06942442. Research Sponsor: Immunocore.

TPS11592 **Poster Session**

SARC046: A phase II trial of nab-sirolimus in patients with progressing or symptomatic epithelioid hemangioendothelioma. First Author: Michael J. Wagner, Dana-Farber Cancer Institute, Boston, MA

Background: Epithelioid hemangioendothelioma (EHE) is an ultra-rare vascular sarcoma with about 120 cases diagnosed in the US per year. Although it is commonly considered an indolent disease, in its aggressive form clinical outcomes are poor. Molecularly, EHE is characterized by the presence of oncogenic fusions with HIPPO pathway effectors TAZ or YAP; TAZ-CAMTA1 or YAP-TFE3. YAP/TAZ are modulators of mTORC1 in preclinical models, suggesting that mTOR inhibition may be an effective treatment mechanism for EHE. Nab-sirolimus is albumin bound sirolimus, which achieves higher intratumoral accumulation compared to oral sirolimus and has demonstrated increased antitumor activity in preclinical cancer models compared to the oral mTOR inhibitors sirolimus and everolimus. This is an open label, multi-center, single arm, phase II clinical trial with a two-stage design, testing nab-sirolimus for progressing or symptomatic EHE. The primary objective is to determine ORR of nab-sirolimus in patients with EHE who require systemic treatment. We hypothesize that nab-sirolimus will have significant clinical efficacy for EHE as measured by the primary endpoint of objective response rate, as well as by secondary outcomes including progression free survival benefit over historical controls and by improvement in patient reported outcomes (PROs). If positive, this trial could lead to a new standard of care for treating EHE. **Methods:** This is a single arm, multi-center, phase 2 study with a two-stage design. Key inclusion criteria include histologically or cytologically confirmed EHE that is either progressing or clinically symptomatic, not a candidate for curative intent surgery, and requires systemic therapy in the opinion of the investigator, radiographically evaluable disease by RECIST v1.1, age $\geq$18 years, ECOG performance status $\leq$ 2, and adequate end organ function. With a Simon two-stage optimal design with one sided alpha 0.10, power 90%, assuming a historical control ORR 5% to detect an ORR of 20% (alternative hypothesis), 12 patients will be included in the first stage. If there is $\geq$ 1 response, an additional 25 patients will be enrolled to a total of 37 patients. $\geq$ 4 responses are needed for a significant result. The total planned accrual is 41 patients to account for unevaluable patients who may be enrolled, 10% above the required evaluable patients. Planned post hoc subgroup analyses will include outcomes by fusion type and presence of serosal effusions at the time of study enrollment. The trial is registered at clinicaltrials.gov NCT07104331. Clinical trial information: NCT07104331. Research Sponsor: U.S. Department of Defense; HT9425-25-1-0418; Aadi Bioscience.

TPS11593 **Poster Session**

Investigator-initiated phase II trial of ABSK043, an oral PD-L1 inhibitor, in patients with angiogenic sarcoma. First Author: Changsu Lawrence Park, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: Angiogenic sarcomas (AS) represent a group of rare mesenchymal malignancies arising from the vascular endothelium. Patients with locally advanced or metastatic disease have poor outcomes due to limited availability of effective systemic treatment options. Emerging data suggest that immune checkpoint blockade (ICB) has activity in select patients, but prospective data is lacking for ultra-rare subtypes of AS including intimal sarcoma and epithelioid hemangioendothelioma (EHE). **Methods:** This is a single institution phase II investigator-initiated open label trial of ABSK043, an oral PD-L1 inhibitor in patients with AS. The primary endpoint is objective response rate. Secondary endpoints include progression free survival, overall survival and incidence of treatment emergent adverse events. Exploratory objectives include tissue- and blood-based correlative analyses to identify molecular biomarkers associated with ICB response/resistance in AS. Key inclusion criteria include histologically proven EHE, intimal sarcoma or scalp angiosarcoma with evidence of disease progression, age $\geq$18 years, ECOG performance status 0-2, adequate organ function, and measurable disease by RECIST v1.1. Exclusion criteria include ongoing systemic immunosuppressive therapy, active autoimmune disease, prior treatment with PD-(L)1 directed therapy, untreated brain metastases, or gastrointestinal conditions that may impair oral drug absorption. Participants will receive ABSK043 800mg orally twice daily until disease progression or unacceptable toxicity. Radiologic assessments by CT or MRI will be performed every 12 weeks. Research bloods will be collected prior to treatment initiation and with radiologic assessments, and biobanked for future correlative analyses (including longitudinal ctDNA assessment). Archival tissue or a fresh biopsy will be collected during screening for all patients. Patients who achieve partial response will undergo on-treatment and post-progression biopsies for correlative analyses (including whole genome and transcriptome sequencing and multiplex immunohistochemistry). This study opened in August 2025 and is actively recruiting. Planned enrollment is 20 patients, with accrual expected to complete by June 2027. Clinical trial information: NCT07014137. Research Sponsor: Abbisko Therapeutics.

TPS11594 **Poster Session**

A phase Ib/II study of mirdametinib in combination with palbociclib in patients with advanced dedifferentiated liposarcoma. First Author: Olayode Babatunde, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Dedifferentiated liposarcoma (DDLPS) is a rare adipocytic malignancy characterized by frequent amplification of *MDM2* and *CDK4* and associated with poor outcomes, with a median overall survival of approximately 15 months. A phase II trial at Memorial Sloan Kettering Cancer Center demonstrated activity of the CDK4/6 inhibitor palbociclib in advanced WD/DDLPS, with a 12-week progression-free survival (PFS) rate of 57%, exceeding historical chemotherapy benchmarks ($<$35%) and leading to its inclusion in the NCCN Guidelines. Despite this, durability of benefit remains limited, and outcomes following progression are poor. Preclinical work from our group demonstrated that CDK4/6 inhibition in DDLPS induces cellular geroconversion from quiescence to irreversible senescence, accompanied by *MDM2* downregulation. This process requires suppression of HRAS signaling and inhibition of the MAPK pathway and is associated with activation of the senescence-associated secretory phenotype (SASP). Preclinical models further suggest that dual CDK4/6 and MEK inhibition enhances SASP activation, providing a mechanistic rationale for combination therapy. Based on these findings, we initiated a phase Ib/II clinical trial of mirdametinib, a MEK1/2 inhibitor, in combination with palbociclib in patients with DDLPS (NCT06843967). **Methods:** This is an ongoing phase Ib/II, single-arm, open-label, single-center study evaluating the safety, tolerability, and efficacy of mirdametinib plus palbociclib in patients with unresectable, recurrent, or metastatic DDLPS (NCT06843967). Patients may enroll at any line of therapy, including first line, consistent with contemporary palbociclib use; patients with prior CDK4/6 inhibitor exposure are eligible for the phase Ib portion. Key eligibility criteria include ECOG performance status 0–2 and RECIST v1.1–measurable disease. Phase Ib uses a Bayesian optimal interval (BOIN) design with three dose levels to determine dose-limiting toxicities, maximum tolerated dose, and recommended phase II dose (RP2D), enrolling up to 24 patients. Phase II will assess efficacy at the RP2D, with the primary endpoint of PFS at 18 weeks by RECIST v1.1 in 30 patients. Enrollment began February 19, 2025. As of January 2026, accrual is ongoing at dose level 2. Enrollment to dose level 3 is anticipated in February 2026. Clinical trial information: NCT06843967. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; 1R01CA296835-01.

TPS11595 **Poster Session**

SATURN-STS: Phase II study of neoadjuvant atezolizumab with doxorubicin, concurrent atezolizumab with pre-operative radiation therapy and adjuvant atezolizumab in patients with high-risk surgically resectable extremity and truncal soft tissue sarcoma. First Author: Ahsan Saleem Farooqi, Department of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: High-risk, localized soft tissue sarcoma (STS) remains associated with high rates of distant relapse despite modern multimodality therapy. Immune checkpoint inhibition (ICI) has demonstrated activity in certain metastatic STS subtypes with signals of enhanced response when combined with doxorubicin in the advanced/metastatic setting, as well as improved disease-free survival when combined with radiotherapy (RT) in the neoadjuvant setting; however, the optimal integration of neoadjuvant chemotherapy, immunotherapy, and RT in resectable disease is unknown. This single-arm phase II trial evaluates whether neoadjuvant atezolizumab combined with doxorubicin, followed by concurrent atezolizumab with preoperative RT and adjuvant atezolizumab, can improve relapse outcomes in patients with resectable, high-risk STS of the extremity and trunk. **Methods:** SATURN-STS is an investigator-initiated phase II study enrolling 50 adults with treatment-naïve, localized, intermediate- to high-grade STS $>$5 cm, including undifferentiated pleomorphic sarcoma, myxofibrosarcoma, de-differentiated/pleomorphic liposarcoma, leiomyosarcoma, and unclassified sarcoma. Neoadjuvant treatment includes 4–6 cycles of doxorubicin (60–75 mg/m^2) plus atezolizumab (1200 mg IV q3w), followed by atezolizumab with preoperative RT (50 Gy in 25 fractions or 42.75 Gy in 15 fractions), surgical resection, and up to 16 cycles of adjuvant atezolizumab. Radiographic imaging is performed at baseline, during neoadjuvant therapy, post-RT prior to surgery, and throughout follow-up. Longitudinal tissue is acquired for translational analyses with biopsy prior to initiation of chemoimmunotherapy and prior to RT/immunotherapy combination, followed by collection at the time of surgery. The primary endpoint is time-to-relapse (TTR), defined from time of surgical resection to the date of documented disease recurrence, compared to a historical control using a single-arm, time-to-event Bayesian monitoring approach. Secondary endpoints include objective response (RECIST 1.1), pathologic response, local recurrence-free survival, distant metastasis-free survival, progression-free survival, overall survival, and safety (CTCAE v5.0). Exploratory objectives include profiling immune microenvironment changes, genomic correlatives, circulating tumor DNA, and spatial analyses. As of January 2026, 6 patients have initiated treatment at an accrual rate of 1-2 patients per month. Clinical trial registration: NCT07049848. Support: The University of Texas MD Anderson Cancer Center and Genentech Strategic Alliance Grant. Clinical trial information: NCT07049848. Research Sponsor: University of Texas MD Anderson Cancer Center and Genentech (Inc) Strategic Alliance.

TPS11596 **Poster Session**

Maintenance pegylated liposomal doxorubicin (PLD) versus active surveillance for advanced soft tissue sarcoma patients who had controlled disease after standard anthracycline-based treatment (MELODY). First Author: Tom Wei-Wu Chen, Center of Excellence for Sarcoma, National Taiwan University Hospital, Taipei, Taiwan

Background: The progression-free survival (PFS) associated with first-line chemotherapy for advanced soft tissue sarcoma (STS) remains unsatisfactory. Extending treatment with an active agent that has demonstrated clinical benefit in a patient (pt)—the maintenance therapy—may offer an opportunity to further delay disease progression. While anthracyclines are the current standard first-line treatment, their cumulative cardiotoxicity limits prolonged use. Pegylated liposomal doxorubicin (PLD) offers a more favorable cardiac safety profile, representing a viable option for extended treatment. **Methods:** MELODY is a randomized, multinational clinical trial designed to evaluate the clinical benefit of maintenance PLD in pts with advanced STS who have achieved disease control following anthracycline-based therapy. The study incorporates patient-reported outcomes (PROs) to explore the balance between extended treatment and active surveillance from the patient's perspective—providing a more holistic understanding of the value of maintenance therapy in this population. Built-in translational studies aim to identify biomarkers that better select pts most likely benefit from maintenance therapy, thereby further personalizing treatment strategies in advanced STS. Eligible criteria include advanced STS patients aged $\geq$ 18 who had either CR, PR, or SD after first-line anthracycline-based therapy (at least five cycles). Pts will be randomized 2:1 to the experimental arm: PLD (40 mg/m^2 every 28 days, up to 12 cycles) or the control arm: active surveillance. The primary endpoint is progression-free survival (PFS) post randomization. Patients in the active surveillance arm will not crossover to PLD upon progression. Secondary endpoints include QoL by EORTC C30 questionnaire, OS, 12-month PFS rate, ORR by RECIST 1.1, and time to next treatment. Left ventricular ejection fraction (LVEF) change will be an interest of safety. Exploratory objectives include efficacy endpoints (PFS, OS, 12-month PFS rate) based on circulating tumor DNA (mandatory) and FDG PET/CT SUVmax (Optional). Based on our systematic review (Lee MJ et al. Ther Adv Med Oncol 2025), the mPFS for the control arm is estimated to be 4 months. A clinically meaningful improvement is anticipated in the experimental arm, with a mPFS of 8 months. Assuming 80% power and an alpha level of 0.1, a total of 63 evaluable subjects are required. Accounting for an anticipated 20% drop-out rate, MELODY plans to enroll a total of 81 subjects. Clinical trial information: NCT06981637. Research Sponsor: Taiwan Oncology Cooperative Group (TCOG) of National Health Research Institute; TTY Biopharm Company Limited; Gene Solutions.

TPS11597 **Poster Session**

STARS (NCT 07265661): Surgical timing after preoperative hypofractionated radiotherapy for patients with primary localized soft tissue sarcoma of the extremity and trunk—A randomized phase 2 clinical trial. First Author: Marco Baia, Sarcoma Service - Department of Surgery, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Local management paradigm for localised soft tissue sarcoma of the extremities and trunk (ESTS) has remained relatively stable, due to the excellent outcomes associated with preoperative radiotherapy combined with limb-sparing surgery. Conventional regimens (50 Gy in 25 fractions) are effective but time-intensive and resource-demanding. Ultra-hypofractionated radiotherapy (HFRT) has emerged as a promising strategy, with comparable oncological outcomes, in preliminary retrospective analyses, prospective cohorts, and Phase II non-randomised trials. However, the optimal interval between HFRT and surgery remains undefined. **Methods:** STARS is a national, multicenter, phase II, randomized, non-inferiority trial promoted by a co-sponsorship between the Italian Sarcoma Group and the Fondazione IRCCS Istituto Nazionale dei Tumori di Milano (NCT07265661). Patients with localised, resectable ESTS scheduled for combined radiotherapy and surgery are randomized 1:1 to receive preoperative HFRT (30 Gy in 5 fractions) followed by surgery at either 1–2 weeks (Arm A) or 4–6 weeks (Arm B). Randomization is stratified by tumor size, depth, site, and comorbidities. The primary endpoint is the incidence of postoperative complications (Clavien–Dindo, any grade) within 90 days. Secondary endpoints include quality of life and patient satisfaction, oncologic outcomes (local recurrence, distant metastasis, disease-free and overall survival), pathological and radiological response, treatment-related toxicity, nutritional status, and economic impact. A concurrent observational cohort will capture outcomes of patients treated with standard approaches (surgery with/without standard radiotherapy). Statistical Design: A total of 142 patients (71 per arm) will be enrolled to test non-inferiority, assuming a 35% postoperative complication rate and a non-inferiority margin of 15% (one-sided α=0.05; power 80%). Approximately 30 additional patients are expected in the observational cohort. Significance: STARS is the first randomized trial specifically designed to address surgical timing following HFRT in ESTS. The study is conducted within a novel co-sponsorship framework involving a national academic tertiary cancer center (Fondazione IRCCS Istituto Nazionale dei Tumori) and the leading non-profit cooperative group for rare cancers in Italy (Italian Sarcoma Group), establishing a sustainable platform for high-quality clinical research in rare diseases. By defining the safest and most effective interval between HFRT and surgery, this trial aims to optimize perioperative outcomes while enabling a shorter, patient-centered, and resource-efficient treatment pathway, informing future standards of care and guideline recommendations for localised ESTS. Clinical trial information: NCT 07265661. Research Sponsor: None.

TPS11598 **Poster Session**

The ATLAS study: A first-in-human phase 1/2 trial of [Ac-225]RTX-2358 in patients with relapsed or refractory soft tissue sarcoma. First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Fibroblast Activation Protein (FAP) is expressed on the surface of cancer-associated fibroblasts and is involved in the formation, maintenance, and spread of tumors. Sarcoma frequently demonstrates high expression of FAP on the tumor cells themselves in contrast to other solid tumors, where it is mainly expressed on CAFs within the tumor stroma. Radioligand therapies utilizing alpha emitting isotopes such as Ac-225 have emerged as promising treatment strategies across multiple targets and indications in oncology. Ac-225 and its daughter radionuclides emit high-energy alpha particles capable of inducing double-stranded DNA breaks, leading to significant cytotoxic effects within cells. Early clinical data for other Ac-225-labeled compounds have shown promising outcomes, particularly in settings where traditional therapies have failed. [Ac-225] RTX-2358 (Ratio Therapeutics Inc, Boston, MA) is a novel FAP-targeted radioligand designed for specific high-affinity binding, resulting in prolonged tumor residence and limited normal tissue uptake. This sustained tumor retention leads to extended delivery of cytotoxic radiation to FAP-expressing tumors. A beta-emitting analog, [Lu-177]RTX-2358, has been administered to more than 25 patients under the German §13.2b compassionate use framework across multiple tumor types. Longitudinal SPECT imaging performed as late as 14 days after administration demonstrated persistent tumor retention with minimal washout. Based on time–activity curve analysis from these data, tumor biological half-time is estimated to be well in excess of 1,000 hours. Renal clearance was observed to be consistent with that reported for established lutetium-177–labeled radioligand therapies. **Methods:** This study is a seamless Phase 1 / 2 dose escalation study. The Phase 1 portion consists of a 3 x 3 dose escalation design, with patients treated in 3 planned dose escalation cohorts (7.5, 11.25 and 15 MBq) with up to 6, 8-week cycles of [Ac-225]RTX-2358. Backfill of phase 1 cohorts is permitted to facilitate selection of the recommended administered activity level for the subsequent Phase 2 expansion cohort. Dose escalation / de-escalation decisions will be made by a Safety Review Committee. Patients over 18yrs with a history of histologically confirmed relapsed or refractory soft tissue sarcoma (measurable disease per RECIST v1.1) are eligible if they have a positive [Cu-64]LNTH-1363S FAP PET, an ECOG PS 0 to 1, and adequate organ reserve and renal function. Recruitment of the first cohort was completed in December 2025. The ATLAS Study: NCT07156565 Clinical trial information: NCT07156565. Research Sponsor: None.

TPS11599 **Poster Session**

A phase I/II study of safety/efficacy using lurbinectedin, combined with ipilimumab, and nivolumab, for advanced soft tissue sarcomas (NCT05876715). First Author: Samantha Jeffrey, Sarcoma Oncology Center, Santa Monica, CA

Background: Soft tissue sarcoma (STS) cells exhibit heightened immunogenicity during the early stages of the disease. Therefore, immunotherapies such as ipilimumab (ipi) and nivolumab (nivo), which enhance sustained T-cell activation by suppressing regulatory T cells, are potentially more effective when administered as first-line therapy in combination with lurbinectedin—a synthetic analog of the marine alkaloid trabectedin—that not only induces apoptosis in cancer cells and exposes tumor neoantigens for immune recognition but also depletes tumor-associated macrophages, thereby restoring immune surveillance and potentially enhancing the efficacy of immunotherapy. **Methods:** This Phase I/II open-label single-site study will evaluate the safety and efficacy of lurbinectedin in combination with ipi and nivo in patients with advanced STS. Phase I patients will be previously treated, whereas phase II patients will be untreated. Objectives: Primary: Evaluate MTD of lurbinectedin in combination with fixed doses of ipi and nivo. Secondary: Evaluate objective response rate by RECIST v1.1 via CT/MRI/PET q 6w until end of treatment (EOT); determine progression-free survival (PFS); determine overall survival (OS). Exploratory: correlate response with amount of ctDNA via Signatera testing q 6w until EOT. Schedule: IV lurbinectedin q 3w (Phase I: escalating doses as per standard "cohort of three" design, 2.6 - 3.2mg/m2, Phase 2: determined MTD), IV ipi 1 mg/kg q 12w, and IV nivo 3 mg/kg q 2w. Participants may continue treatment until significant disease progression or unacceptable toxicity occurs. Key Criteria: Inclusion: pathologic diagnosis of locally advanced unresectable or metastatic STS; measurable disease by RECIST v1.1; ECOG $\leq$ 1; life expectancy of $\geq$ 3 months; acceptable hematological status and liver/renal function. Exclusion: untreated CNS metastases; radiation therapy, targeted therapy, other antitumor treatment, or investigational drug or device study, within 2 weeks prior to study entry; chemotherapy within 21 days prior to study entry; prior exposure to anti-CTLA4 or anti-PD-1 inhibitors; pregnancy or breastfeeding; autoimmune disease, carcinomatous meningitis, systemic immunosuppression, skin rash affecting $>$ 25% of body surface area, or inflammatory bowel disease. Analysis: The Intention-To-Treat population (all patients who received at least one dose of study drug) will be used for OS analysis and adverse event analysis. The Modified Intention-To-Treat population (patients who completed the first two 3-week cycles and follow-up imaging) will be used for analysis of PFS. PFS and OS will be estimated by Kaplan Meir method with two-sided 95% confidence interval. Status: This study has enrolled 40 patients. Clinical trial information: NCT05876715. Research Sponsor: Jazz Pharmaceuticals.

12000 **Oral Abstract Session**

Dexamethasone reduction or omission with NEPA and olanzapine for HEC: A phase III trial. First Author: Jian Zhang, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Prolonged dexamethasone (DEX) in antiemetic regimens for highly emetogenic chemotherapy (HEC) may impair immunotherapy efficacy. We evaluated if DEX can be reduced or omitted when combined with NEPA (netupitant/palonosetron) and olanzapine without compromising control. **Methods:** In this open-label, multicenter, phase III non-inferiority trial, adults receiving HEC were randomized 1:1:1 to: Standard Regimen (NEPA day1, olanzapine days1-4, DEX 12mg day1/8mg days2-4); DEX-sparing Regimen (same, DEX 6mg day1 only); or DEX-free Regimen (same, no DEX). The primary endpoint was overall complete response (CR: no emesis/no rescue) 0-120h. A hierarchical testing sequence (DEX-sparing vs Standard, then DEX-free vs Standard) with a -12% non-inferiority margin controlled type I error (one-sided α=0.025). **Results:** Among 644 randomized patients (median age 54.9 years; 66.9% female), the overall CR rates were 72.4% for Standard, 72.2% for DEX-sparing (rate difference [RD] -0.19%, 95% CI -8.77 to 8.38; P for non-inferiority = 0.004), and 70.1% for DEX-free (RD -2.24%, 95% CI -10.81 to 6.38; P for non-inferiority = 0.013). Both experimental regimens met the non-inferiority criterion. Acute-phase (0-24 h) CR rates were 81.5%, 82.6%, and 80.8% (intergroup comparison, P > 0.05), and delayed-phase (24-120 h) CR rates were 77.1%, 77.6%, and 73.9% ((P > 0.05), respectively, with no significant differences. For complete nausea control, the DEX-free regimen was inferior beyond 24 hours, whereas the DEX-sparing regimen remained comparable to Standard throughout. Steroid-related adverse events, such as insomnia, were primarily reported in the Standard regimen group. **Conclusions:** NEPA plus olanzapine with single-day low-dose or no DEX is non-inferior to standard 4-day DEX for CINV prevention in HEC, supporting steroid-sparing strategies relevant for chemo-immunotherapy. Clinical trial information: NCT06331520. Research Sponsor: None.

Baseline patient characteristics and chemotherapy regimen.

YOCAS yoga, mood disturbance, and insomnia: A URCC NCORP RB nationwide, phase III, randomized, controlled trial with cancer survivors. First Author: Yuri Choi, Department of Surgery, University of Rochester Medical Center, Rochester, NY

Background: Mood disturbance (MoD) and insomnia are two of the most pervasive and troubling side effects experienced by cancer survivors for years after completing adjuvant treatments. MoD and insomnia significantly interfere with survivors' ability to perform essential daily activities such as cleaning, grocery shopping, cooking, taking medications, driving, and communicating with others. We previously reported that Yoga for Cancer Survivors (YOCAS) is effective for treating insomnia. YOCAS may also alleviate MoD, and changes in MoD may mediate the influence of YOCAS on insomnia. **Methods:** We conducted a nationwide, multisite, phase III randomized, controlled trial to examine: 1) the effects of YOCAS on MoD (i.e., overall MoD, anxiety, and fatigue), and 2) whether changes in MoD mediate the association between YOCAS and changes in insomnia. Survivors were recruited via the University of Rochester Cancer Center NCI Community Oncology Research Program Research Base (URCC NCORP RB). Non-metastatic cancer survivors, between 2-24 months post adjuvant therapy, aged 21 or older, with moderate or greater sleep disruption, and with no participation in yoga during the prior 3 months, were randomized to two arms: 1) standard care and 2) standard care plus the 4-week YOCAS intervention (2x/week; 75 min/session). The YOCAS consists of breathing exercises, 18 gentle Hatha and Restorative yoga postures, and meditation. MoD and insomnia were assessed using the Profile of Mood States and Insomnia Severity Index, respectively, at pre- and post-intervention. **Results:** A total of 410 survivors, recruited from 12 community-based oncology practices across the USA, were randomized (mean age = 54 10.4 years; 96% female; 75% breast cancer survivors). ANCOVAs revealed YOCAS participants, compared to standard care participants, experienced significantly less overall MoD (Mean Difference [Standard Error] = -5.08 [1.36]), anxiety (MD [SE] = -0.72 [0.29]), and fatigue (MD [SE] = -1.49 [0.41]; all $p < 0.05$) at post-intervention. Additionally, YOCAS participants reported significant improvements from pre- to post-intervention on overall MoD, anxiety, and fatigue (all $p < 0.05$), whereas standard care participants did not. Causal mediation analyses revealed changes in overall MoD partially mediated (24.9%; 95% CI: 10.9%, 42.6%) the association between YOCAS and changes in insomnia. Changes in fatigue also partially mediated (24.6%; 95% CI: 11.3%, 43.9%) the association between YOCAS and changes in insomnia (all $p < 0.05$). **Conclusions:** YOCAS yoga is effective for treating overall MoD, anxiety, and fatigue among survivors. Additionally, improvements in insomnia stemming from YOCAS yoga may be mediated by changes in overall MoD and fatigue. Clinicians should consider recommending yoga for survivors who experience overall MoD, anxiety, fatigue, and insomnia. Clinical trial information: NCT00397930. Research Sponsor: National Cancer Institute; UG1CA189961; National Cancer Institute; UG1CA189860; National Cancer Institute; UG1CA189953; National Cancer Institute; UG1CA189972; National Cancer Institute; T32CA102618.

12005 **Oral Abstract Session**

A phase III placebo controlled randomized controlled trial using combination therapy for treatment-related fatigue in patients with prostate cancer. First Author: Sriram Yennu, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: To determine if the combination of exercise (EX) plus methylphenidate (MP) is superior to EX plus placebo (PL) for 12 weeks in the treatment of cancer-related-fatigue (CRF) in patients with prostate cancer receiving androgen deprivation therapy (ADT) and/or radiation therapy (RT). **Methods:** Using a phase III randomized double-blind placebo-controlled design, we assessed treatments combining either EX or its stretching (ST) control with either MP (5mg twice a day, with dose titrated up to 20mg a day) or placebo. Patients were eligible if they had prostate cancer patients who are receiving androgen deprivation therapy and/or radiation therapy and had CRF; Eligible patients were randomized into one of four arms, EX + MP, EX + PL, ST + MP, ST + PL (2:1: 1:1). Primary outcome was assessed using linear mixed-effects model comparing the differences in Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scores at Weeks 1, 2, 4, 8 and 12. **Results:** 161 eligible patients were randomly assigned to 4 arms EX+MP (n = 65), EX+PL(n = 34), ST+MP (n = 30), and ST+PL (n = 32). Demographics, including mean age (65-67 years) were similarly distributed between arms (all $p > 0.05$). Bone metastases (~25%), and treatment modality distributions (ADT alone, ADT + RT, or RT alone) were comparable among the arms. The baseline FACIT-F scores [mean (SD) were 28.5(11.0), 28.7(8.9), 28.5(9.3), and 30.3(11.0)] respectively in arms EX+MP, EX+PL, ST+MP, and ST+PL arms. All 4 arms showed CRF improvement over time. There was a nonsignificant improvement in CRF in the EX+MP intervention arm, compared with EX+PL arm [FACIT-F coefficient, 2.73(95% CI, −0.49 to 5.96); P = 0.097]. Methylphenidate-containing arms (EX+MP and ST+MP) significantly improved CRF compared with their placebo counterparts (EX+PL and ST+PL), [FACIT-F coefficient, 3.23 (95% CI 0.84 to 5.63), P = 0.008]. There were no significant differences in CTCAE v.5 grade $\geq$3 adverse events by arms ($P > 0.99$). **Conclusions:** EX+MP arm was not superior to EX+PL arm in improvement of CRF. Methylphenidate-containing arms significantly improved CRF compared with their placebo arms. All four treatment arms showed improvement of CRF overtime suggesting strong placebo response. Further methylphenidate-containing multimodal CRF studies are needed. Clinical trial information: NCT03772834. Research Sponsor: National Institute of Health (NCI).

A digital health intervention to enhance well-being among adolescent and young adult survivors of cancer: Results from the EMPOWER full factorial trial. First Author: John M. Salsman, Atrium Health Wake Forest Baptist, Winston Salem, NC

Background: Adolescent and young adult (AYA) survivors of cancer are at significant risk of adverse psychological outcomes, yet scalable, efficacious interventions to address their needs are limited. We evaluated a self-guided digital health intervention with affective, behavioral, and cognitive skills, "Enhancing Management of Psychological Outcomes With Emotion Regulation" (EMPOWER), for improving psychological outcomes. **Methods:** We recruited AYAs (n = 352; 74% female, median age 33 years) from three comprehensive cancer centers between Dec 2021 and Sept 2024. AYAs were diagnosed at and currently aged 15 to 39 years, within 5 years post-curative treatment, and had internet access. In a full factorial design, AYAs were randomly assigned to 5 weekly components, either EMPOWER intervention or attention control (2^5 = 32 arms): 1. positive events, capitalizing & gratitude (vs. cognitive skills); 2. mindfulness (vs. financial literacy); 3. positive reappraisal (vs. nutrition); 4. personal strengths & goal-setting (vs. weight management); 5. acts of kindness (vs. sun protection). Didactic lessons and skills practices were delivered via a website designed specifically for the study. AYAs completed PROMIS measures for positive affect (primary outcome), and depression and anxiety (secondary outcomes) at pre-intervention, post-intervention, and two and four months post-intervention. Using the intent-to-treat principle and a mixed model with linear contrasts, we estimated average within-person changes over time by component (intervention/control) for AYAs and compared changes by component. **Results:** From pre to post-intervention, positive affect increased ($p<0.05$) among those in 3 of the 5 EMPOWER and 4 of the 5 control components (mean change = 1.4 to 1.9) and anxiety decreased ($p<0.05$) for those in 4 of 5 EMPOWER and 4 of 5 control components (mean change = -1.2 to -2.0). Further, anxiety was significantly lower ($p<0.05$) for all EMPOWER and control components at two and four-months post intervention (mean change = -1.3 to -2.4). There was little change in depression for any group. We found no treatment effects for any outcome whereby AYAs who received intervention content had significantly greater improvements than those receiving attention control content. Instead, some EMPOWER (positive events, capitalizing, & gratitude; acts of kindness) *and* control components (nutrition) were associated with clinically meaningful changes in outcomes, based on PROMIS metrics. **Conclusions:** Our findings suggest a range of affective, behavioral, and cognitive strategies drawn from both positive psychology and health education domains are similarly effective in enhancing positive affect and mitigating post-treatment anxiety and highlight the potential benefit of low-touch, self-guided digital health strategies for AYA survivors of cancer. Clinical trial information: NCT04317417. Research Sponsor: National Institutes of Health, National Cancer Institute; CA242849.

12007 **Oral Abstract Session**

Impact of electronic patient-reported outcome measure (ePROM)–triggered, collaborative care (CC)–based symptom intervention on depression and anxiety in young adults (YAs) with cancer. First Author: Michael H. Storandt, Mayo Clinic Rochester, Rochester, MN

Background: YAs with cancer, defined as those diagnosed prior to the age of 40, may experience greater symptom burden compared to those diagnosed at older ages. We evaluated the impact of an ePROM-triggered, CC-based, supportive care intervention on symptom burden in YAs with cancer. **Methods:** The Enhanced, Electronic Health Record-facilitated Cancer Symptom Control (E2C2) trial was a cluster-randomized, pragmatic trial (NCT03892967) that enrolled oncology patients seen at Mayo Clinic Rochester and within the Mayo Clinic Health System (sites in Minnesota and Wisconsin) between March 2019 and January 2023. Patients routinely reported the severity of six SPPADE symptoms (Sleep deficit, Pain, Physical function impairment, Anxiety, Depression, and Energy deficit/fatigue) on 11-point numerical rating scales. Symptom severity was classified as none to mild (0-3), moderate (4-6), or severe (7-10). Those with moderate or severe symptoms were offered symptom management education, while those with severe symptoms were also offered the option to work virtually with a symptom care manager. In this post hoc analysis, we examined the effects of the intervention on change in symptom scores among YAs and time to improvement to a mild/moderate level in those with at least one severe symptom. **Results:** Among 40,659 patients who responded to at least one survey, 2,598 were YAs and 38,061 were adults $\geq$ 40 years. Among YAs, 10.7%, 24.3%, and 65.1% were 18-24 years, 25-31 years, and 32-39 years, respectively. A greater proportion of YA patients were female (61.5% vs 57.0%), of a non-white race (12.4% vs 5.3%), living in an urban setting (65.7% vs 55.1%), single (36.4% vs 9.6%), on non-government insurance (78.1% vs 36.6%), employed (72.6% vs 37.4%), and had a Bachelor's degree or greater (37.8% vs 28.3%, $p< 0.001$ for all). Fewer YA patients had metastatic disease compared to older patients (24.2% vs 35.2%, $p< 0.001$). Compared to a pre-intervention baseline, the mean change in symptom score for YA patients following the intervention demonstrated improvements in anxiety (-0.195) and depression (-0.168, $p< 0.0001$ for both), while physical function impairment worsened over the intervention period (0.101, p= 0.014). Compared to adults $\geq$ 40 years, YAs experienced greater intervention effects for management of depression ($p <0.001$), fatigue (p= 0.01), pain ($p< 0.0001$), and physical function impairment ($p< 0.0001$). Among YAs with a severe symptom during the intervention period, median time to improvement to a mild/moderate level was longer for anxiety compared to those $\geq$ 40 years (3.5 vs 2.7 months, p= 0.009). **Conclusions:** Routine ePROM surveillance, coupled with CC-based symptom management, led to improvements in anxiety and depression among YAs with cancer, although, time to improvement was longer for anxiety compared to adults $\geq$ 40 years. Research Sponsor: NCI of the National Institutes of Health.

Efficacy of YES, an mHealth intervention for adolescent and young adults (AYA) with breast cancer (BC), to address AYA survivorship concerns. First Author: Shoshana M. Rosenberg, Weill Cornell Medicine, New York, NY

Background: AYA BC survivors often have unmet concerns that are understudied and suboptimally addressed. Primary results from the YES trial (NCT04906200) demonstrated that YES, an AYA-focused mHealth intervention, improved quality of life and reduced specific symptoms in AYA BC survivors at 6 months (mo) post-enrollment. Here we report a prespecified secondary analysis of YES on reducing AYA survivorship concerns. **Methods:** We conducted a multicenter (Dana-Farber Cancer Institute, The Ohio State University, Columbia University Medical Center) RCT of YES, an mHealth intervention which provides tailored information, resources and support in response to monthly electronic patient-reported outcome monitoring, a journal platform, and a chat room. Participants age $\leq$39 at diagnosis (dx) of stage 0-3 BC, $<$ 3 years post-dx were randomized 1:1 to YES or Usual Care (UC). Survivorship concerns were measured at baseline, 3, and 6 mo with AYA HOPE survey items; participants rated their level of concern across a range of domains. Generalized linear mixed effects models analyzed the binary endpoint of somewhat/very vs no/low concern for each issue. Odds of being somewhat/very concerned about a domain at 6 mo were compared between arms, adjusting for baseline concern. **Results:** From 6/2021-12/2024, 360 participants were randomized (YES:179; UC: 181) following baseline survey completion. Participant characteristics were balanced between arms. Median time from dx was 19 (IQR: 12-27) mo. Median age at dx was 34 (IQR: 31-37) yrs; 61% had stage 2 or 3 BC. Overall, a majority of participants endorsed high levels of concern at baseline related to: long-term side effects of treatment (67%), long-term health effects of cancer (70%), recurrence (79%), checking for signs of recurrence (57%), possibility of a new cancer (67%), exercise (60%), nutrition (58%), familial cancer risk (51%), and body image (56%). Other endorsed concerns included: fertility (43%), financial support for medical care (37%), financial concerns (38%), talking about cancer experience with family/friends (27%), having enough information about treatment (25%), meeting other AYAs (22%), alcohol and cancer (15%), and smoking cessation (3%). At 6 mo, adjusting for baseline concern, the YES group (vs UC) had lower odds of being somewhat/very concerned about finances (OR: 0.36, 95% CI: 0.13 – 0.98, p = 0.05), financial support for medical care (OR 0.35, 95% CI 0.13-0.96, p = 0.04), family cancer risk (OR 0.36, 95% CI 0.17-0.77, p = 0.009), and alcohol and cancer (OR 0.15, 95% CI 0.03-0.75, p = 0.02). **Conclusions:** Concerns across a range of survivorship domains are prevalent in AYA BC survivors. The YES mHealth intervention reduced concerns about several survivorship issues, supporting the potential for this highly scalable intervention to help manage these concerns as an adjunct to routine clinical care for AYA BC survivors. Clinical trial information: NCT04906200. Research Sponsor: National Cancer Institute; U01CA246648; Breast Cancer Research Foundation; Susan G. Komen; American Cancer Society.

12010 **Rapid Oral Abstract Session**

Effect of a weight loss intervention (WLI) on quality of life (QOL) and symptoms in women with breast cancer: Results from the Breast Cancer Weight Loss (BWEL) trial. First Author: Jennifer A. Ligibel, Dana-Farber Cancer Institute, Boston, MA

Background: BWEL (Alliance A011401; NCT02750826) is a Phase III trial that randomizes patients (pts) with stage II-III breast cancer and body mass index (BMI) $\geq$27 kg/m^2 1:1 to a 24-month (mo) lifestyle-based WLI + health education (HE) or HE alone. Here we report prespecified secondary outcomes of the impact of the WLI on patient-reported QOL and symptoms. **Methods:** The first 540 BWEL pts (randomized between 9/2016 and 7/2017) were included in this substudy that collected PROMIS 29 Profile 2.0 and Global Health scores at enrollment, 6 and 24 mos. Adjusting for baseline scores, mean physical function (predefined substudy primary outcome), global physical and mental health, fatigue and other scores were compared at 6 and 24 mos using analysis of covariance (ANCOVA). P-values $<$0.05 were considered significant. Positive differences in positive attributes (e.g., physical function) and negative differences in negative attributes (e.g., anxiety) represented better outcomes in the WLI arm. **Results:** At baseline, median BMI was 32.9 kg/m^2 (26.5 – 69.1), median age was 53 (25 - 78) years; 83.9% of pts were non-Hispanic White, 10.7% were Black and 5.9% were Hispanic. At 6 mos, the WLI (vs HE) arm had significantly better physical function (ANCOVA-based mean difference between arms 1.9 [95% CI 0.8, 3.0]; p$<$0.001), global physical health (2.0 [95% CI 0.9, 3.0]; p$<$0.001), global mental health (1.30 [95% CI 0.2, 2.4], p=0.03), social roles and activities (2.3 [95% CI 1.1, 3.6]; p$<$0.001), and fatigue (-1.7 [95% CI -3.1, -0.4], p=0.01) (Table). Improvements were generally maintained at 24 mos. Similar findings were seen in analyses using longitudinal mixed modeling. **Conclusions:** The BWEL WLI demonstrated QOL benefits for patients with breast cancer, resulting in significantly better physical function, global physical and mental health, and symptoms. Future analyses will evaluate which populations experienced the most benefit, as well as the relationships among QOL, symptoms, and weight loss. Analysis of covariance-adjusted least squares means values at 6-mos adjusted for baseline scores.

QOL/Symptom Attributes	HE	WLI	Between arm difference (95% CI)*	P value
Physical Function	47.1	49.0	1.9 (0.8, 3.0)	<0.001
Global Physical Health	46.2	48.1	2.0 (0.9, 3.0)	<0.001
Global Mental Health	48.6	49.9	1.3 (0.2, 2.4)	0.03
Social Roles and Activities	52.7	55.0	2.3 (1.1, 3.6)	<0.001
Anxiety	50.2	50.0	-0.2 (-1.6, 1.2)	0.77
Depression	47.5	47.5	-0.0 (11.2, 1.2)	0.96
Fatigue	50.6	48.9	-1.7 (-3.1, -0.4)	0.01
Sleep Disturbance	51.0	51.1	0.1 (-0.6, 0.8)	0.80
Pain Interference	51.3	50.3	-1.0 (-2.4, 0.4)	0.15

*Positive differences in positive attributes and negative differences in negative attributes favor WLI arm.

12011 **Rapid Oral Abstract Session**

Association of social isolation with overall survival in cancer patients. First Author: Danlin Zeng, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada

Background: Social isolation has been associated with increased all-cause mortality, particularly in cardiovascular and mental health conditions. Prior studies show that larger social networks, greater perceived social support, and marital status are associated with improved survival. However, the impact of social isolation on cancer patients remains incompletely characterized. This study examines the association between social isolation and overall survival (OS) in a large cancer cohort. **Methods:** 47,562 adult cancer patients treated at British Columbia Cancer between April 1, 2011, and December 31, 2016, who completed the Psychosocial Screen for Cancer (PSSCAN-Revised) questionnaire at their initial visit were included. Patients with prior malignancies were excluded. OS was estimated using Kaplan-Meier methods and compared using log-rank tests. Multivariable Cox proportional hazards regression was used to identify independent associations with OS. **Results:** The mean age was 64.5 years (SD 13.9). 55.2% were female. At their initial visit, 67% had non-metastatic disease, 17% had metastatic disease, and metastatic status was unknown in 16%. Social isolation was prevalent: 24.7% lived alone, 14.1% had lost a partner, 11.6% lacked assistance with instrumental activities of daily living (IADLs), 4.7% lacked regular social contact, 6.9% lacked emotional support, and 29.3% had at least one domain of social isolation. Median OS was shorter across all five domains of social isolation: patients living alone (37 vs 58 months), those who lost a partner (34 vs 56 months), those without regular social contact (32 vs 52 months), those without IADL support (49 vs 53 months), and those lacking emotional support (45 vs 53 months; all p$<$0.05). Anxiety (36.8%) and depression (25.6%) were also associated with worse survival (p$<$0.001). In multivariable Cox regression, independent predictors of increased mortality included metastatic disease (HR 4.41), depression (HR 1.44), anxiety (HR 1.29), lack of regular social contact (HR 1.26), male sex (HR 1.22), living alone (HR 1.18), and older age at presentation (HR 1.04 per year; all p$<$0.001). **Conclusions:** Multiple domains of social isolation were independently associated with shorter OS in cancer patients. These findings highlight social isolation as a clinically relevant prognostic factor and support the incorporation of psychosocial risk assessments into oncology care to inform risk stratification and supportive interventions. Research Sponsor: None.

Vitamin D insufficiency and risk of taxane-induced peripheral neuropathy: Results from SWOG S1714. First Author: Nam Nguyen-Hoang, University of Michigan, College of Pharmacy, Ann Arbor, MI

Background: Taxane-induced peripheral neuropathy (TIPN) affects up to 70% of patients treated with taxanes and can lead to functional impairment, reduced quality of life, and treatment disruption. There are no proven TIPN preventive strategies. Vitamin D insufficiency is a modifiable factor that has been linked to increased TIPN risk in paclitaxel-treated patients with breast cancer. We analyzed the association between baseline vitamin D levels and TIPN among patients receiving taxane-based treatments in a large, multicenter, prospective cohort study (SWOG S1714). **Methods:** In a prespecified analysis, baseline vitamin D levels were quantified from plasma samples using liquid chromatography-tandem mass spectrometry. Vitamin D insufficiency was defined as total 25-hydroxyvitamin D $\leq$20 ng/mL. The primary endpoint was development of TIPN, defined as an increase of ^{3}8 points from baseline in the sensory subscale of the EORTC QLQ-CIPN20 (0-100 scale, with higher score indicating worse symptoms) by week 24. The secondary endpoint was the greatest worsening from baseline in the sensory subscale CIPN20 score. Multivariable Cox proportional hazards model was used to evaluate time to initial development of TIPN and linear regression was used for the secondary endpoint, both adjusting for age, cancer stage, race/ethnicity, comorbidities, taxane type, and planned treatment duration. Statistical significance was set at α = 0.05. **Results:** Among 1278 evaluable patients, 610 had available serum samples for vitamin D analysis (mean age 54.8 years [standard deviation 11.9]; 98% female; 85% White; 90% breast cancer; 59% paclitaxel-treated). Of these, 134 (22%) were vitamin D insufficient at baseline, and 383 (63%) developed TIPN during 24 weeks of follow-up. At baseline, CIPN20 sensory score did not differ by vitamin D status (p = 0.70). Baseline vitamin D insufficiency was significantly associated with higher risk of TIPN (adjusted hazard ratio 1.35; 95% confidence interval [CI] 1.06-1.72; p = 0.013). Patients with vitamin D insufficiency had more severe worsening of neuropathy (greatest worsening in CIPN20 sensory score: mean 23.4 vs. 18.5 points; adjusted mean difference 4.7 points; 95% CI 1.0-8.4; p = 0.013). **Conclusions:** Baseline vitamin D insufficiency was associated with significantly increased risk and severity of TIPN in this prospective cohort of patients receiving taxane-based therapy across multiple cancer types. These findings highlight vitamin D status as a potentially modifiable biomarker for TIPN risk and support clinical trials of vitamin D supplementation as a TIPN prevention strategy. Research Sponsor: National Cancer Institute/U.S. National Institutes of Health; R37CA277043, UG1CA189974.

12013 **Rapid Oral Abstract Session**

An international phase III randomized, double-blind, double-dummy trial comparing duloxetine and pregabalin for opioid-refractory neuropathic cancer pain. First Author: Hiromichi Matsuoka, National Cancer Center Japan, Tokyo, Japan

Background: Management of neuropathic cancer pain (NCP) refractory to standard-dose opioids remains a major clinical challenge, and direct comparative evidence between adjuvant analgesics is limited. This study aimed to compare the efficacy and safety of duloxetine and pregabalin in patients with opioid-refractory NCP. **Methods:** We conducted an international, multicenter, double-blind, randomized controlled trial. Adult cancer patients who continued to experience pain despite opioid analgesia were eligible to participate if they met the International Association for the Study of Pain criteria for neuropathic pain and had a Brief Pain Inventory (BPI) Item 3 (worst pain in the past 24 hours) score of $\geq$4. Inpatients and outpatients from Japan and Australia were randomized at a ratio of 1:1 to the duloxetine group (D group) or the pregabalin group (P group). The study drugs were titrated up to duloxetine 60mg daily or pregabalin 150mg twice daily until day 14 (D14). The primary endpoint was BPI item 3 at D14. Secondary endpoints included the change in BPI item 3 from baseline at D14, and the proportion of patients achieving $\geq$1 points, $\geq$2 points, $\geq$30% and $\geq$50% pain reduction. The primary endpoint was analyzed using a two-sided Student's T-test (α=0.05) under the intention-to-treat principle. A sample size of 64 patients per group was estimated to detect a mean difference of 1.0 (SD 2.0) with 80% power. **Results:** Between February 2020 and June 2025, 147 patients were enrolled across 18 institutions. Baseline BPI item 3 scores were similar between the D and P groups (7.23 vs 7.04). At D14, mean scores were 5.62 and 5.45, with no significant difference (P=0.70), corresponding to mean reductions of 1.57 and 1.55, respectively. Rates of pain reduction ($\geq$1 point, $\geq$2 points, $\geq$30%, $\geq$50%) were similar between groups (D: 53/45/36/25% vs P: 50/36/26/19%). Grade $\geq$2 adverse events included decreased appetite (29%), nausea (21%), fatigue (20%), in the D group, and constipation (23%), decreased appetite (16%), dizziness/fatigue (12%), in the P group. **Conclusions:** No significant difference in analgesic efficacy was observed between duloxetine and pregabalin in patients with opioid-refractory NCP. The magnitude of pain reduction exceeded the mean NRS change typically associated with placebo (approximately 0.5–1.0 points), and the response rates for $\geq$50% pain reduction were substantially higher than the $\approx$3% reported for placebo in a prior NCP study. The estimated numbers needed to treat were low (4.6 for duloxetine and 6.3 for pregabalin) and were smaller than those reported in non-cancer neuropathic pain, suggesting comparable or potentially greater efficacy. However, given the relatively high incidence of adverse events and the distinct adverse event profiles of each drug, careful and individualized treatment selection balancing efficacy and tolerability is warranted. Clinical trial information: jRCTs051190097. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

12014 **Rapid Oral Abstract Session**

A URCC NCORP Research Base nationwide phase II randomized controlled trial (RCT) investigating the effect of exercise on chemotherapy-induced peripheral neurotoxicity (CIPN). First Author: Ian Kleckner, University of Maryland Baltimore, Baltimore, MD

Background: Over 60% of patients with cancer receiving taxane, platinum, or other neurotoxic agents experience CIPN, which presents as numbness, tingling, and sometimes pain in the hands and feet. CIPN reduces quality of life and can increase mortality by limiting chemotherapy dose. With extremely limited treatments for CIPN, exercise has emerged as one of the most promising yet unproven treatments with no Phase III RCTs to date. **Methods:** This phase II RCT examines the effect of exercise on CIPN in the University of Rochester Cancer Center (URCC) NCI Community Oncology Research Program (NCORP) Research Base network, recruiting 111 patients across 37 community oncology practices spanning 11 states in the US. Key eligibility include receiving neurotoxic chemotherapy (taxane, platinum, vinca alkaloid, etc.) in the past 9 months and reporting symptoms of CIPN ($\geq$ 4 of 10 at its worst in the past 2 weeks). Participants were randomized 1:1 to 6 weeks of usual care (UC) or virtually delivered Exercise for Cancer Patients (vEXCAP). vEXCAP is a virtually delivered, standardized, individualized, moderate-intensity, home-based, progressive walking and resistance exercise program. We assessed CIPN both pre- and post-intervention using patient-reported CIPN-20 (0-100 scale) and tactile sensitivity in the finger and toe using monofilaments. Each night, participants rated numbness/tingling in the hands/feet on a 0-10 scale. The primary outcome was CIPN-20 total score with CIPN-20 sensory and motor subscales as exploratory. **Results:** The 111 patients were 59.5 $\pm$10.5 yrs, 76% female, 83% White, 37% breast cancer, 36% gastrointestinal cancer. Exercise yielded statistically and clinically meaningful improvements in CIPN sensory symptoms compared to UC (ΔCIPN-20 = -4.7 [MCID = 4], effect size [ES] = -0.27, p = 0.049). Exercise had a weak effect on CIPN motor symptoms (ΔCIPN-20 = 1.5, ES = 0.08, p = 0.936) and the CIPN-20 total score (ΔCIPN-20 = -1.2, ES = -0.07, p = 0.393). Tactile sensitivity was negatively correlated with CIPN sensory symptoms, as expected (finger: rho = -0.21, p = 0.043, toe: rho = -0.18, p = 0.092). Effects of exercise on tactile sensitivity were beneficial yet small and not statistically significant (ES = 0.04 and 0.07, both p $>$ 0.682). Daily symptom ratings suggest that possible benefits of exercise emerge after 24 days (0.75$\pm$0.46 unit reduction, p = 0.104), with clear benefits after 30 days (0.93$\pm$0.46 unit reduction, p = 0.045) that grow further through study completion. **Conclusions:** Six weeks of walking and resistance exercise may reduce CIPN sensory symptoms for patients with CIPN. A future phase III RCT is needed to definitively test for replication and inform clinical practice. Funded by NCI: UG1CA189961, UG1CA189804, UG1CA189822, UG1CA189819, UG1CA189830, R21CA256154, and K07CA221931. Clinical trial: NCT04888988. Clinical trial information: NCT04888988. A multicenter randomized phase II trial of topical betamethasone ointment for preventing severe chemoradiotherapy-induced oral mucositis in head and neck cancer. First Author: Sakiko Soutome, Center for Clinical and Translational Research, Toyama University Hospital, Toyama, Japan

Background: Severe oral mucositis (OM) is a major unmet clinical problem during cisplatin-based chemoradiotherapy (CRT) for head and neck cancer, with no established preventive strategy. Although topical dexamethasone has shown benefit during radiotherapy alone, its efficacy during CRT is limited. This study represents the first randomized trial evaluating a potent topical corticosteroid, betamethasone ointment, for preventing severe OM during cisplatin-based CRT. **Methods:** Patients with head and neck cancer receiving CRT with the oral cavity included in the radiation field were enrolled at six institutions in Japan. Upon development of grade 1 OM (CTCAE v5.0), patients were randomized to standard oral care alone (control) or standard oral care plus topical betamethasone ointment applied three times daily (intervention). Treatment continued until completion of radiotherapy or onset of grade 3 OM. The primary endpoint was time to grade 3 OM, analyzed using multivariable Cox proportional hazards models. Secondary endpoints included time to grade 2/3 OM and incidence of oral candidiasis. **Results:** A total of 68 patients were analyzed (intervention n=35; control n=33). The cumulative incidence of grade 3 OM was significantly lower in the intervention group (14.3%) than in the control group (48.5%). Topical betamethasone significantly reduced the risk of grade 3 OM (HR 0.246, 95% CI 0.081–0.749). Betamethasone also delayed the onset of grade 2/3 OM. Non-use of a spacer was independently associated with grade 2 OM. Betamethasone did not increase oral candidiasis, whereas denture use was a significant risk factor. **Conclusions:** Topical betamethasone ointment substantially reduced the incidence of severe OM during cisplatin-based CRT without increasing oral candidiasis. This simple, low-cost, and widely accessible intervention could be rapidly implemented in routine clinical practice to mitigate CRT-induced toxicity. To our knowledge, this is the first randomized trial demonstrating the efficacy of a potent topical corticosteroid for preventing severe OM during cisplatin-based CRT. Clinical trial information: jRCTs071200013. Research Sponsor: None.

The efficacy and safety of add-on ruxolitinib for patients with severe checkpoint inhibitor pneumonitis management with corticosteroids: A multicenter, open-label, randomised phase 2 trial. First Author: Yan Xu, Peking Union Medical College Hospital, Beijing, China

Background: Checkpoint inhibitor pneumonitis (CIP) stands out as a remarkable complication during ICIs therapy. Severe CIP represents a potentially life-threaten immune-related adverse event (irAE) with limited evidence from clinical trials that guides therapeutic interventions. Ruxolitinib, a selective JAK1/2 inhibitor, effectively attenuates cytokine-release syndrome and show significant anti-fibrotic in mouse lung with BLM model. We conducted a multicenter, investigator-initiated, open-label, phase 2 randomized controlled trial to evaluate the efficacy and safety of add-on ruxolitinib for patients with severe CIP management with corticosteroids. **Methods:** Patients with malignant who were suffered from CTCAE grade (G) 3 or G4 CIP after ICIs therapy were screened. Enrolled CIP patients were randomly assigned 1:1 to control group (only glucocorticoids) or ruxolitinib group (glucocorticoids plus ruxolitinib). Initiated dosage of glucocorticoids was no less than prednisone 1 mg/kg/day (or same steroid equivalent dose) with subsequent tapering off. In ruxolitinib group, enrolled patients were add-on ruxolitinib (5 mg twice daily for 2 weeks, followed with 5 mg daily for 2 weeks). The primary end point was the proportion of patients with a prednisone daily dosage of no more than 10mg and improvement to G1 CIP at week 8. Continuous variables were analyzed using a mixed-effects model for repeated measures with treatment group, study visit and treatment-by-visit interaction. **Results:** From April 2023 to November 2025, a total of 60 eligible patients were recruited and randomly assigned to control group and ruxolitinib group. There were 52 cases of G3 CIP and 8 cases of G4 CIP. There were more patients in the ruxolitinib group improved to G1 CIP and received ≤prednisone 10mg daily at 8th week than in the controlled group (20cases/66.7% vs 11cases/36.7%, p = 0.0379). This effect was more significant in the 2nd and 4th week. Two patients in ruxolitinib group and 4 patients in the control group died within eight weeks. The repeated measures analysis using a generalized linear mixed model demonstrated a significant overall treatment effect, ie. add-on ruxolitinib was associated with significantly higher odds of clinical improvement (adjusted OR = 5.12, 95% CI 1.06 - 24.64; p = 0.04). A total of 13 G3 or higher treatment-related AEs (TRAEs) occurred (7 cases in control group and 6 cases in ruxolitinib group), including 9 cases of infectious diseases. **Conclusions:** Add-on ruxolitinib for malignant patients with severe CIP management with glucocorticoids show with higher resolution rates and earlier response trends than only glucocorticoids treatment. And there were no different adverse events between them. Add-on ruxolitinib with glucocorticoids might be a promising proposed treatment for patients with severe CIP. Clinical trial information: NCT05899725. Research Sponsor: National High Level Hospital Clinical Research Funding; 2022-PUMCH-C-054.

A randomized phase III trial of dexamethasone mouthwash to prevent chemotherapy-induced oral mucositis in patients with breast cancer. First Author: Sayaka Kuba, Nagasaki University Hospital, Nagasaki, Japan

Background: Oral mucositis is a common adverse event in patients undergoing chemotherapy for breast cancer. A previous randomized phase II trial showed that a dexamethasone-based mouthwash significantly reduced the incidence and severity of chemotherapy-induced oral mucositis. The SMASH-BC trial was designed to confirm the efficacy and safety of dexamethasone-based mouthwash for preventing chemotherapy-induced oral mucositis in patients with breast cancer. **Methods:** This multicenter, open-label, randomized phase III trial was conducted in Japan. Patients with early breast cancer scheduled to receive standard adjuvant or neoadjuvant chemotherapy (AC, EC, dose-dense AC/EC, TC, or pembrolizumab-containing regimens) were randomized 1:1 to receive either a dexamethasone-based mouthwash (10 mL of dexamethasone elixir 0.01%) or tap-water mouthwash as a control. The mouthwash was swished for 2 min and spit, four times daily for 8 weeks, starting on day 1 of chemotherapy. Randomization was stratified by chemotherapy regimen, smoking status, and institution. The primary endpoint was the incidence of all-grade oral mucositis at 8 weeks, assessed using electronic patient-reported outcomes (ePRO). Assuming an all-grade oral mucositis incidence of 55% in the control group and 35% in the intervention group, 212 patients were required to provide 80% power with a two-sided α of 0.05. The planned sample size was 230, allowing for 10% attrition. **Results:** Overall, 230 patients were randomized (intervention, n = 117; control, n = 113), and 220 patients (intervention, n = 114; control, n = 106) were included in the analysis. The incidence of ePRO-assessed all-grade oral mucositis at 8 weeks was 58.8% and 63.2% in the intervention and control groups, respectively (risk ratio [RR], 0.93; 95% confidence interval [CI], 0.75–1.15; P = 0.59). The incidence of ePRO-assessed moderate-to-very severe oral mucositis was 13.2% and 18.9% in the intervention and control groups, respectively (RR, 0.70; 95% CI, 0.38–1.29). During the 56-day study period, mucositis reported by ePRO on a median of 2 and 6 days in the intervention and control groups, respectively (median difference −4 days; 95% CI, −5.3 to 8.3 days). The incidence of physician-assessed oral mucositis was 31.9% vs. 41.5% in the intervention and control groups, respectively (RR, 0.77; 95% CI, 0.54–1.09). The incidence of grade ≥ 3 adverse events was 6.2% and 6.6% in the intervention and control groups, respectively (RR, 0.94; 95% CI, 0.34–2.58). However, the incidence of oral candidiasis was higher in the intervention group (5.4% vs 0%). **Conclusions:** Prophylactic dexamethasone mouthwash did not significantly reduce all-grade oral mucositis at 8 weeks. Overall safety was comparable between groups; however, the incidence of oral candidiasis was higher in the intervention group. Clinical trial information: jRCTs071240036. Research Sponsor: Japan Agency for Medical Research and Development.

Cardiovascular disease incidence in women with early-onset breast cancer. First Author: Vidhya Nair, University of Washington, Seattle, WA

Background: Early-onset breast cancer (BC) before age 40 is generally associated with advanced stage at diagnosis and worse outcomes. Improvements in detection and treatment have led to reduction in BC mortality. Cardiovascular disease (CVD) is the leading cause of non-BC death in women with BC, but younger women are traditionally considered to be at lower risk for CVD. Given the limited data on CVD in early-onset BC, this study evaluates incident CVD in women younger than age 40 in the Pathways Heart Study. **Methods:** The Pathways Heart Study (R01/U01CA214057) is an ongoing, prospective cohort study including 14,402 women diagnosed with BC at KPNC from 2005-2013 and followed through 2021. In this study, eligible BC cases were women age 18-39 years at time of stage I-III BC diagnosis without pre-existing CVD. Cases were matched 1:5 to controls without BC on age at diagnosis and race/ethnicity. Cancer treatment, CVD (ischemic heart disease, heart failure, cardiomyopathy, stroke) and cardiometabolic risk factors (hypertension, diabetes, hyperlipidemia) were extracted from electronic health records. Cumulative incidence rates (CIR) were calculated as number of incident CVD events divided by total person-time at risk and expressed per 1,000 person-years. **Results:** A total of 535 women with early-onset BC were matched to 2,651 controls. Mean age was 35.1 years with mean follow up of 7.8 years. Overall, cases had a higher CIR of CVD (3.40 per 1,000 person-years (PY)) than controls (1.37/1000 PY). CIRs of hypertension, dyslipidemia, and diabetes were higher in cases compared to controls (14.89, 12.14, and 9.74/1000 PY, respectively). Among BC types and stage, women with hormone receptor-positive HER2-positive and stage III BC had the highest CVD CIRs (7.14 and 5.65/1000 PY, respectively). Women who received chemotherapy with anthracyclines and those who received endocrine therapy had higher CVD CIRs compared with those who did not, while there were no differences by receipt of radiation therapy (Table 1). **Conclusions:** Although the absolute incidence of CVD was low in BC patients younger than 40 years, these patients experienced a >2 fold higher CVD rate compared with matched controls. Patients treated with anthracyclines and endocrine therapy had higher CIR of CVD compared with those not treated. Future analyses will include formal comparison through survival and regression models of incident CVD and cardiometabolic disease in women with early-onset BC, accounting for confounders, including treatments received, education, income, and comorbidities. Research Sponsor: National Cancer Institute.

Machine learning (ML)-based prediction of fatal immune checkpoint inhibitor (ICI)–associated myocarditis (MC) with multi-cohort validation. First Author: Hassan M. Abushukair, Stephenson Cancer Center, Oklahoma City, OK

Background: ICI-associated MC is a rare but highly fatal immune-related adverse event (irAE). Identifying clinical predictors of MC-specific fatality remains an unmet need. Herein, we develop and externally validate an ML model to predict ICI-MC fatality using clinical and laboratory features. **Methods:** The WHO Vigibase database was queried through December 22, 2024, to identify cases of ICI-MC with complete clinical data, including age, sex, cancer and ICI type, co-occurring irAEs, overlap status with myositis (MS) and/or myasthenia gravis (MG), MC timing from ICI start, and MC-specific fatality. Multivariable logistic regression was used to assess correlates of MC-specific fatality. An XGBoost ML model using all collected clinical data was trained to predict MC-specific fatality using an 80/20 split of data for training and testing. We augmented our clinical ML model with troponin (T or I) values at the time of ICI-MC diagnosis from two institutions (n = 37: OU n = 13, MGH n = 24), normalized to institutional upper limits of normal. Two additional external cohorts (n = 68: VUMC n = 18, MDACC n = 50) were used to validate our final clinical and augmented models. **Results:** We identified 822 cases from VigiBase with ICI-MC, with a median age of 69 years (IQR: 60-76), 59.1% (n = 486) were males. Pts with lung cancer had the highest proportion of cases (23.7%, n = 195). Most patients received ICI monotherapy (59%, n = 485). Median time to MC onset was 30.4 days (IQR: 21-91.3). MC occurred alone in 588 cases (71.5%) and with MS and/or MG in the remainder. MC-specific fatality occurred in 147 cases (17.9%). After multivariable adjustments, MC onset within the first month of ICI start was associated with higher MC-fatality odds vs. later onset (vs 1-3 months: ROR = 0.38 [0.21-0.67], vs 3-12 months: ROR = 0.5 [0.25-0.95]). Co-occurring non-MC major cardiac adverse events (ROR: 0.27 [0.17 - 0.44]) and pneumobronchitis (ROR: 0.29 [0.11 - 0.78]) were also associated with increased MC-specific fatality. The optimized MC-fatality clinical ML model achieved AUCs of 0.76 (training) and 0.73 (testing), with early MC onset as the most contributing feature. External validation (n = 37) of our clinical model yielded an AUC of 0.74. Augmenting our clinical ML model with baseline troponin (n = 37) significantly improved performance (AUC: 0.79, likelihood-ratio p = 0.046), with a further external validation (n = 68) AUC of our augmented ML model of 0.67. Our ML model is available online for use through: https://ohbiolab.shinyapps.io/ici-mc_fatality_predictor/. **Conclusions:** ICI-MC timing and co-occurring cardio-pulmonary reactions are key determinants of MC-specific fatality. Our findings highlight the potential promise for early risk stratification to identify high-risk pts with ICI-MC who could benefit from closer monitoring or more tailored immuno-suppressive interventions at ICI-MC diagnosis. Artificial intelligence surrogate models to predict long-term cardiovascular effects of immune checkpoint inhibitor therapies using electrocardiograms. First Author: Frances Dean, University of California, San Francisco, San Francisco, CA

Background: Immune checkpoint inhibitors (ICI) revolutionized the treatment landscape for many cancers, with close to 50% of cancer patients now ICI eligible. Acutely, ICI are associated with myocarditis. Long term cardiovascular effects of ICI are less clear. We built artificial intelligence (AI) models as surrogates for predicting long-term cardiovascular disease (CVD) after ICI using electrocardiograms (ECG). **Methods:** Using data from over 80,000 cancer patients treated from 1986 to 2021 at the University of California, San Francisco, we develop two ECG AI models as surrogates for risk over time of CVD. First, we built a model of observed CVD using true outcomes in a time to event framework. This model is a surrogate for prevalence under the current standard of care. Second, we build a model for causal outcomes using before-and-after data and estimate risk from ECGs for causal analyses. We hold out patients (N=15,277), including all those treated with anthracyclines (N= 3,681), trastuzumab (N=751), or ICI (N= 3,572), for evaluation. Causal effects are estimated with paired pre and post treatment ECGs within three years. **Results:** Models have average AUC across CVDs and years of 0.78 and 0.77. The observed model estimates ICI treated patients compared to those with any other cancer treatment have higher average 10-year risk of ischemic heart disease (IHD) by 10% (95% CI: 2-18%), venous thromboembolism (VTE) by 10% (1-20%), and critical ventricular arrhythmias (CVA) by 10% (3-19%), largely due to high baseline risk. Anthracycline and trastuzumab treated patients did not have higher 10-year heart failure (HF) risk relative to other treatments in aggregate. The causal framework estimates anthracyclines increased average 10-year risk of HF by 45% and trastuzumab by 46%. Anthracyclines and trastuzumab significantly increased risk of atrial fibrillation, IHD, ischemic stroke, CVA, VTE, and conduction disorders as well. ICI increased risk of each of these significantly by smaller amounts. Notably, after ICI, average 10-year risk of HF increased by 32% and IHD by 17%. **Conclusions:** Our study demonstrates potential long-term CVD effects of ICI as estimated from ECGs. This framework can be used to evaluate effects of new therapies in the future. Research Sponsor: U.S. National Science Foundation; DGE 2146752.

10-year pre/post treatment relative risks.

CVD	Anthracycline	Trastuzumab	ICI
Atrial fibrillation	1.34 [1.29, 1.39]	1.30 [1.24, 1.36]	1.25 [1.21, 1.28]

The impact of body composition on cardiac function in women with early breast cancer taking cardiotoxic chemotherapy. First Author: Gabriel Aleixo, University of Pennsylvania, Philadelphia, PA

Background: Anthracyclines and HER2-directed therapies have improved survival in early breast cancer (EBC), but cardiotoxicity remains a concern for long-term survivors. Cardiovascular disease may ultimately exceed breast cancer as a cause of death, highlighting the need for better understanding of therapy-related cardiac dysfunction. Body composition abnormalities are linked to adverse cardiovascular outcomes but are not well captured by body mass index are understudied. We evaluated longitudinal associations between baseline CT-derived body composition and echocardiography measures of cardiac structure and function. **Methods:** This is a retrospective analysis of women with stage I–III EBC treated with anthracyclines and/or trastuzumab at the University of Pennsylvania. Eligible patients had a pre-treatment and ≥1 follow-up echocardiogram and pre-treatment abdominal CT or PET-CT imaging for body composition assessment. L3-based segmentation quantified skeletal muscle mass, muscle density (SMD), subcutaneous and visceral adiposity (SAT, VAT), and adipose tissue density (SATD, VATD). Core-lab echocardiographic outcomes included systolic function (LVEF, GLS) and diastolic function (E/e′). Using multivariable-adjusted generalized estimating equations (GEE) models, we evaluated longitudinal associations between baseline body composition (per 1-SD increase) and two complementary outcomes for each metric: (1) absolute values over time (overall burden) and (2) change from baseline (within-participant worsening). **Results:** Across 182 participants, the median age was 49.5 years (Q1-Q3 41–60), HER2-positive disease was present in 64 (35.4%), estrogen receptor–positive disease in 114 (62.6%), and triple-negative disease in 37 (20.4%). Anthracycline-based therapy was administered to 150 (82.4%), radiation therapy to 140 (76.9%), and mastectomy was performed in 106 (58.6%). Baseline hypertension, hyperlipidemia, and diabetes were present in 56 (30.8%), 43 (23.6%), and 12 (6.6%), respectively. In multivariable-adjusted GEE models, higher baseline VAT was associated with a greater decline in LVEF over time (−2.1 LVEF points per 1-SD increase; 95% CI −4.1 to −0.1; p=0.04). We next evaluated diastolic function, where higher baseline VAT was associated with a greater increase in E/e′ over time (β 0.38 per 1-SD increase; 95% CI, 0.01 to 0.74; p=0.04). In models evaluating absolute E/e′ over time, higher VAT (β 0.51; 95% CI, 0.11 to 0.91) and SAT (β 0.37; 95% CI, 0.06 to 0.59), and lower SMD (β −0.34; 95% CI, −0.66 to −0.02) and VAT density (β −0.36; 95% CI, −0.67 to −0.05) were associated with higher E/e′. No adjusted associations were observed for longitudinal change in GLS (all p>0.05). **Conclusions:** Baseline visceral adiposity was associated with worsening in longitudinal changes in systolic and diastolic function during cardiotoxic breast cancer therapy. Research Sponsor: None.

12022 **Poster Session**

Exercise and cardiovascular risk among breast cancer patients. First Author: Erika Libiar Estrada, Kaiser Permanente Southern California, Research and Evaluation Department, Pasadena, CA

Background: Breast cancer is the most common cancer among U.S. females, accounting for 15% of new diagnoses. As survivorship increases, cardiovascular disease (CVD) has become a major cause of long-term morbidity and mortality. Survivors remain at elevated risk for CVD due to treatment-related cardiotoxicity and underlying risk factors. Despite this growing burden, evidence on whether exercise mitigates cardiac dysfunction remains limited and inconsistent. This study examines the association between physical activity and subsequent CVD and mortality outcomes among breast cancer patients with documented Exercise Vital Sign (EVS) data. **Methods:** A retrospective cohort study was conducted within the Kaiser Permanente Southern California (KPSC) health system. Adult members (≥18 years) with primary breast cancer diagnosed from 2011–2019 were identified through the KPSC cancer registry. Eligible patients had ≥12 months of continuous enrollment and at least two encounters (separated by ≥1 month) with EVS data in the year prior to diagnosis. Physical activity was defined using median exercise volume: completely inactive (0 min/week; reference), insufficiently active (IA; > 0– < 149 min/week), and sufficiently active (SA; ≥150 min/week). Outcomes included all-cause, cancer-specific, and CVD mortality; congestive heart failure (CHF); cardiomyopathy; and major adverse cardiovascular events (MACE). Cox proportional hazards models adjusted for demographic factors, lifestyle characteristics, tumor features, insurance type, and pre-existing cardiovascular comorbidities. **Results:** Among the cohort (N = 12,481), compared with the completely inactive group, SA was associated with lower risk of CHF (HR 0.74; 95% CI 0.59–0.89). For MACE, both IA (HR 0.78; 95% CI 0.71–0.86) and SA (HR 0.66; 95% CI 0.59–0.74) demonstrated decreased risk. Similar reductions were observed for all-cause mortality (IA HR 0.75; 95% CI 0.68–0.83; SA HR 0.62; 95% CI 0.54–0.70), cancer-specific mortality (IA HR 0.82; 95% CI 0.71–0.96; SA HR 0.69; 95% CI 0.57–0.83), and CVD mortality (IA HR 0.68; 95% CI 0.58–0.79; SA HR 0.53; 95% CI 0.43–0.65). Physical activity was not associated with reduced cardiomyopathy risk. **Conclusions:** Physical activity appears to reduce cardiovascular and mortality risk among breast cancer survivors in a dose-responsive manner, with SA patients experiencing the greatest benefit. Even insufficient activity was associated with improved prognosis compared with complete inactivity, supporting the incorporation of exercise promotion into survivorship care. Regular physical activity may reduce CVD and mortality risk among breast cancer survivors, supporting routine EVS screening and referral to exercise or cardio-oncology programs in survivorship care. These findings also reinforce the need for institutional and payer policies that prioritize exercise assessment and counseling as standard components of cancer survivorship care. Time-resolved cardiovascular risk after immune checkpoint inhibitors: A large real-world cancer cohort study. First Author: Yibin Jia, Qilu Hospital of Shandong University, Jinan, China

Background: With expanding use of immune checkpoint inhibitors (ICIs), immune-related toxicities increasingly influence outcomes beyond tumor control. Cardiovascular events are among the most consequential yet potentially preventable complications. Given the low incidence of major adverse cardiovascular events (MACE) and their relatively narrow post-initiation window, reliable time-resolved risk estimation requires very large cohorts, which remain scarce, limiting evidence to guide surveillance and prevention. **Methods:** We conducted a pan-cancer retrospective cohort study (N = 269,257; mean follow-up 4.5 years) using a large real-world cancer registry from Shandong Provincial Center for Disease Control and Prevention. Patients receiving ICIs after their broad clinical implementation were compared with patients treated in the pre-ICI era without immunotherapy, a design chosen to mitigate indication-related differences observed in the contemporary setting. Propensity scores derived from elastic net regularization were used to construct overlap weights for balancing covariates across cohorts. We evaluated MACE, AMI (acute myocardial infarction), and stroke across four prespecified intervals (0–90, 91–180, 181–270, and 271–365 days) using interval-stratified weighted Cox models. Absolute risk differences were further characterized using weighted incidence density differences and restricted mean survival time. **Results:** All covariates achieved excellent balance (maximum |SMD| = 0.004) after weighting. ICI exposure was associated with higher 1-year MACE risk (HR, 1.17; 95% CI, 1.12–1.23; P < 0.001), corresponding to a weighted incidence density difference of 10.90 per 1,000 person-years (95% CI 8.73–13.06). The largest absolute risk increase was observed during 0–90 days after ICI initiation(weighted incidence density difference, 17.83 per 1000 person-years; 95% CI, 12.43 to 23.24).The risk of AMI peaked early, with a statistically significant association observed only during 0–90 days (HR, 1.86; 95% CI, 1.54–2.24; P < 0.001). In contrast, stroke risk peaked during days 91–180 (HR, 1.27; 95% CI, 1.11–1.44; P < 0.001) and remained significantly elevated through 181–270 days (HR, 1.25; 95% CI, 1.08–1.44; P = 0.003). Stroke accounted for 51% (95% CI: 19% to 83%), 63% (95% CI: 37% to 89%), 66% (95% CI: 43% to 90%), and 67% (95% CI: 45% to 88%) of the total weighted incidence density difference for MACE during days 0–90, 0–180, 0–270, and 0–365, respectively. **Conclusions:** ICI exposure was associated with temporally heterogeneous cardiovascular risk, with AMI concentrated in the first 90 days and stroke risk remaining elevated thereafter. These results suggest a time-tailored approach to cardio-oncology care, characterized by intensified early monitoring for AMI and sustained attention to stroke prevention in subsequent months. The genetic polymorphism underlying immune checkpoint inhibitor–induced endocrine toxicity. First Author: Ming-Hua Cong, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer therapy by enhancing T cell–mediated anti-tumor immunity; however, immune-related adverse events (irAEs)—particularly endocrine toxicities (e.g., thyroiditis, hypophysitis, adrenal insufficiency; incidence 5–15%)—pose significant clinical risks, including lifelong hormonal dependency. Although germline genetic factors, especially human leukocyte antigen (HLA) variants, are implicated in irAE susceptibility, prior studies lack granularity in toxicity subtyping and comprehensive genetic characterization across diverse clinical contexts. **Methods:** We integrated high-resolution HLA genotyping with precise phenotypic annotation of endocrine irAEs (subclassified by organ specificity, onset, severity per CTCAE v5.0) in multi-center retrospective and prospective cohorts. A hypothesis-free genome-wide approach identified novel HLA loci, followed by functional validation of candidate variants. Machine learning models were trained to predict toxicity risk by integrating HLA markers with clinical covariates (ICI type, cancer diagnosis, baseline characteristics). **Results:** Subtype-specific HLA associations were identified (e.g., distinct *HLA-DRB1* alleles linked to thyroiditis versus hypophysitis). Collinearity analysis revealed significant positive correlations between non-endocrine irAE pairs (e.g., capillary hyperpermeability and gastrointestinal ulcers; $P < 0.01$), suggesting shared immunopathogenic pathways. The integrated risk model demonstrated robust stratification performance for endocrine toxicity susceptibility. Cohort demographics reflected real-world ICI utilization patterns (predominantly lung cancer), while clinical response data underscored challenges in achieving durable remission (notable progression rates). **Conclusions:** This study delineates the HLA-driven genetic architecture underlying endocrine irAEs and elucidates interdependencies among irAE subtypes. Integration of genetic risk profiling with clinical parameters enables personalized toxicity risk assessment, advocating for proactive, multidisciplinary monitoring protocols. These findings advance precision immunotherapy by informing biomarker-guided patient selection, optimizing safety, and refining clinical decision-making frameworks for ICI administration. Cardiac safety of L-annamycin at high cumulative anthracycline exposure: Pooled analysis. First Author: Robert C. Shepard, Moleculin Biotech, Houston, TX

Background: Anthracyclines are widely used chemotherapeutic agents but limited by dose-dependent cardiotoxicity and lifetime cumulative dose restrictions. L-Annamycin is a next-generation anthracycline designed to eliminate cardiotoxicity and overcome multidrug resistance. In a Phase 1b/2 study in patients with acute myeloid leukemia (AML), L-Annamycin administered in combination with cytarabine as second-line therapy achieved a 50% complete remission (CR) rate and a 60% composite CR (CRc) rate with a median overall survival of 12.39 months (95% CI, 2.07–13.96) in the intent-to-treat population. We evaluated the cardiac safety of L-Annamycin in multiple clinical trials to assess its ability to support sustained anthracycline exposure in patients with AML and soft tissue sarcoma. **Methods:** Cardiac safety was evaluated across sponsor- and investigator-initiated clinical trials of L-Annamycin. Assessments included serial 12-lead electrocardiograms (ECGs), cardiac biomarkers (troponin I and T), and transthoracic echocardiography with centralized evaluation of left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS), where available. Cardiac data were reviewed independently by a reviewer in the Division of Cardiovascular Medicine at the Cleveland Clinic. Changes in LVEF from baseline to final assessment were analyzed in relation to cumulative L-Annamycin dose and patient age. **Results:** An independent cardiac safety review was conducted for 90 patients who were treated with L-Annamycin across five completed clinical trials; 78 of these patients now have source-verified pre- and post-treatment left ventricular ejection fraction (LVEF) assessments. The median cumulative L-Annamycin dose among these patients was 660 mg/m² (95% CI, 645–690; range, 210–2,970 mg/m²), with most of the cumulative doses exceeding conventional lifetime anthracycline limits. Analysis of the change in LVEF from baseline to final assessment demonstrated no statistically significant difference (mean difference, −0.12%; 95% CI, −1.34 to 1.09; p = 0.84). Linear regression analysis documented no correlation between cumulative L-Annamycin dose and change in LVEF (p = 0.12), nor between patient age and change in LVEF (p = 0.73). Independent review of serial ECGs, cardiac biomarkers, cardiac adverse events, and available global longitudinal strain measurements also demonstrated no evidence of drug-induced cardiotoxicity. **Conclusions:** L-Annamycin was not associated with any detectable cardiotoxicity despite high cumulative anthracycline exposure. These findings suggest that L-Annamycin represents a next-generation anthracycline capable of delivering effective anthracycline therapy without traditional cumulative dose limitations, thus further supporting its ongoing pivotal Phase 2b/3 trial in AML patients. The association between cardiovascular disease risk and breast arterial calcifications identified on screening mammography: A retrospective study. First Author: Tae Hoon Kim, Valley Health System, Paramus, NJ

Background: Screening mammography enables early breast cancer detection and improves outcomes. Breast cancer and cardiovascular disease (CVD) share several overlapping risk factors in women. Breast arterial calcifications (BACs) are non-occlusive calcifications of the medial layer of small to medium-sized arteries in the breast that can be identified on mammography. Prior studies have demonstrated an association between BACs and increased cardiovascular risk with growing evidence suggesting that BACs may serve as a non-invasive, low-cost screening tool for CVD. Currently, routine screening for BACs is not uniformly performed. This study aimed to evaluate the prevalence of BACs in screening mammograms, and to characterize associated atherosclerotic cardiovascular disease (ASCVD) risk scores and cardiovascular risk factors among individuals with BACs. **Methods:** We performed a retrospective analysis of 650 individuals undergoing screening mammography at our institution from 2023 to 2025. Data collected included patient demographics, medical and social history, and cardiovascular risk factors, including blood pressure, diabetes mellitus, and lipid profiles. ASCVD risk scores were calculated for each individual. Statistical analyses, including chi-square test and T-test, were performed to evaluate associations between the presence of BACs, cardiovascular risk factors, and ASCVD scores. **Results:** Among the 650 women who underwent screening mammography, n = 641 had BI-RADS 1 (negative) or 2 (benign) results, while n = 9 had an abnormal mammogram that subsequently led to a breast cancer diagnosis. BACs were identified in 15.1% of the participants (n = 98). BAC prevalence increased significantly with age: 2.3% among women aged 40-49 years, 8% in those aged 50-59 years, 18.4% in those aged 60-69 years, and 42.2% among women aged 70 years and older ($p < 0.001$). Among participants with available ASCVD risk data (n = 429), BAC-positive patients had a significantly higher mean 10-year ASCVD risk when compared with BAC-negative patients (14.0% vs 5.23%, $p < 0.001$). Among the BAC-positive patients, 61.2% were categorized as ASCVD intermediate or high risk versus 20.8% of BAC-negative patients ($p < 0.001$). BAC-positive patients also exhibited higher mean systolic blood pressure (123.76 vs 120.66 mm Hg, p = 0.042). Hemoglobin A1c, total cholesterol, diastolic blood pressure, and smoking status did not differ significantly between the two groups. **Conclusions:** Breast arterial calcifications identified on screening mammograms were significantly associated with less favorable cardiovascular risk profiles. Implementation of routine BAC reporting may enable opportunistic CV risk detection during breast cancer screening, potentially leading to earlier preventive interventions. Research Sponsor: None.

Differences in the receipt of recommended cardiovascular assessment among cancer survivors in the United States by atherosclerotic cardiovascular disease status. First Author: Reed Mszar, Yale School of Public Health, New Haven, CT

Background: Cardio-oncology guidelines recommend annual cardiovascular (CV) assessment among cancer survivors, particularly those with pre-existing atherosclerotic cardiovascular disease (ASCVD). Despite this, little is known regarding the proportion of cancer survivors receiving comprehensive CV assessment and whether certain subgroups experience suboptimal uptake. We investigated the prevalence and predictors of receiving recommended comprehensive CV assessment (i.e., cholesterol, blood pressure, blood glucose) among cancer survivors in the United States. **Methods:** We used self-reported, cross-sectional data from the National Health Interview Survey (2012-2018), an annual, weighted survey that uses multistage sampling and interviews to produce nationally representative estimates of the noninstitutionalized U.S. population. Adults with cancer and complete information on ASCVD status (defined as a history of myocardial infarction, stroke, coronary heart disease, or angina) were included. To examine the association between sociodemographic characteristics and lack of recommended CV assessment within the past year, adjusted odds ratios (aOR) and 95% confidence intervals (CI) were calculated using multivariable logistic regression stratified by ASCVD status. **Results:** Among 16,420 cancer survivors (median age: 65.4 years; 20.1% with ASCVD), representing approximately 15.4 million survivors annually, 38.2% did not receive recommended CV assessment in the past year. Approximately 3.7% of cancer survivors (representing 566,043 individuals annually) received none of the CV assessments. Among cancer survivors with ASCVD, factors associated with increased odds of not receiving recommended CV assessment included lower (vs higher) level of education (aOR, 1.30 [95% CI, 1.01-1.65]). In cancer survivors without ASCVD, these factors included age 18-44 years (vs ≥75 years) (aOR, 1.82 [95% CI, 1.39-2.39]), low/lowest (vs high/middle) income (aOR, 1.23 [95% CI, 1.06-1.44]), uninsured (vs insured) status (aOR, 1.94 [95% CI, 1.37-2.74]), South (vs Northeast) region (aOR, 1.31 [95% CI, 1.05-1.62]), and no (vs yes) usual source of care (aOR, 2.42 [95% CI, 1.66-3.53]). Among all cancer survivors, there was a stepwise increase in receipt of CV assessment with increasing age at initial cancer diagnosis ranging from 52.7% among those aged 18-44 years at diagnosis to 68.5% among those aged 65-74 years at diagnosis ($p < 0.001$). **Conclusions:** More than 1 in 3 cancer survivors did not receive recommended annual CV assessment with several subgroups having even lower screening rates, including by age, socioeconomic status, and access to care. Improving awareness of contemporary cardio-oncology guidelines and targeting interventions during cancer survivorship are needed to increase uptake of optimal CV assessment. Research Sponsor: None.

Efficacy of primary cardioprotection with perindopril, bisoprolol, and trimetazidine in high-risk patients with breast and gastric cancer receiving anthracycline- and trastuzumab-containing therapy. First Author: Evgenia Khatkova, Moscow Clinical Scientific Center Named After A.S. Loginov, Moscow, Russian Federation

Background: Anthracyclines and trastuzumab are the most common antitumor agents associated with a substantial risk of cardiotoxicity (CTX). Patients with high or very high cardiovascular risk represent a vulnerable population where even subclinical myocardial injury can translate into clinically significant cardiac dysfunction. The present study is aimed to evaluate the efficacy of primary cardioprotective therapy (CPT) in preventing both subclinical and overt CTX in high-risk patients undergoing anthracycline (A)- and/or trastuzumab (T)-containing treatment. **Methods:** This single-center prospective observational study included 92 cancer patients (pts) with high or very high risk of CTX according to the Mayo Clinic risk score. The study population consisted of 7 men (8%) and 85 women (92%), with a mean age of 60.6 $\pm$ 11.8 years. Breast cancer (BC) was the most common diagnosis (n = 84; 91%), while gastric cancer (GC) accounted for 8 cases (9%). 17 (33.3%) pts in the intervention group and 16 (39%) pts in the control group had a history of congestive heart failure. AC (doxorubicin/cyclophosphamide) regimen was administered in 54 BC patients, AC followed by T in 30 BC pts, T – in 8 GC pts. The intervention group (n = 51) received primary CPT with perindopril and bisoprolol; trimetazidine was added in patients at very high cardiovascular risk or with established coronary artery disease. The control group (n = 41) did not receive CPT due to intolerance or refusal. Echocardiography with left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS), 24-hour blood pressure monitoring, and multibiomarker assessment (troponin I, NT-proBNP, MPO, sST2) were performed at baseline and at 1, 3, 6, 9, and 12 months. **Results:** The control group showed a significant increase in indexed left atrial volume and indexed left ventricular end-diastolic volume at 6 and 9 months, respectively, indicating cardiac remodeling, which represents one of the earliest manifestations of subclinical cardiotoxicity. GLS reduction $\geq$18% occurred in 21.2% of control pts vs. 7.1% in the intervention group ($p < 0.05$). Clinically significant cardiotoxicity with LVEF decline developed in 6 control pts vs. 1 in the intervention group. Cardiovascular complications were 2.5 times more frequent in the control group (70.1% vs. 24.8%). All-cause mortality at 12 months was significantly higher in the control group (11.7% vs. 5.1%, p = 0.04). **Conclusions:** In high-risk pts with BC and GC receiving anthracycline- and trastuzumab-containing therapy, primary CPT with perindopril, bisoprolol, and trimetazidine effectively prevents adverse cardiac remodeling, preserves myocardial systolic function, reduces the incidence of cardiovascular complications, and is associated with a significant reduction in one-year all-cause mortality. Lipid-lowering therapy use among cancer survivors undergoing lung cancer screening: A cross-sectional analysis. First Author: Sri Gopalsamy Ramaswamy, School of Public Health at Washington University in St. Louis, Saint Louis, MO

Background: Cardiovascular disease (CVD) causes 56% of non-cancer deaths among cancer survivors, yet lipid-lowering therapy (LLT) remains underutilized. Moreover, lung cancer screening (LCS) populations exhibit a dual high-risk profile, characterized by heavy smoking exposure and a history of cancer. We sought to examine the utilization of LLT among cancer survivors undergoing LCS and to identify disparities based on demographics, clinical factors, and social determinants of health. **Methods:** We conducted a cross-sectional study of 7,778 cancer survivors aged 50–80 years who underwent LCS through Barnes-Jewish Healthcare's LCS program between 2015 and 2023. The primary outcome measured was LLT use, specifically statins or statin substitutes, as documented in electronic health records. We assessed for associations with demographics (age, sex, race), clinical factors (prior ASCVD, cancer type), healthcare access (insurance status, rurality via Rural-Urban Commuting Area codes), and the Area Deprivation Index (ADI). The data were analyzed using multivariable logistic regression, adjusted for demographics, insurance status, smoking, indication, and provider, with results stratified by race and sex. **Results:** Overall, 65.8% of cancer survivors undergoing LCS used LLT. Compared with lung cancer, prostate (AOR = 1.35; 95% CI 1.08–1.71), hematologic (AOR = 1.35; 95% CI 1.03–1.76), and other solid cancers (AOR = 1.23; 95% CI 1.07–1.42) were associated with higher LLT use. When stratified by race, among White patients, male sex was associated with higher LLT use (AOR = 1.13; p = 0.036) and rural residence was associated with lower LLT use (AOR = 0.81; p = 0.005); these were not significant factors in Black patients. Prior ASCVD was the strongest associated factor (AOR = 2.54, $p < 0.001$), followed by age $\geq$65 years (AOR = 1.41, $p < 0.001$). Rural residence was associated with 29% lower odds of LLT use (AOR = 0.71, $p < 0.001$) even after adjusting for all other factors. Insurance status, and neighborhood deprivation were not associated with LLT use. **Conclusions:** LLT remains underused among cancer survivors at high cardiovascular risk, even during routine LCS. Rural patients were less likely to receive therapy, underscoring persistent geographic gaps in preventive care. The strong association of prior ASCVD with LLT use suggests that therapy is still primarily utilized reactively rather than preventively. Improving follow-up and care coordination during screening could help close prevention gaps and reduce heart disease deaths in cancer survivors. Research Sponsor: National Cancer Institute; Alvin J. Siteman Cancer Center at Washington University School of Medicine.

Predicting fluoropyrimidine cardiotoxicity using a focus beyond routine cardiovascular risk assessment. First Author: Aminat Maaz Yusupova, Moscow Cardio-Oncology Center of S.S.Yudin City Clinical Hospital, Moscow, Russian Federation

Background: Fluoropyrimidines remain backbone of systemic therapy for colorectal cancer (CRC) but are associated with diverse cardiovascular (CV) toxicities ranging from hypertension to heart failure. Current CV risk stratification tools have uncertain predictive value in cancer populations. We aimed to identify clinically actionable predictors of CV complications during fluoropyrimidine-based therapy. **Methods:** Prospective single-center observational registry included 171 consecutive stage I-IV CRC patients initiating fluoropyrimidine-based chemotherapy between (median follow-up 6.5 months, IQR 3.0-8.0). All patients underwent structured baseline cardio-oncology assessment including CV risk stratification per ESC guidelines, 12-lead ECG, transthoracic echocardiography with global longitudinal strain measurement, and serum biomarkers (NT-proBNP, high-sensitivity troponin I). Primary endpoint was incidence of $\geq$1 prespecified CV complication. Missing data ($<$ 5% for laboratory parameters) were addressed via complete-case analysis. Statistical analysis included χ^2 tests, Mann-Whitney U tests, and multivariable logistic regression with backward elimination (SPSS v28.0, significance $p < 0.05$). **Results:** Overall CV complication incidence was 33%. Event spectrum: Blood pressure destabilization (9%), thromboembolism (pulmonary embolism 5%, deep vein thrombosis 3%), arrhythmias 4,3%, coronary ischemia (angina 2.3%), ischemic stroke 0.6%, left ventricular systolic dysfunction (asymptomatic EF decline 1.8%, symptomatic heart failure 0.6%), moderate hydropericardium (2.3%), and isolated biomarker elevation (2.3%). Univariate analysis identified significant associations with CV complications for: diabetes mellitus (DM) (26.8% vs 10.4%, p = 0.006, OR 3.2), obesity (41.1% vs 26.1%, p = 0.047, OR 2.0), age (median 66.3 vs 63.1 years, p = 0.041), and high/very-high baseline CV risk (37.5% vs 14.3%, p = 0.009, OR 3.6). In multivariable analysis adjusting for age, sex, obesity, hypertension, and baseline CV risk category, only DM retained independent predictive value (adjusted OR 3.14, 95% CI 1.35-7.28, p = 0.008). Baseline NT-proBNP elevation correlated with increased all-cause mortality (58.3% vs 22.0%, p = 0.010) despite absence of CV deaths (all 12 deaths from cancer progression). **Conclusions:** Diabetes mellitus is the strongest independent predictor of CV toxicity in CRC patients receiving fluoropyrimidine chemotherapy, associated with 3-fold increased risk. While baseline CV risk stratification showed univariate association, it lost significance in adjusted analysis, highlighting DM's primacy. Systematic cardio-oncology monitoring appears effective given zero CV mortality. These data support prioritizing diabetic patients for intensified CV surveillance during fluoropyrimidine therapy. Cost-effectiveness of post-discharge home care for reducing potentially avoidable readmissions in stage IV cancer. First Author: Amal AlJuhani, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: Approximately 39% of hospital readmissions among stage IV cancer patients are potentially avoidable. These readmissions increase healthcare costs, reduce quality of life, and increase mortality. Home-based care may reduce avoidable readmissions through symptom management and care coordination, but cost-effectiveness in this population remains unknown. Objective: To evaluate the cost-effectiveness of home with care versus home without care for stage IV solid tumors patients post-discharge, from an Ontario public payer perspective. **Methods:** A four-state Markov model (Care, Readmission, Discharged, Death) was developed with week-long cycles with a 180 day horizon. Weekly potentially avoidable readmission rates were 1.8% (home with care) versus 5.4% (home without care). Utilities (0.65 vs 0.55) and costs (home care $100/day; readmission $994/day) were from Canadian sources. Primary outcome was incremental cost-effectiveness ratio (ICER) per quality-adjusted life-year (QALY). One-way, two-way, and probabilistic sensitivity analyses (1,000 simulations) were conducted. Value of information analysis quantified decision uncertainty. Costs and QALYs were discounted at 1.5% annually. **Results:** Home with care produced 0.166 QALYs at $12,251 versus 0.105 QALYs at $7,386, yielding 0.061 incremental QALYs (22 quality-adjusted days) at $4,865 incremental cost (ICER: $79,955/QALY). Home care cost was the most influential cost parameter with a threshold of $115/day. Probabilistic analysis showed 60% probability of cost-effectiveness at willingness-to-pay (WTP) $100,000/QALY, with acceptability curves crossing at $80,000/QALY. Expected value of perfect information peaked at $1,500/patient. **Conclusions:** Home with care may represent a cost-effective option for stage IV cancer patients at or below the commonly accepted Canadian WTP threshold of $100,000/QALY, with robust findings across sensitivity analyses. Program costs are the primary value determinant, supporting policy consideration for post-discharge support services. Research Sponsor: None.

Cost-effectiveness results: Home with care versus home without care.

Outcome	Home with Care	Home without Care	Difference
Total cost	$12,251	$7,386	+$4,865
Total QALYs	0.166	0.105	+0.061
Quality-adjusted days	60.6	38.3	+22.3
ICER	–	–	$79,955/QALY
Probability cost-effective at WTP $100,000/QALY	60%	40%	–

QALY = quality-adjusted life-year; ICER = incremental cost-effectiveness ratio; WTP = willingness-to-pay. Costs in 2024 Canadian dollars.

12032 Poster Session

County-level palliative care physician density and socioeconomic determinants of place of cancer death in the United States, 2021-2023. First Author: Ruoxi Teng, Department of Biostatistics, Yale University, New Haven, CT

Background: Palliative care, a specialized approach focused on care for individuals with serious illness including cancer, has been shown to improve end-of-life outcomes, including higher rates of death in preferred settings. However, access to palliative care remains inequitable due to significant geographic disparities in workforce distribution. This study examines the association between county-level palliative care physician density and place of death among US decedents died from cancer. **Methods:** We conducted a retrospective cohort study using CDC WONDER multiple cause of death data (2021-2023) linked with palliative care physician supply data from the American Medical Association (AMA) Physician Masterfile. The primary exposure was county-level palliative care physician density, categorized as zero, below-median, or above-median (among non-zero counties). The primary outcome was the county-level percentage of cancer deaths (ICD: C00-C97) occurring in non-hospital settings (home, hospice, long-term care, or nursing home). Covariates include county sociodemographic characteristics (race/ethnicity, median income, region, metropolitan status) and hospice facility availability. Multivariable regression models estimated associations between physician density and place of death, adjusting for other covariates. All models incorporated county population weighting and state-level clustering. **Results:** Most U.S. counties (n = 2056, 66.27%) had no palliative care physicians in 2020. Counties with palliative care physicians showed higher median household incomes, more hospice facilities and metropolitan status, and were concentrated in the Northeast and West (all $p < 0.001$). The average percentage of non-hospital facility deaths across all counties was 56.6% (SD = 7.1) for all causes, 60.5% (SD = 8.1) for heart disease, and 70.7% (SD = 8.0) for malignant neoplasms. Multivariable regression models revealed a dose-response relationship: counties with non-zero below median and above-median palliative care physician density showed 0.9 percentage points (ppts, $p < 0.05$) and 1.1 ppts ($p < 0.05$) higher proportions of cancer death at non-hospital facility-based facilities than counties without palliative care physicians. In addition, Metropolitan and Micropolitan counties had 2.5 ppts ($p < 0.001$) and 2.1 ppts ($p < 0.001$) higher proportions of cancer death at non-hospital facility-based facilities than non-metropolitan counties respectively. **Conclusions:** Higher county-level palliative care physician density is associated with increased non-hospital facility-based deaths for cancer, demonstrating a clear dose-response relationship. These findings suggest that ensuring access to palliative care, through workforce expansion or care delivery model innovation may facilitate end-of-life care planning aligned with patient preferences. Palliative care involvement at the end of life in advanced cancer. First Author: Rhea Sehgal, School of Medicine, Wayne State University, Detroit

Background: High-intensity end-of-life (EoL) care in advanced cancer is common, costly, and often misaligned with patient goals, despite limited survival benefits. Value-based oncology emphasizes high-quality, goal-concordant care while reducing non-beneficial interventions. Palliative care is central to this model, yet its impact on overall spending versus patterns of care intensity near death remains unclear. We evaluated whether palliative care involvement in the final 30 days of life was associated with differences in total expenditures and healthcare resource allocation in patients with advanced cancer. **Methods:** We conducted a retrospective cohort study of adults with advanced cancer who died within an integrated health system between 2022 and 2025. Palliative care exposure was defined as $\geq$1 palliative encounter within 30 days of death. Financial data were obtained from enterprise cost-accounting systems; clinical and utilization data were derived from the electronic health record and institutional cancer registry. Outcomes included total 30-day healthcare charges and proportional spending across major service categories reflecting care intensity. Median charges were compared using Wilcoxon rank-sum tests, and spending distributions were analyzed via chi-square tests. **Results:** Among 1,635 decedents, 195 received palliative care within 30 days of death, a period associated with the highest concentration of EoL healthcare use. Median total 30-day charges did not differ significantly between patients who received palliative care and those who did not ($14,610 vs $17,100; p = 0.054). However, palliative care involvement was associated with a significant shift in spending patterns. Compared with patients without palliative care, those receiving palliative care had a lower proportion of spending on inpatient, procedural, diagnostic, and therapeutic services and a higher proportion on pharmacy, invasive therapeutic, home health, and hospice services. Overall spending distribution differed significantly between groups (p = 0.046). Across the cohort, inpatient and observation services accounted for the largest share of expenditures, followed by pharmacy, procedural, and invasive therapeutic services, with hospice representing a minority of total spending. **Conclusions:** EoL palliative care involvement was not associated with significant reductions in total healthcare spending but was linked to differences in care intensity, reflected by a redistribution of expenditures from inpatient and procedural services to pharmacy, invasive therapeutic, and home health care. The value of palliative care in oncology lies not in cost savings but in promoting high-quality EoL care that aligns with patient goals and oncology care priorities. Future analyses will include patient-reported outcomes to examine how shifts in care intensity and spending relate to EoL symptom burden, quality of life, and goal-concordant care. Research Sponsor: None.

End-of-life anti-cancer treatment (Rx) patterns in patients (pts) with the six most common cancers in the USA. First Author: Umang Swami, Department of Medicine, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: Pts with $\leq$ 6 months of life expectancy qualify for hospice. However, most pts with advanced/metastatic (a/m) cancer continue to receive Rx up to weeks prior to death. Data describing end-of-life Rx patterns in these pts remain limited but are essential to improve clinical care delivery. Herein, we evaluated real-world Rx patterns in relation to the time of death across 6 most common a/m solid tumors: advanced non-small cell lung cancer (aNSCLC), metastatic breast cancer (mBC), metastatic prostate cancer (mPC), advanced colorectal cancer (aCRC), metastatic pancreatic cancer (mPanC), and advanced urothelial carcinoma (aUC). **Methods:** This study used the US-based, electronic health record-derived deidentified Flatiron Health Research Database. Eligibility: diagnosis of aNSCLC, mBC, mPC, aCRC, mPanC and aUC, had a recorded date of death, and information on initiation of first-line (1L) Rx. The data cutoff date was 6/30/2025. Pts were categorized as treatment-free if no systemic Rx was administered within the final 1 or 3 months of life, or on-treatment if systemic Rx was received within 1 or 3 months before death. Demographic and clinical variables at the last line of Rx initiation, including age, race, socioeconomic status, practice type, and insurance, were summarized using medians (IQR) or proportions. **Results:** Of 111,337 pts with aNSCLC, 82,339 had a recorded date of death, of whom 59,777 initiated 1L Rx. Of 43,218 pts with mBC, 26,572 had a recorded date of death, of whom 23,055 initiated 1L Rx. Of 27,979 pts with mPC, 14,793 had a recorded date of death, of whom 9,667 initiated 1L Rx. Of 45,013 pts with aCRC, 29,749 had a recorded date of death, of whom 24,219 initiated 1L Rx. Of 18,942 pts with mPanC, 15,690 had a recorded date of death, of whom 11,528 initiated 1L Rx. Of 15,236 pts with aUC, 10,872 had a recorded date of death, of whom 7,815 initiated 1L Rx. The proportion of pts receiving systemic Rx within 1 month or 3 months before death for each cancer type is summarized in Table. Baseline characteristics, Rx patterns and trends by cancer type will be presented at the meeting. **Conclusions:** Across six most common cancers in the US, systemic Rx use remained common near the end of life, with up to one-third of pts treated in the final month. These findings suggest the need for greater emphasis on early involvement of palliative care teams and timely transition of pts with terminal cancers to comfort care. Research Sponsor: None.

Proportion of pts with a/m cancer receiving systemic Rx within 1 month or 3 months before death.

Cancer type	Eligible pts	Rx within 1 month of death, n (%)	Rx within 3 months of death, n (%)
aNSCLC	59,777	19,268 (32.2)	38,227 (63.9)
mBC	23,055	8,416 (36.5)	15,972 (69.3)
mPC	9,667	2,438 (25.2)	5,762 (59.6)
aCRC	24,219	7,172 (29.6)	15,386 (63.5)
mPanC	11,528	4,191 (36.3)	9,184 (79.7)
aUC	7,815	2,358 (30.2)	5,170 (66.1)

12035 Poster Session

Temporal trends and sociodemographic disparities in place of death among adults with pancreatic cancer in the United States (1999–2023). First Author: Ali Mushtaq, Cleveland Clinic Foundation, Cleveland, OH

Background: Location of death is a critical quality metric for pancreatic cancer due to its rapid trajectory and high symptom burden. While home-based hospice is promoted, it is unclear if shifts from hospital death have been equitable. We analyzed 25-year national trends and independent predictors of place of death. **Methods:** We analyzed CDC WONDER death certificate data (1999–2023) for pancreatic cancer decedents aged $\geq$20 years (ICD-10 C25.x). Place of death categories: Home, Hospice/Nursing Facility, Inpatient, or Outpatient/ER. We calculated annual trends and used multinomial logistic regression to estimate adjusted odds ratios (aOR) with 95% confidence intervals (CI), adjusting for age, sex, race/ethnicity, urbanization, and year. Inpatient death served as the reference category. **Results:** Of 899,332 deaths, acute care hospital deaths declined (34.0% to 21.0%) while home (48.6% to 56.1%) and hospice/nursing facility deaths (15.7% to 21.3%) increased. However, significant disparities persisted. Compared to Non-Hispanic Whites, Black patients were less likely to die at home (aOR 0.55; 95% CI, 0.54–0.56) or in hospice/nursing facilities (aOR 0.63; 95% CI, 0.62–0.65) and significantly more likely to die in Outpatient/ER settings (aOR 1.57; 95% CI, 1.51–1.64). Hispanics were less likely to die in hospice/nursing facilities (aOR 0.57; 95% CI, 0.55–0.58). Rural residents had lower odds of hospice/nursing facility death (aOR 0.89; 95% CI, 0.87–0.91) vs. large metro. Younger age (20–64) was associated with hospital death. **Conclusions:** Despite substantial shifts from hospital to home settings, Black and Hispanic patients remain significantly less likely to access hospice and more likely to die in emergency settings. These findings highlight structural inequities requiring targeted interventions to ensure high-quality end-of-life care for minority populations. Research Sponsor: None.

Multivariable adjusted odds ratios (aOR) for place of death in pancreatic cancer.

Predictor Comparison	Decedent's Home (aOR)	Hospice/Nursing Facility (aOR)	Outpatient or ER (aOR)
Black vs. White	0.55 (0.54–0.56)	0.63 (0.62–0.65)	1.57 (1.51–1.64)
Asian vs. White	0.74 (0.72–0.76)	0.51 (0.49–0.53)	0.85 (0.77–0.95)
Hispanic vs. Non-Hispanic	0.92 (0.90–0.94)	0.57 (0.55–0.58)	1.01 (0.94–1.08)

Impact of social vulnerability on end-of-life care in hematologic malignancies. First Author: Jude O. Ossai, Rutgers/Newark Beth Israel Medical Center, Newark, NJ

Background: Patients with hematologic malignancies frequently receive intensive inpatient care near theend of life. While disparities in end-of-life (EOL) care are well described in oncology, how cumulative social vulnerability shapes treatment intensity and palliative care involvementamong hospitalized patients with hematologic cancers remains unclear. We examined the association between social vulnerability burden and inpatient EOL care patterns using a nationally representative database. **Methods:** We performed a retrospective cohort study using the 2021–2022 National Inpatient Sample of adult hospitalizations with hematologic malignancies. A composite hematologic social vulnerability index (cSVI-Heme) was constructed using validated proxies available in NIS: minoritized race/ethnicity, Medicaid or uninsured status, and lowest ZIP-code income quartile. Hospitalizations were classified as low (0), moderate (1), or high ($\geq$2) vulnerability.The primary outcome was high-intensity EOL care (invasive mechanical ventilation, cardiopulmonary resuscitation, or acute dialysis). Secondary outcomes included palliative care utilization and in-hospital mortality. Associations were assessed using multivariable logistic regression and inverse probability of treatment weighting, adjusting for demographics, comorbidity burden, acute organ failure, sepsis, malignancy subtype, and hospital characteristics. **Results:** The cohort included 202,802 hospitalizations, of which 54.2% were low, 31.0% moderate, and 14.8% high vulnerability. Overall, 5.9% involved high-intensity EOL care, increasing stepwise across vulnerability tiers (5.1% vs 6.5% vs 7.9%; $p < 0.001$). After adjustment, compared with low vulnerability hospitalizations, moderate vulnerability was associated with higher odds of high-intensity EOL care (aOR 1.25, 95% CI 1.19–1.30), and high vulnerability with substantially higher odds (aOR 1.50, 95% CI 1.42–1.58), demonstrating a clear dose–response relationship. Findings were confirmed in propensity-weighted analyses.This gradient was driven primarily by acute dialysis (3.1% vs 4.6% vs 6.2%; $p < 0.001$), while rates of mechanical ventilation and CPR were similar. High vulnerability was independently associated with higher in-hospital mortality (aOR 1.20, 95% CI 1.12–1.28), whereaspalliative care utilization did not increase after adjustment. **Conclusions:** Among hospitalized patients with hematologic malignancies, greater social vulnerability is associated with higher-intensity end-of-life care and increased mortality, with a clear dose–response relationship. These differences are not accompanied by greater palliative care involvement, highlighting a mismatch between treatment intensity and supportive care. Integrating social vulnerability into inpatient hematologic oncology care may support earlier goals-of-care discussions and more equitable EOL care. Research Sponsor: None.

Effects of tai chi qigong on gene expression profiles in older male cancer survivors with fatigue. First Author: Anita Kinney, Department of Biostatistics and Epidemiology, Rutgers School of Public Health, Piscataway, NJ

Background: The HERO trial showed that Tai Chi Qigong (TCQ) reduced fatigue (primary endpoint) in male cancer survivors. Fatigue-related biological pathways influenced by mind-body therapies, such as TCQ, remain poorly defined. This trial hypothesized that TCQ, compared to an exercise-intensity matched (EIM) intervention and usual care (UC), would have a more favorable effect on the regulation of two major fatigue-associated functional gene clusters: a) inflammation-vasodilation-metabolite sensing and b) energy and adrenergic activation among older male cancer survivors with fatigue. **Methods:** In this three-arm randomized trial (NCT 03345563), 113 male cancer survivors aged $\geq$ 55 years with fatigue were randomized to 12 weeks of TCQ (n = 45), EIM (n = 43), or UC (n = 25), delivered twice weekly with recommended home practice. Gene expression profiles were assessed at baseline and at 1 week and 3 months post-intervention using genome-wide transcriptional profiling of blood samples. A key secondary endpoint was changes in gene expression at the 3-month follow-up. A minimum of 8 subjects per study arm is required to achieve 80% power (two-sided alpha = 0.05) to detect a 2.0-fold change in gene expression. Intervention effects were evaluated using an intention-to-treat approach and general mixed linear models, with baseline adjustment and time of sample collection included as time-varying covariates. Multiple comparisons were controlled for using the false discovery rate (FDR). Upregulation of DBI, IL-10, ADRB2, VIPR2, OXTR, ASIC3, P2RX4, P2RX7, ATP5E, NDUFS5 genes and downregulation of TNF, NR3C1, P2RY1, HSPA2 genes were deemed as favorable effects. Mean difference (MD), 95% CI, and FDR corrected p-values were reported. **Results:** TCQ favorably regulated the expression of genes associated with inflammation (TNF: MD = -1.25; CI: -1.97 – -0.53; p = 0.001 and IL-10: MD = 0.51; CI: 0.02 – 1.00; p = 0.043), metabolite-sensing (P2RX4: MD = 0.45; CI: 0.04 – 0.85; p = 0.032), and energy activation (P2RY1: MD = -0.43; CI: -0.95 – -0.08; p = 0.037, ATP5E: MD = 0.15; CI: 0.05 – 0.30; p = 0.035, and NDUFS5: MD = 0.14; CI: 0.02 – 0.28; p = 0.042) at 3 months post-intervention. EIM favorably regulated genes associated with vasodilation (OXTR: MD = 0.89; CI: 0.36 – 1.42; p = 0.001) and inflammation (NR3C1: MD = -0.24; CI: -0.47 – -0.01; p = 0.043). Compared with EIM, TCQ produced greater increases in ADRB2, an adrenergic activator (MD:0.81; CI: 0.26 – 1.35; p = 0.003) and P2RX4 (MD:0.56; CI: 0.12 – 1.01; p = 0.013) and favorably decreased the expression of P2RY1 (MD:-0.93; CI: -1.51 – -0.35; p = 0.002). **Conclusions:** TCQ produced meaningful changes in inflammatory, adrenergic, energy, and metabolic pathways, supporting potential biological mechanisms through which TCQ may reduce fatigue in older male cancer survivors. Larger trials with a broader representation of participants are needed to confirm these pathway-level effects. Clinical trial information: NCT03345563. Digital prehabilitation and functional performance signals in older adults undergoing hepatobiliary cancer surgery: A pilot study. First Author: Mohammed Al-Jumayli, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Older adults undergoing hepatobiliary cancer surgery often have limited functional reserve and face barriers to accessing structured preoperative conditioning. Technology-enabled, home-based prehabilitation may offer a scalable approach to support surgical readiness while generating early signals of functional change. **Methods:** Adults aged $\geq$65 years scheduled for hepatobiliary tumor resection with $\geq$4 weeks before surgery were enrolled in a multimodal, digitally supported prehabilitation program. The intervention combined wearable-monitored aerobic activity ($\geq$90 minutes/week) with twice-weekly, live video–supervised progressive resistance training delivered by certified exercise trainers. Functional performance was assessed using the 30-second chair stand and arm curl tests, and health status was measured with the SF-12 survey at baseline and preoperative follow-up. Implementation and engagement metrics were captured to contextualize delivery in a geographically dispersed population. Analyses of functional outcomes were exploratory and intended to estimate effect sizes and inform future, adequately powered studies. **Results:** Twenty-one participants (median age 78 years; range 66–88) completed baseline and preoperative assessments over a median intervention duration of 4.5 weeks. Participants resided a median of 127 km from the cancer center, supporting remote delivery of the intervention. Improvements were observed in lower extremity function (30-second chair stand: 12.0 $\pm$ 3.2 to 13.8 $\pm$ 4.6 repetitions; p = 0.04) and upper extremity strength (30-second arm curl: 17.7 $\pm$ 5.4 to 22.2 $\pm$ 7.1 repetitions; $p < 0.001$). Patient-reported physical and mental health scores demonstrated favorable, though not statistically significant, trends. Engagement with wearable-monitored aerobic activity exceeded recommended weekly targets, and completion of tele-supervised resistance sessions remained high across the intervention period. **Conclusions:** In this pilot cohort of older adults preparing for hepatobiliary cancer surgery, a digitally supported, home-based prehabilitation model was associated with favorable short-term functional performance signals and high levels of engagement across a geographically dispersed population. These findings are hypothesis-generating and support further evaluation of tele-prehabilitation in trials powered to assess perioperative and clinical outcomes. Research Sponsor: None.

Real-world feasibility and efficacy of a tailored exercise program in patients with cancer. First Author: Alice Avancini, University of Verona, Verona, Italy

Background: Exercise (EX) is associated with improved survival, symptom control, and management of treatment-related side effects in patients (pts) with cancer. However, evidence from large, real-world cohorts including unselected pts across different phases of the disease trajectory remains limited. This study aimed to evaluate the feasibility and effectiveness of a tailored EX program implemented in routine clinical practice. **Methods:** A three-month, bi-weekly supervised EX program was offered to consecutive cancer pts referred at the University Hospital of Verona, regardless of treatment status. The program included moderate-intensity aerobic exercise (10–30 minutes/session) and resistance training (2–3 sets of 8–12 repetitions; six exercises). The primary endpoint was feasibility, assessed by recruitment rate, adherence, and dropout. Secondary endpoints included cardiorespiratory fitness (six-minute walking test, 6MWT), muscular strength (handgrip strength test, HST), waist-hip ratio (WHR), and quality of life (QoL), measured using the EORTC QLQ-C30. Pre- and post-intervention outcomes were analyzed using descriptive statistics and paired Student's t-tests. **Results:** A total of 2276pts were recruited (92% recruitment rate) with a median age of 57$\pm$12 years. The most frequent tumor types were upper gastrointestinal cancers (34%) and breast cancer (31,8%). 84% of patients were receiving systemic treatments, and 47% had metastatic disease. Overall, 156 pts completed the intervention (dropout rate 31%, mainly due to disease progression), with an adherence rate of 84%. Significant improvements were observed in WHR ($-$1.2%, p = 0.03), 6MWT (+25 m, $p < 0.001$), and HST (+1.9 kg, $p < 0.01$). QoL significantly improved in physical, role, emotional, and social functioning (all $p < 0.01$), along with reductions in fatigue, nausea/vomiting, pain, dyspnea, insomnia, appetite loss, and diarrhea. Global QoL and financial difficulties also significantly improved. **Conclusions:** In a real-world, unselected cohort of cancer pts across different treatment phases, a tailored EX program is feasible and associated with meaningful improvements in physical function and QoL. These findings support the integration of structured exercise programs into routine oncology care beyond controlled clinical trial settings. Clinical trial information: NCT04226508. Research Sponsor: None.

Dyadic exercise intervention for LGBTQ+ cancer survivors: Associations with health-related quality of life, fatigue, and inflammation biomarkers. First Author: Hala Awad, University of Rochester Medical Center, Rochester, NY

Background: Mixed training (aerobic/resistance) exercise is a key adjuvant therapy in exercise oncology; it decreases cancer mortality and improves patients' quality of life, in part by modulating the tumor microenvironment, regulating the HPA axis, and inflammatory pathways. LGBTQ cancer survivors and their partners frequently experience excessive fatigue, insomnia, impaired health-related quality of life (HRQOL), and relationship stress, yet remain underrepresented in exercise oncology research. **Methods:** We conducted an RCT with 70 LGBTQ+ cancer survivor-partner dyads (N = 140) to compare a 6-week home-based dyadic exercise program (EXCAP-PA) against a survivor-only intervention. Analyses focused on changes from baseline to post-intervention. Primary outcomes included the Survivor Profile of Mood States (POMS) Fatigue and PROMIS global health change to assess HRQOL. ANCOVA-style linear models regressed change scores on treatment arm and baseline values. Mediation analyses assessed whether changes in dyadic support, cortisol, and C-reactive protein (CRP) mediated the effect of treatment on fatigue and HRQOL. **Results:** Among 56 survivor–partner dyads with analyzable data, delivery of EXCAP-PA was feasible in this LGBTQ+ population. Both survivors and partners in each arm demonstrated improved HRQOL; however, the treatment arm did not significantly predict changes in PROMIS global health for survivors (survivors: B = 0.10, SE = 0.39, p = 0.80; partners: B = 0.03, SE = 0.41, p = 0.94). Baseline symptom burden strongly influenced outcomes: higher baseline fatigue was associated with greater reductions in POMS Fatigue–Inertia (B = −0.55, SE = 0.15, $p < 0.001$), indicating that participants with the highest fatigue experienced the largest improvements. In the CRP model ($n \approx 44$), higher baseline CRP was significantly associated with greater subsequent decreases in log-transformed CRP (B = −0.37, SE = 0.17, p = 0.04). The model relating fatigue change to baseline fatigue, baseline CRP, and CRP change explained a substantial proportion of variance ($R^2 = 0.29$; $F(3,40) = 5.42$, p = 0.003), whereas baseline cortisol was not significantly related to fatigue change. Although mediation analyses using changes in dyadic support, log-transformed CRP, or log-transformed cortisol as mediators of treatment arm effects on fatigue or HRQOL yielded small, non-significant indirect effects, the outcomes are consistent with a beneficial effect in which dyadic processes and reduced inflammation improve symptoms and HRQOL. **Conclusions:** Dyadic EXCAP-PA proved feasible for LGBTQ+ survivor–partner dyads. Although this pilot is underpowered to detect significant effects on global health, fatigue, or inflammation, the findings highlight high-symptom/high-CRP survivors as a priority subgroup for future, larger dyadic exercise trials. Circulating heat shock protein 90 alpha (Hsp90α) as a biomarker for cancer cachexia. First Author: Syed Hasan Raza Jafri, University of Texas, Houston, TX

Background: Cancer cachexia is defined clinically by a consensus definition of ≥5% unintentional weight loss in cancer patients over previous 6 months. There is a need to develop blood-based biomarkers for more accurately identifying patients with cancer cachexia. Tumor-cell derived Hsp90α has been shown to be a key driver for muscle wasting and systemic inflammation in pre-clinical models of cancer cachexia. **Methods:** We conducted a prospective case control study between April 2020 and February 2025 to identify biomarkers of cancer cachexia. Cases were newly diagnosed patients with stage III/IV cancers with ≥5% unintentional weight loss and serum albumin of < 3.5g/dl (Cachexia group). Controls were newly diagnosed patients with stage I-III cancers without weight loss and serum albumin of ≥3.5g/dl (non- cachexia group). We collected 5ml of blood at first visit and analyzed plasma Hsp90α levels using Enzyme linked immunosorbent assay (ELISA). We performed univariable comparisons of geometric means of Hsp90α between the groups using two sample t-test . To evaluate the classification performance of Hsp90α for identifying cancer cachexia, we used receiver operating characteristic (ROC) analysis with area under the curve (AUC). **Results:** A total of 200 patients were consented and 171 were included in final analysis. There were 110 cases and 61 controls. Mean age of cases was 68 years and of controls 62 years (p=0.003). 64% of cases were males as opposed to 30% in controls ($p < 0.001$). There was no significant difference in race between the groups. Cancer types included lung, gastro-intestinal, breast and other cancers in both cases and controls. Mean plasma Hsp90α at diagnosis was significantly higher in cases 40.60 ng/mL than in controls 32.47 ng/mL ($p < 0.001$). On up to one year follow up (6 visits total) the mean Hsp90α remained significantly elevated in cases as compared to controls ($p < 0.001$). Mean Hsp90α levels among cases was highest in patients with GI cancers (49.98 ng/mL) followed by Lung cancer (40.67 ng/mL) and other cancer types (27.92 ng/mL), $p < 0.001$. Based on ROC analysis, Hsp90α level of ≥35 ng/mL has AUC of 94% for differentiating cancer patient with cachexia from those without cachexia. When stratified by sex, Hsp90α ≥35 ng/mL remained significantly higher in cases than in controls for both men and women ($p < 0.001$). **Conclusions:** Hsp90α is a blood-based biomarker that is significantly elevated in cancer patients with cachexia as opposed to those without cachexia. Plasma Hsp90α ≥35 ng/mL accurately identifies cancer patients with cachexia and represents a promising biomarker for cancer cachexia both in clinical care and research. Research Sponsor: U.S. National Institutes of Health; National Center for Advancing Translational Sciences (NCATS); Biostatistics/ Epidemiology/ Research Design (BERD) component of the Center for Clinical and Translational Sciences (CCTSawarded to the University of Texas Health Science Center at Houston, Texas.

Distribution of Hsp90α amongst case-control based on optimal cutoff (≥35 ng/mL).

Variable	Study group	Cutoff category	Number of patients
Hsp90	Case	< 35	20
Hsp90	Case	≥ 35	90
Hsp90	Control	< 35	61
Hsp90	Control	≥ 35	0

Tele-nutritional collaborative care in patients with stage IV gastrointestinal cancer receiving chemotherapy: A randomized clinical trial. First Author: Shihong Xu, Department of Biotherapy, Cancer Center, West China Hospital, Chengdu, China

Background: Cancer cachexia is characterized by systemic inflammation and progressive muscle loss, fundamentally compromising quality of life (QOL) and overall survival. While early nutritional intervention is imperative, patients in resource-constrained regions like Western China often lack timely access. We conducted the tele-nutrition collaborative care (T-NICE) trail to evaluate the efficacy of a hybrid remote care delivery model for patients with stage IV gastrointestinal cancer undergoing chemotherapy. **Methods:** This randomized clinical trial was conducted at West China Hospital. Patients with histologically confirmed stage IV gastrointestinal cancer (esophageal, gastric, or colorectal) were randomly assigned (1:1) to the T-NICE intervention versus Standard Nutrition Care (SNC). The T-NICE group received a collaborative hybrid telecare model involving a lean team (dietitian and social worker), comprising an initial in person education followed by app-based monitoring and adaptive telephone counseling. Primary Endpoint: The incidence of cancer cachexia (defined as involuntary weight loss >5%, or >2% if BMI <20 kg/m²) over 6 months. Secondary Endpoints: Longitudinal changes in nutritional status (PG-SGA, NRS 2002) and body weight. Exploratory end points included the QOL (using the EORTC QLQ-C30), psychology characteristics (using DT, PHQ-9 and HADS) and caregiver burden (using ZBI). Assessments were conducted at monthly intervals through the six months endpoint. **Results:** A total of 160 patients were enrolled (80 to T-NICE, 80 to SNC). Cachexia incidence was significantly lower in T-NICE vs. SNC (22.4% VS. 60.8%; adjusted odds ratio [aOR], 0.18; 95%CI, 0.09-0.37; $P < .001$). After six months, weight stabilized in T-NICE group compared to loss in SNC (mean change, +0.86kg [95% CI, -0.20-1.93] VS −3.61 kg [95% CI, -4.70 to -2.52]), resulting in a mean difference of -4.56 kg (95% CI, -5.73 to -3.39; $P < .001$). The T-NICE group also had lower PG-SGA scores (5.10 [95%CI, 4.14-6.06] VS 6.50 [95%CI, 5.54-7.46]; $P = .015$). T-NICE participants had higher EORTC QLQ-C30 Global Health scores (74.42 vs. 66.67; $P = .004$) and improved various functional status. Psychological benefits and reduced caregiver burden were also observed. **Conclusions:** The T-NICE trial demonstrated that an integrated tele-nutrition model significantly reduced cachexia incidence, improved QOL, nutritional status, psychology status and alleviated caregiver burden. Key strengths included the model's scalability and low staffing requirements, maximizing resource efficiency while delivering substantial clinical benefits. Clinical trial information: NCT06332664. Research Sponsor: None.

A mediation analysis of neurocognitive deficits and patient-reported mood among patients with lung cancer with brain metastases. First Author: Mary Catherine Boulanger, Massachusetts General Hospital, Boston, MA

Background: Advances in lung cancer therapeutics have led to a growing population of patients with lung cancer who are facing the challenges of living with the sequela of brain metastases and the therapies used to treat them. Patients experience neurocognitive deficits, difficulties with functioning, and mood symptoms. However, the mechanisms by which neurocognitive deficits contribute to mood symptoms in this patient population remain to be fully elucidated. In this study, we aimed to evaluate patient-reported functioning as a mediator between neurocognitive deficits and mood symptoms. **Methods:** Using a prospectively collected single-site registry, we conducted an exploratory cross-sectional study among patients with lung cancer with brain metastases at the time of evaluation for stereotactic radiosurgery. The registry included data on patient demographic and clinical characteristics, neurocognitive deficits per clinician exam (visual impairment, cranial nerve deficit, sensory deficit, motor deficit, gait impairment/incoordination, decline in ability to concentrate, decline in memory), and patient-reported functioning (self-care, usual activities, mobility) and mood symptoms (anxiety/depression) from the European Quality of Life 5-Dimensions 3-Level Version. First, we selected functional domains significantly associated with mood symptoms in a logistic regression analysis to test as potential mediators. Then, we used a regression-based path analysis to test the selected functional domain as a mediator between neurocognitive deficits and mood symptoms. The mediation model adjusted for age, performance status, tobacco use, extracranial disease status, prior brain surgery, and prior brain radiation. **Results:** Of 463 patients, 33.9% demonstrated any neurocognitive deficit, 38.7% self-reported any functional difficulty (self-care, usual activities, or mobility), and 15.3% reported mood symptoms. Difficulty with usual activities was associated with increased mood symptoms (OR=1.65, 95% CI=1.36, 1.97), which we then tested as a mediator. Motor deficits (OR=1.66, 95% CI=1.30, 2.38) and gait impairment/incoordination (OR=1.50, 95% CI=1.19, 2.09) had positive indirect effects on mood symptoms (i.e. increased mood symptoms) through difficulties with usual activities. No other neurocognitive deficits showed significant effects on mood symptoms. **Conclusions:** Among patients with lung cancer with brain metastases, the associations of motor deficits and gait impairment/incoordination with worsened mood are mediated by difficulties with engaging in usual activities. These findings underscore the potential for tailored supportive care, utilizing strategies from cognitive rehabilitation, palliative care and psychology, to improve patients' mood by helping them adapt to and cope with difficulties in engaging in their usual activities. ASTRON (OGSG 2401): A multicenter prospective trial of ferric carboxymaltose without erythropoiesis-stimulating agents for iron deficiency anemia in patients with gastric/colorectal cancer receiving chemotherapy. First Author: Ryohei Kawabata, Sakai City Medical Center/Osaka Cancer Institute Center, Osaka, Japan

Background: Iron deficiency anemia (IDA) during chemotherapy for patients with gastrointestinal cancer worsens quality of life (QoL) and may compromise treatment continuity. Ferric carboxymaltose (FCM) enables high-dose intravenous iron supplementation; however, prospective data without concomitant erythropoiesis-stimulating agents (ESAs) remain limited. We conducted a multicenter prospective trial to evaluate intravenous FCM without concomitant ESAs or red blood cell (RBC) transfusion support. **Methods:** This was a multicenter prospective single-arm study. Key eligibility criteria included unresectable or recurrent gastric or colorectal cancer, ongoing chemotherapy, hemoglobin (Hb) $<$10.0 g/dL, and transferrin saturation (TSAT) $<$20%. FCM was administered as three 500 mg doses at $\geq$7-day intervals (total 1500 mg), with all doses completed within 29 days of the first infusion (Day 1). The primary endpoint was Hb improvement rate at week 8, defined as an Hb increase $\geq$1.0 g/dL from baseline without RBC transfusion. The improvement rate was tested against a threshold of 18% using a one-sided exact binomial test (α=0.05). QoL (FACT-An and EQ-5D-5L) was analyzed using linear mixed-effects models. **Results:** Fifty-two patients were enrolled; 51 received FCM. Median age was 72 years (range 45–90). Primary tumors were gastric (71.2%) and colorectal (28.8%); ECOG PS 0/1/2 was 50.0%/46.2%/3.8%. Disease status was unresectable in 55.8% and postoperative recurrence in 44.2%. The primary tumor was present in 40.4%. Most patients (90.4%) were receiving cytotoxic chemotherapy. Baseline median Hb was 9.15 g/dL (IQR 8.50–9.50), TSAT 8.55% (IQR 5.77–12.80), and ferritin 37.6 ng/mL (IQR 17.1–179.0). The week-8 Hb improvement rate was 72.5% (37/51; 95% CI 58.3–84.1; p$<$0.001). Hb improvement rates at weeks 4 and 12 were 58.8% (30/51) and 76.5% (39/51), respectively. FACT-An total score improved at week 8 (mixed-model estimate +4.93; 95% CI 0.23–9.62; p=0.040). EQ-5D also improved at week 8 (estimate +6.72; 95% CI 0.98–12.46; p=0.022). Planned protocol treatment was completed in 49/52 patients (94.2%). No treatment-related serious adverse events or deaths were observed. **Conclusions:** FCM achieved an Hb improvement rate of 72.5% and improved QoL in patients with gastric or colorectal cancer and IDA receiving chemotherapy, with high protocol completing and no treatment-related serious adverse events. These findings support FCM as an effective and feasible option for managing IDA during chemotherapy without ESAs. Clinical trial information: jRCTs051240288. Correlation of University of Texas Cancer Cachexia Staging (UTCCS) with clinical variables of systemic inflammation, nutritional status, and physical function in patients with cancer cachexia. First Author: Harshit Khosla, University of Texas Health Science Center at Houston, Houston, TX

Background: Cancer cachexia is a heterogenous syndrome characterized by ongoing loss of skeletal mass with or without adipose tissue, that is not entirely reversible. University of Texas Cancer Cachexia Staging (UTCCS) is a recently described novel model for staging cachexia using simple clinical parameters such as body mass index (BMI), serum albumin (alb), neutrophil to lymphocyte ratio (NLR) and resting heart rate (RHR). The validity of this model to correlate with functional status, nutrition and overall survival in patients with advanced or metastatic cancer has been assessed in current study. **Methods:** In a prospective study of newly diagnosed cancer patients with stage III/IV cancers, $>$5% body weight loss and serum albumin $<$ 3.5g/dL biomarkers of cachexia were identified. UTCCS was developed using 4 clinical variables namely (BMI), (Alb), (NLR) and (RHR) using quartile as cut off. Based on these variable patients were categorized into stage I, stage II or stage III cancer cachexia. Blood biomarkers, dietary assessment and functional status were estimated. Kaplan-Meier survival curves were generated for patients in each stage. **Results:** Cancer distribution amongst 110 patients included lung cancer (n=50), GI cancers (n=42) and other cancers (n= 18). Cachexia stage distribution in patients was assessed (stage I= 45%, stage II =36% and stage III=18%). Patients with stage III cachexia had statistically significantly lower ECOG performance status (p=0.006), higher inflammatory state as measured by advanced lung cancer inflammation index (p$<$0.001), lower simplified nutritional appetite questionnaire (SNAQ score) (p=0.01), lower skeletal muscle index (p=0.03) and 30 seconds chair rise time (p$<$0.001). Median overall survival (OS) for stage I was 12.7 months, stage II 7.1 months and stage III 3.5 months (p=0.047). **Conclusions:** UTCCS system is a novel way of estimating the severity of cancer cachexia and correlates with inflammatory, dietary and functional parameters expected in patients with increasing severity of cancer cachexia. Research Sponsor: None.

A retrospective cohort studying integrative palliative care in a community oncology practice: Impact and outcomes. First Author: Summiya Nasim, Parkview Hospital Randallia, Fort Wayne, IN

Background: Embedding palliative care within oncology practice supports symptom management and shared decision-making; however, its impact on real-world healthcare utilization and end-of-life planning is less well characterized. In 2018, a dedicated palliative oncology service was implemented at a Midwestern community cancer institute. We evaluated whether this integrated model was associated with differences in healthcare utilization, hospice referral, and advance care planning (ACP) compared with standard oncology care prior to implementation. **Methods:** We conducted an IRB-approved retrospective cohort study of adults with cancer treated at a single institution. Two age-, stage-, and histology-matched cohorts were identified: patients treated after implementation of the embedded palliative oncology service (2018–2021; Cohort A, n=300) and patients treated prior to implementation (2012–2017; Cohort B, n=300). Clinical data were extracted from the electronic medical record. Outcomes included emergency department (ED) visits, inpatient and ICU admissions, inpatient and ICU length of stay, hospice referral, and documented ACP. Continuous variables were compared using two-sample t-tests and categorical variables using χ^2 tests (α=0.05). Post-hoc power analyses were performed for outcomes demonstrating between-group differences. **Results:** Both cohorts were predominantly White (88% in Cohort A vs 93% in Cohort B) with a slight difference in mean age (70.8 vs 75.0 years). Cohort A included a higher proportion of patients with stage III–IV disease (74% vs 53%, p$\leq$0.05). Compared with standard oncology care, the integrated palliative oncology model was associated with a higher mean number of ED visits (4.1 vs 3.0, p$<$0.05). There were no significant differences in inpatient admissions, ICU admissions, or inpatient length of stay between groups. Hospice referral and ACP documentation occurred significantly more frequently in Cohort A (both p$<$0.05). Post-hoc analyses demonstrated adequate power ($>$80%) to detect observed differences in ED utilization, hospice referral, and ACP documentation. **Conclusions:** Implementation of an integrated palliative oncology service was associated with increased ED utilization alongside substantially higher rates of hospice referral and ACP documentation, without an accompanying increase in hospital or ICU admissions or length of stay. These findings suggest that embedded palliative oncology may promote earlier end-of-life planning while maintaining stable inpatient utilization. Prospective studies are needed to better understand drivers of ED use and to further refine integrated palliative oncology care models. Research Sponsor: None.

Behavioral predictors of pain control among adult cancer survivors: Examining the impact of smoking, physical activity, and alcohol consumption. First Author: Clifford A. Atuiri, St. Luke's Hospital, Chesterfield, MO

Background: Cancer-related pain remains a prevalent and debilitating symptom among adult cancer survivors, substantially impairing quality of life. While pharmacologic therapies are central to pain management, growing evidence suggests that modifiable lifestyle behaviors may influence pain outcomes. This study examined the association between smoking status, alcohol consumption, physical activity, and pain control among adult cancer survivors in the United States. **Methods:** We conducted a cross-sectional analysis using data from the 2022 Behavioral Risk Factor Surveillance System (BRFSS), a nationally representative survey of U.S. adults. The study population included adults aged $\geq$18 years with a history of cancer who reported physical pain attributable to cancer or its treatment. The primary outcome was self-reported pain control (controlled vs uncontrolled). Primary predictors included smoking status (current, former, never), heavy alcohol consumption (men $>$14 drinks/week; women $>$7 drinks/week), and physical activity in the past 30 days outside of regular employment. Multivariable logistic regression models were used to estimate odds ratios (ORs) with adjustment for age, sex, race/ethnicity, educational attainment, and household income. Sampling weights were applied to account for the complex survey design. **Results:** A total of 1,380 cancer survivors with cancer-associated pain were included. Most participants were aged $\geq$60 years (62.4%), female (63%), and non-Hispanic White (78.9%). Overall, 76% reported controlled pain, while 24% reported uncontrolled pain. Compared to current smokers, participants who had never smoked had significantly lower odds of having uncontrolled pain (OR=0.45; 95% CI 0.25 – 0.81, p=0.001). Former smokers had a 41% lower odds of having uncontrolled pain than current smokers (OR=0.59; 95% CI 0.33 – 0.94, p=0.04). Heavy alcohol consumption was not significantly associated with pain control (OR=1.03, 95% CI 0.48 – 2.21, p=0.94). Physical inactivity was significantly associated with poorer pain outcomes; participants who were inactive in the past 30 days had 72% higher odds of uncontrolled pain compared with those who engaged in physical activity (OR=1.72, 95% CI 1.11 – 2.67, p=0.01). **Conclusions:** Smoking and physical inactivity are significantly associated with poor pain control among adult cancer survivors. Incorporating smoking cessation and exercise promotion into survivorship care plans may enhance pain management and overall quality of life among cancer survivors. Research Sponsor: None.

Utilisation of the Henry score in malignant bowel obstruction and characterisation of management approaches and outcomes: Experience from a New Zealand regional centre. First Author: Nicole Lundon, Velindre Cancer Centre, Cardiff, United Kingdom

Background: Malignant Bowel Obstruction (MBO) is a common, life-threatening complication of advanced malignancy associated with a high symptom burden and poor prognosis. Henry et al developed the Henry Score to predict 30-day mortality in MBO patients. It has not been routinely used to guide clinical decision-making regarding the management of MBO or validated in populations outside the United States of America. This study was designed to assess the utility of the Henry Score in predicting 30-day mortality in palliative patients presenting to hospital with malignant bowel obstruction in a New Zealand regional centre and to characterise the management approaches and outcomes of surgical versus non-surgical interventions. **Methods:** Retrospective cohort study of 235 patients admitted with MBO to Palmerston North Hospital (2010-2024). The Henry Score (0-5) incorporating five clinical and laboratory factors was calculated for each patient. Management approaches and survival outcomes were analysed. **Results:** Complete Henry Score data was available for 82.1% of patients. Sixty-four underwent surgical management, 171 non-surgical interventions. Median overall survival was 82.5 days (surgical: 130.5 days; non-surgical: 52 days; p=0.005). The 30-day mortality rate was 33.2%. The Henry Score demonstrated prognostic discrimination, with 30-day mortality of 28.0% for low scores (0-2) vs 43.0% for high scores (3-5) (p=0.034), and corresponding median survivals of 83 vs 39 days. Cox analysis identified hypoalbuminemia as the only factor significantly associated with mortality risk (HR 1.67, p=0.001). Māori patients had higher Henry Scores (68.2% vs 41.9% with scores ≥3, p=0.025) and shorter median survival (37 vs 97.5 days) than New Zealand European patients. **Conclusions:** The Henry Score effectively predicts 30-day mortality in MBO patients in New Zealand. Higher scores were associated with increased 30-day mortality, supporting the potential use of this measure for prognostication and advanced care planning. Hypoalbuminemia was the strongest predictor of mortality. Future prospective studies are needed to determine if clinical implementation of the Henry Score improves patient outcomes. Genetic associations with chemotherapy-induced nausea and vomiting: A genome-wide association study. First Author: Aasha I. Hoogland, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Nausea and vomiting affect up to 80% of patients treated with chemotherapy, and the costs of healthcare utilization due to chemotherapy-induced nausea are estimated to cost over $6 billion each year in the United States. Existing antiemetic regimens targeting 5-HT3 and NK1 antagonists are suboptimal, as up to 40% of continue to report nausea despite antiemetic treatment. Further, existing risk prediction algorithms have poor discrimination. **Methods:** In this original research study, we conducted a genome-wide association study of genetic factors associated with patient- and clinician-reported nausea and vomiting at 24 hours after infusion (acute) and 5 days after infusion (delayed) in patients treated with moderately- or highly-emetogenic chemotherapy. Participants were recruited from five ORIEN centers: City of Hope, Moffitt Cancer Center, Ohio State University, Rutgers University, and University of Colorado-Denver. Patient-reported CINV was assessed using the MASCC Antiemesis Tool and clinician-reported CINV was assessed using Common Terminology Criteria for Adverse Events (CTCAE) ratings. The study cohort was divided into a training set (70% of the sample) and a test set (30% of the sample). Machine learning was used to evaluate the predictive performance of a polygenic score along with clinical variables, over and above models with clinical variables only. Areas under the curve (AUC) were used to compare the accuracy of each predictive model. **Results:** Participants (n=1,271) were 58 years of age on average (SD=13), and most were female (74%), White (97%), with breast cancer (41%). Half of participants (50%) had early stage cancer and most were treated with a guideline-concordant prophylactic regimen (70%). Any acute and delayed self-reported nausea was reported by 42% and 70% of participants, respectively. For acute nausea, one gene, *C12orf50*, met the threshold for suggestive significance ($P = 4.58 \times 10^{-6}$). For vomiting, the presence of the G allele at rs9712639 (nearest gene: *OR7E23P*) was linked to an increased likelihood of clinician-reported acute vomiting ($P = 1.83 \times 10^{-8}$). A further 11 SNPS reached the threshold for suggestive significance and were associated with both acute and delayed vomiting reported by clinicians; these were mapped to the *FTLP18* gene. Polygenic scores did not improve predictive risk models based on clinical factors only. **Conclusions:** Results of our GWAS indicate that there are different genetic associations for acute and delayed nausea and vomiting, suggesting potentially distinct genetic factors underlying each outcome. However, regardless of outcome, genetic information did not significantly improve models predicting the development and intensity of CINV. Research Sponsor: National Cancer Institute; R01CA219389.

Early outpatient palliative care for patients with multiple myeloma: A randomized pilot study. First Author: Breffni Hannon, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Early palliative care is recommended for patients with advanced or incurable cancer. Despite these recommendations, patients with multiple myeloma are often referred late to palliative care, or not at all. We assessed the feasibility of an early outpatient palliative care intervention for patients with multiple myeloma. **Methods:** English-speaking adults (≥18 years) with newly-diagnosed or relapsed multiple myeloma and at least one symptom scored ≥3/10 on the revised version of the Edmonton Symptom Assessment System (with constipation and sleep added, ESAS-rCS) were recruited from multiple myeloma outpatient clinics at the Princess Margaret Cancer Centre, Toronto, Canada. Participants were randomized to routine outpatient care from their multiple myeloma team (usual care arm), or to monthly in-person or virtual interdisciplinary outpatient palliative care clinic visits for 3 months alongside usual multiple myeloma care (intervention arm). The primary outcome was feasibility (recruitment of 40 patients/12 months; ≥60% completion of patient-reported outcome measures monthly for 3 months; ≥60% of those randomized to the intervention arm attending ≥1 palliative care clinic visit). Exploratory efficacy outcomes were measured at 1-, 2- and 3-months (primary endpoint), including quality of life (FACIT-Pal, primary efficacy outcome), symptom burden (ESAS-rCS), mood (PHQ-9) and satisfaction with care (FAMCARE-P16). **Results:** Of 40 patients recruited within 12 months (median age 66.5 years [range 33-92]; 17 [42.5%] female), 21 were randomized to the intervention arm and 19 to usual care. The 1-, 2- and 3-month completion rates among all participants for all measures were 37/39 (94.9%), 36/39 (92.3%), and 33/38 (86.8%), respectively; one intervention arm participant withdrew and one died during the study period. In the intervention arm, 17/21 (80.9%) attended at least one palliative care clinic visit; in the usual care arm, 3/19 (15.8%) were referred to the palliative care clinic during the study period. The mean difference (B) in change in the FACIT-Pal total score at 3-months from baseline between the intervention and usual care arm was 15.5 (standard error [SE] 8.8, p=0.09) after adjusting for baseline scores. The change in ESAS-rCS total distress scores at 3-months was improved in the intervention arm compared with usual care (adj. B=-13.7 [SE 5.4], p=0.02]), as were individual symptom scores for drowsiness (adj. B=-2.1 [SE 0.9], p=0.02), constipation (adj. B=-2.1 [SE 1.0], p=0.03) and sleep (adj. B=-3.6 [SE 0.8], p=0.0002). Changes in PHQ-9 and FAMCARE-P16 total scores at 3-months did not differ between study arms. **Conclusions:** This pilot trial demonstrated that a larger randomized controlled trial of early palliative care versus usual care for patients with multiple myeloma is feasible. Preliminary results are encouraging for improvements in symptom burden and quality of life. Clinical trial information: NCT06485076. Research Sponsor: Helga and Antonio De Gasperis Grand Challenges Clinical Trials in Myeloma.

Using IPOS to trigger advance care planning in outpatient palliative oncology: A multicenter real-world study. First Author: Sarah Ananda Gomes, Oncoclinicas & Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: Advance care planning (ACP) is central to high-quality palliative oncology care; however, in Brazil, ACP is not routinely integrated into clinical practice, making timely patient identification challenging. Patient-reported outcomes, such as the Integrated Palliative Outcome Scale (IPOS), may support earlier and more structured ACP discussions. This study evaluated whether IPOS, alone or combined with functional status and follow-up time, can identify patients undergoing ACP in outpatient palliative oncology. **Methods:** This multicenter, observational study used real-world data from a national Brazilian program across eight states. Adult patients with cancer who completed the IPOS at program entry were included. Functional status was assessed using the Palliative Performance Scale (PPS). ACP was defined as documented initiation during follow-up. Logistic regression models evaluated associations between IPOS domains, PPS, and ACP, adjusting for follow-up time. Discrimination was assessed using receiver operating characteristic (ROC) curves based on predicted probabilities from the final model. **Results:** A total of 1,301 patients were included (median age 68 years; SD 15.4), of whom 61.4% were female. The most common cancer types were gastrointestinal (30.3%), breast (16.6%), genitourinary (12.3%), and lung (11.9%). ACP was initiated in 32.1% of patients during follow-up. Median baseline IPOS total score was 22 (SD 10.1) and median PPS at entry was 70 (SD 15.7). Median follow-up time was 11.3 weeks (SD 20.2). Baseline IPOS total score did not discriminate ACP initiation (AUC 0.48), while functional status showed modest inverse discrimination (AUC 0.59). Time in palliative care demonstrated higher standalone discrimination (AUC 0.64). A multivariable model combining functional status, selected IPOS symptom and psychosocial domains, and follow-up time significantly improved discrimination for ACP (AUC 0.66; 95% CI 0.63-0.69). **Conclusions:** IPOS total score alone does not function as a screening tool for ACP initiation. However, when combined with functional status and longitudinal exposure to palliative care, IPOS symptom and psychosocial domains meaningfully improve identification of patients undergoing ACP. These findings support the use of IPOS as a structured clinical trigger to guide timely ACP discussions in outpatient palliative oncology. Research Sponsor: None.

Early symptom signals preceding end-of-life decline in outpatient palliative oncology. First Author: Flavia Santos Dumont Sorice, Oncoclinicas & Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: Timely recognition of clinical decline is challenging in palliative oncology. Symptom trajectories that precede global deterioration are unclear. We aimed to characterize longitudinal changes in total and domain-specific Integrated Palliative Outcome Scale (IPOS) scores and identify early indicators of decline in outpatient palliative oncology care (OPOC). **Methods:** We conducted a longitudinal study within an OPOC embedded in Brazil. Adults with advanced cancer enrolled for ≥6 months were included. IPOS was assessed at baseline, 3 months, 6 months, and the month of death. Paired comparisons evaluated changes in total IPOS scores and individual domains between baseline-3 months and 6 months-month of death. Clinically relevant decline was defined as worsening between 6 months and death. Logistic regression examined associations between IPOS decline, chemotherapy use near death, and place of death. **Results:** Among 126 patients (mean age 64.1 [SD 14.4]; 62.7% women), gastrointestinal (33.3%), breast (19.8%), and lung cancers (11.1%) were most common. At program entry, mean PPS was 65 (SD 13.5). Total IPOS scores improved from baseline to 3 months (mean difference 2.69, p=0.007). However, a marked deterioration occurred between 6 months and the month of death (mean difference -3.98, p<0.001). Domain-level analyses demonstrated early improvement in appetite loss (mean 1.56 to 1.28, p=0.020) and weakness (1.91 to 1.64, p=0.034) from baseline to 3 months, followed by significant worsening as death approached (appetite: 1.42 to 1.75, p=0.006; weakness: 1.94 to 2.25, p=0.003). Anxiety increased significantly between 6 months and the month of death (1.99 to 2.23, p=0.008), whereas pain and depressive symptoms remained relatively stable over time. Neither chemotherapy use in the last 30 days of life (OR 0.78, p=0.58) nor place of death (OR 0.56, p=0.21) was associated with clinically relevant IPOS decline. **Conclusions:** OPOC is associated with early symptom stabilization, followed by a predictable phase of accelerated deterioration near death. Appetite loss and weakness emerge as early and clinically meaningful indicators of decline within the terminal trajectory, independent of treatment or place of death. Routine longitudinal IPOS monitoring may facilitate earlier recognition of impending decline and support more proactive, patient-centered palliative care. Research Sponsor: None.

Prognostic stratification using baseline objective clinical information in patients with stage IV lung cancer receiving best supportive care alone as initial treatment: A multicenter retrospective study (WJOG20824L). First Author: Shunichi Kataoka, Department of Respiratory Medicine, Juntendo University Graduate School of Medicine, Tokyo, Japan

Background: Despite expanded systemic therapy for lung cancer, best supportive care (BSC) alone remains the initial treatment for some patients, often due to advanced age, poor performance status (PS), or comorbidities. However, large-scale data on prognostic heterogeneity and risk stratification in this population are limited. We aimed to stratify overall survival (OS) in stage IV lung cancer patients initially managed with BSC alone using baseline clinical information. **Methods:** We analyzed a multicenter database from WJOG15121L including 6,751 patients with stage IV lung cancer diagnosed between January 2016 and December 2019, identifying those who received BSC alone as initial treatment. Sixty-two baseline variables (demographics, comorbidities, genomic alterations, and laboratory data) were assessed. The primary analysis was conducted in complete cases (BSC complete cohort), with multiple imputation (MI) in the entire cohort as sensitivity analysis. A boosting-based model was used to derive a prognostic risk score for OS and to stratify patients into low-, medium-, and high-risk groups based on the risk score distribution. Survival outcomes were summarized using Kaplan–Meier methods with log-rank tests. Cox regression with Lasso regularization (Cox-Lasso) was also performed as an alternative approach to assess robustness. **Results:** A total of 923 patients received BSC alone as initial treatment; 266 comprised the BSC complete cohort. The BSC population was elderly (mean age: 75.8 years) with a high proportion of poor PS (ECOG PS ≥2: 74.8%). Kaplan–Meier–based risk stratification separated OS (median OS: 277 vs 74 vs 25 days for low-, medium-, and high-risk groups, respectively). The Kaplan–Meier–estimated 90-day OS rates were clearly separated across the three groups (75.4% vs 29.8% vs 0%; log-rank p < 0.001). Baseline characteristics differed by risk group, including PS and metastatic burden (e.g., liver metastasis). Risk stratification was largely driven by routinely available laboratory markers (e.g., LDH, neutrophil count, CRP, ALP, platelet count). Findings were consistent in the MI-based sensitivity analysis and were broadly supported by the Cox-Lasso approach. **Conclusions:** Among patients with stage IV lung cancer initially managed with BSC alone, outcomes are heterogeneous and can be stratified into clinically meaningful risk groups using baseline clinical information. Kaplan–Meier summaries (median OS and 90-day OS) demonstrate marked differences across risk strata, and the dominant contribution of routine laboratory variables highlights the potential practicality of this approach in real-world settings. Further validation and comparative analyses with patients receiving systemic therapy who share similar risk profiles are ongoing. Research Sponsor: None.

12055 **Poster Session**

A first-in-human (FiH) phase I study of GFS202A, a GDF15/IL-6 bispecific antibody, in advanced cancer patients (pts) with pre-cachexia or cachexia. First Author: Hongyun Zhao, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Cachexia is a common syndrome in cancer pts, associated with weight loss, impaired quality of life, and poor treatment outcomes. GDF15, a pleiotropic factor of TGF-β super family, has been verified to be correlated with cancer cachexia and anorexia. IL-6 contributes to cancer cachexia progression via both central and peripheral pathways. GFS202A, a first-in-class bispecific antibody dual-targeting GDF15 and IL-6, improves symptoms in preclinical cachexia models with lean body mass and adipose tissue weight increased. Here, we report the preliminary data from the ongoing FiH study of GFS202A. **Methods:** This is the FiH phase I study (NCT06898255) of GFS202A in advanced cancer pts with pre-cachexia or cachexia. Eligible pts are required to have weight loss in the six months prior to the first dose and decreased appetite, with or without anticancer therapy. Enrolled pts will receive GFS202A Q3W at a starting dose of 5 mg for a 12-week treatment period, followed by a 12-week follow-up period. An accelerated titration design, combined with the Bayesian Optimal Interval (BOIN) and backfilling design, is employed. The primary objectives are to assess safety and determine the recommended dose ranges for future clinical studies. The secondary and exploratory objectives include characterization of PK profiles, PD biomarkers, preliminary efficacy and exploratory biomarkers. **Results:** Data cutoff at Dec 26, 2025, 14 pts had received at least one dose of GFS202A ranging from 5 to 400 mg Q3W (5mg: N=1; 25mg: N=4; 100mg: N=4; 200mg: N=4; 400mg: N=1). The overall safety profile was favorable. No DLT was observed. Adverse events (AEs) of any cause were reported in all pts. Six pts experienced at least one treatment-related AEs (TRAEs). Only one pt had G3 hypertension assessed related to GFS202A, which alleviated during the treatment. The pt did not experience any other cardiovascular events and had no clinically meaningful changes in lipid profiles. All other TRAEs were G1. No ≥ 2pt experienced an identical TRAE. GFS202A exposure was approximately dose-proportional from 5-200 mg, and the mean half-life was 82–138 hours. GDF15 was not detectable immediately at the end of infusion from the 5mg cohort, and durable inhibition of GDF15 was observed from the 100mg dosing cohorts during 21-day dosing interval. CRP decreased significantly post-infusion, with suppressions sustained through Week 6 in 12 out of 13 pts in 5-200 mg Q3W groups. Weight gain was observed across different dose groups, with least-squares mean increases of 1.8, 1.5 and 2.5 kg at Week 6 in the 25, 100, and 200 mg Q3W groups, respectively. **Conclusions:** GFS202A demonstrated favorable safety and encouraging efficacy with systemic inflammation alleviated and weight gain. The data support that dual-targeting GDF15 and IL-6 is a feasible way to mitigate cancer cachexia clinically. Future studies are warranted. Clinical trial information: NCT06898255. Research Sponsor: GenFleet Therapeutics (Shanghai) Inc.

In-person versus telehealth outpatient palliative care visits in oncology: A multicenter study. First Author: Sarah Ananda Gomes, Oncoclinicas & Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo, Brazil

Background: As telehealth becomes integral to outpatient palliative care delivery in oncology, evidence comparing consultation duration and time allocation between in-person and remote visits remains limited, especially in low- and middle-income countries. We compared consultation duration and time composition between in-person and telehealth visits after adjustment for visit type and clinical complexity. **Methods:** This observational study evaluated outpatient oncological palliative care consultations conducted between February and May 2025 across seven practices in Brazil. Total consultation time and predefined time components were recorded. Multivariable linear regression models estimated adjusted differences in consultation duration according to care modality, controlling for visit type (first appointment, follow-up, family meeting), performance status (ECOG), quality-of-life (IPOS), and number of participants. **Results:** A total of 269 consultations were analyzed, including 171 in-person and 98 telehealth visits. Care modality was associated with consultation type (p < 0.001): telehealth was less frequently used for first consultations (15% vs. 35%) and more frequently used for follow-up visits (76% vs. 63%) and family meetings (9% vs. 3%). Telehealth visits involved patients with worse performance status (ECOG 3-4: 36% vs. 17%; p=0.007) and poorer quality of life (higher IPOS distribution; p=0.037). In unadjusted analyses, telehealth consultations were shorter than in-person visits, particularly for follow-up visits. After multivariable adjustment, telehealth visits remained independently and significantly shorter by a mean of 10.5 minutes (95% confidence interval [CI] -15.6 to -5.4; p<0.001). Follow-up consultations were consistently shorter than first consultations by 19.4 minutes (95% CI -24.9 to -14.0; p<0.001), regardless of care modality, while family meetings showed no difference in duration compared with first consultations (95% CI -13.8 to 8.9; p=0.70). Each additional healthcare provider was associated with a 2.9 minute increase in consultation time (95% CI 0.1 to 5.6; p=0.04). ECOG was not independently associated with total consultation duration. **Conclusions:** After accounting for visit type and clinical context, differences in consultation duration between telehealth and in-person are modest. Telehealth was preferentially used for follow-up care and among patients with poorer functional status and quality of life, while preserving consultation complexity when clinically indicated. These findings support telehealth as a viable modality for outpatient palliative care delivery in resource-limited settings. Research Sponsor: None.

Phase II study of mirogabalin for oxaliplatin-associated chemotherapy-induced peripheral neuropathy in gastrointestinal cancer: The SmiliNg trial. First Author: Reiko Ando Makihara, Department of Pharmacy, National Cancer Center Hospital, Japan, Tokyo, Japan

Background: Oxaliplatin is a key drug in the treatment of unresectable advanced or recurrent gastrointestinal (GI) cancers, however, chemotherapy-induced peripheral neuropathy (CIPN) often limits its use. Mirogabalin is an oral gabapentinoid that alleviates neuropathic pain by binding to the $\alpha 2\delta$ subunit of voltage-gated calcium channels, but evidence regarding the efficacy of mirogabalin for CIPN induced by oxaliplatin remains insufficient. SmiliNg trial evaluated the efficacy and safety of mirogabalin in patients with unresectable advanced or recurrent GI cancers who have oxaliplatin-associated CIPN. **Methods:** This single-center, single-arm exploratory phase II trial enrolled patients with unresectable or recurrent GI cancer who were receiving ongoing first-line oxaliplatin-based chemotherapy or continuing fluoropyrimidine-based therapy after discontinuation of oxaliplatin, and who had painful CIPN (including numbness/tingling) with a numerical rating scale (NRS) score of $\geq$ 4. Mirogabalin was administered orally twice daily and titrated weekly according to Cockcroft–Gault creatinine clearance. The primary endpoint was the change in 24-hour average pain NRS from baseline to week 6. Secondary endpoints included PRO-CTCAE-assessed improvement in numbness/tingling, adverse events (CTCAE v5.0), and attainment of maintenance dose. The planned sample size was 30 patients. Clinical trial information: UMIN000049555. **Results:** Between February 2023 and April 2025, 30 patients were enrolled. The median age was 64 years (range, 36–83), with female patients accounting for 33%. The primary cancer types included colorectal (n=17), small bowel (n=7), gastric (n=6), and esophageal (n=1) cancers. The Mean baseline 24-hour pain NRS was 5.80 (SD 1.97). The mean change from baseline at week 6 was -1.46 (SD 2.66) (p = 0.010; 90% CI -2.35 to -0.57) , thereby the prespecified primary endpoint was achieved. The proportions of $\geq$1 -point responders were 58%. On the PRO-CTCAE, the proportions of patients achieving a $\geq$1-category improvement in worst severity were 38% and 38% at weeks 3 and 6, respectively; the corresponding proportions for interference with daily activities were 34% and 27%. Maintenance-dose attainment rates at weeks 3 and 6 were 59% and 68%, respectively. The most common adverse events were somnolence (83%) and dizziness (38%). Grade $\geq$3 adverse events comprised AST/ALT increased, and pulmonary infection, each occurring in one patient; none were related to mirogabalin treatment. **Conclusions:** This study suggests that mirogabalin is effective and well-tolerated for the management of moderate-to-severe painful CIPN during oxaliplatin-based chemotherapy. These findings warrant further evaluation in a confirmatory trial. Clinical trial information: 000049555. Research Sponsor: None.

An automated, EHR-integrated intervention system for patient-reported insomnia symptoms. First Author: Eric S. Zhou, Dana-Farber Cancer Institute, Boston, MA

Background: Insomnia affects >20% of patients on cancer therapy. It is consistently reported to be one of the most burdensome sequelae. Systematic screening for insomnia in cancer patients is uncommon. Without identification, patients cannot access care. Unfortunately, even if insomnia is identified, most cancer centers lack on-site sleep specialists. To address both the screening and treatment gaps, we leveraged our institution's EHR-based patient-reported outcomes (PRO) data collection system to develop a fully automated solution to identify patients with insomnia, and share an evidence-based psychoeducational video intervention with them. **Methods:** Prior to established outpatient appointments at our hospital, all patients are asked to complete eSyM, an electronic PRO-CTCAE symptom assessment. Two insomnia items (symptom severity and interference) are combined to generate an insomnia score (0-3; higher is worse, with present analyses for those reporting a score $\geq$2). Patients with an elevated insomnia score were sent a patient portal message explaining they were identified as having insomnia, and offered an educational video with strategies to improve their sleep. We tracked patient engagement, as well as report of insomnia symptoms via eSyM response at the patient's subsequent appointment closest to 60 days post-Baseline ($\pm$30 days). Data was analyzed from patients who reported completed eSyM insomnia questions at both timepoints between 02/25 to 09/25. **Results:** Patients with insomnia (N=307) were an average of 63 years old, predominantly female (63%), White (84%), married (63%), and possessed a college degree or higher (57%). They were diagnosed with a broad range of cancers (breast = 20%, GI = 15%, thoracic = 10%). The vast majority (92%) opened the patient portal message with the video link, with the video watched in entirety 498 times. Overall, insomnia scores significantly decreased from baseline ($\bar{x}$ = 2.3) to follow-up ($\bar{x}$ = 1.9; $p<.001$), with 42% reporting symptomatic improvement at follow-up (48% no change and 9% worse). Specifically, 41% reported either Severe or Very Severe insomnia symptoms at baseline, improving to 30% at follow-up; 37% reported insomnia interfered with their life Quite a Bit or Very Much at baseline, improving to 23% at follow-up. Multivariate analyses revealed sociodemographic characteristics (Black, Medicare, and disabled) associated with less insomnia improvement. **Conclusions:** We developed a fully automated system that leverages electronic PRO data and our EHR to identify symptomatic cancer patients with insomnia and intervene. Our findings demonstrate that we can successfully connect with patients reporting insomnia and potentially improve outcomes with a low-intensity intervention. This framework can readily be deployed to identify and address other common side effects of cancer treatment (e.g., fatigue, pain) that impair recovery and quality-of-life. Negative effect of malignant pleural effusion on the efficacy of immunotherapy via IL-6–mediated abscopal immunosuppression in advanced non-small cell lung cancer. First Author: Yaping Guan, Department of Oncology, The First Affiliated Hospital of Shandong First Medical University, Jinan, China

Background: The present study is designed to determine the effect and mechanism of malignant pleural effusion (MPE) on the efficacy of immunotherapy in advanced non-small cell lung cancer (NSCLC). **Methods:** We identified patients with advanced NSCLC who underwent immunotherapy as a first-line or second-line regimen in multiple cohorts. The objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS) were analyzed. Using a mouse model with MPE, we determined whether MPE could affect the efficacy of immunotherapy and investigated the mechanism of MPE-related immunosuppression. **Results:** In a cohort with 269 advanced NSCLC patients who received PD-1 inhibitor alone or combined chemotherapy, MPE occurred in 82 (30.5%) patients. Patients with MPE had a shorter median PFS (4.0 vs. 9.8 months) and OS (21.0 vs. 29.9 months) than those without MPE. MPE was an independent factor affecting PFS (HR:1.87) and OS (HR: 2.73). The ORR for patients with and without MPE was 20% and 34%, respectively. In another cohort with 69 advanced NSCLC patients with MPE who receive PD-1 inhibitor plus chemotherapy plus bevacizumab or PD-1 inhibitor plus chemotherapy, there was no significant difference in median PFS (19.1 vs. 13.2 months) and OS (21.8 vs. 21.6 months), ORR (42.1% vs. 36.8%,), and extrapleural ORR (23.9% vs. 26.3%) between the two groups. In addition, IL-6 levels in serum and pleural effusions were significantly higher in NSCLC patients with MPE. Furthermore, in a mouse tumor MPE model by subcutaneous and pleural injection of lung cancer cells, PD-1 inhibitor did not decrease tumor growth and prolong survival in MPE-bearing mice. Immunohistochemistry and flow cytometry demonstrated the proportion of $CD3^+$T cells, $CD4^+$T cells and $CD8^+$T cells were decreased in the subcutaneous tumors with MPE. Dural blockade with PD-1 inhibitor and IL-6 receptor antibody inhibited tumor growth and prolonged survival of MPE-bearing mice. **Conclusions:** The occurrence of MPE is negatively correlated with patient outcomes when receiving PD-1 inhibitor or PD-1 inhibitor plus bevacizumab. Elevated IL-6 levels may be responsible for abscopal inhibitory tumor immune microenvironment and reduced efficacy of immunotherapy. Dural blockade of PD-1 and IL-6 could be a promising therapeutic strategy for advanced NSCLC with MPE. Research Sponsor: None.

Guard-01: A randomized, open-label trial of efbemalenograstim alfa as primary prophylaxis for neutropenia during definitive concurrent chemoradiotherapy. First Author: Yuanyuan Chen, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Concurrent chemoradiotherapy (CCRT), a curative cornerstone for locally advanced malignancies, exerts synergistic antitumor efficacy but is frequently hampered by severe hematologic toxicity (mainly neutropenia), leading to treatment delays, dose reductions and compromised outcomes. GM-CSF, previously evaluated for CCRT-induced hematologic AE prophylaxis, is no longer recommended due to increased immune-related toxicities and limited efficacy. While G-CSF is safe in chemotherapy, high-quality data for long-acting G-CSF as primary CCRT prophylaxis is sparse, creating a critical clinical gap that the Guard-01 study aims to resolve. **Methods:** This multicenter, randomized, open-label, controlled trial plans to enroll 120 patients undergoing definitive CCRT for locally advanced malignancies. Eligible participants are randomized 1:1 to either the study arm or control arm, stratified by chemotherapy regimen. Study arm patients receive efbemalenograstim alfa ~48 ($\pm$4) h post each chemotherapy cycle; control arm patients receive no primary G-CSF prophylaxis, with secondary efbemalenograstim alfa permitted for febrile neutropenia (FN) or dose-limiting neutropenia. The primary endpoint is the incidence of grade 3/4 neutropenia across the entire CCRT course. **Results:** As of December 2, 2025, 122 patients were enrolled (60 study arm, 62 control arm). The incidence of grade 3/4 neutropenia during the entire treatment course was 16.67% in the study arm versus 53.23% in the control arm, with a significant between-group difference of -36.56% (90% CI: -48.98%, -22.84%; $p < 0.0001$). Rates were significantly lower in the study arm across the first (5.00% vs. 45.16%; $p < 0.0001$) and second (12.28% vs. 27.27%; p = 0.0393) chemotherapy cycles. Consistent benefit was observed in subgroup analysis, with a significant difference in paclitaxel- or pemetrexed-based regimens (20.00% vs. 64.52%; p = 0.0004). The study arm had shorter grade 3/4 neutropenia duration (0.62 ± 1.57 vs. 3.27 ± 4.84 days; $p < 0.0001$) and higher ANC nadir (2.82 vs. 0.94×10^9/L; $p < 0.0001$). No neutropenia-related chemotherapy dose reductions or discontinuations occurred in the study arm, compared with 6.45% dose reductions and 1.61% discontinuations in the control arm. The most common TEAEs in the study arm were anemia (71.67%), thrombocytopenia (60.00%), and leukopenia (35.00%). Grade $\geq$3 TEAEs were less frequent in the study arm (41.67% vs. 64.52%), with no grade $\geq$3 TRAEs reported in either group. Exploratory endpoints include 2-year PFS and OS, with immature data pending longer-term follow-up. **Conclusions:** Efbemalenograstim alfa significantly reduces the incidence and duration of grade 3/4 neutropenia in patients undergoing definitive CCRT, with consistent efficacy across different chemotherapy regimens and a favorable safety profile. Clinical trial information: ChiCTR2300077504. Research Sponsor: None.

An anti-EpCAM x anti-CD3 bispecific antibody, M701, for the treatment of malignant pleural effusion due to NSCLC: A prospective randomized controlled phase II trial. First Author: Zhengbo Song, Phase I Clinical Trial Unit, Zhejiang Cancer Hospital, Hangzhou, China

Background: Malignant Pleural Effusion (MPE) is a common complication in patients with advanced NSCLC, associated with poor prognosis, severe symptoms, and reduced quality of life. Indwelling pleural catheter (IPC) is the first-line recommended therapy to alleviate MPE-related symptoms; however, no effective pharmacotherapy has been established in current clinical guidelines for MPE management. **Methods:** Patients with advanced NSCLC and symptomatic MPE who had progressed following at least 1 line of systemic treatment were eligible. Patients were randomized 1:1 to experimental arm (Arm E: IPC + M701 IP at 25 μg on day 1, 400 μg on days 4, 7, 10) or control arm (Arm C: IPC + cisplatin IP 40 mg on days 1, 7 or IPC alone), stratified by prior intrapleural chemotherapy (yes/no). Catheters were removed after day 10. Primary endpoint was puncture-free survival (PuFS), defined as time from catheter removal to next puncture or death. Secondary endpoints included time to next puncture (TTNP), overall survival (OS), MPE objective response rate (ORR), investigator-assessed MPE symptoms (Likert scale), and patient-reported symptoms (LC-13 scale). **Results:** As of December 22, 2025, 92 patients were randomized to Arm E (n=45) or Arm C (cisplatin, n=41; thoracentesis, n=6). Baseline characteristics were generally balanced between the two arms. The proportions of patients positive for actionable genomic alterations (AGA) were 77.77% (n=35) in Arm E and 72.34% (n=34) in Arm C, respectively. M701 demonstrated a significant improvement trend in PuFS and TTNP compared with cisplatin (see Table 1). The MPE ORR was 46.7% for Arm E and 34.0% for Arm C (p=0.217). Patients with prior intrapleural (IP) chemotherapy or without AGA had a more favorable treatment response in Arm E relative to Arm C, whereas the remaining patients did not. Dyspnea symptoms also demonstrated a trend toward greater improvement in Arm E, as assessed by both investigators and patients. OS data were immature, and no significant between-group difference was observed (HR=0.94, p=0.855). Grade 3 or higher treatment-related adverse events (AEs) occurred in 2.2% of patients in Arm E and 6.4% in Arm C. Only one serious adverse event (SAE), grade 2 fever, was deemed related to M701. **Conclusions:** M701 IP infusion showed a promising efficacy on re-accumulation of MPE compared with Cisplatin infusion, and was well tolerated, supporting further clinical development, especially in patients with no AGA or patients who received IP chemotherapy priorly. Clinical trial information: NCT05543330. Research Sponsor: Wuhan YZY Biopharma Co. Ltd.

Efficacy of the FAS set and subgroup.

Population	mPuFS (days)	HR	P value	mTTNP (days)	HR	P value
Full analysis (45 vs 47)	170 vs 72	0.72	0.212	NR vs 86	0.05	0.035

Performance of the NutriPal nutritional screening algorithm in advanced cancer palliative care: A multicenter study. First Author: Jesse Lopes da Silva, Division of Clinical Research and Technological Development, Brazilian National Cancer Institute (INCA), Rio De Janeiro, Brazil

Background: Malnutrition is highly prevalent in advanced cancer and is closely associated with functional decline, systemic inflammation, symptom burden, and impaired quality of life (QoL). Although several nutritional screening tools exist, none were specifically developed for patients with advanced cancer receiving palliative care. The NutriPal nutritional screening algorithm, which integrates the Patient-Generated Subjective Global Assessment short form and the Glasgow Prognostic Score, was recently developed for this population; however, evidence of its performance outside the development cohort remains limited. The objective was to evaluate the performance of the NutriPal nutritional screening algorithm in identifying nutritional risk among patients with advanced cancer receiving palliative care in a multicenter clinical setting and its association with functional status, inflammation, muscle strength, and QoL. **Methods:** This multicenter, cross-sectional study included adults with locally advanced or metastatic cancer receiving palliative care in four private oncology centers in Brazil from June 2024 to November 2025. Nutritional risk was classified using NutriPal in degrees 1 (lower) to 4 (greater nutritional risk). Karnofsky Performance Status (KPS), handgrip strength (HGS), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and QoL (EORTC QLQ-C15-PAL) were evaluated as independent variables. Associations with worsening nutritional risk were examined using ordinal logistic regression. **Results:** A total of 165 patients were included (60% women; 70% ≥60 years). NutriPal classified 54% as degree 1, 25% degree 2, 10% degree 3, and 11% degree 4 nutritional risk. Worse nutritional risk was independently associated with KPS < 60% (OR 2.67; 95% CI 1.17 - 6.07), low HGS in women (< 22 kg; OR 2.69; 95% CI 1.19 - 6.12) and men (< 32 kg; OR 2.06; 95% CI 1.02 - 5.44), NLR ≥2.78 (OR 2.02; 95% CI 1.18–3.15), and PLR ≥171.95 (OR 2.09; 95% CI 1.12 - 3.89). Poorer scores across all QoL domains (except insomnia) were significantly associated with higher nutritional risk (OR range 1.14 - 7.68), including global QoL (OR 4.08; 95% CI 2.14 - 7.61). **Conclusions:** NutriPal effectively discriminated nutritional risk severity and identified clinically relevant profiles characterized by functional impairment, systemic inflammation, and poorer QoL among patients with advanced cancer receiving palliative care in private oncology centers. These findings support its clinical utility as a targeted and pragmatic nutritional screening tool in real-world palliative oncology practice settings. Research Sponsor: None.

Role of palliative care nurse coordination in symptom control and care planning. First Author: Suwanna Rinchai, Bumrungrad International Hospital, Bangkok, Thailand

Background: Effective coordination by palliative care nurses plays a central role in improving communication, symptom assessment, and timely care planning for patients with advanced cancer. However, evidence on the measurable impact of nurse-led palliative coordination—particularly in Asian oncology settings-remains limited. This study evaluates the outcomes of a nurse-coordinated palliative care model on symptom control and care planning among patients with advanced cancer. **Methods:** This retrospective observational study included patients with advanced cancer who received palliative care nurse coordination from January 1, 2025 to December 31, 2025. The intervention consisted of systematic ESAS-based symptom assessment, coordination with oncology teams, family meetings, and facilitation of advance care planning. Outcomes included changes in symptom scores from baseline to follow-up, completion of advance care planning (ACP) and DNR documentation, and health-care utilization indicators.Distress score was derived from the ESAS psychological subscale, calculated as the sum of anxiety and depression scores. Descriptive statistics and paired comparisons were used for analysis. **Results:** A total of 195 patients were included (mean age 60.5 years; range 21–100). Following nurse-led palliative coordination, median pain scores decreased from 8 to 3 ($p < 0.01$). Median dyspnea scores improved from 6 to 1, representing an 83.3% reduction ($p < 0.01$). Median distress scores decreased from 6 to 2, corresponding to a 66.7% improvement ($p < 0.01$).Completion of advance care planning increased from 10% to 97%. DNR documentation improved from 20% to 80%, with the exception of one Arabic patient for whom DNR documentation was not completed. Under the nurse-led palliative care coordination model, 98.5% of patients with advanced cancer did not require unplanned emergency room utilization and avoided unnecessary ICU admissions. These outcomes highlight the effectiveness of proactive symptom management and comprehensive care planning. **Conclusions:** Nurse-led palliative care coordination was associated with significant improvements in symptom control and substantially higher completion rates of care planning among patients with advanced cancer. These results support integrating palliative nurses as key coordinators in oncology settings to enhance patient-centered and goal-concordant care. Research Sponsor: None.

12064 Poster Session

Patterns and timing of palliative care consultation in patients with newly diagnosed metastatic cancer. First Author: Thomas Wayne Butler, University of South Alabama Mitchell Cancer Institute, Mobile, AL

Background: Early integration of palliative care (PC) improves symptom burden, quality of life, and healthcare utilization in advanced cancer, yet referrals frequently occur late in the disease course. We evaluated institutional patterns of PC utilization to quantify consultation rates, timing, and demographic predictors of referral among patients with newly documented metastatic disease. **Methods:** We conducted a retrospective cohort study of adults with newly documented metastatic disease identified using ICD-10 secondary lymph node metastasis codes (C77.x) who received oncology care at the Mitchell Cancer Institute between November 2024 and November 2025. The first metastatic code defined time of diagnosis. Outcomes included PC consultation rate, time from diagnosis to consultation, consultation setting, and timing relative to death. Multivariable logistic regression evaluated associations between age, sex, insurance status, and race with receipt of consultation. **Results:** Among 375 patients (median age 66 years, IQR 56–74), 64 (17.1%) received a PC consultation. Consultation rates varied more than fourfold across primary diagnoses (6%–29%). Among patients with post-diagnosis consultations, the median time to consultation was 66 days (IQR 25–130), with more than half occurring >60 days after diagnosis. Most consultations occurred in the outpatient cancer center (78%). Among decedents who received consultation, 64% were first seen within 90 days of death, consistent with late referral. In multivariable analysis, increasing age was associated with a lower likelihood of consultation (OR 0.97 per year, 95% CI 0.95–0.99, p=0.016), while Black patients had higher odds of consultation compared with White patients (OR 1.82, 95% CI 1.02–3.25, p=0.044). Sex and insurance status were not independently associated with referral. **Conclusions:** PC utilization was low, highly variable, and frequently delayed among patients with metastatic cancer. Although most referrals originated in the outpatient setting, many occurred near the end of life. Diagnosis-triggered referral pathways may promote earlier and more equitable integration of supportive oncology services. Research Sponsor: None.

Palliative care utilization and predictors of consultation.

Characteristic	Value
Total patients	375
Median age, years (IQR)	66 (56–74)
Received PC consultation	64 (17.1%)
Median time diagnosis → consultation, days (IQR)	66 (25–130)
Initial outpatient consultation	78%
Consultation ≤90 days before death (decedents)	64%
Black vs White race, adjusted OR	1.82 (p=0.044)
Age (per year), adjusted OR	0.97 (p=0.016)
Most referrals occurred late in the disease course	>50% after 60 days

PC = palliative care; IQR = interquartile range; OR = odds ratio. Timing calculated among post-diagnosis consultations. Odds ratios from multivariable logistic regression.

Olanzapine for chemotherapy-related anorexia: Impact on body composition. First Author: Sandhya Singuluri, Srivenkateshwara Institute of Cancer Care and Advanced Research, Tirupati, India

Background: Chemotherapy-related anorexia and weight loss are associated with adverse outcomes in patients with advanced gastrointestinal and lung cancers. While olanzapine has demonstrated efficacy in improving appetite and weight gain, the impact of weight gain on body composition remains unclear. We evaluated changes in morphomic parameters among patients receiving olanzapine during chemotherapy. **Methods:** In this phase III, randomized, double-blind, placebo-controlled trial, adults (≥18 years) with untreated locally advanced or metastatic gastric, hepatopancreaticobiliary, or lung cancer were randomized to receive olanzapine 2.5 mg once daily or placebo for 12 weeks, along with standard chemotherapy and nutritional counseling. The primary endpoint was the proportion of patients achieving > 5% weight gain. Secondary endpoints included changes in skeletal muscle index (SMI), subcutaneous fat index (SFI), and visceral fat index (VFI) assessed at the third lumbar vertebra on CT scans. Morphomic analysis was performed in patients with paired baseline and interim CT scans. **Results:** A total of 103 patients (olanzapine, n = 53; placebo, n = 50) were included in the morphomic analysis. Baseline characteristics were comparable between groups. Weight gain > 5% was significantly more frequent in the olanzapine group compared with placebo (60% vs 9%, $p < 0.0001$). Both groups experienced a decline in mean SMI; however, among olanzapine-treated patients with > 5% weight gain, 63% demonstrated improvement or stabilization of SMI. Improvement in SFI was more frequent with olanzapine than placebo (62% vs 40%, p = 0.047). Among patients with > 5% weight gain, a higher proportion in the olanzapine group showed an increase in VFI compared with placebo (72% vs 60%, p = 0.006). **Conclusions:** Olanzapine improves weight gain with favorable changes in skeletal muscle and fat indices, indicating true nutritional gain rather than fluid retention in patients with chemotherapy-related anorexia. These findings suggest that olanzapine may favorably modulate cancer-related anorexia and treatment outcomes, warranting further validation in larger focused studies. Clinical trial information: CTRI/2020/08/027133. Research Sponsor: Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER) - Intramural funding.

Clinical outcomes of gabapentinoids for oncologic pruritus: A retrospective cohort study. First Author: Alim Osman, Department of Medicine, Dermatology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Pruritus is a debilitating symptom in oncologic patients, sometimes leading to interruption of cancer therapy. Gabapentinoids such as gabapentin and pregabalin are effective for the treatment of uremic and neuropathic pruritus. We report on the safety and efficacy of gabapentinoids for oncologic pruritus defined as any pruritus originating from malignancy, oncologic therapies, or other cancer-associated toxicities, such as cutaneous graft-versus-host disease (GVHD). **Methods:** In this single-center retrospective cohort study conducted at the Memorial Sloan Kettering Cancer Center between 4/1/2019 and 8/1/2024, 224 patients who were prescribed gabapentinoids for oncologic pruritus were included. Patients taking gabapentinoids for indications other than pruritus were excluded. The primary efficacy endpoint was ≥ 1-grade improvement for pruritus severity on the Common Terminology Criteria for Adverse Events (CTCAE) v5.0 scale. **Results:** The cohort was predominantly male (54%) and White (67%), with Black (14.3%) and Asian (12.5%) patients also represented; the mean age was 63.2 ± 15 years. Gabapentinoids were most prescribed for drug-induced causes (58.9%) and malignancy-related pruritus (14.3%). Of the drug-induced causes, immune checkpoint inhibitors (40.2%), monoclonal antibodies (12.9%; including mogamulizumab, brentuximab vedotin, and enfortumab vedotin), and tyrosine kinase inhibitors (11.4%) were the most common triggers. Pregabalin was more commonly prescribed compared to gabapentin (80.8% vs. 19.2%). Ninety percent of patients (n=202) experienced a ≥1-CTCAE grade improvement at a median total daily dosage of 50 mg (IQR, 25 mg) for pregabalin and 300 mg (IQR, 50 mg) for gabapentin. Median time for patient-reported improvement was 18.5 days and there was no significant difference in gabapentin response between pruritus etiologies. The most common adverse event was sedation (8.5%), with 3 patients discontinuing gabapentinoids due to fatigue. **Conclusions:** This study is the first to report that gabapentinoids are a safe and effective way to treat oncologic pruritus stemming from malignancy, cancer therapies, or cutaneous GVHD. Prospective trials would further establish gabapentinoids' safety and efficacy profile in the oncologic population. Research Sponsor: None.

Outcomes & adverse events of patients on gabapentinoids.

Variable	Category/Statistic	N (%)
CTCAE Grade Change	Did Not Improve (0 Grade)	22 (9.8%)
	Improved 1 Grade	132 (58.9%)
	Improved ≥ 2 Grade	70 (31.3%)
Antineoplastic Therapy Interrupted Due to Oncologic Pruritus	Yes	26 (11.7%)
	No	157 (70.4%)
	Not Applicable	40 (17.9%)
Adverse Events*	Sedation	19 (8.5%)
	Leg Swelling	2 (0.9%)
	Other	9 (4.0%)

*The remaining 194 (86.6%) patients did not report any adverse events related to the gabapentinoids.

Cancer cachexia and symptomatic toxicity among 706 older adults with advanced cancer receiving treatment: A URCC NCORP nationwide study. First Author: Lindsey Jean Mattick, Department of Surgery, Division of Supportive Care in Cancer, University of Rochester Medical Center, Rochester, NY

Background: Cancer cachexia is a severe wasting condition characterized by rapid weight loss. Its impact on symptomatic toxicity is poorly defined in geriatric oncology populations, who are at high risk for cachexia. Symptomatic toxicity is central to treatment tolerability and is linked to poor quality of life, functional decline, and reduced survival. We evaluated whether cachexia is associated with symptomatic toxicity before and during high-risk cancer treatment in older adults with advanced cancer. **Methods:** In a randomized controlled trial (GAP70+; NCT02054741), adults aged ≥70 with stage III or IV solid tumors or lymphoma were recruited prior to starting a new cancer treatment from 40 community oncology practices affiliated with the University of Rochester NCI Community Oncology Research Program (NCORP) Research Base. Cachexia (≥5% weight loss in the past six months) was assessed at baseline via Mini Nutritional Assessment. Symptoms (fatigue, insomnia, pain, anorexia, dyspnea, concentration problems, nausea, sensory neuropathy, constipation, diarrhea) were assessed at baseline and 3 months using the Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE). Symptoms were measured as mild, moderate, severe, or very severe. Log-binomial regression models examined associations of cachexia with baseline and three-month incident symptoms (baseline-adjusted method). **Results:** Among 706 participants (mean age: 77.2 years; 57% male; 59% gastrointestinal or lung cancer; 26% received prior chemotherapy), 42% had cachexia at baseline. Participants with cachexia were more likely than those without to report severe/very severe baseline symptoms (56% vs. 35%, chi-square $p < 0.01$). Analyses show that those with cachexia were 2-3 times more likely to report baseline severe/very severe anorexia (Risk Ratio (RR): 3.64, 95%CI: 2.44 - 5.42), fatigue (RR: 2.28, 95%CI: 1.65 - 3.16), pain (RR: 2.03, 95%CI: 1.36 - 3.04), and constipation (RR: 2.02, 95%CI: 1.27 - 3.22), as well as moderate or worse nausea (RR: 1.72, 95%CI: 1.16 - 2.55) and concentration problems (RR: 1.56, 95%CI: 1.03 - 2.39; all $p < 0.05$). Baseline cachexia was also associated with the development of severe/very severe anorexia (RR: 1.88, 95%CI: 1.20 - 2.94; $p < 0.01$) from baseline to 3-months. **Conclusions:** Nearly half of older adults with advanced cancer initiating a treatment regimen have cachexia. We demonstrate via PRO-CTCAE that cachexia is associated with a significantly worse pre-treatment symptom burden. Cachexia was linked to severe anorexia before and after treatment initiation, highlighting a critical gap in supportive care. As novel agents targeting appetite and cachexia enter phase III trials, further research is needed to establish the temporal course of cachexia-related symptoms to identify ideal timing and candidates for therapeutic strategies. Clinical trial information: NCT02054741. Enhancing supportive care in malignant bowel obstruction: A QI project using virtual dietitian-led low-fiber diet education. First Author: Bojan Macanovic, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: Malignant bowel obstruction (MBO) is a frequent, debilitating complication in patients with gynecologic malignancies associated with poor prognosis. Low-fibre diet (LFD) is a core component of conservative management; however, adherence is challenging and may be improved with coaching. To address this gap, we implemented a virtual dietitian-led educational intervention and evaluated patient knowledge, attitudes, and practices regarding LFD. **Methods:** This prospective quality improvement project was conducted at Princess Margaret Cancer Centre between October 2024 and April 2025. Adult patients with gynecologic malignancies who had developed or were at risk of MBO participated in interactive virtual LFD classes delivered by a registered dietitian. Electronic surveys assessed patient knowledge, attitudes, and dietary practices at baseline, post-class, and at two-week follow-up. Outcomes were summarized using descriptive statistics. **Results:** Of 71 patients approached, 48 (68%) attended the class. Surveys were completed by 43 patients pre-class (61%), 26 post-class (37%), and 18 at follow-up (25%). Median age was 64 years (range 31–79); 32/43 (74%) had ovarian cancer, and 12/43 (28%) had prior bowel obstruction. At baseline, 40/43 (93%) understood the rationale for LFD, but only 26/43 (60%) reported knowing which foods were permitted and 26/43 (60%) which were restricted. Baseline concerns included inadequate healthy food options (32/43, 74%) and limited cultural food compatibility (12/43, 28%). Following the intervention, understanding of permitted foods increased to 24/26 (92%; +32%) and restricted foods to 22/26 (85%; +24%). Confidence that LFD could reduce the risk of MBO improved from 16/43 (37%) to 16/26 (62%; +25%). The virtual format was well received, with 25/26 (96%) feeling comfortable and 22/26 (85%) identifying the class as an important part of their care. At two-week follow up, 15/18 (83%) felt confident in selecting appropriate foods. Adherence was high with 6/18 (33%) following LFD always and 9/18 (50%) most of the time. Despite improved knowledge and adherence, overall satisfaction with LFD remained low (baseline 7/43, 16%; follow-up 3/18, 17%). Challenges including limited food variety, difficulty identifying appealing options, and managing concurrent dietary restrictions, were reported by 9/18 (50%). Quality of life outcomes were mixed, with equal proportions reporting improved, unchanged or worsened: each 6/18, 33%. **Conclusions:** This quality improvement project demonstrates that a virtual, dietitian-led LFD education is feasible, acceptable, and effective in addressing key knowledge and confidence gaps for patients with or at risk of MBO. Persistent dissatisfaction with LFD highlights the need for future QI efforts focused on developing culturally inclusive resources and integration of multiple dietary needs. Research Sponsor: None.

Fatigue and psychostimulant use in patients with advanced cancer in an oncology palliative care clinic: A retrospective cohort study. First Author: Nicolas Chin-Yee, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Cancer-related fatigue (CRF) is the most common symptom experienced by patients with cancer but is underreported and undertreated. Psychostimulants are prescribed for CRF despite limited evidence; data on real-world use of these medications for CRF is scant. We aimed to describe the prevalence and predictors of CRF and psychostimulant use, and the association of psychostimulant use with CRF improvement in an oncology palliative care clinic (OPC). **Methods:** We conducted a retrospective review of new consultations in the Princess Margaret Cancer Centre OPC from Jan 1, 2018 - Jul 30, 2025. Demographic and clinical characteristics, including Palliative Performance Scale (PPS) and Edmonton Symptom Assessment System (revised, with constipation and sleep, ESAS-rCS) scores were recorded. Psychostimulant prescriptions were extracted from Epic, the electronic medical record system as of Jun 4, 2022. We calculated prevalence of fatigue in the total cohort and psychostimulant prescription following initial OPC visit in the subcohort seen on/after Jun 4, 2022. For the latter group, we reviewed charts to assess adherence, CRF severity, patient perception of efficacy and adverse effects. Multivariable logistic regression evaluated baseline factors associated with moderate-severe fatigue ($\geq$4/10 on ESAS-rCS) and psychostimulant prescription. We compared pre- and post-psychostimulant fatigue scores by Wilcoxon signed rank test. **Results:** 8,439 patients (5,812 with complete ESAS-rCS) were seen in the OPC from Jan 1, 2018 - Jul 30, 2025; 74.4% and 40.6% reported fatigue $\geq$4/10 and $\geq$7/10, respectively. Moderate-severe fatigue was independently associated with lower PPS ($<$ 60 vs $\geq$60, OR 1.66, 95% CI 1.15-2.38, $p < 0.01$) and worse ESAS-rCS scores for pain, drowsiness, appetite, dyspnea, depression, and wellbeing ($p < 0.0001$). Among 3,623 patients seen on/after Jun 4, 2022, 140 (3.9%) were prescribed a psychostimulant by the OPC; no baseline patient factors were associated with psychostimulant prescription. Of these 140 patients, 139 were prescribed methylphenidate at a maximum total daily dose $\leq$10 mg; 77 adhered to treatment and had follow up notes reporting effects. Of evaluable patients, 53 (68.8%) reported improved fatigue, 12 (15.6%) no benefit, and 12 (15.6%) had conflicting notes regarding effectiveness; 3 (3.9%) reported non-serious adverse events related to methylphenidate. Median (interquartile range) fatigue scores pre- and post-psychostimulant treatment were 7 (5-8) and 6 (3-7), respectively ($p <$ 0.01). **Conclusions:** Nearly 3/4 of patients with advanced cancer receiving outpatient palliative care experienced fatigue, yet few were treated with psychostimulants. Most patients reported improvement in fatigue with low-dose methylphenidate. Future studies should address knowledge gaps in assessment and management of CRF and the role of psychostimulants. Association of iterative cannabis care plans with rates of symptom relief and side effect burden in oncology patients. First Author: Brooke Worster, Sidney Kimmel Comprehensive Cancer Center, Jefferson Health, Philadelphia, PA

Background: Cannabis is increasingly used to manage cancer-related symptoms including pain, sleep disturbance, anxiety, and appetite or gastrointestinal complaints. However, patient responses are highly variable, clinicians report limited confidence in guiding use, and optimal dosing is difficult to predict from baseline characteristics. We evaluated whether an iterative, guided cannabis care model incorporating ongoing patient feedback and care-plan adjustments is associated with improved symptom relief and lower side-effect burden in a real-world oncology population. **Methods:** We conducted a retrospective observational analysis of cancer patients receiving cannabis-based symptom management through a structured care-planning program. Baseline demographics, cannabis experience, THC dosing, and number of care-plan adjustments were collected. Patients provided longitudinal feedback on symptom outcomes and tolerability at serial check-ins. Significant symptom relief was defined as a $\geq$3-point reduction in PROMIS T-scores across pain, sleep, anxiety, and appetite/nausea domains. Side-effect burden was assessed as the percentage of follow-up check-ins with reported side effects. Logistic regression examined associations between care-plan adjustments and symptom relief, adjusting for age, cannabis experience, and final THC dose. **Results:** A total of 136 patients receiving active cancer treatment were included (mean age 61 years; range 26–91). Overall, 56% reported significant relief across all symptom domains. Rates of global symptom relief increased with care-plan iteration: 34.6% among patients with no adjustments, 72.4% among those with 1–2 adjustments, and 96.6% among those with $\geq$3 adjustments, demonstrating a strong relationship. Care-plan iteration was also associated with lower longitudinal side-effect burden, with side effects reported at 25.6% of check-ins among patients with no adjustments, 17.5% with 1–2 adjustments, and 11.7% with $\geq$3 adjustments. In adjusted analyses, each additional adjustment was independently associated with higher odds of global symptom relief, while baseline demographic and clinical characteristics were not strong predictors of response. **Conclusions:** Symptom response to cannabis therapy among oncology patients is heterogeneous and not reliably predicted by baseline characteristics. In this real-world cohort, iterative cannabis care plans incorporating ongoing monitoring and adjustment were associated with substantially higher rates of meaningful symptom relief and a lower burden of side effects over time. These findings support adaptive, feedback-driven cannabis care models over fixed dosing strategies in supportive oncology. Research Sponsor: None.

Meaning, distress, and desire for hastened death in homebound adults with advanced cancer: A cluster analysis. First Author: Addison Dean Monroe, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Patients with advanced cancer experience significant anxiety and depression exacerbating existential distress, which is often defined as a loss of meaning and dignity, desire for death, hopelessness, and/or demoralization. Such distress is even more pronounced for homebound adults with cancer who are isolated and engage less in enjoyable activities. While meaning in life, affective distress, and existential distress are related, discrepancies exist in the literature which may reflect the presence of distinct psychosocial profiles as opposed to inconsistencies in the literature. **Methods:** Patients with advanced cancer (N = 64) who had recently completed an episode of home care and completed baseline assessments in a pilot randomized controlled trial (RCT) of Meaning-Centered Psychotherapy for Hospitals, Hospice, and Home (MCP-H) served as the study sample. Baseline assessments included measures of meaning in life, anxiety, depression, and desire for hastened death. A hierarchical agglomerative cluster analysis was conducted to identify naturally occurring subgroups of participants. Subgroup differences in predictor variables, physical symptom burden, and demographic variables were explored. **Results:** A 2-cluster solution emerged from the data: *Low Meaning, High Distress and DHD* (n = 29; 45.3%) and *High Meaning, Low Distress and DHD* (n = 35; 54.7%). Subgroups were statistically discrepant on measures of meaning in life (d = 0.57), anxiety (d = 3.07), depression (d = 2.57), and DHD (d = 2.76), with medium to large effect sizes. Subgroups were also significantly different in physical quality of life (d = 16.50). No significant differences were noted demographically between subgroups. **Conclusions:** To our knowledge, this is the first cluster analysis investigating affective and existential distress in a population of homebound adults with advanced cancer. Results suggest the possibility of 2 distinct subgroups of homebound cancer patients, the first of which is prone to clinically significant anxiety, depression, and moderate DHD, possibly due to a subtle difference in meaning in life. Results also point to physical symptom burden and quality of life being exponentially impacted by affective and existential distress. This study provides valuable information which can aid assessment and treatment for vulnerable homebound adults with advanced cancer. Race/ethnicity-stratified survival differences associated with psychotropic medication use in pancreatic cancer. First Author: Hussein Khalil, Purdue University, West Lafayette, IN

Background: Pancreatic cancer is linked to poor survival and a high burden of neuropsychiatric symptoms. Psychotropic medications are used to manage these symptoms, yet racial/ethnic disparities in use have been reported. The association between psychotropic use and survival in pancreatic cancer across racial and ethnic groups remains unclear. We evaluated race/ethnicity–stratified differences in 2-year survival associated with psychotropic use among older adults with pancreatic cancer. **Methods:** Retrospective cohort study using SEER–Medicare data (2007–2019) including patients aged $\geq$65 years with incident pancreatic cancer and continuous Medicare Parts A, B, and D coverage. Psychotropic use was defined as $\geq$1 Part D claim for antipsychotics, antidepressants, or anxiolytics. Overall survival was assessed using restricted mean survival time (RMST) up to 730 days post-diagnosis. RMST differences between users and non-users were compared within race/ethnicity strata (non-Hispanic White = NHW, non-Hispanic Black = NHB, Hispanic, Other) Sidak-adjusted chi-square tests. **Results:** Among 81,535 patients, 33.8% received at least one psychotropic medication. Overall psychotropic use was associated with a modest increase in RMST (+8.3 days), driven by antidepressants (+10.7 days) and anxiolytics (+26.8 days), while antipsychotic use was associated with shorter RMST (−13.7 days). RMST gains varied by race/ethnicity, with larger increases among NHB (+17.1 days) and Hispanic patients (+16.4 days), smaller gains among NHW (+4.1 days), and no benefit among Other races (−3.6 days). Antipsychotic-associated RMST deficits were greatest among NHB patients (−34.4 days). Antidepressants were associated with longer RMST across all groups whereas anxiolytic benefits were not observed among Other races. **Conclusions:** In this cohort of older adults with pancreatic cancer, psychotropic medication use was associated with modestly longer survival overall, largely attributable to antidepressants and anxiolytics, while antipsychotic use was associated with shorter survival. Survival associations varied by race and ethnicity, with larger gains among NHB and Hispanic patients. These findings underscore the importance of equitable recognition and management of neuropsychiatric symptoms and support further research incorporating symptom severity and medication use. Research Sponsor: None.

RMST difference (days) comparing psychotropic users vs non-users stratified by race/ethnicity.

National trends in palliative care use among hospitalized cancer patients: A seven-year analysis of demographic and socioeconomic disparities. First Author: Aishwarya Ramesh, The New York Medical College Graduate Medical Education Program at St. Mary's General Hospital and St. Clare's Health, Denville, NJ

Background: The 2016 ASCO guidelines recommend that patients with advanced cancer receive dedicated palliative care (PalC) services early in the disease course, concurrent with active treatment, within 8 weeks of diagnosis. Despite these efforts, disparities persist in the use of PalC across various demographic groups. Our study evaluated the pattern and temporal trends in PalC use among adult cancer patients to identify inequities across various clinical factors. **Methods:** We analyzed adult cancer hospitalizations from the 2016-2022 National Inpatient Sample. PalC was identified using ICD-10 code Z51.5. Utilization trends were examined by hospital type, demographics (age, sex, race/ethnicity), income quartile, and insurance type. Trends in mean age and in-hospital mortality among PalC recipients were calculated. Survey-weighted regression models assessed temporal trends, accounting for complex sampling design ($p < 0.05$ significant). **Results:** We analyzed 18,574,934 hospitalizations from 2016 to 2022. PalC utilization increased significantly from 10.61% in 2016 to 14.01% in 2022 ($p < 0.001$), representing a 32% relative increase. The mean age of PalC recipients rose from 68.61 years to 69.63 years ($p < 0.001$), while in-hospital mortality remained stable at approximately 28-29% (p = 0.144). Utilization increased across all subgroups (all $p < 0.001$). By hospital type, urban teaching hospitals had the highest overall utilization (12.40%, range 10.72-14.01%), followed by urban nonteaching hospitals (12.07%, range 10.81-14.63%), and rural hospitals had the lowest (10.77%, range 8.81-12.71%). Black patients had the highest overall utilization (13.44%, range 11.75-15.20%), followed by White (12.15%, range 10.52-14.02%) and Hispanic patients (11.57%, range 10.04-12.48%). Females had higher utilization than males (12.72% vs 11.83%). By insurance, Medicaid had 12.79% utilization (range 11.18-14.60%), Medicare 12.72% (range 11.00-14.52%), and private insurance 10.13% (range 8.86-11.56%). The lowest income quartile had 12.47% utilization (range 10.73-14.31%) compared to 12.04% (range 10.45-13.50%) in the highest quartile. All demographic and socioeconomic subgroups demonstrated significant increasing trends over the study period. **Conclusions:** PalC utilization increased significantly across all groups, with stable mortality rates. However, disparities remain, with lower utilization in rural hospitals, among privately insured patients, and among Hispanic populations. Despite progress in overall adoption, these findings highlight ongoing inequities in PalC access that require targeted interventions to achieve equitable guideline implementation. Research Sponsor: None.

Pilot trial of virtual and in-person symptom screening with targeted early palliative care (STEP2). First Author: Camilla Zimmermann, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: Routine early palliative care (EPC) for patients with advanced cancer improves quality of life. To increase scalability, models of triggered EPC have been encouraged. We assessed feasibility of hybrid virtual/in person Symptom screening and Targeted Early Palliative care (STEP2) to provide EPC triggered by symptoms. **Methods:** Patients with advanced cancer, ECOG 0-2, prognosis 6-36 months, were recruited from lung, gastrointestinal, genitourinary, breast and gynecology outpatient oncology clinics. Symptoms were screened virtually/in person ≤48 hours before oncology visits using Edmonton Symptom Assessment System-revised (ESAS-r+). Moderate to severe symptom scores ("screen positive") triggered an alert to a nurse, who called the patient, offering an EPC visit (in-person/virtual, as per patient preference). Participants completed measures at baseline, 2, 4, and 6 months. The primary endpoint was feasibility, with the following criteria: ≥40 patients accrued in 4 months; ≥60% complete screening for ≥70% of visits; ≥50% triggering a call have ≥1 EPC visit; ≥60% complete all measures. **Results:** From 30/03/2025-26/06/2025 40 patients were enrolled (median age [range], 62 [39-88]; 21/40 [53%] female). Disease site distribution was: 12/40 (30%) lung, 9/40 (23%) gynecology, 8/40 (20%) genitourinary, 6/40 (15%) gastrointestinal, 5/40 (13%) breast. Of the 40 patients enrolled, 36 (90%) completed screening for ≥70% of visits and 29 (73%) screened positive: 18 at baseline and 11 later during the trial. The most common triggering symptoms were anxiety (18/29, 62%), sleep (17/29, 59%), depression (10/29, 35%), pain (8/29, 28%), and dyspnea (8/29, 28%); 21/29 (72%) screen-positive and 0 screen-negative patients received EPC before trial end. Measure completion at 2, 4, and 6 months was 90% (36/40), 85% (34/40), and 83% (33/40). Initial EPC visits were in person for 14/21 (67%) and virtual for 7/21 (33%); 20/21 (95%) of patients received ≥2 follow-up visits. Results for measures at baseline and at trial end are shown in the Table. **Conclusions:** Virtual/in person STEP2 is feasible and directs EPC to those who most need it, with most screen-positive patients accepting EPC. A phase III trial is underway. Clinical trial information: NCT06326554. Research Sponsor: AMS Healthcare.

Variable	Measure (score range)	Time point	N	Mean	Standard Deviation	Difference, 6 mo. vs. baseline (95% CI)

Integrated assessment of cachexia, body composition, and patient-reported outcomes in unplanned hospitalizations of patients with metastatic cancer (PRO-HAND study). First Author: Enes Yeşilbaş, Etlik City Hospital, Department of Medical Oncology, Ankara, Turkey

Background: Patients with metastatic cancer hospitalized for unplanned admissions represent a highly vulnerable population with substantial short-term mortality and readmission risk. Cachexia, altered body composition, and patient-reported outcomes (PROs) frequently coexist in this setting, yet their integrated relevance during hospitalization remains insufficiently characterized. **Methods:** PRO-HAND is a cross-sectional observational study including metastatic cancer patients hospitalized for unplanned admissions between September 2024 and September 2025 who had received systemic anticancer therapy within the preceding 6 months. Cachexia-related indices, bioelectrical impedance analysis (BIA)-derived body composition parameters, and PROs were assessed during hospitalization. Primary outcomes were 30-day mortality, 90-day mortality, and unplanned 30-day hospital readmission. Associations were evaluated using hierarchical multivariable logistic regression models with sequential adjustment for clinical variables, cachexia indices, body composition parameters, and PROs. Results are reported as odds ratios (ORs) with 95% confidence intervals (CIs). **Results:** A total of 233 patients were included (median age 62 years; 71.2% ECOG ≥2). Median follow-up was 3.35 months. Thirty-day mortality occurred in 21.9%, 90-day mortality in 23.2%, and unplanned 30-day readmission in 57.9%. Lower handgrip strength–based cachexia index (H-CXI) was associated with higher odds of 30-day mortality (OR per 10-unit decrease 1.43; 95% CI 1.19–1.74; $p<0.001$). ECOG ≥2 and lower phase angle were also associated with early mortality, whereas the composite triglyceride–glucose and inflammation index was not. For 90-day mortality, lower global quality-of-life scores and higher pain burden showed stronger associations than cachexia indices. For unplanned 30-day readmission, a higher total body water/fat-free mass (TBW/FFM) ratio was associated with increased risk. **Conclusions:** Cachexia severity, body composition abnormalities, and PROs show distinct, outcome-specific associations in metastatic cancer patients hospitalized for unplanned admissions. Integrated assessment during hospitalization may provide complementary clinical information across these domains. Clinical trial identification NCT07167082. Research Sponsor: None.

Selected baseline characteristics and outcomes.

Characteristic	n (%) or median (IQR)
Age ≥65 years	98 (42.1)
ECOG performance status ≥2	167 (71.7)
Weight loss ≥10% (6 months)	126 (54.1)
H-CXI	34.23 (14.95–71.02)
Phase angle, degrees	4.03 (2.95–5.52)
FFMI, kg/m²	17.14 (15.48–19.31)
FACT-G total score	62 (56–68)
Pain score (VAS 0–10)	4 (2–6)
Unplanned 30-day readmission	135 (57.9)
30-day mortality	51 (21.9)

12076 Poster Session

Dermatologic adverse events (dAEs) and emotional quality of life (QoL) in patients (pts) with breast cancer: A mixed-methods study. First Author: Elyssa Kim, Case Western Reserve University School of Medicine, Cleveland, OH

Background: dAEs are a common and impactful aspect of QoL and have an emotional impact. However, its measurement relating to cancer care is limited. Validated tools focus on dermatology or chemotherapy but can be disconnected. Our pilot study utilized several validated tools to assess overall dAEs and their impact. **Methods:** Mixed methods consisting of a cross-sectional survey with qualitative interviews was conducted on pts with breast cancer who recently completed (<1 year) chemotherapy (acute) or completed chemotherapy ≥1 year ago (longitudinal). A panel of dermatologic and oncologic patient-reported outcome measures (PROMs) was: PRO Version of the Common Terminology Criteria for AEs (PRO-CTCAE), Skindex-16 (S-16), Fear of Cancer Recurrence–Short Form (FCR-SF), and Impact of Events–Intrusive Thoughts subscale (IES). Semi-structured interviews were done to elicit responsiveness to this panel. **Results:** 64 pts were screened & 60 enrolled (mean age: 63.0±19.1). Pts were Female and insured (100%), White (78.3%) & Black (20%). Pts were treated with radiation (70%), surgery (66.7%), hormone therapies (23%), targeted or immunotherapies (15%). Common symptoms were xerosis (73.3%), alopecia (66.7%), pruritus (58.3%). Mean total S-16 score was 19.4 (range: 0 (no impact) to 75.5 (most impact)); PRO-CTCAE 22.2 (0, 48.5); FCR-SF 43.2 (0, 97.2); IES 20.8 (0, 65.6). S-16 scores demonstrated moderate correlations with PRO-CTCAE (r=0.60, CI=0.41-0.74, $p<0.001$), indicating related but nonredundant constructs. The S-16 didn't correlate with the FCR-SF or IES, suggesting distinct emotional burdens on pts with cancer. There was no significant difference in survey scores between acute and longitudinal groups. Qualitative analyses revealed this combination of surveys encapsulated QoL and emotional experiences related to dAEs. Several pts were unaware of the dAEs they could experience as well as how to treat them. **Conclusions:** This is a novel assessment of dAEs in QoL, implementing and comparing cancer-specific PROMs to common dermatologic PROMs. Results indicate that dAEs significantly impact QoL and oncological psychometric outcomes are not fully captured with current dermatologic PROMs. Research Sponsor: None.

Sociodemographic determinants of end-of-life care settings and place of death among patients with lung cancer in the United States. First Author: Ali Mushtaq, Cleveland Clinic Foundation, Cleveland, OH

Background: Optimizing the place of death is a key component of quality end-of-life (EOL) cancer care, with home and hospice settings generally preferred over acute care hospitals. While lung cancer mortality has declined, disparities in EOL care utilization remain a concern. This study utilized the CDC WONDER database to analyze longitudinal trends and sociodemographic predictors of place of death for lung cancer decedents over a 25-year period. **Methods:** We performed a retrospective analysis of death certificate data for all lung cancer-related deaths in the U.S. from 1999 to 2023. Place of death was categorized as Decedent's Home, Hospice/Nursing Facility, Medical Facility-Inpatient (referent), or Outpatient/ER. Multinomial logistic regression estimated adjusted odds ratios (aOR) with 95% confidence intervals (CI) for predictors, adjusting for age, sex, race, ethnicity, urbanization, and year. **Results:** A total of 3,563,902 lung cancer deaths were identified. The most common place of death was the decedent's home (44.9%), followed by inpatient medical facilities (30.7%) and hospice/nursing facilities (22.1%). There was a significant longitudinal shift away from inpatient death. For every advancing calendar year, the odds of dying at home increased by 3% (OR 1.03; 95% CI 1.03-1.03) and the odds of dying in a hospice/nursing facility increased by 4% (OR 1.04; 95% CI 1.04-1.04). Compared to White patients, Black patients had significantly lower odds of dying at home (OR 0.57; 95% CI 0.57-0.58) or in a hospice facility (OR 0.68; 95% CI 0.68-0.68). Notably, Black patients had 53% higher odds of dying in an Outpatient/ER setting (OR 1.53; 95% CI 1.53-1.53) compared to White patients. Patients in rural areas had higher odds of dying at home (OR 1.17; 95% CI 1.16-1.17) but lower odds of dying in a hospice/nursing facility (OR 0.93; 95% CI 0.92-0.93) compared to those in large metropolitan areas. **Conclusions:** From 1999 to 2023, lung cancer mortality shifted significantly from inpatient settings to home and hospice care. Yet, Black patients remain significantly less likely to utilize home/hospice care and more likely to die in acute ER settings. Additionally, rural patients show high home death rates but lower facility-based hospice use, suggesting infrastructure gaps. Targeted interventions are required to ensure equitable EOL care access. More than pain relief: Associations between provider compassion, anxiety, and burnout in ED oncology care. First Author: Christopher John Coyne, University of California, San Diego, San Diego, CA

Background: Compassionate care is a cornerstone of high-quality oncology practice, especially in high-stress environments like the emergency department (ED). However, the relationship between perceived provider compassion and patient outcomes such as pain, psychological distress, and provider wellbeing is not well understood. **Methods:** We conducted a cross-sectional survey of oncology patients presenting to the ED. Participants completed validated assessments including the Brief Pain Inventory, the Schwartz Center Compassionate Care Scale (SCCCS), the Pain Catastrophizing Scale, the Pain Anxiety Symptom Scale, and the Self-Compassion Scale. Separately, ED providers were surveyed to assess their own burnout, rated on a 0–8 scale. Patients were grouped into High Compassion (SCCCS $>$100) and Low Compassion ($\leq$100) categories based on their ratings of provider compassion. Group comparisons were performed using t-tests, and linear regressions explored associations between compassion scores and patient-reported and provider-reported outcomes. **Results:** Of 57 patients, 22 (39%) reported high provider compassion. Median final pain was lower in the High Compassion group (2.0 vs 4.0), though not statistically significant (p=0.18). Patients in the High Compassion group had significantly lower pain anxiety scores (29.2 vs 52.5, p=0.014) and were seen by providers with significantly lower burnout scores (3.1 vs 5.6, p=0.022). A trend toward lower pain catastrophizing was also observed (15.6 vs 25.7, p=0.069). No significant differences were found in pain reduction or self-compassion. **Conclusions:** In a cohort of ED oncology patients, higher perceived provider compassion was significantly associated with lower pain anxiety and with lower provider-reported burnout, but not with pain scores. These findings suggest that compassion may be more strongly linked to patients' emotional experiences and the wellbeing of the providers delivering care. Integrating compassionate care practices into acute oncology settings may support both patient psychological health and provider sustainability. Research Sponsor: None.

Key outcomes by compassion group (>100 vs. ≤100).

Outcome	High Compassion (Mean)	Low Compassion (Mean)	p-value

Denosumab versus zoledronic acid in patients with breast cancer: A propensity-matched real-world time-to-event analysis. First Author: Mohammad Salameh, Hamilton Medical Center, Dalton, GA

Background: Bone-modifying agents are routinely used in patients with breast cancer to reduce skeletal-related complications and metabolic disturbances. Denosumab and zoledronic acid are commonly prescribed; however, comparative real-world data evaluating their relative safety and effectiveness remain limited. We compared time-to-event outcomes associated with denosumab versus zoledronic acid in a large real-world cohort of patients with breast cancer. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, comprising electronic health records from 70 healthcare organizations. Adult patients with breast cancer who received either denosumab or zoledronic acid were identified, excluding those with underlying osteoporosis. Patients were propensity score–matched 1:1 based on demographics, comorbidities, concomitant oncologic therapies, and baseline laboratory parameters, yielding 15,147 patients per cohort. Outcomes assessed over a 5-year follow-up period included time to hypercalcemia, severe hypercalcemia (serum calcium $\geq$14.0 mg/dL), hypocalcemia, pathological fracture in neoplastic disease, and bone pain. Time-to-event analyses were performed using Kaplan–Meier methods and compared with log-rank testing; hazard ratios (HRs) with 95% confidence intervals (CIs) were estimated. **Results:** After propensity score matching, 15,147 patients were included in each cohort with well-balanced baseline characteristics. Over 5 years of follow-up, hypercalcemia did not differ between patients treated with zoledronic acid and denosumab (hazard ratio [HR] 0.99, 95% CI 0.88–1.10; log-rank p= 0.831). Severe hypercalcemia (serum calcium $\geq$14.0 mg/dL) was uncommon, with no significant difference between groups (HR 1.25, 95% CI 0.94–1.68; log-rank p= 0.129). Pathological fracture in neoplastic disease occurred less frequently in the zoledronic acid cohort, although this difference did not reach statistical significance (HR 0.88, 95% CI 0.76–1.01; log-rank p= 0.060). Hypocalcemia was significantly less frequent among patients receiving zoledronic acid compared with denosumab (HR 0.44, 95% CI 0.40–0.49; log-rank $p<$ 0.001). Bone pain did not differ significantly between treatment groups (HR 0.95, 95% CI 0.89–1.02; log-rank p= 0.186). **Conclusions:** In this real-world analysis of patients with breast cancer, denosumab and zoledronic acid demonstrated similar time-to-event outcomes for hypercalcemia, severe hypercalcemia, pathological fracture, and bone pain, while zoledronic acid was associated with a significantly lower risk of hypocalcemia. These findings highlight important distinctions in toxicity profiles between agents and may inform individualized selection of bone-modifying therapy. Prospective studies are warranted to further define optimal agent selection in specific clinical subgroups. Research Sponsor: None.

12080 **Poster Session**

BXQ-350 in combination with FOLFOX7 and bevacizumab: Evaluation of effect on oxaliplatin-induced CIPN and neutropenia—A phase 1b/2a trial to assess the efficacy and safety of BXQ-350, a first-in-class sphingolipid metabolism modulator, in newly diagnosed metastatic colorectal carcinoma. First Author: Tariq Arshad, Bexion Pharmaceuticals, Covington, KY

Background: Chemotherapy-induced peripheral neuropathy (CIPN) and Neutropenia are significant side effects associated with many cancer drugs and are highly prevalent in mCRC patients receiving oxaliplatin-based regimens. CIPN can severely impact quality of life (QoL) and may require dose vacation, reduction or interruption. CIPN pathology is complex and not completely understood; preclinical and clinical data have shown inflammatory (IL-6, Il-8, IL-10) and immune involvement as well as elevated levels of sphingolipids, a class of bioactive signaling molecules. Neutropenia can also be a potentially severe side effect and may occur in up to 40% of mCRC patients receiving FOLFOX. BXQ-350 is a nanovesicle formulation of Saposin C, an allosteric activator of sphingolipid metabolism that normalizes dysregulated sphingolipid metabolism by lowering S1P, GM3 and GluCer levels while it increases ceramide level, promoting a return to homeostasis. **Methods:** BXQ-350 is being investigated in a Phase 1b/2 study in combination with mFOLFOX7 and Bevacizumab (SoC) in newly diagnosed mCRC patients (NCT05322590). Primary objectives are to assess safety and preliminary efficacy of this combination, and to determine cumulative oxaliplatin dose. Secondary objectives include intensity, frequency and time to onset of CIPN. **Results:** The Phase Ib trial enrolled 33 oxaliplatin dosing evaluable patients; all patients completed the primary treatment period (6 months of SoC treatment plus BXQ-350). Amongst the 33 patients, 19 completed the full 12 Cycles of oxaliplatin dosing, 28 completed at least 8 Cycles with only 2 patients having dosing halted before Cycle 8 due to CIPN. There were no reported Grade 4 and only 3 reported Grade 3 CIPN AEs, all occurred after Cycle 12. Analysis of Neurofibrillary Light Chain (NfL) biomarkers suggests concordance with physician and patient reported outcomes. Grade 3 or higher Neutropenia was meaningfully reduced to 5% in mCRC patients receiving FOLFOX plus Bevacizumab. **Conclusions:** Results show that BXQ-350 was safe and well tolerated in the combination. Data suggest that BXQ-350 may provide additional clinical benefits and may reduce intensity or delay onset of CIPN while meaningfully reducing Grade 3 or higher Neutropenia, allowing for increased cumulative dosing of oxaliplatin and relative dose intensity in 1L mCRC. Clinical trial information: NCT05322590. Research Sponsor: Bexion Pharmaceuticals.

Results from a pilot feasibility study of a novel community health worker–led intervention delivering stepped palliative care and care navigation for patients with pancreatic ductal adenocarcinoma. First Author: Nikhil Ravi Thiruvengadam, Loma Linda University, Loma Linda, CA

Background: Pancreatic Ductal Adenocarcinoma (PDAC) is associated with substantial morbidity, poor quality of life, and poor overall survival. Early palliative care (PC) has been shown to improve quality of life and reduce symptom burden in PDAC, but specialty PC services are often unavailable for this fast-progressing illness, and even then are only utilized by a minority of PDAC patients. To address this challenge, we developed a digitally enhanced CHW-led intervention to deliver stepped PC to patients with PDAC and to report its feasibility and preliminary efficacy. **Methods:** Adults (aged ≥18 years) with newly diagnosed PDAC (within 2 weeks of diagnosis) were enrolled in a single-arm pilot feasibility study from January to August 2025 (N = 48). The intervention involved early palliative care engagement with targeted escalation (stepping) for patients with untreated symptoms, leading to expedited PC visits, patient education, care navigation, and providing targeted financial resources for patients. The digital component involves using short educational videos and the Twilio SMS to administer the Edmonton Symptom Assessment Scale weekly, with patients with high symptom scores being stepped up to PC visits. The CHW-led intervention was delivered over 12 weeks. Feasibility outcomes were patient engagement with the CHW and completion of the intervention. The acceptability outcome was defined using the AIM-IAM-FIM instrument. Secondary outcomes include symptom burden (NCCN/FACT Hepatobiliary Cancer Symptom Index-18), Advanced Care Planning (ACP) compliance rates, and financial toxicity (measured by the COST instrument). **Results:** The median age of pts (N = 48) was 69 (IQR 62-76), and 29 (60%) were Hispanic. 25 (52%) had metastatic PDAC, 14 (29.1%) had borderline resectable PDAC, and 9 (18.8%) had resectable PDAC at diagnosis. Four patients died before the intervention was completed, while the remaining patients completed it. Regarding acceptability, 94% strongly agreed that the intervention was acceptable. Themes identified from exit-interviews included the critically important role of the CHW in the process, including appointment scheduling, especially as symptoms worsened. Patient's symptom burden (median 68 vs. 55, P = 0.02) and rates of financial toxicity (39% vs. 25%, p = 0.01) decreased from baseline to 12 weeks, while 83% of patients completed ACP by 12 weeks. **Conclusions:** Our digitally-enhanced CHW-led intervention delivering stepped PC was feasible and acceptable to patients with PDAC. The intervention was associated with improvement in symptom burden, reduction in financial toxicity, and higher ACP planning rates. Future prospective comparative studies are needed to understand the intervention's ability to help manage the morbidity associated with PDAC. Research Sponsor: DOD/CDMRP PCARP; PA230343.

Expressive writing for body image distress and anxiety in adolescent and young adult cancer survivors: A pilot, randomized controlled trial. First Author: Victoria A. Wytiaz, Department of Internal Medicine, University of Michigan Rogel Cancer Center, Ann Arbor, MI

Background: Up to 60% of adolescent and young adult cancer survivors (ages 15-39) experience body image distress but this is not well-managed due to multiple factors, including lack of provider expertise and patient hesitancy. Expressive writing invites participants to write openly about their thoughts and feelings related to a traumatic event, such as the cancer experience, to facilitate cognitive and emotional processing of the event. Expressive writing has not been explored in the AYA survivorship population with body image distress. The purpose of this pilot study is to determine the feasibility of implementing a four-week, in-home body image-focused expressive writing intervention for AYA cancer survivors with clinically significant body image distress. **Methods:** AYA cancer survivors with body image distress were recruited from oncology clinics at the University of Michigan and through institutional social media campaigns. Participants were randomized (1:1) to either a 4-week body image-focused expressive writing intervention or a control writing condition. Feasibility was based on recruitment and adherence, defined as completing 75% of writing sessions. Pre- and post-intervention, participants self-reported body image distress and anxiety utilizing the ten-item Body Image Scale (BIS) and the Generalized Anxiety Disorder 7 Scale (GAD-7). Changes in patient-reported outcomes were analyzed using linear mixed-effects models. **Results:** 27 participants were randomized (n=14 expressive writing, n=13 control) and were mainly female (96%) with locally advanced or metastatic cancer (60%). 26/27 (96.3%) completed all writing prompts outcome measures. Both groups demonstrated improvement in body image distress over the 4-week period. Expressive writing participants showed a numerically greater reduction (estimated change −5.57, 95% CI [−8.34, −2.8]). The difference-in-change between groups was −2.77 (time × treatment interaction, not significant). Results in Table 1. **Conclusions:** A four-week, in-home body image-focused expressive writing intervention demonstrated feasibility among AYA cancer survivors with body image distress. AYA cancer survivors face persistent body image distress that can affect quality of life. This intervention can offer a feasible, accessible, and low-cost approach to help mitigate these concerns. Further research is needed to determine the efficacy of the intervention to reduce body image distress among AYA cancer survivors. Clinical trial information: NCT06046014. Research Sponsor: Conquer Cancer Anna Braglia Endowed Young Investigator Award in Cancer Supportive Care.

Estimated change in BIS and GAD-7 from baseline to week 4 by group.

Outcome	Group	Estimated Change	95% CI	p-value
BIS score	Expressive Writing	-5.57	[-8.34, 2.8]	<0.001
BIS score	Control Writing	-2.77	[-5.75, 0.22]	0.0676
GAD-7 score	Expressive Writing	-0.93	[-3.34, 1.48]	0.435
GAD-7 score	Control Writing	-4.67	[-7.26, 2.08]	0.001

The psychosocial status of children who have a parent with cancer. First Author: Erdinc Nayir, Toros University, Mersin, Turkey

Background: While numerous studies have investigated the psychosocial status of children affected by childhood cancer, the number of studies investigating this situation in children whose parents have cancer is extremely limited. The purpose of this study is to determine the prevalence and causes of emotional and behavioral problems in children whose parents have cancer. **Methods:** We conducted the study in the medical oncology outpatient clinics between February and April in 2025. We included 73 children who have a parent diagnosed with cancer (case group) and an age- and gender-matched control group from healthy 59 children between the ages of 8-16. We subjected all the participants to the Revised Child Anxiety and Depression Scale (RCADS), recording their age, gender, parent gender and age, educational status, duration and severity of disease, number of siblings. **Results:** No statistically significant difference was found between the groups in terms of age, gender, education level, parent's age, gender, education level, and number of siblings ($p>0.001$). The case group exhibited significantly elevated anxiety ($p<0.001$) and depression scores (p=0.002), along with higher total scale scores ($p<0.001$), in comparison to the control group . Correlation analyses revealed weak but statistically significant positive correlations between age and total anxiety, depression, and total score in the case group (p= 0.010). Further examination of anxiety subdimensions showed similarly weak yet significant correlations with PaD, SAD, and OCD ($p<0.001$). The females within the case group exhibited significantly higher anxiety (p=0.030) and depression (p=0.035) scores, and higher total scale score (p=0.025) compared to males. Significant differences were observed in anxiety scores (p=0.018) and total scale scores (p=0.047) according to parental education level, with the highest scores consistently found among children whose parents held a master's degree. No significant differences were observed in anxiety, depression, or total scale scores according to the child's educational level, parent age, whether the patient was the father or the mother, disease duration and severity, and sibling status. **Conclusions:** Children of cancer patients are affected by their parents' health problems. These children should be considered in light of the "comprehensive approach to cancer". It should be noted that these children may need psychological rehabilitation at least as much as their parents with cancer. Research Sponsor: None.

Hearing/vestibular dysfunction and longitudinal changes in psychosocial well-being among breast cancer survivors. First Author: Jincong Q. Freeman, Cancer Prevention and Control Research Program, UChicago Medicine Comprehensive Cancer Center, Chicago, IL

Background: Breast cancer treatment, in some cases, can cause hearing/vestibular dysfunction and negatively affect patients' quality of life. The breast cancer survivor population is both growing and aging. Despite evidence that other cancer survivors have higher rates of hearing/vestibular problems than the general population, little is unknown about the impact of hearing/vestibular dysfunction on long-term changes in psychosocial well-being (PSWB) among breast cancer survivors. **Methods:** We surveyed the Chicago Multiethnic Epidemiologic Breast Cancer Cohort regarding whether patients had ever been told by a doctor that they had tinnitus, hearing loss, and/or vertigo between July and September 2023. PSWB was assessed repeatedly using the 10-item PROMIS on psychological distress/social isolation in 2020, 2021, 2022, and 2025. Total scores range from 0 to 40, with higher scores reflecting better PSWB. We fit separate linear mixed-effects models for hearing/vestibular dysfunction, controlling for age, race/ethnicity, marital status, income, insurance, comorbidity, AJCC stage, and treatment modality. Adjusted coefficients (β) and 95% CIs were calculated. **Results:** 1,466 breast cancer survivors were included: the mean age at survey was 63.5 years (SD 11.7); 69.6% identified as White, 22.6% as Black, 3.7% as Asian or Pacific Islander, and 3.6% as Hispanic. Overall, 16.5%, 17.4%, and 8.6% had tinnitus, hearing loss, and vertigo, respectively. The distribution of PSWB scores and trend over time are presented in the table. Survivors with hearing/vestibular dysfunction had lower mean scores than those without. After covariate adjustment, tinnitus (β −1.12; 95% CI −1.93, −0.30), hearing loss (β −1.12; 95% CI −1.93, −0.30), and vertigo (β −1.34; 95% CI −2.44, −0.24) were associated with significantly lower PSWB scores. In all subgroups, the PSWB score increased significantly over the years. Furthermore, Hispanic ethnicity, Medicaid, and being single were correlated with lower scores; whereas higher income levels were associated with higher scores. **Conclusions:** In this diverse cohort, breast cancer survivors with hearing/vestibular dysfunction experienced suboptimal PSWB over the study period. PSWB also varied by socioeconomic status. Oncology programs should consider screening for hearing/vestibular dysfunction and unmet sensory healthcare needs to improve PSWB and quality of life among breast cancer survivors. Cognitive impairment during anti-EGFR targeted therapy in metastatic colorectal cancer patients. First Author: Liubov Yu Vladimirova, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation

Background: Cognitive function is a critical determinant of psychosocial adaptation and quality of life in patients with cancer. Even mild cognitive impairment may negatively affect daily functioning, communication, compliance, and social participation. The psychosocial consequences of cognitive changes during medical treatment are insufficiently studied in metastatic colorectal cancer (mCRC) patients. Anti-EGFR-targeted therapy affects downstream MAPK signaling, a pathway involved in synaptic plasticity and cognitive processes. This provides a biological rationale for investigating cognitive outcomes and their psychosocial relevance. **Methods:** This study included patients with mCRC who received FOLFOX6-based first-line treatment. The main group (n = 50) received FOLFOX6 combined with an anti-EGFR monoclonal antibody (cetuximab or panitumumab), while the control group (n = 50) received FOLFOX6 +/-bevacizumab. Cognitive function was assessed at baseline and after eight cycles of therapy using the Addenbrooke's Cognitive Examination–Revised (ACE-R) and the Frontal Assessment Battery (FAB). Changes in cognitive performance were analyzed in relation to patients' functional vulnerability during ongoing treatment. Cognitive side effects were also evaluated according to CTCAE V.5.0. **Results:** Baseline cognitive performance was comparable between groups. After eight cycles of therapy, patients receiving anti-EGFR-targeted treatment demonstrated a significant decline in cognitive performance, including ACE-R total scores (from 93 [90; 94.5] to 87 [85; 90.5], $p < 0.001$), memory domain scores (from 22 [22; 23.5] to 20 [19; 20], $p < 0.001$), and attention/orientation scores (from 18 [16; 18] to 17 [15; 18], p = 0.005). In contrast, cognitive measures in the control group showed only minimal changes or remained stable over the same observation period. Evaluation according to CTCAE V.5.0. showed cognitive disturbance, memory and concentration impairments of mild and moderate grades, which were significantly more frequent in the anti-EGFR targeted group than in the control group (p<0,005). **Conclusions:** Anti-EGFR-targeted therapy in metastatic colorectal cancer patients may cause significant cognitive impairment, which undoubtedly contributes to psychosocial maladaptation and reduced quality of life. This pattern of selective cognitive decline may compromise functional independence, communication, and psychosocial adaptation during active anticancer treatment. Routine cognitive assessment during treatment may facilitate early identification of patients at risk and support multidisciplinary management strategies. In addition, the role of the MAPK signaling pathway in memory formation should be studied. Research Sponsor: None.

Burnout among caregivers of hospitalized medical oncology patients: A cross-sectional survey study. First Author: Suleyman Sami Guzel, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Medical Oncology, Istanbul, Turkey

Background: Caregivers of patients hospitalized in medical oncology wards play a crucial role in daily care and clinical decision-making, yet they are rarely screened for burnout. While caregiver burden has been widely studied in outpatient and palliative care settings, data focusing on inpatient oncology caregivers remain limited. This study aimed to evaluate burnout levels among caregivers of hospitalized medical oncology patients and to identify associated demographic and caregiving-related factors. **Methods:** This cross-sectional study included 91 caregivers of patients hospitalized in a medical oncology ward. Burnout and psychosocial distress were assessed using a structured 10-item survey developed based on established conceptual domains of burnout and caregiver burden. Items were rated on a 5-point Likert scale, with higher scores indicating greater burnout. Burnout levels were categorized as low (≤2), moderate (2–4), or high (≥4). Internal consistency was assessed using Cronbach's alpha. Group comparisons were performed using Mann–Whitney U and Kruskal–Wallis tests. Correlations were analyzed using Spearman's rho. Multiple linear regression analysis was conducted to identify independent predictors of burnout. **Results:** The median caregiver age was 49 years and 73.6% were female. The median burnout score was 3.0. Overall, 23.1% of caregivers reported low burnout, 57.1% moderate burnout, and 19.8% high burnout. Female caregivers had significantly higher burnout scores compared with males (p = 0.008). Caregivers with additional caregiving responsibilities also reported higher burnout levels (p = 0.026). Burnout scores correlated positively with duration of in-hospital caregiving ($\rho = 0.228$; p = 0.030). In multivariable regression analysis, female gender remained an independent predictor of higher burnout ($\beta = -0.298$; p = 0.003). Table 1 shows demographic and clinical characteristics of caregivers and patients. **Conclusions:** Caregivers of hospitalized medical oncology patients experience substantial levels of burnout, with nearly one in five reporting high burnout. Female caregivers appear to be at particularly high risk. These findings highlight the need for routine psychosocial screening and targeted supportive interventions for caregivers in inpatient oncology settings. Research Sponsor: None.

Longitudinal associations between patient and caregiver quality of life following hematopoietic stem cell transplantation. First Author: Daniel Yang, Duke University School of Medicine, Durham, NC

Background: Caregivers of patients undergoing hematopoietic stem cell transplantation (HSCT) experience high rates of psychological distress, yet patient-level factors most strongly associated with caregiver outcomes over time remain poorly understood. We evaluated longitudinal associations between patient and caregiver quality of life (QoL) following HSCT. **Methods:** We conducted a secondary analysis of the PROTECT randomized trial of integrated palliative care during HSCT. Among enrolled patient-caregiver dyads, we measured patient (FACT-BMT) and caregiver (CarGOQoL) QoL at baseline, week 2, and months 3, 6, and 12. Only patient-caregiver dyads that completed both measures were included in analyses at each timepoint. Linear mixed-effects models were used to assess the relationship between changes in patient QoL and changes in caregiver QoL, adjusting for time and treatment arm. **Results:** Among 186 enrolled patient-caregiver dyads, patients had a mean age of 55.2 ± 12.4 years and 65% were male. Mean CarGOQoL remained stable from baseline through month 12 (range: 74.1–75.9). FACT-BMT declined at week 2 (91.9 ± 20.4) compared to baseline (105.0 ± 18.8), then recovered and improved by month 3 through month 12 (Table 1). In multivariable mixed-effects modeling, within dyads, visits where the patient's QoL exceeded their usual level were associated with higher caregiver QoL ($\beta = 0.11$ per 1-point above the patient's mean; $p < 0.001$), adjusted for time and arm. **Conclusions:** While average caregiver QoL remained stable throughout the follow-up period despite changes in average patient QoL, individual caregiver QoL closely tracked their patient's QoL over the post-HSCT follow-up period. Patient-reported QoL represents a clinically meaningful marker to identify at-risk caregivers. Interventions targeting patient QoL may yield dual benefits for patient-caregiver dyads. Clinical trial information: NCT03641378. Research Sponsor: None.

Closing the depression gap in community oncology: Real-world outcomes from collaborative care. First Author: Tyler Jones, Colla Health, Portland, OR

Background: Depression is prevalent among patients with cancer, yet access to evidence-based care remains uneven. Community oncology clinics, where the majority of cancer care occurs, are less likely to offer integrated mental health services compared to comprehensive cancer centers, resulting in higher underdiagnosis, undertreatment, and persistent depressive symptoms. The Collaborative Care Model (CoCM) offers a potential strategy to address this disparity in community oncology. **Methods:** Community oncology patients with clinically significant symptoms of depression, as measured by a baseline PHQ-9 score ≥ 5, and receiving collaborative care, delivered primarily remotely, for at least 80 days were analyzed as part of this observational study. Patients had their PHQ-9 assessed after 90 (≥ 80 & ≤ 100) days, including evidence of remission (PHQ-9 < 5) and signs of response (decrease of PHQ-9 score by ≥ 50% or ≥ 5 points). Mean within-patient changes among all patients, stratified by baseline depression severity, were measured using paired t-tests. **Results:** Among 307 patients, mean PHQ-9 scores were observed to decline from 12.9 (SD 4.7) at baseline to 8.2 (SD 5.1) after 90 days of collaborative care (mean change -4.72, 95% CI -5.30 to -4.14, P< 0.001); 26.7% were observed to have depressive symptoms in remission and 51.5% had a clinical response. Patients with severe depression (PHQ-9 >=20) at baseline had the largest improvement (mean change -9.60, 95% CI -11.78 to -7.42, P < 0.001). **Conclusions:** Community oncology patients with depressive symptoms receiving collaborative care experienced reductions in PHQ-9 scores after 90 days of care, with a substantial proportion experiencing clinical response and/or remission in this brief timeframe. Symptom changes were observed across the full spectrum of symptom severity. These real-world outcomes highlight meaningful decreases in depressive symptoms, underscoring the promise of CoCM as a scalable care model for community oncology clinics. Research Sponsor: None.

Impact of structured oncologist-led home visits on psychological distress and resilience in patients with solid tumors undergoing chemotherapy: A comparative study. First Author: Sonya Kircheva Draganova, Nadezhda Hospital, Sofia, Bulgaria

Background: Psychological distress is prevalent among patients receiving chemotherapy. Home-based supportive interventions have the potential to address early psychosocial needs; however, data regarding their impact on both distress and resilience remain limited. **Methods:** Between March 1 and December 1, 2025, chemotherapy-naïve patients with solid tumors were invited to participate in a home-based supportive care study. Patients who opted for the intervention received a structured home visit by a medical oncologist following each of the first two chemotherapy cycles. These visits included patient-led discussions where the oncologist addressed questions regarding disease staging, prognosis, treatment protocols, and anticipated side effects. Before each chemotherapy cycle, patients completed self-reported assessments of psychological distress and resilience. Distress was measured using the Distress Thermometer (scale 0–10), with scores $\geq$4 categorized as high distress. Resilience was evaluated using the 10-item Connor-Davidson Resilience Scale, a unidimensional instrument where items are rated on a 5-point Likert scale. Higher scores indicate greater resilience. The control group consisted of patients who did not receive home visits; they completed the same assessments during routine clinic visits. In both cohorts, breast, lung, and colorectal cancers were the most frequent diagnoses. Distress and resilience outcomes were analyzed within each group across three time points using Cochran's Q and Friedman test. **Results:** The intervention group included 66 patients (12 male, 54 female) with a mean age of 58 years (SD $\pm$13.58). The proportion of patients reporting high distress decreased progressively: 72.7% at baseline, 53.0% after the first visit, and 45.5% after the second visit ($p < 0.001$). Mean distress scores also declined significantly from 4.91 $\pm$ 2.79) at baseline to 3.55 $\pm$ 2.71) and 3.53 $\pm$ 2.59) following the first and second visits, respectively ($p < 0.001$). In contrast, mean resilience scores remained stable (30.26 $\pm$7.06, 29.95 $\pm$ 8.82, and 28.24 $\pm$ 12.12; p = 0.72).The control group included 145 patients (39 male, 106 female) with a mean age of 58 years (SD $\pm$ 12.58). In this group, the prevalence of distress remained relatively stable across the three assessments: 66.2% at baseline, 57.9% at the second assessment, and 56.6% at the third (p = 0.074). Mean distress scores showed minimal variation: 4.45 $\pm$, 4.08 $\pm$, and 4.09 $\pm$, respectively (p = 0.163). Mean resilience scores exhibited a downward trend from 30.19 $\pm$ 7.74) to 27.03 $\pm$ 12.20) and 25.52 $\pm$ 13.21), though this did not reach statistical significance (p = 0.076). **Conclusions:** This study demonstrates that oncologist-led home visits during the early stages of chemotherapy can significantly reduce psychological distress in cancer patients while preserving resilience. Research Sponsor: None.

Impact of volunteer-integrated palliative home visits on psychological well-being among metastatic breast cancer patients in northern Malaysia. First Author: Siti Khairizan Binti Rahim, Universiti Sains Malaysia (USM) Medical Center Bertam, Kepala Batas, Malaysia

Background: Metastatic breast cancer patients face overlooked psychosocial challenges, mitigated through home visits. Universiti Sains Malaysia's volunteer-integrated palliative home visits bridge access gaps, support mental health (SDG 3), and foster partnerships (SDG 17). As Malaysia's most common female cancer (2017–2021: 16,430 cases, 22.2% stage IV), breast cancer highlights early palliative integration, yet local home-based outcomes remain unstudied. **Methods:** This prospective cross-sectional study (October 2024 to January 2026) in Northern Malaysia (Penang, Kedah) evaluated the impact of volunteer-integrated palliative home visits on Psychological Well-Being (Ryff 42-item scale, baseline and after 12 weeks). Healthcare professionals provided symptom and psychosocial care, while trained volunteers focused on emotional and practical support. Mixed teams (professionals and volunteers) conducted visits 1 and 6, with flexible staffing for intervening visits. Of 94 recruited patients, 81 completed the study and domain changes analyzed via descriptives, paired t-tests, and Cohen's d. **Results:** Participants were predominantly female (99%), aged 40 to 49 years (34.6%), low-income B40 group (64%) and multi-racial (78% Malay, 15% Chinese, 7% Indian). All had ECOG 0-3 at baseline, but 38% in ECOG 4 post-intervention. High-score groups (>30 on Ryff's subscale sums) increased for positive relations (70% to 95%), environmental mastery (47% to 69%), self-acceptance (45.5% to 68%), and personal growth (70% to 85%), but declined for autonomy (55.6% to 54.3%) and purpose in life (74% to 35%). Paired t-tests (Table 1) revealed significant small-to-moderate improvements in environmental mastery ($p<0.001$, d=0.46), positive relations ($p<0.001$, d=0.41), self-acceptance (p=0.042, d=0.23), and purpose in life (p=0.016, d=0.27). Changes in autonomy and personal growth were not statistically significant. Purpose-in-life declines reflect disease progression. **Conclusions:** The volunteer-integrated palliative care significantly improved environmental mastery, positive relations, self-acceptance, and purpose in life among breast cancer patients, despite ECOG deterioration. Findings support that the home visit enhanced psychological well-being amid disease progression, though refinement is needed for domains with non-significant changes. Research Sponsor: Pfizer Inc; 90835877.

Paired t-test results for Ryff Psychological Well-Being (PWB) domains (pre- vs. post-intervention).

Influence of socioeconomic factors on patient-reported provider communication among patients with cancer. First Author: Nishwant Swami, Hospital of the University of Pennsylvania, Philadelphia, PA

Background: Patient-provider communication is central to patient's understanding and overall experience, particularly in multi-disciplinary cancer care. Socioeconomic disadvantages may amplify downstream consequences of poor communication by eroding trust and exacerbating structural and access-related barriers. Using nationally representative survey data, we examined the association between socioeconomic factors and patient-reported communication experiences among adult cancer survivors. **Methods:** We analyzed pooled 2011-2023 data from the US Medical Expenditure Panel Survey (MEPS) to identify adults ($\geq$18 years) with a history of cancer. Patient-provider communication was assessed by how often providers (1) treated patients with respect, (2) listened carefully, (3) explained things in a way they understood, and (4) spent enough time. Survey-weighted estimates compared communication scores across income and insurance groups. Multivariable ordinal logistic regression (MVA) models including survey year, race/ethnicity, education, region, sex, marital status and age estimated adjusted odds ratios (aORs) for the association of income level and insurance with patient-provider communication. **Results:** Among 9,535 cancer survivors, those in the lowest income quintile (family income $<$ federal poverty line (FPL)) reported the lowest rates of effective provider communication across all domains (57% listened, 53% time, 61% respect, and 57% explained). Survivors who reported being uninsured similarly reported the lowest rates of provider communication (50% listened, 43% time, 49% respect, and 51% explained). In adjusted analyses, lowest-income survivors were less likely than the highest income quintile survivors ($> 4\times$FPL) to report being listened to (aOR 0.76, 95% CI 0.63–0.91), respected (aOR 0.76, 95% CI 0.63–0.93), or receiving clear explanations (aOR 0.75, 95% CI 0.63–0.91). Compared with privately insured patients, uninsured survivors were less likely to report clear explanations (aOR 0.57, 95% CI 0.39–0.85), or feeling listened to (aOR 0.56, 95% CI 0.38–0.82). Both uninsured and Medicaid-insured survivors were less likely to report adequate time (uninsured: aOR 0.54, 95% CI 0.36–0.82; Medicaid: aOR 0.89, 95% CI 0.79–0.99), or feeling respected (uninsured: aOR 0.51, 95% CI 0.35–0.73; Medicaid: aOR 0.86, 95% CI 0.76–0.98). **Conclusions:** Lower income and lack of insurance were associated with worse communication among US cancer survivors. Given substantial financial, logistical, and personal burdens of cancer care, these communication gaps may weaken trust and undermine patients' ability to understand and engage with recommended treatments. Targeted provider interventions aimed at improving clinician communication and care coordination will be essential to advancing equitable cancer care and rebuilding trust in an increasingly fractured healthcare system. Pilot RCT of a patient-centered communication intervention to promote values-based treatment decision-making in older adults with AML. First Author: Rachel Rodenbach, James P. Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY

Background: Older adults with acute myeloid leukemia (AML) often have limited involvement in high-stakes treatment decisions that involve tradeoffs between survival and quality of life. We developed a patient-centered communication intervention (UR-GOAL) to support values-based decision-making. We assessed how patients and oncologists discuss values during treatment decision-making and explored whether UR-GOAL improves these discussions. **Methods:** This pilot RCT randomized patients $\geq$60 years old with newly diagnosed AML to UR-GOAL vs. usual care. UR-GOAL uses best-worst scaling to help patients prior to deciding on treatment to prioritize their values, which are shared with the oncologist. Two team members blinded to arm independently coded transcribed treatment conversations for values talk, defined as discussion of what matters to patients in treatment decisions. Values included patient, disease/treatment, and sociocultural priorities; examples include quality of life, treatment effectiveness, and physician recommendation, respectively. Coders assessed the depth of values discussion (the extent to which the oncologist explored patient values beyond acknowledgment), patient engagement (e.g. patient elaborating on values and asking questions), and values alignment (whether the oncologist incorporated patients' most important values into the treatment plan). Differences in coding were resolved by consensus. Continuous outcomes were compared using t-tests or ANOVA and categorical outcomes using chi-square or Fisher's exact tests. **Results:** We included 92 patients (mean age 74 and SD 7; 63% male; 93% white). A mean of 6.0 values was discussed per encounter (SD 3.0), with fewer explored in depth (mean 1.5; SD 1.5). The number of values discussed in total and in depth did not differ between arms (total values: UR-GOAL 6.4 vs. usual care 5.7, p = 0.28; and in depth: UR-GOAL 1.4 vs. usual care 1.6, p = 0.14). However, patients showed a trend toward greater engagement in values discussions in the UR-GOAL arm compared with usual care (78% vs. 59%, p = 0.07). The values most commonly expressed by patients as most important in driving treatment decisions were treatment effectiveness (44%) and care logistics (e.g. treatment in hospital vs. clinic, 19%), followed by physician recommendation (7%), treatment toxicity (4%), and quality of life (3%). Values aligned with the treatment plan in 70% of cases (UR-GOAL 76% vs. usual care 63%, p = 0.26). Patients whose values aligned discussed more values compared with those whose values were not aligned, not discussed, or indeterminate (6.9 vs. 4.0, $p < 0.01$). **Conclusions:** Older adults with AML discuss several values with their oncologists during treatment decision-making, though fewer in depth. The UR-GOAL communication intervention may promote patient engagement in shared decision-making and value alignment. Clinical trial information: NCT05335369. Using the NCCN distress thermometer to evaluate clinically elevated levels of distress among caregivers of HSCT patients. First Author: Christine Vinci, Department of Health Outcomes and Behavior, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Caregivers of patients receiving an allogeneic hematopoietic stem cell transplant (HSCT) play a vital role in the care and recovery of patients. They must be present with the patient 24/7 for up to 100 days post-transplant, and they often report levels of distress higher than patients. Importantly, caregiver and patient distress are interdependent. Thus, knowing when to deploy appropriate resources and support to a distressed caregiver is essential. To date, the NCCN Distress Thermometer (DT) is a validated, single-item clinical measure consistently used in the oncology setting to assess and intervene upon patient distress. If such a tool was available for HSCT caregivers, oncology providers could assess and provide support for those in heightened distress. To date, limited research has been conducted in this area. This study examines the relationship of DT with self-reported depression and anxiety in a large sample of HSCT caregivers with the goal of proposing a potential clinical cut-point of elevated distress on the DT. **Methods:** Caregivers completed the DT, Center for Depression Studies Depression Scale (CESD), and Generalized Anxiety Disorder 7 (GAD7) 1-2 weeks pre-transplant as part of a larger study. Spearman correlation coefficients evaluated the association of the DT with CESD and GAD7. Logistic regression evaluated DT as a predictor of clinically elevated levels of depression (CESD $>$16) and anxiety (GAD7 $>$10). DT cut points (e.g., $\geq$4) as predictors of clinically elevated depression and anxiety were evaluated using sensitivity, specificity, and area under the curve (AUC). **Results:** Caregivers (N = 287) were 73% female, 75% spouse/partner of the patient, and ranged in age from 22-87 years (M = 58.2, SD = 13.4). The DT ranged from 0-10 with M = 4.5 (SD = 2.6). The CESD ranged from 0-51 with M = 13.3 (SD = 10.3) and 36% scored $>$16. The GAD7 ranged from 0-21 with M = 6.4 (SD = 5.5) and 24% scored $>$10. The DT was very strongly correlated (p's $<$ .0001) with the CESD (r_s= .69) and GAD7 (r_s= .76). DT score significantly predicted elevated depression (OR = 1.92, 95% CI[1.64-2.24]) and elevated anxiety (OR = 2.30, 95% CI[1.84-2.86]). Table 1 presents sensitivity, specificity, and AUC for DT cut points of 4-7. **Conclusions:** Findings suggest that although a cut-point of 4 on the DT has high specificity and a cut-point of 7 has high sensitivity, a cut-point of 6 indicates more balanced specificity and sensitivity when considering both depression and anxiety. In the clinical setting, providing the single-item DT as a measure of caregiver distress should allow for a brief and useful assessment indicating a greater need to provide support resources. Research Sponsor: National Cancer Institute.

A digital educational and decision-support intervention for patients with advanced lung cancer receiving immunotherapy: Results of a multi-phase, mixed-methods study. First Author: Matthias Villalobos, Department of Thoracic Oncology, Thoraxklinik, Heidelberg University Hospital and National Center for Tumor Diseases (NCT), NCT Heidelberg, Translational Lung Research Center Heidelberg (TLRC-H), Member of the German Center for Lung Research (DZL), Heidelberg, Germany

Background: Immunotherapy has transformed the treatment of advanced lung cancer, but it has also increased the complexity of information that patients must navigate. Knowledge deficits may compromise disease-management, shared decision-making, and goal-concordant care including timely integration of palliative care. This study aimed to develop and evaluate a digital application to support patients throughout this process. **Methods:** We employed a multiphase, mixed-methods design comprising: (1) a questionnaire-based online-survey with descriptive analysis (n = 186; SPSS); (2) semi-structured interviews with patients with advanced lung cancer analyzed using qualitative content analysis (n = 20; MAXQDA); (3) user-centered app development involving patients and health-care professionals; and (4) a pre-post pilot study (n = 69) analyzed using Wilcoxon signed-rank test. Primary outcomes for the pilot study were decisional conflict and knowledge; secondary outcomes included preparedness for decision-making, self-efficacy, usability, and acceptability. **Results:** Pre-development data integration revealed limited and frequently inaccurate patient knowledge regarding immunotherapy and treatment goals, as well as a discrepancy between patients' desired and actual involvement in treatment decisions, with minimal participation in physician-patient decision-making. The developed app demonstrated high usability and acceptability. In the pilot study, use of the app was associated with a statistically significant reduction in decisional conflict (median [IQR]: 20.3 [6.6–34.0] pre vs. 10.9 [3.1–29.7] post; p = 0.001), significant improvements in knowledge (p $<$ 0.001), and increased preparedness for decision-making. **Conclusions:** Insufficient patient participation in decision-making, combined with knowledge deficits about immunotherapy, underscores the need for enhanced communication strategies. The digital application developed in this study appears to be a feasible, acceptable, and effective tool to support informed decision-making among patients with advanced lung cancer. Future research should evaluate integration into routine clinical workflows, long-term impact, and adaptations to address diverse patient needs and evolving treatment options. Clinical trial information: 00032683. Research Sponsor: AstraZeneca.

12095 Poster Session

Protective factors supporting caregiver well-being in glioblastoma. First Author: Desiree Reinken, CEUFast, Villa Ridge, MO

Background: Caregiving in glioblastoma (GBM) means dealing with cancer symptoms, plus the neurological decline that comes with this disease. Becoming a caregiver is rarely straightforward. Caregivers often become essential to the patient's daily life and well-being, though this may result in neglecting their own health. Most caregivers develop coping strategies (protective factors such as caregiver mastery or spiritual beliefs) to manage the responsibility of caring for a terminally ill loved one. This study looked at how caregiver protective factors shifted across the disease trajectory and whether these factors were connected. **Methods:** This was a secondary analysis of data from a three-group randomized clinical trial testing a needs-based intervention for neuro-oncology caregivers (NINR # R01 NR013170). Caregivers were included if they were 21 or older, identified by the patient as their unpaid primary caregiver, spoke English, had phone access, were not caring for anyone else (except children under 21), and scored above 6 on the CES-D. Recruitment occurred from March 2014 to July 2016 at the University of Pittsburgh Medical Center, the University of Pittsburgh Cancer Institute, and the MD Anderson Cancer Center. Patients and caregivers gave informed consent prior to participation in the primary study. We conducted an a priori power analysis to determine the sample size required for detecting minimal differences in quality of life (QOL). The final sample included 60 caregivers. We measured outcomes at baseline, two, four, six, and ten months. Analysis used paired samples t-test, bivariate correlations, and linear mixed models. **Results:** Caregiver QOL changed significantly over time, particularly from baseline to four months (p = 0.02) and four to six months (p = 0.01). Protective factors correlated with one another at varying strengths (weak, moderate, and strong). At each time point, religion and spirituality were related to other protective factors. Spirituality had significant positive correlations with caregiver mastery (r = 0.32-0.65, p = $<$ .001-0.01) and QOL (r = 0.44-0.70, p = $<$ .001-0.01) throughout the study. After factoring in optimism, we found significant associations for caregiver mastery, positive aspects of caregiving, social support, and religion. **Conclusions:** Spirituality emerged as a key protective factor, yet most caregiver interventions ignore it. Providers should recognize and support spiritual coping mechanisms throughout GBM care, offering resources that match caregiver values and beliefs. Monitoring caregiver QOL is equally critical as tracking patient outcomes. When QOL declines, early interventions can prevent caregiver burnout and improve care quality for both members of the dyad. "When I'm translating, I'm a daughter as well": Perspectives of caregivers supporting patients with limited language proficiency. First Author: Rinat Nissim, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Family caregivers of people with advanced cancer provide essential support but often experience significant emotional distress. Caring for patients with limited language proficiency (LLP) introduces additional, distinct challenges. Patients with advanced cancer and LLP experience barriers to access and quality of care and advance care planning, resulting in increased reliance on family caregivers even when professional language services are available. This study explored the experiences and challenges of caregivers supporting advanced cancer patients with LLP to inform future interventions aimed at improving patient and caregiver outcomes. **Methods:** Caregivers supporting patients with advanced cancer and limited English proficiency treated at the Princess Margaret Cancer Centre (Toronto, Canada) were recruited via clinician referral and study flyers. Participants completed semi-structured interviews or focus groups exploring healthcare navigation, interpreter use, support needs, and recommendations for service improvement for patients with LLP. Transcripts were analyzed iteratively using practical thematic analysis. **Results:** Ten caregivers (ages 34–63; 6 female, 4 male; 2 spouses, 8 adult children; 5 supporting Chinese-speaking patients) participated. Participants acted as informal interpreters and mediators between patients and providers, a form of 'language brokering' that added substantial emotional and cognitive burden. Their experiences are subsumed under 4 interrelated themes: 1) Protective buffering and information gatekeeping: caregivers often filtered or withheld prognosis and end-of-life information to protect patients' emotional well-being or align with cultural values; 2) Interpreter use representing both relief and loss of control: professional interpretation reduced linguistic burden but created new concerns regarding privacy, cultural sensitivity, and control over sensitive discussions; 3) Constant vigilance: caregivers felt constant pressure to monitor and understand patients' symptoms and preferences, communicate them to providers, and support patient understanding and reassurance; and 4) Invisibility of caregiver needs: caregivers rarely recognized or prioritized their own needs, framing language brokering and caregiving as an expected familial or cultural duty. **Conclusions:** Family caregivers supporting patients with advanced cancer and LLP perform substantial emotional and cognitive labor that remains largely unrecognized in clinical practice. Interventions such as consistent and proactive access to professional interpreters and multilingual educational resources delivered across multiple modalities may support both patients and caregivers. These findings highlight an under-recognized but critical dimension of equitable, patient-centered oncology care. Research Sponsor: Princess Margaret Cancer Centre.

Assessing loneliness in glioblastoma patients and caregivers using a nationwide survey. First Author: Jacob Ellen, Harvard Medical School, Boston, MA

Background: Loneliness is associated with poorer health outcomes and quality of life in cancer patients, yet its prevalence in the glioblastoma (GBM) population remains understudied. GBM's rapid progression and intensive treatment demands affect both patients and caregivers, but the burden of loneliness in these groups is unknown. We conducted a nationwide survey that assessed loneliness prevalence within the GBM community. **Methods:** OurBrainBank, a patient-led GBM nonprofit, distributed a HIPAA-compliant survey from February to September 2024 to GBM patients, current caregivers, and caregivers bereaved within 12 months. Loneliness was measured using the validated 3-item UCLA Loneliness Scale (range 3–9), with scores $\geq$6 indicating loneliness. Multivariable linear and logistic regression examined associations between caregiver status, race (white vs non-white), and financial difficulties in the past year and loneliness, adjusting for age, gender, and urban vs rural residence. **Results:** Among 525 respondents (404 caregivers, 121 patients), median age at diagnosis was 59 years. Overall, 52.0% (273/525) met criteria for loneliness, and the median UCLA score of the sample was 6.0. Caregivers reported higher loneliness than patients: 57.4% (232/404) vs 33.9% (41/121) were lonely, with mean UCLA scores of 5.88 (SD 1.90) versus 4.78 (SD 1.81). In adjusted models, caregivers had nearly threefold higher odds of loneliness (OR 2.97, 95% CI 1.91–4.67) and UCLA scores 1.22 points higher on average compared to GBM patients (95% CI 0.83–1.61; both $p < 0.001$). Financial difficulty in the last year (29% of sample) was similarly associated with greater loneliness (OR = 1.85 for loneliness, p = 0.002; 0.68-point higher average UCLA scores, 95% CI 0.32-1.05, $p < 0.001$). Finally, non-white respondents (12% of the sample) had higher odds of high loneliness compared to white respondents (OR = 4.00, p = 0.01) and had a 0.59 point higher UCLA score on average (p = 0.03). **Conclusions:** In this nationwide survey, GBM caregivers experienced substantially greater loneliness than patients themselves, and loneliness was also concentrated among those facing financial hardship and among non-white respondents. These findings highlight an underrecognized psychosocial burden and support integrating caregiver-focused and equity-oriented interventions into GBM care. Research Sponsor: None.

Parent willingness to enroll children with acute lymphoblastic leukemia in escalation and de-escalation clinical trials. First Author: Kellee Nicole Parker, The University of Utah, Salt Lake City, UT

Background: Patient and parent willingness to participate in clinical trials has and will continue to be essential to improve care for children with acute lymphoblastic leukemia (ALL). Clinical trials for ALL can involve escalation of therapy (i.e., addition or intensification of chemotherapy or immunotherapy) or in subgroups with excellent prognosis, de-escalation of therapy (i.e., removal of agents or blocks of therapy with aim of minimizing toxicity). Understanding parents' decision making for trial participation is particularly important in de-escalation trials. We aimed to characterize parent willingness to enroll children with ALL in escalation and de-escalation clinical trials, identify sociodemographic and clinical determinants of willingness, and delineate decision making information needs. **Methods:** Parents of children currently or previously treated for ALL who are members of the Momcology support and advocacy organization completed an investigator-developed, parent-piloted online survey. Parents were presented with theoretical escalation and de-escalation trial scenarios and completed items about willingness to enroll their child and associated informational needs. Quantitative data were summarized descriptively and Spearman correlations examined associations with sociodemographic and clinical determinants. Qualitative data were analyzed using content analysis. **Results:** A total of 456 parents responded. Mean child age at diagnosis was 5.5 years [SD = 0.2, range 0-19]; 79% (369) had B-ALL and 17% (78) had T-ALL; and 65% (297) had completed therapy and were alive at the time of survey. Results showed that 22% (99) of parents would consider enrolling their child in a de-escalation clinical trial, 47% (216) would not, and 31% (141) were unsure. Responses for escalation trials (N = 423) were similar, with 21% (90) yes, 42% (179) no, and 36% (154) unsure. There was a significant negative correlation between both parent education level (rho = -0.12, p = 0.013) and annual household income (rho = -0.10, p = 0.047) with willingness to consider de-escalation, but not escalation, trial enrollment. Child age at diagnosis, current treatment status and distance from treatment center were not correlated with willingness. Parent decision making information needs clustered into three overarching domains:1) impact on likelihood of relapse, survival outcome, and late effects, 2) evidence credibility, and 3) applicability to their child's individual risk profile. **Conclusions:** Across a large parent sample, substantial hesitation to enroll children with ALL in both escalation and de-escalation trials exists. Sociodemographic factors were associated with de-escalation decision making. Further research is needed to incorporate evidence-based parent decision making support in future ALL trials and to evaluate decision making and correlates in real world scenarios. Research Sponsor: University of Utah, Department of Pediatrics; Children's Oncology Group.

New paradigms of cancer and new language: A qualitative study exploring language around goals of cancer surgery. First Author: Bonnie Odelia Wong, Brigham and Women's Hospital, Boston, MA

Background: Cancer interventions are often discussed amongst providers and presented to patients within the dichotomy of "curative" vs. "palliative" interventions. However, as understanding of cancer biology has shifted and as cancer treatments have evolved, some cancers have become chronic diseases for which surgery may have a non-curative but disease-targeted role. Despite new paradigms of cancer care, language has not evolved to reflect new goals of cancer surgery. **Methods:** Semi-structured interviews were conducted with cancer surgeons from throughout the U.S. via purposive and snowball sampling. Interviews included discussions of two hypothetical scenarios describing non-curative surgical operations and discussion of the term "disease-controlling" surgery as a category of neither palliative nor curative surgical intent. Transcribed and de-identified interviews were analyzed inductively using grounded theory. **Results:** 18 surgeons from 16 institutions were interviewed. Surgeons collectively outlined how changes in the paradigm of cancer treatment have resulted in challenges describing intent of cancer surgery. Specifically, responses to the term "disease controlling" surgery elicited examples of cancer pathologies and treatment courses which fail to fit existing treatment-intent language and which captured new roles for surgery in cancer treatment paradigms. These roles of surgery include "surgery as curative treatment" (including both curative intent with probability of cure and curative intent with possibility of cure), "surgery as adjuvant treatment" (targeted surgery to assist systemic therapies with possible change in disease course), and "surgery as palliative treatment" (symptom relief surgery without possible change in disease course). Within the 'targeted surgery' category, participants described expanded surgical roles for numerous metastatic diseases including debulking for improved systemic therapy efficacy, resection of treatment-resistant disease sites, and "resetting the clock" for indolent tumors. These operations require multidisciplinary coordination and understanding of available systemic treatments, as surgical goals are increasingly defined by each patient's broader treatment trajectory. **Conclusions:** Traditional "curative" vs. "palliative" surgical intent categories inadequately describe contemporary cancer surgery. The emergence of life-extending but non-curative treatments necessitates new language frameworks that better align with current understandings of cancer biology and new treatment modalities. New language is necessary to facilitate clearer communication between providers and patients about surgical goals and expected outcomes and to allow for better research evaluating whether surgical treatments achieve those goals and outcomes. Assessing the efficacy of cognitive behavioral therapy on anxiety, depression, and distress in people with cancer. First Author: Daniela Tregnago, Section of Innovation Biomedicine - Oncology Area, Department of Engineering for Innovation Medicine (DIMI), University of Verona, Verona, Italy

Background: Patients with cancer frequently experience psychological impairments, including anxiety, depression, and emotional distress, which may significantly affect quality of life and overall well-being. Third-generation cognitive-behavioral interventions such as Mindfulness-Based Cognitive Therapy-Cancer (MBCT-Ca), Acceptance and Commitment Therapy (ACT) and Compassion Focused Therapy (CFT) have shown potential benefits in reducing psychological burden, although evidence of their efficacy remains limited. This study aimed to evaluate the efficacy of a structured third-generation cognitive behavioral therapy (CBT) intervention in reducing psychological symptoms in patients (pts) with cancer undergoing active cancer treatment. **Methods:** A third-generation CBT intervention was delivered twice a month. The eight individual 45-minute sessions included psychoeducation, behavioral activation, relaxation and breathing techniques, present-moment awareness, self-compassion, problem-solving, and assertiveness training. Psychological outcomes were assessed using the Hospital Anxiety and Depression Scale (HADS) and Distress Thermometer (DT) at baseline (T0) and post- psychological intervention (T1). Descriptive statistics, Student t-test and Chi-square test were performed. **Results:** Overall 341 pts were recruited. The mean age was 65.8 years (*SD* = 11.80); 60% (n = 204) were women. Most patients were married or partnered 82% (n = 279). Regarding education level, 65% (n = 221) had higher education, 29% (n = 100) secondary education, and 6% (n = 20) primary education.. At baseline psychological assessment, 4.4% of patients (n = 15) had early-stage disease (stage I–II), 50.7% (n = 173) had locally advanced disease (stage III), and 44.9% (n = 153) had advanced-stage disease (stage IV). The most represented cancer sites were gastrointestinal cancer 55.7% (n = 190), followed by lung 11.7% (n = 41) and breast cancer 10.6% (n = 36). Chemotherapy was the most frequently administrated treatment 74% (n = 254), followed by targeted therapy 10% (n = 35) and immunotherapy 10% (n = 34). At T0, clinically significant levels of anxiety, depression, and distress were reported in 33.2%, 31.3%, and 86,9% of patients, respectively. A total of 313 patients completed the intervention (dropout rate 8.2%, mainly due to disease progression), resulting in an adherence rate of 91.8%. At three-months follow up (T1), significant reductions in clinically relevant symptoms were observed for anxiety (-24.6%, $p < 0.001$), depression (-24.0%, $p < 0.001$), and distress (-30.0%, $p < 0.001$). **Conclusions:** These findings support the routine use of validated psychological screening tools in oncology and highlight the clinical value of structured CBT-based psycho-oncological interventions delivered by trained professionals to improve psychological well-being in patients with cancer. Baseline predictors of treatment response in the bounce back mind-body resiliency trial for AYA cancer survivors. First Author: Lucy Finkelstein-Fox, Health Promotion and Resilience Intervention Research Center, Massachusetts General Hospital/Harvard Medical School, Boston, MA

Background: Mind-body interventions hold promise for improving coping and reducing psychological distress among adolescent and young adult (AYA) cancer survivors, yet benefits vary across participants. Little research has identified which survivors stand to benefit most from these programs. This secondary analysis of a randomized controlled trial of a mind-body group intervention tested whether baseline emotion regulation-related factors (worry and intolerance of uncertainty) moderated intervention effects on coping and distress (anxiety and depression). **Methods:** AYA cancer survivors (N = 72; ages 18–39) were randomized 1:1 to an 8-week virtual mind-body resiliency program (Bounce Back) or waitlist control. Primary outcomes were PROMIS anxiety and depression scores and total Measure of Current Status (MOCS) coping score at post-intervention (approximately 3-month follow-up), along with coping self-efficacy. Linear regression models, adjusted for baseline levels of each outcome, tested Randomization Group $\times$ Moderator interaction terms for two baseline moderators examined separately: Penn State Worry Questionnaire (PSWQ) and Intolerance of Uncertainty Scale (IUS). Interactions with $p < 0.05$ were considered evidence of moderation. **Results:** Compared to waitlist, participants assigned to Bounce Back showed greater improvements in anxiety and coping outcomes but similar depression outcomes overall. Randomization group differences in post-intervention anxiety were significantly moderated by both worry and intolerance of uncertainty. The intervention–control difference in anxiety (adjusted for baseline) was larger among participants reporting higher baseline worry (interaction $\beta = -0.39$, $p = 0.033$) and higher baseline intolerance of uncertainty ($\beta = -0.48$, $p = 0.033$). Neither moderator significantly altered randomization group differences in depression. For coping-related outcomes, higher baseline intolerance of uncertainty strengthened the intervention effect on coping self-efficacy (interaction $\beta = 1.92$, $p = 0.047$), and there was a trend for greater total MOCS improvement among participants with higher baseline worry (interaction $\beta = 0.33$, $p = 0.086$). **Conclusions:** In this secondary analysis of a randomized trial, the Bounce Back mind-body resiliency program produced the largest anxiety and coping benefits for AYA cancer survivors with relatively higher baseline worry and intolerance of uncertainty, whereas depression outcomes did not vary by these baseline characteristics. These findings suggest that emotion regulation vulnerabilities such as worry and uncertainty intolerance may help identify higher-risk AYAs who are most likely to benefit from group-based mind-body stress-management interventions. Future trials should confirm these moderators and test whether triaging higher-risk AYAs to mind-body programs improves psychological outcomes. Research Sponsor: None.

COMFORT Survey: A comparison of the comfort level of hematologic and solid tumor oncology specialists with serious illness conversations. First Author: Michael J. Tang, Department of Palliative, Rehabilitation and Integrative Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Serious illness conversations (SICs) are essential in aligning medical care with the values and goals of patients with advanced cancer. It is unclear if hematologic and solid tumors specialists (i.e., physicians [MDs] and advanced practice providers [APPs]) differ in their comfort level with SICs, which may drive end-of-life care outcomes. We compared the comfort level with SICs between hematologic and solid tumor specialists and examined contributing factors. **Methods:** We surveyed 186 hematology and 186 solid tumor specialists at MD Anderson Cancer Center. The 64-question survey examined their comfort with SICs under 5 domains (Transitions of Care [TOC, primary outcome], Dying Process [EOL], Prognosis, Goals, Advance Care Planning [ACP]). Responses were rated from 0 (extremely uncomfortable) to 10 (extremely comfortable). The TOC domain included 4 questions (i.e., stopping cancer therapy / transfusions / artificial nutrition and recommending hospice). We compared groups using simple linear and multivariable models accounting for specialist demographics. **Results:** 245 specialists completed this survey, with a response rate of 66%. Hematologic and solid tumor specialists both reported high comfort with TOC (7.0 [2.4] vs 7.1 [2.2]), with no significant difference between groups (mean difference [95% CI]: 0.1 [-0.5, 0.7]; P=0.78). In univariate analysis, APPs were significantly less comfortable with TOC than MDs among both hematologic (2 [1.2, 2.8]; P<0.0001) and solid tumor specialists (1.4 [0.7, 2.2]; P=0.001). In multivariate analysis, APPs remained the only significant variable associated with less comfort with TOC in hematologic (1.5 [0.4, 2.7]) and solid tumor groups (1.2 [0.2, 2.1]). Similarly, we found no significant difference between hematologic and solid tumor specialists in comfort level with the other 4 SIC domains and observed significant differences between APPs and MDs (Table). **Conclusions:** Both hematologic and solid tumor specialists reported high levels of comfort with SIC; however, APPs were significantly less comfortable. Given that APPs are increasingly involved in SIC, our study underscores the need to provide more training and support for APPs. Research Sponsor: None.

Defining when and how to support palliative care communication: International consensus on timing and clinician training priorities for adolescents and young adults with cancer. First Author: Ursula Sansom-Daly, University of New South Wales and Kids Cancer Centre, Sydney Children's Hospital, Sydney, NSW, Australia

Background: Early, developmentally appropriate palliative care communication is an international standard for adolescents and young adults (AYAs) with cancer, yet remains inconsistently implemented. Clinicians report uncertainty regarding the optimal timing of palliative care discussions and around what training they need. This study aimed to establish international consensus on when key palliative care topics should be introduced with AYAs across the cancer trajectory and to identify clinician training priorities. **Methods:** A three-round international Delphi study was conducted with multidisciplinary health professionals who had worked with at least five AYAs who had died from cancer or its complications. Participants rated the appropriateness of introducing four palliative care communication topics (prognosis/goals of care, emotional/existential issues, quality of life, and end-of-life–related medical care) across prognosis levels and treatment phases. Participants also rated the importance of clinician training topics and likelihood of attending different training modalities. Consensus was defined a priori as $\geq$80% agreement. **Results:** Seventy-seven experts from 14 countries completed the final round. Consensus indicated that emotional and existential issues were appropriate to discuss early, including during active cancer treatment. In contrast, end-of-life–related medical decisions were considered appropriate later, most commonly following relapse, disease progression or poor prognosis. Discussions about prognosis, goals of care and quality of life were generally considered appropriate once cure was uncertain. Conversation timing was the only training topic to reach consensus as a priority (85.8%). Although no training modality reached formal consensus, learning from bereaved family members was the most highly endorsed approach (72.8%), followed by experiential and interdisciplinary learning formats. The presence of complex family or culturally and linguistically diverse dynamics did not fundamentally alter clinicians' views on timing, but was associated with a need for greater team support and time. **Conclusions:** This international consensus provides clear guidance on when different palliative care topics should be discussed with AYAs with cancer and identifies timing as the primary area in which clinicians require additional support. Strong clinician endorsement of experiential and family-informed training approaches highlights opportunities to strengthen workforce capacity for earlier, developmentally appropriate palliative care communication. Reproductive and pregnancy-related outcomes among adolescent and young adult female cancer survivors (15–39 years): A nationwide population-based study in South Korea. First Author: Ja Yoon Heo, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Background: As survival rates among adolescent and young adult (AYA) female cancer patients improve, increasing numbers of survivors pursue pregnancy and childbirth. However, population-level data on reproductive outcomes and pregnancy-related complications among female cancer survivors remain limited. **Methods:** This study collected de-identified data from the South Korean National Health Insurance Service Database. Among 95,264 women aged 15–39 years newly diagnosed with cancer between 2007 and 2010, we identified 58,107 eligible survivors. This cohort was age-matched 1:10 with 719,213 women without cancer. Reproductive outcomes were assessed in the full cohort, and pregnancy-related complications were evaluated among women with documented pregnancies. Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated using logistic regression. **Results:** Compared with matched controls, female cancer survivors had a higher risk of infertility (OR 1.25; 95% CI 1.21–1.28) and lower odds of pregnancy (OR 0.94; 95% CI 0.93–0.96) and childbirth (OR 0.81; 95% CI 0.78–0.84). Among women who became pregnant, cancer survivors experienced higher risks of ectopic pregnancy (OR 1.20; 95% CI 1.11–1.29), miscarriage or abortion (OR 1.23; 95% CI 1.14–1.32), intrauterine infection (OR 1.26; 95% CI 1.01–1.57), and preterm labor (OR 1.21; 95% CI 1.14–1.29). **Conclusions:** AYA female cancer survivors face increased risks of infertility and adverse pregnancy-related outcomes. These findings highlight the need for specialized reproductive counselling and high-risk obstetric care for female cancer survivors. Research Sponsor: National Health Insurance Ilsan Hospital grant (NHIMC 2020-20-009).

Standardized birth rates and access to assisted reproductive technology among female cancer patients in the United States. First Author: Isabel Beshar, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Fertility after cancer is critically under-defined on a national scale, reflecting a substantial gap in survivorship care. We constructed a novel longitudinal dataset to describe 1) live births and 2) use of assisted reproductive technology (ART) among female cancer patients from 2004-2022. **Methods:** We linked population-based cancer registry data (2004–2018 in 12 states; 2004–2011 in California) with live birth certificates and the Society for Assisted Reproductive Technology database (2004-2022), which captures ~90% of ART cycles nationally, to create a dataset integrating oncologic characteristics, obstetric outcomes, and ART utilization. Female patients aged 15-45 at diagnosis of cancer were included. The primary outcome was the standardized birth ratio (SBR) >9 months after cancer diagnosis stratified by age, race/ethnicity, cancer site, stage, and receipt of systemic therapy calculated using Centers for Disease Control (CDC) general population birth rates from the 13 states. Secondary outcome was ART use after cancer diagnosis (≥1 autologous oocyte/embryo cryopreservation or embryo transfer cycles). Patients were categorized by expected fertility detriment, defined as pelvic malignancy and/or receipt of chemotherapy, hormone therapy, or abdominal/pelvic radiation. Associations with ART were evaluated with Cox proportional hazards models adjusted for age, cancer stage, insurance, and race/ethnicity. Person-years accrued from diagnosis date to first post-diagnosis birth/use of ART, death, age 51 (oldest age a post-cancer birth was observed), or December 31, 2022. The study was approved by the institutional review board. **Results:** 286,198 female cancer patients were included, with 25,586 babies born to 19,713 women over a mean follow up of 8.3 years. The overall SBR compared to the general population was 0.38 [0.36, 0.40], with lowest rates in gynecologic and breast cancers (0.22[0.18, 0.27], 0.26[0.23, 0.30]). 46.2% (n=9,110) of patients with births had thyroid cancer or lymphoma. Median time from diagnosis to birth was 3.27 years (2.00-5.27). Only 1.56% (n=5343) of the cohort used ART, with highest use among patients with breast cancer (n=2506, 46.9%). Expected fertility detriment was associated with higher hazard of ART use (aHR 2.37, 95% CI 2.20, 2.54), specifically cryopreservation (5.53[4.89, 6.26]). The 2022 live birth rate from our cohort (44.0%, 70/159) paralleled national trends (42.5%) reported from 457 fertility clinics by the CDC (p=0.69). **Conclusions:** The burden of infertility among reproductive-aged cancer patients is profound, with observed birth rates less than half that of the general population. Among patients who access ART, however, birth rates mirror those published by fertility clinics nationally. Despite this, ART services among cancer patients are underused, highlighting unmet needs in survivorship care delivery. Research Sponsor: U.S. National Institutes of Health; MD017999.

National trends and disparities in early-onset non-colorectal cancer mortality in the United States, 1999–2023: A population-based analysis of 240,190 deaths. First Author: Kumail Mustafa Ali, Jinnah Sindh Medical University, Karachi, Pakistan

Background: Early-onset non-colorectal malignancies account for a substantial share of premature cancer mortality in the United States, yet comprehensive national evaluations of long-term trends and disparities remain limited. **Methods:** We analyzed CDC WONDER Multiple Cause-of-Death data from 1999–2023, identifying deaths among individuals aged 15–54 years with non-colorectal malignancies. Age-adjusted mortality rates (AAMRs) per 1 million population were standardized to the 2000 U.S. standard population. Temporal trends were assessed using Joinpoint regression to estimate annual percent change (APC) and average annual percent change (AAPC). **Results:** A total of 240,190 deaths from early-onset non-colorectal malignancies occurred during the study period. Overall AAMRs declined from 61.45 (95% CI 60.22–62.68) in 1999 to 52.76 (95% CI 51.67–53.87) in 2023. Largest proportion of deaths occurred at home (43.4%), followed by inpatient or medical facilities (39.6%). Among women, AAMRs increased steadily from 36.01 (95% CI 35.02–37.04) in 1999 to 39.03 (95% CI 38.03–40.05) in 2023 (AAPC +0.33%, 95% CI 0.20–0.47). In contrast, men exhibited substantially higher but declining mortality, with an accelerated decline after 2012 (APC −2.25%, 95% CI −2.67 to −2.02). Racial and ethnic disparities persisted. Non-Hispanic Black populations showed significant reductions (AAPC −2.25%), Non-Hispanic Asian/Pacific Islander populations experienced the steepest declines (AAPC −2.22%), while Non-Hispanic American Indian/Alaska Native populations exhibited an early surge (APC +9.57%) followed by prolonged plateauing with persistently high rates. Metropolitan areas experienced faster declines (AAPC −0.72%) than non-metropolitan areas. **Conclusions:** The post-2012 acceleration in mortality reduction suggests progress in cancer management; however, these gains were uneven and masked substantial disparities. Men experienced marked declines but continued to have significantly higher mortality than women, while the steady increase in female mortality raises concern for unaddressed sex-specific risk and disease dynamics. Stagnant trends among individuals aged 15–34 years indicate limited benefit of advances in oncology for the youngest patients. Racial, ethnic, and geographic inequities remained pronounced, with persistently elevated mortality among Non-Hispanic Black and American Indian/Alaska Native populations, slower improvements in non-metropolitan areas, and consistently high rates in several Southern and Appalachian states. Together, these findings indicate that national progress has not translated into equitable outcomes and highlight the urgent need for targeted prevention, earlier diagnosis, and region- and population-specific cancer control strategies to reduce avoidable early-life cancer mortality. Bone mineral density changes in patients treated with anti-PD-1 immune checkpoint inhibitors. First Author: Roma A. Kankaria, Vanderbilt University School of Medicine, Nashville, TN

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment (tx), with almost half of all cancer patients (pts) today eligible for ICI tx. However, these agents frequently cause immune-related adverse events (irAEs). While many irAEs are well-documented, emerging reports suggest that skeletal toxicity may represent an underrecognized complication of ICI tx, particularly with agents that target PD-1. Preclinical models show that global deletion of the PD-1 gene (*Pdcd1*) or anti-PD-1 tx increases bone resorption, decreases bone formation, and weakens bones. However, skeletal effects remain poorly characterized in humans. We performed a retrospective analysis to assess bone mineral density (BMD) changes via dual-energy X-ray absorptiometry (DXA) results in pts treated with anti-PD-1 ICIs. **Methods:** We retrospectively analyzed adult pts from a single institution who received at least one dose of an anti-PD-1 agent with or without chemotherapy from 2014 to 2025 and who had pre- and post-tx DXA scans available. We collected demographics, cancer and treatment history, DXA data (including BMD, T-scores, and Z-scores), and scan timing relative to ICI tx. Descriptive statistics and paired t-tests ($p<0.05$) were used for data analysis. **Results:** Of 382 pts who received anti-PD-1 tx, 103 had only post-tx DXA scans, and 28 had both pre- and post-tx DXA scans. Of these 28 pts, 93% were female with a median age of 70 at the time of tx (range 58-88). Pts had statistically significant decreases in femur BMD and T-scores pre- vs. post-tx: mean BMD 0.85 vs. 0.81 g/cm^2 (p=0.04) and mean T-score -0.95 vs. -1.66 (p=0.02). Mean Z-scores decreased but were not statistically significant: 0.05 vs. -0.24 (p=0.09). In contrast, there was a trend toward increases in lumbar spine BMD, T-scores, and Z-scores, but none of these changes were statistically significant: mean BMD 1.16 vs. 1.15 g/cm^2 (p=0.93), mean T-score -0.19 vs. -0.06 (p=0.73), and mean Z-score 0.96 vs. 0.99 (p=0.72). **Conclusions:** This is the largest reported study to date examining BMD changes after anti-PD-1 ICI tx. Although this sample size is small and consists of mostly female pts, these results show significant decreases in femur BMD and femur T-scores after anti-PD-1 ICI tx, resulting in potentially increased fracture risk. T-scores in particular are more accurate in this older pt population than Z-scores. The site-specific changes seen in this dataset align with preclinical studies showing that in female PD-1 knockout mice of all ages, spinal bone mass does not change, but femoral bone mass is reduced. This could reflect differences in cortical vs. trabecular bone or mechanical loading. These findings underscore the importance of skeletal monitoring and indicate that prospective studies are needed to validate the observed bone changes and better characterize fracture risk in patients receiving anti-PD-1 therapy. Conditional survival in advanced melanoma treated with immune checkpoint inhibitors. First Author: Chloe Lim, BC Cancer - Vancouver, Vancouver, BC, Canada

Background: Immune checkpoint inhibitors (ICI) have improved survival in advanced melanoma, with some patients achieving durable remissions. Traditional survival estimates at diagnosis do not reflect how prognosis changes over time. Conditional survival (CS) provides a framework for time-dependent prognostication in long-term responders. **Methods:** We conducted a population-based retrospective cohort study of patients with unresectable/metastatic cutaneous melanoma treated with ≥1 dose of PD1-inhibitor based therapy in British Columbia (2012 -2022). Progression-free survival (PFS), overall survival (OS), and melanoma-specific survival (MSS) were estimated using Kaplan–Meier methods. Median follow-up was estimated using reverse Kaplan-Meier methods. Conditional PFS was calculated from ICI initiation and stratified by baseline characteristics and treatment response. **Results:** Among 897 patients, median age was 65 years (range 19-99); 48% (n=436) were M1c-d and 32% (n=290) received dual ICI. Median follow-up was 6.0 years (95% CI 5.7-6.3) and median OS was 3.2 years (95% CI 2.8-3.8); 5- and 10-year OS rates were 41% and 27%, respectively, while MSS rates were 49% and 38%, respectively. 5- and 10-year PFS rates were 31% and 22%, respectively. Conditional PFS analyses showed a decreasing risk of progression over time, most pronounced in patients achieving a complete response (Table 1). At 3-years post ICI initiation, patients in a complete response had a 5-year conditional PFS rate of 91% (95% CI 85-95%). Further analysis will assess whether their mortality normalizes relative to age- and sex-matched population controls to contextualize long-term survivorship. **Conclusions:** CS demonstrates dynamic improvement in prognosis among advanced melanoma patients who remain progression-free after ICI and provides clinically meaningful, time-updated prognostic information to guide patient counseling and follow-up strategies. Research Sponsor: None.

Impact of prior malignancy on cardiac complications and mortality in patients with COVID-19. First Author: Samuel Condon, UT San Antonio, South Texas Veterans Health Care Center, San Antonio, TX

Background: Cancer accounts for approximately 600,000 deaths annually in the United States, and patients with cancer are estimated to have nearly twice the risk of death following COVID-19 infection. While active malignancy and cancer-directed therapies are known to increase the risk of cardiac complications, it remains unclear whether patients with a prior history of cancer remain at elevated risk for cardiac events or mortality after COVID-19. This study aimed to evaluate whether a prior history of malignancy is associated with increased cardiac complications or all-cause mortality among Veterans diagnosed with COVID-19. We hypothesized that Veterans with a history of malignancy would have higher rates of cardiac complications and mortality following COVID-19 infection. **Methods:** We conducted a prospective observational cohort study of Veterans diagnosed with COVID-19 at the South Texas Veterans Health Care Center in San Antonio, Texas, using REDCap electronic data capture. Index dates ranged from March 13, 2020, through December 31, 2021, with a 10-month follow-up period. Both inpatient and outpatient Veterans were included. Patients with active malignancy or missing post-COVID cardiac outcome data were excluded. Patients were stratified into two groups: those with a prior history of malignancy and those without. The primary outcome was a composite of acute cardiac complications (arrhythmia, myocarditis, viral pericarditis, or viral cardiomyopathy) and all-cause mortality at 30 and 365 days. **Results:** Among 2,042 patients identified, 90 with active malignancy were excluded, leaving 1,952 patients for analysis. Of these, 5.3% (n=103) had a prior history of malignancy and 94.7% (n=1,849) had no malignancy history. Significant differences were observed in age, race, and BMI between groups. The composite primary outcome occurred more frequently in patients with prior malignancy at both 30 days (50% vs. 26%; OR 2.87, 95% CI 1.92–4.28, $p<0.0001$) and 365 days (53% vs. 29%; OR 3.06, 95% CI 2.05–4.58, $p<0.0001$). All-cause mortality was higher among patients with prior malignancy at 30 days (16% vs. 7%; OR 2.51, 95% CI 1.43–4.42, p=0.0013) and 365 days (16% vs. 14%; OR 3.03, 95% CI 1.97–4.66, $p<0.0001$). Cardiac complications alone were also more common in patients with prior malignancy (41% vs. 23%; OR 2.41, 95% CI 1.60–3.62, $p<0.0001$). **Conclusions:** In this large Veteran cohort, patients with a prior history of malignancy were approximately three times more likely to experience cardiac complications or death following COVID-19 infection compared with patients without a cancer history. These findings suggest that increased risk extends beyond active malignancy and highlight the need for targeted strategies to reduce adverse cardiac outcomes in patients with any history of cancer who develop COVID-19. Microbiome associations with chemotherapy-induced nausea and vomiting: A metagenomic shotgun sequencing study. First Author: Aasha I. Hoogland, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Background: Chemotherapy-induced nausea and vomiting (CINV) is common, with four out of every ten patients reporting moderate to severe nausea even after treatment with antiemetics. Existing risk prediction models have focused on demographic, clinical, and patient-reported factors, but predictive accuracy remains low. A missing predictor may be the gut microbiome, or gut microorganisms that engage in reciprocal signaling with the brain via many of the same pathways known to cause nausea. **Methods:** In this original research study, we conducted whole-metagenomic shotgun sequencing of the gut microbiome to evaluate its association with patient-reported CINV and improve existing risk prediction algorithms by employing a random forest approach. Nausea and vomiting were reported 24 hours after infusion (acute) and 5 days after infusion (delayed) in patients treated with moderately- or highly-emetogenic chemotherapy using the MASCC Antiemesis Tool. Participants were recruited from five ORIEN centers: City of Hope, Moffitt Cancer Center, Ohio State University, Rutgers University, and University of Colorado-Denver. Fecal samples were collected prior to chemotherapy using at-home fecal occult blood test (FOBT) cards. **Results:** Participants (n=233) were 57 years of age on average (SD=12), and most were female (80%), White (89%), with breast cancer (55%). More than half of participants (65%) had early stage cancer. Any acute and delayed self-reported nausea was reported by 40% and 67% of participants, respectively. Any acute and delayed vomiting was reported by 3% and 12% of participants, respectively; the low rate of acute vomiting precluded additional analyses. No significant difference was observed in microbial diversity and the abundance of dominant bacteria at the phylum level between patients who reported nausea or vomiting and those who did not. Bacillota and Pseudomonadota were two phyla identified as the most significantly enriched in patients who reported nausea or vomiting, at either timepoint (FDR-adjusted $p < 0.05$). The predictive performance of risk models based on established factors were improved by incorporating the top 15 differentially abundant bacterial species for acute nausea (AUC=69% vs. 58%), delayed nausea (AUC=68% vs. 53%), and delayed vomiting (AUC=77% vs. 54%). **Conclusions:** Gut microbial diversity did not differ between patients who self-reported acute or delayed nausea and those who did not, but risk prediction models for acute nausea, delayed nausea, and delayed vomiting were all improved by incorporating differentially abundant bacterial species. Results suggest that the gut microbiome is an important factor associated with the development of CINV. Research Sponsor: National Cancer Institute; R01CA219389.

Longitudinal physical activity patterns and patient-reported cognitive function among patients with lymphoma receiving chemotherapy in a nationwide prospective cohort. First Author: Tianming Zhao, Department of Public Health Sciences, University of Rochester Medical Center, Rochester, NY

Background: Up to 70% of patients with cancer experience cancer-related cognitive impairment and physical activity (PA) may prevent or mitigate this concerning symptom. However, longitudinal data on PA before and during therapy for lymphoma and their associations with cognitive function across the treatment continuum are limited. This study examined PA patterns before, during, and after chemotherapy in patients with lymphoma compared with controls, and associations between pre-chemotherapy PA and cognitive changes over time in patients only. **Methods:** Cognitive function was assessed via the patient-reported Functional Assessment of Cancer Therapy-Cognitive Function perceived cognitive impairment subscale, and PA via the Aerobics Center Longitudinal Study questionnaire at pre-chemotherapy (T1), 1 month post-chemotherapy (T2), and 6 months following T2 (T3) in patients with lymphoma and age- and sex-matched non-cancer controls recruited from 19 NCORP sites across the US. MET-hours per week (MET-hrs/wk) were calculated, and meeting PA guidelines was defined as $\geq$150 minutes/week of moderate intensity or $\geq$75 minutes/week of vigorous intensity PA, or an equivalent combination. Linear mixed-effects models (LMMs) examined longitudinal PA changes between patients and controls and pre-chemotherapy PA's association with cognitive changes in patients only, adjusting for age, sex, race, education, cognitive reserve, BMI, anxiety, and depression at T1. **Results:** Participants included 242 patients with lymphoma (74.4% non-Hodgkin) and 209 controls (mean age [SD], 55.3 [14.8] vs 53.7 [14.9] years; male, 62.8% vs 58.9%). In patients, 36.8% met PA guidelines at T1, decreasing to 23.3% at T2 and rising to 40.8% at T3, whereas about half of controls met guidelines across T1-T3 ($p<$ 0.05 at T1 and T2). Compared to controls, patients had lower PA (MET-hrs/wk) at T1 (β*[95% CI]* -4.81[-9.64, 0.02]; p=0.051), which declined to T2, resulting in significantly lower PA at T2 (β*[95% CI]* -7.48[-11.93, -3.03]; p=0.001); from T2 to T3, PA increased more in patients vs controls (β*[95% CI]* 6.38[2.31, 10.45]; p=0.002), reaching comparable levels at T3. Cognition declined from T1 to T2 in patients meeting (β*[95% CI]* -11.42[-15.19, -7.66]; $p<0.001$) and not meeting (β*[95% CI]* -9.29[-12.09, -6.49]; $p<0.001$) PA guidelines at T1; however, only those meeting guidelines showed cognitive recovery from T2 to T3 (β*[95% CI]* 3.64[0.28, 7.00]; p=0.034). **Conclusions:** In patients with lymphoma, PA significantly declined during chemotherapy; despite recovery to pre-treatment levels by 6 months post-chemotherapy, most remained insufficiently active. Further, active patients before treatment showed cognitive recovery after chemotherapy, suggesting that pre-chemotherapy PA may support post-treatment cognitive resilience, warranting further investigation. Organ-specific proteomic aging clocks (PACs) and mortality in cancer survivors. First Author: Shuo Wang, University of Minnesota, Minneapolis, MN

Background: Our study suggested that plasma conventional PACs can reflect, on average, accelerated aging in cancer survivors (Wang et al., JNCI 2026), but may overlook organ-specific variations. Organ-specific PACs may better predict CVD and cancer mortality in this group. **Methods:** We compared the associations of one conventional and 11 organ-specific PACs (Oh et al., Nature 2023) with mortality in 806 cancer survivors (aged 66-90) in the Atherosclerosis Risk in Communities (ARIC) study, 2+ yrs post-diagnosis (up to 12-yr follow-up). ARIC measured 4,712 plasma proteins by SomaScan. We computed PACs (conventional, adipose, artery, brain, heart, immune, intestine, kidney, liver, lung, muscle, pancreas) and their deviations from chronological age (age gap) after regressing PAC on age via LOWESS model. Multivariable Cox proportional hazards regression estimated hazard ratios (HRs) for mortality associated with age gap in survivors of any cancer (455 deaths: 127 CVD, 137 cancer deaths) and the most common cancers (165 breast (BrCa), 255 prostate (PrCa), and 78 colorectal cancer (CRC)). **Results:** In BrCa survivors, all age gaps (except intestine) were higher for those diagnosed 2-10 vs. >10 yrs before the start of follow-up. The pattern was opposite for all age gaps in CRC survivors (except heart and lung gaps). There was no specific pattern across age gaps in PrCa survivors. Further, in all cancer survivors, all age gaps, but artery and kidney, were associated with all-cause mortality (all $p<0.05$), with highest HRs for conventional, heart, and liver gaps (Table 1). Only heart age gap was associated with CVD mortality (HR per 1 SD=1.29, $p<0.05$), with no associations of any age gaps with cancer mortality. In BrCa survivors, conventional (HR=1.81) and 4 organ age gaps (brain, heart, immune, intestine; HRs = 1.45–1.68) were associated with all-cause mortality (all $p<0.05$). In PrCa survivors, conventional, heart, and liver age gaps were associated with all-cause mortality [all HRs=1.35, $p<0.05$]. In CRC survivors, conventional, heart, and immune age gaps were positively, but non-significantly, associated with all-cause mortality [HRs = 1.48–1.56], likely limited by sample size. **Conclusions:** Conventional and heart PACs demonstrated consistent associations with all-cause mortality beyond chronological age and lifestyle factors in total and individual cancer survivors. Heart PAC was most strongly associated with CVD mortality. Further work is needed to replicate this analysis and to test these age gaps as a predictor for mortality. Funding: NHLBI, NCI, NPCR. Research Sponsor: National Cancer Institute; National Center for Advancing Translational Sciences (NCATS); National Heart, Lung, and Blood Institute (NHLBI); National Program of Cancer Registries (NPCR).

Age gaps and all-cause mortality in cancer survivors; ARIC (2011-23).

Age gap	HR (95% CI) per 1 SD	Age gap	HR (95% CI) per 1 SD
Conventional	1.48 (1.32, 1.66)	Intestine	1.13 (1.01, 1.26)
Adipose	1.13 (1.00, 1.27)	Liver	1.42 (1.26, 1.60)
Brain	1.19 (1.05, 1.34)	Lung	1.14 (1.02, 1.26)
Heart	1.41 (1.26, 1.59)	Muscle	1.19 (1.06, 1.33)
Immune	1.24 (1.10, 1.40)	Pancreas	1.33 (1.18, 1.49)

Common symptoms, quality of life, and lifestyle factors reported by cancer survivors attending the Sydney Cancer Survivorship Multidisciplinary Clinic. First Author: Janette L. Vardy, Faculty of Medicine and Health, University of Sydney & Sydney Cancer Survivorship Centre, New South Wales, Australia

Background: Sydney Cancer Survivorship Clinic (SCSC) provides multidisciplinary care for cancer survivors. During an initial visit, survivors consult with a medical oncologist or hematologist, cancer nurse specialist, dietitian, clinical psychologist, and exercise physiologist. Over 12 years, we assessed the health status of cancer survivors after curative-intent treatment. **Methods:** Survivors completed patient-reported outcomes assessing symptoms (PT-DATA), quality of life (QOL) (FACT-G), distress (Distress thermometer), fear of cancer recurrence (FCR-7, and psychologist assessment), diet, and physical activity (LTEQ) before initial clinic visit. Clinical data were obtained from the medical record. Simple descriptive statistical methods were used. FACT-G scores were standardized and compared to Australian general population and population with cancer (T-score 50, SD 10). **Results:** Between September 2013 and December 2025, 1181 survivors attended initial SCSC; 1081 (95%) consented to the use of their data. Of these, 68% were female; median age 58 years (range 18-91). Median time from diagnosis 10.7 months (IQR 8.4-16.6). Tumor types: 38% breast, 33% colorectal, 16% hematological, 14% other. Primary treatment: surgery 84%, chemotherapy 90%, radiotherapy 40%. Overall, 47% had 5+ symptoms of at least moderate severity (4+/10). Most frequently reported moderate-severe symptoms were: fatigue (50%), insomnia (40%), anxiety (36%), pain (35%), numbness (33%), sore hands/feet (32%), trouble concentrating (32%). Moderate-severe distress was reported in 44%. On the FCR-7, 32% had moderate-severe FCR. The psychologist rated 46% as having moderate-severe FCR. Mean QOL (FACT-G): total 79.9: domains physical 22.1; social 21.2, emotional 18, functional 18.6. Comparison to Australian populations: Total T-score 46.0: physical and emotional domains both 0.8 SD below. 59% were overweight or obese (mean BMI 27.2kg/m^2 (range 16.2-59.1)). Only 7% met national exercise guidelines for both resistance and aerobic exercise (18% resistance exercise alone, 24% aerobic exercise alone). **Conclusions:** Symptom burden remains high almost a year after diagnosis, with 47% reporting at least five moderate-severe symptoms; most commonly distress, fatigue, insomnia, anxiety and FCR. Overweight/obesity (59%) and physical inactivity remain lifestyle risk factors. Research Sponsor: National Health and Medical Research Council Australia.

Prevalence and financial burden of WHO-defined disability among childhood cancer survivors: A report from the St. Jude Lifetime Cohort study (SJLIFE). First Author: Joshua Burns, St. Jude Children's Research Hospital, Memphis, TN

Background: Survivors of childhood cancer are at high risk for chronic health conditions that may result in disability. However, the prevalence and financial burden of disability, defined using the World Health Organization International Classification of Functioning, Disability and Health (WHO ICF), have not been described in this population. **Methods:** Disability-related items ascertained using clinical and patient-report data from SJLIFE were classified using standardized WHO ICF childhood cancer components, including impairments in body function or structure (strength, neurocognition, vision, hearing, speech, balance, neuropathy, ataxia, hemiparesis, tone, bowel and bladder, flexibility, gait, posture, pain, fatigue), activity limitations (motor function, communication, personal care), and participation restrictions (physical activity, education, independent living, employment, quality of life). Aggregate disability severity scores (ADSS) were calculated by summing item-level indicators (0 = none/mild; 1 = moderate, severe, or life-threatening disability) across 55 items spanning 3 components (38 body impairments, 5 activity limitations, and 12 participation restrictions). Disability was classified using either age- and sex-specific z-scores derived from 815 community controls (0 = ≥ -1.5; 1 = < -1.5) or NCI Common Terminology Criteria for Adverse Events (CTCAE) grades (0 = < 2; 1 = ≥ 2). Logistic regression evaluated associations between disability and financial burden (cancer-related financial impact), adjusting for sex, race, age at evaluation, and cancer treatment exposures (chemotherapy, cranial radiation, amputation). **Results:** Among 3,549 survivors (mean age at evaluation 33.6 years; range 18.0–68.9; 52.1% male; 80.7% White non-Hispanic), the most common diagnoses were acute lymphoblastic leukemia (31.9%), central nervous system tumors (14.5%), and Hodgkin lymphoma (10.5%). The point (most recent visit) prevalence (95% CI) of $\geq$1 item rated as moderate or greater disability was 87.4% (86.3–88.5). Component-specific prevalence was 74.6% (73.2–76.0) for body impairments, 32.9% (31.3–34.4) for activity limitations, and 63.3% (61.7–64.9) for participation restrictions; all were higher than controls ($p < 0.001$). Higher overall ADSS was associated with greater financial hardship (OR = 2.97; 95% CI 2.05–4.30) with similar associations across all components, including body impairments (OR = 2.67; 95% CI 2.09–3.41), activity limitations (OR = 2.28; 95% CI 1.91–2.72), and participation restrictions (OR = 2.61; 95% CI 2.13–3.21). **Conclusions:** WHO-defined disability is highly prevalent among adult survivors of childhood cancer and is strongly associated with financial burden. These findings highlight the need for integrated survivorship care that addresses both medical and socioeconomic risk factors. Research Sponsor: NIH, NCI; U01 CA195547.

The neurotoxicity rating scale: A novel patient-reported outcome (PRO) measure for neuro-psycho-behavioral late effects in head and neck cancer (HNC) survivors. First Author: Matthew Stewart, Vanderbilt University Medical Center, Nashville, TN

Background: Chronic fatigue, mood disorders and cognitive dysfunction are well recognized but understudied late toxicities experienced by HNC survivors. In addition to these well recognized central symptoms, patients also experience an array of less well recognized psycho-behavioral complaints (see table below). These symptoms may profoundly affect a patient's ability to function within society. The neurotoxicity rating scale (NRS) was developed to assess the breadth of neuro-psycho-behavioral symptoms in cancer patients treated with interferon. We conducted a prospective cohort study in HNC survivors to assess the psychometric properties of this tool. **Methods:** Eligible patients included HNC survivors without evidence of disease $\geq$6 months after completion of therapy. The NRS was administered as part of a battery of patient reported outcome measures to assess pain and central symptoms. The NRS is a patient reported outcome measure which includes 36 items ranked from 0-4 (0 = no symptoms, 4 = severe). Hierarchical clustering was applied. **Results:** 243 patients were included with an average age of 72 years. Patients experienced clinically significant levels of neuro-psycho-behavioral symptoms; prevalence for selected items are shown in the table below. Preliminary analysis results in a group of six of clusters. The six-cluster solution was chosen as the most appropriate fit based on expert opinion. Clusters included: pain (α=0.89), sleep (α=0.83), general systemic symptoms (α=0.67), neuromotor-autonomic (α=0.73), cognitive (α=0.82), and psycho-behavioral (α=0.94). **Conclusions:** The NRS is a unique tool that comprehensively captures neuro-psycho-behavioral symptoms not assessed by existing instruments. The preliminary analysis amongst HNC survivors confirms the high prevalence of neuro-psycho-behavioral symptoms in this population. We identified six distinct symptom clusters: all demonstrated good internal constancy. This instrument allows for systematic study of neurotoxicity patterns, identification of high-risk patients, and evaluation of targeted interventions. Future directions include longitudinal validation and correlation with objective neuropsychiatric testing. Research Sponsor: None.

Selected items from the NRS with prevalence.

Item	Prevalence (%)
Tiredness/Fatigue	68%
Difficulty staying asleep	58%
Loss of interest in sex	41%
Restlessness	44%
Distractibility	41%
Word-finding difficulty	41%
No interest in activities	35%
Memory problems	50%
Decreased motivation	43%

Effect of "watch and wait" on fear of recurrence in rectal cancer: A multicenter cross-sectional study. First Author: Ahmet Oruc, Necmettin Erbakan University Meram Medical Faculty Medical Oncology Department, Konya, Turkey

Background: Total neoadjuvant therapy (TNT) is now the standard of care for locally advanced rectal cancer. Watch-and-wait (WW) is the most commonly used approach for patients with a complete clinical response. This study aimed to investigate fear of recurrence, presence of depression, clinical symptoms, and functional capacities in WW patients and to identify differences between them and patients who underwent surgery after TNT. **Methods:** In this multicenter, cross-sectional study, patients were interviewed individually and completed the Fear of Cancer Recurrence Inventory-Short Form (FCRI-SF), Patient Health Questionnaire-9 (PHQ-9), and EORTC QLQ-ANL27. The EORTC QLQ-ANL27 results in two parameters: the symptom scale (SS) and the functional scale (FS). **Results:** The study included 121 patients who received TNT. The median age was 60 (54-65), and male patients were in the majority at 71 (58.7%). The most common disease location was the distal rectum at 56 (46.3%). In clinical staging, the most common findings were T3 disease at 86 (71.1%) and N1 lymph node status at 63 (52.1%). The number of patients followed up with WW after TNT was 17 (14%). 27 (22.3%) patients achieved a pathological complete response (pCR) after surgery. The median disease-free survival was 21 (11-37.5) months. In surgical patients (n = 104), FCR was 16 (7.25-21), while in WW patients (n = 17), FCR was 18 (9-25), p = 0.464. The PHQ-9 score was 3 (1–10) in surgical patients and 5 (1–9) in WW patients, p = 0.669. SS was 31.7 (21.5-38.8) in surgical patients and 15.9 (12.1-38.6) in WW patients, p = 0.045. FS was 84 (61.3-87.8) in WW patients and 68.2 (61.1-78.4) in surgical patients, p = 0.045. When WW patients and pCR patients were also evaluated, no statistically significant difference was observed in terms of FCR and PHQ-9. SS was 15.9 (12.1-38.6) in WW patients and 31.8 (21.7-49.2) in pCR patients, p = 0.027. FS was 84 (61.3-87.8) in WW patients and 68.1 (50.7-78.2) in pCR patients, p = 0.027. pCR patients were evaluated according to the presence of a permanent stoma. In patients with a stoma (n:9), FCR was 19 (17.5-24.5), while in patients without a permanent stoma (n:18), FCR was 11.5 (3.75-20), p = 0.022. PHQ-9 was 12 (1.5-17) in those with a permanent stoma and 1.5 (1-8) in those without a permanent stoma, p = 0.020.There was no difference between these two groups in terms of SS and FS, p = 0.253. **Conclusions:** In WW patients, the fear of recurrence does not increase compared to those who underwent surgery after TNT; the level of depression is similar, but their symptoms are fewer, and their functional capacities are better. Considering both the fear of recurrence and the severe depression levels in patients who are particularly pCR and followed up with a permanent stoma, the decision to undergo WW should always be taken into account. Post-treatment recovery patterns among patients with early-stage cancer who develop taxane-induced peripheral neuropathy (TIPN): SWOG S1714 (NCT03939481). First Author: Meghna S. Trivedi, Columbia University Irving Medical Center, New York, NY

Background: The primary analysis of S1714 developed and validated a TIPN risk prediction model including 5 clinical risk factors. Recovery patterns of TIPN are not well described. Although some symptoms may improve with time, other symptoms may persist or worsen as a result of permanent nerve damage. We describe the incidence of TIPN over 3 years and report on the post-treatment patterns of TIPN in those individuals who report TIPN at the end of taxane treatment (EOT) as a secondary analysis of S1714. **Methods:** S1714 enrolled participants $>$ 18 years with Stage I-III primary lung, breast, or ovarian cancer starting treatment with a taxane-based regimen for a planned duration of 8 to 18 weeks. Participants were followed over the course of 3 years and assessed for TIPN using the patient-reported EORTC QLQ-CIPN20, which is composed of 3 subscale scores reported from 0-100, with increasing scores representing worse TIPN. EOT TIPN was defined as an increase in the CIPN20 sensory subscale score of $\geq$8 points from pre-treatment to EOT. **Results:** Among 1336 enrolled patients, N = 1321 were evaluable: Median age 55.7 years (range 23-85), 98.9% female, 11.3% Black/4.5% Asian/10.5% Hispanic/Latino, 90.7% with breast cancer. Paclitaxel was administered to 60.3% and docetaxel to 39.7%; 98.4% planned to start treatment with full dose of taxane. EOT TIPN was reported in 553 participants (41.9%). We identified 3 patterns of TIPN in these 553 participants over the 3 year period using the EOT CIPN20 sensory score as the reference. Improvement in TIPN from EOT was seen in 268 participants (48.5%), defined as a decrease of $\geq$8 points from the EOT CIPN20 sensory score. Stable TIPN was seen in 187 participants (33.8%), defined as $<$ 8 point increase or decrease from the EOT CIPN20 sensory score. Worsening of TIPN from EOT was seen in 98 participants (17.7%), defined as an increase of $\geq$8 points from the EOT CIPN20 sensory score. Of the 553 individuals with TIPN at EOT, 283 (51.2%) still had clinically meaningful TIPN at 3 years compared to the baseline pre-treatment CIPN20 sensory score (defined as increase in CIPN20 sensory score $>$ 8 points from pre-treatment timepoint to final assessment). **Conclusions:** Among individuals experiencing TIPN at EOT, nearly half experienced clinically meaningful TIPN improvement but almost one fifth had worsening of TIPN by the final 3-year assessment. The identification of clinical and correlative risk factors for persistent or worsening TIPN after completion of taxane treatment will allow for more informed decision-making regarding the long-term risks of taxane treatment and prioritize selection of patients in the investigation of interventions for prevention and treatment of TIPN. Funding: NIH/NCI/NCORP grant UG1CA189974, The Hope Foundation for Cancer Research. Clinical trial information: NCT03939481. Untargeted baseline metabolomic profiling to identify candidate markers of long-term severe cancer-related fatigue (CRF) in breast cancer (BC) survivors. First Author: Antonio Di Meglio, Cancer Survivorship Program, Université Paris-Saclay, UVSQ, Gustave Roussy, Inserm, CESP, Villejuif, France

Background: CRF is common and debilitating among BC survivors; however its predictors and underlying biology remain partially defined. We sought to identify baseline plasma metabolomic markers of subsequent CRF to inform risk prediction and symptom mechanisms. **Methods:** Baseline (pre-treatment [tx]) plasma samples from women with stage I-III ER+/HER2− BC in the CANTO cohort (NCT01993498) underwent untargeted metabolomic profiling (liquid chromatography and high-resolution mass spectrometry with electrospray ionization), yielding metabolic features for analysis. CRF was measured using EORTC QLQ-C30 (severe CRF: score$\geq$40/100). Three penalized regression approaches (lasso, adaptive lasso, elastic net) were used to select baseline metabolites associated with severe CRF, adjusting for clinical covariates, including pre-tx CRF, age, body mass index, comorbidities, socioeconomic status, psychological distress, health behaviors, and tx. The cohort was split 2/3:1/3 (train:test); penalization factor λ was tuned in the train set by cross-validation. Clinical-only and clinical+metabolite features models were compared using test-set AUC, with bootstrap confidence intervals from resampled predictions (B = 1000). Covariate missingness was addressed by multiple imputation on 15 datasets. Metabolite annotation was conducted computationally using W4M, with manual curation and interpretation of spectra to identify key metabolites relevant to CRF. **Results:** In the train set (N = 645), mean age was 58 years (SD 10), 44% received chemo- and 90% endocrine-tx, 20% reported severe pre-tx CRF (similar characteristics in the test set; N = 325). 1935 metabolic features were analyzed. For severe global CRF at year-4 (prevalence 31%) the adaptive lasso clinical+metabolite features model included a 51-feature signature and had AUC = 0.70, specificity = 0.89, and sensitivity = 0.39 (sensitivity difference vs. clinical-only +0.17 [95% CI +0.06 to +0.29; $p < .001$]). Features with the largest penalized coefficients were concordant with univariate associations (all in the same direction) and showed clear differences in standardized levels between severe vs non-severe CRF. Nineteen features belonged to the annotated reference dataset, enabling putative identification of metabolites spanning endogenous pathways (including glycine [inverse association] and chenodeoxycholic acid [positive association]) and a likely exogenous/xenobiotic-related feature (mandelonitrile [positive association]). **Conclusions:** Baseline untargeted metabolomics identified a 51-feature signature associated with severe global CRF at year-4 after ER+/HER2− BC. Adding features selected via adaptive lasso to clinical covariates increased model sensitivity, and putative pathway mapping highlighted candidates for targeted validation and mechanistic studies. Social determinants of health and long-term outcomes in prostate cancer: Mortality, survival, and comorbidity risks in a propensity score–matched federated database analysis. First Author: Ashu Singh, Division of Hematology Oncology, Department of Medicine, Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY

Background: Social determinants of health (SDOH) such as housing instability, food insecurity, and low income are known to influence health outcomes, but their long-term effects on prostate cancer (PCa) patients remain underexplored. To compare long-term outcomes, including mortality, sepsis, sexual dysfunction, and comorbidities across major organ systems, between prostate cancer patients with and without adverse SDOH. **Methods:** Retrospective cohort study using the TriNetX federated database (deprecated COVID-19 Research Network, 88 healthcare organizations). Cohort 1 included adults ($\geq$18 years) with PCa (ICD-10-CM C61) and at least one adverse SDOH code (n = 14,595). Cohort 2 included PCa patients without SDOH codes (n = 875,545). Propensity score matching (1:1) balanced cohorts on demographics, external morbidity causes, ECOG status, and BMI (final n = 12,626 per cohort). The index event was the first prostate cancer diagnosis (with SDOH for Cohort 1). Outcomes assessed from 1-day post-index onward (up to 20 years prior exclusion). Risk ratios (RR), hazard ratios (HR) from Kaplan-Meier survival, and mean instances via t-tests for mortality, severe sepsis, sexual dysfunction, and diseases of genitourinary, circulatory, endocrine/metabolic, respiratory, digestive, and infectious systems. **Results:** After matching, cohorts were balanced (mean age ~72 years, ~56% White, ~25% Black). PCa with adverse SDOH had higher mortality risk (22.0% vs 17.3%; RR 1.272 [95% CI, 1.209-1.338]; $p < 0.001$) and worse survival (median 2821 vs 5246 days; HR 2.018 [95% CI, 1.906-2.137]; $p < 0.001$). Severe sepsis risk was elevated (5.6% vs 4.7%; RR 1.199 [95% CI, 1.074-1.339]; $p < 0.001$; HR 1.824 [95% CI, 1.626-2.047]; $p < 0.001$). Sexual dysfunction risk was lower (0.2% vs 0.4%; RR 0.493 [95% CI, 0.305-0.794]; p = 0.003). For comorbidities, PCa with adverse SDOH showed mixed risks—genitourinary diseases had a lower risk but poorer survival (HR 1.113, 95% CI 1.017-1.218, p = 0.020); circulatory diseases showed equivalent risk but worse survival (HR 1.223, 95% CI 1.089-1.374, p = 0.001); endocrine/nutritional/metabolic conditions had similar risk but reduced survival (HR 1.277, 95% CI 1.151-1.418, $p < 0.001$); respiratory diseases had equivalent risk but poorer survival (HR 1.531, 95% CI 1.416-1.656, $p < 0.001$); digestive diseases demonstrated lower risk with worse survival (HR 1.308, 95% CI 1.200-1.425, $p < 0.001$). **Conclusions:** Adverse SDOH are associated with increased mortality and poorer survival in prostate cancer, alongside heightened sepsis risk and differential comorbidity patterns. Interventions targeting SDOH may improve long-term outcomes. Correlative analysis between external and internal lymphedema in head and neck cancer survivors. First Author: Jessica Abene, University of Pennsylvania, Philadelphia, PA

Background: More than 75% of head and neck cancer (HNC) survivors develop lymphedema following cancer treatment. Lymphedema can affect both external (e.g., soft tissue of the face and neck) and internal (e.g., pharynx and larynx) structures. Early identification and timely referral are essential for maintaining functionality and minimizing symptom burden. Understanding the relationship between external and internal lymphedema may inform assessment and treatment strategies. However, data describing the association between external and internal lymphedema remains limited. The purpose of this report is to fill this gap. **Methods:** A prospective, longitudinal descriptive study included 117 patients with oral cavity and oropharyngeal cancer. External lymphedema was evaluated through physical examination using the validated Head and Neck External Lymphedema and Fibrosis Assessment Criteria. Internal lymphedema was evaluated using an endoscopic examination scored with the Modified Patterson Scale. Examinations were performed at baseline and every three months for 12 months post-treatment. Somers'd correlation coefficients were calculated to test associations between external and internal lymphedema measures. **Results:** Both the total number of sites with external lymphedema and the total external lymphedema severity score correlated with the presence of at least one site of internal lymphedema (both d = 0.31). The total number of external sites of lymphedema moderately correlated with internal lymphedema involving the following structures: epiglottis (d = 0.31), pharyngoepiglottic folds (d = 0.35), aryepiglottic folds (d = 0.34), and anterior commissure (d = 0.32). The total external lymphedema severity score correlated with internal lymphedema involving the following structures: the epiglottis (d = 0.32), pharyngoepiglottic folds (d = 0.35), and aryepiglottic folds (d = 0.34). External submental lymphedema correlated with internal lymphedema involving the buccal mucosa (d = 0.27), epiglottis (d = 0.28), pharyngoepiglottic folds (d = 0.28), and pyriform sinus (d = 0.28). External lymphedema of the neck correlated with internal lymphedema in the pharyngoepiglottic folds (d = 0.28), arytenoids (d = 0.27), and anterior commissure (d = 0.29). External cheek lymphedema failed to correlate significantly with internal lymphedema. **Conclusions:** HNC survivors with external lymphedema are likely to have concurrent internal lymphedema. The presence of external lymphedema should initiate evaluation for internal lymphedema, particularly in patients with dysphagia or shortness of breath. The site of external lymphedema correlates with the sites of internal lymphedema: this may help inform assessment and management. Estimation of the impact of chemotherapy-induced biological age acceleration on breast cancer survivorship using multi-scale simulation modeling. First Author: Swarnavo Sarkar, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC

Background: Treatment of breast cancer with chemotherapy improves breast cancer survival. But chemotherapy also increases the accumulation of senescent cells in breast cancer survivors, which induces more senescent cells through paracrine signaling. The increased accumulation of senescent cells increases inflammation and tissue damage, which leads to earlier onset of aging-related diseases in survivors. We developed a simulation model connecting the biology of aging with breast cancer epidemiology to estimate the impact of chemotherapy-induced biological age acceleration on breast cancer survivorship. **Methods:** We integrated a systems biology model of accumulation of senescent cells with chronological age and an established Cancer Intervention and Surveillance Modeling Network (CISNET) breast cancer simulation model to estimate the impact of biological age-acceleration on breast cancer survivorship outcomes. We used published clinical data on senescence biomarker expression level ($p16^{INK4a}$ mRNA expression) in chemotherapy recipient breast cancer survivors to simulate the elevated senescence expression level in the remaining lifetime of breast cancer survivors. The difference in the senescence expression level in the chemotherapy group was evaluated against the senescence expression level in the general female population to quantify the excess biological age, or the biological age acceleration, after chemotherapy. The modified biological age induced by chemotherapy was used to determine the hazard of non-breast cancer mortality in breast cancer survivors. We used the CISNET breast cancer simulation model to simulate multi-birth cohorts of US females diagnosed with breast cancer to estimate survivorship outcomes after chemotherapy. Outcomes included remaining life years after breast cancer diagnosis, absolute number of non-breast cancer deaths, and the time-point at which the risk non-breast cancer mortality starts to dominate breast cancer mortality. **Results:** Biological age acceleration after anthracycline-based regimes caused a greater loss of life years than anthracycline-free regimens for women diagnosed at ages 30-39 years (median of 11.7 years vs. 2.1 years lost). This loss in life years diminished with increasing age at diagnosis (median of 6.0 years vs. 1.4 years lost for 70-79 year old women). The risk of non-breast cancer mortality exceeded breast cancer mortality up to 10-15 years earlier than expected based on chronological age after anthracycline-based regimens. **Conclusions:** Integration of computational systems biology modeling with breast cancer population-level modeling helps to identify subgroups of breast cancer survivors who are likely to experience survivorship loss due to biological age acceleration and may need survivorship care targeting non-breast cancer mortality. The effectiveness of a multidisciplinary pain program in improving adherence to the use of aromatase inhibitors in breast cancer survivors. First Author: Panuch Eiamprapaporn, Department of Medical Oncology, Mayo Clinic Florida, Jacksonville, FL

Background: Aromatase Inhibitors (AI) have become the standard of care to reduce breast cancer recurrence in hormone receptor-positive (HR+) breast cancer patients. AIs have been shown to be effective in reducing the risk of breast cancer recurrence by 47%. However, up to 52% of patients prematurely discontinue their use due to AI-associated musculoskeletal pain symptoms called Aromatase Inhibitor-associated musculoskeletal pain syndrome (AIMSS). No effective treatment exists to treat AIMSS. The present study examined the effectiveness of a multicomponent pain treatment program in reducing symptoms of AIMSS with the goal of improving adherence to AI medication. **Methods:** This trial enrolled breast cancer survivors with AIMSS in an intensive multicomponent pain treatment program. Pain, impact on functioning, fatigue, and mood were assessed with the Brief Pain Inventory, Center for Epidemiologic Studies of Depression- Revised Questionnaire, Pain Catastrophizing Scale, Symptom Impact Questionnaire Revised, and Fatigue Questionnaire at baseline, 3-month, 6-month, 9-month, and 12-month intervals. Adherence to AI medication was obtained from patients' self-reports. The treatment program consisted of a two-day structured intervention focused on Cognitive-Behavioral skills to address strategies to improve pain control, fatigue, sleep disturbance, and stress while educating patients on the efficacy of Aromatase Inhibitors in prolonging cancer-free survival. **Results:** A total of 73 patients were enrolled, with a median age of 63 years (range 31-79). Participants were primarily white, married, and highly educated. The measures showed elevated levels of pain, fatigue, and psychological distress at baseline with decrements in self-reported levels of functioning. Significant improvements across all measures were observed at the 3-month follow-up after participation in the multicomponent pain treatment program. Significant improvements in painrelated outcomes were observed at 3 months (WPI $\Delta -1.6$; SS $\Delta -4.0$; both $p < 0.001$), with sustained reductions in symptom severity through 6-month, 9-month, and 12-month follow-up. Self-report of AI medication adherence at one year showed that 77.9% of patients were still taking their prescribed medication. **Conclusions:** Patients with AIMSS experienced substantial emotional distress, pain, fatigue, and functional impairment at baseline. Following the intervention, significant improvements were observed across pain, physical functioning, fatigue, and psychological distress, with benefits sustained at one year. Importantly, the intervention was associated with high long-term adherence at one-year follow-up, highlighting its potential to improve both quality of life and treatment persistence. Cardiac substructure dose signatures as predictors of late cardiovascular events in childhood cancer survivors. First Author: Hrushikesh Reddy Pamreddy, Saint Vincent Hospital, Worcester, MA

Background: Radiation-associated cardiovascular disease (CVD) remains a major late toxicity in childhood cancer survivors. Whole-heart dose may mask heterogeneous substructure exposure, limiting precision in survivorship surveillance and modern radiotherapy planning. **Methods:** Using the Childhood Cancer Survivor Study (CCSS) open-access cardiac substructure dosimetry dataset (12 mean-dose structures; Gy), we modeled time from cancer diagnosis to CAD, CHF, valvular disease, and arrhythmia with elastic-net Cox (α=0.5; 10-fold CV). Bootstrap stability selection (200 resamples) quantified reproducible substructure predictors; "core" structures were defined by selection frequency $\geq$0.80. Parsimonious Cox models were fit using core structures (dose scaled per 5 Gy) and adjusted for sex, race, age at diagnosis, anthropometric category, and smoking. Model discrimination was assessed using the concordance index (C-index). Model-based predicted 20-year absolute risks were used to estimate dose thresholds for clinically interpretable risk targets (reference profile: median covariates; modal factor levels). **Results:** Among 25,481 survivors, events occurred for CAD (n=475), CHF (n=544), valvular disease (n=131), and arrhythmia (n=181). LAD and aorta emerged as reproducible, endpoint-specific predictors: LAD was core across CAD/CHF/valvular outcomes; aorta and LMCA were core for CAD/valvular; pericardium was core for CAD/CHF. In adjusted core models, aortic dose was associated with CAD (HR 1.59 per 5 Gy; 95% CI 1.14–2.21; C-index 0.796) and valvular disease (HR 1.96; 95% CI 1.15–3.32; C-index 0.773). LAD dose was associated with CAD (HR 1.26; 95% CI 1.05–1.53; C-index 0.796) and CHF (HR 1.23; 95% CI 1.02–1.47; C-index 0.818). Absolute risk translation identified interpretable thresholds: predicted 20-year CAD risk crossed ~1% at 13 Gy mean aortic dose and ~2% at 20 Gy; CAD risk crossed ~1% at 24 Gy mean LAD dose. Predicted 20-year CHF risk crossed ~0.5% at 21 Gy mean LAD dose. Predicted 20-year valvular risk crossed ~1% at 23 Gy mean aortic dose. **Conclusions:** Substructure-specific dosimetry yields reproducible radiation "signatures," with LAD and aorta dose consistently linked to late CVD. These dose–risk thresholds provide actionable benchmarks for risk-stratified survivorship surveillance and may inform substructure-sparing dose constraints in contemporary radiotherapy planning moving beyond whole-heart dose to endpoint-specific substructure constraints. Research Sponsor: None.

Substructure-specific dose thresholds for 20-year cardiovascular risk.

Outcome	Core Substructure	HR per 5 Gy (95% CI)	20-Year Risk Target	Dose Threshold (Gy)
CAD	Aorta	1.59 (1.14–2.21)	1%	13
CAD	Aorta	1.59 (1.14–2.21)	2%	20
CAD	LAD	1.26 (1.05–1.53)	1%	24
CHF	LAD	1.23 (1.02–1.47)	0.5%	21
Valvular	Aorta	1.96 (1.15–3.32)	1%	23

Toxicity assessment clinic as an efficacious tool to provide fast care to oncology patients on systemic therapy by minimizing emergency department visits and streamlining admissions directly from the cancer clinics. First Author: Andrew R. Maher, Queen's University, Kingston, ON, Canada

Background: The Toxicity Assessment Clinic (TAC) at the Hudson Regional Cancer Centre was established to improve access to care for cancer patients experiencing treatment-related toxicities, ensuring timely access to oncology-specific symptom management. The TAC is nurse led and utilizes an evidence-based oncology assessment tool to determine the appropriate care pathway, ensuring symptom assessment and treatment in a timely and safe manner. **Methods:** We reviewed the volume and characteristics of patients seen in the TAC for one year (2024), including visit modality, primary causes for TAC consultation, and appropriateness of TAC referrals by identifying related vs. unrelated complaints and determining the proportion of patients without a family physician who utilized TAC services for unrelated concerns. **Results:** There were 15,387 total chemotherapy clinic visits. Among them, there were 692 visits to TAC (4.5%). In total, 94.8% of patients had a family physician. Majority (93.9%) called TAC directly, 4.6% were sent by chemo suite nurses and 1.4% were referred from outside the cancer center. In addition, there were 997 registered nurse phone calls to follow up on health issues occurring within the clinic hours. Median age was 69 years [range 19-93]; 61% of patients were over 65. 61.9% of TAC patients had a solid tumor diagnosis, 24.5% had a hematological malignancy, and 6.8% had gynecological cancers. Gastrointestinal malignancies (26.9%), breast (17.5%) and lung (12.3%) were most prevalent. 47.9% had stage IV cancer, 27.2% had stage III. 93.5% of patients were on active systemic therapy, with 80.8% on first line. In-person TAC visits composed 89.1% of consults, and 10.9% had assessments over the phone. Skin lesions (7.8%), diarrhea (6.9%), disease progression (6.5%), urinary tract infection (5.8%) and respiratory infections (5.6%) were the most common issues. In 92.3% of cases, the presenting complaint was considered directly related to the cancer or therapy. Consult assessment durations were the following: 30 minutes or less (23.2%), 30-60 minutes (71.8%), and $\geq$60 minutes (4.9%). Of note, 76% of phone calls required $\leq$30 minutes compared to 39% patients who attended TAC in person. 52.6% of admitted patients from TAC required $\geq$ 60 min of assessment time. In 85.7% of cases, medical problems were resolved during the TAC visit; 1.4% were sent to ED and 12.9% were directly admitted to hospital. **Conclusions:** The TAC model is feasible and provides rapid assessment of patients on systemic therapy, particularly in the front-line setting. It is a cost-effective alternative to ED visits and streamlines admissions directly from cancer clinics. TAC improves patient flow for vulnerable populations such as elderly and immunocompromised patients. Research Sponsor: None.

12125 Poster Session

A prospective study of the early treatment of recombinant human thrombopoietin for chemoradiation-induced thrombocytopenia in cervical squamous cell carcinoma patients. First Author: Lu Li, Department of Radiation Oncology, Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China

Background: To explore the early intervention timing of recombinant human thrombopoietin (rhTPO) for cancer treatment-induced thrombocytopenia (CTIT) in cervical squamous cell carcinoma (CSCC) patients during concurrent chemoradiotherapy. **Methods:** Patients with stage I-IVa CSCC who developed CTIT during radical concurrent chemoradiotherapy were prospectively enrolled in our study. rhTPO intervention was used at the first presentation of G1 or G2 CTIT during concurrent chemotherapy respectively. The key indexes, including nadir platelet count, platelet recovery time, platelet transfusion and incidence of G3-5 CTIT were recorded in two groups. χ^2 test was used for the effective analysis, and univariate and multivariate analyses logistic regression analysis was used to predict the potential factors for the G3-5 CTIT. **Results:** From February 2021 to June 2024, 204 CSCC patients who developed CTIT during radical chemoradiotherapy at Sichuan Cancer Hospital were prospectively enrolled. 75 patients who occurred G1 and G2 CTIT at the first presentation during concurrent chemoradiotherapy received rhTPO intervention. They were included in the intent-to-treat (ITT) population analysis. According to the timing of the rhTPO intervention, the patients were divided into G1 group (100×10^9/L>PLT>75×10^9/L) and G2 group (75×10^9/L>PLT>50×10^9/L). For effective analysis, the nadir platelet count in G1 group was greater than that in G2 group (67×10^9/L vs. 54×10^9/L, p = 0.000), and the platelet recovery time in G1 group was shorter than that in G2 group (8 days vs. 14 days, p = 0.003). Moreover, patients in G1 group had a significantly lower incidence of G3-5 CTIT than that in G2 group (14.3% vs. 35%, p = 0.04). In two groups, only 1 patient in G2 group received 4 apheresis platelet units transfusion. Univariate and multivariate analysis showed the early intervention of the rhTPO was a substantial factor for decreasing the incidence of G3-5 CTIT. The sensitivity was 0.67 and the specificity was 0.74. **Conclusions:** For CSCC patients received with radical concurrent chemoradiotherapy, the early intervention of rhTPO was a substantial factor for decreasing the incidence of G3-5 CTIT. It could significantly improve the nadir platelet count, shorten the platelet recovery time, and reduce the incidence of G3-5 CTIT, thereby ensuring the uninterrupted continuation of treatment. Research Sponsor: None.

Platelet recovery time and the degree of CTIT.

Data	Baseline platelet count($\times10^9$/L)	Days with platelet count recover ≥100×10^9(Days)	Minimal mean platelet count ($\times10^9$/L)	Incidence of G3-5 CTIT(%)

Comparison of prophylactic effects for chemotherapy-induced neutropenia between same-day versus next-day administration of pegteograstim in chemotherapy regimen composed of day 1 intensive myelosuppressive agent: A randomized clinical trial (CONCISE, KCSG PC22-11). First Author: Kwonoh Park, Division of Hematology & Medical Oncology, Department of Internal Medicine, Dongguk University Ilsan Hospital, Goyang, South Korea

Background: Same-day administration of pegylated G-CSF is frequently used in clinical practice despite guideline recommendations favoring next-day administration. This study evaluated whether same-day administration of pegteograstim is noninferior to next-day administration with respect to the duration of grade (Gr) 4 chemotherapy induced neutropenia (CIN) in multi-day regimens containing day 1-intensive myelosuppressive agents. **Methods:** This multicenter, open-label, randomized, noninferiority trial (originally designed as a phase III study) enrolled patients receiving adjuvant/neoadjuvant or first-line palliative chemotherapy, including mFOLFIRINOX, ECb, EP, FOLFIRI, and FOLFOX. Patients were assigned in a 1:1 ratio to receive pegteograstim 6mg either within 4 hours after completion of chemotherapy (same-day group) or 24-36 hours (next-day group). The primary endpoint was Gr 4 CIN duration during cycle 1 (C1). A total sample size of 160 patients was calculated to verify noninferiority with a margin of 0.6 days; however, the trial closed prematurely after enrolling 90 patients. **Results:** Of the 90 enrolled patients, 81 were included in the analyses (37 same-day, 44 next-day). Mean Gr4 CIN duration was 0.43 days (95% CI, 0.13–0.74) in the same-day group and 0.09 days (95% CI, 0.00–0.29) in the Next-day group. The mean difference (Same-day minus Next-day) was 0.342 days (90% CI, 0.037 - 0.646). Because the upper bound exceeded the prespecified noninferiority margin of 0.6 days, noninferiority was not demonstrated (p-value = 0.080 for noninferiority). The incidence of Gr4 CIN was 21.1% (8 patients) of same-day group and 2.3% (1 patient) in the next-day group. During cycles 1-4, febrile neutropenia occurred in 1 patient (2.6%) in the same-day group and 3 patients (6.8%) in the next-day group. Two deaths occurred in each group: one FN-related death occurred in the same-day group. **Conclusions:** Same-day administration of pegteograstim did not meet the prespecified criterion for noninferiority compared with next-day administration. The incidence of grade 4 CIN, a key secondary outcome, favored next-day administration. These randomized data support maintaining next-day pegteograstim as standard practice in multi-day regimens with day 1–intensive myelosuppression. Clinical trial information: KCT0007694. Research Sponsor: GC Pharma.

Evaluating the impact of treatment timing with recombinant human thrombopoietin for cancer treatment–induced thrombocytopenia: A retrospective cohort study. First Author: Xin Wang, Department of Oncology, Nanchong Hospital, Beijing Anzhen Hospital Affiliated to Capital Medical University / Nanchong Central Hospital, Nanchong, China

Background: Recombinant human thrombopoietin (rhTPO) is utilized for cancer treatment-induced thrombocytopenia (CTIT) to ensure timely and full-dose chemotherapy delivery. This study investigated the differential clinical benefits of platelet-guided intervention timing strategies to provide evidence-based support for early initiation protocols. **Methods:** This single-center retrospective cohort study enrolled CTIT patients receiving rhTPO therapy. Participants were stratified into three groups based on platelet count at rhTPO initiation: early intervention group 1 (platelets 75-<100×10^9/L), early intervention group 2 (50-<75×10^9/L), and salvage therapy group (<50×10^9/L). Comparative analyses among the three groups encompassed time to platelet recovery and recovery rates, severe CTIT incidence, platelet transfusion requirements, bleeding event rates, chemotherapy continuity parameters (dose reduction, delay, or discontinuation), and safety profiles. **Results:** Among 456 solid tumor patients with CTIT, 159 (34.9%) were in early intervention group 1, 172 (37.7%) in early intervention group 2, and 125 (27.4%) in the salvage therapy group. Median time to platelet threshold achievement was significantly shorter in group 1 (7.0 d) versus group 2 and salvage therapy (both 11.0 d; P<0.001), with concomitantly shorter rhTPO treatment duration (5.0 d vs. 7.0 d vs. 7.0 d; P<0.001). Severe CTIT incidence was significantly reduced in early intervention groups (12.6% in group 1 and 19.2% in group 2 vs. 56.0% in salvage therapy; both P<0.001). Platelet recovery rates were superior in early intervention groups (81.1% in group 1 and 75.0% in group 2 vs. 59.2% in salvage therapy; P<0.001 and P=0.004, respectively). Platelet transfusion requirements were significantly lower (0.6% in group 1 and 1.2% in group 2 vs. 12.0% in salvage therapy; both P<0.001). Chemotherapy continuity was significantly improved, with lower rates of delay/discontinuation (18.9% in group 1 and 33.1% in group 2 vs. 46.4% in salvage therapy; all P<0.05). No significant inter-group differences in bleeding incidence were observed, and no rhTPO-related serious adverse events or thromboembolic events occurred. **Conclusions:** rhTPO therapy for CTIT exhibits a pronounced threshold effect, with early intervention (platelet count ≥50×10^9/L) conferring substantially greater clinical benefit than salvage therapy. Initiation at 50-<75×10^9/L effectively preserves chemotherapy continuity and reduces transfusion burden, while initiation at 75-<100×10^9/L optimizes platelet recovery kinetics and cost-effectiveness. Research Sponsor: None.

AQP4 and MOG as definers of distinct autoantibody signatures in immune checkpoint inhibitor–induced optic neuritis. First Author: Jingyao Zhang, Department of Medicine, Nuvance Health/Northwell Health Danbury Hospital, Danbury, CT

Background: Checkpoint blockade–induced optic neuritis (CBON) is a rare but vision-threatening immune-related adverse event with limited response to standard immunosuppression and no established diagnostic biomarkers. The humoral immune mechanisms underlying CBON remain poorly characterized, limiting early recognition and mechanistic understanding. **Methods:** We conducted a multicenter study integrating three independent CBON cohorts (n=25, 29, and 34) and 49 ICI-treated controls without neuro-ophthalmic complications, enrolled between January 2020 and June 2025. CBON cases were identified from a prospective biospecimen bank of >2,300 ICI-treated patients. Leveraging pre-ICI baseline, prodromal-phase, onset, and follow-up serum samples (>2,300 total samples), IgG autoantibodies against 25 neural surface antigens were assessed using cell-based assays. Longitudinal antibody dynamics and associations with clinical and oncologic features were evaluated. **Results:** Across 88 CBON patients, the autoantibody response was highly antigen-specific and dominated by aquaporin-4 (AQP4) and myelin oligodendrocyte glycoprotein (MOG). AQP4-IgG or MOG-IgG was detected in 32–48% of CBON cases across cohorts, while paraneoplastic, synaptic, and other neural autoantibodies were rare (<12%). AQP4-IgG and MOG-IgG were largely mutually exclusive, suggesting distinct immunologic subtypes of CBON. These antibodies were virtually absent in ICI-treated controls (0–2%). Longitudinal analyses demonstrated consistent seronegativity prior to ICI exposure, followed by seroconversion at symptom onset with persistent antibody titers during follow-up despite corticosteroid therapy, consistent with a sustained humoral immune response. Autoantibody status showed limited and inconsistent associations with demographic, oncologic, or clinical characteristics. **Conclusions:** CBON is characterized by a distinct, antigen-specific humoral immune response targeting AQP4 or MOG that emerges following ICI exposure. These findings support an ICI-triggered breakdown of immune tolerance and establish a serologic framework for CBON diagnosis and classification. Incorporation of AQP4-IgG and MOG-IgG testing may aid early recognition and risk stratification of visual immune-related adverse events during immunotherapy. Research Sponsor: None.

Prevention of paclitaxel-induced neurotoxicity with lithium: Results from a multicenter, randomized, double-blind, placebo-controlled phase 2 trial (PREPARE). First Author: Wolfgang Boehmerle, Charité Universitätsmedizin Berlin, Department of Neurology, Berlin, Germany

Background: Chemotherapy-induced neurotoxicity is a frequent adverse effect of paclitaxel (PTX). It reduces quality of life and often necessitates treatment modifications. The objective of this clinical trial was to determine the safety and efficacy of lithium (Li^+) co-treatment on chemotherapy-induced neurotoxicity in breast cancer patients treated with PTX. **Methods:** Multicenter, randomized, double-blind, placebo-controlled phase-2 trial (parallel-group design) conducted in eight primary care centers in Germany between August 2022 and July 2024. Eligible breast cancer patients aged 18-70 years, with no pre-existing polyneuropathy and to be treated with PTX were randomized 1:1 to either oral Li^+ or placebo with sham dose adjustments. The intervention started 10-14 days prior to the first and lasted until three days after the last PTX infusion. **Results:** A total of 94 patients were enrolled, 86 patients were randomized and 78 were analyzed according to the intention-to-treat principle. Targeted Li^+ trough serum concentrations of 0.5 to 0.8mmol/l were reliably reached prior to PTX therapy. The total neuropathy score reduced (TNSr) was 0.5 points higher in the placebo group than in the Li^+ group (95% CI 1.6 to -0.6, not significant), while serum neurofilament light chain levels showed no difference. Structural MRI showed slightly higher total intracranial volume in the Li^+ group, but no difference in hippocampal volume. Cognitive testing using the CANTAB indicated a strong trend towards better performance in hippocampus-dependent tasks, including delayed matching to sample and spatial working memory for the Li^+ group. The patient reported outcome measures (PROM) completion rates were high (baseline 99%, endpoint 95%). Patients receiving Li^+ consistently reported higher quality of life and less pain scores on the EORTC QLQ-C30 during and after therapy, with between-group differences of 11 AU (95% CI 18 to 4) for global health status and -14 AU (95% CI −27 to -0.2) for pain, exceeding established minimal clinically important differences. The latter finding was supported by a lower reported intake of pain medication in the Li^+ group of 54% vs 70% in the placebo group. Eleven serious adverse events were reported in the trial, six in the placebo group and five in the Li^+ group. Patients in the Li^+ group experienced fewer adverse events compared to patients in the placebo group with a relative risk reduction of 26% for any CTCAE grade and 45% for grade ≥ 3. **Conclusions:** Among breast cancer patients receiving PTX chemotherapy co-treatment with Li^+ was not superior to placebo for the development of polyneuropathy as measured by TNSr. However, there were better patient-reported outcomes including quality of life and pain, as well as lower rates of adverse events. These observations warrant confirmation in a larger phase-3 interventional trial. Clinical trial information: DRKS00027165. Research Sponsor: Federal Ministry of Research, Technology and Space; 01KG2123.

Hetrombopag plus caffeic acid tablets for the treatment of chemotherapy-induced thrombocytopenia in solid tumors: A single-center, open-label, phase II trial. First Author: Xiao Li Xiao, Department of Oncology, Zhongshan Hospital of Xiamen University, School of Medicine, Xiamen, Fujian, China

Background: Chemotherapy-induced thrombocytopenia (CIT) frequently complicates cancer therapy, resulting in treatment delays, dose reductions, and premature discontinuation. However, no widely approved therapies are currently available to address this clinical gap. This phase II trial was designed to evaluate the efficacy and safety of the thrombopoietin receptor agonist hetrombopag combined with caffeic acid tablets in this patient population. **Methods:** This is a single-arm, single-center, prospective phase II trial (ChiCTR2400086043) designed to enroll patients with malignancies experiencing thrombocytopenia (platelet count ≤ 75 ×10⁹/L) during anti-cancer therapy. Eligible participants received hetrombopag 5 mg once daily (QD) plus caffeic acid tablets 0.3 g three times daily (TID) for 14 consecutive days. The primary endpoint is the proportion of patients achieving a platelet count ≥100×10⁹/L after treatment; secondary endpoints included time to first response (platelet count ≥100×10⁹/L), proportion of patients with platelet recovery to ≥ 75×10⁹/L, and safety profile of the regimen. **Results:** A total of 65 patients were enrolled between 24 June 2024 and 25 December 2025.The median age of enrolled patients was 60.0 years, and 70.8% of patients had a baseline platelet count of ≥50×10⁹/L. The most common tumor types were colorectal cancer (23.1%) and gastric cancer (13.8%). The majority (41.5%) received oxaliplatin-based chemotherapy, 26.2% received immunotherapy plus chemotherapy, and 18.5% received targeted therapy plus chemotherapy. After treatment with hetrombopag plus caffeic acid tablets, 84.6% (55/65) of patients achieved platelet counts ≥100×10⁹/L and 87.7% (57/65) achieved ≥75×10⁹/L. The median durations from the first dose of hetrombopag plus caffeic acid tablets platelet response ≥100×10⁹/L was 7 days (range:5–9). Adverse drug reactions were reported in 17 patients; no drug-related adverse events of grade ≥3 occurred. **Conclusions:** Hetrombopag plus caffeic acid tablets confer outstanding therapeutic efficacy in CIT while maintaining a well-tolerated safety profile. This oral regimen fulfills an unmet clinical need and provides a practical, non-invasive therapeutic option for CIT management. Clinical trial information: ChiCTR2400086043. Research Sponsor: None.

Efficacy of surgical glove-compression therapy as a prevention of paclitaxel-induced peripheral neuropathy: Randomized controlled trial. First Author: Saowani Thantaviraya, Oncology Unit, Department of Medicine, Rajavithi Hospital, Thailand, Bangkok, Thailand

Background: Paclitaxel is a common cause of chemotherapy-induced peripheral neuropathy (CIPN), a dose-limiting toxicity for which no preventive intervention is currently recommended. This randomized controlled trial evaluated the efficacy of surgical glove-compression therapy (SGCT) in preventing paclitaxel-induced peripheral neuropathy. **Methods:** Patients with solid malignancies scheduled to receive paclitaxel every three weeks were randomized 1:1 to SGCT or placebo. SGCT consisted of bilateral double-layer surgical gloves one size smaller than patient's hand size, covered with outer cotton gloves, worn from 30 minutes before paclitaxel infusion until 30 minutes after completion. The placebo group wore non-compression gloves with identical cotton gloves for the same duration. Patients were followed for four cycles of paclitaxel. The primary endpoint was the incidence of paclitaxel-induced sensory neuropathy of Common Terminology Criteria for Adverse Events (CTCAE) version 6.0 grade ≥2. Secondary endpoints included Patient Neurotoxicity Questionnaire (PNQ) grade ≥D, Functional Assessment of Cancer Therapy–Gynecologic Oncology Group–Neurotoxicity (FACT/GOG-NTX) scores, and loss of protective sensation assessed by monofilament testing. Analyses were conducted using the intention-to-treat approach. Sensitivity analyses included per-protocol analysis and treatment effect adjustment for important prognostic factors for CIPN. **Results:** Between November 2024 and November 2025, 39 patients were randomized to SGCT (n=19) or placebo (n=20). Most patients were female, had breast cancer, and received single-agent paclitaxel. In the intention-to-treat analysis, sensory CIPN grade ≥2 occurred significantly less frequently in the SGCT group than in the placebo group (26.3% vs. 60.0%; p=0.034). This finding was consistent in the per-protocol analysis (27.8% vs. 66.7%; p=0.019). The protective effect of SGCT remained statistically significant after adjustment for sex, cancer type, and chemotherapy regimen (adjusted OR 0.10; 95% CI, 0.02 to 0.58; p=0.010). No significant differences were observed in secondary outcomes, including motor CIPN, PNQ grade ≥D, monofilament test abnormalities, or FACT/GOG-NTX scores. Any-grade sensory CIPN was common and did not differ between groups. SGCT was well tolerated, with no serious adverse events and high adherence. **Conclusions:** SGCT significantly reduced the incidence of clinically meaningful paclitaxel-induced sensory neuropathy and was safe and well-tolerated. These findings support SGCT as a simple, low-cost preventive strategy for CIPN. Clinical trial information: NCT06763575. Research Sponsor: Rajavithi Hospital.

Natural language processing chatbot and continuous activity monitoring in a phase II randomized trial: Impact on hospitalizations and quality of life. First Author: Casey Hollawell, Hospital of the University of Pennsylvania Radiation Oncology, Philadelphia, PA

Background: Toxicities associated with concurrent chemoradiotherapy (CRT) can lead to hospitalizations and impaired quality of life (QoL). This study reports on secondary endpoints investigating whether combining continuous activity monitoring (CAM) with an AI-driven chatbot can support symptom identification, triage, reduce hospitalizations, and improve QoL. **Methods:** Patients receiving CRT for head and neck (H&N), gastrointestinal (GI) or thoracic cancers were recruited from radiation oncology clinics at a single, urban institution. Subjects were randomized to: (1) CAM with nursing triage or (2) CAM with chatbot triage with as needed symptom assessments. A Fitbit device monitored the step count and heart rate (HR) relative to baseline. Triage was triggered when the daily average HR was >100 or 20% above their resting average or if there was a decrease of >1000 steps from baseline. In the control arm, triage prompted a nursing assessment within 1 business day. In the intervention arm, triage visits were triggered based on a low-, intermediate-, or high-risk symptom algorithm determined by the chatbot (next OTV, next business day, within 24 hrs, respectively). Hospitalizations during CRT and one month post treatment were counted. Logistic regression controlled for ECOG and sex. EORTC C30 QoL instruments were administered at baseline, during OTVs, and during follow-up. A mixed method for repeated measures model assessed global health status/QoL, fatigue, and physical, role, emotional, cognitive, and social functioning scales adjusting for ECOG, race, and stage. All statistical tests were completed on SAS 9.4. **Results:** From June 2023 to January 2025, 77 patients undergoing CRT for their H&N (n=30, 39%), GI (n=29, 38%), or thoracic cancers (n=18, 23%) were enrolled. The median age at consent was 59 years (range 28-81 years). Subjects were randomized to either nursing (N = 36, 50%) or chatbot triage (N = 36, 50%). There were no statistically significant demographic or clinical differences between arms. Subjects in the chatbot arm had significantly fewer hospitalizations (11%, n=4 chatbot; 39%, n=14 nursing triage, p=0.01). On logistic regression, subjects on the chatbot arm (p=0.0125) and those who had ECOG 0 (p=0.0131) were less likely to be hospitalized. In both arms, global QoL/health, fatigue, and physical, social, cognitive, and emotional functioning declined during CRT. Chatbot subjects had significantly inferior global QoL/Health status (p=0.049), cognitive functioning (p=0.005), and physical functioning (p=0.02) vs nursing triage. **Conclusions:** Patients undergoing CRT experience functional decline. While AI-driven chatbots may reduce hospitalizations, they are not a perfect substitute for a compassionate healthcare team. An analysis of alerts and triage visits will be reported with our primary endpoint. Research Sponsor: GI Cancer Service Line.

Applying a large language model to detect immune-related adverse events in electronic health records: Effect of integrating prescription and laboratory data on accuracy. First Author: Yukiko Shimoda Igawa, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Accurate identification of immune-related adverse events (irAEs) is essential; however, manual review of electronic health records poses a significant burden on clinicians. Furthermore, conventional text-only approaches may fail to capture clinically important events. In this study, we evaluated whether a Large Language Model (LLM) with a multimodal approach could improve patient-level identification of irAEs. **Methods:** Among patients who received immune checkpoint inhibitors (ICIs) monotherapy at National Cancer Center Hospital, Tokyo, Japan between October 2014 and July 2023, a subset of patients was randomly sampled for analysis. A zero-shot prompt was designed to identify irAEs. Using a standalone local LLM (gpt-oss-20b), single-modal analysis utilized clinical notes alone, whereas multimodal analysis additionally incorporated systemic steroid prescriptions and laboratory data. Patient-level predictions were aggregated, using the threshold that maximizes the micro-averaged F1-score. The irAEs were clinically adjudicated by board-certified oncologists. Analyses were limited to major irAEs, and performance was evaluated using precision, recall, and the F1-score (α = 0.05). **Results:** The median number of cases reviewed per day by physicians was 18, whereas the LLM processed 25. During the study period, 296 patients (207 with irAEs and 89 without irAEs) were randomly sampled. Among patients with irAEs, irAE types included rash, pneumonitis, endocrine disorders, colitis, and hepatitis. For the identification of irAE occurrence, the precision of the multimodal approach was significantly higher than that of the single-modal approach (88.7% to 83.7%, p = 0.01). In organ-specific analyses, precision for colitis and rash and recall for endocrine were significantly improved. In addition, the multimodal approach reduced false-positive classifications from 33% to 22% and false-negative classifications from 37% to 35%. IrAE onset timing also differed significantly between the two approaches, with earlier identification by the multimodal LLM ($-$21.9 vs $-$17.7 days, p = 0.04); both approaches detected onset earlier than clinical adjudication. **Conclusions:** A multimodal LLM framework improves irAE detection accuracy and may reduce clinician workload. Research Sponsor: National Cancer Center Hospital "Mirai Project".

Prophylactic vedolizumab to facilitate use of immune-checkpoint inhibitors in cancer patients at high risk of immune-mediated colitis. First Author: Hemant Khandelia, Department of Medicine/Division of Hematology and Oncology, University of Washington, and Clinical Research Division, Fred Hutchinson Cancer Cancer, Seattle, WA

Background: Inflammatory diarrhea/colitis is a frequent immune-related adverse event (IRAE) associated with immune checkpoint inhibitors (ICIs). Treatment with ICI is relatively contraindicated in patients with history of severe ICI-colitis or those with pre-existing severe inflammatory bowel diseases (IBD). Vedolizumab (VDZ), an anti-$\alpha4\beta7$ integrin antibody associated with selective immune suppression in the gastrointestinal (GI) tract, is approved for IBD treatment and is also effective in treating steroid-refractory ICI-colitis. However, limited data exist for its utility as a prophylactic treatment for primary or secondary prevention of ICI-colitis in high-risk patients. **Methods:** We conducted a single-center, retrospective study of patients with advanced skin cancers, who were deemed "high-risk" due to prior severe ICI colitis or IBD, and received VDZ prophylaxis prior to ICI (re) treatment. VDZ efficacy was assessed by analyzing the frequency, severity, duration and treatment details of GI symptoms. In patients with prior ICI-colitis, outcomes with and without VDZ prophylaxis were compared using descriptive statistics. ICI efficacy in the presence of VDZ was evaluated by objective response rate (ORR) per RECIST v1.1. **Results:** We identified 16 high-risk patients (11- prior ICI colitis, 5 – IBD) who received VDZ prophylaxis (typically 300 mg at weeks 0, 2, and 6 initially, then q8 weeks) prior to ICI (re)treatment, between 2015-2025. Median number of VDZ doses before (re) introducing ICI was 2 (range, 1-3). In the ICI-colitis cohort, VDZ prophylaxis prior to ICI re-treatment resulted in less frequent and milder GI symptoms not needing corticosteroids, than previously observed with initial ICI treatment without VDZ prophylaxis (see Table). Among 14 patients with evaluable disease (measurable and progressing at the time of VDZ treatment), ORR was 33% (3/9) in the ICI-colitis cohort and 80% (4/5) in the IBD cohort. **Conclusions:** Use of prophylactic VDZ can facilitate successful, long-term ICI treatment in high-risk patients with prior ICI-colitis or IBD, while mitigating GI symptoms, reducing corticosteroid usage and preserving anti-tumor responses. Research Sponsor: None.

Gabapentin plus intranasal ketamine for the prevention and treatment of pain in patients undergoing radiotherapy for head and neck cancer: Phase II trial results. First Author: Natalie A. Lockney, Vanderbilt University Medical Center, Nashville, TN

Background: Prophylactic gabapentin decreases pain, opioid use, and weight loss in head and neck (HNC) patients treated with chemoradiotherapy. Nonetheless, significant symptom burden remains. Ketamine is an NMDA receptor antagonist which has neuromodulator and anti-inflammatory properties. We undertook a phase I/II study to explore safety, feasibility, and obtain preliminary efficacy data pertaining to the combination of ketamine and gabapentin in HNC patients undergoing radiation +/- chemotherapy. Results of the phase I study were previously reported. Herein we report preliminary results of the phase II portion of the study. Primary outcomes were toxicity and feasibility; secondary outcomes were symptom burden. **Methods:** Eligibility: locally advanced HNC patients planned for primary or adjuvant radiotherapy +/- chemotherapy. Treatment: Day 1: gabapentin 100 mg PO TID; Day 8: increase gabapentin to 300 mg PO TID; Day 15: continue gabapentin and start intranasal ketamine 30 mg TID. Dose modifications were allowed for both agents. Toxicity: assessed using CTCAE 5.0. Feasibility: data capture by pill counts and patient medication logs. Efficacy: patient reported outcomes measures completed at baseline, weekly during radiation and 1-, 2-, and 3-months post-radiation. **Results:** Patient characteristics: median age 60 yrs, 85% males, 67% p16-positive, 21 post-operative. Toxicity: Of 45 patients who completed treatment, 7 patients (16%) experienced a grade 2+ toxicity (5 were probably related to ketamine). Four patients required ketamine dose de-escalation due to dizziness. Six patients (13%) eventually discontinued ketamine due to toxicity. Feasibility: 41 (91%) patients missed <5% of gabapentin doses; 35 (78%) patients missed <5% of ketamine doses. Preliminary Efficacy: Eight patients (18%) required PEG placement. median score on the pain subscale of the Vanderbilt Head and Neck Symptom Survey 2.0 was highest at the end of treatment (4.3/10) and decreased rapidly (2.4/10 at 1 month and 1.7/10 at 2 months post-treatment). During treatment, 8 patients (18%) required no opioids, and 24 patients (55%) required immediate-release (IR) opioids only. The median of the maximum morphine milligram equivalent (MME) per day for IR opioids alone was 90 MME/day(range 10 – 180 MME/day). The median duration of IR prescription alone was 30 days (range 10 – 347 days). Twelve patients (27%) required addition of extended-release (ER) opioids with a median duration 35 days (range 28 - 220 days). Only 3 patients (7%) required ER opioids for >90 days. **Conclusions:** The combination of gabapentin and ketamine was safe and feasible. Preliminary data indicates the majority of patients experienced low to moderate levels of pain with minimal use of opioids. Larger, randomized studies are warranted to confirm the benefit of the combination of gabapentin and ketamine. Clinical trial information: NCT05156060. Research Sponsor: NCATS/NIH Grant Support for REDCAP use (UL1 TR000445); Ingram Industries Pain & Symptom Management Program Endowment.

The role of pretreatment vitamin D insufficiency in racial disparity in taxane-induced peripheral neuropathy: Results from the SWOG S0221 trial. First Author: Nam Nguyen-Hoang, University of Michigan, Ann Arbor, MI

Background: Taxane-induced peripheral neuropathy (TIPN) affects up to 70% of patients receiving taxanes and can lead to severe, irreversible symptoms that impair daily functioning and quality of life. Approximately 25% of patients require taxane dose modification or discontinuation to prevent TIPN, compromising treatment effectiveness and survival. Self-reported Black patients experience nearly two times greater incidence of TIPN compared to White patients, contributing to treatment alterations and worse cancer outcomes. Vitamin D insufficiency, which is more common among Black patients, has been implicated as a modifiable risk factor for TIPN. This study assessed the extent to which vitamin D insufficiency mediates the racial disparity in TIPN. **Methods:** This secondary analysis included self-reported Black or White female patients with early-stage breast cancer treated with paclitaxel-based chemotherapy on the SWOG S0221 phase III trial. The primary endpoint was clinician-assessed grade ≥3 sensory neuropathy per NCI CTCAE attributed to paclitaxel. The mediator was pretreatment vitamin D insufficiency, defined as total 25-hydroxyvitamin D ≤20 ng/mL. Causal mediation analysis decomposed the total effect of race on TIPN into its direct effect and an indirect effect mediated through vitamin D insufficiency, adjusted for age and paclitaxel regimen (weekly or every other week). Log-linear model with modified Poisson regression and weighted logistic regression were used for the outcome model and the mediator model, respectively. Confidence intervals were computed via bootstrapping, and significance was set at α=0.05. **Results:** A total of 1,106 participants (mean age 51.2 [SD 10] years) were included, of whom 109 were Black and 997 were White. Black patients had a higher prevalence of vitamin D insufficiency (77% vs. 28%, p <0.001) and a higher incidence of grade ≥3 sensory TIPN (29% vs. 14%, p <0.001). The adjusted risk ratio (RR) for TIPN comparing Black to White patients was 2.24 (95% CI, 1.54-3.19; p <0.001). Vitamin D insufficiency statistically mediated this association, with an indirect effect RR of 1.18 (95% CI, 1.01-1.38; p = 0.048), accounting for 27% of the racial disparity in TIPN. The direct effect of race on TIPN, independent of vitamin D status, remained significant (RR 1.90; 95% CI, 1.30-2.85; p <0.001). **Conclusions:** Vitamin D insufficiency contributes to, but does not entirely explain, the racial disparity in TIPN. While other unaccounted factors may interact with or modify this association, vitamin D supplementation in insufficient patients could partially reduce racial disparities in TIPN and improve pharmacoequity. Value of risk-directed thromboprophylaxis in ambulatory lung and gastrointestinal cancer care: Economic evaluation of the TARGET-TP randomized trial. First Author: Marliese Alexander, Pharmacy Department, Peter MacCallum Cancer Centre & Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia

Background: Thromboembolism (TE) is a major and preventable hematological complication in patients with cancer, contributing to substantial adverse health impacts for patients and the health system. Targeted Thromboprophylaxis in Ambulatory Patients Receiving Anticancer Therapies (TARGET-TP; ACTRN12618000811202) was an Australian phase III randomized trial of biomarker risk-directed enoxaparin thromboprophylaxis. The TARGET-TP intervention reduced TE (HR 0.31, p = 0.005) and six-month mortality (HR 0.48, p = 0.03) versus usual care (no prophylaxis). This study evaluated the value for money of the TARGET-TP intervention versus usual care. **Methods:** A within-trial and modelled economic evaluation was conducted from the Australian health system perspective. Resource use collected within the trial reflected risk stratification, thromboprophylaxis, side-effect management, and treatment of TE events. Health benefits were quantified as quality-adjusted life years (QALYs), utilities derived from SF-12v2 data. Bootstrapping was used to evaluate sampling uncertainty. A Markov model estimated long-term costs and outcomes over a 5-year horizon. Scenarios assessed the use of oral anticoagulants and stewardship, while probabilistic sensitivity analysis (PSA) tested parameter uncertainty. **Results:** Within-trial analysis showed the TARGET-TP intervention was associated with lower costs, while being more effective (i.e., dominant), reducing costs by $1,095 per patient and generating an additional 0.0097 QALYs, driven mainly by fewer hospitalizations. The TARGET-TP intervention was dominant in $>$ 83% of bootstrap iterations. Modelled analyses supported these findings, with cost savings of $3,551 per patient and a gain of 0.4 QALYs. PSA demonstrated dominance in $>$ 95% of iterations (Figure 1). The oral anticoagulant and stewardship scenarios remained dominant for rivaroxaban, while apixaban was highly cost-effective, driven by bleeding events and drug costs. **Conclusions:** Biomarker-driven primary thromboprophylaxis in patients with lung and gastrointestinal cancer was less costly and more effective from the healthcare system perspective, supporting its implementation in routine care. Clinical trial information: ACTRN12618000811202. Research Sponsor: Victorian Cancer Agency; ECHSRF18006; Australian National Health and Medical Research Council; 1196211.

Pharmacokinetic variability with pembrolizumab dosage switching and its impact on immune-related adverse events in patients with non-small cell lung cancer. First Author: Yoshihiro Masui, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Pembrolizumab 400 mg every 6 weeks (Q6W) was approved based on population pharmacokinetic (pop-PK) modeling rather than direct pharmacokinetic measurements, leaving its real-world concentrations insufficiently characterized. The impact of concentration changes when switching from 200 mg every 3 weeks (Q3W) to Q6W on immune-related adverse events (irAEs) remains unclear. **Methods:** We retrospectively identified patients with advanced non-small cell lung cancer who switched pembrolizumab from Q3W to Q6W between March 2017 and September 2023. Serum concentrations were quantified by liquid chromatography–tandem mass spectrometry; pop-PK analysis estimated maximum concentration (eCmax) and trough concentration (eCtrough). Inter-cycle variability was expressed as percentage coefficient of variation (% CV) using all available Q3W cycles. Early irAEs were defined as events within 126 days. In exploratory analysis, associations between pop-PK metrics and after switching irAEs (including pneumonitis) were evaluated using Wilcoxon rank-sum tests and multivariable logistic regression. Clinical correlates of %CV-eCmax were examined using multivariable stepwise linear regression. **Results:** Seventy-nine patients switched, and pop-PK analysis was feasible in 66. Median age was 70 years, 50 were male and 62 had a smoking history. Median Q3W cycles were 6 (range, 1–37) and median follow-up after switching was 463 days. After switching, 42 patients developed new or worsened irAEs, with 16 pneumonitis, and 22 had early irAEs, with 12 early pneumonitis. First-dose 400 mg eCmax and cross-regimen exposure ratios were not associated with the occurrence of irAEs. Among 64 patients who received $\geq$2 cycles of Q3W, those who developed irAEs after switching showed higher %CV-eCmax during Q3W (p = 0.036). Similar associations were observed for early irAEs (p = 0.024), pneumonitis (p = 0.023), and early pneumonitis (p = 0.007). %CV-eCtrough during Q3W was not associated with irAEs after switching (irAEs, p = 0.24; early irAEs, p = 0.13; pneumonitis, p = 0.16), with an association observed only for early pneumonitis (p = 0.044). High %CV-eCmax during Q3W was associated with increased odds of irAEs (odds ratio [OR] 8.4, p = 0.02), pneumonitis (OR 14.3, p = 0.03), early irAEs (OR 15.2, p = 0.017), and early pneumonitis (OR 30.0, p = 0.03). No significant associations were observed between %CV-eCtrough and irAEs or early irAEs. Higher platelet count and renal dysfunction were independently associated with increased %CV-eCmax. **Conclusions:** Higher inter-cycle variability in eCmax during 200 mg Q3W was associated with an increased risk of new or worsened irAEs, particularly pneumonitis, after switching to 400 mg Q6W. These findings suggest that inter-cycle variation in Cmax may be an important safety consideration when transitioning to a 400 mg Q6W regimen. Research Sponsor: None.

Impact of synbindin deficiency on immune checkpoint blocker–induced systemic inflammation and multi-organ damage. First Author: Zhenghang Xu, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Immune-related adverse events (irAEs) are a major safety limitation for the broad application of immune checkpoint blockade (ICB) in oncology, yet their precise molecular mechanisms remain unclear. Synbindin, a tethering-associated protein involved in vesicular trafficking and related processes, plays a key role in immune-cell activation and activation of inflammatory signaling pathways and therefore may represent an important initiator and predictive factor for irAEs. **Methods:** We generated constitutive whole-body Trappc4 knockout (Trappc4-KO) C57BL/6 mice and administered either anti-PD-1 monotherapy or combined anti-PD-1 plus anti-CTLA-4 immune checkpoint blockade via intraperitoneal injection. Plasma biochemical indices and the extent of organ injury were assessed following treatment. **Results:** Trappc4-KO mice receiving combined anti-PD-1/anti-CTLA-4 treatment exhibited markedly more severe immune-related toxicity and multi-organ injury than wild-type controls. Biochemically, markers of hepatic injury (AST, ALT) were substantially elevated, indicating liver dysfunction; renal function markers (serum creatinine and blood urea nitrogen) were significantly increased, consistent with kidney injury; and cardiac markers (CK-MB, cTnT, cTnI) were also markedly raised. A similar trend, although less pronounced, was observed following anti-PD-1 monotherapy. Histopathological examination corroborated these findings: H&E sections of affected organs showed prominent focal immune cell infiltration, cellular swelling, and areas of necrosis. **Conclusions:** These data demonstrate that Trappc4 deficiency significantly exacerbates ICB-induced systemic inflammation and multi-organ damage, suggesting that Synbindin plays a critical protective role in the development of irAEs. A randomized controlled pilot study of aromatherapy to reduce anxiety and pain during bone marrow aspiration and biopsy. First Author: Krisstina Gowin, City of Hope, Irvine, CA

Background: Bone marrow aspiration and biopsy (BMAB) is associated with substantial anxiety and pain among patients with hematologic malignancies. Nonpharmacologic strategies to improve procedural tolerance are needed. Aromatherapy with lavender essential oil and its primary active constituent, linalool, has demonstrated anxiolytic effects in preclinical and peri-procedural settings but has not been rigorously evaluated during BMAB. **Methods:** We conducted a single-center, randomized pilot study of adult patients with cancer receiving a BMAB. Subjects were randomized (1:1:1) to lavender essential oil ($\geq$25% linalool), pure linalool oil ($\geq$97%), or placebo (jojoba oil). Aromatherapy was administered via inhalation prior to and throughout the procedure. Primary outcomes included feasibility ($>$70% completion) and patient satisfaction. Secondary outcomes included anxiety and pain assessed by visual analog scales (VAS) before, during, and after BMAB. Exploratory physiologic outcomes included bispectral index (BIS), an electroencephalogram-based measure of cortical arousal. **Results:** Forty-five patients were enrolled, with 43 (96%) completing the study, meeting feasibility criteria. Most participants (88%) agreed or strongly agreed that aromatherapy was relaxing and enjoyable. All groups demonstrated significant within-group reductions in VAS-anxiety from pre- to post-procedure, with the largest reduction observed in the linalool arm (-3.1 ± 0.70 (mean$\pm$SE); $p<0.01$), compared with lavender (-1.8 ± 0.67; p=0.02) and placebo (-2.4 ± 0.61; $p<0.01$). During BMAB, anxiety reduction favored the lavender and linalool arms, with a trend toward between-group significance (p=0.053). Pain increased during BMAB across all groups; however, the linalool arm demonstrated the smallest increase (2.6 ± 0.69; $p<0.01$)) compared with lavender (3.8 ± 0.93; $p<0.01$)) and placebo (4.0 ± 1.3; $p<0.01$). Post-BMAB, between group analysis trended toward significantly less pain with lavender and linalool compared to placebo (p=0.057). Exploratory within-group BIS scores analyses demonstrated significant reductions in average BIS after aromatherapy treatment prior to BMAB with lavender showing the greatest reductions (-6.0$\pm$2.0; p=0.01), as compared to linalool (-3.6$\pm$1.6; p=0.047) and placebo (-1.6$\pm$1.3, p=0.27). No serious adverse events occurred. **Conclusions:** Aromatherapy using lavender and linalool during BMAB is feasible, safe, and potentially associated with meaningful reductions in procedural anxiety and pain. These preliminary findings support a larger randomized control trial to confirm efficacy and explore integration into routine supportive oncology care. Clinical trial information: NCT06581211. Research Sponsor: None.

Cumulative toxicity assessed by area-under-the-curve (AUC) in targeted therapy versus chemotherapy for advanced *EGFR*-mutant NSCLC. First Author: William J. Phillips, University of Colorado Denver, Anschutz Medical Campus, Aurora, CO

Background: Current adverse event (AE) reporting standards emphasize peak toxicity, which may inadequately capture the cumulative burden of persistent low-grade AEs characteristic of targeted therapies. We conducted a post-hoc analysis of the LUX-Lung 3 trial to compare longitudinal toxicity patterns of targeted therapy and chemotherapy over time. **Methods:** This post-hoc analysis used individual, de-identified patient-level data from the phase III LUX-Lung3 clinical trial comparing afatinib with platinum-based chemotherapy as first-line treatment for advanced EGFR-mutant NSCLC, accessed through Vivli. Select treatment-related AEs were evaluated longitudinally by grade. Cumulative toxicity burden was quantified using the area-under-the-curve (AUC) of AE grade prevalence over time. Pearson correlation was used to assess temporal trends in AUC. **Results:** A total of 340 patients had evaluable AE data, including 229 (67%) treated with afatinib and 111 (33%) treated with chemotherapy. The median onset of grade 1-2 AEs generally occurred earlier with chemotherapy than afatinib. The median onset of chemotherapy-related fatigue was 4 days and nausea 2 days, whereas median onset of afatinib-related diarrhea was 4 days, rash 8 days, and paronychia 37 days. Longitudinal AUC analysis (Table 1) demonstrated a significant improvement in grade 1-2 chemotherapy-related nausea (p=0.003) and stomatitis (p=0.05), and a trend towards improvement in fatigue (p=0.2) by 12-months. In contrast, grade 1-2 afatinib-related rash (p=0.4) and diarrhea (p=0.99), remained stable, while paronychia increased over time (p=0.004). For grade 3+ AEs, the AUC improved over time for both the chemotherapy (p=0.04) and afatinib (p=0.02) groups. **Conclusions:** Assessment of time to onset and longitudinal AUC reveal distinct temporal AE patterns for targeted therapy and chemotherapy. Longitudinal toxicity reporting is feasible and highlights the sustained burden of chronic AEs associated with targeted therapies that are clinically meaningful yet underrepresented by conventional peak toxicity reporting. Research Sponsor: Thoracic Oncology Research Initiative (TORI), University of Colorado.

Cumulative toxicity of afatinib and chemotherapy was quantified using the area under the curve of grade 1-2 adverse events prevalence at landmark time points.*

Adverse event	Month 1	Month 3	Month 6	Month 12	Pearson's coefficient	p-value
Afatinib (%)						
Rash	0.24	0.39	0.44	0.45	0.24	0.4
Diarrhea	0.30	0.44	0.47	0.45	-0.002	0.99
Paronychia	0.02	0.20	0.32	0.39	0.74	0.004
Chemotherapy (%)						
Fatigue	0.05	0.09	0.09	0.07	-0.36	0.2
Nausea	0.07	0.17	0.17	0.10	-0.60	0.03
Stomatitis	0.02	0.02	0.02	0.01	-0.56	0.05

The price of a breath: The economic and mortality burden of checkpoint inhibitor pneumonitis (2016–2020). First Author: Milan Regmi, Southeast Health Medical Center, Dothan, AL

Background: The landscape of oncologic toxicity has drastically changed because of the rapid introduction of Immune Checkpoint Inhibitor (ICI) indications, ranging from the treatment of melanoma to thoracic cancers. Immune-related adverse events (irAEs) are a novel range of toxicities brought about by the rapid growth of ICI. The overall national burden of severe inpatient toxicities is still unknown, despite the well-described outpatient care of irAEs. We measured the prevalence, mortality, and financial impact of severe irAEs necessitating hospitalization using the Nationwide Inpatient Sample (NIS). **Methods:** We evaluated adult hospitalizations secondary to major irAEs (pneumonitis, colitis, hepatitis, and endocrinopathies) using ICD-10-CM codes for a retrospective cohort analysis of the National Inpatient Sample database from 2016 to 2020. Only patient with cancer diagnosis associated complications were included to reduce confounders. Statistical evaluations and outcomes were generated using STATA version 19. The use of mechanical ventilation, total hospital charges, and in-hospital mortality were the major outcomes. Temporal trends and mortality factors were examined using survey-weighted regression models. **Results:** We identified a weighted national cohort of 109,225 irAE-related hospitalizations from 2016 to 2020. Epidemiology: Immune-mediated Colitis was the dominant driver of volume (54.6%) for inpatient admission, followed by Pneumonitis (22.2%) and Hepatitis (18.2%). The proportion of admissions attributable to Pneumonitis was increased from 21.1% in 2016 to 24.0% in 2020 ($p < 0.001$), coincident with expanded ICI use in lung cancer. Outcomes & Acuity: Pneumonitis was associated with the longest mean length of stay (LOS) of 6.9 days and the highest raw mortality (7.8%) compared to Colitis (1.6%). In multivariable analysis, Pneumonitis was the strongest independent predictor of in-hospital mortality (aOR 4.98; 95% CI 4.12–6.02; $p < 0.001$)relative to Colitis. Conversely, female sex was associated with a significant survival advantage (aOR 0.76; p = 0.001). Economic Burden: Pneumonitis was the most resource-intensive toxicity (Mean Charge: $74,298 vs. $43,831 for Colitis). The aggregate national hospital bill for irAEs rose from $1.14 Billion in 2016 to a peak of $1.75 Billion in 2020. **Conclusions:** Pneumonitis is the primary cause of death and economic expense, whereas colitis is the primary cause of irAE hospitalizations. Between 2016 and 2020, the total cost of hospitalization in the United States almost doubled, reaching approximately $1.75 billion per year. Health systems need to prepare for an increase in high-acuity, resource-intensive pulmonary toxicity as ICI indications spread into the adjuvant environment. Research Sponsor: None.

A risk prediction model for severe, life-threatening, and fatal treatment-related toxicity. First Author: Joseph M. Unger, SWOG Statistics and Data Management Center, Fred Hutchinson Cancer Center, Seattle, WA

Background: Adverse events are major contributors to morbidity and mortality in patients receiving systemic cancer therapy. Accurate prediction of high-grade toxicity could inform risk-adapted treatment strategies. **Methods:** This cohort study included data from 18 SWOG adult phase 2 and 3 treatment trials conducted from 1990 to 2022. Baseline patient-reported symptoms (fatigue, pain, and anxiety, classified as clinically meaningful yes vs. no), baseline sociodemographic (age, sex, race, ethnicity), and performance status (PS) variables were used. The aim was to develop a unified risk score applicable across multiple toxicity severity thresholds; adverse events were classified using the Common Terminology Criteria for Adverse Events. The primary outcomes were severe (Grade >3), life-threatening (Grade >4), and fatal toxic events. A training set was derived using a random 60% sample, balanced by study and arm; validation will occur in the remaining 40%. Best-subsets logistic regression was used for variable selection; final models were stratified by cancer type (hematologic, hormone-driven solid tumor, or other solid tumor) and treatment status (untreated vs refractory). Model discrimination was assessed using the concordance (c) statistic. Patients were divided into tertiles according to their total risk score. Toxicity rates and odds ratios were evaluated across tertiles (Ts). **Results:** Of 7,936 patients, 4,776 (60.2%; median age 64.9 (range, 18-95.3); female 28.0%; Black 10.8%) formed the training cohort. Increased toxicity was associated with age ≥60 years, fatigue, female sex, and PS ≥1. The multivariable risk models demonstrated good discrimination for grade ≥3 (c=0.76), grade ≥4 (c=0.77), and grade 5 toxicity (c=0.77). Severe toxicity increased from 15.8% in the lowest risk tertile (T1) to 64.6% in T3; life-threatening toxicity increased from 2.7% in T1 to 26.2% in T3 (Table). Compared with the lowest tertile, the highest risk tertile had markedly higher odds of grade ≥3 (OR 9.76), grade ≥4 (OR 12.96), and grade 5 toxicity (OR 7.15; all p<.001). Model validation results will be presented. **Conclusions:** This risk model accurately identified patients with substantially elevated risk for severe, life-threatening, and fatal toxicities. Risk stratification may support individualized treatment counseling, risk-guided monitoring, and proactive toxicity management. Dentist-led systematic oral education programs in the prevention of radiation-induced oral toxicities in patients with head and neck cancer (BRIGHT): A randomized clinical trial. First Author: Yu Min, Department of Biotherapy, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Radiotherapy-induced oral toxicity (RIOT) is a common complication in patients with head and neck cancer (HNC). International guidelines have recognized the role of oral-health education in preventing RIOT. However, most recommendations remained at the level of general principles and lacked a detailed, systematic and operationalized process, which hinders effective clinical delivery of oral-health education. Given that dentists are uniquely positioned to manage oral health, this study aims to evaluate the effectiveness of a dentist-led systematic oral-health education program (OHEP) on RIOT and provide a standard operating procedure (SOP) for its implementation. **Methods:** In this single-centre, assessor-blinded, randomised controlled trial, 150 patients with non-metastatic HNC scheduled for definitive radiotherapy (60–72 Gy) were enrolled at West China Hospital in China. Participants were randomly assigned (1:1) to receive either a dentist-led oral health education program (OHEP) or routine oral health care. The primary endpoint was the incidence of oral mucositis (OM), assessed by the WHO Oral Mucositis Grading Scale. Secondary endpoints included the incidence of severe oral mucositis (SOM, defined as WHO grade 3–4) as well as the time to onset and duration of OM (SOM). Outcome assessments were conducted by trained research assistants blinded to group allocation. Analyses were performed in both intention-to-treat and per-protocol populations, with two-sided $P < 0.05$ considered statistically significant. This study is registered with ClinicalTrials.gov, NCT06690346, and is now complete. **Results:** Of 150 randomised patients, 75 were allocated to each arm, and 142 (94.7%) completed the trial and were included in the intention-to-treat analysis. The incidence of OM was significantly lower in the OHEP arm than in the control arm (70.7% [53/75] vs. 88.0% [66/75] $P = 0.016$), with a significantly delayed onset (median 17 vs. 14 days; $P = 0.006$) and shorter duration (median 39 vs. 60 days; $P < 0.001$). Consistent results were observed in the per-protocol population. However, no significant difference was observed in the incidence, onset, or duration of SOM between arms. **Conclusions:** Dentist-led OHEP significantly reduced the incidence and delayed the onset of radiotherapy-induced OM. These results support dentist-led OHEP as a feasible, non-pharmacological approach to mitigate oral toxicity and improve supportive care in patients receiving radiotherapy for HNC. Clinical trial information: NCT06690346. Research Sponsor: Ministry of Science and Technology of the People's Republic of China; 2023ZD0503000, 2023ZD0503004; National Natural Science Foundation of China; U24A20735; Ministry of Education of the People's Republic of China; 82473434.

Efficacy and safety of Meilian Fuxin liquid for radiation-induced oral mucositis in head and neck cancer: A multicenter randomized clinical trial. First Author: Huaju Yang, Cancer Center and State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, China

Background: Radiation-induced oral mucositis (RIOM) is common during head and neck radiotherapy (> 90% incidence), and 40–70% of patients develop severe oral mucositis (SOM; WHO grade 3–4), which markedly impairs quality of life and may lead to radiotherapy interruptions. Given the limited effective therapies and the lack of evidence-based standard of care, we assessed the efficacy and safety of MeiLianFuXin Liquid (*Periplaneta americana* extract) for reducing SOM incidence. **Methods:** This multicenter, randomized, double-blind, placebo-controlled phase II trial was conducted across 7 hospitals in China from June 12, 2024, through October 31, 2025. Eligible patients (18–80 years) had non-metastatic head and neck cancer planned for radiotherapy (planned total dose ≥60 Gy), with cisplatin as the only allowed concurrent agent. Following investigator-confirmed WHO grade 1 oral mucositis, patients were randomized (1:1:1) via a centralized interactive web response system (IWRS) using a dynamic minimization algorithm to receive low-dose MeiLianFuXin Liquid, high-dose MeiLianFuXin Liquid, or a matched placebo. The study drug was administered three times daily until 14 days post-radiotherapy. The primary endpoint was SOM incidence. Adjusted proportion differences were estimated using logistic regression. Adverse events were graded according to the Common Terminology Criteria for Adverse Events (CTCAE), version 5.0. **Results:** In the full analysis set (FAS), 215 patients received treatment (low-dose, n = 72; high-dose, n = 72; placebo, n = 71). The incidence of SOM was 22.2% (95% CI, 13.3 to 33.6) in the low-dose group, 29.2% (95% CI, 19.0 to 41.1) in the high-dose group, and 43.7% (95% CI, 31.9 to 56.0) in the placebo group. Compared with placebo, adjusted proportion differences were −22.5% (95% CI, −37.3 to −7.8; *P* = .0042) for the low-dose group and −16.4% (95% CI, −32.2 to −0.5; *P* = .0463) for the high-dose group. Adverse events and serious adverse events were generally similar across groups. **Conclusions:** To our knowledge, this is the first randomized, double-blind, placebo-controlled trial of a traditional Chinese medicine for RIOM showing that MeiLianFuXin Liquid reduces SOM incidence versus placebo with a favorable safety profile. These findings support MeiLianFuXin Liquid as a promising treatment strategy to mitigate RIOM. Clinical trial information: ChiCTR2400084288. Oral mannitol for chemotherapy-induced constipation (CIC): A randomized, multicenter, controlled study. First Author: Chaomin Liu, The First Affiliated Hospital of Chengdu Medical College, Chengdu, China

Background: Chemotherapy-induced constipation (CIC) is a common yet frequently overlooked supportive care issue, currently, there is still a lack of efficient and affordable methods. This trial was designed to compare the efficacy and safety of orally administered mannitol injection versus lactulose in cancer patients with CIC. **Methods:** An open-label, multicenter, prospective RCT (ChiCTR2200056847) planned to enroll 114 adults. Participants were randomized 1:1 to oral mannitol 50 mL post-meal 3–5×/day or lactulose 30 mL once daily for 3 days. Primary endpoint: time to first spontaneous defecation (TFSD). Secondary endpoints included weekly complete spontaneous bowel movements (CSBMs), Bristol Stool Form Scale, PAC-QOL, and CTCAE v5.0 adverse events (AEs). Interim analysis was performed when 112 participants had completed the 7-day assessment; database was locked on 30 January 2026. **Results:** A nationwide survey (14 provinces, n=1,174) revealed significantly higher constipation rates in stage IV cancer patients ($p<0.05$), and found that the managements vary in effectiveness. In an RCT interim analysis (112 patients), baseline demographics were balanced between mannitol (n=56) and lactulose (n=56) groups. Median time to first defecation was significantly shorter in mannitol group with 5.5 hours (IQR 3.0-15.8) than in lactulose with 16.0 hours (IQR 5.3-27.5) (p=0.003)(Fig. 1). Secondary outcomes were comparable: weekly mCSBMs (3.0 vs. 3.0, p=0.083); Bristol Scale improvement ≥1 category (60.7% vs. 58.9%, p=0.847); and PAC-QOL score (-26 vs. -18 points, p=0.105). Both treatments were safe, with only mild, transient adverse events at similar rates (3.6% vs. 5.4%, p=0.647)(Table 1). **Conclusions:** Survey data confirm under-recognition of CIC and therapeutic gaps for advanced-stage patients. In this interim analysis, oral mannitol significantly shorten TFSD than lactulose, with mild adverse events, which is a rapid-onset, low-cost option for CIC management. Clinical trial information: ChiCTR2200056847. Research Sponsor: None.

TFSD, weekly CSBMs, adverse events, PAC-QOL.

Outcome	Mannitol (n=56)	Lactulose (n=56)	p-value
TFSD (median, IQR)	5.5 (3.0–15.8) hrs	16.0 (5.3–27.5) hrs	0.003
Weekly CSBMs (median, IQR)	3.0 (3.0–4.0)	3.0 (2.0–3.0)	0.083
Stool form improvement (≥1 Bristol)	34 (60.7%)	33 (58.9%)	0.847
PAC-QOL change (Δ, mean)	-26 (18.3–40.5)	-18 (12.5-37.5)	0.105
Any AE (%)	2 (3.6%)	3 (5.4%)	0.647

Efficacy and safety of mixed formulation aprepitant and palonosetron (QLM2010) for prevention of cisplatin-based highly emetogenic chemotherapy-induced nausea and vomiting: A multicenter, randomized, double-blind, double-dummy, positive-controlled phase III study. First Author: Jieer Ying, Department of Hepatobiliary, Pancreatic and Gastric Medicine, Zhejiang Cancer Hospital, Chinese Academy of Sciences, Hangzhou, Zhejiang, China

Background: QLM2010, a novel fixed-dose intravenous antiemetic combination of aprepitant and palonosetron (PALO), can simultaneously antagonize 5-hydroxytryptamine-3 and neurokinin-1 receptors. This study aimed to assess the efficacy and safety of QLM2010 plus dexamethasone (DEX) versus fosaprepitant (FAPR) combined with PALO and DEX for preventing chemotherapy-induced nausea and vomiting (CINV) in patients receiving highly emetogenic chemotherapy (HEC). **Methods:** This was a multicenter, randomized, double-blind, double-dummy, positive-controlled Phase III trial. Chemotherapy-naïve patients with solid tumors were randomly assigned 1:1 to receive QLM2010 (Day 1) or FAPR + PALO (Day 1) prior to cisplatin-based HEC, together with oral DEX (Days 1–4). The primary efficacy endpoint was complete response (CR: no emesis/no rescue medication) during the overall (0–120 hours) phase. **Results:** Baseline demographic and clinical characteristics were well-balanced between the two groups (QLM2010 group: n = 329; FAPR+PALO group: n = 331). The overall CR rate was 82.67% versus 80.97% (risk difference, 1.65%; 95% CI, −4.21–7.50%), confirming the non-inferiority of QLM2010 + DEX to FAPR + PALO + DEX. CR rates in both the acute (0–24 hours) and delayed (24–120 hours) phases were comparable between groups. Across all phases, the QLM2010 group showed similar rates to the FAPR+PALO group for no emesis, no nausea, no significant nausea, no rescue therapy, and complete protection (all P > 0.05). Notably, QLM2010 + DEX showed greater proportions of patients reporting no impact on daily life on Day 2 after treatment compared with FAPR + PALO + DEX (P = 0.0279). A single injection-site reaction (0.30 %) was confined to the FAPR+PALO group; none was observed in the QLM2010 group. The incidence of hiccups was numerically lower in the QLM2010 group compared with the FAPR+PALO group (8.2% vs. 15.1%). **Conclusions:** QLM2010 + DEX was non-inferior to FAPR + PALO + DEX for preventing CINV in cisplatin-based HEC patients and well tolerated, with the potential to reduce the impact of CINV on daily life. QLM2010 furnishes a novel, more convenient therapeutic alternative for the clinical management of CINV. Clinical trial information: NCT07081256. Research Sponsor: None.

SARM1 inhibition to prevent chemotherapy-induced peripheral neuropathy: Translational and early clinical evaluation of SIR2501. First Author: Linping Yu, Sironax, Beijing, China

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common, cumulative, and often irreversible toxicity that limits dose intensity, disrupts cancer treatment, and substantially impairs quality of life. Despite its prevalence, no approved disease-modifying therapies exist. Axonal degeneration is a central pathological driver of CIPN. Sterile alpha and TIR motif–containing protein 1 (SARM1) is a key executioner of programmed axon degeneration across neurotoxic insults. Inhibiting SARM1 offers a mechanism-based strategy to prevent axonal injury without compromising anticancer activity. SIR2501 is a potent, selective, orally bioavailable small-molecule SARM1 inhibitor in clinical development for CIPN prevention. **Methods:** SIR2501 was evaluated in rodent models of paclitaxel (PTX)-induced peripheral neuropathy using prophylactic and therapeutic dosing paradigms. Endpoints included sensory neuropathy (mechanical allodynia), axonal injury biomarkers (serum neurofilament light chain [sNfL]), and peripheral nerve integrity (intraepidermal nerve fiber density). The impact of SIR2501 on PTX antitumor efficacy was assessed in rodent tumor models.A randomized, double-blind, placebo-controlled Phase 1 study in healthy volunteers evaluated safety, pharmacokinetics (PK), CNS penetration, and pharmacodynamic evidence of SARM1 target engagement following single and multiple ascending doses. **Results:** SIR2501 robustly attenuated PTX-induced neuropathy in preclinical models, with concordant functional, biomarker, and structural protection, and did not impair PTX-mediated tumor growth inhibition. In Phase 1, 82 volunteers received SIR2501 (up to 600 mg single dose; up to 150 mg once-daily multiple dose). SIR2501 was well tolerated, with no dose-limiting toxicities or clinically meaningful neurologic adverse events. PK supported once-daily dosing with minimal food effect and no CYP3A-mediated drug–drug interaction risk. Dose- and exposure-dependent suppression of circulating cyclic ADP-ribose (cADPR) confirmed SARM1 target engagement at plasma exposures aligned with preclinical efficacy. **Conclusions:** These translational data support SARM1 inhibition as a disease-modifying approach for CIPN. These data have enabled initiation of a global Phase 1b/2 trial of SIR2501 in patients receiving taxane-based chemotherapy in the United States, Australia, and China. Research Sponsor: Sironax Inc.

Baseline telomere length and prediction of cognitive recovery after chemotherapy in patients with breast cancer: An NCORP prospective cohort study. First Author: Jonas M. Ndeke, Department of Surgery, Division of Supportive Care in Cancer, University of Rochester Medical Center, Rochester, NY

Background: Chemotherapy-related cognitive impairment (CRCI) affects up to 70% of breast cancer survivors, yet recovery varies. Telomere length (TL), a marker of biological aging, may reflect biological resilience to CRCI. We evaluated whether baseline TL predicts longitudinal cognitive recovery following chemotherapy. **Methods:** In a nationwide prospective cohort study across 19 NCORP-affiliated community oncology clinics (URCC 10055), 185 women with stage I–IIIC breast cancer were assessed before chemotherapy (T1), post-chemotherapy (T2), and 6 months post-chemotherapy (T3). Baseline TL was measured by qPCR, normalized, and categorized into three groups: Short (S, n = 63, 34.1%), Average (A, n = 75, 40.5%), and Long (L, n = 47, 25.4%). Perceived cognitive function was assessed using the Functional Assessment of Cancer Therapy–Cognitive Function (FACT-Cog; minimum clinically important difference for total ≈7 pts), including total score and subscales for perceived cognitive impairments (PCI), perceived cognitive abilities (PCA), comments from others (OTH), and impact on quality of life (QoL). Changes from T1→T2 and T2→T3 were evaluated using repeated-measures mixed-effects analysis of covariance models adjusted for baseline values. **Results:** Baseline FACT-Cog total scores were similar across TL groups. At T2, all groups experienced comparable acute PCI (FACT-Cog change: S = −13.2, A = −13.3, L = −18.7). By T3, recovery differed by TL. While all groups remained below baseline, patients with long TL demonstrated substantially greater recovery, with a smaller overall decline from T1 (L = −8.6) compared with persistent impairment in Short (S = −14.0) and Average (A = −11.4) groups. This reflected a clinically meaningful improvement in cognitive function from post-chemotherapy to 6-month of +10.0 pts in the Long group (p = .016), whereas changes in the other two groups was not clinically or statistically significant. This recovery pattern was supported by clinically significant improvement in PCI (+7.2) and statistically significant change in OTH (+1.0; p = .003) in the Long group from T2 to T3, while it was attenuated in the Average and Short groups. In contrast, PCA showed minimal change across groups. Impact on quality of life also improved significantly in the Long group over the same period (FACT-Cog QoL T3−T2 change = +2.0; p = .019), reinforcing a coherent cognitive recovery phenotype. **Conclusions:** Baseline TL does not determine susceptibility to acute chemotherapy-related toxicity but strongly predicts cognitive recovery over time. Patients with longer telomeres demonstrate clinically meaningful recovery of cognition, whereas those with shorter telomeres show more persistent perceived cognitive impairment. TL may identify patients at higher risk for long-term impairment who could benefit from early supportive and rehabilitative interventions. Prophylactic vs reactive PEG tube placement in early-stage head and neck (H&N) cancer treated with curative-intent radiotherapy: Balancing benefit and burden in real-world practice. First Author: Fayaz Aijaz Ahmed Khan, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Timing of Percutaneous Endoscopic Gastrostomy (PEG) placement during curative-intent radiotherapy for H&N cancer remains controversial. We compared 6-month and 1-year outcomes after prophylactic (pPEG) versus reactive (rPEG) PEG placement in real-world practice. **Methods:** We conducted a retrospective study using the TriNetX Network database. Adults (≥18 years) with H&N cancer treated with curative-intent radiotherapy who received PEG were stratified by PEG timing: pPEG (≤30 days before or at radiotherapy initiation) versus rPEG (30–90 days after radiotherapy initiation). The index date was PEG insertion. After 1:1 propensity-matching with demographics, comorbidities, nutrition/weight variables, BMI, stage, chemotherapy/surgery, 2,752 patients remained in each cohort. Outcomes at 6 months and 1 year were analyzed using Kaplan–Meier methods with log-rank tests and Cox proportional-hazards models (HR, 95% CI). **Results:** At 6 months, compared with rPEG, pPEG was associated with lower all-cause mortality, but higher hospitalization, sepsis, PEG tube dependence, and PEG tube complications. ICU admission, aspiration pneumonitis, pneumonia, and dehydration were similar between cohorts. At 1 year, all-cause mortality and ICU admission remained similar between groups. However, pPEG was associated with higher hospitalization, aspiration pneumonitis, pneumonia, sepsis, and PEG tube complications, while dehydration and PEG tube dependence were similar (see Table). pPEG was associated with higher risk of dysphagia at 6 months (HR 1.3, 95% CI 1.1–1.6; p<0.01) and 1 year (HR 1.2, 95% CI 1.1–1.5; p=0.01), and malnutrition at 6 months (HR 1.3, 95% CI 1.1–1.6; p<0.01) and 1 year (HR 1.3, 95% CI 1.1–1.6; p<0.01). Unintentional weight loss and PEG tube removal did not differ between groups. **Conclusions:** In this real-world cohort study, pPEG was not associated with improved 1-year survival and was associated with higher acute care utilization, infections, and PEG-related complications compared with rPEG. These findings support selective, risk-stratified pPEG use rather than routine prophylactic placement. Research Sponsor: None.

Outcome	6 Month HR (95% CI, p-value)	1 Year HR (95% CI, p-value)
All-cause mortality	0.8 (0.7-0.9, p=0.04)	0.9 (0.8-1.1, p=0.6)
Hospitalization	1.3 (1.01-1.6, p=0.04)	1.2 (1.1-1.5, p=0.04)
ICU admission	1.0 (0.8-1.3, p=0.6)	1.1 (0.9-1.3, p=0.3)
Aspiration pneumonitis	1.2 (0.9-1.5, p=0.07)	1.2 (1.1-1.5, p=0.03)
Pneumonia	1.2 (0.9-1.4, p=0.1)	1.2 (1.1-1.4, p=0.04)
Sepsis	1.3 (1.01-1.5, p=0.03)	1.3 (1.1-1.5, p=0.01)
Dehydration	1.6 (0.9-2.6, p=0.08)	1.5 (0.9-2.3, p=0.1)
PEG tube dependence	1.2 (1.01-1.3, p=0.04)	1.1 (0.9-1.3, p=0.07)
PEG tube complication	1.2 (1.1-1.4, p<0.01)	1.2 (1.1-1.3, p<0.01)

HR > 1 indicates higher hazard in pPEG vs rPEG; HR < 1 indicates lower hazard.

The influence of exercise on the mediational relationship between chemotherapy-induced sensory neuropathy and cancer-related fatigue: A nationwide phase II RCT in 111 patients receiving chemotherapy. First Author: Po-Ju Lin, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY

Background: Cancer-related fatigue (CRF) and chemotherapy-induced sensory neuropathy (e.g., numbness, tingling, and pain) are common, sometimes debilitating toxicities that often co-occur in patients receiving neurotoxic chemotherapy. Both CRF and sensory neuropathy significantly diminish daily function and quality of life. Exercise is recommended for treating CRF and may also alleviate sensory neuropathy. Whether exercise-induced reductions in CRF are mediated by improvements in sensory neuropathy remains unknown. **Methods:** We conducted a nationwide phase II randomized controlled trial (RCT) through the University of Rochester Cancer Center NCI Community Oncology Research Program (URCC NCORP) Research Base. Patients who received neurotoxic chemotherapy in the past 9 months and developed moderate or severe (rated ≥4 on a 0-10 numerical scale) chemotherapy-induced sensory neuropathy (e.g., numbness, tingling, hot/burning or sharp/shooting pain in the hands and feet) in the past 2 weeks were randomized to virtually delivered Exercise for Cancer Patients (vEXCAP) or usual care (UC). vEXCAP is a 6-week, individually tailored, progressive walking and resistance band exercise intervention delivered virtually. CRF severity and sensory neuropathy were assessed via the Brief Fatigue Inventory severity score and the EORTC QLQ-CIPN20 sensory subscale (0-100 scale), respectively, at pre- and post-intervention. Causal mediation analyses were conducted to determine the extent to which exercise-induced improvements in CRF were mediated by changes in sensory neuropathy at post-intervention. **Results:** One hundred eleven patients (mean age 59.5 years; 76% female; 84% white; 37% breast cancer; 36% gastrointestinal cancer) were randomized and completed pre- and post-intervention assessments. vEXCAP participants, compared to UC participants, experienced significantly greater reductions in CRF (-0.95±0.33, p = 0.014) and clinically meaningful improvements in sensory neuropathy at post-intervention (-5.38±2.77 [MCID = 4.2], p = 0.055). Causal mediation analyses indicated that reductions in sensory neuropathy significantly mediate exercise-induced improvements in CRF severity (-0.18±0.13, p = 0.056), accounting for 19% (95% CI: 0% - 64%) of the exercise effect on CRF severity at post-intervention. **Conclusions:** vEXCAP reduces CRF severity and chemotherapy-induced sensory neuropathy among patients receiving neurotoxic chemotherapy. Approximately 19% of the exercise-induced improvements in CRF severity are mediated by reductions in chemotherapy-induced sensory neuropathy. Future Phase III RCTs are needed to confirm these findings and further explore the mediational role of chemotherapy-induced sensory neuropathy on CRF to help optimize the treatment of CRF using exercise. Clinical trial information: NCT04888988. Research Sponsor: National Cancer Institute; R21CA256154, K07CA221931, UG1CA189961, UG1CA189804, UG1CA189822, UG1CA189819, UG1CA189830, T32CA102618.

Trilaciclib for myeloprotection in adjuvant and first-line chemotherapy for advanced gastric/gastroesophageal junction adenocarcinoma: A multicohort study. First Author: Wenhui Yang, Department of Gastroenterology, Shanxi Province Cancer Hospital/Shanxi Hospital Affiliated to Cancer Hospital, Chinese Academy of Medical Sciences/Cancer Hospital Affiliated to Shanxi Medical University, Taiyuan, China

Background: Chemotherapy-induced myelosuppression (CIM) has become one of the important limiting factors in the treatment of gastric cancer, which significantly impairs patients' prognosis.Trilaciclib, a highly selective reversible CDK4/6 inhibitor, reduces chemotherapy-induced hematopoietic stem/progenitor cell (HSPC) damage via transient G1 arrest when administered intravenously pre-chemotherapy, while its transient T-cell suppression may modulate the tumor immune microenvironment.This study evaluates trilaciclib's myeloprotective efficacy in adjuvant and first-line metastatic gastric/gastroesophageal junction adenocarcinoma (GA/GEJA) and explores immunomodulatory effects. **Methods:** This prospective multicohort study (ChiCTR2500097520) enrolled Cohort 1 (resectable GA/GEJA, T1-4bN0-3M0 post-D2/R0 resection; n = 75) and Cohort 2 (first-line metastatic GA/GEJA, including recurrence > 6 months post-adjuvant; n = 40). Regimens included SOX/XELOX/FOLFOX ± immune checkpoint inhibitors (ICIs) ± trastuzumab. Trilaciclib (240 mg/m²) was given on days 1 and 3 every 21 days for 6–8 cycles. Primary endpoints: incidence of grade ≥3 neutropenia and febrile neutropenia (FN); exploratory analyses included immune biomarkers and antitumor efficacy. **Results:** As of January 2026, 204 patients were enrolled (male: 158 ; female: 46; median age: 63 years [range: 31–82]). Cohort 1: 118 patients (primary prophylaxis [PP]: 98 ; secondary prophylaxis [SP]: 20). Cohort 2: 86 patients (PP: 48 ; SP: 38). Grade ≥3 CIM incidence: Cohort 1 vs. Cohort 2: 4.46% vs. 2.96%; grade ≥3 neutropenia: 3.24% vs. 1.73%; thrombocytopenia: 1.54% vs. 0.74%; anemia: 0.77% vs. 1.97%. Prophylaxis-stratified analysis showed superior myeloprotection with PP: overall grade ≥3 CIM (PP:3.35% vs. SP: 4.56%), neutropenia (PP: 2.75% vs. SP:1.83%), thrombocytopenia (PP: 0.6% vs. SP: 2.29%), and anemia (PP: 1.32% vs. SP: 0.91%). Furthermore, the collection and detection of immune cells from 97 patients before and after treatment revealed that: the total number of T cells in patients showed an increasing trend after prophylactic medication. The number of CD4+ T cells showed an increasing trend; the number of CD8+ T cells began to decline after more than 3 cycles of chemotherapy; the number of Treg T cells increased and returned to the pre-chemotherapy level after more than 4 cycles. **Conclusions:** Trilaciclib demonstrated effective myeloprotection and immunoregulation in GA/GEJA, with PP showing a favorable trend. Grade ≥3 CIM rates were ≤5.88% (adjuvant) and ≤3.49% (metastatic), with no new safety signals. The studies will continue to analyze the correlation between immune-related indicators and anti-tumor efficacy. Clinical trial information: ChiCTR2500097520. Research Sponsor: None.

Machine learning approach for prediction of immune-related pneumonitis. First Author: Barliz Waissengrin, Medicine, Cedars Sinai Cancer Center, Los Angeles, CA

Background: Immune-related adverse events (irAE) associated with immune checkpoint inhibitors (ICI) substantially contribute to treatment-related morbidity, yet reliable pretreatment predictors remain unavailable. Immune-related pneumonitis (irP) is among the most serious irAE and is associated with a significant risk for mortality. Machine learning (ML) offers an opportunity to analyze complex clinical data to improve risk stratification. We aimed to develop a personalized ML-based model to identify and predict irP from electronic health records (EHR) using patient characteristics prior to ICI initiation. **Methods:** We extracted data from the EHR of patients with solid malignancies, in various disease stages, who were treated with ICI at Cedars-Sinai Medical Center between 2015 and 2024. For each patient, we collected comprehensive treatment data, including demographics and clinical variables from structured fields and clinical notes. Variables not reliably captured in structured fields, such as smoking or family history, were extracted using our pipeline. Using a large language model (LLM)-based pipeline, we identified irAE cases, enabling precise extraction and classification of irAE subtypes, and validated results against physician annotations for irP (excluding pneumonitis due to other causes). Chi-square analyses assessed associations between features and irAE. We used TPOT, an automated machine learning tool, to develop predictive models and explore sampling strategies for class imbalance. The model was trained on a balanced dataset, evaluated on an unbalanced test set (80/20 split), and hyperparameter-optimized using five-fold cross-validation. **Results:** Our study included 4,302 cancer patients treated with ICI, of whom 910 were identified by our pipeline as having an irAE and 276 cases of irP. The model achieved a sensitivity of 0.964 on a physician-annotated irP dataset. The best-performing predictive model was a tree-based classifier with an AUC of 0.68. Chi-square analysis identified significant associations ($p < 0.05$) between irP and multiple clinical features, including prior lung disease, radiotherapy, age at immunotherapy, comorbidity burden, and inflammatory markers. Odds ratio analysis based on model-derived risk score quartiles, showing that patients in the highest-risk quartile exhibited an average 10.3-fold increase in the odds of developing pneumonitis compared to those in the lowest-risk quartile. **Conclusions:** This study establishes a strong baseline for ML algorithms to identify and predict irP specifically in patients treated with ICI, using EHR-derived data. Our results demonstrate that pre-treatment clinical and laboratory variables can be effectively used to stratify irP risk. Future research should aim to refine these predictive models and incorporate a broader range of EHR-based features to further improve predictive performance and clinical applicability. Efficacy and safety of a temperature-controlled oral cryotherapy device in preventing oral mucositis among patients receiving high-risk anticancer regimens. First Author: Xiaojia Wang, Department of Breast Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: Oral mucositis (OM) is a severe dose-limiting toxicity in cancer patients receiving intensive chemotherapy or novel antibody-drug conjugates (ADCs). Recent clinical data indicate that the incidence of OM with Sacituzumab Tirumotecan (sac-TMT) is as high as 54.1%, with approximately 11.1% of patients experiencing severe (Grade≥3) events. For Liposomal Doxorubicin, reported OM incidence is approximately 22%. Established therapies such as Docetaxel, Paclitaxel plus Carboplatin, and Sacituzumab Govitecan exhibit OM rates ranging from 10% to 30%. Severe OM frequently leads to excruciating pain, nutritional compromise, and treatment delays. This study evaluated the efficacy of a specialized oral cryotherapy (OC) device in preventing treatment-induced OM across these high-risk regimens. **Methods:** In this prospective trial, patients scheduled for high-risk regimens including Sacituzumab Tirumotecan, Sacituzumab Govitecan, Liposomal Doxorubicin, Docetaxel, or Taxane plus Carboplatin were enrolled. The intervention group received continuous OC using 8°C purified water, delivered via safe, non-toxic intraoral molds regulated by a temperature-controlled device. The protocol was administered 15 minutes prior to, throughout, and 30 minutes post-infusion. Primary endpoints included time to first OM onset, OM incidence, and WHO severity grading. **Results:** From September, 2025 to January, 2026, 116 patients were enrolled, with the most frequent user completing 13 OC sessions. The overall incidence of OM was only 6.9% (8/116), and all cases were Grade 1, with no interference with oral intake. In the Sacituzumab Tirumotecan (sac-TMT) subgroup (n = 26), the OM incidence was 11.5% (3/26)occurring at C2D1 (n = 2) and C4D8 (n = 1). Other subgroup incidences were as follows: Sacituzumab Govitecan, 50.0% (1/2) occurring at C2D1; Liposomal Doxorubicin, 4.2% (1/24) occurring at C2D1; Taxanes, 7.1% (2/28) both occurring at C2D8; and Epirubicin, 5.6% (1/18) occurring in C3D1. Notably, zero Grade ≥ 2 OM events were observed across all cohorts. No serious adverse events related to the temperature-controlled device were reported, and patient compliance with the OC protocol was high. **Conclusions:** Regulated oral cryotherapy using a temperature-controlled device and intraoral molds is a simple, cost-effective, and well-tolerated intervention that significantly reduces the incidence and severity of treatment-induced oral mucositis. Particularly for patients receiving high-risk ADCs such as Sacituzumab Tirumotecan, this standardized OC protocol should be considered a standard prophylactic measure to improve clinical outcomes and treatment adherence. Cardiovascular toxicity across epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors in *EGFR*-mutated non–small cell lung cancer: A population-based retrospective cohort study. First Author: Yun-Gyoo Lee, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are the therapeutic backbone for *EGFR*-mutated non-small cell lung cancer (NSCLC) and often requiring prolonged exposure. Adverse cardiovascular events limit a long-term treatment and remain a major concern for cancer survivors. Osimertinib, the 3rd generation EGFR TKI, was associated with cardiac dysfunction. Although Osimertinib is a preferred first-line option, many countries still use first- or second-generation EGFR TKIs upfront; therefore, robust studies are needed to define cardiotoxicity across these earlier-generation EGFR TKIs. **Methods:** In this retrospective cohort study using a nationwide Health Insurance Claim Database in Korea, patients newly diagnosed with NSCLC between 2010 and 2023 were identified. Patients were classified into three groups: first-generation (1G) EGFR TKIs (gefitinib or erlotinib), second-generation (2G) TKIs (afatinib or dacomitinib), and third-generation (3G) TKI sequence (initial first- or second-generation TKI followed by a switched to osimertinib). The incidence of cardiovascular disease (CVD) during treatment period was compared between groups. CVD included ischemic heart disease, heart failure, atrial tachyarrhythmias, and stroke. For patients with pre-existing CVD, only new-onset CVD were counted as events. Follow-up was completed December 31, 2024. **Results:** Among the 51,218 patients (58,317 [51%] female; mean [SD] age, 65.5 [10.8] years), 36,335 (70.9%), 8173 (16.0%), 6710 (13.1%) were treated with 1G, 2G and 3G EGFR TKI respectively. Among all patients, 16.7% were receiving medication for diabetes, 52.7% for hypertension, and 19.8% for dyslipidemia. Before lung cancer diagnosis, 1.1% had coronary artery disease and 2.7% had heart failure. In patients treated with 1G EGFR TKIs, the cumulative incidence of CVD at 1, 2, 3, and 5 years was 4.8%, 8.1%, 11.2%, and 16.2%, respectively. In those treated with 2G EGFR TKIs, the corresponding cumulative incidence was 4.2%, 7.0%, 9.4%, and 12.3%. In the group of 3G TKI sequence, the cumulative incidence of CVD at 1, 2, 3, and 5 years was 2.9%, 6.1%, 8.9%, and 14.8%, respectively. There was no statistically significant long-term difference in CVD incidence between the 1G TKI and the 3G TKI group (p = .245). **Conclusions:** The long-term risk of CVD associated with sustained treatment with 1G EGFR TKIs appears comparable to the risk observed among patients who started with 1G or 2G and switched to 3G EGFR TKI sequence. As long-term survivors with EGFR mutant NSCLC increases in number, ongoing surveillance for cardiotoxicity and proactive risk mitigation are essential. Research Sponsor: None.

Oncologic outcomes following biologic therapy for immune-related cutaneous adverse events. First Author: Tara Maier, Stony Brook University, Stony Brook, NY

Background: Biologic agents are increasingly used to treat immune-related cutaneous adverse events (ircAEs). However, limited data exist regarding immune checkpoint inhibitor (ICI) rechallenge and ICI efficacy following biologic therapy for ircAE management. **Methods:** We conducted a retrospective cohort study of patients enrolled under U01AR077511-01 (PIs Leung, Kern, Lacouture) treated with ICIs who developed dermatologist-confirmed grade ≥2 ircAEs. Demographics, ircAE treatments, and dermatologic and oncologic outcomes were collected via chart review and compared using t-tests and chi-square tests. **Results:** We identified 159 patients who developed grade ≥2 ircAEs, including 80 treated with biologic agents. Mean age was 66.8 years; 40% were female, 79% White, and 78% had stage IV disease. The most common tumor types were kidney (20%), lung (16%), and melanoma (12%). Common ICI regimens included ICI monotherapy (46%), ICI–ICI combination (21%), and ICI+chemotherapy (19%). Pruritus (23%), maculopapular rash (21%), and eczema (19%) were the most common ircAEs. Most patients received topical steroids (88%), while systemic steroids were used sparsely (13%). Biologics were used in ~50% of patients; the most common agents were dupilumab (43%), omalizumab (33%), and ustekinumab (11%). Median biologic duration was 16 weeks, with 25% receiving therapy for >40 weeks. ICI rechallenge occurred in 60% of biologic-treated versus 67% of non-biologic patients (p=0.35). Rechallenge rates were 67% vs 65% for grade 2 (p=0.85) and 44% vs 74% for grade 3 ircAEs (p=0.05) (biologic vs non-biologic, respectively). Antitumor outcomes were similar between biologics and non-biologic groups: 31% vs 28% achieved partial/complete response, 43% had stable disease, and 26% vs 29% had progressive disease, respectively. **Conclusions:** In this oncodermatology-managed cohort, ircAEs were primarily treated with topical corticosteroids and targeted biologics, with infrequent systemic steroid use. Biologic therapy enabled ICI rechallenge in most patients, and oncologic outcomes were comparable to those not receiving biologics. Overall, these findings support biologics as a steroid-sparing option for moderate-to-severe ircAEs that may allow continued immunotherapy without apparent loss of antitumor efficacy, warranting prospective validation. Research Sponsor: None.

Major adverse cardiovascular events among prostate cancer patients in the VA, stratified by HIV status and androgen deprivation therapy. First Author: Debanjan Pain, Department of Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite the rapidly increasing trend in incidence of prostate cancer among persons with HIV (PWH), comprehensive data outlining outcomes and treatment toxicities of prostate cancer in this population remain sparse. Notably, both HIV infection and prostate cancer treatment independently increase the risk of cardiovascular disease. We sought to quantify the risk of major cardiovascular adverse events (MACE) among a large Veterans Affairs (VA) cohort of PWH and people without HIV (PWoH). **Methods:** We used patient data from the VA Corporate Data Warehouse and the VA Central Cancer Registry, including demographics, laboratory data, medications administered in inpatient/outpatient pharmacies, International Classification of Diseases 9th Edition and 10th edition diagnoses and procedure codes. Patients were included if they had diagnosis of prostate adenocarcinoma between 1/1/2008 and 12/31/2020. Patients were excluded if they had a diagnosis with any prior invasive cancer on or prior to prostate cancer diagnosis, diagnosis with prostate cancer prior to HIV positive diagnosis, or MACE within 6 months prior to prostate cancer diagnosis. MACE was defined as having a diagnosis code of myocardial infarction, stroke, or arrhythmia, within five years of start of treatment approach for prostate cancer (defined as androgen deprivation therapy (ADT) or active surveillance). We conducted a time-to-event analysis using the Cox proportional hazards model to examine the time to first occurrence of MACE, accounting for censoring and varying follow-up times. **Results:** A total of 87,144 prostate cancer patients were included (654 PWH and 86,490 PWoH). About 37.5% of PWH were $<$ 60-years-old at time of prostate cancer diagnosis (compared with 19.6% of PWoH). Among 62,259 patients with low-risk or intermediate-risk localized prostate cancer, the risk of MACE was 24% greater among PWH compared with PWoH (HR 1.24, 95% CI 1.02-1.51, p = 0.03) after controlling for age, race, and cardiovascular risk factors at time of cancer diagnosis. Among PWH with prostate cancer, receiving ADT was associated with a 3.5 fold increased risk of developing MACE vs. those not receiving ADT (HR 3.51, 95% CI 2.25-5.49, p $<$ 0.01). Among PWoH with prostate cancer, receiving ADT had a 2.7-fold increased risk of developing MACE vs. those not receiving ADT (HR 2.72, 95% CI 2.61-2.84). **Conclusions:** Both HIV infection and ADT increase the risk of MACE among prostate cancer patients. Future studies are warranted to explore the mechanistic links between HIV infection, ADT, and cardiovascular health. Research Sponsor: None.

Identification of nutritional risk in chimeric antigen receptor T-cell (CAR-T) therapy: Protein-energy malnutrition and its impact on patient outcomes. First Author: Anu Priyamvadha Ramakrishnan, Nassau Health Care Corporation, East Meadow, NY

Background: Protein-energy malnutrition (PEM), an imbalance between protein and energy intake and the body's requirements, is highly prevalent in cancer, affecting 20–70% of patients, with an overall prevalence of approximately 41%. PEM and cachexia impair therapeutic efficacy, increase treatment-related toxicities, and worsen survival outcomes. Although CAR T-cell therapy has revolutionized oncology, its associated complications—such as cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) further affects nutritional status, creating a complex bidirectional relationship between PEM and CAR-T complications. This study utilizes the National Inpatient Sample (NIS) to assess nutritional status in CAR T-cell therapy recipients and potential impact on outcomes and treatment-related complications. **Methods:** A retrospective cohort study was conducted using the 2021–2023 National Inpatient Sample (NIS) database. Adult patients (aged ≥18 years) who were hospitalized and received CAR-T therapy were identified using ICD-10 codes and stratified according to the presence of PEM. The primary outcome was the inpatient mortality rate, while secondary outcomes included length of hospital stay, total hospital charges, incidence of CRS, ICANS, and other medical complications. **Results:** Among 10,690 hospitalized adult CAR-T recipients, 2,190 (20%) had PEM. In-hospital mortality in this group was 190 (9%). The PEM cohort was predominantly male (79%) and White (74%), with a mean age of 61.5 years. Compared to patients without PEM, those with PEM experienced higher in-hospital mortality (8% vs 1.2%; OR 7.2; P $<$ 0.001), longer hospital stays (LHS) (24 vs 15 days; Coefficient 9.2; P $<$ 0.001), and higher costs ($1,428,895 vs $1,106,642; Coefficient 322,253; P $<$ 0.001) and more CAR-T-related complications, including CRS (44% vs 39%; OR 1.3; P $<$ 0.05), ICANS (12% vs 7%; OR 1.7; P $<$ 0.05), sepsis (OR 3.13; P $<$ 0.001), stroke (OR 4; P $<$ 0.001), and cardiovascular events (OR 1.6; P $<$ 0.001). **Conclusions:** This analysis identifies PEM as a significant predictor of mortality, prolonged hospitalization, higher costs and increased complications among CAR-T recipients. This highlights baseline nutritional status as a critical outcome determinant. This emphasizes the need for pre-treatment nutritional screening and early, targeted interventions to break the vicious cycle of malnutrition, improve treatment tolerance, reduce adverse events, and optimize outcomes. Further studies should evaluate tailored nutritional strategies and supportive care to enhance CAR-T safety and efficacy. Research Sponsor: None.

Impact of corticosteroid exposure on long-term immune checkpoint inhibitor responses in solid tumors. First Author: Theresa Medina, University of Colorado, Aurora, CO

Background: Multiple analyses offer conflicting evidence regarding the implications of immune related adverse events (irAE) on survival of patients with solid tumors treated with immune checkpoint inhibitor(s) (ICIs). Furthermore, the treatments used to manage irAEs also have an unclear impact on progression free survival (PFS) and overall survival (OS) on patients with solid tumors treated with ICIs. We present the PFS, OS and tumor specific survival (TSS) for pts with metastatic solid tumors treated with ICIs at an academic cancer center. **Methods:** 848 pts with metastatic solid tumors diagnosed between 2014 through January 2026 were identified via retrospective chart review. PFS was defined as the time from starting ICIs to progression or death, OS was defined as the time from starting ICIs to death and TSS was defined as the time from starting ICIs to death from malignancy (when available). The corticosteroid (CS) exposure was defined as low if prednisone (or equivalent) $<$ 1mg/kg/day and/or length of exposure $<$ / = 21 days. The CS exposure was defined as high if prednisone (or equivalent) was $>$ / = 1mg/kg/day and/or length of exposure $>$ / = 22 days. The CS exposure was defined as very high if prednisone (or equivalent) $>$ 20mg/day and length of exposure was $>$ 42 days. Steroid sparing agents were considered low impact if given once and within 14 days of starting CS. Steroid sparing agents were considered high impact if given more than once. Steroid sparing agents were considered very high impact if given more than once and/or given after 14 days of starting CS. Acute irAE was defined if symptom and immunosuppression resolved within 42 days. Chronic irAE was defined if symptom and/or immunosuppression continued beyond 42 days. The effects of CS, steroid sparing agent exposure on PFS, OS, TSS were evaluated using multivariable Cox proportional hazards models. The effect of acute irAE versus chronic irAE on PFS, OS, TSS were evaluated using multivariable Cox proportional hazards models. **Results:** 64.8% of patients experienced an irAE and 44.7% of patients developed G3-4 irAE requiring corticosteroids +/- steroid sparing agent. The low impact corticosteroid exposure did not affect PFS, OS or tumor specific survival. The very high impact CS exposure was associated with decrease in PFS (p = 0.02) but not with OS or TSS (p = 0.3). The high impact steroid sparing agent was associated with decrease in PFS (not significant) but the very high impact steroid sparing agent was associated with decrease in PFS. The chronic irAE was associated with slight improvement in PFS (not significant). **Conclusions:** The presence of an irAE was not significantly associated with PFS, OS or tumor specific survival treated with ICIs. There was a negative impact on the length of corticosteroid exposure and steroid sparing agents on PFS, TSS. The delay or interruption in treatment due to irAE did not affect survival. Research Sponsor: None.

Supporting treatment resilience with optimized nutrition and guided exercise (STRONGER) in head and neck cancer patients undergoing chemoradiation. First Author: Anton Jose Agana, University of Nevada, Reno School of Medicine, Reno, NV

Background: Patients with head and neck cancer (HNC) undergoing concurrent chemoradiation (chemoRT) frequently experience debilitating toxicities, including mucositis, dysphagia, fatigue, and anorexia. These treatment-related effects are associated with weight loss, sarcopenia, and functional decline, which may adversely impact treatment adherence and quality of life. Although patients commonly seek lifestyle-based supportive interventions, evidence-based, structured multimodal programs integrated during active chemoradiation remain limited. The STRONGER pilot study was designed to evaluate the feasibility and acceptability of an integrated nutrition, guided exercise, and wellness education intervention aimed at supporting treatment resilience and characterizing functional and body composition changes in this population. **Methods:** STRONGER is a single-arm pilot study enrolling up to 30 adult patients with biopsy-confirmed squamous cell carcinoma of the head and neck undergoing definitive or adjuvant chemoRT at Renown Health and the William N. Pennington Institute for Cancer. Eligible participants have an ECOG performance status of 0 to 2 and are able to participate in light-to-moderate physical activity. Patients with severe malnutrition, defined by Global Leadership Initiative on Malnutrition criteria and greater than 90% caloric intake via enteral feeding, or with comorbidities precluding safe exercise participation, are excluded. The 20-week multimodal intervention begins at pre-treatment baseline and continues through three months post-chemoRT, incorporating individualized nutrition counseling with calorie and protein targets informed by indirect calorimetry, twice-weekly virtual home-based resistance and mobility training with prescribed daily walking goals, and structured wellness programming, including facilitated group sessions focused on stress and fatigue management and a speech-language pathology education series. The primary objective is to assess feasibility and acceptability, defined by prespecified thresholds for recruitment, retention, and intervention adherence, as well as participant-reported acceptability measured using Likert-scaled surveys. Secondary exploratory outcomes include measures of body composition, physical function, and patient-reported quality of life and symptom burden assessed using validated instruments. Descriptive statistics and exploratory paired analyses will be used to characterize within-participant changes over time. Enrollment is ongoing. As of January 24, 2026, 2 of 30 planned participants have been enrolled. Clinical trial information: NCT07160296. Research Sponsor: Renown Health Foundation.

TPS12162 **Poster Session**

Hetrombopag in patients with chemotherapy-induced thrombocytopenia: A global phase 3, randomized, double-blind study. First Author: Jodi Victoria Mones, Department of Medicine, Hematology Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Chemotherapy-induced thrombocytopenia (CIT) is a common complication of cancer therapy, frequently resulting in chemotherapy modifications including dose reduction, delay, or discontinuation. Thrombopoietin receptor agonists (TPO-RAs) represent a therapeutic approach aimed at stimulating platelet production. Given there are limited society-sanctioned therapies, contemporary management converges on platelet transfusions which are limited in global supply or parenteral TPO-RAs which are inconvenient. Hetrombopag is an oral TPO-RA that supports platelet counts and facilitates chemotherapy delivery, as evidenced by a prior positive randomized, controlled study conducted in China (ASH 2025; NCT05864014). This global phase 3 study is designed to evaluate the efficacy and safety of hetrombopag in patients with CIT (NCT07286032). **Methods:** This study comprises two sequential parts: an open-label, single-arm, pharmacokinetic (PK) lead-in part (A) and a randomized, double-blind, placebo-controlled part (B). In Part A, approximately 8-12 non-Asian patients with CIT are planned to be enrolled to receive oral hetrombopag (15.0 mg once daily, fasted) to evaluate the PK profile. Part B will enroll approximately 138 patients with solid tumors who have experienced a $\geq$ 7-day chemotherapy delay due to CIT during platinum- and/or gemcitabine-based therapy at schedule of 21-day cycles. Eligible patients will be randomized in 2:1 to hetrombopag or placebo, stratified by baseline platelet count (PC; $\geq 50 \times 10^9$/L vs. $< 50 \times 10^9$/L) and enrollment region (Asia vs. rest of world). Hetrombopag will be initiated at 7.5-or 15 mg (dose will be finalized after considering results from Part A) once daily, with dose adjustments based on platelet counts. All enrolled patients are expected, per investigator assessment, to be eligible to complete two consecutive cycles of on-study chemotherapy (C1 and C2) of the same regimen administered prior to enrollment. Initiation of each chemotherapy cycle requires a PC $\geq 100 \times 10^9$/L; if the PC remains $< 100 \times 10^9$/L on day 14 after hetrombopag initiation (for C1) or at the C1D21 visit (for C2), the investigator may exercise discretion to proceed with the respective chemotherapy cycle and/or implement rescue therapy (platelet transfusions and/or approved TPO-RAs). The primary endpoint of Part A is the PK profile of hetrombopag in non-Asian patients with CIT; the primary endpoint of Part B is the proportion of treatment responders, defined as patients who achieve a PC $\geq 100 \times 10^9$/L within 14 days of hetrombopag initiation and who complete two consecutive chemotherapy cycles without either thrombocytopenia-related modifications, or thrombocytopenia rescue therapy through C2D21. Clinical trial information: NCT07286032. Research Sponsor: Jiangsu Hengrui Pharmaceuticals.

TPS12163 **Poster Session**

A randomized, double-blind, placebo-controlled trial of antiviral prophylaxis and oral *Herpesviridae* dynamics during radiotherapy for head and neck cancer. First Author: Renata Ferrari, Hospital Sirio Libanes, Sao Paulo, Brazil

Background: Oral mucositis (OM) is a frequent and debilitating toxicity of radiotherapy (RT) for head and neck cancer (HNC), often leading to pain, nutritional compromise, and treatment interruptions. Reactivation of viruses from the *Herpesviridae* family has been proposed as a potential contributor to the pathogenesis and severity of OM, but prospective, controlled data remain limited. Antiviral prophylaxis is not standard of care in this setting, and its role in preventing viral reactivation and modulating OM severity during RT has not been systematically evaluated. This randomized trial investigates the association between oral *Herpesviridae* detection, antiviral prophylaxis, and OM development in patients undergoing RT for HNC. **Methods:** This is a prospective, randomized, double-blind, placebo-controlled phase II trial conducted across four oncology centers in Brazil. Adult patients ($\geq$18 years) with HNC undergoing intensity-modulated radiotherapy (IMRT), with or without concurrent systemic therapy, are randomized 1:1 to receive antiviral prophylaxis or placebo. Randomization is stratified by age ($<$ 60 vs $\geq$60 years) and anatomic tumor site (oral cavity/salivary glands; oropharynx/pharynx; nasopharynx/paranasal sinuses). The investigational intervention consists of oral antiviral prophylaxis administered once weekly throughout the course of RT; the control arm receives a matching placebo. Comprehensive dental evaluation and oral care optimization are performed prior to RT initiation in all patients. Serial oral mucosal and saliva samples are collected weekly during RT and after treatment completion. Quantitative real-time PCR is used to detect and quantify viruses from the *Herpesviridae* family, including HSV-1, HSV-2, VZV, EBV, CMV, HHV-6A/B, HHV-7, and HHV-8. Clinical assessments include OM incidence, severity graded by CTCAE criteria, pain intensity, and timing of OM onset and resolution. Correlative analyses will explore temporal associations between viral detection, viral load, antiviral prophylaxis, and OM outcomes. The planned sample size is 84 patients (42 per arm), providing adequate power to detect differences in viral manifestation and OM-related outcomes. Clinical trial information: NCT07363031. Research Sponsor: None.

TPS12164 **Poster Session**

Symptom monitoring program linked to electronic referrals (SyMPLER): A single-arm pilot feasibility study of remote symptom monitoring with palliative care self-referral. First Author: Julia L. Agne, The Ohio State University Comprehensive Cancer Center – Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, Columbus, OH

Background: Symptoms often fluctuate during an individual's cancer trajectory, and this can impact patients' health-related quality of life (HRQOL). Two evidence-based approaches—symptom monitoring programs (SMPs) and specialty palliative care (PC)—have independently been shown to improve HRQOL through identification and treatment of cancer-related symptoms, especially among patients with thoracic cancers (i.e. lung cancer). However, PC remains underutilized when patients report uncontrolled symptoms via SMPs. Therefore, we developed SyMPLER, a digital SMP with an integrated option for PC self-referral. The primary aim of this phase 1 clinical trial is to determine the feasibility of SyMPLER among patients newly diagnosed with a thoracic cancer. If feasible for remote symptom reporting, SyMPLER may overcome logistical and attitudinal barriers towards provider-driven PC referral processes for cancer symptom management. **Methods:** SyMPLER is a prospective single-arm feasibility study of a novel digital health intervention for remote symptom reporting with an optional PC self-referral for cancer symptom management (NCT06396598). SyMPLER includes 5 main components: (1) a brief education about PC, (2) weekly text reminders to encourage symptom logging, (3) on-demand symptom reporting using the Edmonton Symptom Assessment System on a mobile health application interface, (4) an active choice option for PC self-referral, and (5) the ability to request a callback from oncology clinicians to discuss symptom concerns. Per the IRB-approved protocol, adults ($>$ 18 years) with any stage thoracic malignancy, without a prior PC referral, are consented within the first 12 weeks of outpatient oncology care. The primary outcome is frequency of symptom reporting with a feasibility benchmark set at 50% of participants logging symptoms at least monthly over a 6-month intervention period. PC referrals (secondary outcome) and exploratory outcomes, including telephone encounters with the oncology team, HRQOL (Function Assessment of Cancer Therapy – Lung; FACT-L), and patient satisfaction with medical care (FAMCARE-P13) are measured every 3 months for up to 12 months post-enrollment. Study enrollment commenced in February 2024. The target enrollment of 94 evaluable participants was achieved in August 2025. Data collection is ongoing for 23 patients still active on study. Clinical trial information: NCT06396598. Research Sponsor: None.

TPS12165 **Poster Session**

Structured interventional strategies to prevent and reduce burnout in medical oncologists: The Resilience–Spanish Society of Medical Oncology (SEOM) multicenter project. First Author: Yago Garitaonaindia, National Center for Cancer Immune Therapy, Department of Oncology, Copenhagen University Hospital, Herlev, Denmark

Background: Burnout is highly prevalent among young medical oncologists, with an estimated incidence exceeding 70% in Europe, and poses a growing threat to physician well-being and quality of care. Early-career oncologists are particularly vulnerable due to high clinical workload, emotional burden, and limited access to structured psychological support. Evidence-based interventions integrated into routine professional activity remain scarce. The Spanish Resilience-SEOM project previously demonstrated that communication skills workshops improved personal achievement and group psychotherapy was feasible to address emotional distress. Building on these findings, this study evaluates a structured, hospital-based structured intervention combining communication skills training and psychotherapy to prevent and mitigate burnout in early-career medical oncologists. **Methods:** This is a prospective, post-authorization, multicenter cohort study including residents and medical oncologists across 7 hospitals in Spain, with a planned follow-up of 6 months. Baseline assessments include demographic data, the Maslach Burnout Inventory (MBI), and the Clance Impostor Phenomenon Scale (CIPS). The intervention consists of eight modules: 1) individual interviews, 2) biopsychosocial model workshop, 3) coregulation workshop, 4) communication skills workshop, 5) individual sessions, 6) vulnerability workshop, and 7–8) emotional regulation workshops. The program combines individualized sessions to activate personal coping resources with six progressive group workshops addressing systemic contributors to burnout, holistic patient perception, professional vulnerability, and practical emotional regulation strategies. Follow-up MBI and CIPS assessments are conducted at program completion and at 6- and 12-month intervals. Current enrollment includes 62 participants across 7 hospitals. Research Sponsor: Fundación SEOM.

Enhancing communication about cancer management and cancer care delivery for older adults with dementia and their care partners. First Author: Molly Wilgucki, Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY

Background: Dementia affects 7–10% of older adults with cancer and is associated with worse cancer outcomes. Many patients (pts) have reduced decisional capacity, leading care partners (CPs) to play a major role in cancer management decision-making, which can increase CP burden and negatively affect their well-being. Cancer communication in this population is complex, requiring clinicians to balance pt preferences, CP input, and dementia-related considerations. Despite this, no standard approach exists to support triadic communication in this setting. COACH-Cog is a triadic communication intervention that promotes shared decision-making by integrating CP involvement while centering pt values in cancer care. **Methods:** *Eligibility:* Pts are age ≥65 with a diagnosis of dementia and cancer (any type or stage), have an identified CP, and receive oncology care from a participating clinician. CPs are age ≥18 and identified by the pt. Oncology clinicians (physicians or advanced practice providers) must practice at the Wilmot Cancer Institute. *Study Design:* This is a pilot cluster-randomized trial (clinician-level randomization). The COACH-Cog intervention includes: 1) a brief clinician training video on dementia and its relevance to cancer care; 2) distribution of pt geriatric assessment results with care recommendations to clinicians, pts, and CPs; and (3) CP communication coaching to elicit dementia-related concerns and develop questions for the next oncology visit. Baseline measures include pt geriatric assessment and dementia severity, CP well-being (burden, quality of life, depression, anxiety), and pt/CP communication and decision-making preferences. Pts and CPs receive either COACH-Cog or usual care based on clinician randomization. The subsequent clinical encounter is audio-recorded. *Outcome Measures:* The primary outcome is CP autonomy support, which evaluates how supported CPs feel in the decision-making process. Secondary outcomes include healthcare communication and CP well-being. Tertiary outcomes assess goal-concordant care and decisional regret. Exploratory outcomes evaluate communication impact by integrating qualitative clinical encounter data with quantitative measures. Current enrollment includes 36 clinicians and 36 pt/CP dyads (target 40 clinicians, 130 dyads). Accrual initiated April 2025. Data collection will conclude May 2027 (NCT06313853; NIA R01 AG077053). *Novel/Innovative aspects:* (1) This is the first study to prospectively enroll patients with dementia in an oncology intervention trial; (2) We are evaluation of a novel triadic communication intervention targeting clinicians, pts, and CPs; and (3) We have incorporated standard procedures for assessing consent capacity and engaging Legally Authorized Representatives for pts lacking capacity given enrollment of pts with dementia. Clinical trial information: NCT06313853. Research Sponsor: National Institute of Health/National Institute on Aging; R01 AG077053.

TPS12167 **Poster Session**

RISE trial: A novel virtually delivered supervised exercise intervention targeting cognitive impairment and gut microbiome in adolescent and young adult (AYA) brain tumor survivors. First Author: Elizabeth Pan, Duke University, School of Medicine, Durham, NC

Background: Up to 45% of AYA brain tumor survivors experience cancer-related cognitive impairment (CRCI) affecting processing speed, attention, working memory, and executive function—domains critically impacting quality of life (QOL). Moderate-intensity exercise can improve cognitive function by enhancing gut microbiome composition and function. However, only 50% of AYA cancer survivors receive any exercise information from medical providers, with 42% actually meeting physical activity recommendations. Considering developmental milestones and the unique needs of AYA brain tumor survivors, tailoring virtually delivered exercise interventions paired with behavioral coaching and supportive care navigation to promote the adoption of a physically active lifestyle may be a promising approach to reducing CRCI through modulation of gut microbiome health. Few randomized controlled trials (RCTs) have examined this type of exercise intervention for AYA brain tumor survivors. Additionally, the influence of the gut microbiome on the relationship between exercise and cognitive function in AYA brain tumor survivors has not yet been studied. To address these gaps, we developed the Remote Implementation of Supervised Exercise (RISE) intervention, a 12-week personalized aerobic and strength training exercise intervention with behavior coaching and supportive care navigation. The RISE trial aims to evaluate feasibility (primary), cognitive and physical activity (secondary), and gut microbial composition changes (exploratory). **Methods:** RISE is a two-arm 1:1 pilot RCT (NCT06799481) of 40 AYA brain tumor survivors (aged 18-39) with CRCI enrolled at Emory University and MD Anderson Cancer Center. Controls receive an activity tracker and 18 wellness calls from a trainer inquiring about adverse events and survivorship topics. Intervention participants participate in 18 virtual exercise sessions with an exercise coach, consisting of progressive aerobic and strength training exercises with active lifestyle behavior coaching. Intervention participants also receive an activity tracker and participate in self-led exercise sessions via the Physitrack telehealth app for 12 weeks. Assessments at baseline, 6, 12, and 18 weeks measure cognitive function, physical activity levels, gut microbiome, physical function, diet, and QOL. Descriptive analysis will be used to assess feasibility, defined as enrollment of 50% eligible AYAs, 75% adherence to intervention, and 80% retention at the end of the 12-week intervention. As of January 2026, 17 of 40 patients have been enrolled, and accrual is expected to be complete within 1 year. Clinical trial information: NCT06799481. Research Sponsor: NRG Oncology Foundation.

TPS12168 **Poster Session**

Targeting cellular senescence to enhance skeletal muscle recovery in survivors of breast cancer: An ancillary study of the phase II randomized PROFFi clinical trial. First Author: Jingran Ji, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Postmenopausal survivors of breast cancer frequently experience persistent physical function decline after chemotherapy. A key contributor is skeletal muscle dysfunction, leading to weakness, fatigue, and reduced physical activity. One potentially targetable mechanism of chemotherapy-induced skeletal muscle dysfunction is cellular senescence. Senescence is a state of terminal growth arrest that leads to a senescence-associated secretory phenotype marked by the secretion of pro-inflammatory cytokines. These cytokines worsen muscle dysfunction by impairing calcium handling and muscle fiber contractility. Emerging evidence suggests senolytics and exercise may reduce senescent cell (SnC) burden. Senolytics are agents that selectively eliminate Sncs and can improve physical function in non-cancer populations. Exercise not only enhances physical function but also reduces blood markers of senescence. Preclinical studies demonstrate a synergistic effect of senolytics and exercise on SnC reduction. However, no human studies have examined the independent or combined effects of senolytics and exercise on skeletal muscle function and senescence in cancer survivors. We hypothesize that fisetin plus exercise will produce independent and synergistic effects that enhance skeletal muscle recovery in survivors of breast cancer. **Methods:** This site-specific ancillary mechanistic study at UCLA is embedded within PROFFi (Prevention of Frailty with Fisetin), an ongoing phase II multicenter, randomized, placebo-controlled clinical trial evaluating fisetin and exercise in postmenopausal survivors of breast cancer. Eligible participants are within 12 months of completing neo/adjuvant chemotherapy and have reduced physical function as measured by a 6-minute walk distance of 400-480 meters. PROFFi uses a 2x2 factorial design, randomizing 200 participants 1:1:1:1 to exercise plus fisetin, exercise alone, fisetin alone, or placebo for 16 weeks. Fisetin is administered orally at 20mg/kg/day on days 1-3 every 14 days. Exercise is individually tailored and remotely supervised by an exercise physiologist and includes aerobic and resistance exercises. The ancillary study will enroll 84 of the 200 participants (21 per arm) to undergo additional muscle-specific assessments including Biodex strength testing, thigh magnetic resonance imaging (MRI), and vastus lateralis muscle biopsies. The primary objectives of the ancillary study are to evaluate the effects of fisetin and/or exercise on muscle strength (Biodex peak torque), muscle volume (on MRI), and muscle mitochondrial function (oxidative phosphorylation capacity). Secondary objectives include assessing changes in blood and muscle-specific markers of senescence from baseline to end of study. Enrollment to this study began July 2024 and is ongoing (NCT06113016). Clinical trial information: NCT06113016. Research Sponsor: U.S. National Institutes of Health; R01 CA280088; The Breast Cancer Research Foundation; Rising Tide Foundation for Clinical Cancer Research.

TPS12169 **Poster Session**

Exercise therapy in survivors of gastroesophageal cancer: A phase I, randomized dose-finding study of an individually tailored, remotely supervised exercise intervention. First Author: Jingran Ji, UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Advances in perioperative systemic therapy and surgery have extended survival for patients with locoregional gastroesophageal cancer (GEC). However, intensive multimodality treatment often causes substantial physical function decline, leading to loss of independence and poor quality of life. No evidence-based interventions are currently approved to prevent or reverse this decline. Although exercise can improve fatigue, quality of life, and functional outcomes in other malignancies, it remains poorly studied in survivors of GEC. In patients with colon cancer, exercise after treatment is feasible, improves quality of life, and alleviates anxiety and depression. More recently, the CHALLENGE randomized trial demonstrated that a structured, in-person, supervised exercise intervention after chemotherapy for early-stage colon cancer can improve physical function, decrease cancer recurrence, and increase survival versus health education alone. However, the in-person exercise intervention was limited by low adherence and lack of exercise dose optimization, with only one target dose tested. These findings may not generalize to survivors of GEC, where treatment is more intensive and surgery more morbid. In this patient population, we hypothesize that aerobic exercise up to 225 minutes per week will be feasible, but higher doses will lead to lower levels of relative exercise dose intensity (REDI), defined as the ratio of completed to prescribed exercise dose over the course of the intervention. **Methods:** This phase I, randomized dose-finding study will enroll 24 adults (age ≥18 years) with stage I-III GEC who completed perioperative systemic therapy within 12 months and are sedentary (< 30 minutes/week of moderate-to-vigorous physical activity). Participants will be randomized 1:1:1 to one of three individually tailored, remotely supervised aerobic programs led by an exercise physiologist. Each 16-week program will target either 75 minutes (25 minutes, 3x/week), 140 minutes (35 minutes, 4x/week), or 225 minutes (45 minutes, 5x/week) of moderate-intensity exercise. Demographic and disease/treatment data will be collected at enrollment. Assessments at baseline and post-intervention include measures of cardiorespiratory fitness (submaximal exercise test), other measures of physical, cognitive, and psychological function, and quality of life. Heart rate, body weight/composition, and step count will be measured throughout using remote monitoring devices. The primary outcome is feasibility, as measured by the REDI. An exercise dose will be considered feasible if > 60% of the participants (≥5/8 per arm) achieve a REDI of > 75%. Secondary outcomes include changes in cardiorespiratory fitness and other functional and quality of life measures. This study has been IRB approved and is ongoing (NCI202600630). Clinical trial information: NCI202600630. Research Sponsor: U.S. National Institutes of Health; R03 AG095803; Jonsson Comprehensive Cancer Center Seed Grant.

TPS12170 **Poster Session**

MPOWER: A pilot trial among men with prostate cancer—Optimizing wellness by enhanced relief from hot flashes with acupuncture. First Author: Jeanny B. Aragon-Ching, Inova Schar Cancer Institute, Fairfax, VA

Background: Prostate cancer is the most commonly diagnosed cancer among men, and advanced disease often requires androgen deprivation therapy (ADT). ADT is associated with distressing side-effects, including hot flashes, sleep disturbance, fatigue, and cognitive symptoms. Acupuncture is a nonpharmacologic intervention shown to reduce hot flashes in other hormone-treated cancers, such as breast cancer; however, standardized acupuncture protocols for men receiving ADT are lacking. The primary objective of the MPOWER trial (NCT07335224) is to evaluate the feasibility and acceptability of study procedures, recruitment strategies, and delivery of a standardized acupuncture protocol to reduce hot flashes in men with prostate cancer. Feasibility will be assessed through enrollment and intervention engagement, and acceptability through satisfaction ratings and post-intervention qualitative feedback. Secondary objectives include patient-reported hot flash frequency and severity, hot flash interference, endocrine symptoms, sleep disturbance, and health-related quality of life. **Methods:** This randomized study compares Immediate Start Acupuncture (IA) with an Active Comparator: Delayed-Start Acupuncture (DA), allowing all participants eventual access to the intervention, among 24 men treated with ADT and/or androgen receptor pathway inhibitors. The intervention consists of a standardized 10-week protocol with weekly 30-minute manual acupuncture sessions delivered by a certified acupuncturist with oncology expertise. All participants receive lifestyle education from a nurse navigator as part of usual care. Participants randomized to the IA arm receive the acupuncture protocol during the initial 10-week intervention period, followed by 12 weeks of follow-up without acupuncture. Participants randomized to the activate comparator DA arm will receive lifestyle education per usual care without acupuncture during the initial 10-week comparison period, with bi-weekly check-ins serving as an attention control, and then initiate the acupuncture protocol after the delay period. Study assessments integrate real-time patient-reported hot flash diaries collected via a secure mobile application for remote symptom monitoring (Locus Health), validated patient-reported outcome measures, and continuous Fitbit monitoring to capture physiologic and sleep metrics, including heart rate variability, sleep duration, and nighttime awakenings. Feasibility outcomes include enrollment rates and intervention engagement. Acceptability is assessed quantitatively at multiple time points and qualitatively through semi-structured interviews. The primary patient outcome is the Hot Flash Severity Score, calculated as weekly mean hot flash frequency multiplied by severity. Enrollment began in January 2026, with accrual expected within 12 months. Clinical trial information: NCT07335224. Research Sponsor: Inova Seed Grant.

TPS12171 **Poster Session**

SWIVEL: A randomized phase II trial of switching medications versus guideline-directed interventions for adjuvant aromatase inhibitor side effects in breast cancer patients. First Author: Elaine Patricia Kuhn, Dartmouth-Hitchcock Medical Center, Lebanon, NH

Background: Approximately half of breast cancer patients do not complete the standard 5-year course of adjuvant hormone therapy due to side effects, a finding associated with increased recurrence rates and breast cancer-specific mortality. In clinical practice, side effects are commonly addressed by switching to an alternative hormone therapy; however, this strategy has not been prospectively evaluated. In prior retrospective work, adherence was significantly lower among patients who switched therapies compared with those who remained on the same therapy and received treatment for side effects (62% vs 91%, p=0.013); however, interpretation is limited by the retrospective design. Therefore, a prospective randomized clinical trial was initiated to address this evidence gap by directly comparing medication switching with guideline-directed symptom management. **Methods:** SWIVEL is an ongoing phase II randomized trial comparing medication switching with guideline-directed interventions for the management of aromatase inhibitor side effects. Eligible patients are postmenopausal women or men with stage I–III ER-positive/HER2-negative breast cancer who are planning to initiate aromatase inhibitor monotherapy in the adjuvant setting. Upon enrollment, participants will be screened every 4 weeks with a validated single-item questionnaire (FACIT/GP5). Those who respond that they are 'quite a bit' or 'very much' bothered by side effects of treatment will be randomized to either (1) switch to a different hormone therapy, which may include an alternative aromatase inhibitor or tamoxifen, or (2) initiate an evidence-based intervention for side effects in accordance with NCCN guidelines and patient-provider preference. Participants may crossover between strategies at any time. The primary outcome is change in patient-reported symptom burden at 3 months following randomization or at crossover, whichever occurs first, measured by the FACT-ES survey. Secondary outcomes include patient-reported symptom burden at 6 months assessed in an intention-to-treat analysis using FACT-ES and PROMIS measures, and medication adherence assessed at 3, 6, 12, and 24 months using a multi-modal approach incorporating validated patient-reported measures (VOILS), pharmacy records, and urine testing for drug metabolites. Additional outcomes include patient-reported quality of life (FACT-G) and sexual function (FSFI), factors associated with adherence including access to care among rural communities, and evaluation of a novel screening tool to identify patients at higher risk for non-adherence. The study is open at Dartmouth Health and has enrolled 7 of 200 planned participants (NCT# 07071038). Clinical trial information: RCT07071038. Research Sponsor: Dartmouth Cancer Center.

TPS12172 **Poster Session**

A late-phase randomized open-label multi-cohort trial to evaluate immune-related adverse events with different standard-of-care dosing strategies of standard-of-care immunotherapies: ImmuRAd trial. First Author: Anup Kasi, University of Kansas Cancer Center, Kansas City, KS

Background: Programmed cell death-1 (PD-1) inhibitors, such as nivolumab and pembrolizumab, are widely used in treating solid tumors. These inhibitors have multiple FDA-approved dosing schedules. Extended-interval, higher-dose regimens offer patient convenience and health-system efficiencies. However, there is limited comparative prospective data evaluating immune-related adverse events (irAEs) across different dosing strategies. Our study aims to evaluate this important safety question in routine clinical practice. **Methods:** ImmuRAd is an investigator-initiated, open-label, randomized late phase trial. Adults ($\geq$18 years) with histologically or cytologically confirmed solid tumor malignancies who are scheduled to receive standard-of-care PD-1 inhibitor-based therapy in any disease setting or line of therapy are eligible for the study. Participants are randomly assigned to one of two pre-defined standard dosing strategies based on their physician-selected PD-1 inhibitor cohort. In the nivolumab cohort, patients are randomized 1:1 to receive nivolumab 240 mg every 2 weeks or nivolumab 480 mg every 4 weeks. In the pembrolizumab cohort, patients are randomized 1:1 to receive pembrolizumab 200 mg every 3 weeks or pembrolizumab 400 mg every 6 weeks. Route of administration is at the discretion of the investigator and can be given intravenous or subcutaneous. After completing 12 weeks of therapy, patients meeting predefined treatment-tolerance criteria may transition to extended-interval dosing at the discretion of the treating investigator. The primary objective is to determine the proportion of patients experiencing grade $\geq$3 immune-related adverse events (CTCAE v5.0) in each dosing arm within each cohort. Secondary endpoints include the incidence of all-grade immune-related adverse events, the time to resolution of these adverse events, treatment discontinuation due to immune-related adverse events, the overall response rate (for patients with measurable disease), progression-free or disease-free survival, and overall survival. Exploratory analyses will investigate the associations between immune-related adverse events and factors such as tumor type, treatment setting, microsatellite instability status, tumor mutational burden, and NGS biomarker profiles. The planned sample size is 192 evaluable patients (96 per cohort and 48 per arm). The study will enroll patients over a period of 24 months and will have a follow-up period of up to 2 years. In this IRB approved clinical trial, safety oversight will be provided by the institutional Data Safety Monitoring Committee. Trial Status: The study is actively enrolling at The University of Kansas Cancer Center and affiliated network sites. Clinical trial information: NCT07174453. Research Sponsor: Kansas University IIT Steering Committee.

Interrupting sedentary time to improve cardiometabolic health and toxicity in patients with lymphoma receiving chemotherapy: The iSTAND trial. First Author: Rebekah Wilson, Dana-Farber Cancer Institute, Boston, MA

Background: Among lymphoma patients treated with steroids, hyperglycemia is a common side effect. Episodes of hyperglycemia increase the likelihood of chemotherapy alterations, infection risk, and decreased overall survival. Interrupting sedentary time (IST) helps manage glycemic control in the diabetic population but is understudied among lymphoma patients. Additionally, there is preliminary evidence that IST during a chemotherapy infusion may reduce chemotherapy-related adverse effects. Therefore, we designed the iSTAND study to assess the feasibility of a 12-week IST intervention at home and during chemotherapy infusion appointments, and the preliminary efficacy on said intervention on a) cardiometabolic biomarkers and b) chemotherapy completion and toxicities among lymphoma patients. **Methods:** The iSTAND study is a prospective study aiming to recruit 24 patients diagnosed with lymphoma receiving either R-CHOP or POLA-R-CHP chemotherapy regimens. The first 3 enrolled patients will automatically be assigned to the intervention group to pilot the intervention (pre-pilot group). The remaining 21 patients will be randomly assigned IST intervention (n = 14) or control (n = 7). Five patients have been enrolled thus far (January 2026). The 12-week intervention will include a supervised component completed during chemotherapy infusion appointments and a self-directed home-based component. The in-clinic component will involve 2-minutes of walking every 30-minutes at 65-70% age predicted heart rate maximum, and two lower body resistance exercises every hour (1 set, 5-12 repetitions, 6-7 RPE) repeated for up to 4 hours of the infusion appointment. The home-based component will involve walking 250 steps per hour and alternating two lower and two upper body resistance exercises every hour (6 days/week for 6-12 hours/day). Patients will receive a Fitbit and resistance bands. Additionally, patients will receive daily movement prompts via Fitbit and text messages to encourage and assess adherence. Outcomes will be assessed at baseline prior to the second infusion and post-intervention after the 12-week intervention period. The primary outcome will be feasibility assessed via completion of $\geq$70% of prescribed activities, $\leq$50% rate of refusal, $\geq$70% retention rate, and $\geq$70% acceptance rate via acceptability of intervention questionnaire. Secondary outcomes include glucose levels and insulin assessed via continuous glucose monitor and fasting blood. Exploratory outcomes include quality of life, sleep quality, chemotherapy completion rate, and chemotoxicities assessed via questionnaires and medical records. Clinical trial information: NCT06923397. Research Sponsor: Helen B Gurley Foundation.

WINSHIP 4468-18: Phase II evaluation of the effect of 2- versus 6-hour oxaliplatin infusions on neuropathy and pharmacokinetics in patients with gastrointestinal cancers. First Author: Olumide B. Gbolahan, Emory University School of Medicine and Winship Cancer Institute, Atlanta, GA

Background: Oxaliplatin, a third-generation platinum agent, improves outcomes in gastrointestinal (GI) cancers when combined with fluoropyrimidines. However, it is also associated with clinically significant acute and chronic neurotoxicity. Approximately 33% of patients develop grade 3–4 sensory neuropathy, and up to 11% discontinue therapy due to neuropathy. Acute neurotoxicity is linked to the maximum plasma concentration (Cmax) of platinum ultrafiltrate, and greater acute sensory neuropathic symptoms predict later chronic neuropathy. Prior data suggest that extending infusion duration from 2 hours to 4–6 hours lowers Cmax by ~32–50% and reduces recurrence of acute neuropathic symptoms. We hypothesize that a 6-hour oxaliplatin infusion will reduce platinum ultrafiltrate Cmax and decrease the incidence and severity of chronic sensory neuropathy. **Methods:** WINSHIP 4468-18 is a randomized, open-label phase II trial enrolling a real-world population of patients with gastrointestinal (GI) cancers for whom oxaliplatin-containing combination therapy is indicated. All participants receive IV infusion of oxaliplatin 85 mg/m² every 2 weeks as part of a standard combination regimen. Sixty patients will be randomized 2:1 to 6-hour (n = 40) versus 2-hour (n = 20) oxaliplatin infusion duration. Eligibility includes confirmed GI malignancy, ECOG 0–2, and adequate organ function. Key exclusion criteria are baseline grade $\geq$2 neuropathy and prior hypersensitivity/intolerance to oxaliplatin. The primary endpoint is the between-arm difference in EORTC Chemotherapy Induced Peipheral Neuropathy (CIPN) 20 sensory scores from baseline to cycle 4. Secondary endpoints include comparison of pharmacokinetic parameters, particularly Cmax of platinum ultrafiltrate. With an assumed 10-point between-group difference in CIPN20 sensory score at cycle 4, 60 patients provide 80% power (two-sided α = 0.05). The study is open and accruing (NCT03800693). Clinical trial information: NCT03800693. Research Sponsor: None.
